Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] AR[31:0]: Add Request

Each Tx Buffer has its own Add Request bit. Writing a "1" will set the corresponding Add Request bit; writing a "0" has no impact. This enables the CPU to set transmission requests for multiple Tx Buffers with one write to TXBAR.

TXBAR bits are set only for those Tx Buffers that are configured by the TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers) fields.

When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

Bit	Description
0	No transmission request added.
1	Transmission requested added.

Note:

- If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.

5.38. Tx Buffer Cancellation Request (MCG_CANFDx_TXBCR, CPG_CANFDx_TXBCR)

Used to cancel transmission requests of each corresponding Tx Buffer.

bit	31	30	29	28	27	26	25	24
Field	CR31	CR30	CR29	CR28	CR27	CR26	CR25	CR24
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] CR[31:0]: Cancellation Request

Each Tx Buffer has its own Cancellation Request bit. Writing a "1" will set the corresponding Cancellation Request bit; writing a "0" has no impact. This enables the CPU to set cancellation requests for multiple Tx Buffers with one write to TXBCR.

TXBCR bits are set only for those Tx Buffers that are configured by the TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers) fields. The bits remain set until the corresponding bit of TXBRP (Tx Buffer Request Pending) is reset.

Bit	Description
0	No cancellation pending.
1	Cancellation pending.

5.39. Tx Buffer Transmission Occurred (MCG_CANFDx_TXBTO, CPG_CANFDx_TXBTO)

Displays the status of whether the corresponding Tx Buffer has been transmitted or not.

bit	31	30	29	28	27	26	25	24
Field	TO31	TO30	TO29	TO28	TO27	TO26	TO25	TO24

Initial value	0	0	0	0	0	0	0	0

[bit31:0] TO[31:0]: Transmission Occurred

Each Tx Buffer has its own Transmission Occurred bit.

The bits are set when the corresponding TXBRP (Tx Buffer Request Pending) bit is cleared after a successful transmission.

The bits are reset when a new transmission is requested by writing a "1" to the corresponding bit of register TXBAR (Tx Buffer Add Request).

Bit	Description
0	No transmission occurred.
1	Transmission occurred.

5.40. Tx Buffer Cancellation Finished (MCG_CANFDx_TXBCF, CPG_CANFDx_TXBCF)

Signals whether the cancellation request of the corresponding Tx Buffer has been successful or not.

bit	31	30	29	28	27	26	25	24
Field	CF31	CF30	CF29	CF28	CF27	CF26	CF25	CF24

Field	CF7	CF6	CF5	CF4	CF3	CF2	CF1	CF0
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] CF[31:0]: Cancellation Finished

Each Tx Buffer has its own Cancellation Finished bit.

The bits are set when the corresponding TXBRP (Tx Buffer Request Pending) bit is cleared after a cancellation was requested via TXBCR (Tx Buffer Cancellation Request). In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. CF is also set for an unsuccessful transmission when in DAR mode.

The bits are reset when a new transmission is requested by writing a "1" to the corresponding bit of register TXBAR (Tx Buffer Add Request).

Bit	Description
0	No transmit buffer cancellation.
1	Transmit buffer cancellation finished.

5.41. Tx Buffer Transmission Interrupt Enable (MCG_CANFDx_TXBTIE, CPG_CANFDx_TXBTIE)

The settings in the Tx Buffer Transmission Interrupt Enable determine which Tx Buffer will assert an interrupt upon transmission.

bit	31	30	29	28	27	26	25	24
Field	TIE31	TIE30	TIE29	TIE28	TIE27	TIE26	TIE25	TIE24

Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] TIE[31:0]: Transmission Interrupt Enable

Each Tx Buffer has its own Transmission Interrupt Enable bit.

Bit	Description
0	Transmission interrupt disabled.
1	Transmission interrupt enable.

5.42. Tx Buffer Cancellation Finished Interrupt Enable (MCG_CANFDx_TXBCIE, CPG_CANFDx_TXBCIE)

The settings in the Tx Buffer Cancellation Finished Interrupt Enable determine which Tx Buffer will assert an interrupt upon completion of a transmission cancellation request.

bit	31	30	29	28	27	26	25	24
Field	CFIE31	CFIE30	CFIE29	CFIE28	CFIE27	CFIE26	CFIE25	CFIE24

R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] CFIE[31:0]: Cancellation Finished Interrupt Enable

Each Tx Buffer has its own Cancellation Finished Interrupt Enable bit.

Bit	Description
0	Cancellation finished interrupt disabled.
1	Cancellation finished interrupt enabled.

5.43. Tx Event FIFO Configuration (MCG_CANFDx_TXEFC, CPG_CANFDx_TXEFC)

Settings for the Tx Event FIFO.

Write access to the Tx Event FIFO Configuration (TXEFC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved		EFWM[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

Bit	23	22	21	20	19	18	17	16
Field	Reserved		EFS[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

Bit	15	14	13	12	11	10	9	8
Field	EFSA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	EFSA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:30] Reserved: Reserved bits

When writing, always write "0". When reading, "0" is always read.

[bit29:24] EFWM[5:0]: Event FIFO Watermark

EFWM[5:0]	Description
0	Watermark interrupt disabled.
1 to 32	Level for Tx Event FIFO Watermark Reached interrupt (IR.TEFW).
>32	Watermark interrupt disabled.

[bit23:22] Reserved: Reserved bits

When writing, always write "0". When reading, "0" is always read.

[bit21:16] EFS[5:0]: Event FIFO Size

The Tx Event FIFO elements are indexed from 0 to EFS[5:0] - 1.

EFS[5:0]	Description
0	Tx Event FIFO disabled.
1 to 32	Number of Tx Event FIFO elements.
>32	Values greater than 32 are interpreted as 32.

[bit15:2] EFSA[15:2]: Event FIFO Start Address

Start address of Tx Event FIFO in Message RAM (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved bits

When writing, always write "0". When reading, "0" is always read.

5.44. Tx Event FIFO Status (MCG_CANFDx_TXEFS, CPG_CANFDx_TXEFS)

Status of the Tx Event FIFO.

bit	31	30	29	28	27	26	25	24
Field	Reserved						TEFL	EFF
R/W Attribute	RX,W0						R,WX	R,WX
Protection Attribute	-						-	-
Initial value	XXXXXX						0	0

bit	23	22	21	20	19	18	17	16
Field	Reserved			EFPI[4:0]				
R/W Attribute	RX,W0			R,WX				
Protection Attribute	-			-				
Initial value	XXX			00000				

Bit	15	14	13	12	11	10	9	8
Field	Reserved			EFGI[4:0]				
R/W Attribute	RX,W0			R,WX				
Protection Attribute	-			-				
Initial value	XXX			00000				

bit	7	6	5	4	3	2	1	0
Field	Reserved		EFFL[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

[bit31:26] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

[bit25] TEFL: Tx Event FIFO Element Lost

This bit is a copy of interrupt flag IR.TEFL (Tx Event FIFO Element Lost). When IR.TEFL is reset, this bit is also reset.

Bit	Description
0	No Tx Event FIFO element lost.
1	Tx Event FIFO element lost. Also set after write attempt to Tx Event FIFO of size zero.

[bit24] EFF: Event FIFO Full

Bit	Description
0	Tx Event FIFO not full.
1	Tx Event FIFO full.

[bit23:21] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

[bit20:16] EFPI[4:0]: Event FIFO Put Index

EFPI[4:0]	Description
0 to 31	Tx Event FIFO write index pointer, range 0 to 31.

[bit15:13] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

[bit12:8] EFGI[4:0]: Event FIFO Get Index

EFGI[4:0]	Description
0 to 31	Tx Event FIFO read index pointer, range 0 to 31.

[bit7:6] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

[bit5:0] EFFL[5:0]: Event FIFO Fill Level

EFFL[5:0]	Description
0 to 32	Number of elements stored in Tx Event FIFO, range 0 to 32.

5.45. Tx Event FIFO Acknowledge (MCG_CANFDx_TXEFA, CPG_CANFDx_TXEFA)

The Tx Event FIFO Acknowledge is used to acknowledge that the CPU has read an event from the Tx Event FIFO to indicate to the CAN FD Controller that the corresponding Message RAM area may be released. See "3.6. FIFO Acknowledge Handling" for details.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved			EFAI[4:0]				
R/W Attribute	R0,W0			R/W				
Protection Attribute	-			-				
Initial value	000			00000				

[bit31:5] Reserved: Reserved bits

When writing, always write "0". When reading, "0" is always read.

[bit4:0] EFAI[4:0]: Event FIFO Acknowledge Index

After the CPU has read an element or a sequence of elements from the Tx Event FIFO, it has to write the index of the last element read from Tx Event FIFO to EFAI[4:0]. This will set the Tx Event FIFO Get Index TXEFS.EFGI[4:0] to EFAI[4:0] + 1 and update the FIFO 0 Fill Level TXEFS.EFFL[5:0].

6. Message RAM

The Message RAM stores Rx/Tx messages and filter configurations.

6.1. Message RAM Configuration

6.2. Rx Buffer and FIFO Element

6.3. Tx Buffer Element

6.4. Tx Event FIFO Element

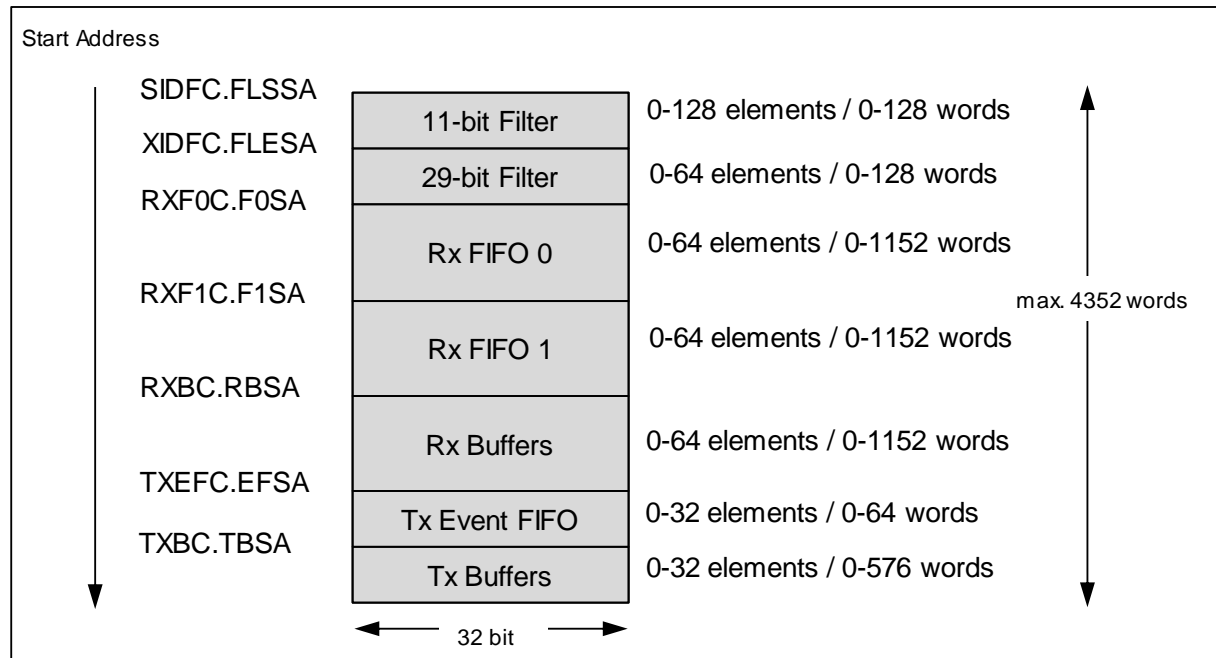

6.5. Standard Message ID Filter Element

6.6. Extended Message ID Filter Element

6.1. Message RAM Configuration

The Message RAM has a width of 32 bits. The CAN FD Controller can be configured to allocate up to 4352 words in the Message RAM (note that the number of words that can be used will be limited by the size of the actual Message RAM). It is not necessary to configure each of the sections listed in Figure 6-1, nor is there any restriction with respect to the sequence of the sections.

Figure 6-1 Message RAM Configuration

The CAN FD Controller addresses the Message RAM in 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Notes:

- *The CAN FD Controller does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.*
- *Message RAM accesses by the CPU will take two to four Bus clock cycles.*

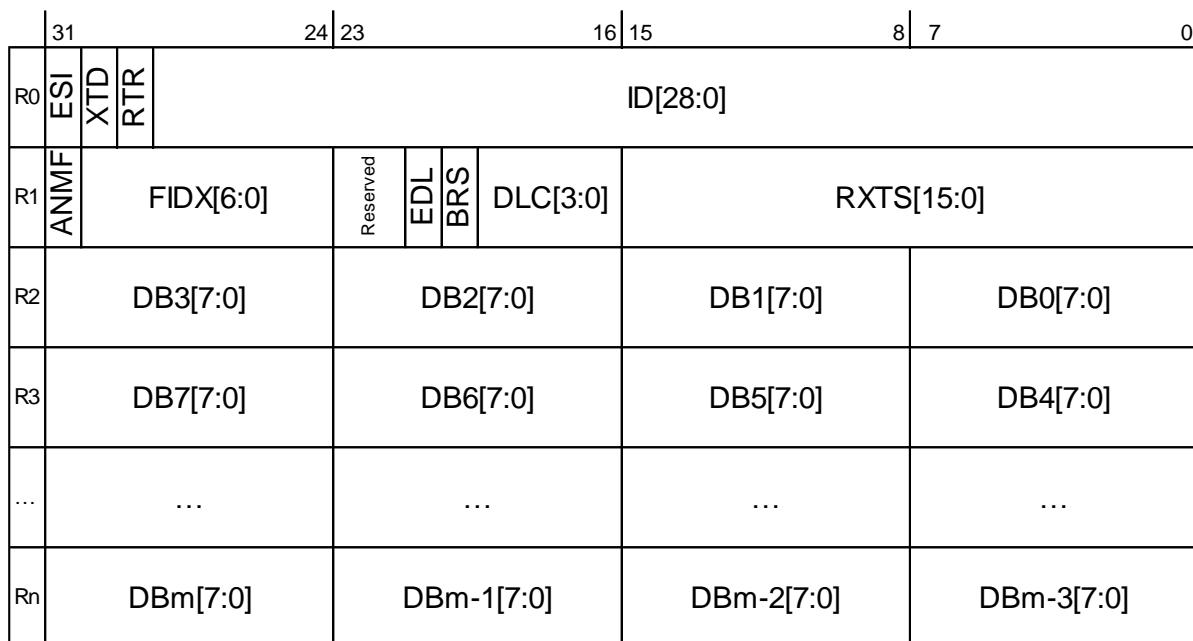

List of Message RAM Elements

Abbreviation	Reference
Rx Buffer and FIFO Element	6.2
Tx Buffer Element	6.3
Tx Event FIFO Element	6.4
Standard Message ID Filter Element	6.5
Extended Message ID Filter Element	6.6

6.2. Rx Buffer and FIFO Element

An Rx Buffer and FIFO Element is a block of 32-bit words that holds the data and status of a received frame that was stored in the Message RAM.

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of an Rx Buffer and FIFO element is shown in the figure below. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC (Rx Buffer/FIFO Element Size Configuration).

R0 [bit31] ESI: Error State Indicator

Bit	Description
0	Transmitting node is error active.
1	Transmitting node is error passive.

R0 [bit30] XTD: Extended Identifier

Signals to the CPU whether the received frame has a standard or extended identifier.

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

R0 [bit29] RTR: Remote Transmission Request

Signals to the CPU whether the received frame is a data frame or a remote frame.

Bit	Description
0	Received frame is a data frame.

1	Received frame is a remote frame.
---	-----------------------------------

Note:

- There are no remote frames in CAN FD format. In case a CAN FD frame was received (EDL = 1), bit RTR reflects the state of the reserved bit r1.

R0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].

R1 [bit31] ANMF: Accepted Non-matching Frame

Acceptance of non-matching frames may be enabled via GFC.ANFS[1:0] (Accept Non-matching Frames Standard) and GFC.ANFE[1:0] (Accept Non-matching Frames Extended).

Bit	Description
0	Received frame matching filter index FIDX.
1	Received frame did not match any Rx filter element.

R1 [bit30:24] FIDX[6:0]: Filter Index

FIDX[6:0]	Description
0 to 127	Index of matching Rx acceptance filter element (invalid if ANMF = 1). Range is 0 to List Size Standard/Extended minus 1 (i.e. SIDFC.LSS - 1 resp. XIDFC.LSE - 1).

R1 [bit23:22] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

R1 [bit21] EDL: Extended Data Length

Bit	Description
0	Standard frame format.
1	CAN FD frame format.

R1 [bit20] BRS: Bit Rate Switch

Bit	Description
0	Frame received without bit rate switching.
1	Frame received with bit rate switching.

R1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0 to 8	CAN + CAN FD: received frame has 0-8 data bytes.

9 to 15	<p>CAN: received frame has 8 data bytes.</p> <p>CAN FD: received frame has 12/16/20/24/32/48/64 data bytes.</p> <p>See Table 3-1 for details.</p>
---------	---

R1 [bit15:0] RXTS[15:0]: Rx Timestamp

Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC.TCP[3:0].

R2 [bit31:24]	DB3[7:0]:	Data Byte 3
R2 [bit23:16]	DB2[7:0]:	Data Byte 2
R2 [bit15:8]	DB1[7:0]:	Data Byte 1
R2 [bit7:0]	DB0[7:0]:	Data Byte 0
R3 [bit31:24]	DB7[7:0]:	Data Byte 7
R3 [bit23:16]	DB6[7:0]:	Data Byte 6
R3 [bit15:8]	DB5[7:0]:	Data Byte 5
R3 [bit7:0]	DB4[7:0]:	Data Byte 4
...
Rn [bit31:24]	DBm[7:0]:	Data Byte m
Rn [bit23:16]	DBm-1[7:0]:	Data Byte m-1
Rn [bit15:8]	DBm-2[7:0]:	Data Byte m-2
Rn [bit7:0]	DBm-3[7:0]:	Data Byte m-3

Notes:

- Depending on the configuration of the element size (defined by Rx Buffer/FIFO Element Size Configuration (RXESC)), Rn will vary from n = 3 to 17.
- m is a function of n, $m = (n - 1) \times 4 - 1$.
- The number of valid data bytes are defined by the Data Length Code.

6.3. Tx Buffer Element

A Tx Buffer Element is a block of 32-bit words stored in the Message RAM that holds data and control information of a frame to be transmitted by the CAN FD Controller.

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO/Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers). The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC (Tx Buffer Element Size Configuration).

	31	24	23	16	15	8	7	0
T0	Reserved	XTD	RTR	ID[28:0]				
T1	MM[7:0]		EFC	Reserved	DLC[3:0]	Reserved		
T2	DB3[7:0]		DB2[7:0]		DB1[7:0]		DB0[7:0]	
T3	DB7[7:0]		DB6[7:0]		DB5[7:0]		DB4[7:0]	
...	
Tn	DBm[7:0]		DBm-1[7:0]		DBm-2[7:0]		DBm-3[7:0]	

T0 [bit31] Reserved: Reserved bit

When writing, always write "0". The read value is undefined.

T0 [bit30] XTD: Extended Identifier

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

T0 [bit29] RTR: Remote Transmission Request

Bit	Description
0	Transmit data frame.
1	Transmit remote frame.

Note:

- When $RTR = 1$, the CAN FD Controller transmits a remote frame according to ISO11898-1, even if the CAN Mode Enable field (CCCR.CME[1:0]) enables the transmission in CAN FD format.

T0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].

T1 [bit31:24] MM[7:0]: Message Marker

Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

T1 [bit23] EFC: Event FIFO Control

Bit	Description
0	Don't store Tx events.
1	Store Tx events.

T1 [bit22:20] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

T1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0 to 8	CAN + CAN FD: transmit frame has 0-8 data bytes.
9 to 15	CAN: transmit frame has 8 data bytes. CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes. See Table 3-1 for details.

T1 [bit15:0] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

T2 [bit31:24]	DB3[7:0]:	Data Byte 3
T2 [bit23:16]	DB2[7:0]:	Data Byte 2
T2 [bit15:8]	DB1[7:0]:	Data Byte 1
T2 [bit7:0]	DB0[7:0]:	Data Byte 0
T3 [bit31:24]	DB7[7:0]:	Data Byte 7
T3 [bit23:16]	DB6[7:0]:	Data Byte 6
T3 [bit15:8]	DB5[7:0]:	Data Byte 5
T3 [bit7:0]	DB4[7:0]:	Data Byte 4

...
Tn [bit31:24]	DBm[7:0]:	Data Byte m
Tn [bit23:16]	DBm-1[7:0]:	Data Byte m-1
Tn [bit15:8]	DBm-2[7:0]:	Data Byte m-2
Tn [bit7:0]	DBm-3[7:0]:	Data Byte m-3

Notes:

- Depending on the configuration of the element size (TXESC), Tn will vary from n = 3 to 17.
- m is a function of n: $m = (n - 1) \times 4 - 1$.

6.4. Tx Event FIFO Element

Each Tx Event FIFO Element stores information about transmitted messages. By reading the Tx Event FIFO the CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS (Tx Event FIFO Status).

E0 [bit31] ESI: Error State Indicator

Bit	Description
0	Transmitting node is error active.
1	Transmitting node is error passive.

E0 [bit30] XTD: Extended Identifier

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

E0 [bit29] RTR: Remote Transmission Request

Bit	Description
0	Data frame transmitted.
1	Remote frame transmitted.

E0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].

E1 [bit31:24] MM[7:0]: Message Marker

Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.

E1 [bit23:22] ET[1:0]: Event Type

Bits	Description
00	Reserved.
01	Tx event.
10	Transmission in spite of cancellation.
11	Reserved.

E1 [bit21] EDL: Extended Data Length

Bit	Description
0	Standard frame format.
1	CAN FD frame format (new DLC-coding and CRC).

E1 [bit20] BRS: Bit Rate Switch

Bit	Description
0	Frame transmitted without bit rate switching.
1	Frame transmitted with bit rate switching.

E1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0 to 8	CAN + CAN FD: frame with 0-8 data bytes transmitted.
9 to 15	CAN: frame with 8 data bytes transmitted. CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted. See Table 3-1 for details.

E1 [bit15:0] TXTS[15:0]: Tx Timestamp

Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler (TSCC.TCP[3:0]).

6.5. Standard Message ID Filter Element

A Standard Message ID Filter Element consists of a single 32-bit word, and can be configured as a range filter, dual filter, classic bit mask filter, or filter for a single dedicated ID, for messages with 11-bit standard IDs.

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is

Filter List Standard Start Address (SIDFC.FLSSA[15:2]) + index of the filter element (0 to 127).

	31		24	23		16	15		8	7		0
S0	SFT [1:0]	SFEC [2:0]	SFID1[10:0]			Reserved			SFID2[10:0]			

S0 [bit31:30] SFT[1:0]: Standard Filter Type

Bits	Description
00	Range filter from SFID1[10:0] to SFID2[10:0] (SFID2[10:0] ≥ received ID ≥ SFID1[10:0]).
01	Dual ID filter for SFID1[10:0] or SFID2[10:0].
10	Classic filter: SFID1[10:0] = filter, SFID2[10:0] = mask. Only those bits of SFID1[10:0] where the corresponding SFID2[10:0] bits are "1" are relevant.
11	Reserved.

Note:

- The setting SFT[1:0] = 0b11 is reserved and should not be used. The setting SFT[1:0] = 0b11 will disable the filter element, but use SFEC[2:0] = 0b000 instead.

S0 [bit29:27] SFEC[2:0]: Standard Filter Element Configuration

All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached.

If SFEC[2:0] = 0b100, 0b101, or 0b110 a match sets interrupt flag IR.HPM (High Priority Message) and, if enabled, an interrupt is generated. In this case register HPMS (High Priority Message Status) is updated with the status of the priority match.

Bits	Description
000	Disable filter element.
001	Store in Rx FIFO 0 if filter matches.
010	Store in Rx FIFO 1 if filter matches.
011	Reject ID if filter matches.
100	Set priority if filter matches.
101	Set priority and store in Rx FIFO 0 if filter matches.
110	Set priority and store in Rx FIFO 1 if filter matches.
111	Store into dedicated Rx Buffer or as debug message, configuration of SFT[1:0] ignored.

S0 [bit26:16] SFID1[10:0]: Standard Filter ID 1

This bit field has a different meaning depending on the configuration of SFEC[2:0]:

- SFEC[2:0] = 0b001 to 0b110
Set SFID1[10:0] according to the SFT[1:0] setting.
- SFEC[2:0] = 0b111
SFID1[10:0] defines the ID of a standard dedicated Rx Buffer or debug message to be stored.
The received identifiers must match exactly, no masking mechanism is used.

S0 [bit15:11] Reserved: Reserved bits

When writing, always write "0". The read value is undefined.

S0 [bit10:0] SFID2[10:0]: Standard Filter ID 2

This bit field has a different meaning depending on the configuration of SFEC[2:0]:

- SFEC[2:0] = 0b001 to 0b110
Set SFID2[10:0] according to the SFT[1:0] setting
- SFEC[2:0] = 0b111
Filter for dedicated Rx Buffers or for debug messages

SFID2[10:9] decides whether the received message is stored into a dedicated Rx Buffer or treated as message A, B, or C of the debug message sequence.

SFID2[10:9]	Description
00	Store message into a dedicated Rx Buffer.
01	Debug Message A.
10	Debug Message B.
11	Debug Message C.

SFID2[8:6] are reserved bits. When writing, always write "0". The read value is undefined.

SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA[15:2] for storage of a matching message.

Notes:

- *Debug message is used for Debug on CAN feature.*
- *Debug on CAN feature is not supported for TRAVEO™ T1G Platform.*

6.6. Extended Message ID Filter Element

An Extended Message ID Filter Element consists of two 32-bit words, and can be configured as a range filter, dual filter, classic bit mask filter, or filter for a single dedicated ID, for messages with 29-bit extended IDs.

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is

Filter List Extended Start Address (XIDFC.FLESA[15:2]) + 2 × index of the filter element (0 to 63).

	31	24	23	16	15	8	7	0
F0	EFEC [2:0]		EFID1[28:0]					
F1	EFT [1:0]	Reserved	EFID2[28:0]					

F0 [bit31:29] EFEC[2:0]: Extended Filter Element Configuration

All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached.

If EFEC[2:0] = 0b100, 0b101, or 0b110 a match sets interrupt flag IR.HPM (High Priority Message) and, if enabled, an interrupt is generated. In this case register HPMS (High Priority Message Status) is updated with the status of the priority match.

Bits	Description
000	Disable filter element.
001	Store in Rx FIFO 0 if filter matches.
010	Store in Rx FIFO 1 if filter matches.
011	Reject ID if filter matches.
100	Set priority if filter matches.
101	Set priority and store in Rx FIFO 0 if filter matches.
110	Set priority and store in Rx FIFO 1 if filter matches.
111	Store into dedicated Rx Buffer or as debug message, configuration of EFT[1:0] ignored.

F0 [bit28:0] EFID1[28:0]: Extended Filter ID 1

This bit field has a different meaning depending on the configuration of EFEC[2:0].

- EFEC[2:0] = 0b001 to 0b110
Set EFID1[28:0] according to the EFT[1:0] setting.
- EFEC[2:0] = 0b111
EFID1[28:0] defines the ID of an extended dedicated Rx Buffer or debug message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see "3.4.1.3. Extended Message ID Filtering") is used.

F1 [bit31:30] EFT[1:0]: Extended Filter Type

Bits	Description
00	Range filter from EFID1[28:0] to EFID2[28:0] (EFID2[28:0] ≥ received ID ANDed with XIDAM ≥ EFID1[28:0]).
01	Dual ID filter Matches when EFID1[28:0] or EFID2[28:0] is equal to received ID ANDed with XIDAM.
10	Classic filter: EFID1[28:0] = filter, EFID2[28:0] = mask. Only those bits of EFID1[28:0] where the corresponding EFID2[28:0] bits are "1" are relevant. Matches when the received ID ANDed with XIDAM is equal to EFID1[28:0] masked by EFID2[28:0].
11	Range filter from EFID1[28:0] to EFID2[28:0] (EFID2[28:0] ≥ EFID1[28:0]), XIDAM mask not applied.

F1 [bit29] Reserved: Reserved bit

When writing, always write "0". The read value is undefined.

F1 [bit28:0] EFID2[28:0]: Extended Filter ID 2

This bit field has a different meaning depending on the configuration of EFEC[2:0]:

- EFEC[2:0] = 0b001 to 0b110
Set EFID2[28:0] according to the EFT[1:0] setting
 - EFEC[2:0] = 0b111
EFID2[28:0] is used to configure this filter for dedicated Rx Buffers or for debug messages
- EFID2[28:11] are reserved bits. When writing, always write "0". The read value is undefined.
- EFID2[10:9] decides whether the received message is stored into a dedicated Rx Buffer or treated as message A, B, or C of the debug message sequence.

Bits	Description
00	Store message into a dedicated Rx Buffer.
01	Debug Message A.
10	Debug Message B.
11	Debug Message C.

EFID2[8:6] are reserved bits. When writing, always write "0". The read value is undefined.

EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA[15:2] for storage of a matching message.

Notes:

- *Debug message is used for Debug on CAN feature.*
- *Debug on CAN feature is not supported for TRAVEO™ T1G Platform.*

CHAPTER 31: CAN FD Controller(MCAN3.2)

This chapter explains the functions and operations of the CAN FD Controller.

1. Overview
2. Configuration
3. Explanation of Operations
4. Setup Procedure Examples
5. Registers
6. Message RAM

CANFD-TXXPT03P01R02L06-E1-XX

1. Overview

The CAN FD Controller performs communication according to ISO11898-1 (CAN specification Rev. 2.0 part A, B) and to the CAN FD specification V1.0.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN Core to a Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN Core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 192 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The CAN FD Controller is accessible by the CPU using a data width of 8/16/32-bits. The CAN FD Controller's clock domain concept allows the separation between the two input clocks, the CAN clock and the Bus clock.

Features of the CAN FD Controller

- Conform with CAN protocol version 2.0 part A, B and ISO 11898-1
- CAN FD with up to 64 data bytes supported
- CAN Error Logging
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for CPU
- Programmable loop-back test mode
- Maskable interrupts
- Two clock domains (CAN clock and Bus clock)
- Power-down support
- Debug on CAN support

Note:

- *Debug on CAN feature is not supported for TRAVEO™ T1G Platform.*

Terms and Abbreviations

This document uses the following terms and abbreviations.

Term	Meaning
mtq	minimum time quantum = CAN clock period (canfd_cclk)
tq	time quantum
SSP	Secondary Sample Point
TSEG1	Time Segment before Sample Point
TSEG2	Time Segment after Sample Point

2. Configuration

This section provides configuration related information about the CAN FD controller.

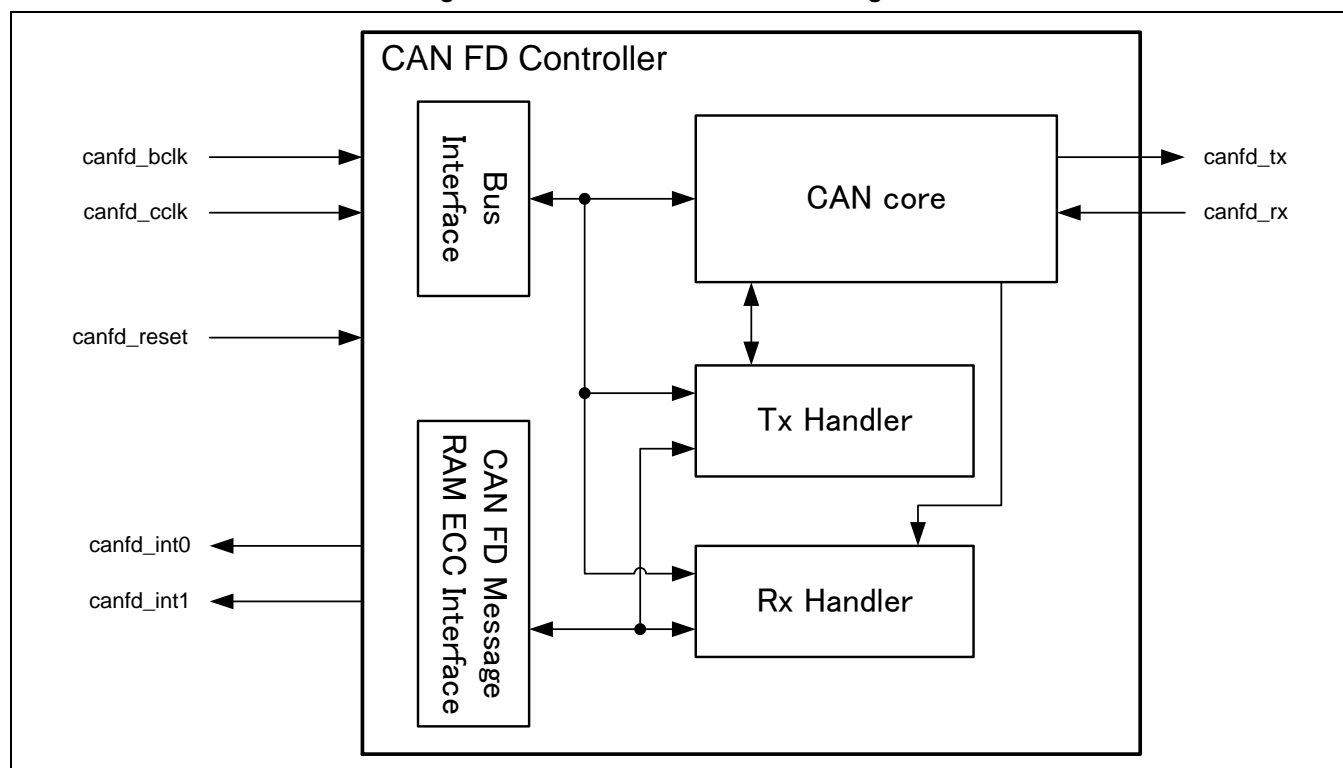

2.1. Block Diagram

2.2. Dual Clock Sources

2.3. Dual Interrupt Lines

2.1. Block Diagram

Figure 2-1 CAN FD Controller Block Diagram

CAN Core

CAN Protocol Controller. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.

CAN FD Message RAM ECC Interface

Interface with the CAN FD Message RAM ECC module. This module contains

- a Message RAM that stores messages to be transmitted, received messages, acceptance filter elements, and Tx Events, and
- ECC (Error Correction Code) logic for the Message RAM.

Bus Interface

CPU interface bus with a data width of 8/16/32-bits.

Tx Handler

Controls the message transfer from the Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

Rx Handler

Controls the transfer of received messages from the CAN Core to the Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.

2.2. Dual Clock Sources

The two clocks of the CAN FD Controller must be configured to meet the following requirement in order to guarantee proper operation:

Bus clock (canfd_bclk) frequency > CAN clock (canfd_cclk) frequency

Note:

- Message RAM Access Failure (see "5.15 Interrupt Register (MCG_CANFDx_IR, CPG_CANFDx_IR)") may be generated depending on between Bus clock (canfd_bclk) and the bit rate of CAN (or CAN FD). Therefore we show the examples of Bus clock frequency to the following tables for preventing Message RAM Access Failure. Bus clock frequency must be input more than the frequency shown in the following tables.

Table 2-1 Required Frequencies [min] for CAN

	Bit Rate		
	250kbps	500kbps	1Mbps
Required Frequency (Bus Clock: canfd_bclk)	5.1MHz	10.1MHz	20.3MHz

Table 2-2 Required Frequencies [min] for CAN FD

	Bit Rate					
	250kbps (nominal)	250kbps (nominal)	500kbps (nominal)	500kbps (nominal)	500kbps (nominal)	1Mbps (nominal)
	1Mbps (FD)	2Mbps (FD)	2Mbps (FD)	4Mbps (FD)	5Mbps (FD)	2Mbps (FD)
Required Frequency (Bus Clock: canfd_bclk)	9.4MHz	12.0MHz	18.8MHz	23.9MHz	25.3MHz	26.3MHz

2.3. Dual Interrupt Lines

The CAN FD Controller provides two interrupt lines. Interrupts can be routed either to canfd_int0 or to canfd_int1. By default all interrupts are routed to interrupt line canfd_int0. By programming bits Enable Interrupt Line 0 (ILE.EINT0) and Enable Interrupt Line 1 (ILE.EINT1) the interrupt lines can be enabled or disabled separately.

3. Explanation of Operations

This section explains the operations of the CAN FD Controller.

- 3.1. Operating Modes
- 3.2. Timestamp Generation
- 3.3. Timeout Counter
- 3.4. Rx Handling
- 3.5. Tx Handling
- 3.6. FIFO Acknowledge Handling
- 3.7. Configuring the CAN Bit Timing

3.1. Operating Modes

This section explains the operating modes of the CAN FD Controller.

- 3.1.1. Software Initialization
- 3.1.2. Normal Operation
- 3.1.3. CAN FD Operation
- 3.1.4. Transmitter Delay Compensation
- 3.1.5. Restricted Operation Mode
- 3.1.6. Bus Monitoring Mode
- 3.1.7. Disabled Automatic Retransmission
- 3.1.8. Power Down (Sleep Mode)
- 3.1.9. Test Modes

3.1.1. Software Initialization

Setting/Resetting the Initialization Bit (CCCR.INIT)

Software initialization is started by setting bit Initialization (CCCR.INIT),

- either by software or by a hardware reset,
- when an uncorrected bit error was detected in the Message RAM,
- or by going Bus_Off.

While CCCR.INIT is set,

- message transfer from and to the CAN bus is stopped,
- the status of the CAN bus output canfd_tx is recessive,
- the protocol error counters are unchanged.

Setting CCCR.INIT does not change any configuration register.

Resetting CCCR.INIT finishes the software initialization. Afterwards the CAN FD Controller synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (\equiv Bus_Idle) before it can take part in bus activities and start the message transfer.

Access/Set/Reset Properties of Registers Affected by Configuration Change Enable (CCCR.CCE)

Access to the configuration registers is only enabled when both bits CCCR.INIT and Configuration Change Enable (CCCR.CCE) are set (protected write). CCCR.CCE can only be set/reset while CCCR.INIT = "1". CCCR.CCE is automatically reset when CCCR.INIT is reset.

The following registers are reset when CCCR.CCE is set

- HPMS - High Priority Message Status
- RXF0S - Rx FIFO 0 Status
- RXF1S - Rx FIFO 1 Status
- TXFQS - Tx FIFO/Queue Status
- TXBRP - Tx Buffer Request Pending
- TXBTO - Tx Buffer Transmission Occurred
- TXBCF - Tx Buffer Cancellation Finished
- TXEFS - Tx Event FIFO Status

In addition

- the Timeout Counter value (TOCV.TOC[15:0]) is preset to the value configured by the Timeout Period (TOCC.TOP[15:0]) when CCCR.CCE is set.
- the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR.CCE = "1".

The following registers are only writeable while CCCR.CCE = "0".

- TXBAR - Tx Buffer Add Request
- TXBCR - Tx Buffer Cancellation Request

Test Mode Enable (CCCR.TEST) and Bus Monitoring Mode (CCCR.MON) can only be set by the CPU while CCCR.INIT = "1" and CCCR.CCE = "1". Both bits may be reset at any time.

Disable Automatic Retransmission (CCCR.DAR) can only be set/reset while CCCR.INIT = "1" and CCCR.CCE = "1".

Message RAM Initialization

The Message RAM should be zeroized before configuration of the CAN FD Controller in order to prevent Message RAM bit errors when reading uninitialized words, and also to avoid unexpected filter element configurations in the Message RAM.

3.1.2. Normal Operation

Once the CAN FD Controller is initialized and Initialization (CCCR.INIT) is reset to "0", the CAN FD Controller synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC (Data Length Code) are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted, dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

3.1.3. CAN FD Operation

There are two variants in the CAN FD frame format,

- the CAN FD frame without bit rate switching.
- the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

Interpretation of Received Frames

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit.

- FDF = recessive signifies a CAN FD frame,
- FDF = dominant signifies a Classic CAN frame.

In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive.

The coding of res = recessive is reserved for future expansion of the protocol. In case receiving a frame with FDF = recessive and res = recessive,

- With Protocol Exception Handling enabled (CCCR.PXHD = "0"), it will signal a Protocol Exception Event by setting PSR.PXE. This causes the operation state to change from Receiver (PSR.ACT = "10") to Integrating (PSR.ACT = "00") at the next sample point.
- With Protocol Exception Handling disabled (CCCR.PXHD = "1"), it will treat a recessive res bit as a form error and will respond with an error frame.

Enabling CAN FD Operation via FD Operation Enable (CCCR.FDOE)

CAN FD operation is enabled by programming FD Operation Enable (CCCR.FDOE). In case CCCR.FDOE = "1", transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element. With CCCR.FDOE = "0", received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set. The transmission properties of CAN FD operation can be changed via FD Operation Enable and Bit Rate Switch Enable (CCCR.FDOE and CCCR.BRSE. See next paragraph for details).

- With CCCR.FDOE = "0", the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format.
- With CCCR.FDOE = "1" and CCCR.BRSE = "0", only bit FDF of a Tx Buffer element is evaluated.
- With CCCR.FDOE = "1" and CCCR.BRSE = "1", transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

CCCR.FDOE and CCCR.BRSE can only be changed while CCCR.INIT and CCCR.CCE are both set.

Changing a Mode during CAN Operation

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significantly higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Bus Monitoring mode until programming has completed. Then all nodes switch back to Classic CAN communication.

The DLC Field

In the CAN FD format, the coding of the DLC differs from the Classic CAN format. The DLC codes 0 to 8 have the same coding as in Classic CAN, the codes 9 to 15, which in Classic CAN all code a data field of 8 bytes, are coded according to Table 3-1 below.

Table 3-1 Coding of DLC in CAN FD

DLC	9	10	11	12	13	14	15
Number of Data Bytes	12	16	20	24	32	48	64

Bit Rate Switching

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the nominal CAN bit timing is used as defined by the Nominal Bit Timing & Prescaler Register (NBTP). In the following CAN FD data phase, the data phase bit timing is used as defined by the Data Bit Timing & Prescaler Register (DBTP). The bit timing is switched back from the data phase timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency (canfd_cclk).

Example:

- *With a CAN clock frequency of 20MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.*

The Error Status Indicator ESI

In both data frame formats, CAN FD and CAN FD with bit rate switching, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

3.1.4. Transmitter Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin `canfd_tx` the protocol controller receives the transmitted data from its local CAN transceiver via pin `canfd_rx`. The received data is delayed by the transmitter delay. In case this delay is greater than the time segment before the sample point of a data phase bit time, a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

3.1.4.1 Description

The CAN FD protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit Transmitter Delay Compensation (DBTP.TDC).

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the transmit output `canfd_tx` through the transceiver to the receive input `canfd_rx` plus the transmitter delay compensation offset as configured by Transmitter Delay Compensation Offset (TDCR.TDCO[6:0]). The transmitter delay compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of `mtq` (`canfd_cclk` period).

Transmitter Delay Compensation Value (PSR.TDCV[6:0]) shows the actual transmitter delay compensation value. PSR.TDCV[6:0] is cleared when CCCR.INIT is set and is updated at each transmission of an FD frame while DBTP.TDC is set.

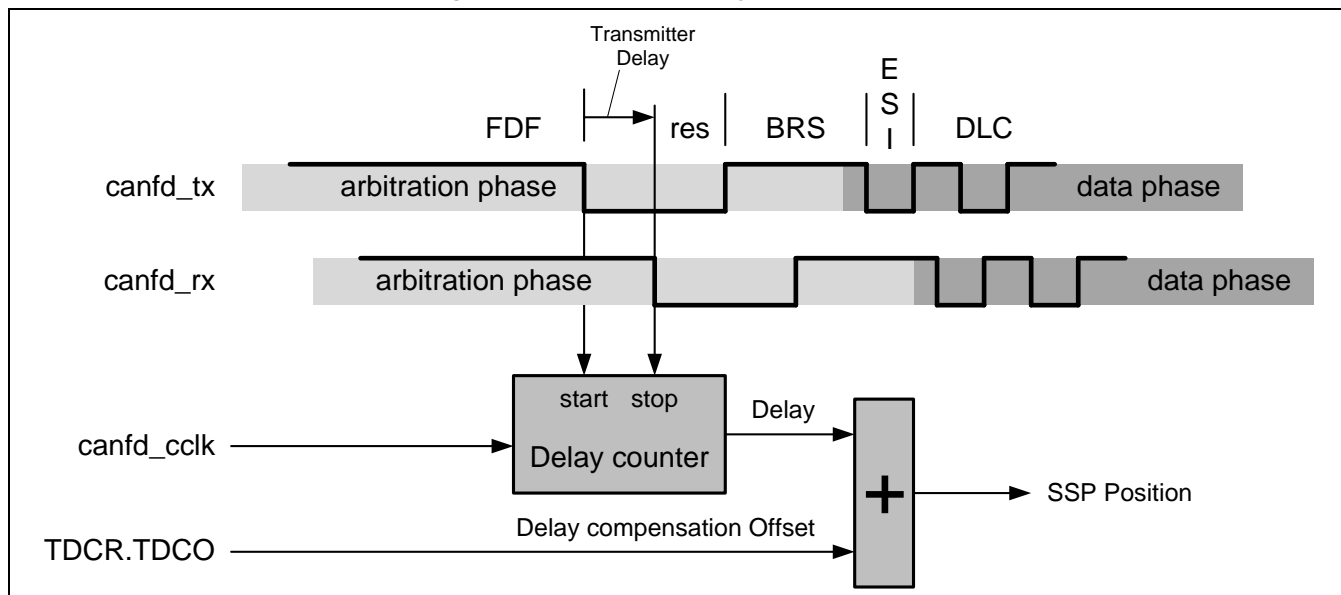

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the CAN FD Controller:

- The sum of the measured delay from `canfd_tx` to `canfd_rx` and the configured transmitter delay compensation offset TDCR.TDCO[6:0] has to be less than 6 bit times in the data phase.
- The sum of the measured delay from `canfd_tx` to `canfd_rx` and the configured transmitter delay compensation offset TDCR.TDCO[6:0] has to be less or equal 127 `mtq`. In case this sum exceeds 127 `mtq`, the maximum value of 127 `mtq` is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

3.1.4.2 Transmitter Delay Compensation Measurement

Figure 3-1 below describes how the transmitter delay is measured.

Figure 3-1 Transmitter Delay Measurement

If transmitter delay compensation is enabled by programming Transmitter Delay Compensation (DBTP.TDC) = "1", the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input **canfd_rx** of the transmitter. The resolution of this measurement is one mtq.

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming Transmitter Delay Compensation Filter Window Length (TDCR.TDCF[6:0]). This defines a minimum value for the SSP position. Dominant edges on **canfd_rx**, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR.TDCF[6:0] AND **canfd_rx** is low.

3.1.5. Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (ECR.REC[6:0], ECR.TEC[7:0]) are frozen while Error Logging (ECR.CEL) is active.

The CPU can set the CAN FD Controller into Restricted Operation Mode by setting the Restricted Operation Mode bit (CCCR.ASM). CCCR.ASM can only be set by the CPU when both Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) are set to "1". CCCR.ASM can be reset by the CPU at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the CPU has to reset CCCR.ASM.

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

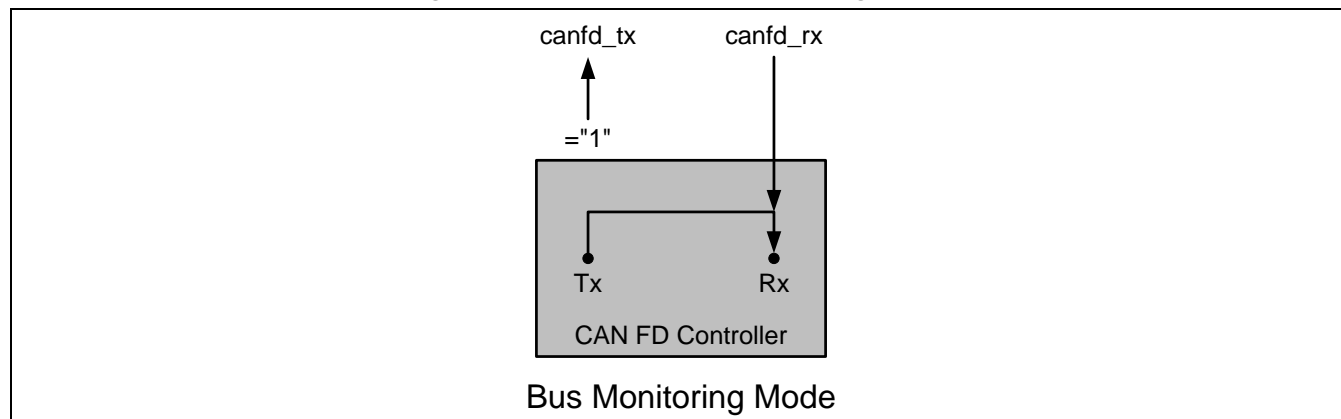

Note:

- *The Restricted Operation Mode must not be combined with the Loop Back Mode (internal or external).*

3.1.6. Bus Monitoring Mode

The CAN FD Controller is set in Bus Monitoring Mode by programming the Bus Monitoring Mode bit (CCCR.MON) to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the CAN FD Controller is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the CAN FD Controller is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the CAN FD Controller monitors this dominant bit, although the CAN bus may remain in recessive state. The Tx Buffer Request Pending register (TXBRP) will be cleared when setting Configuration Change Enable CCCR.CCE = "1" upon entering Bus Monitoring Mode via CCCR.MON = "1", and will be held in reset state while it is in this mode.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. Figure 3-2 shows the connection of signals canfd_tx and canfd_rx to the CAN FD Controller in Bus Monitoring Mode.

Figure 3-2 Pin Control in Bus Monitoring Mode

3.1.7. Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the CAN FD Controller provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. The automatic retransmission may be disabled via the Disable Automatic Retransmission bit (CCCR.DAR).

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. In this mode the CAN FD Controller will internally reset the corresponding Tx Buffer's Tx Request Pending bit (TXBRP.TRPn) when one of the following conditions occur:

- A successful transmission has occurred. This can be observed as
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO.TOn set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF.CFn not set

or, in case a successful transmission was executed in spite of cancellation,

- Corresponding Tx Buffer Transmission Occurred bit TXBTO.TOn set
- Corresponding Tx Buffer Cancellation Finished bit TXBCF.CFn set

In both these cases, if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET "10" (transmission in spite of cancellation).

- A transmission has not yet been started at the point of cancellation
- A transmission has been aborted due to lost arbitration or frame transmission disturbed. This can be observed by
 - Corresponding Tx Buffer Transmission Occurred bit TXBTO.TOn not set
 - Corresponding Tx Buffer Cancellation Finished bit TXBCF.CFn set

3.1.8. Power Down (Sleep Mode)

The CAN FD Controller can be set into power down mode via Clock Stop Request (CCCR.CSR).

When all pending transmission requests have completed (when Tx Buffer Request Pending Register TXBRP = 0x00000000), the CAN FD Controller waits until bus idle state is detected. Then the CAN FD Controller sets Initialization (CCCR.INIT) to one to prevent any further CAN transfers. Now the CAN FD Controller acknowledges that it is ready for power down by setting Clock Stop Acknowledge (CCCR.CSA) to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR.INIT will have no effect. Now the CAN FD Controller clock inputs canfd_bclk and canfd_cclk may be switched off.

To leave power down mode, the application has to turn on the CAN FD Controller clocks before resetting Clock Stop Request (CCCR.CSR). The CAN FD Controller will acknowledge this by resetting CCCR.CSA. Afterwards, the application can restart CAN communication by resetting bit CCCR.INIT.

3.1.9. Test Modes

To enable write access to the Test register TEST, Test Mode Enable (CCCR.TEST) has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin canfd_tx by programming Control of Transmit Pin (TEST.TX). These are

- the default function – the serial data output
- drive the CAN Sample Point signal to monitor the CAN FD Controller's bit timing
- drive constant dominant values
- drive constant recessive values.

The actual value at pin canfd_rx can be read from Receive Pin (TEST.RX). Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between the CAN clock and Bus clock domains, there may be a delay of several Bus clock periods between writing to TEST.TX until the new configuration is visible at output pin canfd_tx. This applies also when reading input pin canfd_rx via TEST.RX.

Note:

- *Test modes should be used for self test only. The software control for pin canfd_tx interferes with all CAN protocol functions. It is not recommended to use test modes for application.*

3.1.9.1 External Loop Back Mode

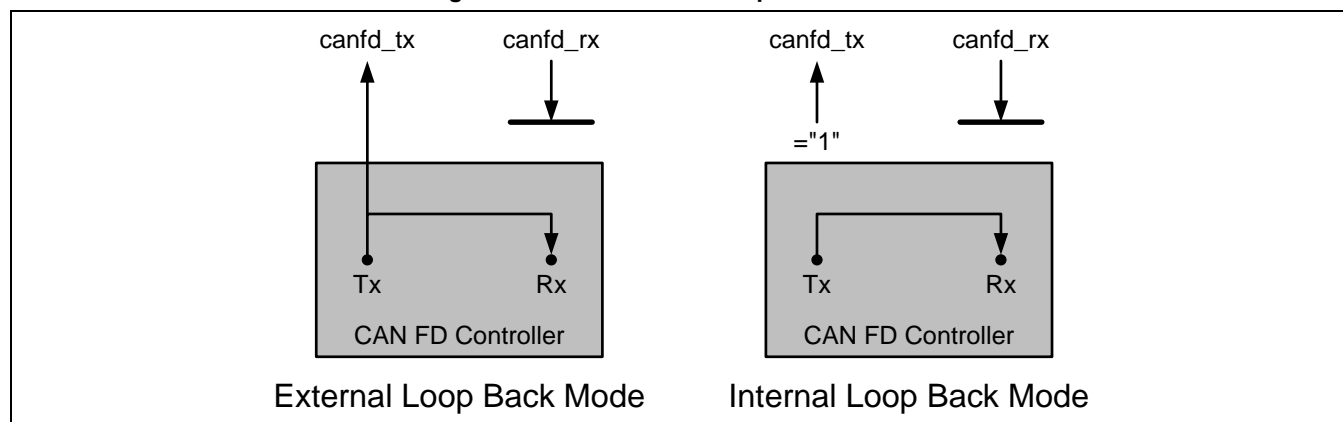

The CAN FD Controller can be set in External Loop Back Mode by programming the Loop Back Mode bit (TEST.LBCK) to one. In External Loop Back Mode, the CAN FD Controller treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into a dedicated Rx Buffer or an Rx FIFO. Figure 3-3 shows the connection of signals canfd_tx and canfd_rx to the CAN FD Controller in External Loop Back Mode.

This mode is provided for hardware self test. The CAN FD Controller ignores acknowledge errors in External Loop Back Mode. In this mode the CAN FD Controller performs an internal feedback from its Tx output to its Rx input. The actual value of the canfd_rx input pin is disregarded by the CAN FD Controller. The transmitted messages can be monitored at the canfd_tx pin.

3.1.9.2 Internal Loop Back Mode

Internal Loop Back Mode is entered by programming bits Loop Back Mode (TEST.LBCK) and Bus Monitoring Mode (CCCR.MON) to one. This mode can be used for a "Hot Self test", meaning the CAN FD Controller can be tested without affecting a running CAN system connected to the pins canfd_tx and canfd_rx. In this mode pin canfd_rx is disconnected from the CAN FD Controller and pin canfd_tx is held recessive. Figure 3-3 shows the connection of canfd_tx and canfd_rx to the CAN FD Controller in case of Internal Loop Back Mode.

Figure 3-3 Pin Control in Loop Back Modes

3.2. Timestamp Generation

For timestamp generation the CAN FD Controller supplies a 16-bit wrap-around counter. On start of frame reception/transmission the counter value is captured and stored into the timestamp section of an Rx Buffer and FIFO or Tx Event FIFO element (fields RXTS[15:0] and TXTS[15:0] of the respective elements).

For more details, see "5.8. Timestamp Counter Configuration (MCG_CANFDx_TSCC, CPG_CANFDx_TSCC)" and "5.9. Timestamp Counter Value (MCG_CANFDx_TSCV, CPG_CANFDx_TSCV)".

3.3. Timeout Counter

To signal timeout conditions, the CAN FD Controller supplies a 16-bit Timeout Counter. For Rx FIFO 0, Rx FIFO 1, and Tx Event FIFO triggered operations, it starts down counting when an element is stored, and stops counting when the FIFO is emptied by the CPU. The Timeout Counter may also be triggered by a "0" write to the Initialization bit CCCR.INIT, and count down repeatedly until CCCR.INIT is set back to "1".

The Timeout Counter operates as down-counter and uses the same prescaler controlled by Timestamp Counter Prescaler (TSCC.TCP[3:0]) as the Timestamp Counter. The Timeout Counter is configured via register Timeout Counter Configuration (TOCC). The actual counter value can be read from Timeout Counter (TOCV.TOC[15:0]). The Timeout Counter is operable only when CCCR.INIT = "0". It is stopped when Initialization CCCR.INIT = "1", e.g. when the CAN FD Controller enters Bus_Off state.

The operation mode is selected by the Timeout Select field TOCC.TOS[1:0]. For details, see "5.11. Timeout Counter Value (MCG_CANFDx_TOCV, CPG_CANFDx_TOCV)".

Note:

- When Timestamp Select TSCC.TSS[1:0] = "01", the clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore, if the bit rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

3.4. Rx Handling

The Rx Handler controls the acceptance filtering, the transfer of received messages to the dedicated Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

3.4.1. Acceptance Filtering

3.4.2. Rx FIFOs

3.4.3. Dedicated Rx Buffers

3.4.4. Debug on CAN Support

3.4.5. Protocol Exception Event

3.4.1. Acceptance Filtering

The CAN FD Controller offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to a dedicated Rx Buffer or to Rx FIFO 0, 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

Main Features

- Each filter element can be configured as
 - range filter (from - to)
 - filter for one or two specific IDs (dual filter)
 - classic bit mask filter
 - filter for a single dedicated ID
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled/disabled individually
- Filters are checked sequentially from filter element 0, execution stops with the first matching filter element

Related Configuration Registers

- Global Filter Configuration GFC
- Standard ID Filter Configuration SIDFC
- Extended ID Filter Configuration XIDFC
- Extended ID AND Mask XIDAM

Filter Properties

Depending on the configuration of the filter element configuration fields (SFEC[2:0]/EFEC[2:0]) a match triggers one of the following actions:

- Store received frame in Rx FIFO 0 or Rx FIFO 1
- Store received frame in dedicated Rx Buffer
- Reject received frame
- Set High Priority Message interrupt flag IR.HPM
- Set High Priority Message interrupt flag IR.HPM and store received frame in Rx FIFO 0 or Rx FIFO 1

Description

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching dedicated Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bits to the matching dedicated Rx Buffer or Rx FIFO.

If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected dedicated Rx Buffer or Rx FIFO:

- Dedicated Rx Buffer
 - New Data flag NDAT1/2.NDn of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see Last Error Code (PSR.LEC[2:0]) respectively Data Phase Last Error Code (PSR.DLEC[2:0]).
- Rx FIFO

Put index of matching Rx FIFO RXFnS.FnPI[5:0] is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR.LEC[2:0] respectively PSR.DLEC[2:0].

In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in "3.4.2.2. Rx FIFO Overwrite Mode" have to be considered.

3.4.1.1 Filter Types

Range Filter

A range filter matches all received frames with Message IDs in the range defined by the Standard Message ID Filter Element SFID1[10:0]/SFID2[10:0] fields resp. Extended Message ID Filter Element EFID1[28:0]/EFID2[28:0] fields (the range includes the end points SFID1[10:0]/SFID2[10:0] resp. EFID1[28:0]/EFID2[28:0]).

There are two possibilities for the Extended Filter Type of the Extended Message ID Filter Element (EFT[1:0]) when range filtering is used together with extended frames:

- EFT[1:0] = "00":
The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT[1:0] = "11":
The Extended ID AND Mask (XIDAM) is not used for range filtering

Filter for Specific IDs (Dual Filter)

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SFID1[10:0] = SFID2[10:0] resp. EFID1[28:0] = EFID2[28:0].

Classic Bit Mask Filter

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SFID1[10:0]/EFID1[28:0] is used as Message ID filter, while SFID2[10:0]/EFID2[28:0] is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

Filter for a Single Dedicated ID

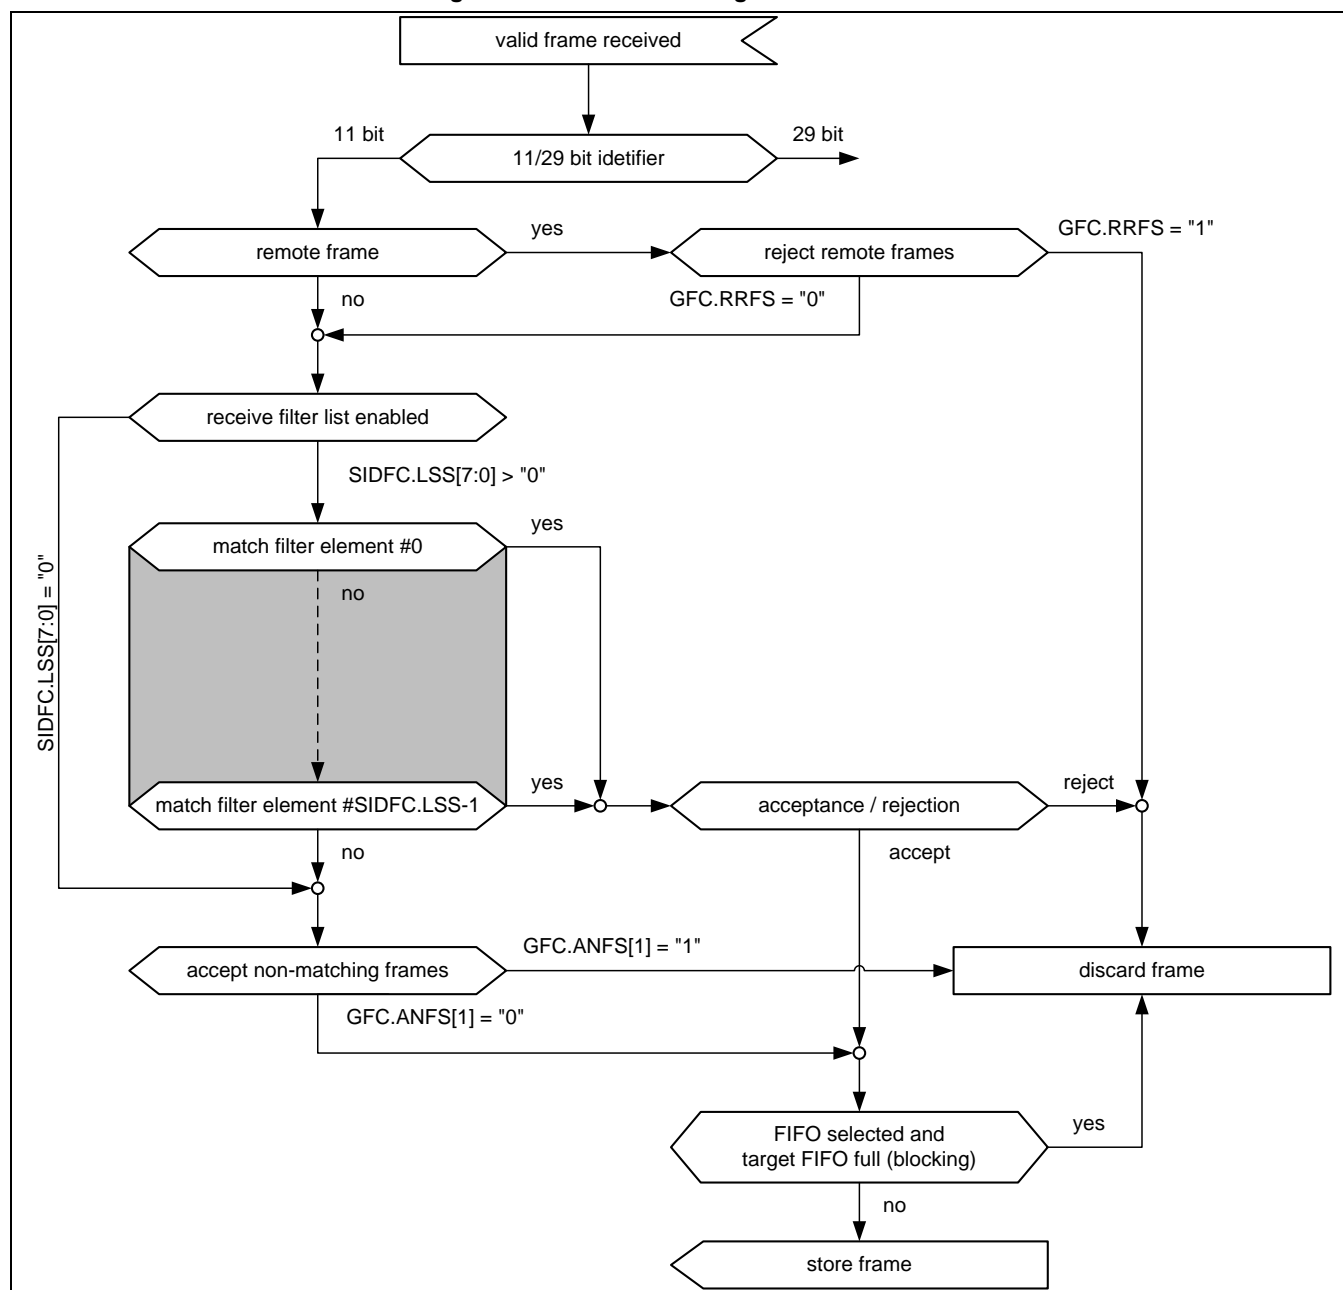

A filter for a single dedicated ID stores received messages in dedicated Rx Buffers if the received ID matches SFID1[10:0]/EFID1[28:0]. SFID2[10:0]/EFID2[28:0] is used to configure the offset to the Rx Buffer Start Address (RXBC.RBSA[15:2]) of where the message is to be stored, and also to define how the message is to be treated (Debug message or Dedicated Rx message).

3.4.1.2 Standard Message ID Filtering

Figure 3-4 below shows the flow for standard Message ID (11-bit Identifier) filtering.

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC, Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 3-4 Standard Message ID Filter Path

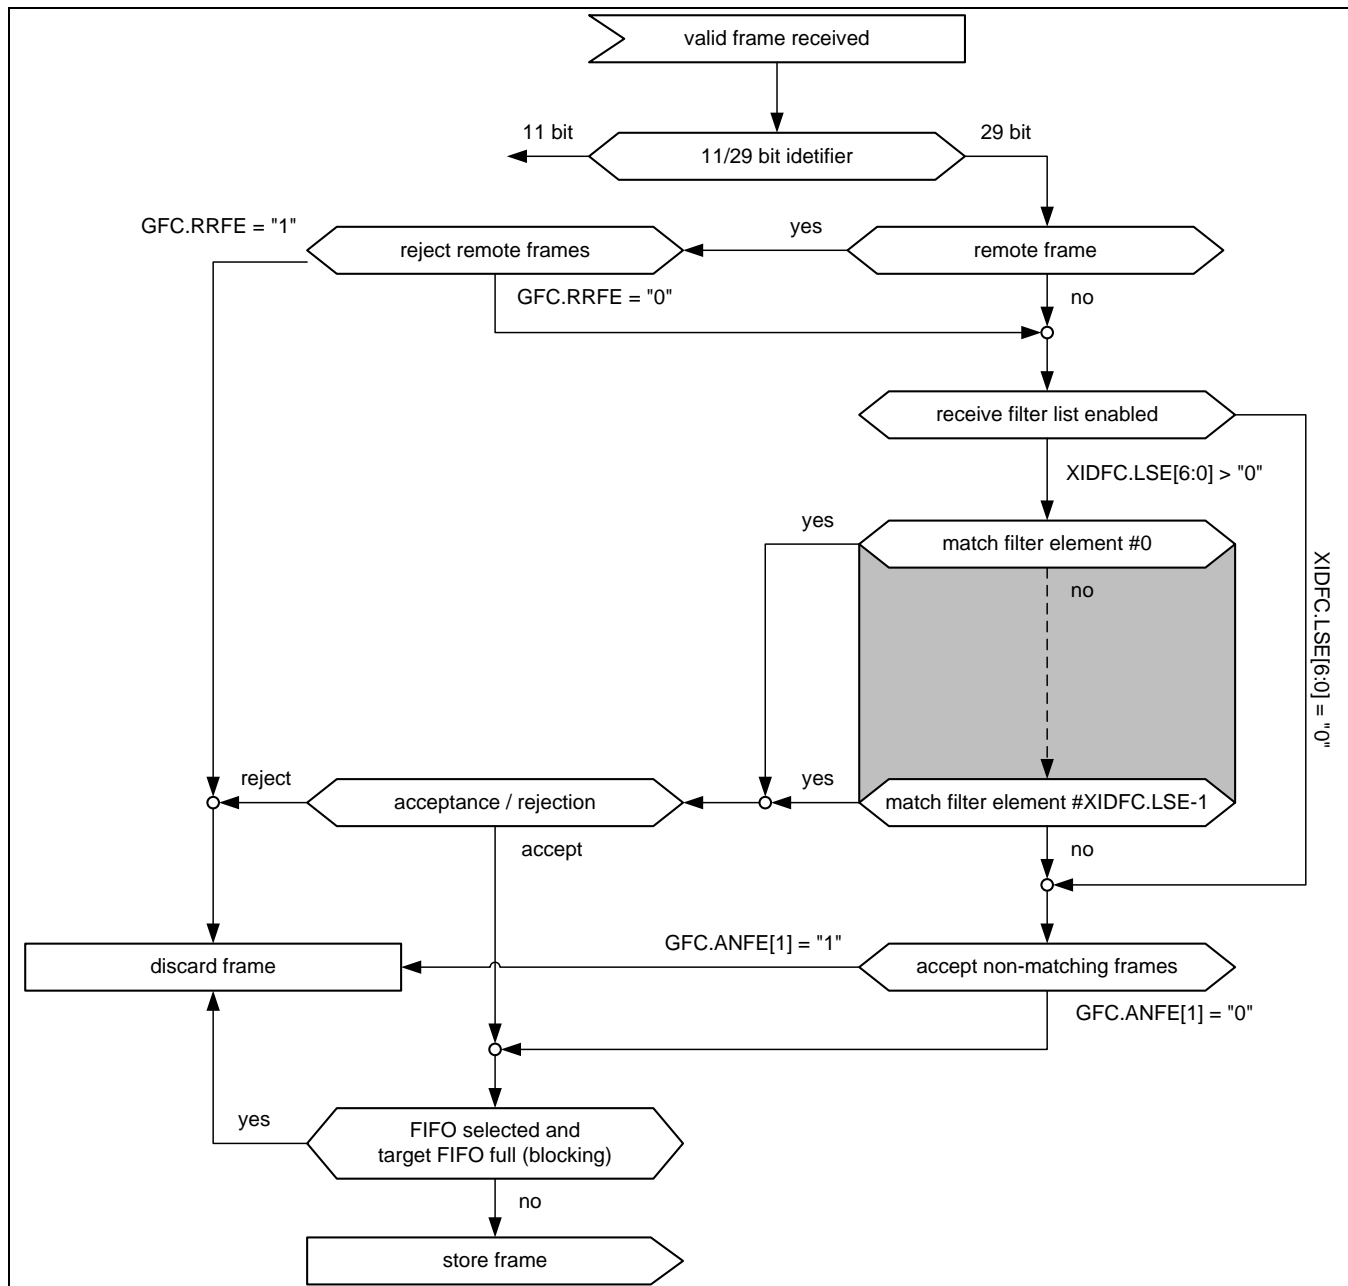

3.4.1.3 Extended Message ID Filtering

Figure 3-5 below shows the flow for extended Message ID (29-bit Identifier) filtering.

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC, Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask XIDAM.EIDM[28:0] is ANDed with the received identifier before the filter list is executed.

Figure 3-5 Extended Message ID Filter Path

3.4.2. Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via the Rx FIFO 0 and 1 Configuration registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element.

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level $RxFnS.FnFL[6:0]$ reaches the Rx FIFO watermark configured by Rx FIFO n Watermark ($RxFnC.FnWM[6:0]$), interrupt flag Rx FIFO n Watermark Reached (IR.RFnW) is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by Rx FIFO n Full ($RxFnS.FnF$). In addition interrupt flag Rx FIFO n Full (IR.RFnF) is set.

Figure 3-6 RX FIFO Status

Addressing Rx Buffers

An Rx Buffer allocates Element Size 32-bit words in the Message RAM (see Table 3-2). Therefore when reading from an Rx FIFO, the start address of an Rx Buffer will be

Rx FIFO Get Index ($RxFnS.FnGI[5:0]$) × Element Size
+ corresponding Rx FIFO start address ($RxFnC.FnSA[15:2]$).

Table 3-2 Rx Buffer/FIFO Element Size

RXESC.RBDS[2:0] RXESC.FnDS[2:0]	Data Field [Bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

3.4.2.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by FIFO n Operation Mode $RXFnC.FnOM = "0"$. This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached ($RXFnS.FnPI[5:0] = RXFnS.FnGI[5:0]$), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by Rx FIFO n Full ($RXFnS.FnF = "1"$). In addition interrupt flag Rx FIFO n Full (IR.RFnF) is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by Rx FIFO n Message Lost $RXFnS.RFnL = "1"$. In addition interrupt flag Rx FIFO n Message Lost (IR.RFnL) is set.

3.4.2.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by FIFO n Operation Mode $RXFnC.FnOM = "1"$.

When an Rx FIFO full condition ($RXFnS.FnPI[5:0] = RXFnS.FnGI[5:0]$) is signalled by Rx FIFO n Full $RXFnS.FnF = "1"$, the next message accepted for the Rx FIFO will overwrite the oldest Rx FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. Figure 3-7 shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 3-7 RX FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index (RxFnA.FnA[5:0]). This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (Rx FIFO n Full RxFnS.FnF = "0").

3.4.3. Dedicated Rx Buffers

The CAN FD Controller supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via the Rx Buffer Start Address field (RXBC.RBSA[15:2]).

For each dedicated Rx Buffer a Standard or Extended Message ID Filter Element with SFEC[2:0]/EFEC[2:0] = "111" and SFID2[10:9]/EFID2[10:9] = "00" has to be configured.

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR.DRX (Message stored to Dedicated Rx Buffer) in the interrupt register is set.

Table 3-3 Example Filter Configuration for Rx Buffers

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID message 1	00	00 0000
1	ID message 2	00	00 0001
2	ID message 3	00	00 0010

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1, 2 is set. As long as the New Data flag is set, the respective dedicated Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the CPU by writing a "1" to the respective bit position.

While a dedicated Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific dedicated Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another dedicated Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration.

Addressing Dedicated Rx Buffers

A Dedicated Rx Buffer allocates Element Size 32-bit words in the Message RAM (see Table 3-2). Therefore the start address of a dedicated Rx Buffer in the Message RAM is calculated by

(Offset defined in Message ID Filter Element SFID2[5:0] resp. EFID2[5:0]) × Element Size + Rx Buffer Start Address (RXBC.RBSA[15:2]).

3.4.4. Debug on CAN Support

For debug handling, three consecutive Rx buffers (e.g. #61, #62, #63) can be used for storage of three specific debug messages A, B, and C. The format is the same as for a dedicated Rx Buffer or an Rx FIFO element.

For filtering of debug messages Standard/Extended Filter Elements with Standard/Extended Filter Configuration SFEC[2:0]/EFEC[2:0] = "111" have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by the lower six bits of the Standard/Extended Message ID Filter Element fields SFID2[5:0]/EFID2[5:0]. The upper two bits SFID2[10:9]/EFID2[10:9] are used to define the Debug Message that is to be stored in the respective Rx Buffer.

When a debug message is stored, neither the respective New Data flag (NDAT1.NDn / NDAT2.NDn) nor the interrupt IR.DRX (Message stored to Dedicated Rx Buffer) are set.

After the three messages have been received in correct order, a DMA transfer is requested. After the DMA transfer has completed, the CAN FD Controller is prepared to receive the next set of debug messages.

Table 3-4 Example Filter Configuration for Debug Messages

Filter Element	SFID1[10:0] EFID1[28:0]	SFID2[10:9] EFID2[10:9]	SFID2[5:0] EFID2[5:0]
0	ID debug message A	01	11 1101
1	ID debug message B	10	11 1110
2	ID debug message C	11	11 1111

Notes:

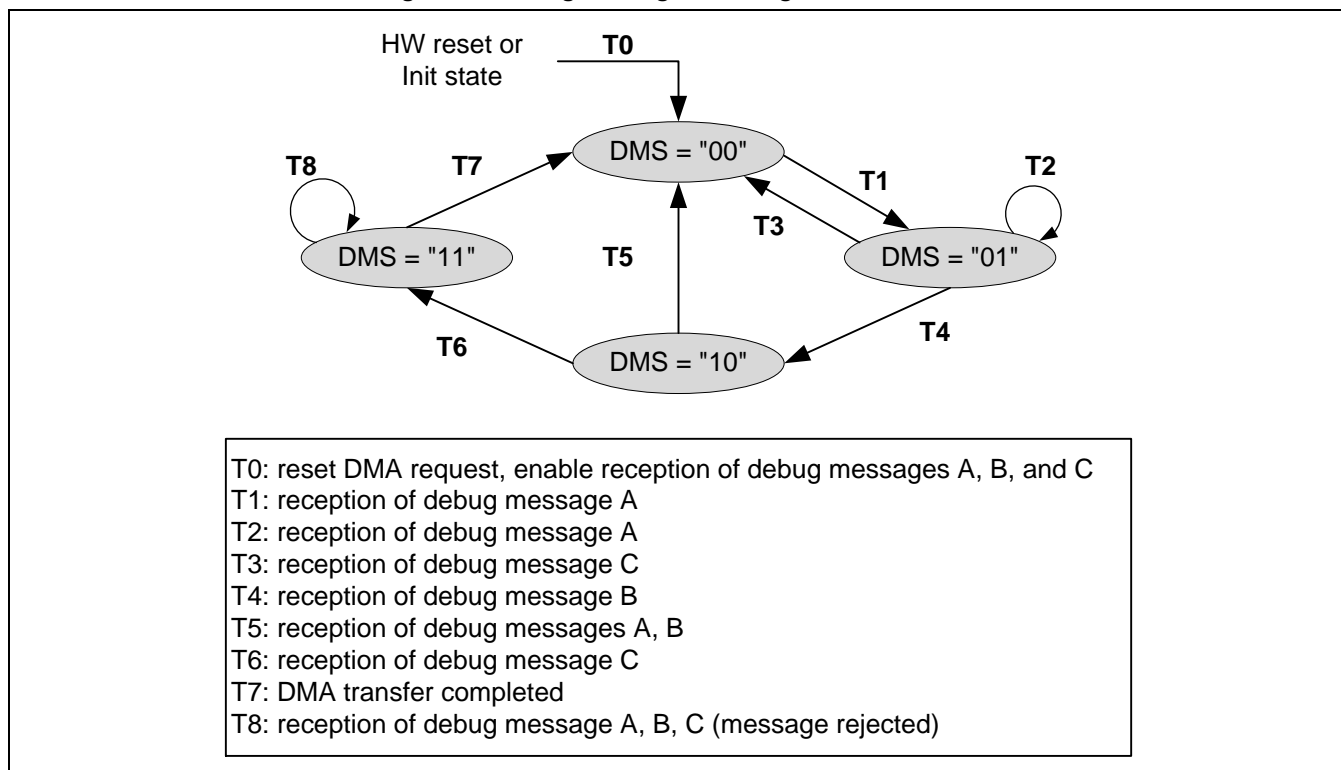

- Debug on CAN feature is not supported for TRAVEO™ T1G Platform.
- DMA transfer request is not supported also.

3.4.4.1 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signalled via the Debug Message Status field (RXF1S.DMS[1:0]).

Figure 3-8 Debug Message Handling State Machine

Notes:

- Debug message is used for Debug on CAN feature.
- Debug on CAN feature is not supported for TRAVEO™ T1G Platform.

3.4.5. Protocol Exception Event

When the CAN FD Controller is enabled both CAN FD operation (CCCR.FDOE = "1") and Protocol exception handling (CCCR.PXHD = "0"), the CAN FD Controller detects the res bit following the FDF bit in a received message to be recessive, it treats this detection as a Protocol Exception Event. As reaction to the Protocol Exception Event,

- the error counters (ECR.REC[6:0] and ECR.TEC[7:0]) are not changed
- hard synchronization is enabled
- the CAN FD Controller will send recessive bits
- Protocol Exception Event (PSR.PXE) bit is set, then the operation state will change from Receiver (PSR.ACT[1:0] = "10") to Integrating (PSR.ACT[1:0] = "00") at the next sample point

The CAN FD Controller will also start an internal bit counter that counts the number of recessive bits detected on the CAN bus. If the counter detects eleven consecutive recessive bits, the CAN FD Controller will recover from the Protocol Exception Event and enter an idle state. In case an edge that causes synchronization is detected during the wait period, the CAN FD Controller will reset the internal bit counter and restart counting the number of recessive bits detected.

3.5. Tx Handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in "6.3. Tx Buffer Element". Table 3-5 below describes the possible configurations for frame transmission.

Table 3-5 Possible Configurations for Frame Transmission

CCCR		Tx Buffer Element		Frame Transmission
BRSE	FDOE	FDF	BRS	
ignored	0	ignored	ignored	Classic CAN
0	1	0	ignored	Classic CAN
0	1	1	ignored	FD without bit rate switching
1	1	0	ignored	Classic CAN
1	1	1	0	FD without bit rate switching
1	1	1	1	FD with bit rate switching

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

3.5.1. Transmit Pause

3.5.2. Dedicated Tx Buffers

3.5.3. Tx FIFO

3.5.4. Tx Queue

3.5.5. Mixed Dedicated Tx Buffers/Tx FIFO

3.5.6. Mixed Dedicated Tx Buffers/Tx Queue

3.5.7. Transmit Cancellation

3.5.8. Tx Event Handling

3.5.1. Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU (Electronic Control Unit) sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If e.g. CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two nominal bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate

with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by the Transmit Pause bit (CCCR.TXP). If the bit is set, the CAN FD Controller will, each time it has successfully transmitted a message, pause for two nominal bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR.TXP = "0").

This feature looses up burst transmissions coming from a single node and it protects against "babbling idiot" scenarios where the application program erroneously requests too many transmissions.

3.5.2. Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR.ARn. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

Addressing Dedicated Tx Buffers

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see Table 3-6).

Therefore the start address of a dedicated Tx Buffer in the Message RAM is calculated by

transmit buffer index (0 to 31) × Element Size + Tx Buffers Start Address (TXBC.TBSA[15:2]).

Table 3-6 Tx Buffer/FIFO/Queue Element Size

TXESC.TBDS[2:0]	Data Field [Bytes]	Element Size [RAM words]
000	8	4
001	12	5
010	16	6
011	20	7
100	24	8
101	32	10
110	48	14
111	64	18

3.5.3. Tx FIFO

Tx FIFO operation is configured by programming the Tx FIFO/Queue Mode bit (TXBC.TFQM) to "0". Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Tx FIFO Get Index (TXFQS.TFGI[4:0]). After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The CAN FD Controller calculates the number of available (free) Tx FIFO elements TXFQS.TFFL[5:0] (Tx FIFO Free Level) as difference between Tx FIFO Get Index (TXFQS.TFGI[4:0]) and Tx FIFO/Queue Put Index (TXFQS.TFQPI[4:0]).

Adding Messages and Requesting Transmissions

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index (TXFQS.TFQPI[4:0]). An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS.TFQF = "1") is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a "1" to the Add Request bit (TXBAR.ARn. n is the index of the requested Tx Buffer) related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via the Tx Buffer Add Request register (TXBAR) by requesting all n Tx FIFO Buffers in a single command. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level (TXFQS.TFFL[5:0]). Transmission should not be requested to Tx Buffers outside the Put Index since this will cause the TXFQS.TFFL[5:0] to return a false value.

Cancelling Transmissions

Transmit Cancellation is intended for Tx Queues and Dedicated Tx Buffers. Cancelling requested Tx FIFO Buffer transmissions are not supported and is not recommended, except for the case where all Tx Buffers within the Tx FIFO are cancelled simultaneously (with a single command).

In the case that a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

Addressing Tx Buffers in the Tx FIFO

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (see Table 3-6). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by

Tx FIFO/Queue Put Index (TXFQS.TFQPI[4:0]) (0 to 31) × Element Size
+ Tx Buffers Start Address (TXBC.TBSA[15:2]).

3.5.4. Tx Queue

Tx Queue operation is configured by programming the Tx FIFO/Queue Mode bit TXBC.TFQM to "1". Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

Adding Messages and Requesting Transmissions

New messages have to be written to the Tx Buffer referenced by the Tx FIFO/Queue Put Index TXFQS.TFQPI[4:0]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS.TFQF = "1"), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use the Tx Buffer Request Pending register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

Addressing Tx Buffers in the Tx Queue

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see Table 3-6). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by

Tx FIFO/Queue Put Index (TXFQS.TFQPI[4:0]) (0 to 31) × Element Size
 + *Tx Buffers Start Address (TXBC.TBSA[15:2]).*

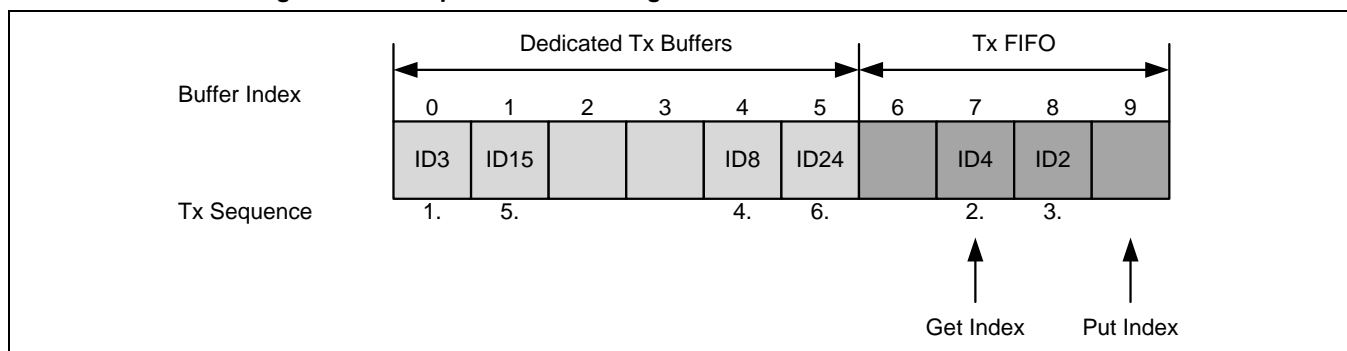

3.5.5. Mixed Dedicated Tx Buffers/Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO.

The number of Dedicated Tx Buffers is configured by TXBC.NDTB[5:0].

The number of Tx Buffers assigned to the Tx FIFO is configured by the Tx FIFO/Queue Size TXBC.TFQS[5:0]. In case TXBC.TFQS[5:0] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 3-9 Example of Mixed Configuration Dedicated Tx Buffers/Tx FIFO

Tx Prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by the Tx FIFO Get Index TXFQS.TFGI[4:0])
- Buffer with lowest Message ID gets highest priority and is transmitted next

Note:

- *Mixed Dedicated Tx Buffers/Tx FIFO isn't supported. Don't use combination Dedicated Tx Buffers and Tx FIFO.*

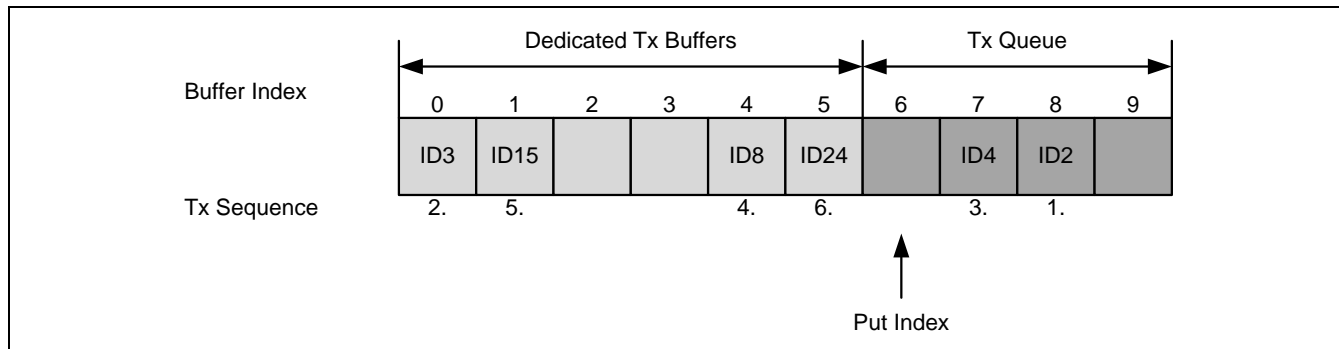

3.5.6. Mixed Dedicated Tx Buffers/Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue.

The number of Dedicated Tx Buffers is configured by TXBC.NDTB[5:0].

The number of Tx Queue Buffers is configured by the Tx FIFO/Queue Size TXBC.TFQS[5:0]. In case TXBC.TFQS[5:0] is programmed to zero, only Dedicated Tx Buffers are used.

Figure 3-10 Example of Mixed Configuration Dedicated Tx Buffers/Tx Queue

Tx Prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

3.5.7. Transmit Cancellation

The CAN FD Controller supports transmit cancellation. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the CPU has to write a "1" to the corresponding bit position of the Tx Buffer Cancellation Request register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of the Tx Buffer Cancellation Finished register TXBCF to "1".

A cancellation request resets the corresponding Transmission Request Pending bit (TXBRP.TRPn). In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP.TRPn bit remains set as long as the transmission is in progress.

- If the transmission was successful, the corresponding Transmission Occurred (TXBTO.TOn) and Cancellation Finished (TXBCF.CFn) bits are set.
- If the transmission was not successful (the transmission has been aborted due to lost arbitration, error occurred during frame transmission), it is not repeated and only the corresponding Cancellation Finished bit (TXBCF.CFn) is set.

TXBCF.CFn is also set when the transmission has not yet been started at the point of cancellation,

The cancellation request bits (TXBCR.CRn) are reset directly after the corresponding Transmission Request Pending bit (TXBRP.TRPn) has been reset.

Note:

- In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority (a greater message ID) than the second message in this node.

3.5.8. Tx Event Handling

To support Tx event handling the CAN FD Controller has implemented a Tx Event FIFO. After the CAN FD Controller has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer MM[7:0] is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured by Event FIFO Size (TXEFC.EFS[5:0]) to a maximum of 32 elements.

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by interrupt flag Tx Event FIFO Full (IR.TEFF), no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index TXEFS.EFGI[4:0] has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag Tx Event FIFO Element Lost IR.TEFL is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level TXEFS.EFFL[5:0] reaches the Tx Event FIFO watermark configured by TXEFC.EFWM[5:0], interrupt flag Tx Event FIFO Watermark Reached IR.TEFW is set.

■ Addressing Tx Events in the Tx Event FIFO

The start address when reading from the Tx Event FIFO will be

$2 \times \text{Tx Event FIFO Get Index TXEFS.EFGI[4:0]} + \text{Tx Event FIFO start address TXEFC.EFSA[15:2]}.$

3.6. FIFO Acknowledge Handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO (RXF0S.F0GI[5:0], RXF1S.F1GI[5:0], and TXEFS.EFGI[4:0], respectively) are controlled by writing to the corresponding FIFO Acknowledge Index (RXF0A.F0AI[5:0], RXF1A.F1AI[5:0], and TXEFA.EFAI[4:0], respectively). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index. (Multiple elements may be read by repeating this operation)
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the Rx FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position, alter the Rx FIFO's Fill Level, and also cause some of the older Rx FIFO elements to be lost.

Note:

- The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The CAN FD Controller does not check for erroneous values.

3.7. Configuring the CAN Bit Timing

Each CAN node in the CAN network has its own clock generator (usually a quartz oscillator). The time parameter of the bit time can be configured individually for each CAN node. Even if each CAN node's oscillator has a different period, a common bit rate can be generated.

The oscillator frequencies vary slightly because of changes in temperature or voltage, or deterioration of components. As long as the frequencies vary only within the tolerance range of the oscillators, the CAN nodes can compensate for the different bit rates by resynchronizing to the bit stream.

3.7.1. CAN Bit Timing

The CAN FD operation defines two bit times - nominal bit time and data bit time. The nominal bit time is for the arbitration phase. The data bit time has an equal or shorter length and can be used to accelerate the data phase (see Bit Rate Switching in "3.1.3. CAN FD Operation" for details).

The basic construction of a bit time is shared with both the nominal and data bit times. The bit time can be divided into four segments according to the CAN specifications (see Figure 3-11): the synchronization segment (Sync_Seg), the propagation time segment (Prop_Seg), the phase buffer segment 1 (Phase_Seg1), and the phase buffer segment 2 (Phase_Seg2). The sample point, the point of time at which the bus level is read and interpreted as the value of that respective bit, is located at the end of Phase_Seg1.

Figure 3-11 Bit Time Construction

Each segment consists of a programmable number of time quanta, which is a multiple of the time quantum that is defined by `canfd_cclk` and a prescaler. The values and prescalers used to define these parameters differ for the nominal and data bit times, and are configured by NBTP (Nominal Bit Timing & Prescaler Register) and DBTP (Data Bit Timing & Prescaler Register) as shown in the table below (Table 3-7).

Table 3-7 Bit Time Parameters

Parameter	Description
Time quantum tq (nominal) and tqd (data)	<p>Time quantum. Derived by multiplying the basic unit time quanta (i.e. the canfd_cclk period) with the respective prescaler.</p> <p>The time quantum is configured by the CAN FD Controller as nominal : $tq = (NBTP.NBRP[8:0] + 1) \times \text{canfd_cclk period}$ data : $tqd = (DBTP.DBRP[4:0] + 1) \times \text{canfd_cclk period}$</p>
Sync_Seg	<p>Sync_Seg is fixed to 1 time quantum as defined by the CAN specifications and is therefore not configurable (inherently built into the CAN FD Controller).</p> <p>nominal : 1 tq data : 1 tqd</p>
Prop_Seg	<p>Prop_Seg is the part of the bit time that is used to compensate for the physical delay times within the network. The CAN FD Controller configures the sum of Prop_Seg and Phase_Seg1 with a single parameter, i.e.</p> <p>nominal : $\text{Prop_Seg} + \text{Phase_Seg1} = NBTP.NTSEG1[7:0] + 1$ data : $\text{Prop_Seg} + \text{Phase_Seg1} = DBTP.DTSEG1[4:0] + 1$</p>
Phase_Seg1	<p>Phase_Seg1 is used to compensate for edge phase errors before the sampling point. Can be lengthened by the resynchronization jump width.</p> <p>The sum of Prop_Seg and Phase_Seg1 is configured by the CAN FD Controller as nominal : $NBTP.NTSEG1[7:0] + 1$ data : $DBTP.DTSEG1[4:0] + 1$</p>
Phase_Seg2	<p>Phase_Seg2 is used to compensate for edge phase errors after the sampling point. Can be shortened by the resynchronization jump width.</p> <p>Phase_Seg2 is configured by the CAN FD Controller as nominal : $NBTP.NTSEG2[6:0] + 1$ data : $DBTP.DTSEG2[3:0] + 1$</p>
SJW	<p>Resynchronization Jump Width. Used to adjust the length of Phase_Seg1 and Phase_Seg2. SJW will not be longer than either Phase_Seg1 or Phase_Seg2.</p> <p>SJW is configured by the CAN FD Controller as nominal : $NBTP.NSJW[6:0] + 1$ data : $DBTP.DSJW[3:0] + 1$</p>

These relations result in the following equations for the nominal and data bit times:

Nominal Bit time

$$\begin{aligned}
 &= [\text{Sync_Seg} + \text{Prop_Seg} + \text{Phase_Seg1} + \text{Phase_Seg2}] \times tq \\
 &= [1 + (NBTP.NTSEG1[7:0] + 1) + (NBTP.NTSEG2[6:0] + 1)] \times [(NBTP.NBRP[8:0] + 1) \times \text{canfd_cclk period}]
 \end{aligned}$$

and for the data bit time

$$= [1 + (DBTP.DTSEG1[4:0] + 1) + (DBTP.DTSEG2[3:0] + 1)] \times [(DBTP.DBRP[4:0] + 1) \times \text{canfd_cclk period}]$$

Note:

- The Information Processing Time (IPT) of the CAN FD Controller is zero, meaning the data for the next bit is available at the first CAN clock edge after the sample point. Therefore, the IPT does not have to be accounted for when configuring Phase_Seg2, which is the maximum of Phase_Seg1 and the IPT.

3.7.2. CAN Bit Rates

Since the bit rate is the inverse of the bit time, the nominal bit rate is

$$1 / \{ [1 + (NBTP.NTSEG1[7:0] + 1) + (NBTP.NTSEG2[6:0] + 1)] \times \{ (NBTP.NBRP[8:0] + 1) \times \text{canfd_cclk period} \} \}$$

and the data bit rate is

$$1 / \{ [1 + (DBTP.DTSEG1[4:0] + 1) + (DBTP.DTSEG2[3:0] + 1)] \times \{ (DBTP.DBRP[4:0] + 1) \times \text{canfd_cclk period} \} \}$$

From these formula we can see that the bit rates of the CAN FD Controller will depend on the CAN clock (i.e. canfd_cclk) period, and the range each parameter can be configured to. The tables below lists examples of the configurable bit rates at varying CAN clock frequencies. Empty boxes indicate that the desired bit rate cannot be configured at the specified input CAN clock frequency.

Table 3-8 Example Configurations for Nominal Bit Rates

CAN clock frequency	8MHz		10MHz		16MHz		20MHz		32MHz		40MHz	
configuration nominal bit rate	Number of tqsp per bit time	NBTP.NBRP + 1	Number of tqsp per bit time	NBTP.NBRP + 1	Number of tqsp per bit time	NBTP.NBRP + 1	Number of tqsp per bit time	NBTP.NBRP + 1	Number of tqsp per bit time	NBTP.NBRP + 1	Number of tqsp per bit time	NBTP.NBRP + 1
125kbps	64tq 32tq 16tq 8tq	1 2 4 8	80tq 40tq 20tq 10tq	1 2 4 8	128tq 64tq 32tq 16tq 8tq	1 2 4 8 16	160tq 80tq 40tq 20tq 10tq	1 2 4 8 16	256tq 128tq 64tq 32tq 16tq 8tq	1 2 4 8 16 32	320tq 160tq 80tq 40tq 20tq 10tq	1 2 4 8 16 32

1Mbps	8tq	1	10tq	1	16tq 8tq	1 2	20tq 10tq	1 2	32tq 16tq 8tq	1 2 4	40tq 20tq 10tq	1 2 4

Table 3-9 Example Configurations for Data Bit Rates

CAN clock frequency	8MHz		10MHz		16MHz		20MHz		32MHz		40MHz	
configuration data bit rate	Number of tqps per bit time	DBTP,DBRP + 1	Number of tqps per bit time	DBTP,DBRP + 1	Number of tqps per bit time	DBTP,DBRP + 1	Number of tqps per bit time	DBTP,DBRP + 1	Number of tqps per bit time	DBTP,DBRP + 1	Number of tqps per bit time	DBTP,DBRP + 1
500kbps	16tqd 8tqd	1 2	20tqd 10tqd	1 2	32tqd 16tqd 8tqd	1 2 4	40tqd 20tqd 10tqd	1 2 4	32tqd 16tqd 8tqd	2 4 8	40tqd 20tqd 10tqd	2 4 8
1Mbps	8tqd	1	10tqd	1	16tqd 8tqd	1 2	20tqd 10tqd	1 2	32tqd 16tqd 8tqd	1 2 4	40tqd 20tqd 10tqd	1 2 4
2Mbps	-	-	-	-	8tqd	1	10tqd	1	16tqd 8tqd	1 2	20tqd 10tqd	1 2
4Mbps	-	-	-	-	-	-	-	-	8tqd	1	10tqd	1
5Mbps	-	-	-	-	-	-	-	-	-	-	8tqd	1

Note:

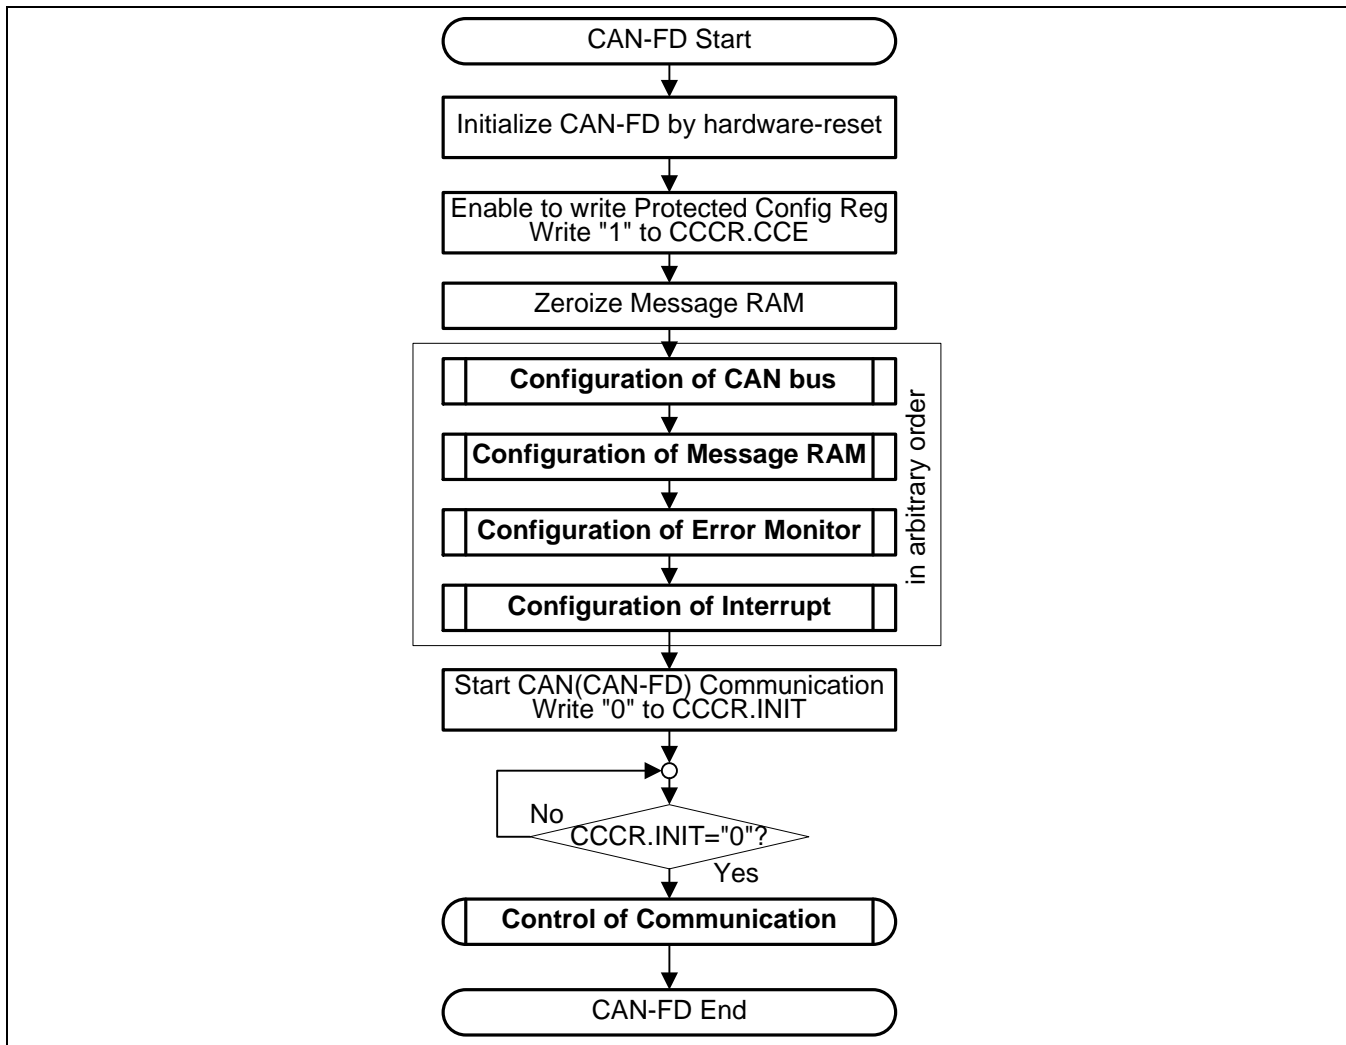

- The user must configure the CAN bit timings so that comply with the corresponding CAN standards to ensure proper communication on the CAN bus.

4. Setup Procedure Examples

This section provides examples of setup procedures for the CAN FD Controller.

- 4.1. Configuration of CAN Bus
- 4.2. Configuration of Message RAM
 - 4.2.1. Configuration of ID Filter List
 - 4.2.2. Configuration of Rx Buffer and Rx FIFO
 - 4.2.3. Configuration of Tx Buffer and Tx FIFO/Queue
 - 4.2.4. Configuration of ID Filter
- 4.3. Configuration of Error Monitor
- 4.4. Configuration of Interrupt
- 4.5. Control of Communication
 - 4.5.1. Configuration of Transmission Frame
- 4.6. Interrupt Handling Operation
 - 4.6.1. Bus_Off Status Handling Operation
 - 4.6.2. Message RAM Access Failure Handling Operation
 - 4.6.3. Bit Error Handling Operation
 - 4.6.4. Tx Event FIFO Handling Operation
 - 4.6.5. Dedicated Rx Buffer Handling Operation
 - 4.6.6. High Priority Message Handling Operation
 - 4.6.7. Rx FIFO Handling Operation

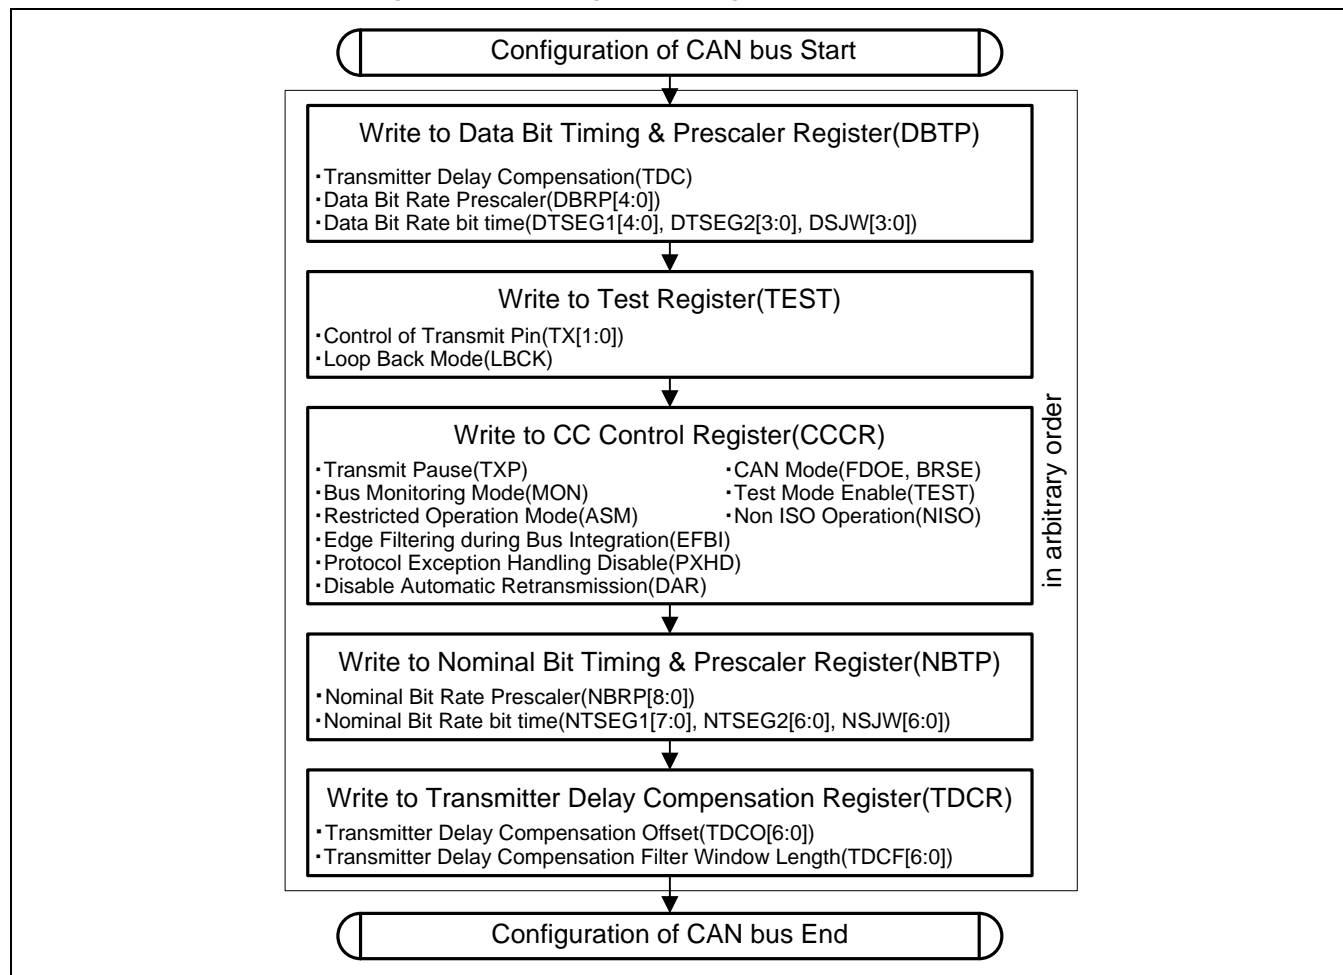

Figure 4-1 shows the general flow of a program. The following sections will describe each step in more detail.

Figure 4-1 General Program Flow

4.1. Configuration of CAN Bus

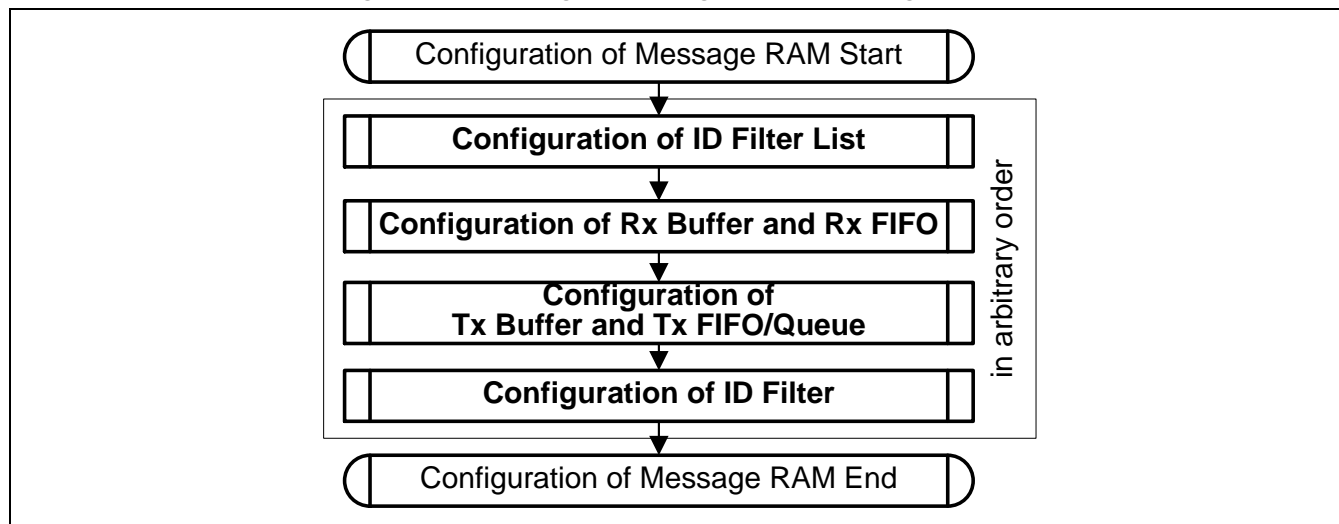

Figure 4-2 lists what to configure in order to set up the CAN bus related functions.

Figure 4-2 Flow Diagram "Configuration of CAN Bus"

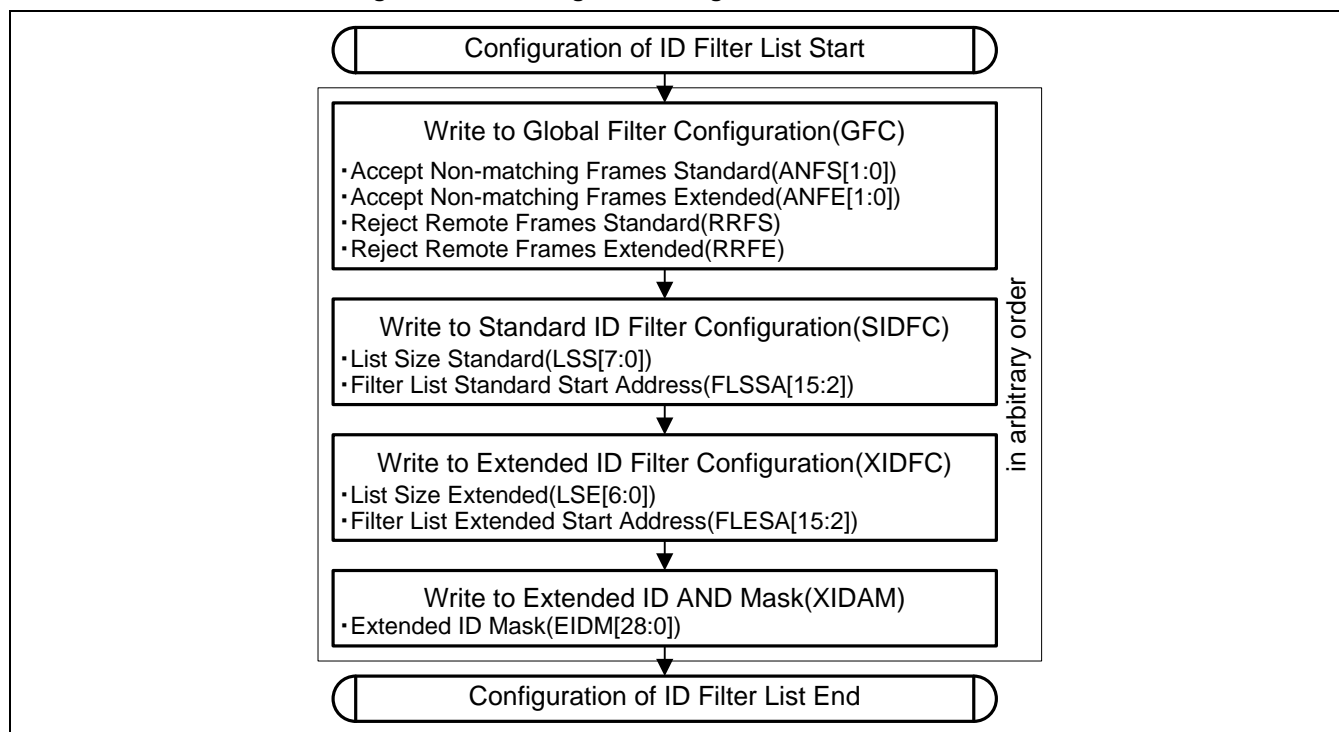

4.2. Configuration of Message RAM

Figure 4-3 shows the overall configuration procedure of the Message RAM.

Figure 4-3 Flow Diagram "Configuration of Message RAM"

4.2.1. Configuration of ID Filter List

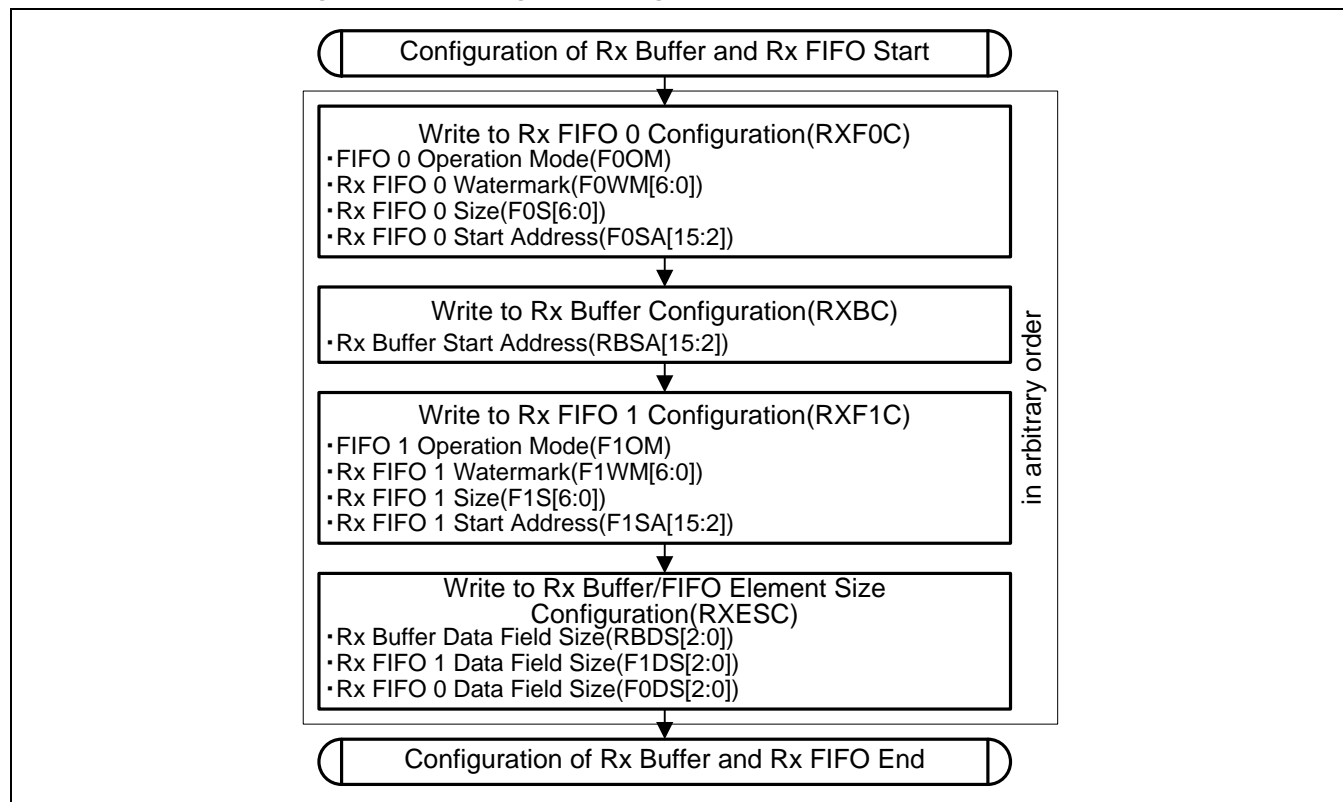

Figure 4-4 lists what to configure in order to set up the ID Filter lists.

Figure 4-4 Flow Diagram "Configuration of ID Filter List"

4.2.2. Configuration of Rx Buffer and Rx FIFO

Figure 4-5 lists what to configure in order to set up the Dedicated Rx Buffers and Rx FIFOs.

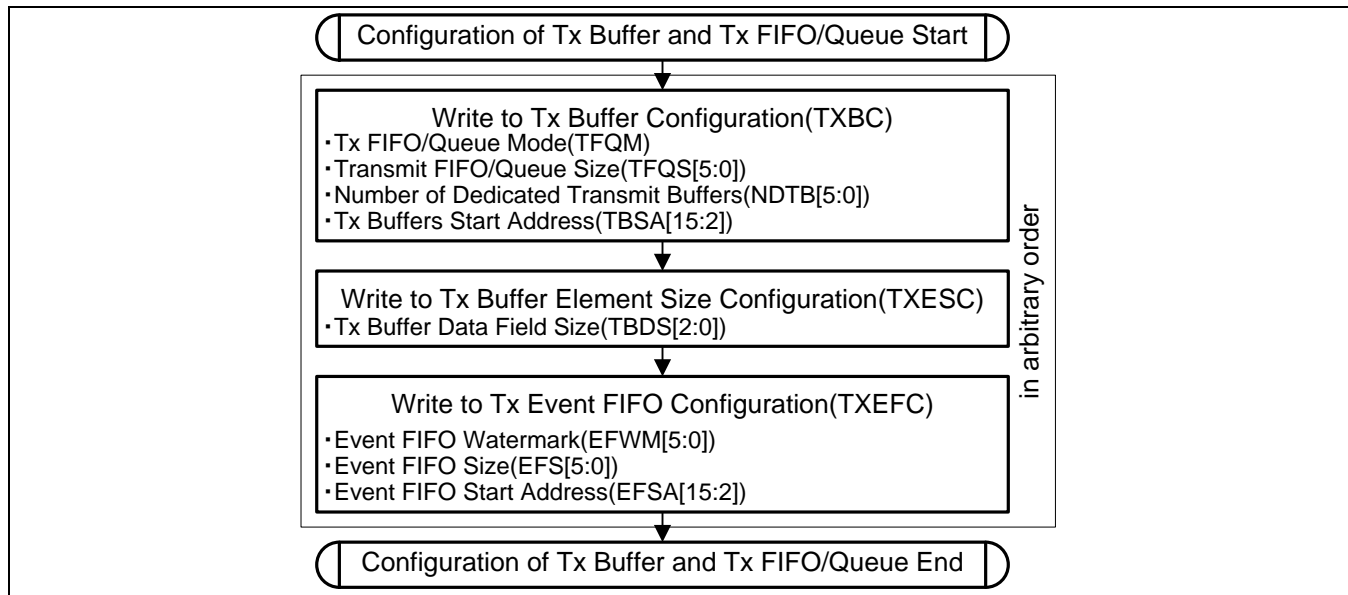

Figure 4-5 Flow Diagram "Configuration of Rx Buffer and Rx FIFO"

4.2.3. Configuration of Tx Buffer and Tx FIFO/Queue

Figure 4-6 lists what to configure in order to set up the Tx Buffers and Tx Event FIFO.

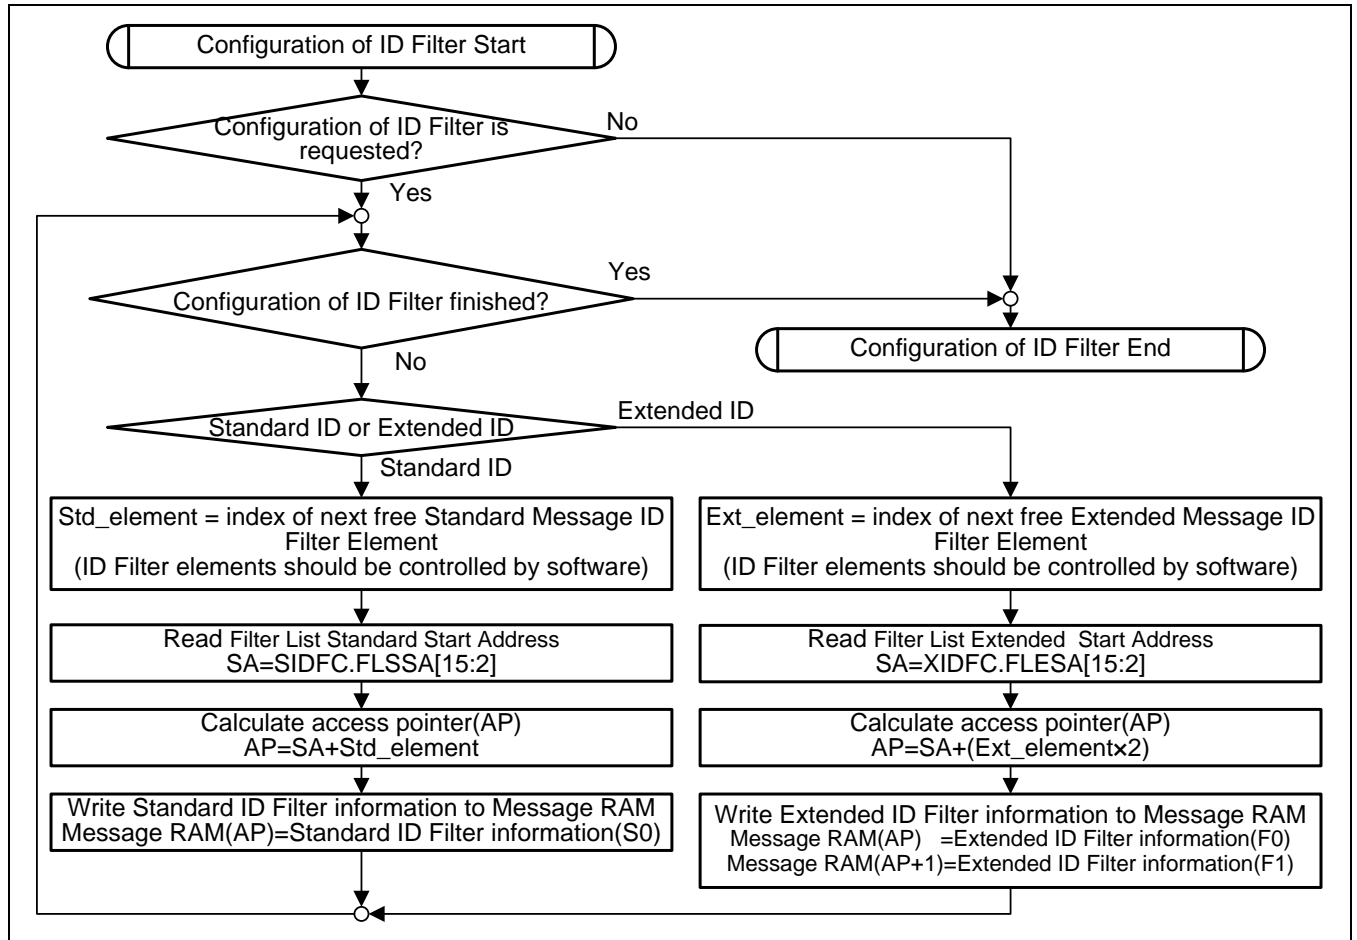

Figure 4-6 Flow Diagram "Configuration of Tx Buffer and Tx FIFO/Queue"

4.2.4. Configuration of ID Filter

Figure 4-7 shows the steps to set up an ID Filter.

Figure 4-7 Flow Diagram "Configuration of ID Filter"

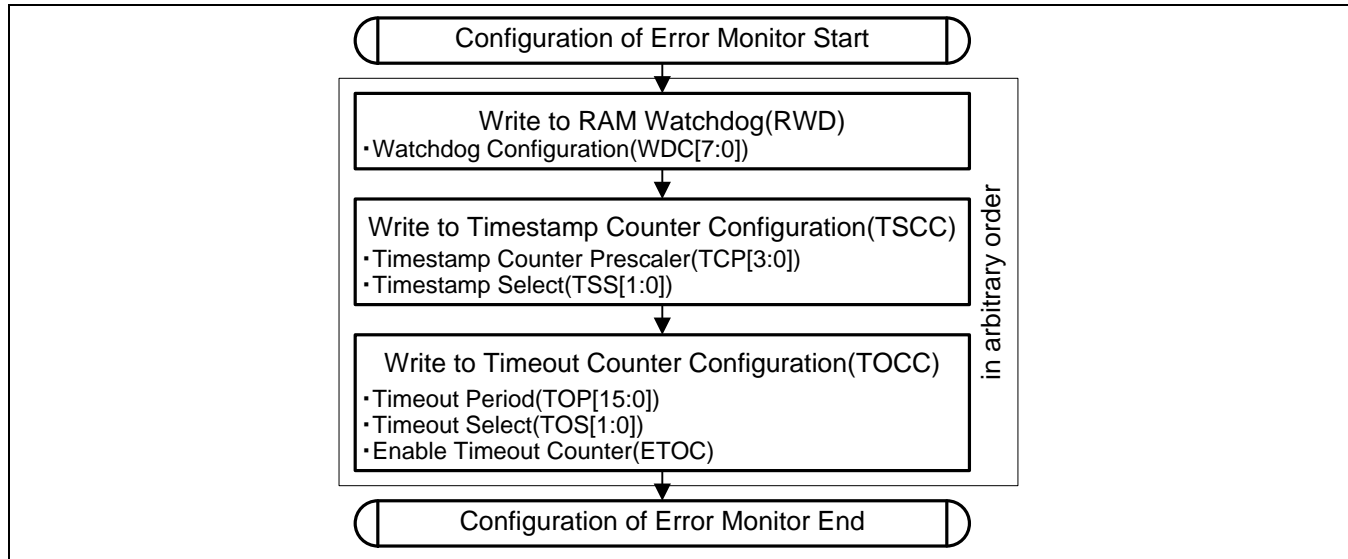

Note:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.

4.3. Configuration of Error Monitor

Figure 4-8 lists the error monitoring functions that can be used.

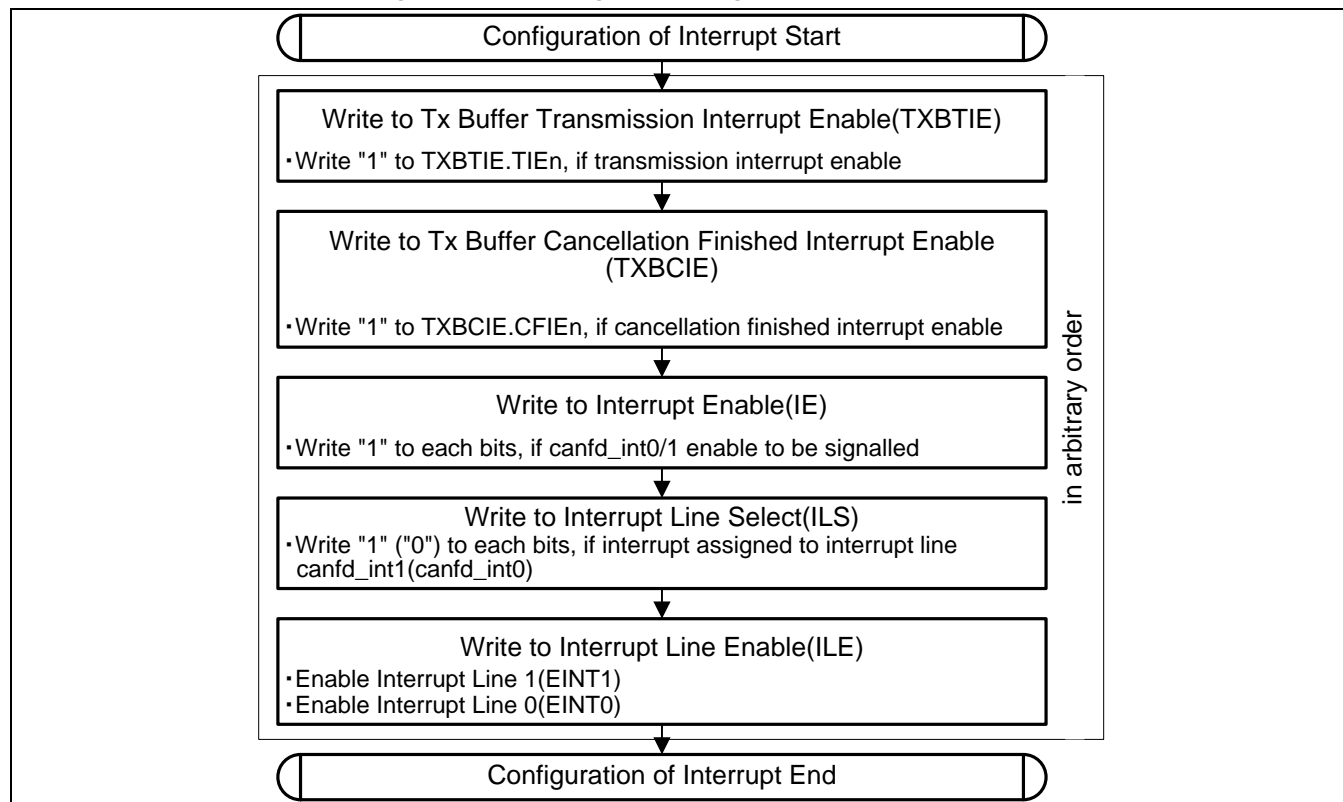

Figure 4-8 Flow Diagram "Configuration of Error Monitor"

4.4. Configuration of Interrupt

Figure 4-9 lists what to configure in order to set up the Interrupt related logic.

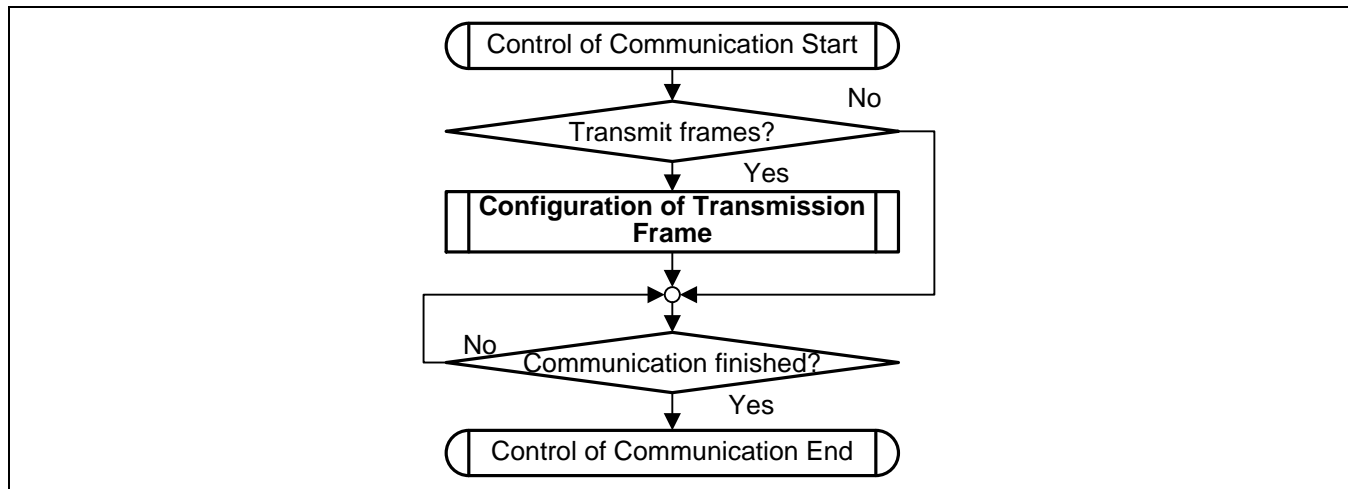

Figure 4-9 Flow Diagram "Configuration of Interrupt"

4.5. Control of Communication

Figure 4-10 shows the overall configuration procedure for communication on the CAN bus.

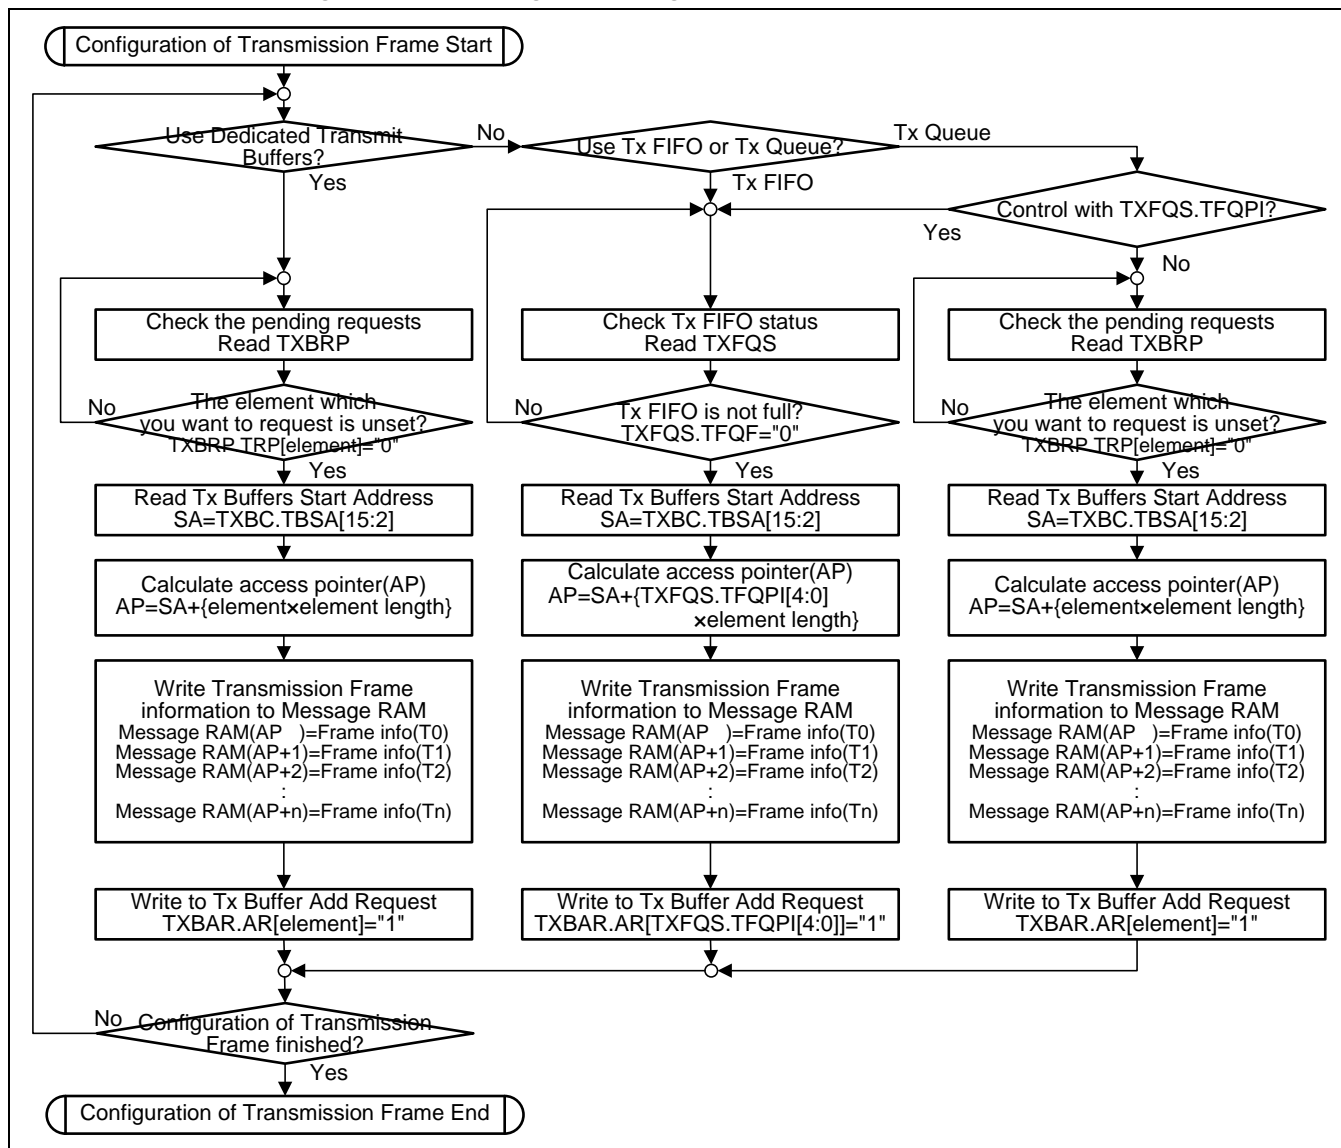

Figure 4-10 Flow Diagram "Control of Communication"

4.5.1. Configuration of Transmission Frame

Figure 4-11 shows how to set and transmit frames.

Figure 4-11 Flow Diagram "Configuration of Transmission Frame"

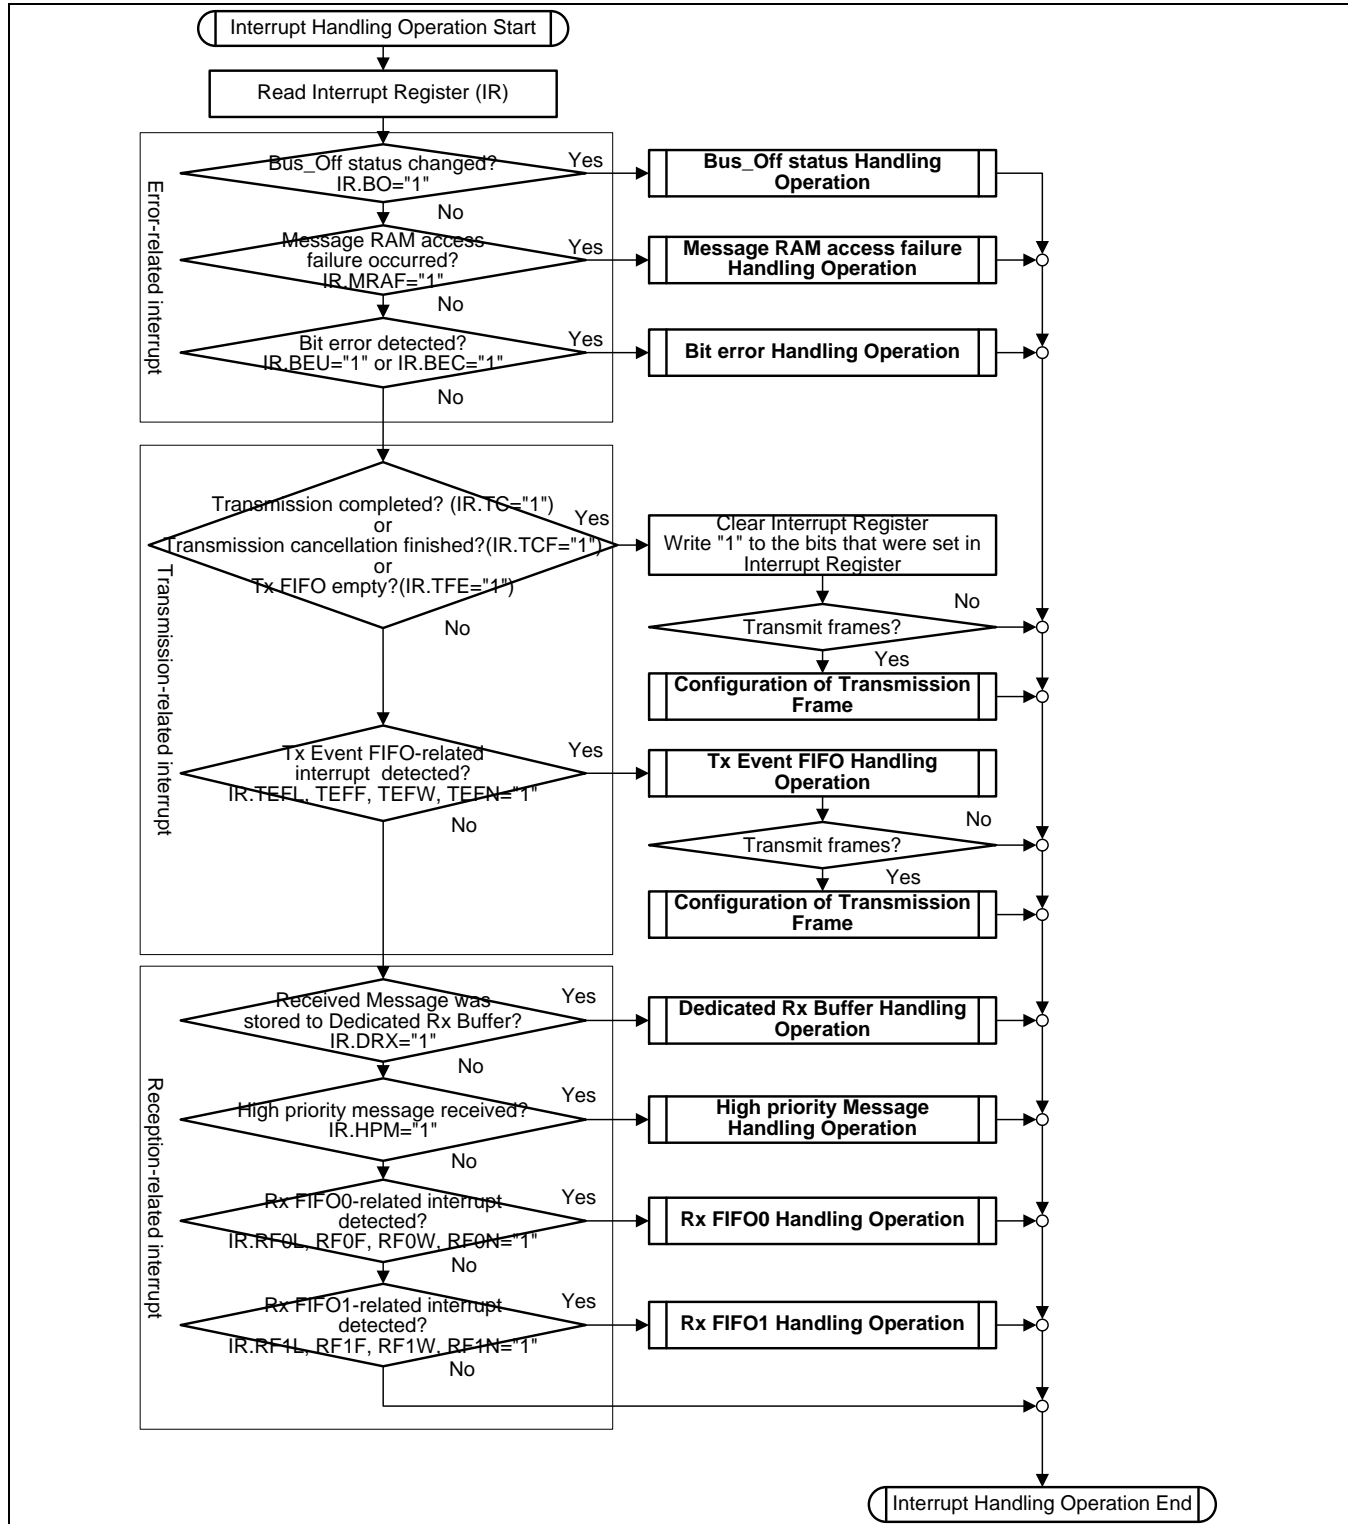

Notes:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.
- Dedicated Transmit Buffers are normally configured with a single specific identifier.

4.6. Interrupt Handling Operation

Figure 4-12 shows the overall picture of how interrupts are processed.

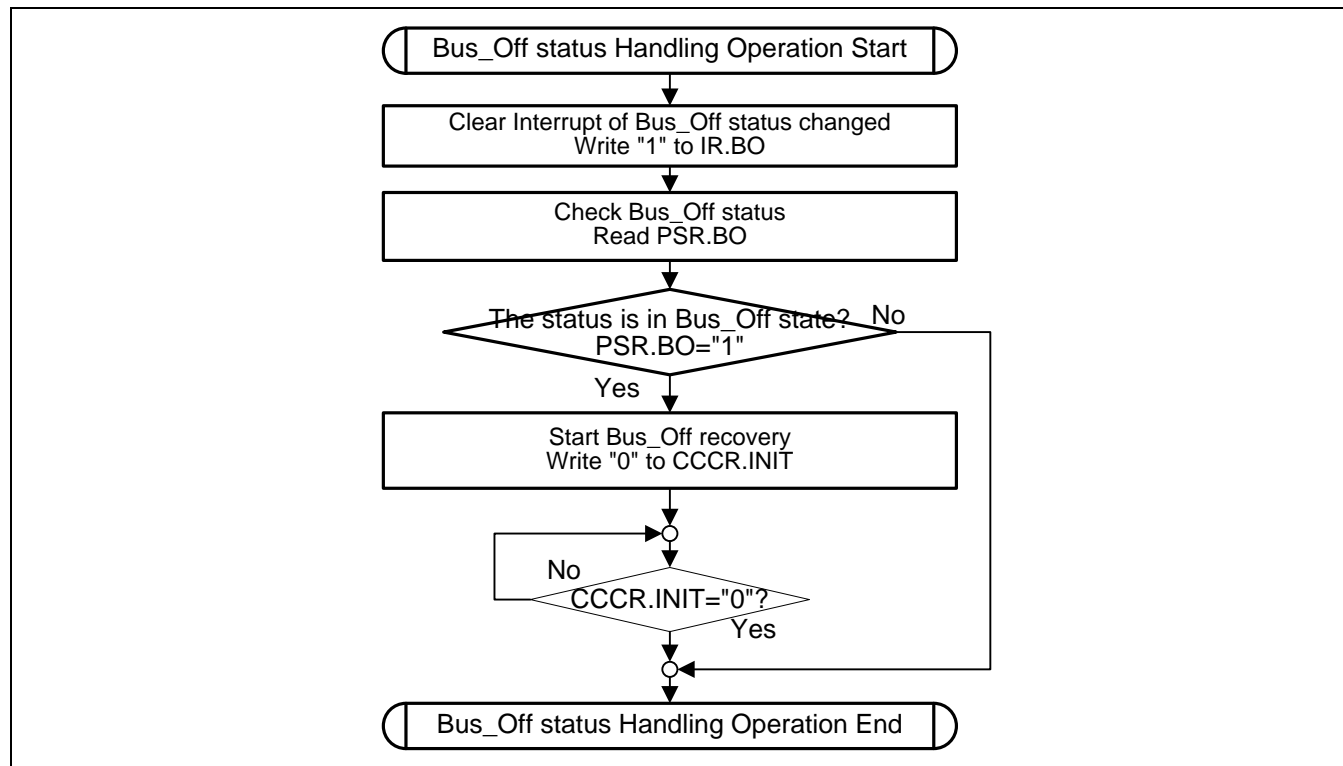

Figure 4-12 Flow Diagram "Interrupt Handling Operation"

4.6.1. Bus_Off Status Handling Operation

Figure 4-13 shows how to process a "Bus_Off Status" interrupt (IR.BO).

Figure 4-13 Flow Diagram "Bus_Off Status Handling Operation"

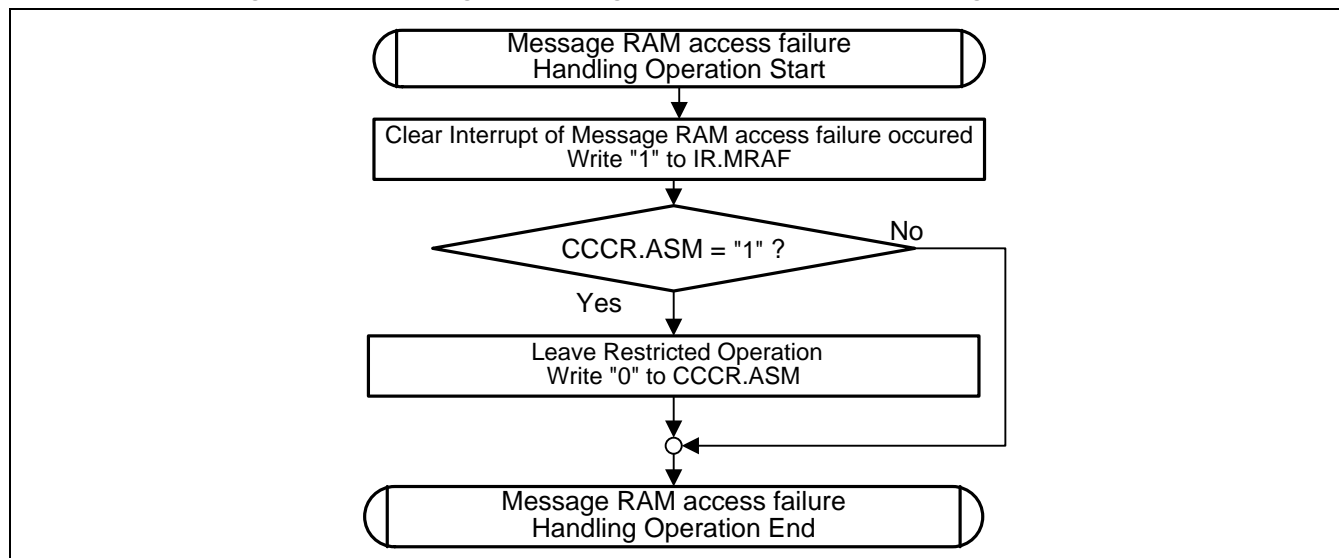

Note:

- Once the Initialization bit (CCCR.INIT) has been cleared by the CPU, the CAN FD Controller will then wait for 129 occurrences of Bus Idle (129×11 consecutive recessive bits) before resuming normal operation.

4.6.2. Message RAM Access Failure Handling Operation

Figure 4-14 shows how to process a "Message RAM Access Failure" interrupt (IR.MRAF).

Figure 4-14 Flow Diagram "Message RAM Access Failure Handling Operation"

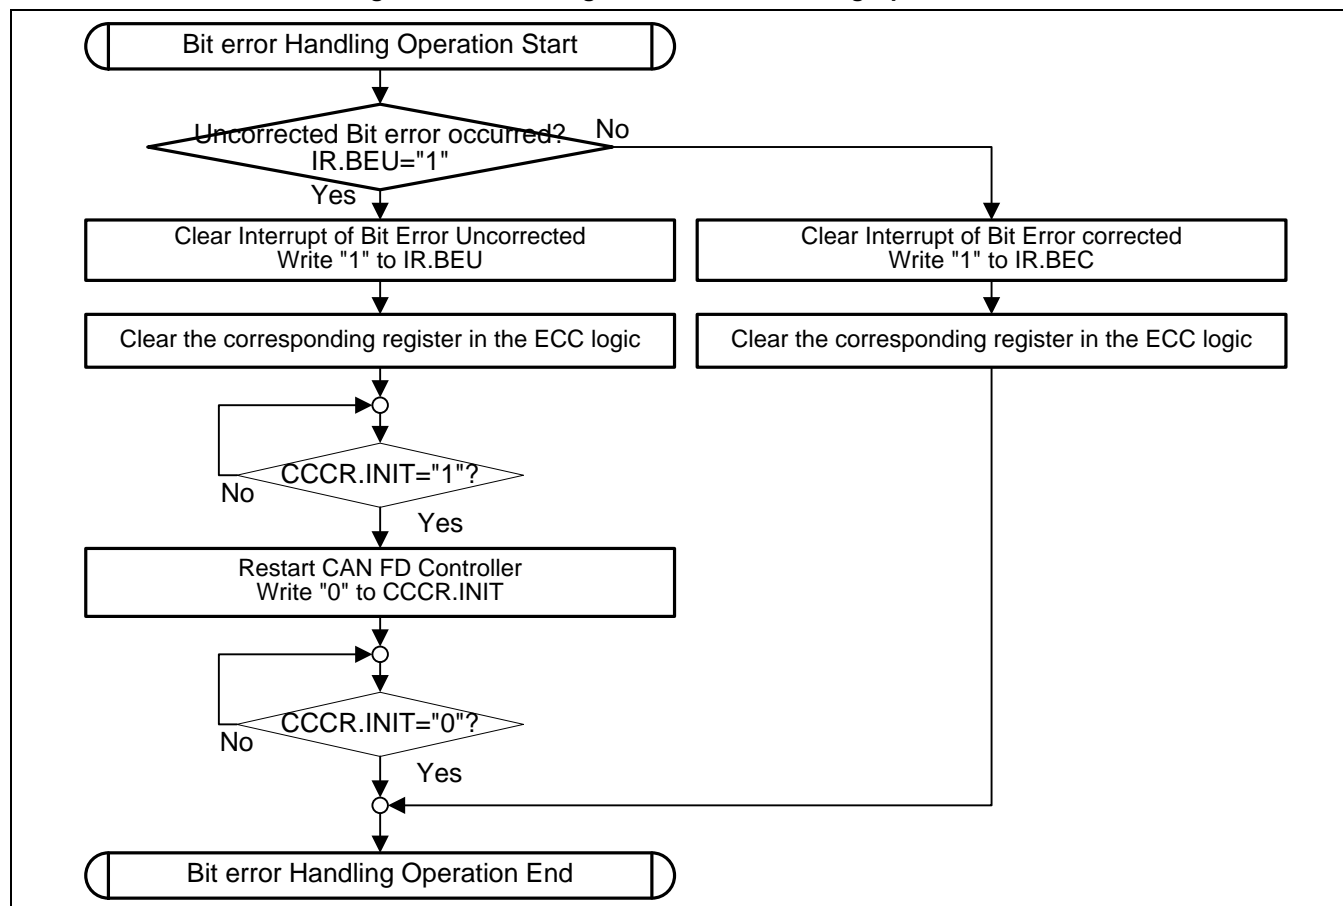

Note:

- The data of a received frame may be incompletely stored to the Message RAM after Message RAM Access Failure occurs (IR.MRAF = "1") without setting Restricted Operation Mode (CCCR.ASM). In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.

4.6.3. Bit Error Handling Operation

Figure 4-15 shows how to process the "Bit Error" interrupts (IR.BEU, IR.BEC).

Figure 4-15 Flow Diagram "Bit Error Handling Operation"

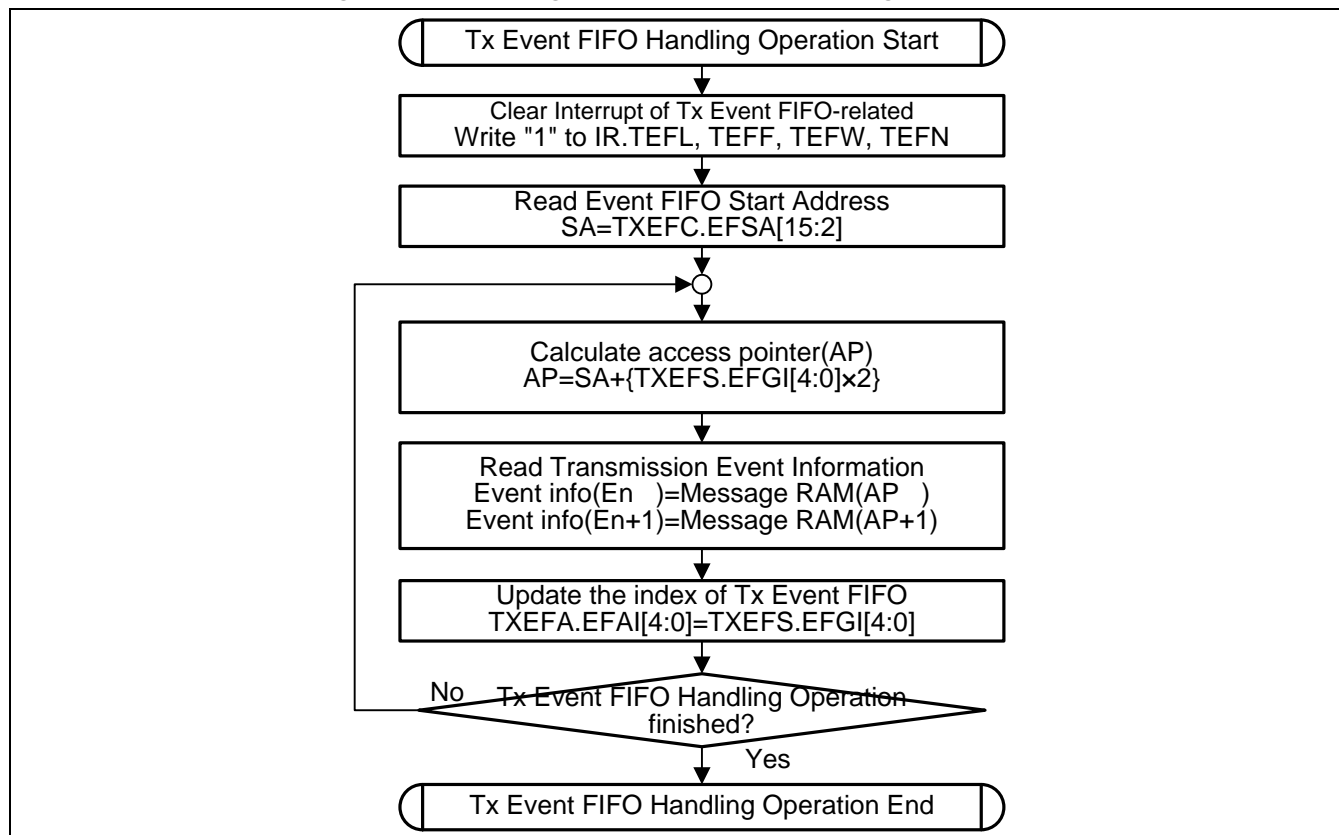

Note:

- In case Bit Error Uncorrected IR.BEU occurs, due to the synchronization mechanism between the Bus clock and the CAN clock, there may be a delay until Initialization CCCR.INIT set to "1". Therefore the programmer has to assure that CCCR.INIT has been set to "1" by reading CCCR.INIT before resetting CCCR.INIT to "0".

4.6.4. Tx Event FIFO Handling Operation

Figure 4-16 shows how to process Tx Event FIFO related interrupts.

Figure 4-16 Flow Diagram "Tx Event FIFO Handling Operation"

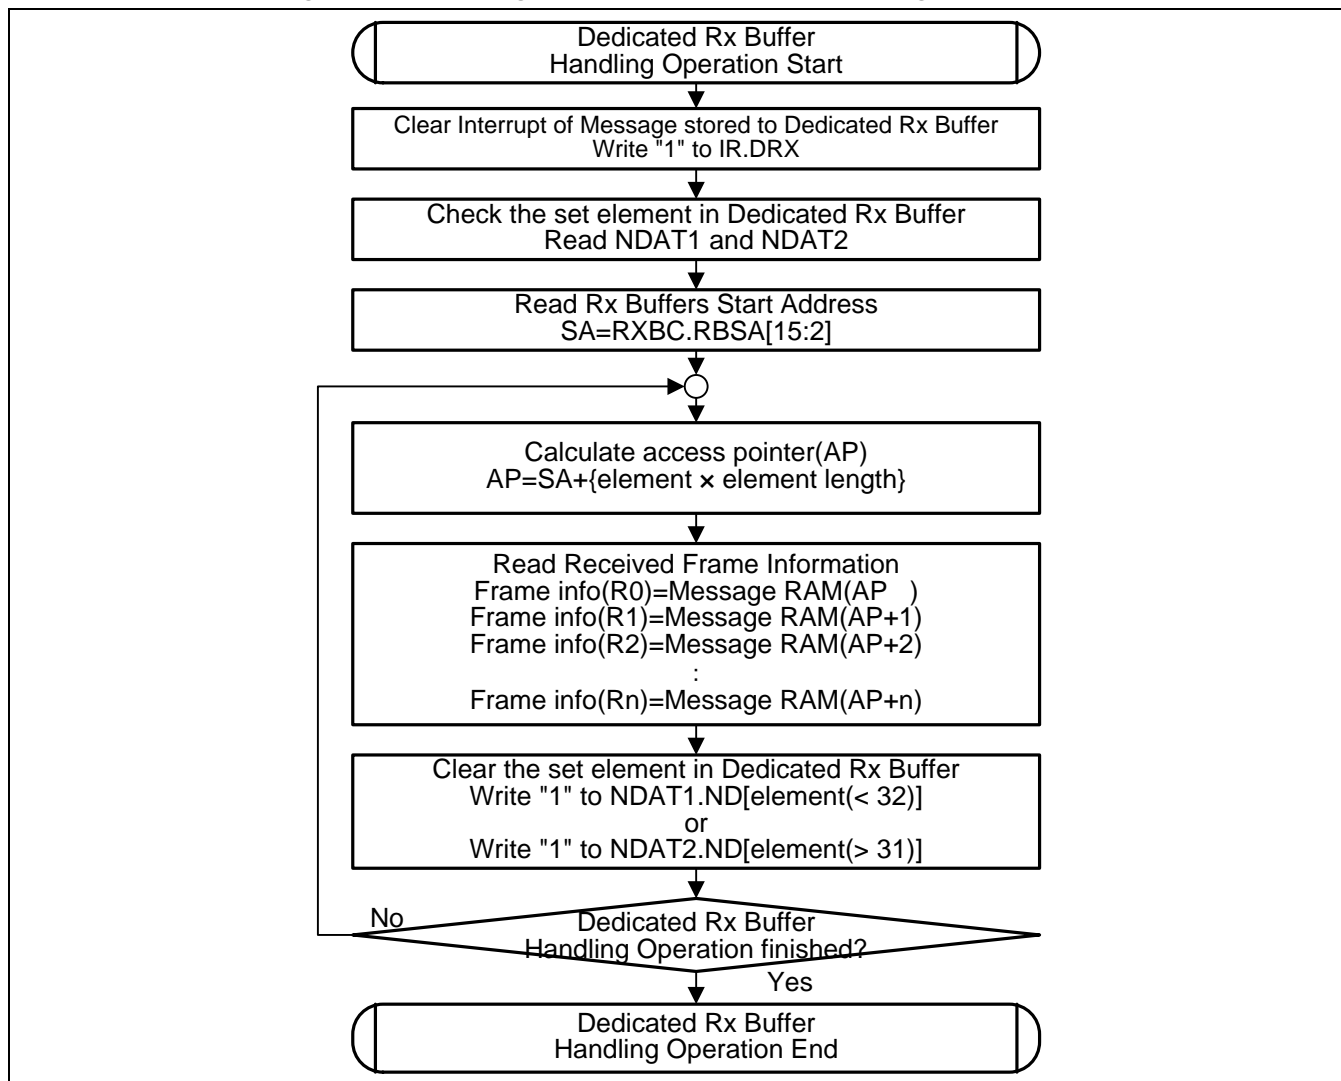

Note:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.

4.6.5. Dedicated Rx Buffer Handling Operation

Figure 4-17 shows how to process a "Message stored to Dedicated Rx Buffer" interrupt (IR.DRX).

Figure 4-17 Flow Diagram "Dedicated Rx Buffer Handling Operation"

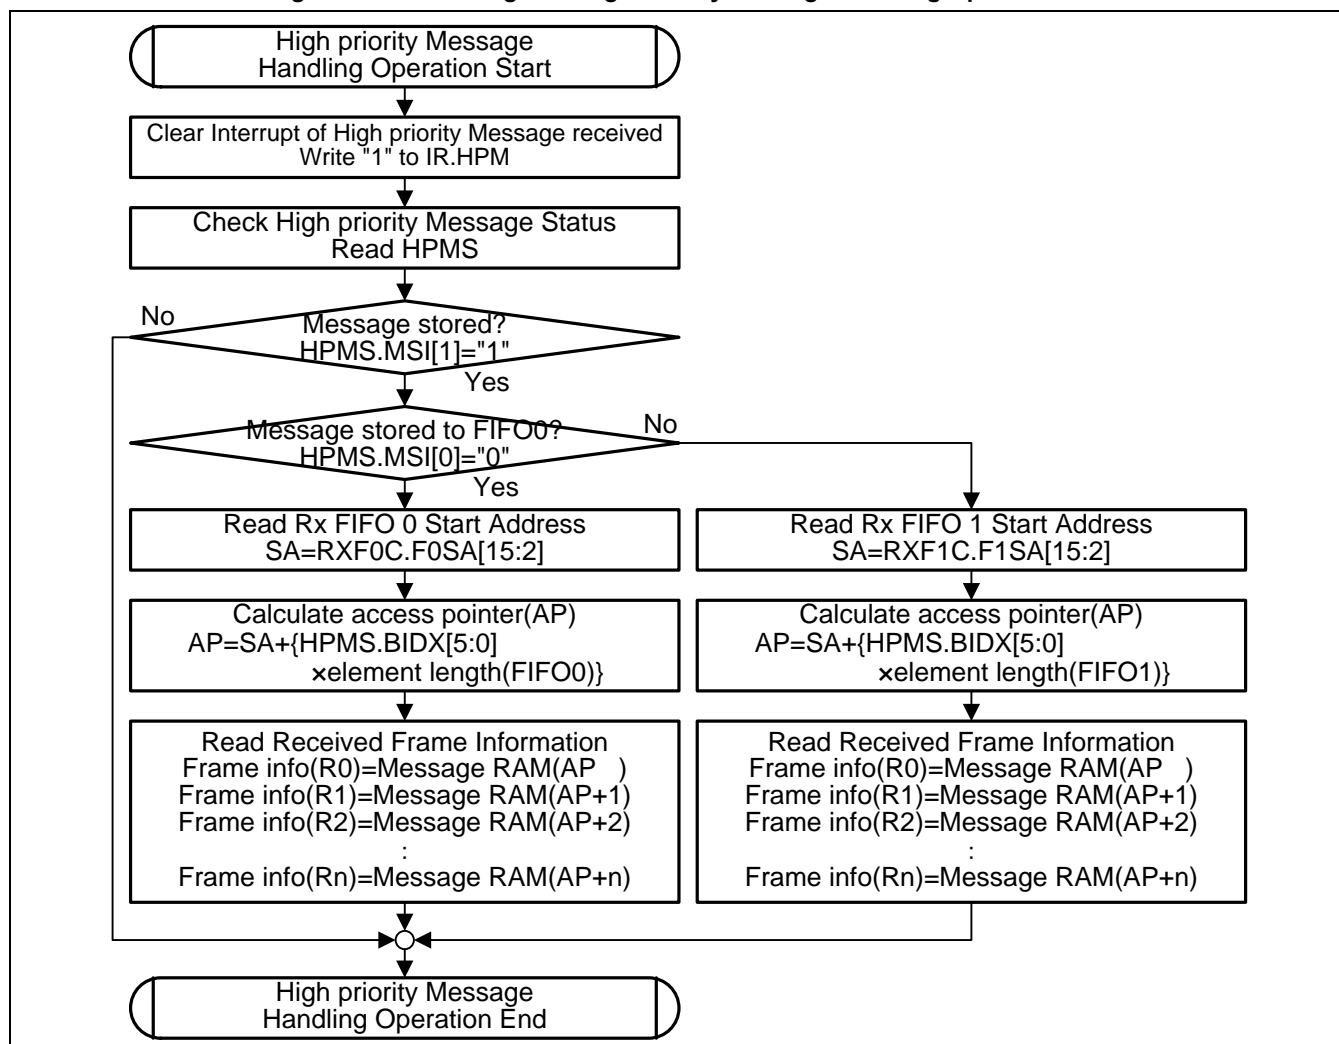

Note:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.

4.6.6. High Priority Message Handling Operation

Figure 4-18 shows how to process a High Priority Message interrupt (IR.HPM).

Figure 4-18 Flow Diagram "High Priority Message Handling Operation"

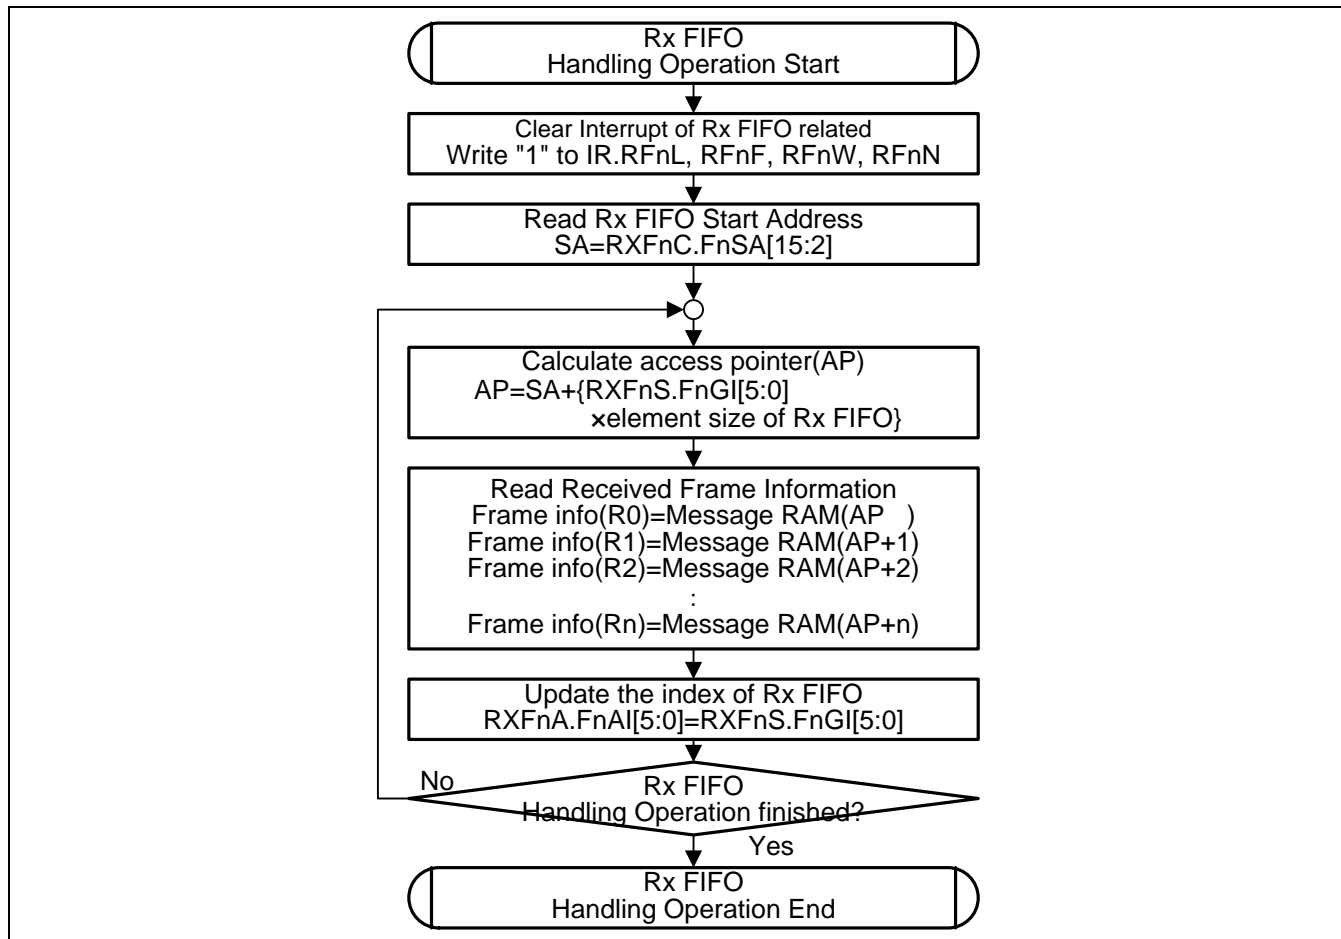

Note:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.

4.6.7. Rx FIFO Handling Operation

Figure 4-19 shows how to process Rx FIFO related interrupts.

Figure 4-19 Flow Diagram "Rx FIFO Handling Operation"

Notes:

- Use 32-bit word address values when calculating the pointers in the flow diagram above.
- The "n"s in the register/bit names (e.g. "RXFnS.FnGI") stand for "0" or "1".
- If a high priority message is received and processed by the "High priority Message Handling Operation" flow, this flow (i.e. Rx FIFO Handling Operation) may be skipped for that particular message. The following message received by the Rx FIFO may resume with this flow again.

5. Registers

This section explains the configuration and functions of the registers used for the CAN FD Controller.

Hardware Reset Description

After hardware reset, the registers of the CAN FD Controller hold the reset values as indicated in each relative register description. Additionally the Bus_Off state is reset and the output canfd_tx is set to recessive. Setting the Initialization bit CCCR.INIT to "1" in the CC Control Register enables software initialization. The CAN FD Controller does not influence the CAN bus until the CPU resets CCCR.INIT to "0".

Register Map

The CAN FD Controller allocates an address space of 256 bytes for the registers.

All registers are organized as 32-bit registers. The registers are accessible by the CPU using a data width of 8 bit (byte access), 16 bit (half-word access), or 32 bit (word access).

Note:

- As an exception, the Protocol Status Register (PSR) does not allow byte accessing.

Write access by the CPU to several of the registers/bits that configure the basic operation of the CAN FD Controller is possible only with Configuration Change Enable CCCR.CCE="1" AND Initialization CCCR.INIT="1".

There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

Access to Reserved Register Addresses

In case the application software wants to access one of the reserved addresses in the CAN FD Controller register map (read or write access), interrupt flag Access to Reserved Address (IR.ARA) is set, and if enable the interrupt is signalled via the assigned interrupt line (canfd_int0/1). Table 5-1 below describes the reserved addresses, the offsets from the start address of the CAN FD Controller.

Table 5-1 Reserved Addresses in the CAN FD Controller

Offset	Number of Words
0x30-0x3C	4
0x4C	1
0x60-7C	8
0x8C	1
0xE8-EC	2
0xFC	1

Table 5-2 List of Registers for the CAN FD Controller

Abbreviation	Register Name	Reference
CREL	Core Release Register	5.1
ENDN	Endian Register	5.2
DBTP	Data Bit Timing & Prescaler Register	5.3
TEST	Test Register	5.4
RWD	RAM Watchdog	5.5

Abbreviation	Register Name	Reference
CCCR	CC Control Register	5.6
NBTP	Nominal Bit Timing & Prescaler Register	5.7
TSCC	Timestamp Counter Configuration	5.8
TSCV	Timestamp Counter Value	5.9
TOCC	Timeout Counter Configuration	5.10
TOCV	Timeout Counter Value	5.11
ECR	Error Counter Register	5.12
PSR	Protocol Status Register	5.13
TDCR	Transmitter Delay Compensation Register	5.14
IR	Interrupt Register	5.15
IE	Interrupt Enable	5.16
ILS	Interrupt Line Select	5.17
ILE	Interrupt Line Enable	5.18
GFC	Global Filter Configuration	5.19
SIDFC	Standard ID Filter Configuration	5.20
XIDFC	Extended ID Filter Configuration	5.21
XIDAM	Extended ID AND Mask	5.22
HPMS	High Priority Message Status	5.23
NDAT1	New Data 1	5.24
NDAT2	New Data 2	5.25

Table 5-4 Register Mirror Area CAN FD CONTROLLER

Address of Register Mirror Area	Mirrored Peripheral	Mirror Area Behavior	PPU
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.0	Accessing this region results to the access to MCU_CONFIG CAN FD ch.0 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #47 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.1	Accessing this region results to the access to MCU_CONFIG CAN FD ch.1 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #48 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	MCU_CONFIG CAN FD ch.2	Accessing this region results to the access to MCU_CONFIG CAN FD ch.2 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #49 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.0	Accessing this region results to the access to CommonPERI#0 CAN FD ch.0 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #256 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.1	Accessing this region results to the access to CommonPERI#0 CAN FD ch.1 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #257 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.2	Accessing this region results to the access to CommonPERI#0 CAN FD ch.2 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #258 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.3	Accessing this region results to the access to CommonPERI#0 CAN FD ch.3 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #259 as well as the mirrored peripheral.
0000_C000 to 0000_FFFF	CommonPERI#0 CAN FD ch.4	Accessing this region results to the access to CommonPERI#0 CAN FD ch.4 Message RAM area (0000_0000 to 0000_BFFF)	This area is covered by PPU #260 as well as the mirrored peripheral.

5.1. Core Release Register (MCG_CANFDx_CREL, CPG_CANFDx_CREL)

The Core Release Register displays the revision of the CAN FD Controller.

bit	31	30	29	28	27	26	25	24
Field	REL[3:0]				STEP[3:0]			
R/W Attribute	R,WX				R,WX			
Protection Attribute	-				-			
Initial value	0x3				0x2			

bit	23	22	21	20	19	18	17	16
Field	SUBSTEP[3:0]				YEAR[3:0]			
R/W Attribute	R,WX				R,WX			
Protection Attribute	-				-			
Initial value	0x0				0x4			

bit	15	14	13	12	11	10	9	8
Field	MON[7:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial value	0x12							

bit	7	6	5	4	3	2	1	0
Field	DAY[7:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial value	0x18							

[bit31:28] REL[3:0]: Core Release

One digit, BCD-coded.

[bit27:24] STEP[3:0]: Step of Core Release

One digit, BCD-coded.

[bit23:20] SUBSTEP[3:0]: Sub-Step of Core Release

One digit, BCD-coded.

[bit19:16] YEAR[3:0]: Time Stamp Year

One digit, BCD-coded.

[bit15:8] MON[7:0]: Time Stamp Month

Two digits, BCD-coded.

[bit7:0] DAY[7:0]: Time Stamp Day

Two digits, BCD-coded.

Table 5-5 Example for Coding of Revisions

Release	Step	SubStep	Year	Month	Day	Name
3	2	0	4	12	18	Revision 3.2.0, Date 2014/12/18

5.2. Endian Register (MCG_CANFDx_ENDN, CPG_CANFDx_ENDN)

The Endian Register can be used to check the endianness of the CAN FD Controller when accessed by the CPU.

bit	31	30	29	28	27	26	25	24
Field	ETV[31:24]							
R/W Attribute	R, WX							
Protection Attribute	-							
Initial value	0x87							

bit	23	22	21	20	19	18	17	16
Field	ETV[23:16]							
R/W Attribute	R, WX							
Protection Attribute	-							
Initial value	0x65							

bit	15	14	13	12	11	10	9	8
Field	ETV[15:8]							
R/W Attribute	R, WX							
Protection Attribute	-							
Initial value	0x43							

bit	7	6	5	4	3	2	1	0
Field	ETV[7:0]							
R/W Attribute	R, WX							
Protection Attribute	-							
Initial value	0x21							

[bit31:0] ETV[31:0]: Endianness Test Value

The endianness test value is 0x87654321.

5.3. Data Bit Timing & Prescaler Register (MCG_CANFDx_DBTP, CPG_CANFDx_DBTP)

The Data Bit Timing & Prescaler Register configures the data bit time and enables Transmitter Delay Compensation.

This register is only writable if bits Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) are set.

See "3.1.4. Transmitter Delay Compensation" for a description of TDC fields.

See "3.7. Configuring the CAN Bit Timing" for a description of all other fields.

Notes:

- With a CAN clock (*canfd_cclk*) of 8 MHz, the reset value of 0x00000A33 configures the CAN FD Controller for a data phase bit rate of 500 kBit/s.
- The bit rate configured for the CAN FD data phase via the Data Bit Timing & Prescaler Register (DBTP) must be higher or equal to the bit rate configured for the arbitration phase via the Nominal Bit Timing & Prescaler Register (NBTP).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	TDC	Reserved		DBRP[4:0]				
R/W Attribute	R/W	R0,W0		R/W				
Protection Attribute	-	-		-				
Initial value	0	00		00000				

Bit	15	14	13	12	11	10	9	8
Field	Reserved			DTSEG1[4:0]				
R/W Attribute	R0,W0			R/W				
Protection Attribute	-			-				
Initial value	000			0x0A				

bit	7	6	5	4	3	2	1	0
Field	DTSEG2[3:0]				DSJW[3:0]			
R/W Attribute	R/W				R/W			
Protection Attribute	-				-			
Initial value	0x3				0x3			

[bit31:24] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit23] TDC: Transmitter Delay Compensation

Bit	Description
0	Transmitter Delay Compensation disabled.
1	Transmitter Delay Compensation enabled.

[bit22:21] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit20:16] DBRP[4:0]: Data Bit Rate Prescaler

DBRP[4:0]	Description
0x00-0x1F	<p>The value by which the oscillator frequency is divided for generating the data bit time quanta. The data bit time is built up from a multiple of this quanta.</p> <p>Valid values for the Data Bit Rate Prescaler are 0 to 31. When DBTP.TDC = "1", the range is limited to 0, 1.</p> <p>This limitation is required by the ISO. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p>

[bit15:13] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit12:8] DTSEG1[4:0]: Data Time Segment before sample Point

DTSEG1[4:0]	Description
0x00-0x1F	Valid values are 0 to 31. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

[bit7:4] DTSEG2[3:0]: Data Time Segment after sample Point

DTSEG2[3:0]	Description
0x0-0xF	Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.

[bit3:0] DSJW[3:0]: Data (Re) Synchronization Jump Width

DSJW[3:0]	Description
0x0-0xF	Valid values are 0 to 15. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

5.4. Test Register (MCG_CANFDx_TEST, CPG_CANFDx_TEST)

The Test Register monitors the canfd_rx/canfd_tx pins. It is also used to enable the Loop Back Modes.

Write access to the Test Register has to be enabled by setting the Test Mode Enable bit CCCR.TEST to "1".

All Test Register functions are set to their reset values when bit CCCR.TEST is reset.

Loop Back Mode and software control of pin canfd_tx are hardware test modes. Programming of TX ≠ "00" may disturb the message transfer on the CAN bus.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	7	6	5	4	3	2	1	0
Field	RX	TX[1:0]		LBCK	Reserved			
R/W Attribute	R,WX	R/W		R/W	R0,W0			
Protection Attribute	-	-		-	-			
Initial value	U	00		0	0000			

U = undefined. The RX bit will reflect the actual level at pin canfd_rx.

[bit31:8] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit7] RX: Receive Pin

Monitors the actual value of pin canfd_rx

Bit	Description
0	The CAN bus is dominant (dominant level at pin canfd_rx).
1	The CAN bus is recessive (recessive level at pin canfd_rx).

[bit6:5] TX[1:0]: Control of Transmit Pin

TX[1:0]	Description
00	Reset value. canfd_tx controlled by the CAN Core, updated at the end of the bit time.
01	Sample Point can be monitored at pin canfd_tx.
10	Dominant level at pin canfd_tx.
11	Recessive level at pin canfd_tx.

[bit4] LBCK: Loop Back Mode

Bit	Description
0	Reset value, Loop Back Mode is disabled.
1	Loop Back Mode is enabled.

[bit3:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.5. RAM Watchdog (MCG_CANFDx_RWD, CPG_CANFDx_RWD)

The RAM Watchdog monitors the Message RAM to see if it is ready to be accessed or not.

A Message RAM access starts the RAM Watchdog Counter with the value configured by the Watchdog Configuration (RWD.WDC[7:0]). The counter is reloaded with RWD.WDC when a successful access to the Message RAM has been completed. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag Watchdog Interrupt (IR.WDI) is set.

The RAM Watchdog Counter is clocked by the Bus clock (canfd_bclk).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	15	14	13	12	11	10	9	8
Field	WDV[7:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial value	0x00							

bit	7	6	5	4	3	2	1	0
Field	WDC[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0x00							

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit15:8] WDV[7:0]: Watchdog Value

WDV[7:0]	Description
0x00-0xFF	Actual Message RAM Watchdog Counter Value

[bit7:0] WDC[7:0]: Watchdog Configuration

Start value of the Message RAM Watchdog Counter. With the reset value of 0x00 the counter is disabled.

Write access to this field is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

5.6. CC Control Register (MCG_CANFDx_CCCR, CPG_CANFDx_CCCR)

The CC Control Register configures various operating modes of the CAN FD Controller.

For details about setting and resetting of single bits see "3.1.1. Software Initialization".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	15	14	13	12	11	10	9	8
Field	NISO	TXP	EFBI	PXHD	Reserved		BRSE	FDOE
R/W Attribute	R/W	R/W	R/W	R/W	R0,W0		R/W	R/W
Protection Attribute	-	-	-	-	-		-	-
Initial value	0	0	0	0	00		0	0

bit	7	6	5	4	3	2	1	0
Field	TEST	DAR	MON	CSR	CSA	ASM	CCE	INIT
R/W Attribute	R/W	R/W	R/W	R/W	R,WX	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	1

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit15] NISO: Non ISO Operation

If this bit is set, the CAN FD Controller uses the CAN FD frame format as specified by Bosch CAN FD Specification V1.0.

Write access to this bit is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Bit	Description
0	CAN FD frame format according to ISO 11898-1.
1	CAN FD frame format according to Bosch CAN FD Specification V1.0.

[bit14] TXP: Transmit Pause

If this bit is set, the CAN FD Controller pauses for two nominal bit times before starting the next transmission after it has successfully transmitted a frame.

Write access to this bit is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Bit	Description
0	Transmit pause disabled.
1	Transmit pause enabled.

[bit13] EFBI: Edge Filtering during Bus Integration

Write access to this bit is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Bit	Description
0	Edge filtering disabled.
1	Two consecutive dominant tq required to detect an edge for hard synchronization.

Note:

- *In case that all of the following conditions are fulfilled, it may happen that the CAN FD Controller synchronizes itself wrongly. And it will rate the received CAN FD frame as faulty and error frame will be send. When that frame is retransmitted, Bus integration has finished and the frame is received correctly.*
- *when edge filtering is activated and*
- *when the end of Bus integration coincides with a falling edge (or dominant) at pin canfd_rx, and a CAN FD frame reception is started*

[bit12] PXHD: Protocol Exception Handling Disable

Write access to this bit is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Bit	Description
0	Protocol exception handling enabled.
1	Protocol exception handling disabled.

Note:

- *When protocol exception handling is disabled, the CAN FD Controller will transmit an error frame when it detects a protocol exception condition.*

[bit11:10] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit9] BRSE: Bit Rate Switch Enable

Write access to this bit is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Bit	Description
0	Bit rate switching for transmissions disabled.
1	Bit rate switching for transmissions enabled.

Note:

- When CAN FD operation is disabled `CCCR.FDOE = "0"`, `CCCR.BRSE` is not evaluated.

[bit8] FDOE: FD Operation Enable

Write access to this bit is possible only when the Configuration Change Enable (`CCCR.CCE`) and Initialization (`CCCR.INIT`) bits are both "1".

Bit	Description
0	FD operation disabled.
1	FD operation enabled.

[bit7] TEST: Test Mode Enable

Bit TEST can only be set by the CPU when the Configuration Change Enable (`CCCR.CCE`) and Initialization (`CCCR.INIT`) bits are both "1".

The bit can be reset by the CPU at any time.

Bit	Description
0	Normal operation, register TEST holds reset values.
1	Test Mode, write access to register TEST enabled.

Note:

- When `CCCR.DAR` is set "1", always set "00" to first two identifier (Arbitration field) bits on transmission frame configuration.

[bit6] DAR: Disable Automatic Retransmission

Write access to this bit is possible only when the Configuration Change Enable (`CCCR.CCE`) and Initialization (`CCCR.INIT`) bits are both "1". For a description of DAR mode, see "3.1.7. Disabled Automatic Retransmission".

Bit	Description
0	Automatic retransmission of messages not transmitted successfully enabled.
1	Automatic retransmission disabled.

[bit5] MON: Bus Monitoring Mode

Bit MON can only be set by the CPU when the Configuration Change Enable (`CCCR.CCE`) and Initialization (`CCCR.INIT`) bits are both "1".

The bit can be reset by the CPU at any time.

Bit	Description
0	Bus Monitoring Mode is disabled.
1	Bus Monitoring Mode is enabled.

[bit4] CSR: Clock Stop Request

For a description of Power Down, see "3.1.8. Power Down (Sleep Mode)".

Bit	Description
0	No clock stop is requested.
1	Clock stop requested. When clock stop is requested, first CCCR.INIT and then CCCR.CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.

[bit3] CSA: Clock Stop Acknowledge

For a description of Power Down, see "3.1.8. Power Down (Sleep Mode)".

Bit	Description
0	No clock stop acknowledged.
1	CAN FD Controller may be set in power down by stopping canfd_bclk and canfd_cclk.

[bit2] ASM: Restricted Operation Mode

Bit ASM can only be set by the CPU when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1"

The bit can be reset by the CPU at any time. For a description of the Restricted Operation Mode see "3.1.5. Restricted Operation Mode".

Bit	Description
0	Normal CAN operation.
1	Restricted Operation Mode active.

[bit1] CCE: Configuration Change Enable

Write access to this bit is possible only when the Initialization (CCCR.INIT) bit is "1". This bit (CCCR.CCE) is reset to "0" when CCCR.INIT is set to "0".

Bit	Description
0	The CPU has no write access to the protected configuration registers.
1	The CPU has write access to the protected configuration registers (while bit Initialization CCCR.INIT = "1").

[bit0] INIT: Initialization

Bit	Description
0	Normal Operation.
1	Initialization is started.

Note:

- *Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to Initialization CCCR.INIT can be read back (the maximum length of the delay is four Bus clocks plus five CAN clocks). Therefore the programmer has to assure that the previous value written to CCCR.INIT has been accepted by reading CCCR.INIT before setting CCCR.INIT to a new value.*

5.7. Nominal Bit Timing & Prescaler Register (MCG_CANFDx_NBTP, CPG_CANFDx_NBTP)

The Nominal Bit Timing & Prescaler Register configures the nominal bit time of the CAN FD Controller.

This register is only writable if bits Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) are set.

See "3.7. Configuring the CAN Bit Timing" for a description of the Bit Timing.

Note:

- With a CAN clock (*canfd_cclk*) of 8 MHz, the reset value of 0x06000A03 configures the CAN FD Controller for a bit rate of 500 kBit/s.

bit	31	30	29	28	27	26	25	24
Field	NSJW[6:0]							NBRP[8]
R/W Attribute	R/W							R/W
Protection Attribute	-							-
Initial value	0x03							0

bit	23	22	21	20	19	18	17	16
Field	NBRP[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	NTSEG1[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0x0A							

Bit	7	6	5	4	3	2	1	0
Field	Reserved	NTSEG2[6:0]						
R/W Attribute	R0,W0	R/W						
Protection Attribute	-	-						
Initial value	0	0x03						

[bit31:25] NSJW[6:0]: Nominal (Re) Synchronization Jump Width

NSJW[6:0]	Description
0x00-0x7F	Valid values are 0 to 127. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

[bit24:16] NBRP[8:0]: Nominal Bit Rate Prescaler

NBRP[8:0]	Description
0x000-0x1FF	<p>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quanta.</p> <p>Valid values for the Nominal Bit Rate Prescaler are 0 to 511. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.</p>

[bit15:8] NTSEG1[7:0]: Nominal Time Segment before sample Point

NTSEG1[7:0]	Description
0x01-0xFF	<p>Valid values are 1 to 255. The value 0 must not be used. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.</p>

[bit7] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit6:0] NTSEG2[6:0]: Nominal Time Segment after sample Point

NTSEG2[6:0]	Description
0x01-0x7F	<p>Valid values are 1 to 127. The value 0 must not be used. The actual interpretation by the hardware of this value is such that one more than the programmed value is used.</p>

5.8. Timestamp Counter Configuration (MCG_CANFDx_TSCC, CPG_CANFDx_TSCC)

The Timestamp Counter Configuration holds the settings for Timestamp Generation.

Write access to the Timestamp Counter Configuration (TSCC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

For a description of the Timestamp Counter see "3.2. Timestamp Generation".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved				TCP[3:0]			
R/W Attribute	R0,W0				R/W			
Protection Attribute	-				-			
Initial value	0x0				0x0			

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved						TSS[1:0]	
R/W Attribute	R0,W0						R/W	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:20] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit19:16] TCP[3:0]: Timestamp Counter Prescaler

TCP[3:0]	Description
0x0-0xF	Configures the timestamp and timeout counters time unit in multiples of bit times [1 to 16]. The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.

Note:

- For each timestamp and timeout counter time unit tick, the CAN FD Controller counts the number of bit times that have elapsed with an internal counter, up to the configured `TSCC.TCP[3:0]` value. This internal counter is not initialized by Initialization (`CCCR.INIT`), but only by a hardware reset.

[bit15:2] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit1:0] TSS[1:0]: Timestamp Select

TSS[1:0]	Description
00	Timestamp counter (<code>TSCV.TSC[15:0]</code>) value always 0x0000.
01	Timestamp counter value incremented according to Timestamp Counter Prescaler (<code>TSCC.TCP[3:0]</code>).
10	Timestamp counter value of a counter external to the CAN FD Controller used.
11	Same as "00".

Note:

- When Timestamp Select `TSCC.TSS[1:0] = "01"`, the clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore, if the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

5.9. Timestamp Counter Value (MCG_CANFDx_TSCV, CPG_CANFDx_TSCV)

Holds the value of the Timestamp Counter.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	15	14	13	12	11	10	9	8
Field	TSC[15:8]							
R/W Attribute	R,W							
Protection Attribute	-							
Initial value	0x00							

bit	7	6	5	4	3	2	1	0
Field	TSC[7:0]							
R/W Attribute	R,W							
Protection Attribute	-							
Initial value	0x00							

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit15:0] TSC[15:0]: Timestamp Counter

The internal/external Timestamp Counter value is captured on start of frame (both Rx and Tx).

- When Timestamp Select TSCC.TSS[1:0] = "01", the Timestamp Counter TSCV.TSC[15:0] is incremented in multiples of bit times [1 to 16] depending on the configuration of the Timestamp Counter Prescaler (TSCC.TCP[3:0]). A wrap around sets interrupt flag Timestamp Wraparound (IR.TSW). Write access to TSCV resets the counter to zero.
- When Timestamp Select TSCC.TSS[1:0] = "10", TSCV.TSC[15:0] reflects a 16-bit Timestamp Counter value obtained from a counter external to the CAN FD Controller. For this case, a write access has no impact and will not clear the counter value.

Note:

- *A "wrap around" is a change of the Timestamp Counter value from non-zero to zero not caused by write access to Timestamp Counter Value (TSCV). Such write access will not set IR.TSW to "1".*

5.10. Timeout Counter Configuration (MCG_CANFDx_TOCC, CPG_CANFDx_TOCC)

The Timeout Counter Configuration holds the settings for the Timeout Counter.

Write access to the Timeout Counter Configuration (TOCC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

For a description of the Timeout Counter see "3.3. Timeout Counter".

bit	31	30	29	28	27	26	25	24
Field	TOP[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0xFF							

bit	23	22	21	20	19	18	17	16
Field	TOP[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0xFF							

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved					TOS[1:0]		ETOC
R/W Attribute	R0,W0					R/W		R/W
Protection Attribute	-					-		-
Initial value	00000					00		0

[bit31:16] TOP[15:0]: Timeout Period

Start value of the Timeout Counter (down-counter). Configures the Timeout Period.

[bit15:3] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit2:1] TOS[1:0]: Timeout Select

When operating in Continuous mode (TOS = "00"), a write to Timeout Counter Value (TOCV) presets the counter to the value configured by Timeout Period (TOCC.TOP[15:0]) and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs (TOS = "01"/"10"/"11"), an empty FIFO presets the counter to the value configured by Timeout Period (TOCC.TOP[15:0]). Down-counting is started when the first FIFO element is stored.

TOS[1:0]	Description
00	Continuous operation.
01	Timeout controlled by Tx Event FIFO.
10	Timeout controlled by Rx FIFO 0.
11	Timeout controlled by Rx FIFO 1.

[bit0] ETOC: Enable Timeout Counter

Bit	Description
0	Timeout Counter disabled.
1	Timeout Counter enabled.

5.11. Timeout Counter Value (MCG_CANFDx_TOCV, CPG_CANFDx_TOCV)

Holds the value of the Timeout Counter.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	TOC[15:8]							
R/W Attribute	R,W							
Protection Attribute	-							
Initial value	0xFF							

bit	7	6	5	4	3	2	1	0
Field	TOC[7:0]							
R/W Attribute	R,W							
Protection Attribute	-							
Initial value	0xFF							

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit15:0] TOC[15:0]: Timeout Counter

The Timeout Counter is decremented in multiples of bit times [1 to 16] depending on the configuration of Timestamp Counter Prescaler (TSCC.TCP[3:0]). Setting Configuration Change Enable (CCCR.CCE) will preset the Timeout Counter (TOCV.TOC[15:0]) to the Timeout Period value (TOCC.TOP[15:0]).

- When Timeout Select TOCC.TOS[1:0] = "00" (Continuous Mode), the counter starts when Initialization CCCR.INIT is reset. A write to the Timeout Counter Value register TOCV presets the counter to the value configured by Timeout Period (TOCC.TOP[15:0]) and continues

- down-counting. When the counter reaches zero, interrupt flag Timeout Occurred (IR.TOO) is set, and the counter is immediately restarted at Timeout Period (TOCC.TOP[15:0]).
- When Timeout Select TOCC.TOS \neq "00" (counter is controlled by one of the FIFOs), an empty FIFO presets the counter to the value configured by Timeout Period (TOCC.TOP[15:0]). Down-counting is started when the first FIFO element is stored. In this setting, writing to Timeout Counter Value (TOCV) has no effect. When the counter reaches zero, interrupt flag Timeout Occurred (IR.TOO) is set, and the Timeout Counter is stopped.

5.12. Error Counter Register (MCG_CANFDx_ECR, CPG_CANFDx_ECR)

Holds the values of the Error Counters.

Note:

- When Restricted Operation Mode (CCCR.ASM) is set, the CAN protocol controller does not increment the Transmit Error Counter (ECR.TEC[7:0]) and Receive Error Counter (ECR.REC[6:0]) when a CAN protocol error is detected, but CAN Error Logging (ECR.CEL[7:0]) is still incremented.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	RX,W0							
Protection Attribute	-							
Initial value	0xXX							

bit	23	22	21	20	19	18	17	16
Field	CEL[7:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial value	0x00							

bit	15	14	13	12	11	10	9	8
Field	RP	REC[6:0]						
R/W Attribute	R,WX	R,WX						
Protection Attribute	-	-						
Initial value	0	0000000						

bit	7	6	5	4	3	2	1	0
Field	TEC[7:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial value	0x00							

[bit31:24] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit23:16] CEL[7:0]: CAN Error Logging

The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL.

The counter stops at 0xFF; the next increment of Transmit Error Counter (ECR.TEC[7:0]) or Receive Error Counter (ECR.REC[6:0]) sets interrupt flag Error Logging Overflow (IR.ELO).

[bit15] RP: Receive Error Passive

Bit	Description
0	The Receive Error Counter is below the error passive level of 128.
1	The Receive Error Counter has reached the error passive level of 128.

[bit14:8] REC[6:0]: Receive Error Counter

REC[6:0]	Description
0-127	Actual state of the Receive Error Counter, values between 0 and 127.

[bit7:0] TEC[7:0]: Transmit Error Counter

TEC[7:0]	Description
0-255	Actual state of the Transmit Error Counter, values between 0 and 255.

5.13. Protocol Status Register (MCG_CANFDx_PSR, CPG_CANFDx_PSR)

The Protocol Status Register displays the CAN protocol status of the CAN FD Controller.

Note:

- The PSR register accepts only 16 bit half-word and 32 bit word accesses. 8 bit byte accesses to this register are prohibited.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	RX,W0							
Protection Attribute	-							
Initial value	0xXX							

Bit	23	22	21	20	19	18	17	16
Field	Reserved	TDCV[6:0]						
R/W Attribute	RX,W0	R,WX						
Protection Attribute	-	-						
Initial value	X	0x00						

bit	15	14	13	12	11	10	9	8
Field	Reserved	PXE	RFDF	RBRS	RESI	DLEC[2:0]		
R/W Attribute	RX,W0	R,WX	R,WX	R,WX	R,WX	R,WX		
Protection Attribute	-	-	-	-	-	-		
Initial value	X	0	0	0	0	111		

Bit	7	6	5	4	3	2	1	0
Field	BO	EW	EP	ACT[1:0]		LEC[2:0]		
R/W Attribute	R,WX	R,WX	R,WX	R,WX		R,WX		
Protection Attribute	-	-	-	-		-		
Initial value	0	0	0	00		111		

[bit31:23] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit22:16] TDCV[6:0]: Transmitter Delay Compensation Value

TDCV[6:0]	Description
0x00-0x7F	Position of the secondary sample point, defined by the sum of the measured delay from canfd_tx to canfd_rx and Transmitter Delay Compensation Offset (TDCR.TDCO[6:0]). The SSP position is, in the data phase, the number of mtq between the start of the transmitted bit and the secondary sample point. Valid values are 0 to 127 mtq.

[bit15] Reserved: Reserved Bit

When writing, always write "0". The read value is undefined.

[bit14] PXE: Protocol Exception Event

A read access will reset this bit to "0".

Bit	Description
0	No protocol exception event occurred since last read access.
1	Protocol exception event occurred.

Note:

- Once set to "1", PXE will be held at "1" until it is reset to "0" by the CPU.

[bit13] RFDF: Received a CAN FD Message

This bit is set independent of acceptance filtering. A read access will reset this bit to "0".

Bit	Description
0	Since this bit was reset by the CPU, no CAN FD message has been received.
1	Message in CAN FD format with FDF flag set has been received.

Note:

- Once set to "1", RFDF will be held at "1" until it is reset to "0" by the CPU.

[bit12] RBRS: BRS Flag of last Received CAN FD Message

This bit is set together with "Received a CAN FD Message" (PSR.RFDF), independent of acceptance filtering. A read access will reset this bit to "0".

Bit	Description
0	Last received CAN FD message did not have its BRS flag set.
1	Last received CAN FD message had its BRS flag set.

[bit11] RESI: ESI Flag of last Received CAN FD Message

This bit is set together with "Received a CAN FD Message" (PSR.RFDF), independent of acceptance filtering. A read access will reset this bit to "0".

Bit	Description
0	Last received CAN FD message did not have its ESI flag set.
1	Last received CAN FD message had its ESI flag set.

[bit10:8] DLEC[2:0]: Data Phase Last Error Code

Type of last error that occurred in the data phase of a CAN FD format frame with its BRS flag set. Coding is the same as for Last Error Code (PSR.LEC[2:0]).

This field will be cleared to zero when a CAN FD format frame with its BRS flag set has been transferred (reception or transmission) without error.

A read access will set this field to 7.

[bit7] BO: Bus_Off Status

Bit	Description
0	The CAN FD Controller is not Bus_Off.
1	The CAN FD Controller is in Bus_Off state.

[bit6] EW: Warning Status

Bit	Description
0	Both error counters are below the Error_Warning limit of 96.
1	At least one of error counter has reached the Error_Warning limit of 96.

[bit5] EP: Error Passive

Bit	Description
0	The CAN FD Controller is in the Error_Active state. It normally takes part in bus communication and sends an active error flag when an error has been detected.
1	The CAN FD Controller is in the Error_Passive state.

[bit4:3] ACT[1:0]: Activity

Monitors the CAN communication state. This field is reset to "00" when Initialize (CCCR.INIT) is set to "1".

ACT[1:0]	Description
00	Synchronizing - node is synchronizing on CAN communication.
01	Idle - node is neither receiver nor transmitter.
10	Receiver - node is operating as receiver.
11	Transmitter - node is operating as transmitter.

Note:

- PSR.ACT[1:0] is set to "00" by a Protocol Exception Event.

[bit2:0] LEC[2:0]: Last Error Code

The LEC indicates the type of the last error to occur on the CAN bus.

This field will be cleared to 0 when a message has been transferred (reception or transmission) without error.

LEC[2:0]	Description
0	No Error: No error occurred since LEC has been reset by successful reception or transmission.
1	Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
2	Form Error: A fixed format part of a received frame has the wrong format.
3	AckError: The message transmitted by the CAN FD Controller was not acknowledged by another node.
4	Bit1Error: During the transmission of a message (with the exception of the arbitration field), the CAN FD Controller wanted to send a recessive level, but the monitored bus value was dominant.
5	Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the CAN FD Controller wanted to send a dominant level, but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).
6	CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.
7	NoChange: Any read access to the Protocol Status Register (PSR) re-initializes the Last Error Code field (LEC[2:0]) to 7. When the LEC[2:0] shows the value 7, no CAN bus event was detected since the last CPU read access to the Protocol Status Register.

Notes:

- When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in the Data Phase Last Error Code field (PSR.DLEC[2:0]) instead of the Last Error Code field (PSR.LEC[2:0]). An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.
- The Bus_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting Initialization (CCCR.INIT). If the CAN FD Controller goes Bus_Off, it will set CCCR.INIT of its own accord, stopping all bus activities. Once CCCR.INIT has been cleared by the CPU, the CAN FD Controller will then wait for 129 occurrences of Bus Idle (129×11 consecutive recessive bits) before resuming normal operation. At the end of the Bus_Off recovery sequence, the Receive and Transmit Error Counters (ECR.REC[6:0] and ECR.TEC[7:0]) will be reset. During the waiting time after the resetting of CCCR.INIT, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the Last Error Code field (PSR.LEC[2:0]), enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed, and to monitor the Bus_Off recovery sequence. The Receive Error Counter (ECR.REC[6:0]) is used to count these sequences

5.14. Transmitter Delay Compensation Register (MCG_CANFDx_TDCR, CPG_CANFDx_TDCR)

The Transmitter Delay Compensation Register configures the offset value and the filter window length for Transmitter Delay Compensation.

This register is only writable if bits Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) are set.

See "3.1.4. Transmitter Delay Compensation" for a description of the TDCO[6:0] and TDCF[6:0].

bit	31	30	29	28	27	26	25	24
Field	Reserved

Initial value	0	0x00						

bit	7	6	5	4	3	2	1	0
Field	Reserved	TDCF[6:0]						
R/W Attribute	R0, W0	R/W						
Protection Attribute	-	-						
Initial value	0	0x00						

[bit31:15] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit14:8] TDCO[6:0]: Transmitter Delay Compensation Offset

TDCO[6:0]	Description
0x00-0x7F	Offset value defining the distance between the measured delay from canfd_tx to canfd_rx and the secondary sample point. Valid values are 0 to 127 mtq.

[bit7] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit6:0] TDCF[6:0]: Transmitter Delay Compensation Filter Window Length

TDCF[6:0]	Description
0x00-0x7F	Defines the minimum value for the SSP position, dominant edges on canfd_rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO[6:0]. Valid values are 0 to 127 mtq.

5.15. Interrupt Register (MCG_CANFDx_IR, CPG_CANFDx_IR)

The Interrupt Register holds the flags that are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the CPU clears them. A flag is cleared by writing a "1" to the corresponding bit position. Writing a "0" has no effect. A hard reset will clear the register.

The configuration of Interrupt Enable (IE) controls whether an interrupt is generated.

The configuration of Interrupt Line Select (ILS) controls on which interrupt line (canfd_int0/1) an interrupt is signalled.

Note:

- The TEFW, RF1W, and RF0W interrupts are asserted only when their respective FIFO levels are equal to their configured watermarks. If at this point the interrupt is cleared, and the respective FIFO continues to be filled, the interrupt will not be re-asserted even if the respective FIFO level is greater than the configured watermark.

Initial value	0	0	0	0	0	0	0	0

[bit31:30] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit29] ARA: Access to Reserved Address

See Table 5-1 for the reserved addresses in the CAN FD Controller.

Bit	Description
0	No access to reserved address occurred.
1	Access to reserved address occurred.

[bit28] PED: Protocol Error in Data Phase (Data Bit Time is Used)

Bit	Description
0	No protocol error in data phase.
1	Protocol error in data phase detected (Data Phase Last Error Code PSR.DLEC[2:0] ≠ 0, 7).

[bit27] PEA: Protocol Error in Arbitration Phase (Nominal Bit Time is Used)

Bit	Description
0	No protocol error in arbitration phase.
1	Protocol error in arbitration phase detected (Last Error Code PSR.LEC[2:0] ≠ 0, 7).

[bit26] WDI: Watchdog Interrupt

Bit	Description
0	No Message RAM Watchdog event occurred.
1	Message RAM Watchdog event due to incomplete access of Message RAM.

[bit25] BO: Bus_Off Status

Bit	Description
0	Bus_Off status unchanged.
1	Bus_Off status changed.

[bit24] EW: Warning Status

Bit	Description
0	Error_Warning status unchanged.
1	Error_Warning status changed.

[bit23] EP: Error Passive

Bit	Description
0	Error_Passive status unchanged.
1	Error_Passive status changed.

[bit22] ELO: Error Logging Overflow

Bit	Description
0	CAN Error Logging Counter (ECR.CEL[7:0]) did not overflow.
1	Overflow of CAN Error Logging Counter (ECR.CEL[7:0]) occurred.

[bit21] BEU: Bit Error Uncorrected

Message RAM bit error during access from CAN FD Controller detected, but could not be corrected by the ECC (Error Correction Code) logic attached to the Message RAM.

An uncorrected Message RAM bit error sets Initialization (CCCR.INIT) to "1". This is done to avoid transmission of corrupted data.

Bit	Description
0	No bit error detected when reading from Message RAM.
1	Bit error detected, but could not be corrected.

Notes:

- The corresponding bit in the ECC logic must also be cleared when clearing IR.BEU.
- In case Bit Error Uncorrected IR.BEU occurs, due to the synchronization mechanism between the Bus clock and the CAN clock, there may be a delay until Initialization CCCR.INIT set to "1". Therefore the programmer has to assure that CCCR.INIT has been set to "1" by reading CCCR.INIT before resetting CCCR.INIT to "0".

[bit20] BEC: Bit Error Corrected

Message RAM bit error during access from CAN FD Controller detected and corrected by the ECC logic attached to the Message RAM.

Bit	Description
0	No bit error detected when reading from Message RAM.
1	Bit error detected and corrected by ECC logic.

Note:

- The corresponding bit in the ECC logic must also be cleared when clearing IR.BEC.

[bit19] DRX: Message Stored to Dedicated Rx Buffer

The flag is set whenever a received message has been stored into a dedicated Rx Buffer. This flag is not set by reception of a Debug message.

Bit	Description
0	No Rx Buffer updated.
1	At least one received message stored into an Rx Buffer.

[bit18] TOO: Timeout Occurred

Bit	Description
0	No timeout.
1	Timeout reached.

[bit17] MRAF: Message RAM Access Failure

The flag is set, when the Rx Handler

- has not completed acceptance filtering or storage of an accepted message until the arbitration field of the following message has been received. In this case acceptance filtering or message storage is aborted and the Rx Handler starts processing of the following message.
- completed message reception operation, but was not able to write the message to the Message RAM. In this case message storage is aborted.
- The data of a received frame may be incompletely stored to the Message RAM after the flag is set by the Rx Handler operation. In addition, Rx FIFO 0 Status (RXF0S), Rx FIFO 1 Status (RXF1S), or New Data 1/2 (NDAT1/2) is also updated according as the storage location (Rx FIFO0, Rx FIFO1, or an Rx Buffer). Therefore, in this case discard the received frame data.

The flag is also set when the Tx Handler was not able to read a message from the Message RAM in time. In this case message transmission is aborted. In case of a Tx Handler access failure the CAN FD Controller is switched into Restricted Operation Mode (see "3.1.5. Restricted Operation Mode"). To leave Restricted Operation Mode, the CPU has to reset the Restricted Operation Mode bit (CCCR.ASM).

Bit	Description
0	No Message RAM access failure occurred.
1	Message RAM access failure occurred.

[bit16] TSW: Timestamp Wraparound

Bit	Description
0	No timestamp counter wrap-around.
1	Timestamp counter wrapped around.

[bit15] TEFL: Tx Event FIFO Element Lost

Bit	Description
0	No Tx Event FIFO element lost.
1	Tx Event FIFO element lost. Also set after write attempt to Tx Event FIFO of size zero.

[bit14] TEFF: Tx Event FIFO Full

Bit	Description
0	Tx Event FIFO not full.
1	Tx Event FIFO full.

[bit13] TEFW: Tx Event FIFO Watermark Reached

Bit	Description
0	Tx Event FIFO fill level below watermark.
1	Tx Event FIFO fill level reached watermark.

[bit12] TEFN: Tx Event FIFO New Entry

Bit	Description
0	Tx Event FIFO unchanged.
1	Tx Handler wrote Tx Event FIFO element.

[bit11] TFE: Tx FIFO Empty

Bit	Description
0	Tx FIFO non-empty.
1	Tx FIFO empty.

Note:

- The TFE bit will not be asserted for an empty Tx Queue.

[bit10] TCF: Transmission Cancellation Finished

Bit	Description
0	No transmission cancellation finished.
1	Transmission cancellation finished.

[bit9] TC: Transmission Completed

Bit	Description
0	No transmission completed.
1	Transmission completed.

[bit8] HPM: High Priority Message

Bit	Description
0	No high priority message received.
1	High priority message received.

[bit7] RF1L: Rx FIFO 1 Message Lost

Bit	Description
0	No Rx FIFO 1 message lost.
1	Rx FIFO 1 message lost. Also set after write attempt to Rx FIFO 1 of size zero.

[bit6] RF1F: Rx FIFO 1 Full

Bit	Description
0	Rx FIFO 1 not full.
1	Rx FIFO 1 full.

[bit5] RF1W: Rx FIFO 1 Watermark Reached

Bit	Description
0	Rx FIFO 1 fill level below watermark.
1	Rx FIFO 1 fill level reached watermark.

[bit4] RF1N: Rx FIFO 1 New Message

Bit	Description
0	No new message written to Rx FIFO 1.
1	New message written to Rx FIFO 1.

[bit3] RF0L: Rx FIFO 0 Message Lost

Bit	Description
0	No Rx FIFO 0 message lost.
1	Rx FIFO 0 message lost. Also set after write attempt to Rx FIFO 0 of size zero.

[bit2] RF0F: Rx FIFO 0 Full

Bit	Description
0	Rx FIFO 0 not full.
1	Rx FIFO 0 full.

[bit1] RF0W: Rx FIFO 0 Watermark Reached

Bit	Description
0	Rx FIFO 0 fill level below watermark.
1	Rx FIFO 0 fill level reached watermark.

[bit0] RF0N: Rx FIFO 0 New Message

Bit	Description
0	No new message written to Rx FIFO 0.
1	New message written to Rx FIFO 0.

5.16. Interrupt Enable (MCG_CANFDx_IE, CPG_CANFDx_IE)

The settings in the Interrupt Enable register determine which status changes in the Interrupt Register (IR) will be signalled on an interrupt line.

Bit	Description
0	Interrupt disabled.
1	Interrupt enabled.

bit	31	30	29	28	27	26	25	24
Field	Reserved		ARAE	PEDE	PEAE	WDIE	BOE	EWE

[bit31:30] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit29] ARAE: Access to Reserved Address Enable

[bit28] PEDE: Protocol Error in Data Phase Enable

[bit27] PEAE: Protocol Error in Arbitration Phase Enable

[bit26] WDIE: Watchdog Interrupt Enable

[bit25] BOE: Bus_Off Status Interrupt Enable

[bit24] EWE: Warning Status Interrupt Enable

[bit23] EPE: Error Passive Interrupt Enable

[bit22] ELOE: Error Logging Overflow Interrupt Enable

[bit21] BEUE: Bit Error Uncorrected Interrupt Enable

[bit20] BECE: Bit Error Corrected Interrupt Enable

[bit19] DRXE: Message Stored to Dedicated Rx Buffer Interrupt Enable

[bit18] TOOE: Timeout Occurred Interrupt Enable

[bit17] MRAFE: Message RAM Access Failure Interrupt Enable

[bit16] TSWE: Timestamp Wraparound Interrupt Enable

[bit15] TEFLE: Tx Event FIFO Event Lost Interrupt Enable

[bit14] TEFPE: Tx Event FIFO Full Interrupt Enable

[bit13] TEFWE: Tx Event FIFO Watermark Reached Interrupt Enable

[bit12] TEFNE: Tx Event FIFO New Entry Interrupt Enable

[bit11] TFEE: Tx FIFO Empty Interrupt Enable

[bit10] TCFE: Transmission Cancellation Finished Interrupt Enable

[bit9] TCE: Transmission Completed Interrupt Enable

[bit8] HPME: High Priority Message Interrupt Enable

[bit7] RF1LE: Rx FIFO 1 Message Lost Interrupt Enable

[bit6] RF1FE: Rx FIFO 1 Full Interrupt Enable

[bit5] RF1WE: Rx FIFO 1 Watermark Reached Interrupt Enable

[bit4] RF1NE: Rx FIFO 1 New Message Interrupt Enable

[bit3] RF0LE: Rx FIFO 0 Message Lost Interrupt Enable

[bit2] RF0FE: Rx FIFO 0 Full Interrupt Enable

[bit1] RF0WE: Rx FIFO 0 Watermark Reached Interrupt Enable

[bit0] RF0NE: Rx FIFO 0 New Message Interrupt Enable

5.17. Interrupt Line Select (MCG_CANFDx_ILS, CPG_CANFDx_ILS)

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register (IR) to one of the two CAN FD Controller interrupt lines (canfd_int0/1).

Bit	Description
0	Interrupt assigned to interrupt line canfd_int0.
1	Interrupt assigned to interrupt line canfd_int1.

bit	31	30	29	28	27	26	25	24
Field	Reserved		ARAL	PEDL	PEAL	WDIL	BOL	EWL

5.18. Interrupt Line Enable (MCG_CANFDx_ILE, CPG_CANFDx_ILE)

Interrupt Line Enable can separately enable/disable each of the two interrupt lines to the CPU by the values set to Enable Interrupt Line 0 (ILE.EINT0) and Enable Interrupt Line 1 (ILE.EINT1).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved						EINT1	EINT0
R/W Attribute	R0,W0						R/W	R/W
Protection Attribute	-						-	-
Initial value	000000						0	0

[bit31:2] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit1] EINT1: Enable Interrupt Line 1

Bit	Description
0	Interrupt line canfd_int1 disabled.
1	Interrupt line canfd_int1 enabled.

[bit0] EINT0: Enable Interrupt Line 0

Bit	Description
0	Interrupt line canfd_int0 disabled.
1	Interrupt line canfd_int0 enabled.

5.19. Global Filter Configuration (MCG_CANFDx_GFC, CPG_CANFDx_GFC)

Global settings for Message ID filtering. The Global Filter Configuration (GFC) controls the filter path for standard and extended messages as described in Figure 3-4 and Figure 3-5.

Write access to the Global Filter Configuration (GFC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved	ANFS[1:0]		ANFE[1:0]		RRFS	RRFE	
R/W Attribute	R0,W0	R/W		R/W		R/W	R/W	
Protection Attribute	-	-		-		-	-	
Initial value	00	00		00		0	0	

[bit31:6] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit5:4] ANFS[1:0]: Accept Non-matching Frames Standard

Defines how received messages with 11-bit IDs that do not match any element of the filter list are treated.

ANFS[1:0]	Description
00	Accept in Rx FIFO 0.
01	Accept in Rx FIFO 1.
10	Reject.
11	Reject.

[bit3:2] ANFE[1:0]: Accept Non-matching Frames Extended

Defines how received messages with 29-bit IDs that do not match any element of the filter list are treated.

ANFE[1:0]	Description
00	Accept in Rx FIFO 0.
01	Accept in Rx FIFO 1.
10	Reject.
11	Reject.

[bit1] RRFS: Reject Remote Frames Standard

Bit	Description
0	Filter remote frames with 11-bit standard IDs.
1	Reject all remote frames with 11-bit standard IDs.

[bit0] RRFE: Reject Remote Frames Extended

Bit	Description
0	Filter remote frames with 29-bit extended IDs.
1	Reject all remote frames with 29-bit extended IDs.

5.20. Standard ID Filter Configuration (MCG_CANFDx_SIDFC, CPG_CANFDx_SIDFC)

Settings for 11-bit standard Message ID filtering. The Standard ID Filter Configuration controls the filter path for standard messages as described in Figure 3-4.

Write access to the Standard ID Filter Configuration (SIDFC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	LSS[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	FLSSA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	FLSSA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:24] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit23:16] LSS[7:0]: List Size Standard

LSS[7:0]	Description
0	No standard Message ID filter.
1-128	Number of standard Message ID filter elements.
>128	Values greater than 128 are interpreted as 128.

[bit15:2] FLSSA[15:2]: Filter List Standard Start Address

Start address of standard Message ID filter list (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.21. Extended ID Filter Configuration (MCG_CANFDx_XIDFC, CPG_CANFDx_XIDFC)

Settings for 29-bit extended Message ID filtering. The Extended ID Filter Configuration controls the filter path for extended messages as described in Figure 3-5.

Write access to the Extended ID Filter Configuration (XIDFC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved	LSE[6:0]						
R/W Attribute	R0,W0	R/W						
Protection Attribute	-	-						
Initial value	0	0000000						

Bit	15	14	13	12	11	10	9	8
Field	FLESA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	FLESA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:23] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit22:16] LSE[6:0]: List Size Extended

LSE[6:0]	Description
0	No extended Message ID filter.
1-64	Number of extended Message ID filter elements.
>64	Values greater than 64 are interpreted as 64.

[bit15:2] FLESA[15:2]: Filter List Extended Start Address

Start address of extended Message ID filter list (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.22. Extended ID AND Mask (MCG_CANFDx_XIDAM, CPG_CANFDx_XIDAM)

The Extended ID AND Mask defines the valid bits of a 29-bit ID for acceptance filtering.

Write access to the Extended ID AND Mask (XIDAM) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved			EIDM[28:24]				
R/W Attribute	R0,W0			R/W				
Protection Attribute	-			-				
Initial value	000			11111				

Bit	23	22	21	20	19	18	17	16
Field	EIDM[23:16]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0xff							

Bit	15	14	13	12	11	10	9	8
Field	EIDM[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0xff							

bit	7	6	5	4	3	2	1	0
Field	EIDM[7:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	0xff							

[bit31:29] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit28:0] EIDM[28:0]: Extended ID Mask

For acceptance filtering of extended frames the Extended ID AND Mask is ANDed with the Message ID of a received frame.

With the reset value of all bits set to one the mask is not active.

5.23. High Priority Message Status (MCG_CANFDx_HPMS, CPG_CANFDx_HPMS)

This register is updated every time a Message ID filter element configured to generate a priority event matches. This can be used to monitor the status of incoming high priority messages and to enable fast access to these messages.

Note:

- If all the following conditions are fulfilled, set at least 1 to both List Size Standard (SIDFC.LSS[7:0]) and List Size Extended (XIDFC.LSE[6:0]).
 - To use high priority events
 - To use both standard and extended frame format

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	RX,W0							
Protection Attribute	-							
Initial value	0xXX							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	RX,W0							
Protection Attribute	-							
Initial value	0xXX							

Bit	15	14	13	12	11	10	9	8
Field	FLST	FIDX[6:0]						
R/W Attribute	R,WX	R,WX						
Protection Attribute	-	-						
Initial value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	MSI[1:0]		BIDX[5:0]					
R/W Attribute	R,WX		R,WX					
Protection Attribute	-		-					
Initial value	00		000000					

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit15] FLST: Filter List

Indicates the filter list of the matching filter element.

Bit	Description
0	Standard Filter List.
1	Extended Filter List.

[bit14:8] FIDX[6:0]: Filter Index

FIDX[6:0]	Description
0-127	Index of matching Rx acceptance filter element. Range is 0 to List Size Standard/Extended minus 1 (i.e. SIDFC.LSS[7:0] - 1 resp. XIDFC.LSE[6:0] - 1).

[bit7:6] MSI[1:0]: Message Storage Indicator

MSI[1:0]	Description
00	No Rx FIFO selected.
01	Rx FIFO message lost.
10	Message stored in Rx FIFO 0.
11	Message stored in Rx FIFO 1.

[bit5:0] BIDX[5:0]: Buffer Index

Index of Rx FIFO element to which the message was stored. Only valid when bit[1] of the Message Storage Indicator MSI[1] = "1".

5.24. New Data 1 (MCG_CANFDx_NDAT1, CPG_CANFDx_NDAT1)

New Data 1 holds flags that are set when the respective dedicated Rx Buffer receives a frame.

bit	31	30	29	28	27	26	25	24
Field	ND31	ND30	ND29	ND28	ND27	ND26	ND25	ND24
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	23	22	21	20	19	18	17	16
Field	ND23	ND22	ND21	ND20	ND19	ND18	ND17	ND16
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Field	ND15	ND14	ND13	ND12	ND11	ND10	ND9	ND8
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	ND7	ND6	ND5	ND4	ND3	ND2	ND1	ND0
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] ND[31:0]: New Data

The register holds the New Data flags of dedicated Rx Buffers 0 to 31.

The flags are set when the respective dedicated Rx Buffer has been updated from a received frame. The flags remain set until the CPU clears them.

A flag is cleared by writing a "1" to the corresponding bit position. Writing a "0" has no effect. A hard reset will clear the register.

Bit	Description
0	Rx Buffer not updated.
1	Rx Buffer updated from new message.

5.25. New Data 2 (MCG_CANFDx_NDAT 2, CPG_CANFDx_NDAT 2)

New Data 2 holds flags that are set when the respective dedicated Rx Buffer receives a frame.

bit	31	30	29	28	27	26	25	24
Field	ND63	ND62	ND61	ND60	ND59	ND58	ND57	ND56
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	ND55	ND54	ND53	ND52	ND51	ND50	ND49	ND48
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Field	ND47	ND46	ND45	ND44	ND43	ND42	ND41	ND40
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	ND39	ND38	ND37	ND36	ND35	ND34	ND33	ND32
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] ND[63:32]: New Data

The register holds the New Data flags of dedicated Rx Buffers 32 to 63.

The flags are set when the respective dedicated Rx Buffer has been updated from a received frame.

The flags remain set until the CPU clears them.

A flag is cleared by writing a "1" to the corresponding bit position. Writing a "0" has no effect. A hard reset will clear the register.

Bit	Description
0	Rx Buffer not updated.
1	Rx Buffer updated from new message.

5.26. Rx FIFO 0 Configuration (MCG_CANFDx_RXF0C, CPG_CANFDx_RXF0C)

Settings for the Rx FIFO 0.

Write access to the Rx FIFO 0 Configuration (RXF0C) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	F0OM	F0WM[6:0]						
R/W Attribute	R/W	R/W						
Protection Attribute	-	-						
Initial value	0	0000000						

bit	23	22	21	20	19	18	17	16
Field	Reserved	F0S[6:0]						
R/W Attribute	R0,W0	R/W						
Protection Attribute	-	-						
Initial value	0	0000000						

Bit	15	14	13	12	11	10	9	8
Field	F0SA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	F0SA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31] F0OM: FIFO 0 Operation Mode

Rx FIFO 0 can be operated in blocking or in overwrite mode (see "3.4.2. Rx FIFOs").

Bit	Description
0	Rx FIFO 0 blocking mode.
1	Rx FIFO 0 overwrite mode.

[bit30:24] F0WM[6:0]: Rx FIFO 0 Watermark

F0WM[6:0]	Description
0	Watermark interrupt disabled.
1-64	Level for Rx FIFO 0 Watermark Reached interrupt (IR.RF0W).
>64	Watermark interrupt disabled.

[bit23] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit22:16] F0S[6:0]: Rx FIFO 0 Size

The Rx FIFO 0 elements are indexed from 0 to F0S[6:0] - 1.

F0S[6:0]	Description
0	No Rx FIFO 0.
1-64	Number of Rx FIFO 0 elements.
>64	Values greater than 64 are interpreted as 64.

[bit15:2] F0SA[15:2]: Rx FIFO 0 Start Address

Start address of Rx FIFO 0 in Message RAM (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.27. Rx FIFO 0 Status (MCG_CANFDx_RXF0S, CPG_CANFDx_RXF0S)

Status of the Rx FIFO 0.

bit	31	30	29	28	27	26	25	24
Field	Reserved						RF0L	F0F
R/W Attribute	RX,W0						R,WX	R,WX
Protection Attribute	-						-	-
Initial value	XXXXXX						0	0

Bit	23	22	21	20	19	18	17	16
Field	Reserved		F0PI[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

Bit	15	14	13	12	11	10	9	8
Field	Reserved		F0GI[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

Bit	7	6	5	4	3	2	1	0
Field	Reserved	F0FL[6:0]						
R/W Attribute	RX,W0	R,WX						
Protection Attribute	-	-						
Initial value	X	0000000						

[bit31:26] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit25] RF0L: Rx FIFO 0 Message Lost

This bit is a copy of interrupt flag IR.RF0L (Rx FIFO 0 Message Lost).

When IR.RF0L is reset, this bit is also reset.

Bit	Description
0	No Rx FIFO 0 message lost.
1	Rx FIFO 0 message lost. Also set after write attempt to Rx FIFO 0 of size zero.

Note:

- Overwriting a message when the FIFO is in overwrite mode ($RXF0C.FOOM = "1"$) will not set this flag.

[bit24] F0F: Rx FIFO 0 Full

Bit	Description
0	Rx FIFO 0 not full.
1	Rx FIFO 0 full.

[bit23:22] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit21:16] F0PI[5:0]: Rx FIFO 0 Put Index

F0PI[5:0]	Description
0-63	Rx FIFO 0 write index pointer, range 0 to 63.

[bit15:14] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit13:8] F0GI[5:0]: Rx FIFO 0 Get Index

F0GI[5:0]	Description
0-63	Rx FIFO 0 read index pointer, range 0 to 63.

[bit7] Reserved: Reserved Bit

When writing, always write "0". The read value is undefined.

[bit6:0] F0FL[6:0]: Rx FIFO 0 Fill Level

F0FL[6:0]	Description
0-64	Number of elements stored in Rx FIFO 0, range 0 to 64.

5.28. Rx FIFO 0 Acknowledge (MCG_CANFDx_RXF0A, CPG_CANFDx_RXF0A)

The Rx FIFO 0 Acknowledge is used to acknowledge that the CPU has read a message or a sequence of messages from the Rx FIFO 0 to indicate to the CAN FD Controller that the corresponding Message RAM area may be released. See "3.6. FIFO Acknowledge Handling" for details.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved		F0AI[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

[bit31:6] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit5:0] F0AI[5:0]: Rx FIFO 0 Acknowledge Index

After the CPU has read a message or a sequence of messages from Rx FIFO 0, it has to write the buffer index of the last element read from Rx FIFO 0 to this field (F0AI[5:0]). This will set the Rx FIFO 0 Get Index RXF0S.F0GI[5:0] to F0AI[5:0] + 1 and update the FIFO 0 Fill Level RXF0S.F0FL[6:0].

5.29. Rx Buffer Configuration (MCG_CANFDx_RXBC, CPG_CANFDx_RXBC)

Defines the start address of the Rx Buffers section in the Message RAM.

Write access to the Rx Buffer Configuration (RXBC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	RBSA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	RBSA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:16] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit15:2] RBSA[15:2]: Rx Buffer Start Address

Configures the start address of the Rx Buffers section in the Message RAM (32-bit word address).

Also used to reference debug messages A, B, C.

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.30. Rx FIFO 1 Configuration (MCG_CANFDx_RXF1C, CPG_CANFDx_RXF1C)

Settings for the Rx FIFO 1.

Write access to the Rx FIFO 1 Configuration (RXF1C) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	F1OM	F1WM[6:0]						
R/W Attribute	R/W	R/W						
Protection Attribute	-	-						
Initial value	0	0000000						

bit	23	22	21	20	19	18	17	16
Field	Reserved	F1S[6:0]						
R/W Attribute	R0,W0	R/W						
Protection Attribute	-	-						
Initial value	0	0000000						

bit	15	14	13	12	11	10	9	8
Field	F1SA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	F1SA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31] F1OM: FIFO 1 Operation Mode

Rx FIFO 1 can be operated in blocking or in overwrite mode (see "3.4.2. Rx FIFOs").

Bit	Description
0	Rx FIFO 1 blocking mode.
1	Rx FIFO 1 overwrite mode.

[bit30:24] F1WM[6:0]: Rx FIFO 1 Watermark

F1WM[6:0]	Description
0	Watermark interrupt disabled.
1-64	Level for Rx FIFO 1 Watermark Reached interrupt (IR.RF1W).
>64	Watermark interrupt disabled.

[bit23] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit22:16] F1S[6:0]: Rx FIFO 1 Size

The Rx FIFO 1 elements are indexed from 0 to F1S[6:0] - 1.

F1S[6:0]	Description
0	No Rx FIFO 1.
1-64	Number of Rx FIFO 1 elements.
>64	Values greater than 64 are interpreted as 64.

[bit15:2] F1SA[15:2]: Rx FIFO 1 Start Address

Start address of Rx FIFO 1 in Message RAM (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.31. Rx FIFO 1 Status (MCG_CANFDx_RXF1S, CPG_CANFDx_RXF1S)

Status of the Rx FIFO 1.

bit	31	30	29	28	27	26	25	24
Field	DMS[1:0]		Reserved				RF1L	F1F
R/W Attribute	R,WX		RX,W0				R,WX	R,WX
Protection Attribute	-		-				-	-
Initial value	00		XXXX				0	0

bit	23	22	21	20	19	18	17	16
Field	Reserved		F1PI[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

Bit	15	14	13	12	11	10	9	8
Field	Reserved		F1GI[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

Bit	7	6	5	4	3	2	1	0
Field	Reserved	F1FL[6:0]						
R/W Attribute	RX,W0	R,WX						
Protection Attribute	-	-						
Initial value	X	0000000						

[bit31:30] DMS[1:0]: Debug Message Status

DMS[1:0]	Description
00	Idle state, wait for reception of debug messages, DMA request is cleared.
01	Debug message A received.
10	Debug messages A, B received.
11	Debug messages A, B, C received, DMA request is set.

Notes:

- Debug message is used for Debug on CAN feature.
- Debug on CAN feature is not supported for TRAVEO™ T1G Platform.

[bit29:26] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit25] RF1L: Rx FIFO 1 Message Lost

This bit is a copy of interrupt flag IR.RF1L (Rx FIFO 1 Message Lost).

When IR.RF1L is reset, this bit is also reset.

Bit	Description
0	No Rx FIFO 1 message lost.
1	Rx FIFO 1 message lost. Also set after write attempt to Rx FIFO 1 of size zero.

Note:

- Overwriting a message when the FIFO is in overwrite mode ($RXF1C.F1OM = "1"$) will not set this flag.

[bit24] F1F: Rx FIFO 1 Full

Bit	Description
0	Rx FIFO 1 not full.
1	Rx FIFO 1 full.

[bit23:22] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit21:16] F1PI[5:0]: Rx FIFO 1 Put Index

F1PI[5:0]	Description
0-63	Rx FIFO 1 write index pointer, range 0 to 63.

[bit15:14] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit13:8] F1GI[5:0]: Rx FIFO 1 Get Index

F1GI[5:0]	Description
0-63	Rx FIFO 1 read index pointer, range 0 to 63.

[bit7] Reserved: Reserved Bit

When writing, always write "0". The read value is undefined.

[bit6:0] F1FL[6:0]: Rx FIFO 1 Fill Level

F1FL[6:0]	Description
0-64	Number of elements stored in Rx FIFO 1, range 0 to 64.

5.32. Rx FIFO 1 Acknowledge (MCG_CANFDx_RXF1A, CPG_CANFDx_RXF1A)

The Rx FIFO 1 Acknowledge is used to acknowledge that the CPU has read a message or a sequence of messages from the Rx FIFO 1 to indicate to the CAN FD Controller that the corresponding Message RAM area may be released. See "3.6. FIFO Acknowledge Handling" for details.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved		F1AI[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

[bit31:6] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit5:0] F1AI[5:0]: Rx FIFO 1 Acknowledge Index

After the CPU has read a message or a sequence of messages from Rx FIFO 1, it has to write the buffer index of the last element read from Rx FIFO 1 to this field (F1AI[5:0]). This will set the Rx FIFO 1 Get Index RXF1S.F1GI[5:0] to F1AI[5:0] + 1 and update the FIFO 1 Fill Level RXF1S.F1FL[6:0].

5.33. Rx Buffer/FIFO Element Size Configuration (MCG_CANFDx_RXESC, CPG_CANFDx_RXESC)

Configures the number of data bytes belonging to an Rx Buffer and FIFO element. Data field sizes > 8 bytes are intended for CAN FD operation only.

Write access to the Rx Buffer/FIFO Element Size Configuration (RXESC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Note:

- In case the data field size of an accepted CAN frame exceeds the data field size configured for the matching Rx Buffer or Rx FIFO, only the number of bytes as configured by this register (i.e. RXESC) are stored to the Rx Buffer resp. Rx FIFO element. The rest of the frame's data field is ignored.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved					RBDS[2:0]		
R/W Attribute	R0,W0					R/W		
Protection Attribute	-					-		
Initial value	00000					000		

Bit	7	6	5	4	3	2	1	0
Field	Reserved	F1DS[2:0]		Reserved	F0DS[2:0]			
R/W Attribute	R0,W0	R/W		R0,W0	R/W			
Protection Attribute	-	-		-	-			
Initial value	0	000		0	000			

[bit31:11] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit10:8] RBDS[2:0]: Rx Buffer Data Field Size

RBDS[2:0]	Description
000	8 byte data field.
001	12 byte data field.
010	16 byte data field.
011	20 byte data field.
100	24 byte data field.
101	32 byte data field.
110	48 byte data field.
111	64 byte data field.

[bit7] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit6:4] F1DS[2:0]: Rx FIFO 1 Data Field Size

F1DS[2:0]	Description
000	8 byte data field.
001	12 byte data field.
010	16 byte data field.
011	20 byte data field.
100	24 byte data field.
101	32 byte data field.
110	48 byte data field.
111	64 byte data field.

[bit3] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit2:0] F0DS[2:0]: Rx FIFO 0 Data Field Size

F0DS[2:0]	Description
000	8 byte data field.
001	12 byte data field.
010	16 byte data field.
011	20 byte data field.
100	24 byte data field.
101	32 byte data field.
110	48 byte data field.
111	64 byte data field.

5.34. Tx Buffer Configuration (MCG_CANFDx_TXBC, CPG_CANFDx_TXBC)

Settings for Tx Buffers stored in the Message RAM.

Write access to the Tx Buffer Configuration (TXBC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Notes:

- Be aware that the sum of Transmit FIFO/Queue Size (TXBC.TFQS[5:0]) and Number of Dedicated Transmit Buffers (TXBC.NDTB[5:0]) may be not greater than 32. There is no check for erroneous configurations.
- The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.
- Don't use combination Tx FIFO and Dedicated Tx Buffers. In case of setting "1" to Tx FIFO/Queue Mode (TXBC.TFQM), set 0 to TXBC.NDTB[5:0].

bit	31	30	29	28	27	26	25	24
Field	Reserved	TFQM	TFQS[5:0]					
R/W Attribute	R0,W0	R/W	R/W					
Protection Attribute	-	-	-					
Initial value	0	0	000000					

bit	23	22	21	20	19	18	17	16
Field	Reserved		NDTB[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

bit	15	14	13	12	11	10	9	8
Field	TBSA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	TBSA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31] Reserved: Reserved Bit

When writing, always write "0". When reading, "0" is always read.

[bit30] TFQM: Tx FIFO/Queue Mode

Bit	Description
0	Tx FIFO operation.
1	Tx Queue operation.

[bit29:24] TFQS[5:0]: Transmit FIFO/Queue Size

TFQS[5:0]	Description
0	No Tx FIFO/Queue.
1-32	Number of Tx Buffers used for Tx FIFO/Queue.
>32	Values greater than 32 are interpreted as 32.

[bit23:22] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit21:16] NDTB[5:0]: Number of Dedicated Transmit Buffers

NDTB[5:0]	Description
0	No Dedicated Tx Buffers.
1-32	Number of Dedicated Tx Buffers.
>32	Values greater than 32 are interpreted as 32.

[bit15:2] TBSA[15:2]: Tx Buffers Start Address

Start address of Tx Buffers section in Message RAM (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.35. Tx FIFO/Queue Status (MCG_CANFDx_TXFQS, CPG_CANFDx_TXFQS)

The Tx FIFO/Queue status is related to the pending Tx requests listed in the Tx Buffer Request Pending register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

Note:

- In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices (TXFQS.TFQPI[4:0] resp. TXFQS.TFGI[4:0]) indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

Example:

- For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	RX,W0							
Protection Attribute	-							
Initial value	0xXX							

bit	23	22	21	20	19	18	17	16
Field	Reserved		TFQF	TFQPI[4:0]				
R/W Attribute	RX,W0		R,WX	R,WX				
Protection Attribute	-		-	-				
Initial value	XX		0	00000				

Bit	15	14	13	12	11	10	9	8
Field	Reserved			TFGI[4:0]				
R/W Attribute	RX,W0			R,WX				
Protection Attribute	-			-				
Initial value	XXX			00000				

Bit	7	6	5	4	3	2	1	0
Field	Reserved		TFFL[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

[bit31:22] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit21] TFQF: Tx FIFO/Queue Full

Bit	Description
0	Tx FIFO/Queue not full.
1	Tx FIFO/Queue full.

[bit20:16] TFQPI[4:0]: Tx FIFO/Queue Put Index

TFQPI[4:0]	Description
0-31	Tx FIFO/Queue write index pointer, range 0 to 31.

[bit15:13] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit12:8] TFGI[4:0]: Tx FIFO Get Index

TFGI[4:0]	Description
0-31	Tx FIFO read index pointer, range 0 to 31. Read as zero when Tx Queue operation is configured (Tx FIFO/Queue Mode TXBC.TFQM = "1").

[bit7:6] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit5:0] TFFL[5:0]: Tx FIFO Free Level

TFFL[5:0]	Description
0-32	Number of consecutive free Tx FIFO elements starting from the Tx FIFO Get Index (TXFQS.TFGI[4:0]), range 0 to 32. Read as zero when Tx Queue operation is configured (Tx FIFO/Queue Mode TXBC.TFQM = "1").

5.36. Tx Buffer Element Size Configuration (MCG_CANFDx_TXESC, CPG_CANFDx_TXESC)

Configures the number of data bytes belonging to a Tx Buffer element. Data field sizes > 8 bytes are intended for CAN FD operation only.

Write access to the Tx Buffer Element Size Configuration (TXESC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

Note:

- In case the data length code DLC of a Tx Buffer element is configured to a value higher than the Tx Buffer data field size TXESC.TBDS[2:0], the bytes not defined by the Tx Buffer are transmitted as "0xCC" (padding bytes).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-

[bit31:3] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit2:0] TBDS[2:0]: Tx Buffer Data Field Size

TBDS[2:0]	Description
000	8 byte data field.
001	12 byte data field.
010	16 byte data field.
011	20 byte data field.
100	24 byte data field.
101	32 byte data field.
110	48 byte data field.
111	64 byte data field.

5.37. Tx Buffer Request Pending (MCG_CANFDx_TXBRP, CPG_CANFDx_TXBRP)

Tx Buffer Request Pending holds the status of the transmission requests of each corresponding Tx Buffer.

bit	31	30	29	28	27	26	25	24
Field	TRP31	TRP30	TRP29	TRP28	TRP27	TRP26	TRP25	TRP24

[bit31:0] TRP[31:0]: Transmission Request Pending

Each Tx Buffer has its own Transmission Request Pending bit. The bits are set via register TXBAR (Tx Buffer Add Request). The bits are reset after a requested transmission has completed or has been cancelled via register TXBCR (Tx Buffer Cancellation Request).

TXBRP bits are set only for those Tx Buffers that are configured by the TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers) fields. After a TXBRP bit has been set, a Tx scan (see "3.5. Tx Handling") is started to check for the pending Tx request with the highest priority (Tx Buffer with lowest Message ID).

Bit	Description
0	No transmission request pending.
1	Transmission request pending.

Note:

- *TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.*

5.38. Tx Buffer Add Request (MCG_CANFDx_TXBAR, CPG_CANFDx_TXBAR)

Tx Buffer Add Request is used to request the transmission of each corresponding Tx Buffer.

bit	31	30	29	28	27	26	25	24
Field	AR31	AR30	AR29	AR28	AR27	AR26	AR25	AR24

R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] AR[31:0]: Add Request

Each Tx Buffer has its own Add Request bit. Writing a "1" will set the corresponding Add Request bit; writing a "0" has no impact. This enables the CPU to set transmission requests for multiple Tx Buffers with one write to TXBAR.

TXBAR bits are set only for those Tx Buffers that are configured by the TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers) fields.

When no Tx scan is running, the bits are reset immediately, else the bits remain set until the Tx scan process has completed.

Bit	Description
0	No transmission request added.
1	Transmission requested added.

Note:

- *If an add request is applied for a Tx Buffer with pending transmission request (corresponding TXBRP bit already set), this add request is ignored.*

5.39. Tx Buffer Cancellation Request (MCG_CANFDx_TXBCR, CPG_CANFDx_TXBCR)

Used to cancel transmission requests of each corresponding Tx Buffer.

bit	31	30	29	28	27	26	25	24
Field	CR31	CR30	CR29	CR28	CR27	CR26	CR25	CR24

[bit31:0] CR[31:0]: Cancellation Request

Each Tx Buffer has its own Cancellation Request bit. Writing a "1" will set the corresponding Cancellation Request bit; writing a "0" has no impact. This enables the CPU to set cancellation requests for multiple Tx Buffers with one write to TXBCR.

TXBCR bits are set only for those Tx Buffers that are configured by the TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers) fields. The bits remain set until the corresponding bit of TXBRP (Tx Buffer Request Pending) is reset.

Bit	Description
0	No cancellation pending.
1	Cancellation pending.

5.40. Tx Buffer Transmission Occurred (MCG_CANFDx_TXBTO, CPG_CANFDx_TXBTO)

Displays the status of whether the corresponding Tx Buffer has been transmitted or not.

bit	31	30	29	28	27	26	25	24
Field	TO31	TO30	TO29	TO28	TO27	TO26	TO25	TO24

[bit31:0] TO[31:0]: Transmission Occurred

Each Tx Buffer has its own Transmission Occurred bit.

The bits are set when the corresponding TXBRP (Tx Buffer Request Pending) bit is cleared after a successful transmission.

The bits are reset when a new transmission is requested by writing a "1" to the corresponding bit of register TXBAR (Tx Buffer Add Request).

Bit	Description
0	No transmission occurred.
1	Transmission occurred.

5.41. Tx Buffer Cancellation Finished (MCG_CANFDx_TXBCF, CPG_CANFDx_TXBCF)

Signals whether the cancellation request of the corresponding Tx Buffer has been successful or not.

bit	31	30	29	28	27	26	25	24
Field	CF31	CF30	CF29	CF28	CF27	CF26	CF25	CF24

Initial value	0	0	0	0	0	0	0	0

[bit31:0] CF[31:0]: Cancellation Finished

Each Tx Buffer has its own Cancellation Finished bit.

The bits are set when the corresponding TXBRP (Tx Buffer Request Pending) bit is cleared after a cancellation was requested via TXBCR (Tx Buffer Cancellation Request). In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. CF is also set for an unsuccessful transmission when in DAR mode.

The bits are reset when a new transmission is requested by writing a "1" to the corresponding bit of register TXBAR (Tx Buffer Add Request).

Bit	Description
0	No transmit buffer cancellation.
1	Transmit buffer cancellation finished.

5.42. Tx Buffer Transmission Interrupt Enable (MCG_CANFDx_TXBTIE, CPG_CANFDx_TXBTIE)

The settings in the Tx Buffer Transmission Interrupt Enable determine which Tx Buffer will assert an interrupt upon transmission.

bit	31	30	29	28	27	26	25	24

Initial value	0	0	0	0	0	0	0	0

[bit31:0] TIE[31:0]: Transmission Interrupt Enable

Each Tx Buffer has its own Transmission Interrupt Enable bit.

Bit	Description
0	Transmission interrupt disabled.
1	Transmission interrupt enable.

5.43. Tx Buffer Cancellation Finished Interrupt Enable (MCG_CANFDx_TXBCIE, CPG_CANFDx_TXBCIE)

The settings in the Tx Buffer Cancellation Finished Interrupt Enable determine which Tx Buffer will assert an interrupt upon completion of a transmission cancellation request.

bit	31	30	29	28	27	26	25	24
Field	CFIE31	CFIE30	CFIE29	CFIE28	CFIE27	CFIE26	CFIE25	CFIE24

R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:0] CFIE[31:0]: Cancellation Finished Interrupt Enable

Each Tx Buffer has its own Cancellation Finished Interrupt Enable bit.

Bit	Description
0	Cancellation finished interrupt disabled.
1	Cancellation finished interrupt enabled.

5.44. Tx Event FIFO Configuration (MCG_CANFDx_TXEFC, CPG_CANFDx_TXEFC)

Settings for the Tx Event FIFO.

Write access to the Tx Event FIFO Configuration (TXEFC) is possible only when the Configuration Change Enable (CCCR.CCE) and Initialization (CCCR.INIT) bits are both "1".

bit	31	30	29	28	27	26	25	24
Field	Reserved		EFWM[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

Bit	23	22	21	20	19	18	17	16
Field	Reserved		EFS[5:0]					
R/W Attribute	R0,W0		R/W					
Protection Attribute	-		-					
Initial value	00		000000					

Bit	15	14	13	12	11	10	9	8
Field	EFSA[15:8]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	EFSA[7:2]						Reserved	
R/W Attribute	R/W						R0,W0	
Protection Attribute	-						-	
Initial value	000000						00	

[bit31:30] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit29:24] EFWM[5:0]: Event FIFO Watermark

EFWM[5:0]	Description
0	Watermark interrupt disabled.
1-32	Level for Tx Event FIFO Watermark Reached interrupt (IR.TEFW).
>32	Watermark interrupt disabled.

[bit23:22] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit21:16] EFS[5:0]: Event FIFO Size

The Tx Event FIFO elements are indexed from 0 to EFS[5:0] - 1.

EFS[5:0]	Description
0	Tx Event FIFO disabled.
1-32	Number of Tx Event FIFO elements.
>32	Values greater than 32 are interpreted as 32.

[bit15:2] EFSA[15:2]: Event FIFO Start Address

Start address of Tx Event FIFO in Message RAM (32-bit word address, see Figure 6-1).

[bit1:0] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

5.45. Tx Event FIFO Status (MCG_CANFDx_TXEFS, CPG_CANFDx_TXEFS)

Status of the Tx Event FIFO.

bit	31	30	29	28	27	26	25	24
Field	Reserved						TEFL	EFF
R/W Attribute	RX,W0						R,WX	R,WX
Protection Attribute	-						-	-
Initial value	XXXXXX						0	0

bit	23	22	21	20	19	18	17	16
Field	Reserved			EFPI[4:0]				
R/W Attribute	RX,W0			R,WX				
Protection Attribute	-			-				
Initial value	XXX			00000				

Bit	15	14	13	12	11	10	9	8
Field	Reserved			EFGI[4:0]				
R/W Attribute	RX,W0			R,WX				
Protection Attribute	-			-				
Initial value	XXX			00000				

bit	7	6	5	4	3	2	1	0
Field	Reserved		EFFL[5:0]					
R/W Attribute	RX,W0		R,WX					
Protection Attribute	-		-					
Initial value	XX		000000					

[bit31:26] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit25] TEFL: Tx Event FIFO Element Lost

This bit is a copy of interrupt flag IR.TEFL (Tx Event FIFO Element Lost). When IR.TEFL is reset, this bit is also reset.

Bit	Description
0	No Tx Event FIFO element lost.
1	Tx Event FIFO element lost. Also set after write attempt to Tx Event FIFO of size zero.

[bit24] EFF: Event FIFO Full

Bit	Description
0	Tx Event FIFO not full.
1	Tx Event FIFO full.

[bit23:21] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit20:16] EFPI[4:0]: Event FIFO Put Index

EFPI[4:0]	Description
0-31	Tx Event FIFO write index pointer, range 0 to 31.

[bit15:13] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit12:8] EFGI[4:0]: Event FIFO Get Index

EFGI[4:0]	Description
0-31	Tx Event FIFO read index pointer, range 0 to 31.

[bit7:6] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

[bit5:0] EFFL[5:0]: Event FIFO Fill Level

EFFL[5:0]	Description
0-32	Number of elements stored in Tx Event FIFO, range 0 to 32.

5.46. Tx Event FIFO Acknowledge (MCG_CANFDx_TXEFA, CPG_CANFDx_TXEFA)

The Tx Event FIFO Acknowledge is used to acknowledge that the CPU has read an event from the Tx Event FIFO to indicate to the CAN FD Controller that the corresponding Message RAM area may be released. See "3.6. FIFO Acknowledge Handling" for details.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial value	0x00							

Bit	7	6	5	4	3	2	1	0
Field	Reserved			EFAI[4:0]				
R/W Attribute	R0,W0			R/W				
Protection Attribute	-			-				
Initial value	000			00000				

[bit31:5] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit4:0] EFAI[4:0]: Event FIFO Acknowledge Index

After the CPU has read an element or a sequence of elements from the Tx Event FIFO, it has to write the index of the last element read from Tx Event FIFO to EFAI[4:0]. This will set the Tx Event FIFO Get Index TXEFS.EFGI[4:0] to EFAI[4:0] + 1 and update the Event FIFO 0 Fill Level TXEFS.EFFL[5:0].

6. Message RAM

The Message RAM stores Rx/Tx messages and filter configurations.

Note:

- *The Message RAM should be zeroized before configuration of the CAN FD Controller in order to prevent Message RAM bit errors when reading uninitialized words, and also to avoid unexpected filter element configurations in the Message RAM.*

6.1. Message RAM Configuration

6.2. Rx Buffer and FIFO Element

6.3. Tx Buffer Element

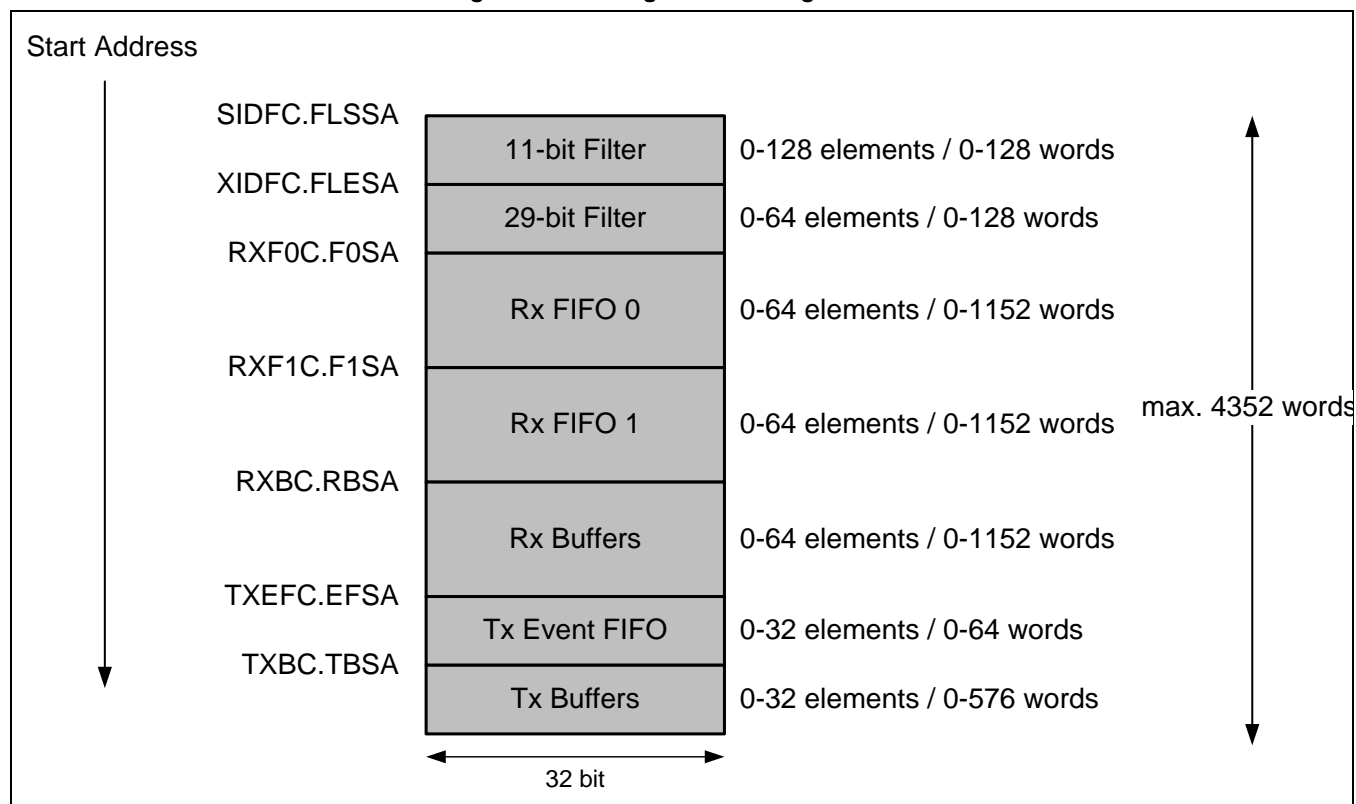

6.4. Tx Event FIFO Element

6.5. Standard Message ID Filter Element

6.6. Extended Message ID Filter Element

6.1. Message RAM Configuration

The Message RAM has a width of 32 bits. The CAN FD Controller can be configured to allocate up to 4352 words in the Message RAM (note that the number of words that can be used will be limited by the size of the actual Message RAM). It is not necessary to configure each of the sections listed in Figure 6-1, nor is there any restriction with respect to the sequence of the sections.

Figure 6-1 Message RAM Configuration

The CAN FD Controller addresses the Message RAM in 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

Notes:

- The CAN FD Controller does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.
- Message RAM accesses by the CPU will take two to four Bus clock cycles.

List of Message RAM Elements

Abbreviation	Reference
Rx Buffer and FIFO Element	6.2
Tx Buffer Element	6.3
Tx Event FIFO Element	6.4
Standard Message ID Filter Element	6.5
Extended Message ID Filter Element	6.6

6.2. Rx Buffer and FIFO Element

An Rx Buffer and FIFO Element is a block of 32-bit words that holds the data and status of a received frame that was stored in the Message RAM.

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of an Rx Buffer and FIFO element is shown in the figure below. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC (Rx Buffer/FIFO Element Size Configuration).

	31	24	23	16	15	8	7	0
R0	ESI	XTD	RTR	ID[28:0]				
R1	ANMF	FIDX[6:0]		reserved	FDF	BRS	DLC[3:0]	RXTS[15:0]
R2	DB3[7:0]		DB2[7:0]		DB1[7:0]		DB0[7:0]	
R3	DB7[7:0]		DB6[7:0]		DB5[7:0]		DB4[7:0]	
...	
Rn	DBm[7:0]		DBm-1[7:0]		DBm-2[7:0]		DBm-3[7:0]	

R0 [bit31] ESI: Error State Indicator

Bit	Description
0	Transmitting node is error active.
1	Transmitting node is error passive.

R0 [bit30] XTD: Extended Identifier

Signals to the CPU whether the received frame has a standard or extended identifier.

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

R0 [bit29] RTR: Remote Transmission Request

Signals to the CPU whether the received frame is a data frame or a remote frame.

Bit	Description
0	Received frame is a data frame.
1	Received frame is a remote frame.

Note:

- There are no remote frames in CAN FD format. In CAN FD frames (FDF = "1"), the dominant RRS (Remote Request Substitution) bit replaces bit RTR (Remote Transmission Request).

R0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].

R1 [bit31] ANMF: Accepted Non-matching Frame

Acceptance of non-matching frames may be enabled via GFC.ANFS[1:0] (Accept Non-matching Frames Standard) and GFC.ANFE[1:0] (Accept Non-matching Frames Extended).

Bit	Description
0	Received frame matching filter index FIDX.
1	Received frame did not match any Rx filter element.

R1 [bit30:24] FIDX[6:0]: Filter Index

FIDX[6:0]	Description
0-127	Index of matching Rx acceptance filter element (invalid if ANMF = "1"). Range is 0 to List Size Standard/Extended minus 1 (i.e. SIDFC.LSS - 1 resp. XIDFC.LSE - 1).

R1 [bit23:22] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

R1 [bit21] FDF: Extended Data Length

Bit	Description
0	Classic CAN frame format.
1	CAN FD frame format.

R1 [bit20] BRS: Bit Rate Switch

Bit	Description
0	Frame received without bit rate switching.
1	Frame received with bit rate switching.

R1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0-8	Classic CAN + CAN FD: received frame has 0-8 data bytes.
9-15	Classic CAN: received frame has 8 data bytes. CAN FD: received frame has 12/16/20/24/32/48/64 data bytes. See Table 3-1 for details.

R1 [bit15:0] RXTS[15:0]: Rx Timestamp

Timestamp Counter value captured on start of frame reception. Resolution depending on configuration of the Timestamp Counter Prescaler TSCC.TCP[3:0].

R2 [bit31:24]	DB3[7:0] :	Data Byte 3
R2 [bit23:16]	DB2[7:0] :	Data Byte 2
R2 [bit15:8]	DB1[7:0] :	Data Byte 1
R2 [bit7:0]	DB0[7:0] :	Data Byte 0
R3 [bit31:24]	DB7[7:0] :	Data Byte 7
R3 [bit23:16]	DB6[7:0] :	Data Byte 6
R3 [bit15:8]	DB5[7:0] :	Data Byte 5
R3 [bit7:0]	DB4[7:0] :	Data Byte 4
...
Rn [bit31:24]	DBm[7:0]:	Data Byte m
Rn [bit23:16]	DBm-1[7:0]:	Data Byte m-1
Rn [bit15:8]	DBm-2[7:0]:	Data Byte m-2
Rn [bit7:0]	DBm-3[7:0]:	Data Byte m-3

Notes:

- Depending on the configuration of the element size (defined by Rx Buffer/FIFO Element Size Configuration (RXESC)), Rn will vary from n = 3 to 17.
- m is a function of n, $m = (n - 1) \times 4 - 1$.
- The number of valid data bytes are defined by the Data Length Code.

6.3. Tx Buffer Element

A Tx Buffer Element is a block of 32-bit words stored in the Message RAM that holds data and control information of a frame to be transmitted by the CAN FD Controller.

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO/Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO/Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO/Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS[5:0] (Transmit FIFO/Queue Size) and TXBC.NDTB[5:0] (Number of Dedicated Transmit Buffers). The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC (Tx Buffer Element Size Configuration).

	31	24	23	16	15	8	7	0
T0	ESI	XTD	RTR	ID[28:0]				
T1	MM[7:0]			EFC	reserved	FDF	BRS	DLC[3:0]
T2	DB3[7:0]			DB2[7:0]			DB1[7:0]	
T3	DB7[7:0]			DB6[7:0]			DB5[7:0]	
...	
Tn	DBm[7:0]			DBm-1[7:0]			DBm-2[7:0]	

T0 [bit31] ESI: Error State Indicator

Bit	Description
0	ESI bit in CAN FD format depends only on error passive flag.
1	ESI bit in CAN FD format transmitted recessive.

Note:

- The ESI bit of the transmit buffer is ORed with the error passive flag to decide the value of the ESI bit in the transmitted FD frame. As required by the CAN FD protocol specification, an error active node may optionally transmit the ESI bit recessive, but an error passive node will always transmit the ESI bit recessive.

T0 [bit30] XTD: Extended Identifier

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

T0 [bit29] RTR: Remote Transmission Request

Bit	Description
0	Transmit data frame.
1	Transmit remote frame.

Note:

- When RTR = "1", the CAN FD Controller transmits a remote frame according to ISO11898-1, even if FD Operation Enable (CCCR.FDOE) enables the transmission in CAN FD format.

T0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier has to be written to ID[28:18].

T1 [bit31:24] MM[7:0]: Message Marker

Written by CPU during Tx Buffer configuration. Copied into Tx Event FIFO element for identification of Tx message status.

T1 [bit23] EFC: Event FIFO Control

Bit	Description
0	Don't store Tx events.
1	Store Tx events.

T1 [bit22] Reserved: Reserved Bit

When writing, always write "0". The read value is undefined.

T1 [bit21] FDF: FD Format

Bit	Description
0	Frame transmitted in Classic CAN format.
1	Frame transmitted in CAN FD format.

T1 [bit20] BRS: Bit Rate Switching

Bit	Description
0	CAN FD frames transmitted without bit rate switching.
1	CAN FD frames transmitted with bit rate switching.

Note:

- Bits *ESI*, *FDF*, and *BRS* are only evaluated when CAN FD operation is enabled *CCCR.FDOE* = "1". Bit *BRS* is only evaluated when in addition *CCCR.BRSE* = "1". See Table 3-5 for details of bits *FDF* and *BRS*.

T1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0-8	Classic CAN + CAN FD: transmit frame has 0-8 data bytes.
9-15	Classic CAN: transmit frame has 8 data bytes. CAN FD: transmit frame has 12/16/20/24/32/48/64 data bytes. See Table 3-1 for details.

T1 [bit15:0] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

T2 [bit31:24]	DB3[7:0] :	Data Byte 3
T2 [bit23:16]	DB2[7:0] :	Data Byte 2
T2 [bit15:8]	DB1[7:0] :	Data Byte 1
T2 [bit7:0]	DB0[7:0] :	Data Byte 0
T3 [bit31:24]	DB7[7:0] :	Data Byte 7
T3 [bit23:16]	DB6[7:0] :	Data Byte 6
T3 [bit15:8]	DB5[7:0] :	Data Byte 5
T3 [bit7:0]	DB4[7:0] :	Data Byte 4
...
Tn [bit31:24]	DBm[7:0]:	Data Byte m
Tn [bit23:16]	DBm-1[7:0]:	Data Byte m-1
Tn [bit15:8]	DBm-2[7:0]:	Data Byte m-2
Tn [bit7:0]	DBm-3[7:0]:	Data Byte m-3

Notes:

- Depending on the configuration of the element size (*TXESC*), *Tn* will vary from *n* = 3 to 17.
- *m* is a function of *n*: $m = (n - 1) \times 4 - 1$.

6.4. Tx Event FIFO Element

Each Tx Event FIFO Element stores information about transmitted messages. By reading the Tx Event FIFO the CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS (Tx Event FIFO Status).

	31		24	23		16	15		8	7		0
E0	ESI	XTD	RTR	ID[28:0]								
E1	MM[7:0]			ET [1:0]	EDF	BRS	DLC[3:0]	TXTS[15:0]				

E0 [bit31] ESI: Error State Indicator

Bit	Description
0	Transmitting node is error active.
1	Transmitting node is error passive.

E0 [bit30] XTD: Extended Identifier

Bit	Description
0	11-bit standard identifier.
1	29-bit extended identifier.

E0 [bit29] RTR: Remote Transmission Request

Bit	Description
0	Data frame transmitted.
1	Remote frame transmitted.

E0 [bit28:0] ID[28:0]: Identifier

Standard or extended identifier depending on bit XTD. A standard identifier is stored into ID[28:18].

E1 [bit31:24] MM[7:0]: Message Marker

Copied from Tx Buffer into Tx Event FIFO element for identification of Tx message status.

E1 [bit23:22] ET[1:0]: Event Type

ET[1:0]	Description
00	Reserved.
01	Tx event.
10	Transmission in spite of cancellation. Always set for transmissions in DAR mode (Disable Automatic Retransmission mode).
11	Reserved.

E1 [bit21] FDF: FD Format

Bit	Description
0	Classic CAN frame format.
1	CAN FD frame format (new DLC-coding and CRC).

E1 [bit20] BRS: Bit Rate Switching

Bit	Description
0	Frame transmitted without bit rate switching.
1	Frame transmitted with bit rate switching.

E1 [bit19:16] DLC[3:0]: Data Length Code

DLC[3:0]	Description
0-8	Classic CAN + CAN FD: frame with 0-8 data bytes transmitted.
9-15	Classic CAN: frame with 8 data bytes transmitted. CAN FD: frame with 12/16/20/24/32/48/64 data bytes transmitted. See Table 3-1 for details.

E1 [bit15:0] TXTS[15:0]: Tx Timestamp

Timestamp Counter value captured on start of frame transmission. Resolution depending on configuration of the Timestamp Counter Prescaler (TSCC.TCP[3:0]).

6.5. Standard Message ID Filter Element

A Standard Message ID Filter Element consists of a single 32-bit word, and can be configured as a range filter, dual filter, classic bit mask filter, or filter for a single dedicated ID, for messages with 11-bit standard IDs.

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is

Filter List Standard Start Address (SIDFC.FLSSA[15:2]) + index of the filter element (0 to 127).

	31		24	23		16	15		8	7		0
S0	SFT [1:0]	SFEC [2:0]	SFID1[10:0]				reserved		SFID2[10:0]			

S0 [bit31:30] SFT[1:0]: Standard Filter Type

SFT[1:0]	Description
00	Range filter from SFID1[10:0] to SFID2[10:0] (SFID2[10:0] ≥ received ID ≥ SFID1[10:0]).
01	Dual ID filter for SFID1[10:0] or SFID2[10:0].
10	Classic filter: SFID1[10:0] = filter, SFID2[10:0] = mask. Only those bits of SFID1[10:0] where the corresponding SFID2[10:0] bits are "1" are relevant.
11	Filter element disabled.

Note:

- With SFT = "11" the filter element is disabled and the acceptance filtering continues.
(same behaviour as with SFEC = "000")

S0 [bit29:27] SFEC[2:0]: Standard Filter Element Configuration

All enabled filter elements are used for acceptance filtering of standard frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached.

If SFEC[2:0] = "100", "101", or "110" a match sets interrupt flag IR.HPM (High Priority Message) and, if enabled, an interrupt is generated. In this case register HPMS (High Priority Message Status) is updated with the status of the priority match.

SFEC[2:0]	Description
000	Disable filter element.
001	Store in Rx FIFO 0 if filter matches.
010	Store in Rx FIFO 1 if filter matches.
011	Reject ID if filter matches.
100	Set priority if filter matches.
101	Set priority and store in Rx FIFO 0 if filter matches.
110	Set priority and store in Rx FIFO 1 if filter matches.
111	Store into dedicated Rx Buffer or as debug message, configuration of SFT[1:0] ignored.

S0 [bit26:16] SFID1[10:0]: Standard Filter ID 1

This bit field has a different meaning depending on the configuration of SFEC[2:0]:

- SFEC[2:0] = "001" to "110"
Set SFID1[10:0] according to the SFT[1:0] setting.
- SFEC[2:0] = "111"
SFID1[10:0] defines the ID of a standard dedicated Rx Buffer or debug message to be stored.
The received identifiers must match exactly, no masking mechanism is used.

S0 [bit15:11] Reserved: Reserved Bits

When writing, always write "0". The read value is undefined.

S0 [bit10:0] SFID2[10:0]: Standard Filter ID 2

This bit field has a different meaning depending on the configuration of SFEC[2:0]:

- SFEC[2:0] = "001" to "110"
Set SFID2[10:0] according to the SFT[1:0] setting
- SFEC[2:0] = "111"
Filter for dedicated Rx Buffers or for debug messages

SFID2[10:9] decides whether the received message is stored into a dedicated Rx Buffer or treated as message A, B, or C of the debug message sequence.

SFID2[10:9]	Description
00	Store message into a dedicated Rx Buffer.
01	Debug Message A.
10	Debug Message B.
11	Debug Message C.

SFID2[8:6] are reserved bits. When writing, always write "0". The read value is undefined.

SFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA[15:2] for storage of a matching message.

Notes:

- Debug message is used for Debug on CAN feature.
- Debug on CAN feature is not supported for TRAVEO™ T1G Platform.

6.6. Extended Message ID Filter Element

An Extended Message ID Filter Element consists of two 32-bit words, and can be configured as a range filter, dual filter, classic bit mask filter, or filter for a single dedicated ID, for messages with 29-bit extended IDs.

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is

Filter List Extended Start Address (XIDFC.FLESA[15:2]) + 2 × index of the filter element (0 to 63).

	31	24	23	16	15	8	7	0
F0	EFEC [2:0]	EFID1[28:0]						
F1	EFT [1:0]	reserved	EFID2[28:0]					

F0 [bit31:29] EFEC[2:0]: Extended Filter Element Configuration

All enabled filter elements are used for acceptance filtering of extended frames. Acceptance filtering stops at the first matching enabled filter element or when the end of the filter list is reached.

If EFEC[2:0] = "100", "101", or "110" a match sets interrupt flag IR.HPM (High Priority Message) and, if enabled, an interrupt is generated. In this case register HPMS (High Priority Message Status) is updated with the status of the priority match.

EFEC[2:0]	Description
000	Disable filter element.
001	Store in Rx FIFO 0 if filter matches.
010	Store in Rx FIFO 1 if filter matches.
011	Reject ID if filter matches.
100	Set priority if filter matches.
101	Set priority and store in Rx FIFO 0 if filter matches.
110	Set priority and store in Rx FIFO 1 if filter matches.
111	Store into dedicated Rx Buffer or as debug message, configuration of EFT[1:0] ignored.

F0 [bit28:0] EFID1[28:0]: Extended Filter ID 1

This bit field has a different meaning depending on the configuration of EFEC[2:0].

- EFEC[2:0] = "001" to "110"
Set EFID1[28:0] according to the EFT[1:0] setting.
- EFEC[2:0] = "111"
EFID1[28:0] defines the ID of an extended dedicated Rx Buffer or debug message to be stored. The received identifiers must match exactly, only XIDAM masking mechanism (see "3.4.1.3. Extended Message ID Filtering") is used.

F1 [bit31:30] EFT[1:0]: Extended Filter Type

EFT[1:0]	Description
00	Range filter from EFID1[28:0] to EFID2[28:0] (EFID2[28:0] ≥ received ID ANDed with XIDAM ≥ EFID1[28:0]).
01	Dual ID filter Matches when EFID1[28:0] or EFID2[28:0] is equal to received ID ANDed with XIDAM.
10	Classic filter: EFID1[28:0] = filter, EFID2[28:0] = mask. Only those bits of EFID1[28:0] where the corresponding EFID2[28:0] bits are "1" are relevant. Matches when the received ID ANDed with XIDAM is equal to EFID1[28:0] masked by EFID2[28:0].
11	Range filter from EFID1[28:0] to EFID2[28:0] (EFID2[28:0] ≥ EFID1[28:0]), XIDAM mask not applied.

F1 [bit29] Reserved: Reserved Bit

When writing, always write "0". The read value is undefined.

F1 [bit28:0] EFID2[28:0]: Extended Filter ID 2

This bit field has a different meaning depending on the configuration of EFEC[2:0]:

- EFEC[2:0] = "001" to "110"
Set EFID2[28:0] according to the EFT[1:0] setting
- EFEC[2:0] = "111"
EFID2[28:0] is used to configure this filter for dedicated Rx Buffers or for debug messages

EFID2[28:11] are reserved bits. When writing, always write "0". The read value is undefined.

EFID2[10:9] decides whether the received message is stored into a dedicated Rx Buffer or treated as message A, B, or C of the debug message sequence.

EFID2[10:9]	Description
00	Store message into a dedicated Rx Buffer.
01	Debug Message A.
10	Debug Message B.
11	Debug Message C.

EFID2[8:6] are reserved bits. When writing, always write "0". The read value is undefined.

EFID2[5:0] defines the offset to the Rx Buffer Start Address RXBC.RBSA[15:2] for storage of a matching message.

Notes:

- Debug message is used for Debug on CAN feature.
- Debug on CAN feature is not supported for TRAVEO™ T1G Platform.

CHAPTER 32: External Time Stamp Counter For CAN FD

This chapter explains the functions and operations of the External Time Stamp Counter for CAN FD.

1. Overview
2. Configuration
3. Operations
4. Example of the Operation
5. Register

CANFDETSC-TXXPT03P01R02L02-E1-XX

1. Overview

The Time Stamp Counter for CAN FD is the 16-bit counter of external time stamp function.

Time stamp Counter

- This counter is a 16-bit counter, and only counts up.
- If the counter is enable, it counts up from the current value.
- If the counter is disable, it holds current value.
- Setting enable/disable the counter is programmable by software.
- The counter counts up to the comparison value.
- When counter value comes to greater than or equal to the comparison value, the counter loads 0 by the next bus clock cycle and continues counting up.
- The limit value of the counter can be programmable by software.
- Time Stamp Counter Data Register (TSCDTR) indicates the count value.

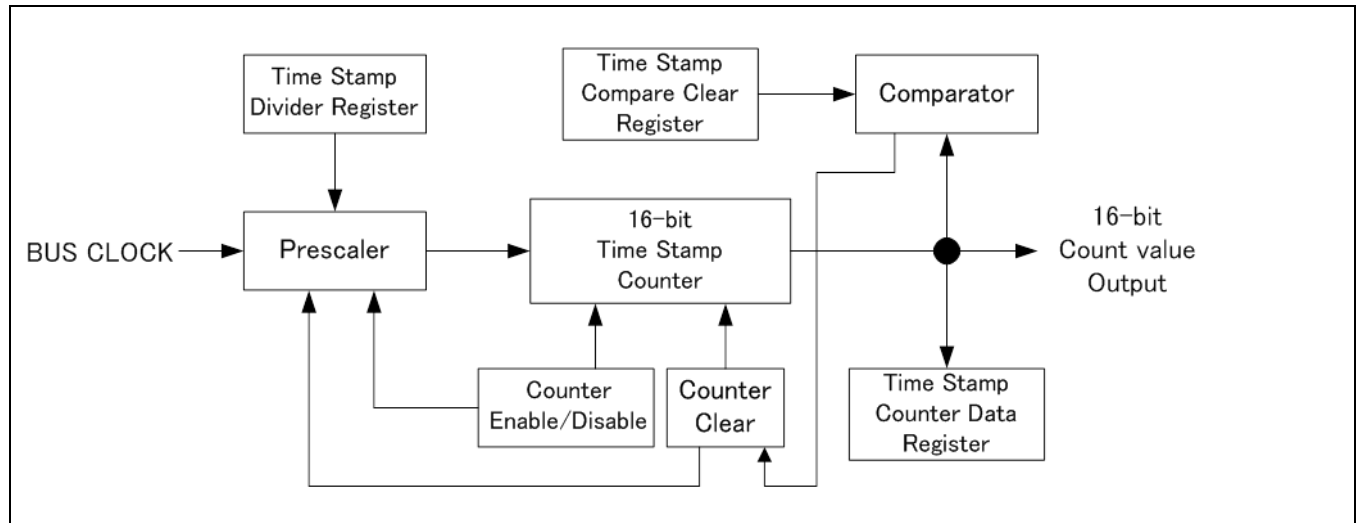

Count Up Cycle of the Time stamp Counter

- Enable to select a count up cycle (divided from bus clock ; 1 - 65536 division)
- Enable to set the division ratio any value (i.e. each step)
- Enable to set a count up cycle by software.

2. Configuration

This section explains configuration of the time stamp counter for CAN FD.

Figure 2 1 Block Diagram of Time Stamp Counter for CAN FD

3. Operations

3.1. Operation of Time Stamp Counter for CAN FD

This section explains the operation of Time Stamp Counter for CAN FD.

3.1.1. Count Up Cycle for Time Stamp Counter

Count up cycle for the Time Stamp Counter can be set for each step between 1 to 65536. Count up cycle is set by the Time Stamp Divider register (TSDIVR).

3.1.2. Time Stamp Counter

After setting the count enable (TSCNTR: CNTEN=1), the count up is started for the current counter value. After setting the counter disable (TSCNTR: CNTEN=0), the count up is stopped and the count value is held.

The counter counts up to the value that is set in the Time Stamp Compare Clear Register (TSCPCLR). When counter value comes to greater than or equal to the value that is set in the Time Stamp Compare Clear Register (TSCPCLR), the counter loads 0 by the next bus clock cycle and continues counting up. The count value can be seen by reading Time Stamp Counter Data Register (TSCDTR).

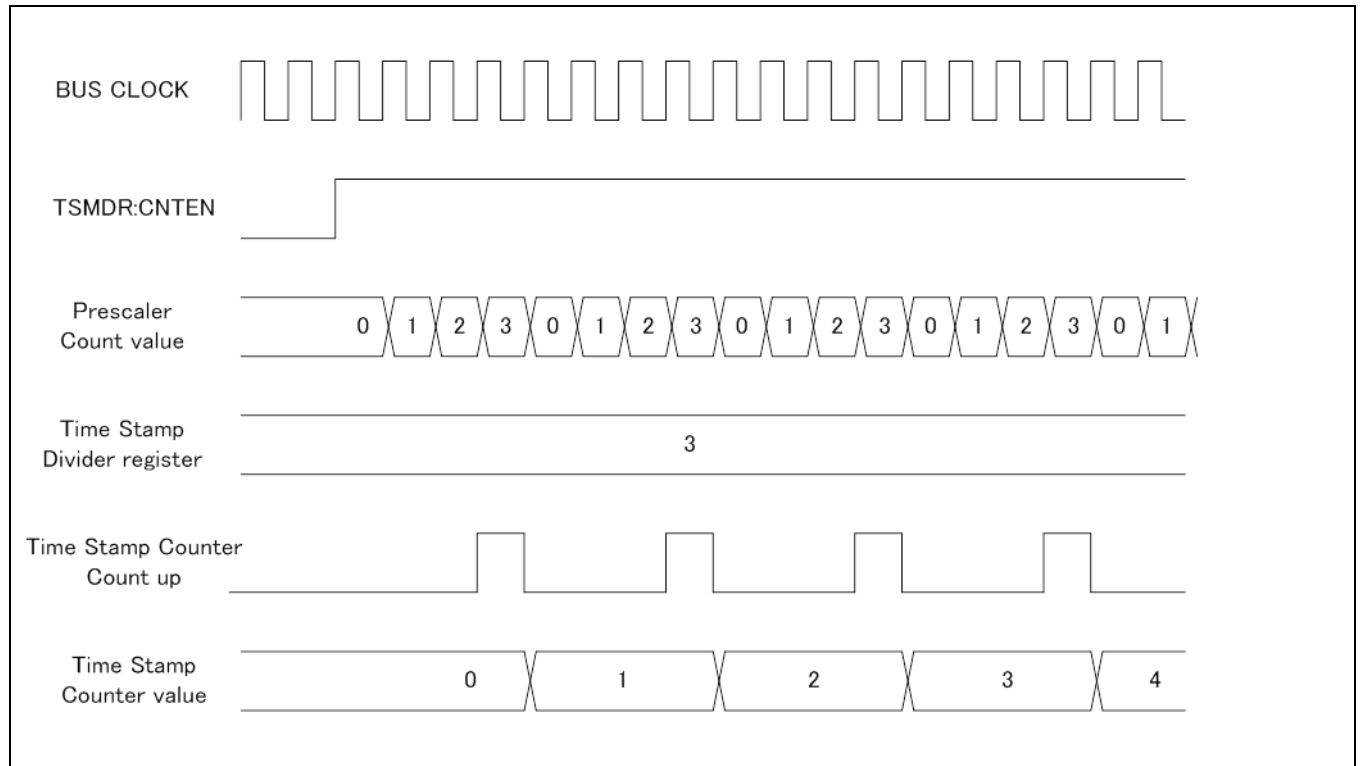

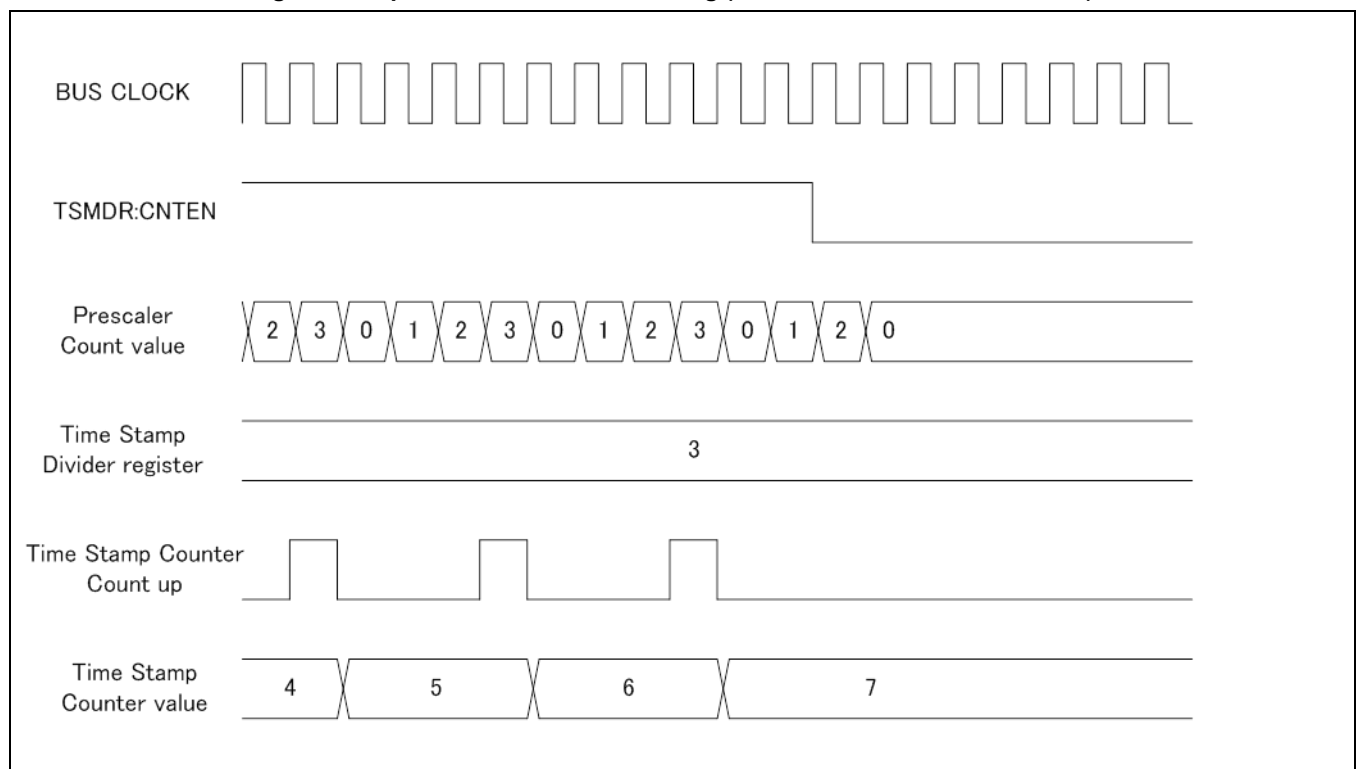

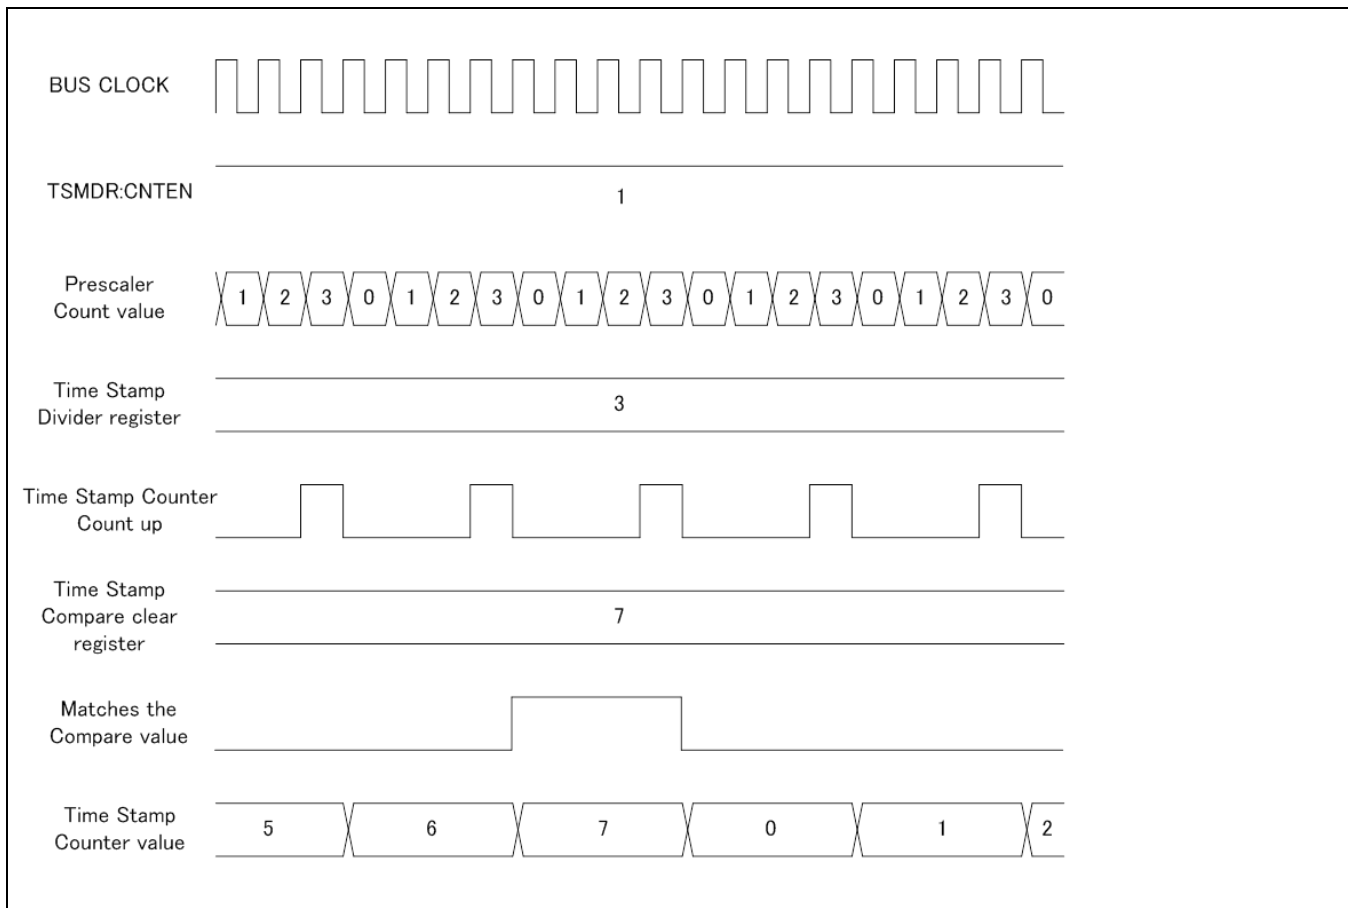

Figure 3-1 Operation to Enable Counting (TSDIVR:CDIV15-CDIV0=0x0003)

Figure 3-2 Operation to Disable Counting (TSDIVR:CDIV15-CDIV0=0x0003)

Figure 3-3 Operation to Clear the Time Stamp Counter by matching TSCPCLR (TSDIVR:CDIV15-CDIV0=0x0003, TSCPCLR:CMP15-CMP0=0x0007)

3.1.3. Clear Request

By setting the Counter Clear Request of the Time Stamp Control register (TSCNTR), the counters in the macro (Timestamp Counter, Prescaler) are cleared. Time Stamp Mode register (TSMR), Time Stamp Divider register (TSDIVR), Time Stamp Compare Clear register (TSCPCLR) are not cleared by this request.

When the Counter Clear Request is set with the counter enabled, Time Stamp Counter and Prescaler are cleared, and the counter keeps counting up.

When the Counter Clear Request is set with the counter disabled, Time Stamp Counter and Prescaler are cleared.

Figure 3-4 Setting Counter Clear Request with the Counter Enabled (TSDIVR:CDIV15-CDIV0=0x0003, TSCPCLR:CMP15-CMP0=0x0007)

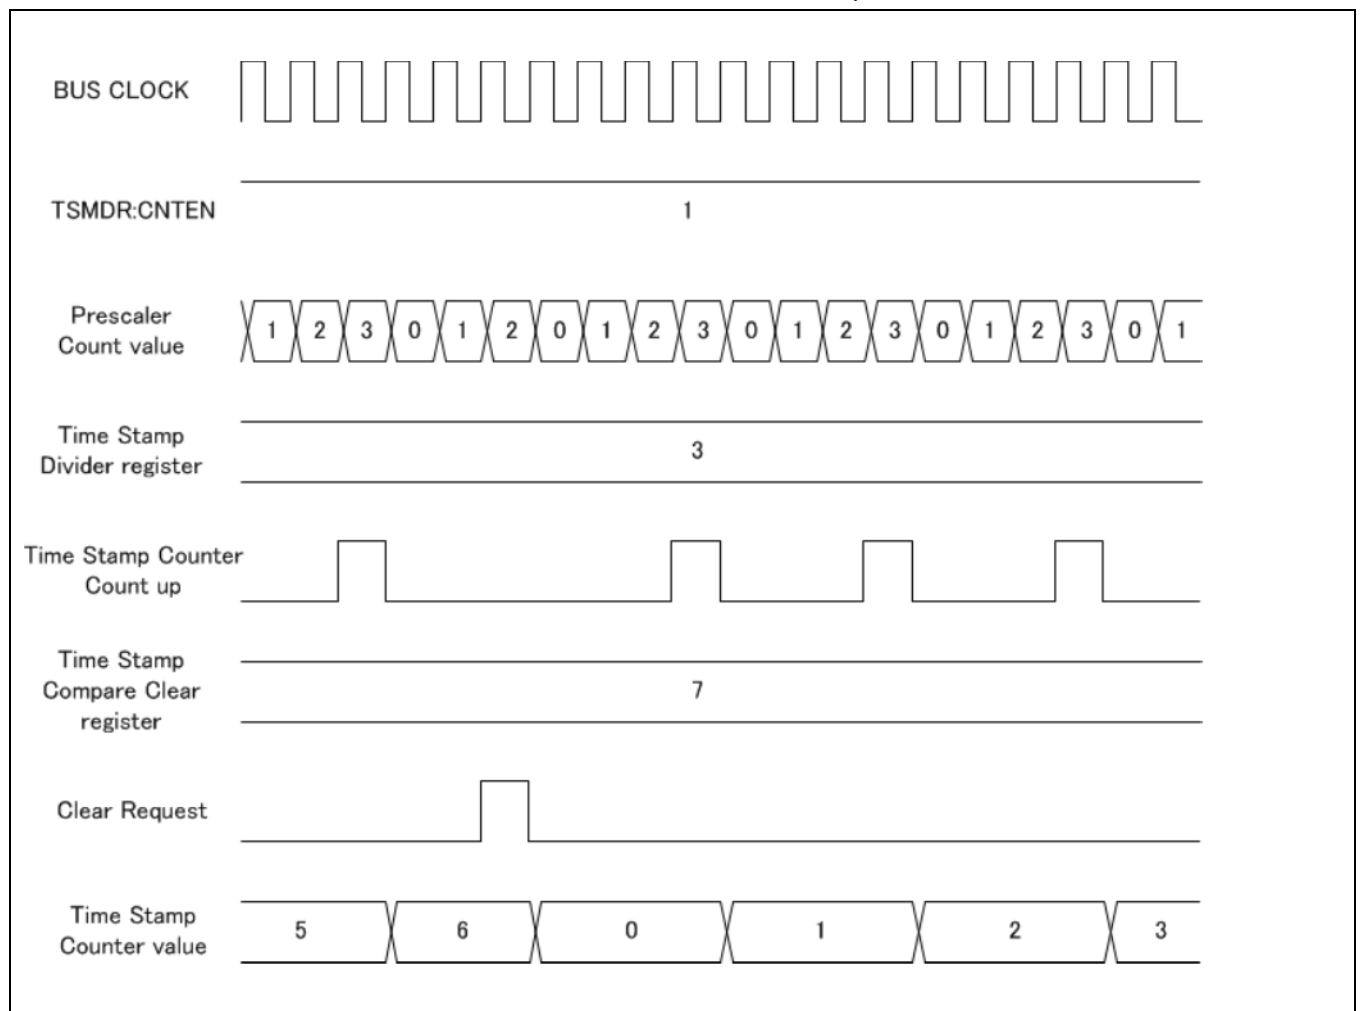

Figure 3 5 Setting Counter Clear Request with the Counter Disabled

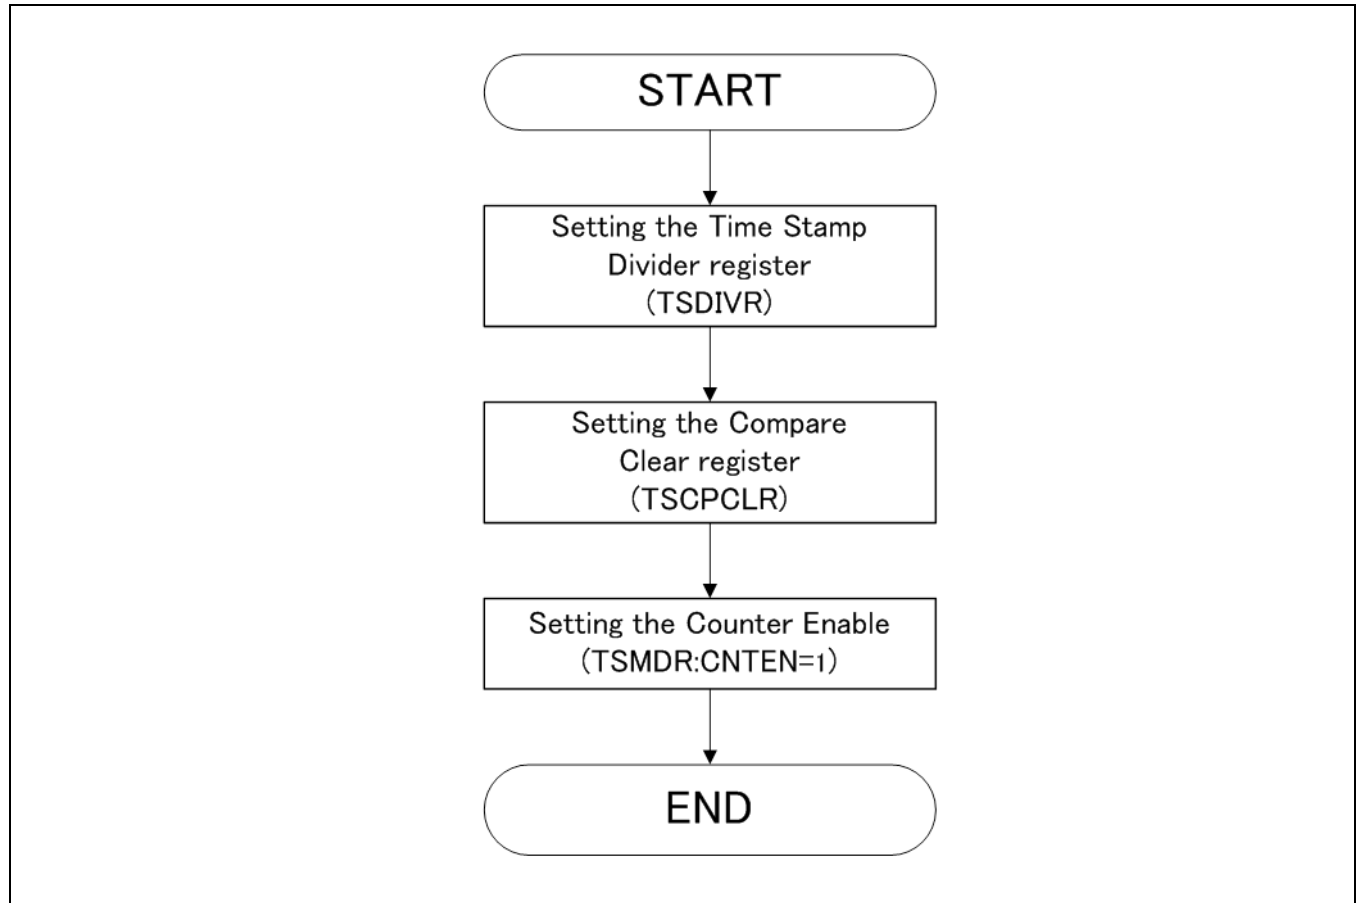

4. Example of the Operation

This section explains the example of operating Time Stamp Counter for CAN FD.

The procedure for setting Time Stamp Counter for CAN FD is shown in Figure 4-1.

Figure 4-1 The Setting Procedure for the Time Stamp Counter for CAN FD.

5. Register

This section explains the configuration and functions of the registers used for the CAN FD Time Stamp Counter.

■ List of CAN FD Time Stamp Counter registers

Table 5-1 List of CAN FD Time Stamp Counter Registers

Abbreviation	Register name	See
MCG_CANFDx_TSCNTR	Time Stamp Control Register of MCU Config Group (channel 0, 1, 2)	5.1
CPG_CANFDx_TSCNTR	Time Stamp Control Register of Common Peripheral #0 Group (channel 0, 1, 2, 3, 4)	5.1
MCG_CANFDx_TSMR	Time Stamp Mode Register of MCU Config Group (channel 0, 1, 2)	5.2
CPG_CANFDx_TSMR	Time Stamp Mode Register of Common Peripheral #0 Group (channel 0, 1, 2, 3, 4)	5.2
MCG_CANFDx_TSDIVR	Time Stamp Divider Register of MCU Config Group (channel 0, 1, 2)	5.3
CPG_CANFDx_TSDIVR	Time Stamp Divider Register of Common Peripheral #0 Group (channel 0, 1, 2, 3, 4)	5.3
MCG_CANFDx_TSCDTR	Time Stamp Counter Data Register of MCU Config Group (channel 0, 1, 2)	5.4
CPG_CANFDx_TSCDTR	Time Stamp Counter Data Register of Common Peripheral #0 Group (channel 0, 1, 2, 3, 4)	5.4
MCG_CANFDx_TSCPCLR	Time Stamp Compare Clear Register of MCU Config Group (channel 0, 1, 2)	5.5
CPG_CANFDx_TSCPCLR	Time Stamp Compare Clear Register of Common Peripheral #0 Group (channel 0, 1, 2, 3, 4)	5.5

Table 5-2 Register Map of CAN FD Time Stamp Counter

MCU Config Group (Channel No.: 0, 1, and 2)

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x300	MCG_CANFDx_TSMR 00000000_00000000		MCG_CANFDx_TSCNTR 00000000_00000000	
0x304	MCG_CANFDx_TSDIVR 00000000_00000000_00000000_00000000			
0x308	MCG_CANFDx_TSCPCLR 00000000_00000000		MCG_CANFDx_TSCDTR 00000000_00000000	
0x30C-0x3FC	Reserved			

Note:

- *x is the channel number. (0 to 2)*

Common Peripheral #0 Group (Channel No.: 0, 1, 2, 3, and 4)

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x300	CPG_CANFDx_TSMDR 00000000_00000000		CPG_CANFDx_TSCNTR 00000000_00000000	
0x304	CPG_CANFDx_TSDIVR 00000000_00000000_00000000_00000000			
0x308	CPG_CANFDx_TSCPCLR 00000000_00000000		CPG_CANFDx_TSCDTR 00000000_00000000	
0x30C-0x3FC	Reserved			

Note:

- *x is the channel number. (0 to 4)*

5.1. Time Stamp Control Register (MCG_CANFDx_TSCNTR, CPG_CANFDx_TSCNTR)

(MCG_CANFD0_TSCNTR, MCG_CANFD1_TSCNTR, MCG_CANFD2_TSCNTR, CPG_CANFD0_TSCNTR, CPG_CANFD1_TSCNTR, CPG_CANFD2_TSCNTR, CPG_CANFD3_TSCNTR, CPG_CANFD4_TSCNTR)

The Time Stamp Control Register (TSCNTR) is used to clear the counter in the macro.

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0, W0							
Protection attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	Reserved							CCLR
R/W Attribute	R0, W0							R0, W
Protection attribute	-							-
Initial value	0000000							0

[bit15:1] Reserved: Reserved bits

Always write "0" to these bits. The read value is "0".

[bit0] CCLR : Counter clear bit

The read value is "0".

bit	Description
	Write
0	No effect
1	Clear the counter(time stamp counter, prescaler).

Note:

- Time Stamp Counter Mode Register, Time Stamp Divider Register and Time Stamp Compare Clear Register are not cleared.

5.2. Time Stamp Mode Register(MCG_CANFDx_TSMDR, CPG_CANFDx_TSMDR)

(MCG_CANFD0_TSMDR, MCG_CANFD1_TSMDR, MCG_CANFD2_TSMDR, CPG_CANFD0_TSMDR, CPG_CANFD1_TSMDR, CPG_CANFD2_TSMDR, CPG_CANFD3_TSMDR, CPG_CANFD4_TSMDR)

The Time Stamp Mode Register (TSMDR) is used to enable/disable the counter.

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection attribute	-							
Initial value	00000000							

bit	7	6	5	4	3	2	1	0
Field	Reserved							CNTEN
R/W Attribute	R0,W0							R/W
Protection attribute	-							-
Initial value	0000000							0

[bit15:1] Reserved: Reserved bits

Always write "0" to these bits. The read value is "0".

[bit0] CNTEN : Counter enable bit

CNTEN	Description
0	Count disabled Stop counting up and keep the counter value.
1	Count enabled Start counting up from the current value.

5.3. Time Stamp Divider Register(MCG_CANFDx_TSDIVR, CPG_CANFDx_TSDIVR)

(MCG_CANFD0_TSDIVR, MCG_CANFD1_TSDIVR, MCG_CANFD2_TSDIVR, CPG_CANFD0_TSDIVR, CPG_CANFD1_TSDIVR, CPG_CANFD2_TSDIVR, CPG_CANFD3_TSDIVR, CPG_CANFD4_TSDIVR)

The Time Stamp Divider Register (TSDIVR) is used to set the clock division ratio for the counter.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection attribute	-							
Initial value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection attribute	-							
Initial value	00000000							

bit	15	14	13	12	11	10	9	8
Field	CDIV15	CDIV14	CDIV13	CDIV12	CDIV11	CDIV10	CDIV9	CDIV8
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	CDIV7	CDIV6	CDIV5	CDIV4	CDIV3	CDIV2	CDIV1	CDIV0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31:16] Reserved: Reserved bits

Always write "0" to these bits. The read value is "0".

[bit15:0] CDIV15 to CDIV0 : Counter clock division ratio setting bit.

These bits set the counter clock division ratio.

The division ratio corresponds to the value added 1 to CDIV15-CDIV0.

Notes:

- If counter is enabled (TSMDR:CNTEN=1), operating this bit is prohibited
- This register must be accessed in 16-bit mode.

5.4. Time Stamp Counter Data Register(MCG_CANFDx_TSCDTR, CPG_CANFDx_TSCDTR)

(MCG_CANFD0_TSCDTR, MCG_CANFD1_TSCDTR, MCG_CANFD2_TSCDTR, CPG_CANFD0_TSCDTR, CPG_CANFD1_TSCDTR, CPG_CANFD2_TSCDTR, CPG_CANFD3_TSCDTR, CPG_CANFD4_TSCDTR)

The Time Stamp Counter Data Register (TSCDTR) indicates the count value of the Time Stamp Counter.

bit	15	14	13	12	11	10	9	8
Field	CNT15	CNT14	CNT13	CNT12	CNT11	CNT10	CNT9	CNT8
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	CNT7	CNT6	CNT5	CNT4	CNT3	CNT2	CNT1	CNT0
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit15:0] CNT15 to CNT0 : Counter value bits

The counter value of the Time Stamp Counter is indicated.

These bits are cleared to "0" by setting Counter Clear bit to "1" (TSCNTR:CCLR=1).

Note:

- This register must be accessed in 16-bit mode.

5.5. Time Stamp Compare Clear Register(MCG_CANFDx_TSCPCLR, CPG_CANFDx_TSCPCLR)

(MCG_CANFD0_TSCPCLR, MCG_CANFD1_TSCPCLR, MCG_CANFD2_TSCPCLR, CPG_CANFD0_TSCPCLR, CPG_CANFD1_TSCPCLR, CPG_CANFD2_TSCPCLR, CPG_CANFD3_TSCPCLR, CPG_CANFD4_TSCPCLR)

The Time Stamp Compare Clear Register (TSCPCLR) is used to set the comparison value for clearing the counter.

bit	15	14	13	12	11	10	9	8
Field	CMP15	CMP14	CMP13	CMP12	CMP11	CMP10	CMP9	CMP8
R/W attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	CMP7	CMP6	CMP5	CMP4	CMP3	CMP2	CMP1	CMP0
R/W attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit15:0] CMP15 to CMP0 : Compare clear setting bits

These bits are compared with the counter value, and the counter is cleared when the counter value is greater than or equal to these bits.

If these bits are "0x0000", the Time Stamp Counter is always "0".

Notes:

- If counter is enabled (TSMDR:CNTEN=1), operating this bit is prohibited.
- This register must be accessed in 16-bit mode.

CHAPTER 33: CAN FD Message RAM ECC Function

This chapter explains the functions and operations of the CAN FD Message RAM ECC Function.

1. Overview
2. Configuration
3. Interrupts
4. Explanation of Operation
5. Setup Procedure Examples
6. Registers
7. Precautions

This chapter explains only the block of the CAN FD Message RAM ECC Function.

For the functions and operations of the CAN FD Controller, see CAN FD Controller External Specification.

CANFDMRE-TXXPT03P01R02L03-E1-XX

1. Overview

In the CAN FD Message RAM, CAN message objects are stored. The ECC Function of the CAN FD Message RAM enables detection and correction of data errors in the Message RAM.

The CAN FD Message RAM ECC Function has the following features.

- 2-bit error detection and 1-bit error correction for 32-bit data in the Message RAM
- Stopping of the CAN FD Controller upon error detection
- Not support for the error generation function of the Message RAM

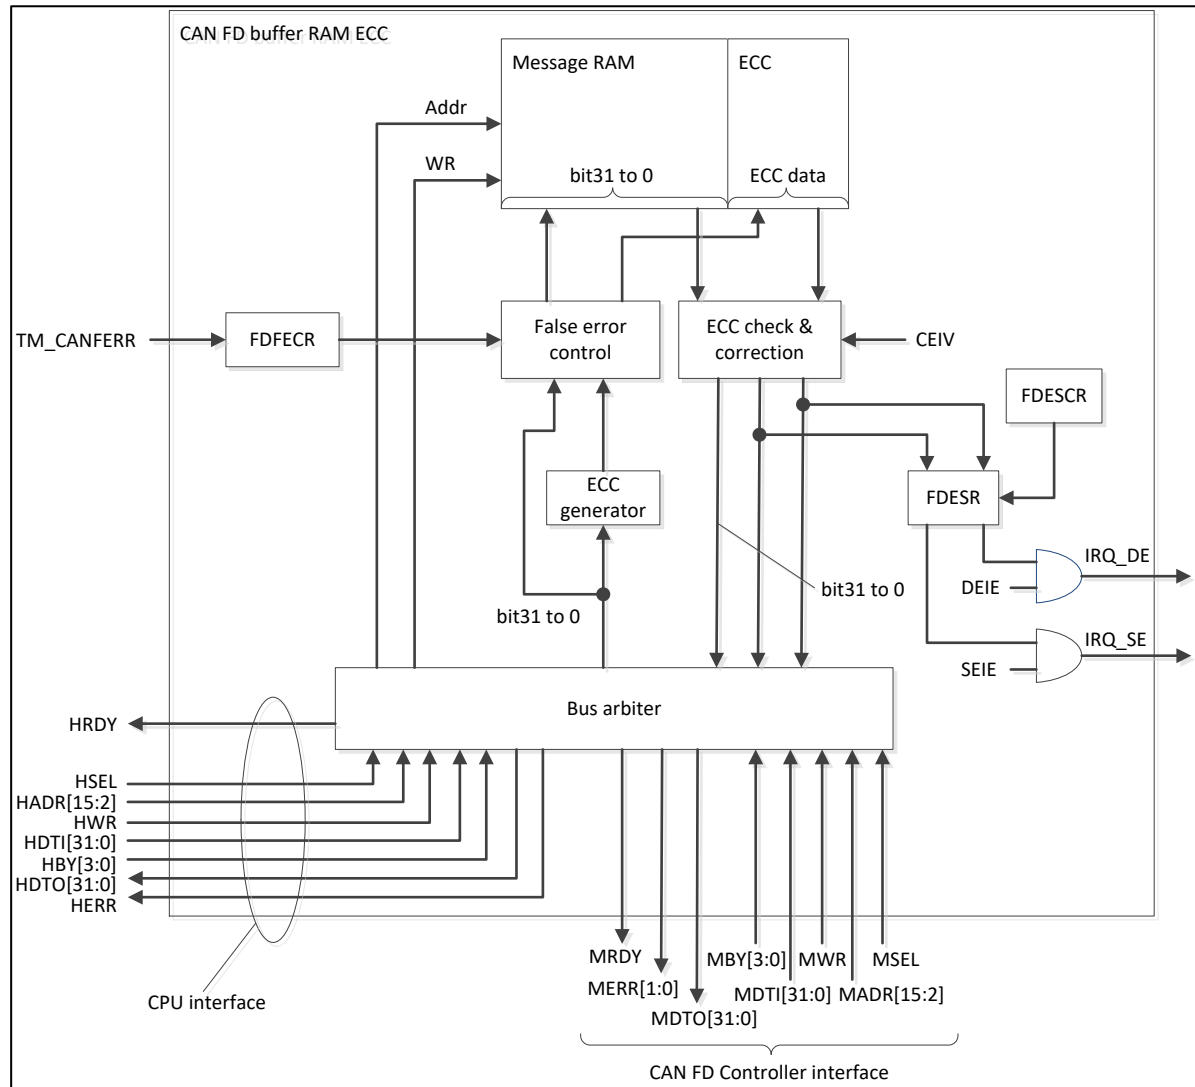

Note:

- *ECC error generation function of the message RAM is not supported for TRAVEO™ T1G Platform. Therefore CAN FD ECC False Error Control Register (FDFECCR) is not writeable.*

2. Configuration

Figure 2-1 is a block diagram of the CAN FD Message RAM ECC Function.

Figure 2-1 Block Diagram of the CAN FD Message RAM ECC Function

- **Message RAM**
Consists of 32-bit RAM, in which Tx/Rx messages is stored.
- **ECC**
Consists of 7 bits, in which the ECC data for bits 31 to 0 of the Message RAM is stored.
- **ECC generator**
Generates ECC data from data to be written in the Message RAM.
- **False error control**
Controls whether to generate ECC data that causes an ECC error or to output normal ECC data.
- **ECC check & correction**
Combines Message RAM data and ECC data together to check for a single- or double-bit error. For a single-bit error, this circuit corrects the data.
- **Bus arbiter**
Arbitrates access by the CPU and CAN FD Controller, and reads data from or writes data to the Message RAM.
- **FDESCR**
CAN FD ECC error status clear register
- **FDESR**
CAN FD ECC error status register
- **FD FECR**
CAN FD ECC false error control register

3. Interrupts

This section explains the interrupts of the CAN FD Message RAM ECC Function.

Interrupts of the CAN FD Message RAM ECC Function

The Message RAM ECC Function supports the following interrupts.

Table 3-1 Interrupt Controller Bits and Interrupt Factors of the CAN FD Message RAM ECC Function

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Double-bit error interrupt	DEI	FDESR	2-bit data error	FDECR.DEIE	Write "1" to the double-bit error clear bit (FDESCR.DEIC).
Single-bit error interrupt	SEI	FDESR	1-bit data error	FDECR.SEIE	Write "1" to the single-bit error clear bit (FDESCR.SEIC).

4. Explanation of Operation

This section explains the operations and functions of the CAN FD Message RAM ECC.

This section explains the following functions.

- Message RAM ECC generation
- Message RAM ECC check
- ECC false error control function of the Message RAM

4.1. Message RAM ECC Generation

This section explains ECC generation of the Message RAM.

ECC Generation

The CAN FD Message RAM is made up of 32 bits and an additional 7 bits for ECC. When data is written to the CAN FD Message RAM, ECC data is generated from the write data based on the syndrome, and is written together with the write data.

4.2. Message RAM ECC Check

This section explains the ECC check of the Message RAM.

ECC Check

When data is read from the Message RAM, the ECC data is also read. In the ECC check, calculation is performed based on the syndrome to determine whether the data in the Message RAM is correct. If it is determined from the check result that the data in the Message RAM, the following operation is performed.

- In the case where only 1 bit in the data is incorrect (single-bit error):
The single-bit error occurrence bit (FDESR.SEI) is set and the RAM address is set in the CAN FD ECC single-bit error address register (FDSEAR). The incorrect 1-bit data is corrected and then is read as normal data.
- In the case where 2 bits in the data are incorrect (double-bit error):
The double-bit error occurrence bit (FDESR.DEI) is set and the RAM address is set in the CAN FD ECC double-bit error address register (FDDEAR). The incorrect data is not corrected and then is read as it is.

If the interrupt enable bit corresponding to each error bit (FDESR.SEI or FDESR.DEI) has been set to "1", an interrupt occurs when the error bit is set to "1".

Stopping of the CAN FD Controller upon Error Detection

If the CAN FD Controller detects a double-bit error when it reads the Message RAM, it sets the INIT bit in its CC control register (CCCR). Then, the CAN FD Controller stops.

Error Response to CPU upon Error Detection

When error response is enabled (FDECR.CEREN = "1"), if the CPU reads the Message RAM and a double-bit error is detected at this time, an error response is returned to the CPU.

4.3. ECC False Error Control Function of the Message RAM

This section explains the ECC false error control function. This function is used for testing program operation for when an ECC error occurs.

ECC False Error Control Function

The ECC false error control function allows you to write data that causes an ECC error in the Message RAM. By reading such data from the Message RAM, you can generate a single- or double-bit error. If the error interrupt has been enabled, the interrupt occurs. If ECC error processing has been programmed in the interrupt processing, you can verify whether the ECC error processing operates correctly.

Setting Method

Setting "H" to the TM_CANFERR signal allows you to set the CAN FD ECC false error control register, enabling the use of the ECC false error control function. The following is the setting method.

1. Set "H" to the TM_CANFERR.
This allows you to set registers related to CAN FD ECC false error control.
2. Configure the CAN FD ECC false error control register (FDFECCR).
Set "1" to FERR, and set each bit of EY2 to EY0 and EI15 to EI0 for the bits which you want to make an error.
3. Write data to the Message RAM.
The bits are inverted according to the CAN FD ECC false error control register (FDFECCR), and then they are written to the Message RAM.

After this setting is made, reading the Message RAM generates an ECC error.

Notes:

- Even if the TM_CANFERR signal is set to "L" after error data is written to the Message RAM by using the ECC false error control function, the error data remains in the Message RAM. Therefore, reading this error data generates an ECC error.
- When the TM_CANFERR signal is "L", the CAN FD ECC false error control register (FDFECCR) cannot be written. When the TM_CANFERR signal becomes "L", the bits that have been set to "1" become "0".

5. Setup Procedure Examples

This section provides examples of setup procedures for the CAN FD Message RAM ECC Function.

Setup Procedures for the CAN FD Message RAM ECC Function

This section explains a setting procedure example for the CAN FD Message RAM ECC Function. For details on the setting of the CAN FD Controller, see the chapter on the CAN FD Controller.

- 1) Set "1" in the INIT bit and CCE bit in the CC control register (CCCR) of the CAN FD Controller.

This enables write operation to the control bit of registers.

- 2) Set the CAN FD Controller registers.

Make the settings of the CAN FD Controller according to the use conditions.

- 3) Initialize the Message RAM.

Initializing the RAM, which is in an undefined state, prevents an ECC error from being detected by mistake.

- 4) Set "1" to the SEIC bit and DEIC bit in the CAN FD ECC error status clear register (FDESCR).

This clears the SEI bit and DEI bit in the CAN FD ECC error status register (FDESR).

- 5) Set each bit in the CAN FD ECC error control register.

Make the settings of the CAN FD ECC Function according to the use conditions.

Performing the above setting procedure enables the use of the CAN FD Message RAM ECC Function. Since the INIT bit in the CC control register (CCCR) is "1", the CAN FD Controller is in the operation stop state. To enable operation of the CAN FD Controller, set "0" in the INIT bit in the CC control register (CCCR) after performing the above procedure.

6. Registers

This section explains the registers of the CAN FD Message RAM ECC Function.

Table 6-1 List of the Registers of the CAN FD Message RAM ECC Function

Abbreviated Register Name	Register Name	Reference
MCG_CANFDx_FDECR	CAN FD ECC error control register of MCU Config Group (channel 0,1,2)	6.1
CPG_CANFDx_FDECR	CAN FD ECC error control register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.1
MCG_CANFDx_FDESR	CAN FD ECC error status register of MCU Config Group (channel 0,1,2)	6.2
CPG_CANFDx_FDESR	CAN FD ECC error status register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.2
MCG_CANFDx_FDESCR	CAN FD ECC error status clear register of MCU Config Group (channel 0,1,2)	6.3
CPG_CANFDx_FDESCR	CAN FD ECC error status clear register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.3
MCG_CANFDx_FDDEAR	CAN FD ECC double-bit error address register of MCU Config Group (channel 0,1,2)	6.4
CPG_CANFDx_FDDEAR	CAN FD ECC double-bit error address register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.4
MCG_CANFDx_FDSEAR	CAN FD ECC single-bit error address register of MCU Config Group (channel 0,1,2)	6.5
CPG_CANFDx_FDSEAR	CAN FD ECC single-bit error address register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.5
MCG_CANFDx_FDFECR	CAN FD ECC false error control register of MCU Config Group (channel 0,1,2)	6.6
CPG_CANFDx_FDFECR	CAN FD ECC false error control register of Common Peripheral #0 Group (channel 0,1,2,3,4)	6.6

Register Map

Table 6-2 Register Map of CAN FD MESSAGE RAM ECC FUNCTION

MCU Config Group (Channel No.: 0, 1, and 2)

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x200	MCG_CANFDx_FDSEAR 00000000_00000000		MCG_CANFDx_FDESR 00000000	MCG_CANFDx_FDECR 00000000
0x204	MCG_CANFDx_FDDEAR 00000000_00000000		MCG_CANFDx_FDESCR 00000000	Reserved
0x208	MCG_CANFDx_FDFECR 00000000_00000000_00000000_00000000			
0x20A	Reserved	Reserved	Reserved	
0x20C-0x2FC	Reserved			

Notes:

- *x is the channel number. (0 to 2)*
- *It depends on the product spec whether to use MCG_CANFDx_*** register group.*
- *Please refer to Hardware Manual or Data Sheet for more details.*

Common Peripheral #0 Group (Channel No.: 0, 1, 2, 3, and 4)

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x200	CPG_CANFDx_FDSEAR 00000000_00000000		CPG_CANFDx_FDESR 00000000	CPG_CANFDx_FDECR 00000000
0x204	CPG_CANFDx_FDDEAR 00000000_00000000		CPG_CANFDx_FDESCR 00000000	Reserved
0x208	CPG_CANFDx_FDFECR 00000000_00000000_00000000_00000000			
0x20A	Reserved	Reserved	Reserved	
0x20C-0x2FC	Reserved			

Notes:

- *x is the channel number. (0 to 4)*
- *It depends on the product spec whether to use CPG_CANFDx_*** register group.*
- *Please refer to Hardware Manual or Data Sheet for more details.*

6.1. CAN FD ECC Error Control Register (MCG_CANFDx_FDECR, CPG_CANFDx_FDECR)

(MCG_CANFD0_FDECR, MCG_CANFD1_FDECR, MCG_CANFD2_FDECR, CPG_CANFD0_FDECR, CPG_CANFD1_FDECR, CPG_CANFD2_FDECR, CPG_CANFD3_FDECR, CPG_CANFD4_FDECR)

The CAN FD ECC error control register (FDECR) is used to set whether to enable the interrupt when single-bit error correction or double-bit error detection occurs during the ECC check. It is also used to set ECC error detection stop and response to the CPU.

bit	7	6	5	4	3	2	1	0
Field	Reserved				CEIV	CEREN	DEIE	SEIE
R/W attribute	R0,W0				R/W	R/W	R/W	R/W
Protection attribute	-				-	-	-	-
Initial value	0000				0	0	0	0

[bit7:4] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit3] CEIV: ECC Check Disable Bit

Bit	Description
0	Enable ECC check. [Initial value]
1	Disable ECC check.

- This bit can be changed when the CCE bit in the CC control register (CCCR) of the CAN FD Controller is set "1".
- When CEIV bit is "0", the ECC check is enabled.
- When CEIV bit is "1", ECC check is disabled.

[bit2] CEREN: ECC Error Response Enable Bit

Bit	Description
0	Disable error response for double-bit error detection. [Initial value]
1	Enable error response for double-bit error detection.

- This bit can be changed when the CCE bit in the CC control register (CCCR) of the CAN FD Controller is set "1".
- When CEREN bit is "0", even if a double-bit error is detected in the read operation of the Message RAM by the CPU, an error response is not made for this setting.
- When CEREN bit is "1", if a double-bit error is detected in the read operation of the Message RAM by the CPU, an error response is made for this setting.

Note:

- The CEREN bit does not apply to the single-bit error.

[bit1] DEIE: Double-Bit Error Factor Interrupt Enable Bit

Bit	Description
0	Disable the interrupt caused by the double-bit error (FDESR.DEI). [Initial value]
1	Enable the interrupt caused by the double-bit error (FDESR.DEI).

- When DEIE bit is "0", even if a double-bit error is detected (FDESR.DEI = "1"), the IRQ_DE signal remains "L".
- When DEIE bit is "1", if a double-bit error is detected (FDESR.DEI = "1"), the IRQ_DE signal becomes "H" to request an interrupt.

[bit0] SEIE: Single-Bit Error Factor Interrupt Enable Bit

Bit	Description
0	Disable the interrupt caused by the single-bit error (FDESR.SEI). [Initial value]
1	Enable the interrupt caused by the single-bit error (FDESR.SEI).

- When SEIE bit is "0", even if a single-bit error is detected (FDESR.SEI = "1"), the IRQ_SE signal remains "L".
- When SEIE bit is "1", if a single-bit error is detected (FDESR.SEI = "1"), the IRQ_SE signal becomes "H" to request an interrupt.

6.2. CAN FD ECC Error Status Register (MCG_CANFDx_FDESR, CPG_CANFDx_FDESR)

(MCG_CANFD0_FDESR, MCG_CANFD1_FDESR, MCG_CANFD2_FDESR, CPG_CANFD0_FDESR, CPG_CANFD1_FDESR, CPG_CANFD2_FDESR, CPG_CANFD3_FDESR, CPG_CANFD4_FDESR)

The CAN FD ECC error status register (FDESR) displays whether a single-bit error has been corrected in the ECC check and whether a double-bit error has been detected. When any bit in this register becomes "1", it remains "1" unless it is cleared by using CAN FD ECC error status clear register (FDESCR).

bit	7	6	5	4	3	2	1	0
Field	Reserved						DEI	SEI
R/W attribute	R0,W0						R,WX	R,WX
Protection attribute	-						-	-
Initial value	000000						0	0

[bit7:2] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit1] DEI: Double-Bit Error Occurrence Bit

Bit	Description
0	Indicate that a double-bit error has not been detected. [Initial value]
1	Indicate that a double-bit error has been detected.

- Any value written in the DEI bit is ignored.
- When the DEI bit is "1", to clear this bit to "0", write "1" to the DEIC bit in the CAN FD ECC error status clear register (FDESCR).

Notes:

- When the DEI bit is "1", the CAN FD ECC double-bit error address register (FDDEAR) behaves as follows: If a double-bit error is detected in the Message RAM read operation at an address other than the one retained in this register, the register is not updated, and retains the previous address value.
- Even if the DEI bit is "1", a single-bit error can be detected.
- If a double-bit error is detected when the CAN FD Controller or CPU reads data from the Message RAM, this bit is set "1".

[bit0] SEI: Single-Bit Error Occurrence Bit

Bit	Description
0	Indicate that a single-bit error has not been detected. [Initial value]
1	Indicate that a single-bit error has been detected.

- Any value written in the SEI bit is ignored.

- When the SEI bit is "1", to clear this bit to "0", write "1" to the SEIC bit in the CAN FD ECC error status clear register (FDESCR).

Notes:

- *When the SEI bit is "1", the CAN FD ECC single-bit error address register (FDSEAR) behaves as follows: if a single-bit error is detected in the Message RAM read operation at an address other than the one retained in this register, the register is not updated, and retains the previous address value.*
- *Even if the SEI bit is "1", a double-bit error can be detected.*
- *If a single-bit error is detected when the CAN FD Controller or CPU reads data from the Message RAM, this bit is set "1".*

6.3. CAN FD ECC Error Status Clear Register (MCG_CANFDx_FDESCR, CPG_CANFDx_FDESCR)

(MCG_CANFD0_FDESCR, MCG_CANFD1_FDESCR, MCG_CANFD2_FDESCR, CPG_CANFD0_FDESCR, CPG_CANFD1_FDESCR, CPG_CANFD2_FDESCR, CPG_CANFD3_FDESCR, CPG_CANFD4_FDESCR)

The CAN FD ECC error status clear register (FDESCR) is used to clear bits in the CAN FD ECC error status register.

bit	7	6	5	4	3	2	1	0
Field	Reserved						DEIC	SEIC
R/W attribute	R0,W0						R0,W	R0,W
Protection attribute	-						-	-
Initial value	000000						0	0

[bit7:2] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit1] DEIC: Double-Bit Error Clear Bit

Bit	Description
	During Write Operation
0	No effect
1	Change the double-bit error occurrence bit (FDESR.DEI) to "0".

■ "0" is always read.

[bit0] SEIC: Single-Bit Error Clear Bit

Bit	Description
	During Write Operation
0	No effect
1	Change the single-bit error occurrence bit (FDESR.SEI) to "0".

■ "0" is always read.

6.4. CAN FD ECC Double-Bit Error Address Register (MCG_CANFDx_FDDEAR, CPG_CANFDx_FDDEAR)

(MCG_CANFD0_FDDEAR, MCG_CANFD1_FDDEAR, MCG_CANFD2_FDDEAR,
CPG_CANFD0_FDDEAR, CPG_CANFD1_FDDEAR, CPG_CANFD2_FDDEAR,
CPG_CANFD3_FDDEAR, CPG_CANFD4_FDDEAR)

The CAN FD ECC double-bit error address register (FDDEAR) indicates the address which a double-bit error has occurred at the Message RAM during the ECC check. This register is valid when the DEI bit in the CAN FD ECC error status register (FDESR) is "1". While the DEI bit in the CAN FD ECC error status register (FDESR) is "1", the value of this register is retained.

bit	15	14	13	12	11	10	9	8
Field	DRA15	DRA14	DRA13	DRA12	DRA11	DRA10	DRA9	DRA8
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	DRA7	DRA6	DRA5	DRA4	DRA3	DRA2	DRA1*	DRA0*
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R0,WX	R0,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

*: DRA1 and DRA0 are fixed to "0".

[bit15:0] DRA15 to DRA0: Double-Bit Error Message RAM Address Bits

DRA15 to DRA0	Description
0x0000	Indicates that a double-bit error has occurred at Message RAM address 0.
0x0004	Indicates that a double-bit error has occurred at Message RAM address 4.
0x0008	Indicates that a double-bit error has occurred at Message RAM address 8.
...

- Writing access to DRA15 to DRA0 bits is ignored.
- DRA15 to DRA0 bits are valid when the DEI bit in the CAN FD ECC error status register (FDESR) is "1".
- When the DEI bit in the CAN FD ECC error status register (FDESR) changes from "0" to "1", the Message RAM address is set to the CAN FD ECC double-bit error address register (FDDEAR). Then, this value is retained as long as the DEI bit in the CAN FD ECC error status register (FDESR) is "1". Therefore, even if a double-bit error is detected more than once, this register retains the address value for the first detected error until the DEI bit in the CAN FD ECC error status register (FDESR) is cleared to "0".

6.5. CAN FD ECC Single-Bit Error Address Register (MCG_CANFDx_FDSEAR, CPG_CANFDx_FDSEAR)

(MCG_CANFD0_FDSEAR, MCG_CANFD1_FDSEAR, MCG_CANFD2_FDSEAR,
CPG_CANFD0_FDSEAR, CPG_CANFD1_FDSEAR, CPG_CANFD2_FDSEAR,
CPG_CANFD3_FDSEAR, CPG_CANFD4_FDSEAR)

The CAN FD ECC single-bit error address register (FDSEAR) indicates the address which a single-bit error has occurred at the Message RAM during the ECC check. This register is valid when the SEI bit in the CAN FD ECC error status register (FDESr) is "1". While the SEI bit in the CAN FD ECC error status register (FDESr) is "1", the value of this register is retained.

bit	15	14	13	12	11	10	9	8
Field	SRA15	SRA14	SRA13	SRA12	SRA11	SRA10	SRA9	SRA8
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	SRA7	SRA6	SRA5	SRA4	SRA3	SRA2	SRA1*	SRA0*
R/W attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R0,WX	R0,WX
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

*: SRA1 and SRA0 are fixed to "0".

[bit15:0] SRA15 to SRA0: Single-Bit Error Message RAM Address Bits

SRA15 to SRA0	Description
0x0000	Indicates that a single-bit error has occurred at Message RAM address 0.
0x0004	Indicates that a single-bit error has occurred at Message RAM address 4.
0x0008	Indicates that a single-bit error has occurred at Message RAM address 8.
...

- Writing access to SRA15 to SRA0 bits is ignored.
- SRA15 to SRA0 bits are valid when the SEI bit in the CAN FD ECC error status register (FDESr) is "1".
- When the SEI bit in the CAN FD ECC error status register (FDESr) changes from "0" to "1", the Message RAM address is set to the CAN FD ECC single-bit error address register (FDSEAR). Then, this value is retained as long as the SEI bit in the CAN FD ECC error status register (FDESr) is "1". Therefore, even if a single-bit error is detected more than once, this register retains the address value for the first detected error until the SEI bit in the CAN FD ECC error status register (FDESr) is cleared to "0".

6.6. CAN FD ECC False Error Control Register (MCG_CANFDx_FDFECR, CPG_CANFDx_FDFECR)

(MCG_CANFD0_FDFECR, MCG_CANFD1_FDFECR, MCG_CANFD2_FDFECR, CPG_CANFD0_FDFECR, CPG_CANFD1_FDFECR, CPG_CANFD2_FDFECR, CPG_CANFD3_FDFECR, CPG_CANFD4_FDFECR)

The CAN FD ECC false error control register (FDFECR) is used to specify the bytes and bits in which an error is to be generated. This register can be set when the TM_CANFERR signal is "H".

bit	31	30	29	28	27	26	25	24
Field	FERR	Reserved						
R/W attribute	R/W	R0,W0						
Protection attribute	-	-						
Initial value	0	0000000						

bit	23	22	21	20	19	18	17	16
Field	Reserved					EY2	EY1	EY0
R/W attribute	R0,W0					R/W	R/W	R/W
Protection attribute	-					-	-	-
Initial value	00000					0	0	0

bit	15	14	13	12	11	10	9	8
Field	EI15	EI14	EI13	EI12	EI11	EI10	EI9	EI8
R/W attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	EI7	EI6	EI5	EI4	EI3	EI2	EI1	EI0
R/W attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-	-	-	-	-	-	-	-
Initial value	0	0	0	0	0	0	0	0

[bit31] FERR: Error insertion Enable Bit

Bit	Description
0	Disable writing of error data. [Initial value]
1	Enable writing of error data.

- When the TM_CANFERR signal is "L", the FERR bit is fixed to "0" and writing to this bit is ignored.
- When the TM_CANFERR signal is "H", the FERR bit is writable.

- When the FERR bit is "1", error data is written to the Message RAM according to EY2 to EY0 bits and EI15 to EI0 bits.

[bit30:19] Reserved: Reserved Bits

When writing, always write "0". When reading, "0" is always read.

[bit18:16] EY2 to EY0: Error Byte Specification Bits

bit	Description
EY0	Sets bit15 to 0 in the Message RAM as error targets.
EY1	Sets bit31 to 16 in the Message RAM as error targets.
EY2	Sets bit38 to 32 in the Message RAM (bits for ECC) error targets.

- When "1" is set, the specified 2-byte range of the Message RAM is the error target.
Example 1) In the case of EY0 = "1", and EY1 and EY2 = "0", bit15 to 0 in the Message RAM are the error targets.

Example 2) In the case of EY0 = EY2 = "1", and EY1 = "0", bit15 to 0 and bit38 to 32 in the Message RAM are the error targets.
- When EY2 to EY0 bits are all "0", error data is not written.
- EY2 sets the 7-bit range in the Message RAM as the error target. Use EI6 to EI0 to specify bits.
- When the TM_CANFERR signal is "L", the EY2 to EY0 bits are all fixed to "0" and writing to these bits is ignored.
- When the TM_CANFERR signal is "H", the EY2 to EY0 bits are writable.

[bit15:0] EI15 to EI0: Error Bit Specification Bits

bit	Description
EI0	In the 2 bytes specified by EY2 to EY0, bit0 is an error target.
EI1	In the 2 bytes specified by EY2 to EY0, bit1 is an error target.
EI2	In the 2 bytes specified by EY2 to EY0, bit2 is an error target.
EI3	In the 2 bytes specified by EY2 to EY0, bit3 is an error target.
EI4	In the 2 bytes specified by EY2 to EY0, bit4 is an error target.
EI5	In the 2 bytes specified by EY2 to EY0, bit5 is an error target.
EI6	In the 2 bytes specified by EY2 to EY0, bit6 is an error target.
EI7	In the 2 bytes specified by EY1 to EY0, bit7 is an error target.
EI8	In the 2 bytes specified by EY1 to EY0, bit8 is an error target.
EI9	In the 2 bytes specified by EY1 to EY0, bit9 is an error target.
EI10	In the 2 bytes specified by EY1 to EY0, bit10 is an error target.
EI11	In the 2 bytes specified by EY1 to EY0, bit11 is an error target.
EI12	In the 2 bytes specified by EY1 to EY0, bit12 is an error target.
EI13	In the 2 bytes specified by EY1 to EY0, bit13 is an error target.
EI14	In the 2 bytes specified by EY1 to EY0, bit14 is an error target.
EI15	In the 2 bytes specified by EY1 to EY0, bit15 is an error target.

- When data is written to the Message RAM, if "1" has been set, the specified bits in the specified 2 bytes are inverted before they are written.

Example 1) In the case of EY1 = "1", EY0 = EY2 = "0", EI3 = "1", and EI0 to EI2 = EI4 to EI15 = "0", the value of bit19 in the Message RAM is inverted before it is written. The other bits are written as they are.

Example 2) In the case of EY0 = EY1 = "1", EY2 = "0", EI3 = "1", and EI0 to EI2 = EI4 to EI15 = "0", the values of bit3 and bit19 in the Message RAM is inverted before it is written. The other bits are written as they are.

- When EI15 to EI0 bits are all "0", error data is not written.
- EY2 sets the 7-bit range in the Message RAM as the error target. Use EI6 to EI0 to specify bits.
- When the TM_CANFERR signal is "L", the EI15 to EI0 bits are all fixed to "0" and writing to these bits is ignored.
- When the TM_CANFERR signal is "H", the EI15 to EI0 bits are writable.

7. Precautions

This section explains precautions on the use of the CAN FD Message RAM ECC.

Access to the Message RAM

- To access the Message RAM, perform 32-bit access. Using another number of bits as the unit of access may cause an ECC error or the writing of wrong data to the Message RAM because the data in the Message RAM is tested as 32-bit long data.

ECC Check

- The data in the Message RAM is undefined after power-on. Therefore, a double- or single-bit error may occur if the Message RAM is read before data is written to the Message RAM area to be used. After power-on, write data to the Message RAM area to be used before reading the Message RAM.
- The following bits can be changed when the configuration change enable bit in the CC control register of the CAN FD Controller (CCCR.CCE bit) is "1".
 - ECC error response enable bit (CEREN) in the CAN FD ECC error control register (FDECR)
 - ECC check disable bit (CEIV) in the CAN FD ECC error control register (FDECR)
- If an ECC error is detected in read access to the Message RAM from the CAN FD Controller, the following bits are set: the error flags regarding the ECC of the CAN FD Controller (IR.BEU and IR.BEC) and the error flags regarding the ECC of the Message RAM (FDESR.DEI and FDESR.SEI).
- If an ECC error is detected in read access to the Message RAM from the CPU, the error flags regarding the ECC of the Message RAM (FDESR.DEI and FDESR.SEI) are set.

ECC False Error Control Function

- Even if the TM_CANFERR signal is set to "L" after error data is written to the Message RAM by using the ECC false error control function, the error data remains in the Message RAM. Therefore, reading this error data detects an ECC error.
- When the TM_CANFERR signal is "L", the CAN FD ECC false error control register (FDFECCR) cannot be written. When the TM_CANFERR signal becomes "H", the bits that have been set to "1" become "0".
- With the ECC false error control function, error data can be written to the Message RAM by the CAN FD Controller or CPU.

CHAPTER 34: CAN Prescaler

This chapter describes the CAN prescaler.

1. Overview
2. Configuration
3. Explanation of Operation
4. Setting Procedure
5. Registers
6. Restriction

CANP-TXXPT03P01R01L05-E1-XX

1. Overview

This section provides an overview of CAN prescaler.

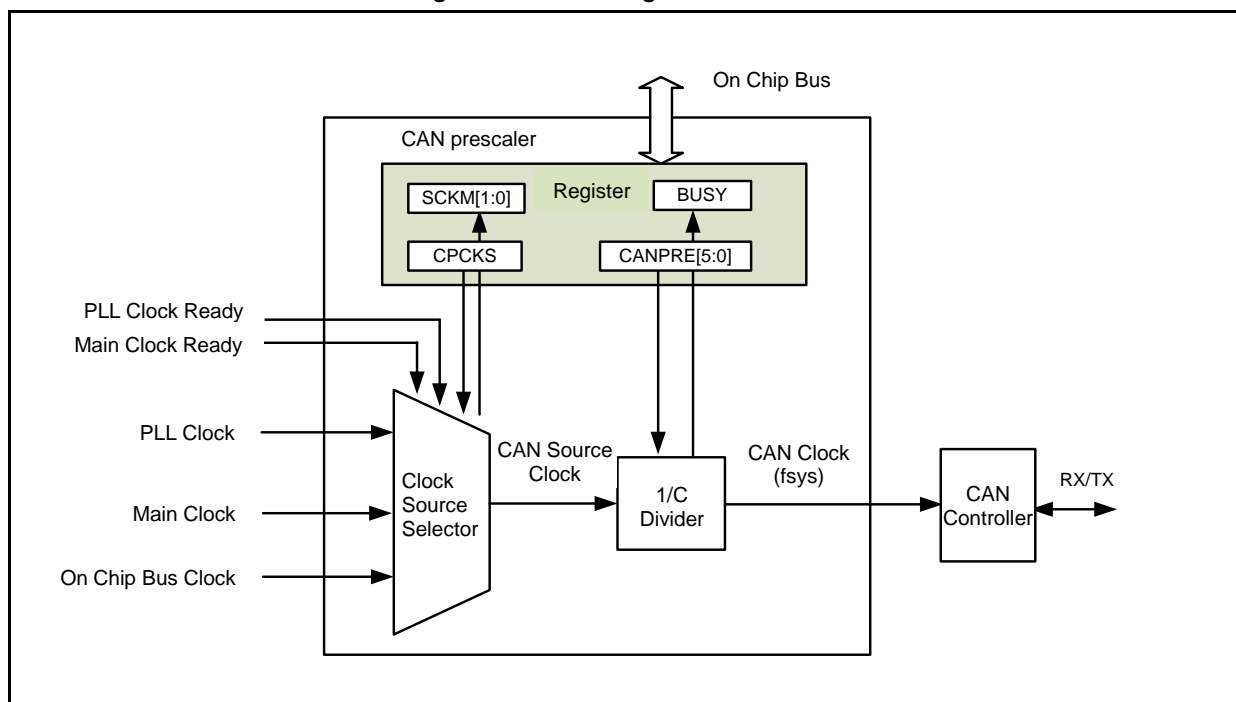

This module generates clocks (fsys) to be supplied from each clock source to the CAN macro.

2. Configuration

This section provides a block diagram of CAN prescaler.

The following block diagram shows the CAN controller and the CAN prescaler (register, clock source selector circuit, and division circuit).

Figure 2-1 Block Diagram of CAN Prescaler

3. Explanation of Operation

This section describes the operation of CAN prescaler.

Source Clock Selection

PLL(product specification) clock and main clock are selectable for a source clock of the CAN prescaler.

If the PLL(product specification) clock is selected but PLL(product specification) clock ready is not valid (oscillation is stopped or oscillation stabilization wait operation is in progress), a bus clock is selected.

Similarly, if the main clock is selected but main clock ready is not valid (oscillation is stopped or oscillation stabilization wait operation is in progress), a bus clock is selected.

The currently selected clock source can be read from the status register.

Division Circuit

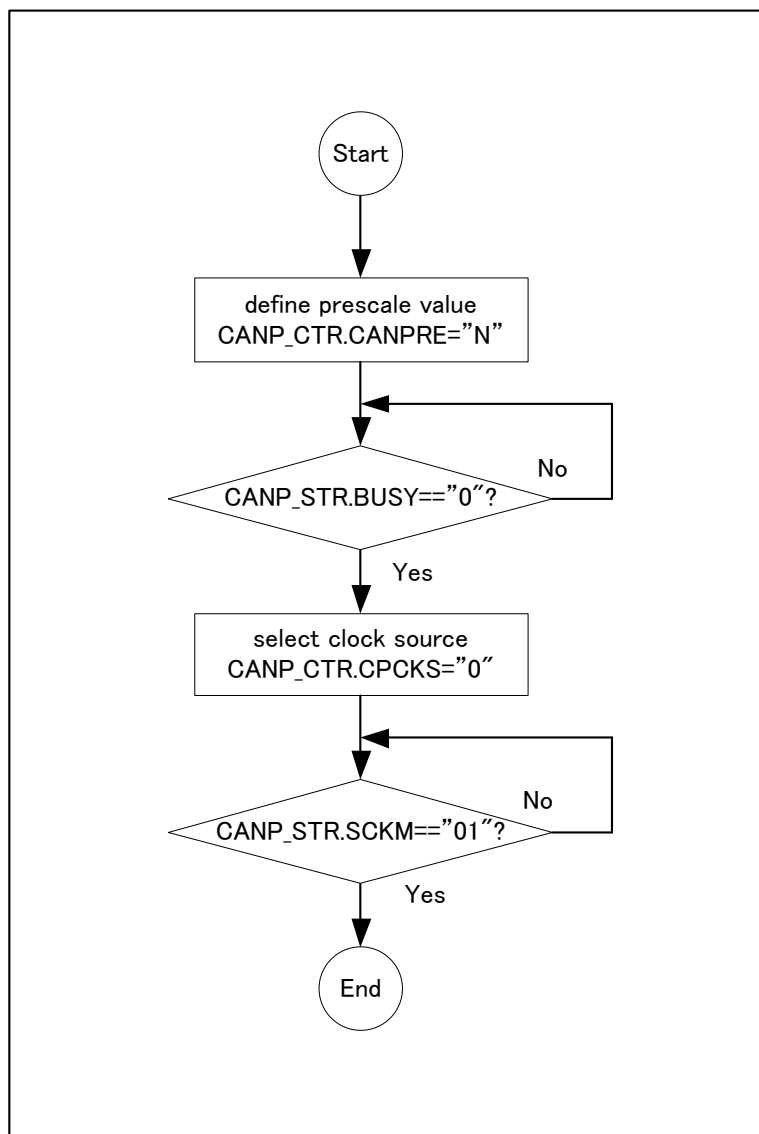

This module has the C division circuit that can change the CAN system clock (fsys) cycle. A division ratio from C = 1 to 64 can be set.

While the division setting is being changed, the status is busy. The next division setting change cannot be accepted until the current division setting is completed. The busy status can be read from the status register. If you make a new change in the busy status, a bus error response is returned.

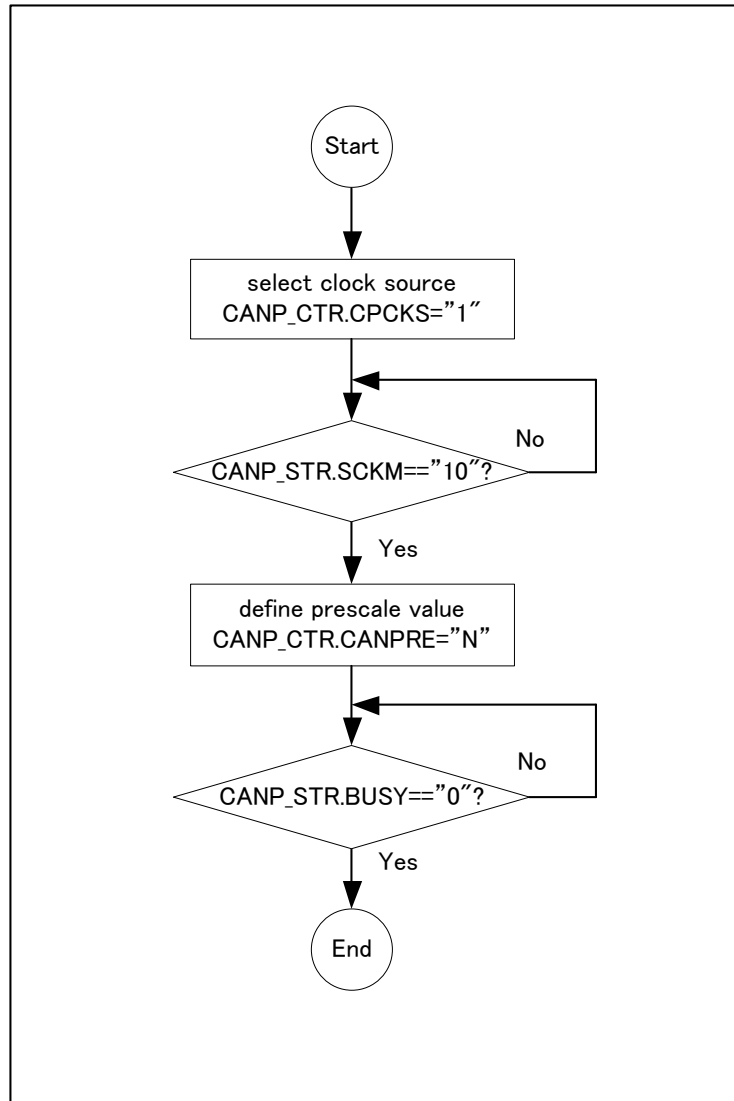

4. Setting Procedure

This section describes the procedure for setting the registers of CAN prescaler.

The following shows the procedure for switching from the main clock to the PLL (product specification) clock.

The following shows the procedure for switching from the PLL(product specification) clock to the main clock.

5. Registers

This section describes the registers of CAN prescaler.

Register List

Table 5-1 Register List

Abbreviated Register Name	Register Name	Reference
CANP_CTR	CAN prescaler control register	5.1
CANP_STR	CAN prescaler status register	5.2

Register Map

Table 5-2 Register Map

Offset	Register Name
0x0000_0000	CANP_CTR 00000000_00000000_00000001_00000000
0x0000_0004	CANP_STR 00000000_00000000_00000000_00000000

5.1. CAN Prescaler Control Register (CANP_CTR)

This register sets the division ratio of the CAN system clock and selects a clock source.

Bit	31	16
Field	Reserved	
R/W Attribute	R0,WX	
Protection Attribute	-	
Initial Value	00000000_00000000	

Bit	15	14	13	12	11	10	9	8
Field	Reserved							CPCKS
R/W Attribute	R0,WX							R/W
Protection Attribute	-							
Initial Value	0000000							1

Bit	7	6	5	4	3	2	1	0
Field	Reserved		CANPRE[5:0]					
R/W Attribute	R0,WX		R/W					
Protection Attribute			--					
Initial Value	00		000000					

[bit31:9] Reserved: Reserved Bits

[bit8] CPCKS: CAN Prescaler Source Clock Selection Bit

This bit selects the source clock to be used for the CAN system clock.

Bit	Description
0	Select the PLL(product specification) clock.
1	Select the main clock [initial value].

Note:

- Before changing the CAN prescaler source clock selection bit, set the initial bit (CCCR.Init) of the control register of the CAN controller to "0x1" to stop the CAN controller.

[bit7:6] Reserved: Reserved Bits

[bit5:0] CANPRE: CAN Prescaler Division Setting Bits

These bits set the division ratio from the CAN source clock of the CAN system clock.

Bit5:0						Description
0	0	0	0	0	0	No division [initial value]
0	0	0	0	0	1	Divided by 2
0	0	0	0	1	0	Divided by 3
...						
1	1	1	1	1	0	Divided by 63
1	1	1	1	1	1	Divided by 64

Notes:

- Before changing the CAN prescaler division setting bits, set the initial bit (CCCR.Init) of the control register of the CAN controller to "0x1" to stop the CAN controller.
- While the clock division setting is being changed, the CANP_STR.BUSY bit in the CAN prescaler status register is "1". If a new division ratio is set during the setting change, a bus error response is returned.
The new division ratio setting becomes invalid.
- If you select a clock for which oscillation is stopped or oscillation stabilization wait operation is in progress, the on-chip bus clock is selected. Confirm that a clock is selected based on the setting of the bit by reading CANP_STR.SCKM in the CAN prescaler status register.
- If you use the PLL(product specification) clock, confirm that the PLL(product specification) clock is selected by reading CANP_STR.SCKM in the CAN prescaler status register before starting communication with CAN.
- The CAN prescaler division setting bits have to be set before PLL(product specification) clock is selected.

5.2. CAN Prescaler Status Register (CANP_STR)

This register displays the status of CAN prescaler.

Bit	31										8									
Field	Reserved																			
R/W Attribute	R0,WX																			
Protection Attribute	-																			
Initial Value	00000000_00000000_00000000																			

Bit	7			6		5		4		3		2		1		0	
Field	Reserved										SCKM[1:0]				BUSY		
R/W Attribute	R0,WX										R,WX				R,WX		
Protection Attribute	-																
Initial Value	00000										00				0		

[bit31:3] Reserved: Reserved Bits

[bit2:1] SCKM: Source Clock Display

These bits indicate the currently selected source clock.

Bit1:0		Description
0	0	Clock stop
0	1	PLL(product specification) clock
1	0	Main clock
1	1	State in the middle of the source clock selection

Note:

- In case of the middle of the source clock selection, On-chip bus clock is selected.

[bit0] BUSY:

This bit indicates the status of switching by the CAN prescaler division setting register.

Bit	Description
0	Clock division setting is completed.
1	Clock division setting is being changed.

Notes:

- While the clock division setting is being changed, the CANP_STR.BUSY bit in the CAN prescaler status register is "1". If a division ratio is changed to a new one during the setting change, a bus error response is returned and the setting becomes invalid.

6. Restriction

This section describes the restriction of CAN clock(f_{sys}).

Frequency of Bus clock and CAN clock for CAN macro(CAN FD) have to meet conditions as below.

Bus clock frequency > CAN clock frequency

Therefore CAN macro of MCU Config Group and Common Peripheral Group have to meet conditions as below.

Bus clock(CLK_COMH) frequency for MCU Config Group > CAN clock frequency

Bus clock(CLK_LCP) frequency for Common Peripheral Group > CAN clock frequency

CHAPTER 35: Overview of Multi-function Serial Interface

This chapter provides an overview of the Multi-function Serial Interface.

1. Overview of the UART (Asynchronous Serial Interface)
2. Overview of the CSIO (Clock Synchronous Serial Interface)
3. Overview of the LIN Interface (v2.1) (LIN Communication Control Interface (v2.1))
4. Overview of the I²C Interface (I²C Communication Control Interface)
5. Block Diagram
6. Registers of the Multi-Function Serial Interface

MFS-TXXPT03P01R01L08-E1-XX

1. Overview of the UART (Asynchronous Serial Interface)

The UART (asynchronous serial interface) is a general-purpose serial data communication interface for asynchronous communication with external devices. This interface supports the bidirectional communication function (normal mode) and master/slave-type communication function (multi-processor mode: both master and slave roles are supported). In addition, this interface has FIFOs for transmission and reception.

Functions of the UART (Asynchronous Serial Interface)

	Function	Description
1	Data	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed 3 times by the bus clock. The reception value is determined by majority decision.
3	Transfer format	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator (15-bit reload counter configuration) The external clock input can be adjusted by the reload counter.
5	Data length	<ul style="list-style-type: none"> 5 to 9 bits (for normal mode), or 7 to 8 bits (for multi-processor mode)
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero) and inverted NRZ
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit (for NRZ method) Synchronized to rising edges of the start bit (for inverted NRZ method)
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error Parity error*1
9	Hardware flow control	<ul style="list-style-type: none"> Transmission/reception auto control by CTS and RTS
10	Synchronous transmission function	<ul style="list-style-type: none"> Can automatically transmit data periodically in synchronization with the serial timer. Can transmit in synchronization with an external trigger.
11	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
12	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, framing error, overrun error, parity error *1, and reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, and transmission block transfer error) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA transfer is supported for both transmission and reception. Status interrupt (serial timer interrupt)
13	Master/slave-type communication function (multi-processor mode)	<ul style="list-style-type: none"> 1 (master) -to-n (slave) communication is possible. (Both master and slave systems are supported.)
14	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

*1 Parity errors are for normal mode only.

2. Overview of the CSIO (Clock Synchronous Serial Interface)

The CSIO (clock synchronous serial interface) is a general-purpose serial data communication interface for synchronous communication with external devices (supports SPI). In addition, this interface has FIFOs for transmission and reception.

Functions of the CSIO (Clock Synchronous Serial Interface)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Transfer format	<ul style="list-style-type: none"> Clock synchronization (no start bits/stop bits) Master/slave function Supports SPI (supports both master and slave)
3	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter during master operation). External clock input is enabled (during slave operation).
4	Data length	<ul style="list-style-type: none"> Variable to 5 to 16, 20, 24, and 32 bits.
5	Reception error detection	<ul style="list-style-type: none"> Overrun error
6	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, overrun error, and reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, chip error interrupt, and transmission block transfer error) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA transfer is supported for both transmission and reception. Status interrupt (serial timer interrupt)
7	Serial chip select	<ul style="list-style-type: none"> 4-channel control (independent control, round control) The setup/hold/deselect times can be set to variable. The active level can be selected for each channel.
8	Synchronous transmission function	<ul style="list-style-type: none"> Can automatically transmit data periodically in synchronization with the serial timer. Can transmit in synchronization with an external trigger.
9	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. <ul style="list-style-type: none"> A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
10	Synchronous mode	<ul style="list-style-type: none"> Master or slave function
11	Pin access	<ul style="list-style-type: none"> The serial data output pin can be set to "1".
12	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

3. Overview of the LIN Interface (v2.1) (LIN Communication Control Interface (v2.1))

3.1. Manual Mode

The LIN interface (v2.1) (LIN communication control interface (v2.1)) provides the functions to support the LIN bus. In addition, this interface has FIFOs (64 bytes each) for transmission and reception.

**Functions of the LIN Interface (v2.1) (LIN Communication Control Interface (v2.1))
 (Manual Mode)**

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed 3 times by the bus clock. The reception value is determined by majority decision.
3	Transfer mode	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter). The external clock can be adjusted by the reload counter. Auto baud rate adjustment with Sync Field reception.
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error
9	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, framing error, overrun error, and reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, and transmission block transfer error) Status interrupt (LIN Break field detection and serial timer interrupt) Interrupt request to ICU (LIN Sync field detection: LSYN) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA transfer is supported for both transmission and reception.
10	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
11	LIN bus option	<ul style="list-style-type: none"> Support for LIN Protocol Revision 2.1 Master device operation Slave device operation LIN Break field generation (changeable from 13 to 16 bits) LIN Break delimiter generation (changeable from 1 to 4 bits) LIN Break field detection Detection of the start/stop edge of the LIN Sync field connected to an input capture
12	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

Note:

- The Wake Up function of the LIN is not supported.

3.2. Assist Mode

The LIN interface (v2.1) (LIN communication control interface (v2.1)) provides the functions to support the LIN bus. The header section can be automatically transmitted/detected in LIN communication. In addition, this interface has FIFOs (64 bytes each) for transmission and reception.

Functions of the LIN Interface (v2.1) (LIN Communication Control Interface (v2.1)) (Assist Mode)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed 3 times by the bus clock. The reception value is determined by majority decision.
3	Transfer mode	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter). The external clock can be adjusted by the reload counter. Auto baud rate adjustment with Sync Field reception.
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error LIN bus error LIN ID parity error LIN checksum error
9	Interrupt request	<ul style="list-style-type: none"> Transmission interrupt <ul style="list-style-type: none"> ➤ Data transmission interrupt (transmission data empty, transmission bus idle, and transmission block transfer error) ➤ Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) Reception interrupt <ul style="list-style-type: none"> ➤ Data reception interrupt (reception completion and reception block transfer error) ➤ Reception FIFO interrupt (when the reception FIFO is higher than the interrupt threshold, reception FIFO under run) ➤ Various types of error interrupts (LIN bus error, LIN Sync Data error, LIN ID parity error, framing error, overrun error, and LIN checksum error) Status interrupt <ul style="list-style-type: none"> ➤ Auto header completion interrupt ➤ Sync Field detection interrupt ➤ Checksum calculation completion interrupt DMA transfer is supported for both transmission and reception.
10	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.

	Function	Description
11	LIN bus option	<ul style="list-style-type: none"> - Support for LIN Protocol Revision 2.1 - Automatic transmission/reception of the header of the master/slave device <ul style="list-style-type: none"> ➤ LIN Break field generation (changeable from 13 to 20 bits) ➤ LIN Break delimiter generation (changeable from 1 to 4 bits) ➤ Automatic generation of the Sync Field and automatic check of data value (0x55) ➤ Automatic generation/check of the parity value of the ID Field ➤ Automatic generation/check of a checksum (support for standard/extended checksum)
12	FIFO option	<ul style="list-style-type: none"> - Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). - Transmission FIFO and reception FIFO can be selected. - Transmission data can be retransmitted. - The timing of the transmission/reception FIFO interrupt can be changed by software. - Independent FIFO reset is supported.
13	LIN communication test function	<ul style="list-style-type: none"> - Serial communication test function - Pseudo error generation functions (LIN bus error, LIN ID parity error, LIN checksum error, LIN Sync Field error, and framing error)

Note:

- The Wake Up function of the LIN is not supported.

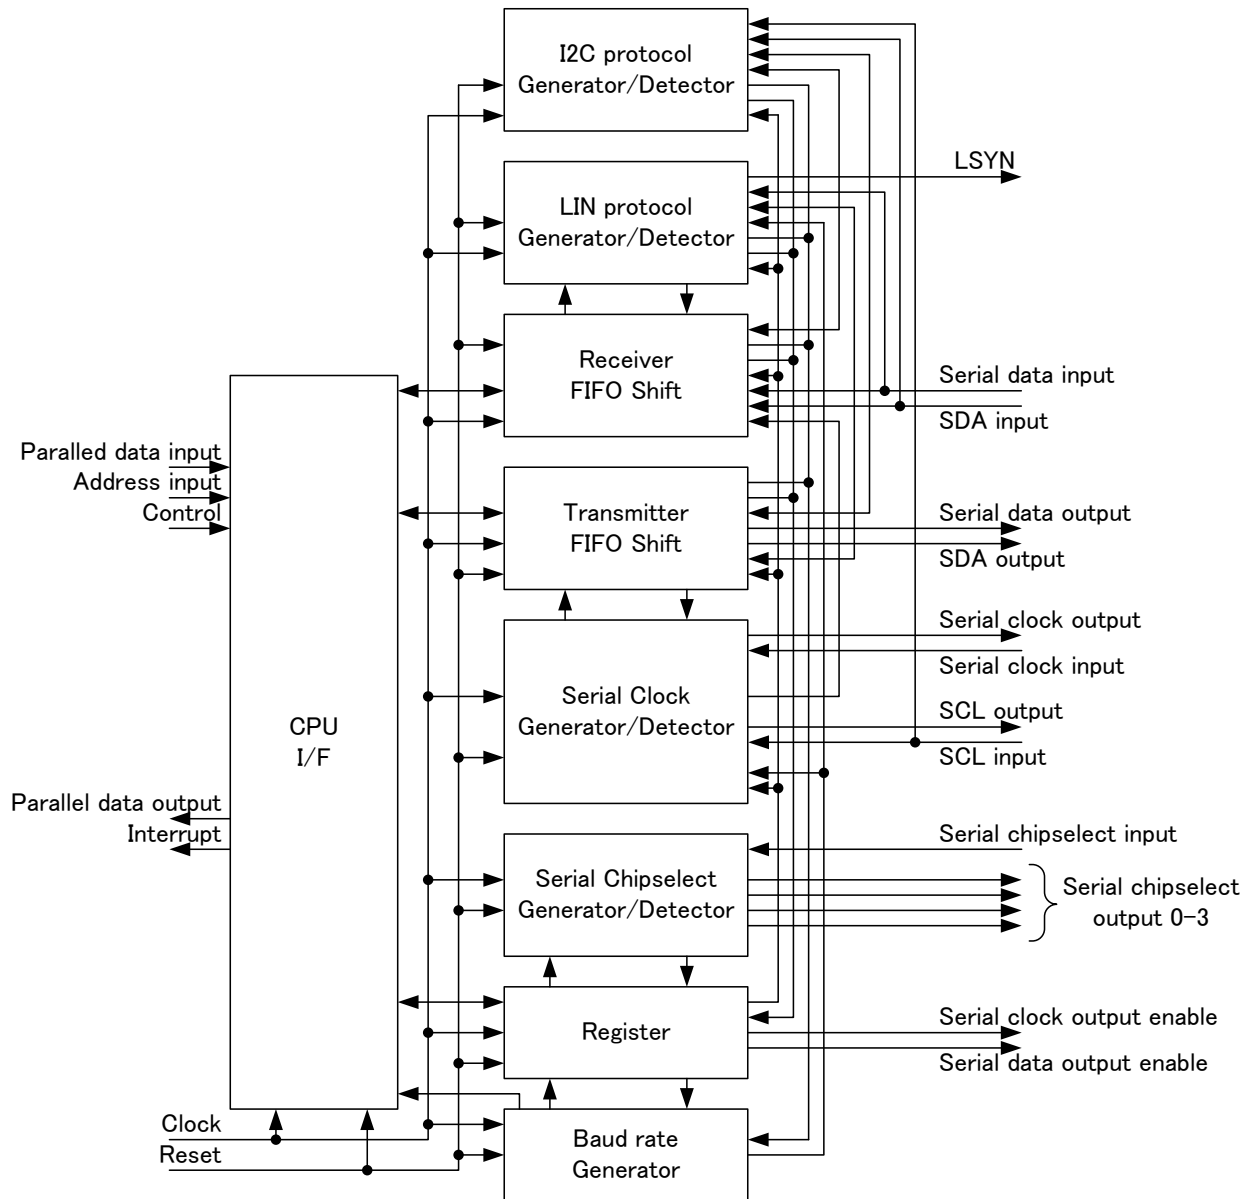

4. Overview of the I²C Interface (I²C Communication Control Interface)

The I²C interface (I²C communication control interface) supports the I²C bus and operates as a master/slave device on the I²C bus. In addition, this interface has FIFOs (64 bytes each) for transmission and reception.

Functions of the I²C Interface (I²C Communication Control Interface)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> For serial clock and data input, noise from 2 to 38 bus clocks is filtered out.
3	Transfer mode	<ul style="list-style-type: none"> Synchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter).
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Interrupt request	<ul style="list-style-type: none"> Reception interrupt Transmission interrupt Status interrupt (INT interrupt, stop condition interrupt, repeated start detection interrupt, and serial timer interrupt) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, reception FIFO under run) Reception FIFO interrupt (reception FIFO under run) DMA transfer is supported for both transmission and reception.
8	I ² C	<ul style="list-style-type: none"> Master/slave transmission and reception function Arbitration function Clock synchronization function Transfer direction detection function Function to generate and detect the repeated start condition Bus error detection function General call addressing function 7-bit addressing as master and slave An interrupt can be generated upon transfer and bus error occurrence. 10-bit addressing function can be supported by program. Standard-mode and Fast-mode are supported. Fast-mode Plus, High-speed mode, and Ultra Fast-mode are not supported.
9	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
10	FIFO	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

5. Block Diagram

Explanation of Each Block**Baud Rate Generator**

This 15-bit reload counter functions as a dedicated baud rate generator. This block consists of 15-bit registers for reload values, and it generates reception and transmission clocks and LIN Break field detection clocks from external or internal clocks. Also, the count value of the transmission reload counter is read from BGR1 or BGR0.

Receiver/FIFO Shift

This block consists of a reception shift register, reception FIFO, reception bit counter, start bit detection circuit, and reception parity counter. When the reception bit counter counts the reception data bit and completes the reception of 1 piece of data corresponding to the set data length, the reception data full flag bit (SSR:RDRF) is set to "1". At this time, if reception interrupts are enabled, it generates a reception interrupt request. The start bit detection circuit detects the start bit from a serial input signal, synchronizes the falling edge of the start bit, and sends a signal to the reload counter. The reception parity counter calculates the reception data parity.

The reception shift register fetches the received data input from the SIN (serial data input) pin while bits are shifted. After the completion of reception, the register transfers the received data to the RDR register, or to the reception FIFO when using the reception FIFO.

Transmitter/FIFO Shift

This block consists of a transmission shift register, transmission bit counter, transmission start circuit, and transmission parity counter. The transmission bit counter counts the transmission data bits and transmits 1 piece of data corresponding to the set data length. When the transmission bit counter indicates the start of write data transmission, a flag is set in the serial status register. At this time, if transmission interrupts are enabled, it generates a transmission interrupt request. The transmission start circuit starts a transmission operation with data writing of the TDR register. If the transmission parity counter uses parity bits, it generates a parity bit for the transmission data.

The transmission shift register transfers the written data in the TDR register, or in the transmission FIFO when using the transmission FIFO, to the transmission shift register and outputs it to SOUT (serial data output) while bits are shifted.

Serial Clock Generator/Detector

The serial clock generator generates a serial clock during master operations in CSIO or I²C mode.

The serial clock detector detects the serial clock during slave operations in CSIO or I²C mode. There is synchronization with the detected serial clock to transmit and receive serial data.

LIN Protocol Generator/Detector

The LIN protocol Detector detects the LIN Break field when the LIN master node transmits the message header. Upon detecting the LIN Break field, the detector sets "1" in the LIN Break field detection flag bit (SSR:LBD). It outputs an internal signal (LSYN) to a capture unit to detect the first and the fifth falling edges of the LIN Sync field and to measure the synchronization of the actual serial clock transmitted by the LIN master node.

The LIN protocol Generator generates the LIN break field corresponding to the length selected with the LIN break field length selection bit in the extended status control register.

I²C Protocol Generator/Detector

The I²C protocol detector detects start and stop conditions and monitors the status of the I²C bus.

The I²C protocol generator generates start and stop conditions and controls wait for the I²C bus.

Serial Chip Select Generator/Detector

The serial chip select generator controls each chip select pin during master operations in CSIO mode.

The serial chip select detector monitors the chip select input status during slave operations in CSIO mode.

Register

This is the setting part of each register.

CPU I/F

This is the interface part between the bus and a register.

6. Registers of the Multi-Function Serial Interface

This section lists the multi-function serial interface registers.

operation mode	register select signal	DATAO[31:24]/ DATAI[31:24]	DATAO[23:16]/ DATAI[23:16]	DATAO[15:8]/ DATAI[15:8]	DATAO[7:0]/ DATAI[7:0]
mode0 to 3	SSRSEL, ESCRSEL	SSR[7:0]	ESCR[7:0]	SCR[7:0]	SMR[7:0]

CHAPTER 36: UART (Asynchronous Serial Interface)

This chapter describes the UART (Asynchronous Serial Interface) function supported by operation modes 0 and 1 of the multi-function serial interface.

1. Overview of the UART (Asynchronous Serial Interface)
2. Interrupts from the UART
3. UART Operation
4. Serial Timer Operation
5. Test Mode
6. Dedicated Baud Rate Generator
7. Block Transfer
8. Setup Procedure and Program Flow for Operation Mode 0 (Asynchronous Normal Mode)
9. Setup Procedure and Program Flow for Operation Mode 1 (Asynchronous Multi-processor Mode)
10. Registers of UART (Asynchronous Serial Interface)

UART-TXXPT03P01R01L11-E1-XX

1. Overview of the UART (Asynchronous Serial Interface)

UART (Asynchronous Serial Interface) is a general-purpose serial data communication interface for asynchronous communication with external devices. This interface supports bidirectional communication (normal mode) and master/slave-type communication (multi-processor mode: both master and slave roles are supported). In addition, this interface has FIFOs for transmission and reception.

UART (Asynchronous Serial Interface) Functions

	Function	Description
1	Data	<ul style="list-style-type: none"> Full-duplex double buffer (when FIFO is not used) Transmission and reception FIFOs (64 bytes for each) (when FIFO is used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed by the bus clock 3 times. The received value is determined by the rule of majority.
3	Transfer format	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator (15-bit reload counter configuration) The external clock input can be adjusted by the reload counter.
5	Data length	<ul style="list-style-type: none"> 5 to 9 bits (for normal mode), or 7 to 8 bits (multi-processor mode)
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero) and inverted NRZ
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit (for NRZ method) Synchronized to rising edges of the start bit (for inverted NRZ method)
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error Parity error *1
9	Hardware flow control	<ul style="list-style-type: none"> Transmission/reception auto control by CTS and RTS
10	Synchronous transmission function	<ul style="list-style-type: none"> Can automatically transmit data periodically in synchronization with the serial timer. Can transmit in synchronization with an external trigger.
11	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is available. A division value can be selected for the operation clock (1 to 256 divisions). Activation by an external trigger is available.
12	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, framing error, overrun error, parity error *1, reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, transmission block transfer error) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA Transfer is supported for both transmission and reception. Status interrupt (serial timer interrupt)
13	Master/slave-type communication function (Multi-processor mode)	<ul style="list-style-type: none"> 1 (master) -to-n (slave) communication is possible. (Both master and slave systems are supported.)
14	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are available (transmission FIFO: 64 bytes, reception FIFO: 64 bytes). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

*1: Parity errors occur only in normal mode.

Interrupt request and DMA request

- Interrupt request of this module can be used for purposes below:
 1. Interrupt request to CPU (via Interrupt Controller)
 2. DMA request to DMA Controller
- To use the interrupt as interrupt request to CPU, following configuration is necessary:
 - Enable the interrupt request in this module
 - Enable the interrupt channel of the interrupt in Interrupt Controller
- To use the interrupt as DMA request to DMA Controller, following configuration is necessary:
 - Enable the interrupt request in this module
 - Select the DMA channel from this module as DMA client in DMA Controller

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Interrupts from the UART

UART has transmission/reception interrupts and status interrupts. Interrupt requests can be generated with the factors described below.

- When reception data is set in the reception data register (RDR), or when a reception error occurs
- When transmission data is transferred from the transmission data register (TDR) to the transmission shift register and transmission starts
- Transmission bus idle (no transmission)
- Transmission FIFO data request
- When the serial timer comparison value (STMCR) and the serial timer value (STMR) coincide

Interrupts from the UART

Table 2-1 lists the interrupt control bits and interrupt factors of UART.

Table 2-1 UART Interrupt Control Bits and Interrupt Factors

Interrupt Types	Interrupt Request Flag Bit	Flag Register	Operation Mode		Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
			0	1			
Reception	RDRF	SSR	Appl	Appl	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL=1)
					Reception of as much data as the amount set in FBYTE		- Reading of reception data (RDR) until the reception FIFO is empty - Software reset (SCR:UPCL=1)
					Detection of reception idle for the 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Appl	Appl	Overrun error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL=1)
	FRE	SSR	Appl	Appl	Framing error		
	PE	SSR	Appl	NA	Parity error	ECR:REIE	- Writing "1" to the reception FIFO under run flag clear bit (ESRC:RXUDRC) - Software reset (SCR:UPCL=1) - Disable reception FIFO (1) When FCR1:FSEL=0, set FCR0.FE2=0 (2) When FCR1:FSEL=1, set FCR0.FE1=0
	RXUDR	ESR	Appl	Appl	Reception FIFO under run		
	RBERR	ESR	Appl	Appl	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit (ESRC:RBERRC) - Software reset(SCR:UPCL=1) - Disable reception block transfer mode (ECR:RXBLKEN=0)

Interrupt Types	Interrupt Request Flag Bit	Flag Register	Operation Mode		Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
			0	1			
Transmission	TDRE	SSR	Appl	Appl	The transmission register is empty.	SCR:TIE	Writing to the transmission data register (TDR), or writing "1" to the transmission FIFO operation enable bit (retransmission) when the bit value is "0" and the transmission FIFO contains valid data*1
	TBI	SSR	Appl	Appl	No transmission	SCR:TBIE	Writing to the transmission data register (TDR), or writing "1" to the transmission FIFO operation enable bit (retransmission) when the bit value is "0" and the transmission FIFO contains valid data*1
	FDRQ	FCR1	Appl	Appl	The transmission FIFO stores a data amount equal to or smaller than the FTICR setting value or is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC), or the transmission FIFO is full.
	TXOVR	ESR	Appl	Appl	Transmission FIFO overrun	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVR) - Software reset(SCR:UPCL=1) - Disable transmission FIFO (1) When FCR1:FSEL=0, set FCR0:FE1=0 (2) When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Appl	Appl	Transmission block transfer error	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission block transfer error clear bit (ESRC:TBERR) - Software reset(SCR:UPCL=1) - Disable transmission block transfer (ECR:TXBLKEN=0)
Status	TINT	SACSR	Appl	Appl	Coincidence of the serial timer register (STMR) and the serial timer comparison register (STMCR) values	SACSR:TINTE	<ul style="list-style-type: none"> - Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset(SCR:UPCL=1)

*1: Set the TIE bit to "1" after the TDRE bit becomes "0".

Error Interrupt Request Output switching

Depending on the settings of the error interrupt request output switch bit (ECR:EISEL), transmission and reception error interrupt enable bits (ECR:REIE, TEIE), and transmission and reception interrupt enable bits (SCR:RIE, TIE, TBIE, FCR1:FTIE), the error interrupt request output method differs.

Table 2-2 Transmission Interrupt Request Output Method

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Transmission interrupt request output	SCR:TIE	No transmission data (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)
	Transmission error interrupt request output	-	No interrupt factor
1	Transmission interrupt request output	SCR:TIE	No transmission data (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
	Transmission error interrupt request output	ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)

Table 2-3 Reception Interrupt Request Output Method

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF) Framing error (SSR:FRE) Overrun error (SSR:ORE) Parity error (SSR:PE)
		ECR:REIE	Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)
	Reception error interrupt request output	-	No interrupt factor
1	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF)
	Reception error interrupt request output	ECR:REIE	Framing error (SSR:FRE) Overrun error (SSR:ORE) Parity error (SSR:PE) Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)

2.1. Occurrence of Reception Interrupts and Flag Set Timing

There are 2 reception interrupt types: Reception completion (SSR:RDRF) and reception error (SSR:PE, ORE, FRE).

Occurrence of Reception Interrupts and Flag Set Timing

Upon the detection of the first stop bit, the reception data is stored in the reception data register (RDR). Related flags are set upon the completion of reception (SSR:RDRF = 1) or upon a reception error (SSR:PE, ORE, FRE = 1). At that time, a reception interrupt occurs if the reception interrupt is enabled (SCR:RIE = 1).

Note:

- If a reception error occurs, the data in the reception data register (RDR) will be invalid.

Figure 2-1 Set Timing of RDRF (Reception Data Full) Flag Bit

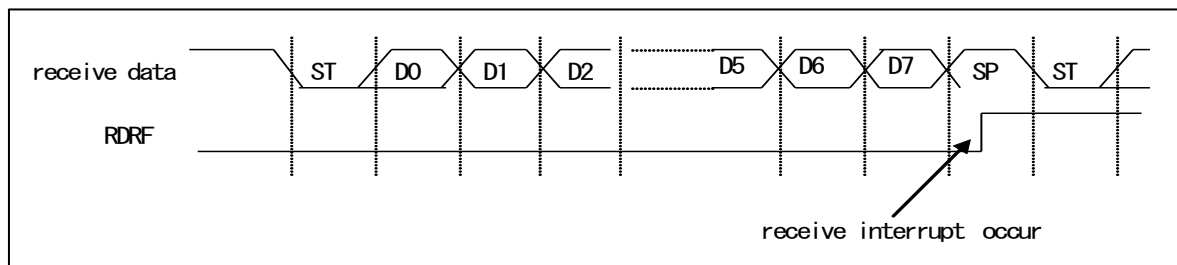

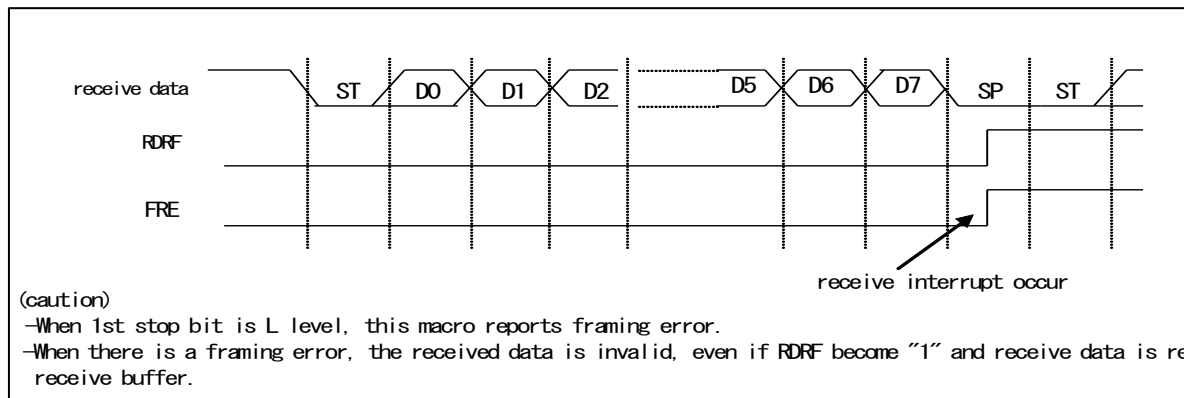

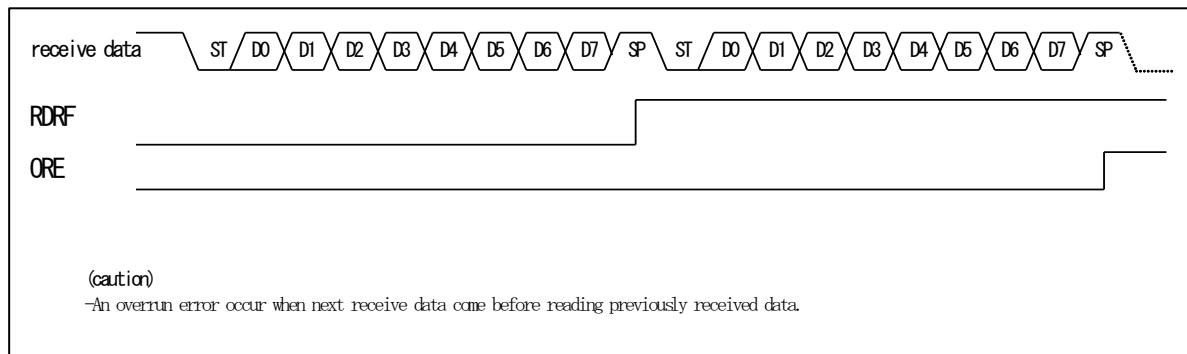

Figure 2-2 Set Timing of FRE (Framing Error) Flag Bit

Note:

- During data reception, the following will happen if one of the following edges is detected at the same time as, or 1 or 2 bus clocks earlier than, the stop bit sampling point: The edge becomes invalid and the data that follows may not be received normally. Consecutive frames must have intervals between them.
 - Falling edge of serial data (when ESCR:INV = 0)
 - Rising edge of serial data (when ESCR:INV = 1)

Figure 2-3 Set Timing of ORE (Overrun Error) Flag Bit

2.2. Occurrence of Interrupts and Flag Set Timing When the Reception FIFO Is Used

When the reception FIFO is used, an interrupt occurs if an amount of data equal to the amount set in the FBYTE register (FBYTE) is received.

Occurrence of Reception Interrupts and Flag Set Timing When the Reception FIFO is Used

When the reception FIFO is used, occurrence of interrupts is determined by the value set in the FBYTE register.

- If as much transfer data as the amount set in the FBYTE register is received, the reception data full flag (SSR:RDRF) in the serial status register is set to "1". At this time, a reception interrupt occurs if the reception interrupt is enabled (SCR:RIE).
- When both of the following conditions are satisfied, the continuation of reception idle status for 8 baud rate clocks or longer sets the interrupt flag (SSR:RDRF) to "1".
 - The reception FIFO idle detection enable bit (FCR1:FRIDE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, then the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when there is data remaining in the reception FIFO, counting restarts.

- When the reception FIFO becomes empty as a result of reading the reception data (RDR), the reception data full flag (SSR:RDRF) is cleared.
- If the reception valid data count becomes equal to the value of the FIFO capacity, reception of any subsequent data triggers an overrun error (SSR:ORE = 1).

Figure 2-4 Occurrence Timing of Reception Interrupt When Reception FIFO Is Used

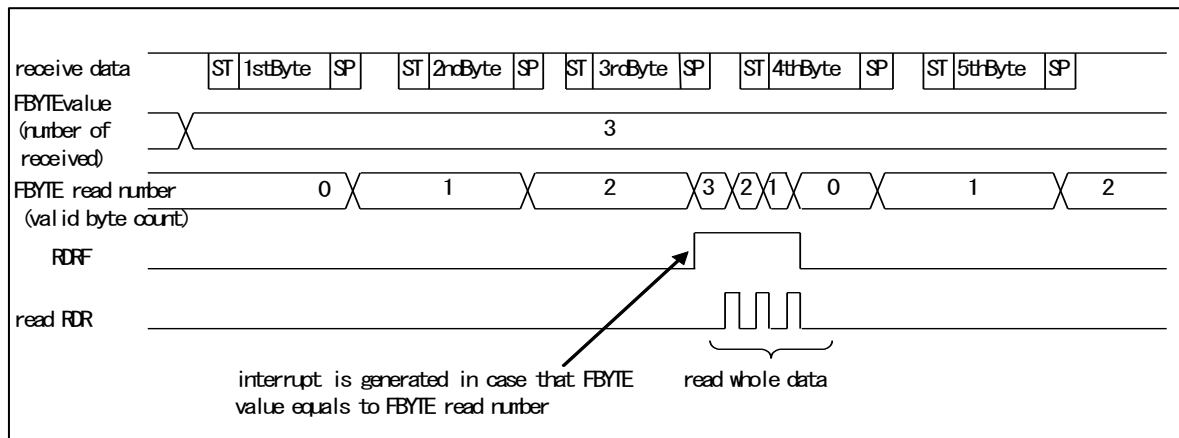

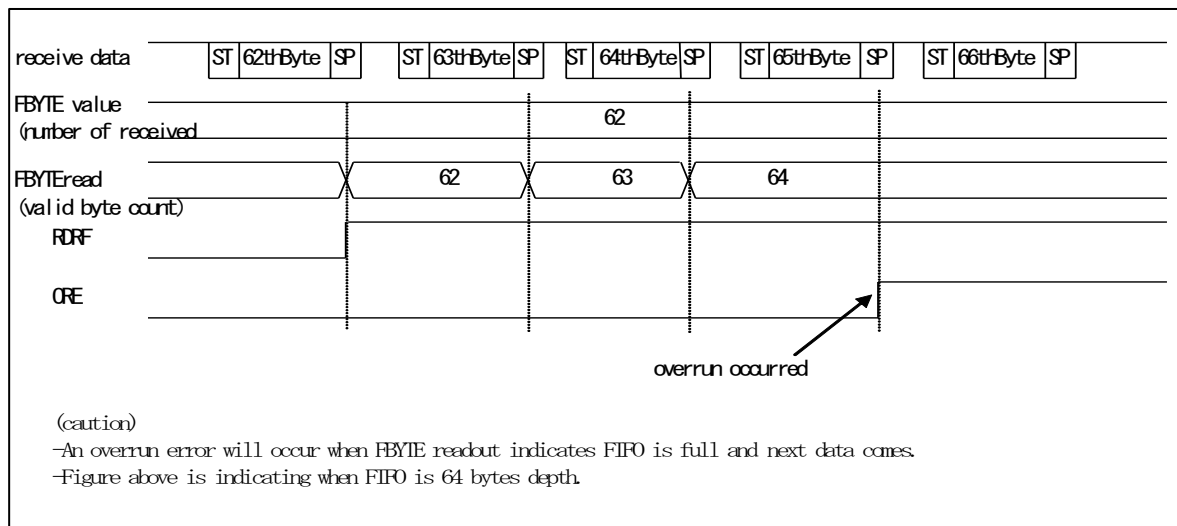

Figure 2-5 Set Timing of ORE (Overrun Error) Flag Bit

2.3. Occurrence of Transmission Interrupts and Flag Set Timing

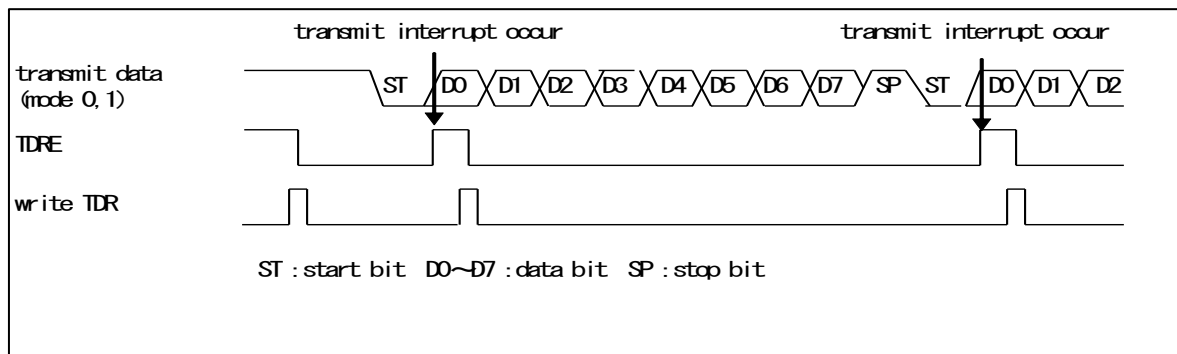

A data transmission interrupt occurs in the following cases: 1. The transmission data is transferred from the transmission data register (TDR) to the transmission shift register (SSR:TDRE = 1) to start data transmission. 2. The transmission operation is not performed (SSR:TBI = 1).

Occurrence of Transmission Interrupts and Flag Set Timing

Set Timing of Transmission Data Empty Flag (SSR:TDRE)

Transfer of data from the transmission data register (TDR) to the transmission shift register allows the next data to be written (SSR:TDRE = 1). At that time, a transmission interrupt occurs if the transmission interrupt is enabled (SCR:TIE = 1). The SSR:TDRE bit is a read-only bit, and it is cleared to "0" when data is written to the transmission data register (TDR).

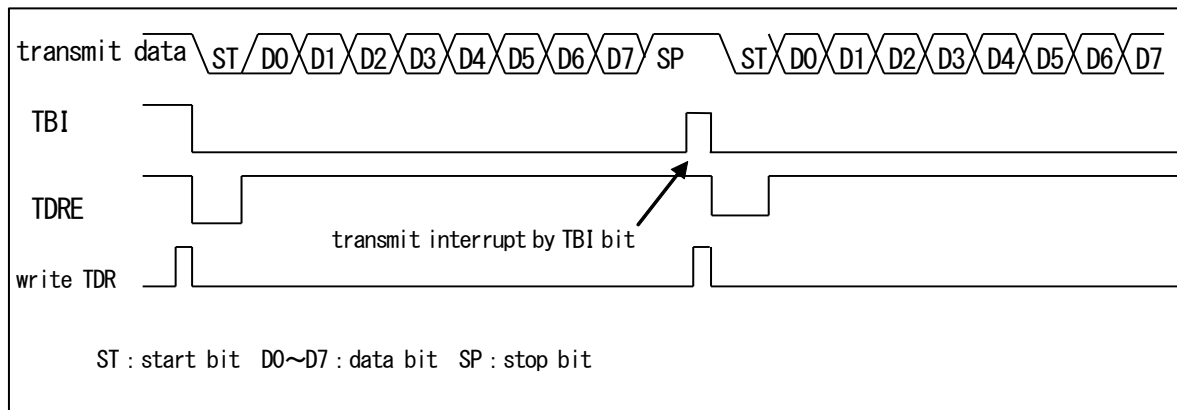

Figure 2-6 Set Timing of Transmission Data Empty Flag (SSR:TDRE)

Set Timing of Transmission Bus Idle Flag (SSR:TBI)

The SSR:TBI bit is set to "1" when the transmission data register is empty (SSR:TDRE = 1) and transmission is not performed. At that time, a transmission interrupt occurs if the transmission bus idle interrupt is enabled (SCR:TBIE = 1). Writing transmission data to the transmission data register (TDR) clears the SSR:TBI bit and the transmission interrupt request.

Figure 2-7 Set Timing of Transmission Bus Idle Flag (TBI) (Synchronous Transmission Disabled SACS:TSYNE = 0)

Note:

- In the case of synchronous transmission (SACS:TSYNE = 1), the SSR:TBI bit is set to "1" if the transmission data register is empty (SSR:TDRE = 0) after transmitting data for the byte count set in the transfer byte count (TBYTE0).

2.4. Occurrence of Interrupts and Flag Set Timing When the Transmission FIFO Is Used

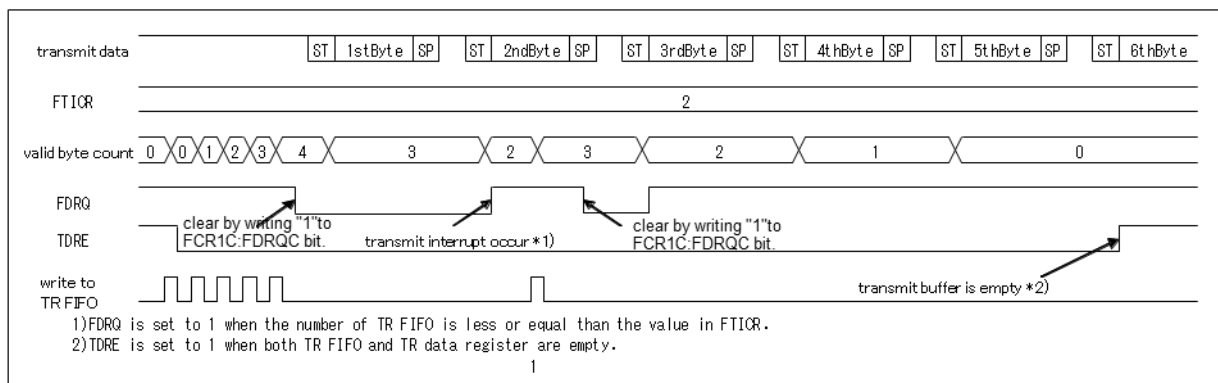

When the transmission FIFO is used, an interrupt occurs if the number of data items stored in the transmission FIFO is equal to or less than the setting of the FTICR register (FTICR).

Occurrence of Transmission Interrupts and Flag Set Timing When the Transmission FIFO is Used

When the transmission FIFO is used, occurrence of interrupts is determined by the value set in the FTICR register.

- When the amount of data stored in the transmission FIFO is equal to or less than the value set for the FTICR register, the FIFO transmission data request bit (FCR1:FDRQ) is set to "1".
At that time, a transmission interrupt occurs if the FIFO transmission interrupt is enabled (FCR1:FTIE = 1).
- When you write the necessary data to the transmission FIFO after a transmission interrupt occurs, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.
- The FIFO transmission data request bit (FCR1:FDRQ) is set to "0" once the transmission FIFO is full.
- The existence of data in the transmission FIFO can be verified by reading the FIFO byte register (FBYTE) or the transmission FIFO interrupt control register (FTICR).
FBYTE = 0x00 and FTICR = 0x00 indicate that the transmission FIFO does not contain data.

Figure 2-8 Occurrence Timing of Transmission Interrupt When Transmission FIFO is Used

2.5. Occurrence of Timer Interrupts and Flag Set Timing

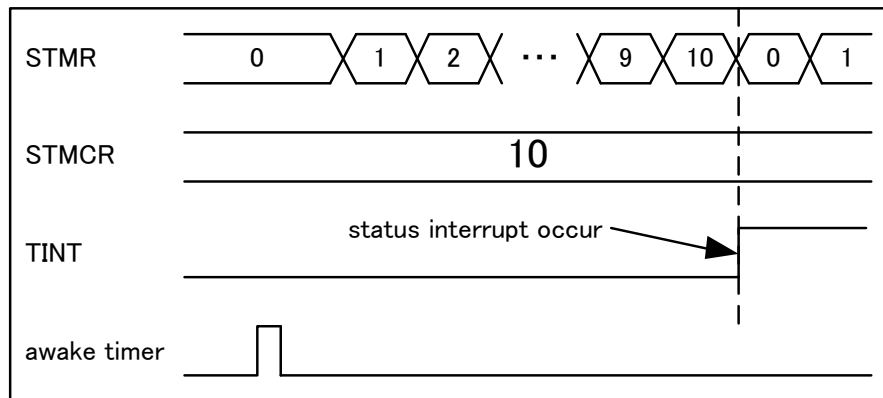

A timer interrupt occurs when the serial timer register (STMR) coincides with the serial timer comparison register (STMCR).

Timer Interrupt Generation and Flag Set Timing

The timer interrupt flag (SACSR:TINT) is set to "1" when the serial timer register (STMR) coincides with the serial timer comparison register.

At that time, a status interrupt occurs if the timer interrupt is enabled (SACSR:TINTE = 1).

Figure 2-9 Occurrence Timing of Timer Interrupt

3. UART Operation

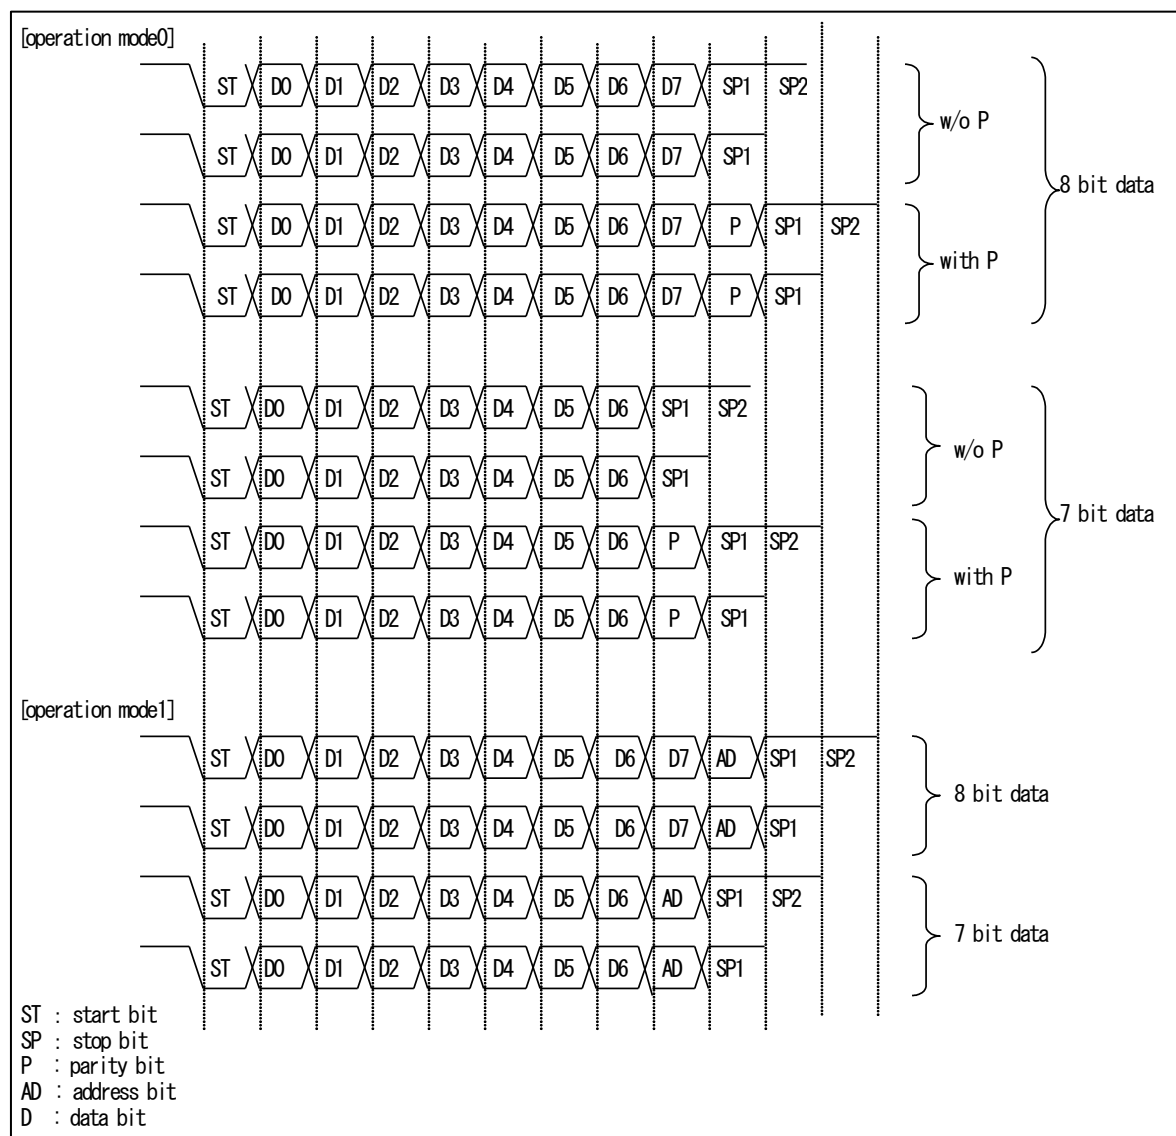

UART operates in mode 0, which corresponds to bidirectional serial asynchronous communication, and also in mode 1, which corresponds to master/slave multi-processor communication.

UART Operation

Transmission and Reception Data Format

- Transmission or reception data always starts with a start bit followed by transmission/reception of a specified data bit length and ending with at least one stop bit.
- The data transfer direction (LSB first or MSB first) is determined by the BDS bit in the serial mode register (SMR). If parity check is enabled, the parity bit is always placed between the last data bit and the first stop bit.
- Parity check can be enabled or disabled for operation mode 0 (normal mode).
- In operation mode 1 (multi-processor mode), AD bits are appended instead of parity bits.

Figure 3-1 shows the transmission and reception data formats of operation modes 0 and 1.

Figure 3-1 Example of Transmission and Reception Data Formats (Operation Modes 0 and 1)**Notes:**

- The above figure show cases for data lengths of 7 bits and 8 bits. (Data length can be set to 5 bits to 9 bits for operation mode 0.)
- When the BDS bit in the serial mode register (SMR) is set to "1" (MSB first), bits are processed in the order of D7, D6, D5, ..., D1, D0 (P).
- If the data length is set to X bits, the lowest X bits of the transmission and reception data register (RDR/TDR) are valid.

Transmission Operation

- When the transmission data empty flag bit (TDRE) in the serial status register (SSR) is "1", transmission data can be written to the transmission data register (TDR). (When the transmission FIFO is enabled, transmission data can be written even if TDRE = 0.)
- Writing transmission data to the transmission data register (TDR) sets the transmission data empty flag bit (SSR:TDRE) to "0".
- Setting the transmission operation enable bit (SCR:TXE) in the serial control register to "1" loads the transmission data to the transmission shift register and starts transmission from the start bit.
- The transmission data empty flag bit (SSR:TDRE) is set to "1" again when transmission starts. At this time, a transmission interrupt occurs if transmission interrupts are enabled (SCR:TIE = 1). The interrupt processing can write the next transmission data to the transmission data register.

Notes:

- *Because the initial value of the transmission data empty flag bit (SSR:TDRE) is "1", a transmission interrupt occurs as soon as the transmission interrupt is enabled (SCR:TIE).*
- *Because the initial value of the FIFO transmission data request bit (FCR1:FDRQ) is "1", a transmission interrupt occurs as soon as the FIFO transmission interrupt is enabled (FCR1:FTIE = 1).*

Reception Operation

- When the reception operation is enabled (SCR:RXE = 1), the reception operation starts.
- After a start bit is detected, 1-frame data is received according to the data format set in the extended communication control register (ESCR:PEN, P, L2, L1, and L0) and the serial mode register (SMR:BDS). A start bit is detected when both of the following are satisfied: 1. The noise-filtered result (the result of applying the rule of majority to the 3-time bus clock sampling of the serial data input) shows falling (when ESCR:INV = 0) or rising (when ESCR:INV = 1). 2. The filtered data shows "L" at the sampling point.
- The reception data full flag bit (SSR:RDRF) is set to "1" when 1-frame data has been received. At that time, a reception interrupt occurs if the reception interrupt is enabled (SCR:RIE = 1).
- When reading the reception data, read the reception data after all of the 1-frame data has been received, and check the error flag in the serial status register (SSR). If a reception error occurs, perform error processing.
- Reading the reception data clears the reception data full flag bit (SSR:RDRF) to "0".
- If the reception FIFO is enabled, the reception data full flag bit (SSR:RDRF) is set to "1" upon the reception of as many frames of data as the value set in the reception FBYTE.
- When both of the following conditions are satisfied, continuation of reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1".
 - The reception FIFO idle detection enable bit (FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled while data remains in the reception FIFO, counting restarts.
- When the error flag in the serial status register (SSR) is set to "1" while the reception FIFO is enabled, the data related to the error is not stored in the reception FIFO. At that time, the reception data full flag bit (SSR:RDRF) is not set to "1". (However, an overrun error sets the RDRF flag to "1".) The reception FBYTE indicates the data count that had been received normally before the error occurred. The reception FIFO is not enabled unless the error flag in the serial status register (SSR) is cleared to "0".
- If the reception FIFO is enabled, the reception data full flag bit (SSR:RDRF) is cleared to "0" when the reception FIFO becomes empty.

Notes:

- The reception data register (RDR) is effective when the reception data register full flag bit (SSR:RDRF) is set to "1" and there has been no reception error (SSR:PE, ORE, FRE = 0).
- There is a built-in noise filter (where the rule of majority is applied to the 3-time bus clock sampling of the serial data input), but erroneous data is received if noise has passed through the filter. We suggest that you design the board in such a way that noise does not pass through the filter. Alternatively, we suggest that you implement a communication method whereby noise passing through the filter does not cause a problem (by, for example, appending a checksum to the data at the end of transmission for retransmission in the event of an error).
- During data reception, the following will happen if one of the following edges is detected at the same time as, or 1 or 2 bus clocks earlier than, the stop bit sampling point: The edge becomes invalid and the data that follows may not be received normally. Consecutive frames must have intervals between them.
 - Falling edge of serial data (when ESCR:INV = 0)
 - Rising edge of serial data (when ESCR:INV = 1)

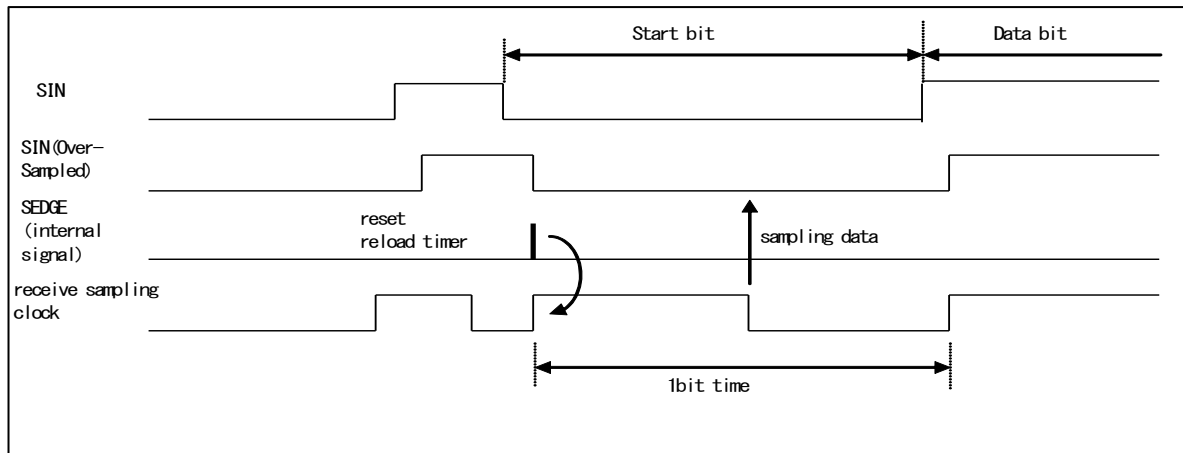

Clock Selection

- An internal clock or an external clock can be used.
- Set BGR1:EXT = 1 when using an external clock. In this case, the external clock is divided by a baud rate generator.

Start Bit Detection

- In the case of asynchronous mode, a start bit is identified by a falling edge of the SIN signal. Therefore, enabling reception operation (SCR:RXE = 1) does not start the reception operation unless there is a falling edge input of the SIN signal.
- When a falling edge of the start bit is detected, the reception reload counter of the baud rate generator is reset, reloaded again, and then starts counting down. This ensures that sampling is always performed in the center of the data.

Figure 3-2 Start Bit Detection

Stop Bit

- A bit length from 1 to 4 can be selected.
- The reception data full flag bit (SSR:RDRF) is set to "1" when the first stop bit is detected.

Error Detection

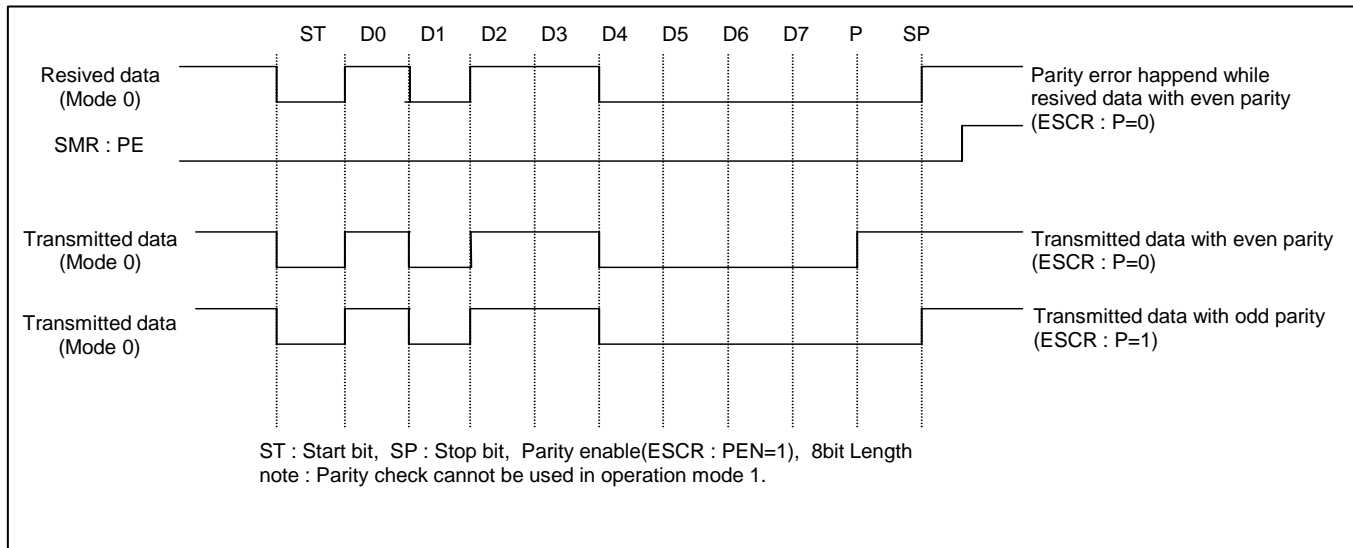

- Operation mode 0 allows the detection of parity errors, overrun errors, and framing errors.
- Operation mode 1 allows the detection of overrun errors and framing errors. The detection of parity errors is not possible.

Parity Bit

- A parity bit can be appended only in operation mode 0. The parity enable bit (ESCR:PEN) sets the presence or absence of parity check, while the parity selection bit (ESCR:P) sets even or odd parity.
- Parity check cannot be used in operation mode 1.

Figure 3-3 shows the transmission and reception data when parity check is enabled.

Figure 3-3 Operation with Parity Check Enabled

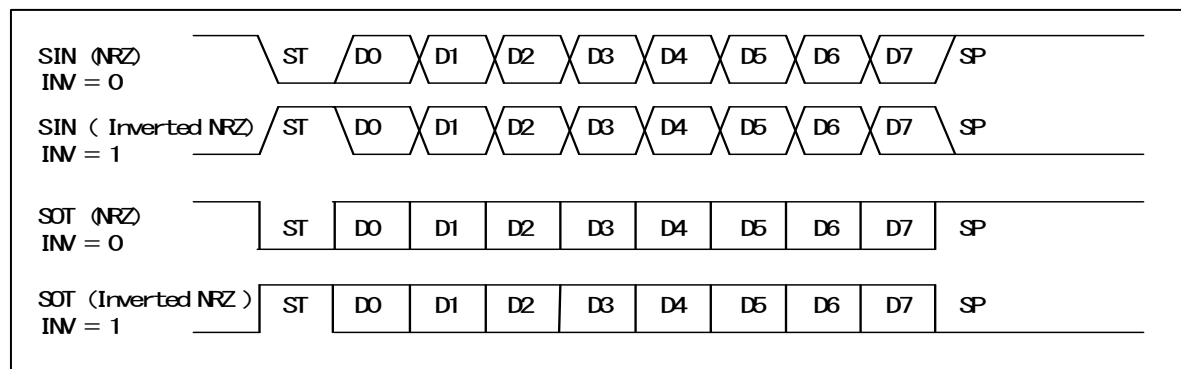

Data Signaling Method

- Setting of the INV bit in the extended communication control register selects the NRZ (Non Return to Zero) signaling method (ESCR:INV = 0) or the inverted NRZ signaling method (ESCR:INV = 1).

Figure 3-4 shows the NRZ signaling method and the inverted NRZ signaling method.

Figure 3-4 NRZ (Non Return to Zero) Signaling Method and Inverted NRZ Signaling Method

Data Transfer Method

- Either LSB first or MSB first can be selected as the data bit transfer method.

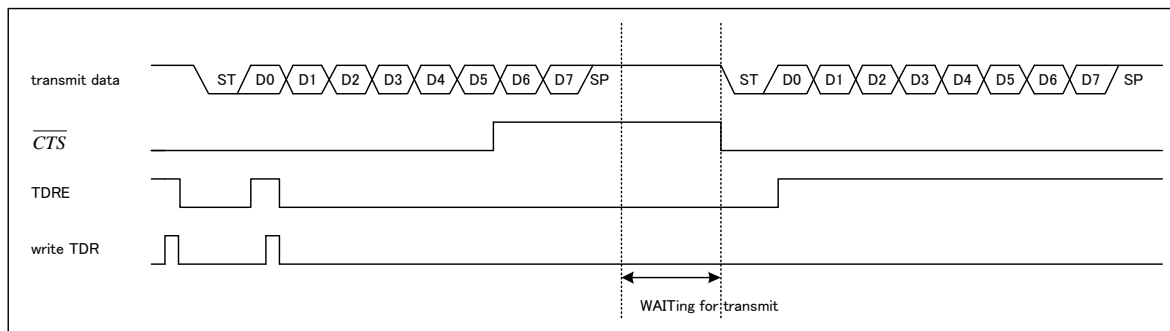

Hardware Flow Control

When flow control is enabled (ESCR:FLWEN = 1), UART performs hardware flow control.

■ During data transmission

If \overline{CTS} is "H" after data transmission, the next data is not transmitted even if data exists in the transmission buffer (TDRE = 0). Transmission of the data is suspended until \overline{CTS} becomes "L". To suspend transmission, set \overline{CTS} to "H" before the completion of the stop bit transmission. However, to suspend transmission when synchronous transmission is enabled (SACSR:TSYNE = 1, TMRE = 1), set \overline{CTS} to "H" before the start of transmission of the last stop bit. If \overline{CTS} is set to "H" during transmission, the transmission continues until after the stop bit.

Figure 3-5 Hardware Flow Control for Data Transmission
 (SMR:SBL = 0, ESCR:ESBL = INV = PEN = L2 = L1 = L0 = 0)

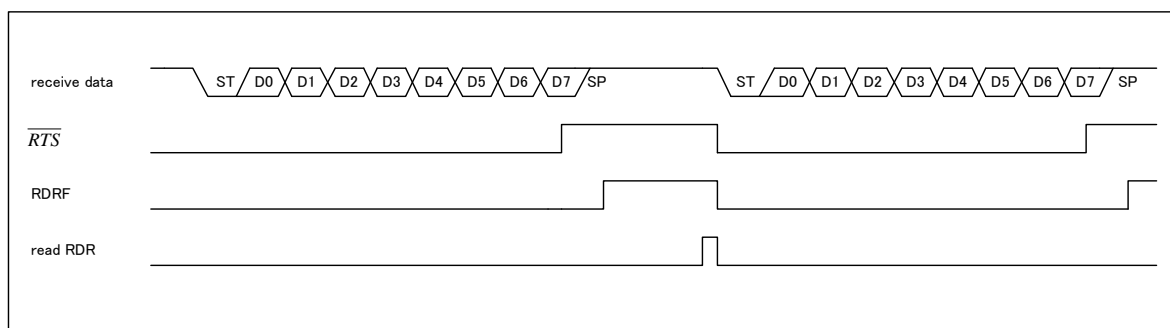

■ During data reception

- FIFO not used

\overline{RTS} outputs "H" upon the reception of the bit preceding the stop bit. After reading the reception data, \overline{RTS} outputs "L".

Figure 3-6 Hardware Flow Control for Data Reception (FIFO Not Used)
 (SMR:SBL = 0, ESCR:ESBL = INV = PEN = L2 = L1 = L0 = 0)

- FIFO used

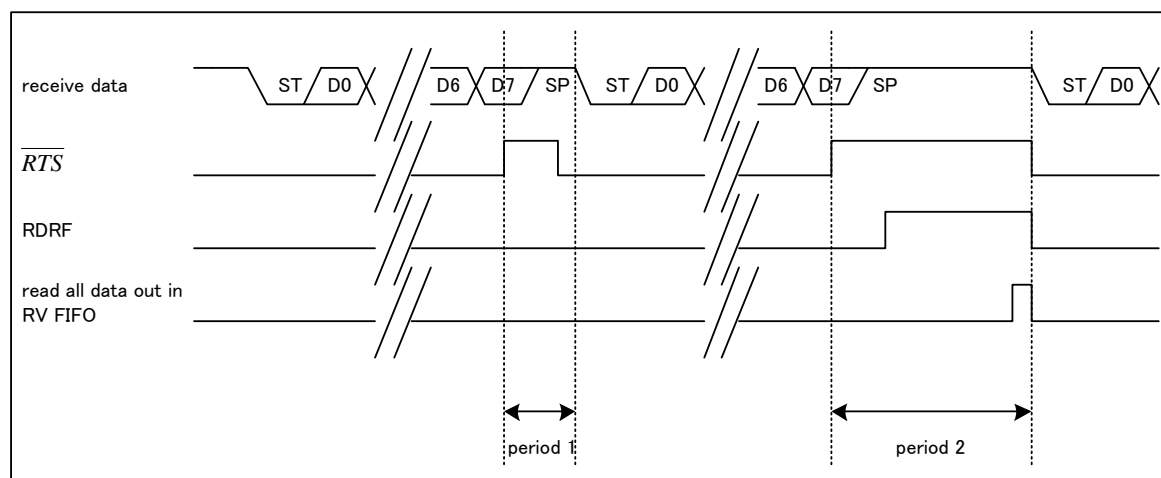

If SSR:RDRF is not set (if the reception FIFO has not received the predefined data count),

\overline{RTS} outputs "H" upon the reception of the bit preceding the stop bit. However, \overline{RTS} is set to "L" upon the detection of a stop bit. (period 1)

If SSR:RDRF is set (if the reception FIFO has received the predefined data count), \overline{RTS}

outputs "H" upon the reception of the bit preceding the stop bit. \overline{RTS} outputs "L" once all the reception FIFO data has been read. (period 2)

Figure 3-7 Hardware Flow Control for Data Reception (FIFO Used)
 (SMR:SBL = 0, ESCR:ESBL = INV = PEN = L2 = L1 = L0 = 0)

Notes:

- When reception operation is disabled ($RXE = 0$), the \overline{RTS} signal is fixed to "L".
- During the use of the reception FIFO, if both of the following conditions are satisfied, $RDRF$ is set to "1" when the reception idle condition continues for 8 baud rate clocks, but the \overline{RTS} signal remains at "L".
 - The reception FIFO idle detection enable bit (FCR1:FRIIE) is "1".
 - The reception FIFO contains data but the data count has not reached the predefined data count.
- Programmable reset ($SCR:UPCL = 1$) clears the \overline{RTS} signal to "L".

4. Serial Timer Operation

The serial timer can be used as either a timer function or a synchronous transmission function.

Serial Timer Operation

Activating the Serial Timer

The serial timer can be activated either by setting the serial timer enable bit (SACSR:TMRE) to "1" or by an external trigger.

■ Activation by the serial timer enable bit (SACSR:TMRE)

When the external trigger enable bit (SACSR:TRGE) is set to "0", setting the serial timer enable bit (SACSR:TMRE) to "1" activates the serial timer and causes the serial timer register (STMR) to start counting from 0.

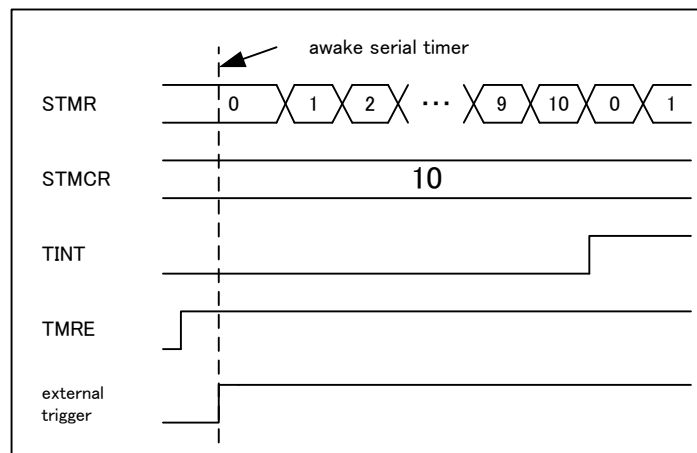

Figure 4-1 Activation by Serial Timer Enable Bit (STMCR = 10, SACSR:TRGE = 0, TSYNE = 0)

■ Activation by an external trigger

The serial timer is activated and the serial timer register (STMR) starts counting from 0 when all of the following are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is set to "1". 2. An external trigger edge specified by the trigger selection bit (TRG1, 0) is detected. 3. The serial timer enable bit (SACSR:TMRE) is set to "1".

Figure 4-2 Activation by an External Trigger (STMCR = 10, SACSR:TRGE = 1, TSYNE = 0, TRG1 = 0, TRG0 = 0)

Note:

- Detection of an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) does not start the serial timer if both of the following cases are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is "1". 2. The serial timer enable bit (SACSR:TMRE) is "0".

Stopping the Serial Timer

The serial timer stops when the serial timer enable bit (SACSR:TMRE) is set to "0". At that time, the value of the serial timer register (STMR) is retained.

Timer Operation

When the synchronous transmission enable bit (SACSR:TSYNE) is "0", the serial timer operates as a timer.

The timer interrupt flag (SACSR:TINT) is set to "1" and the serial timer register (STMR) is reset to 0 when the serial timer register (STMR) coincides with the serial timer comparison register (STMCR).

Figure 4-3 Timer Operation (STMCR = 10, SACSR:TSYNE = 0)

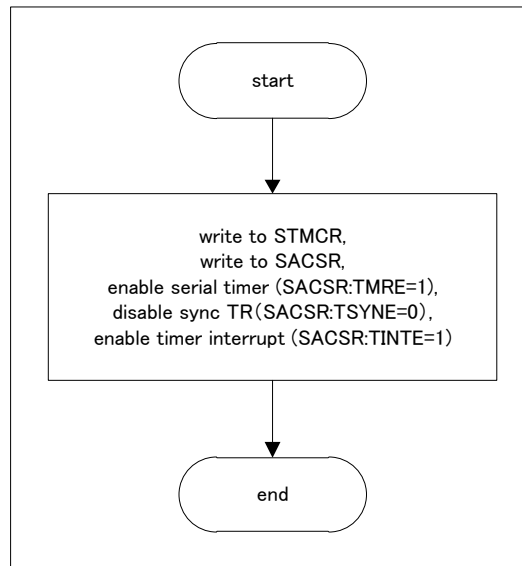

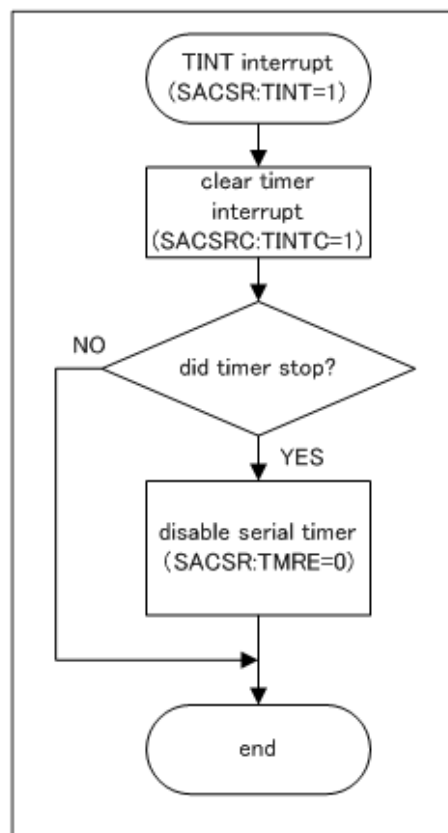

Figure 4-4 Flow Chart of Serial Timer Initialization

Figure 4-5 Flow Chart of Serial Timer Interrupt Processing

Note:

- In the state in which synchronous transmission is disabled (SACSr:TSYNE = 0) and 0x0000 is set in the timer comparison register (STMCR), if the timer is operating and the division value

(SACSR:TDIV3-0) of the timer operation clock is set to 0b0000, the timer interrupt flag (SACSR:TINT) is fixed to "1".

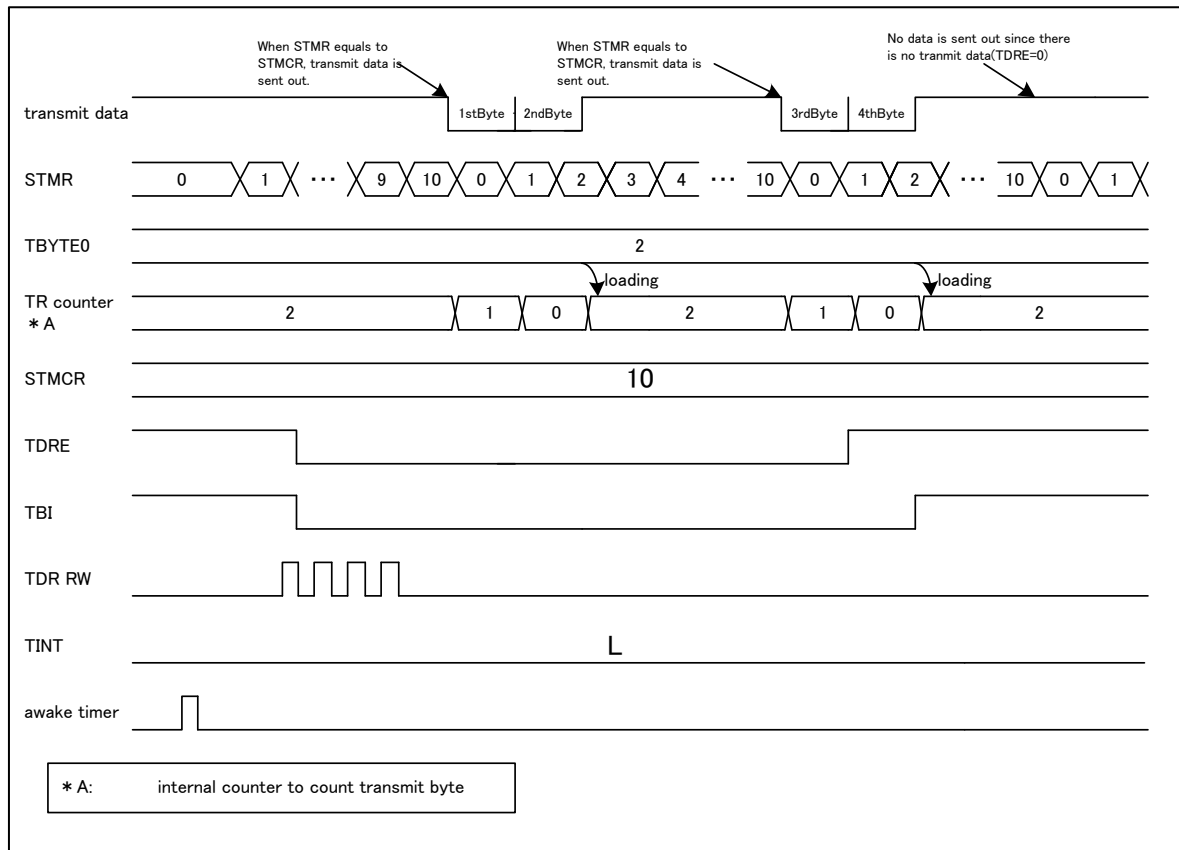

Transmission Operation Synchronized with the Timer

The serial timer is used for synchronous transmission when the synchronous transmission enable bit (SACSR:TSYNE) is "1".

Timer-synchronized transmission operates in the following manner:

1. If the transmission data register contains data (SSR:TDRE = 0) and if the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide, transmission operation starts, and the serial timer register (STMR) is reset to 0. Data transmission is performed for the data count specified in TBYTE0.
2. After transmitting the data count as specified by TBYTE0, transmission is suspended until the next time the serial timer register (STMR) and serial timer comparison register (STMCR) coincide.

Figure 4-6 Timer-Synchronized Transmission (SACSR:TSYNE = 1, STMR = 10, TBYTE0 = 2)

When synchronous transmission is enabled (SACSR:TSYNE = 1) and the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide, transmission is not activated under the following conditions:

- Transmission is disabled (SCR:TXE = 0).
- The transmission data register does not contain valid data (SSR:TDRE = 1).

However, writing transmission data to the transmission data register instantly starts transmission when all of the following are satisfied: 1. The transmission data register does not contain valid data

(SSR:TDRE = 1). 2. Synchronous transmission is enabled (SACSR:TSYNE = 1). 3. The serial timer register (STMR) and serial timer comparison register (STMCR) coincide.

If the transmission data register (TDR) contains valid data (SSR:TDRE = 0) after transmission of the data count specified by TBYTE0, the data is not transmitted until the next time the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide.

If, however, synchronous transmission is enabled (SACSR:TSYNE = 1) and transmission operation is in progress (SSR:TBI = 0), and the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide, a transmission reservation is made. If transmission reservation has been made, transmission does not stop after transmission of the data count specified by TBYTE0, and the subsequent transmission is performed.

Transmission reservation is released under one of the conditions below.

- Programmable reset (SCR:UPCL = 1)
- Transmission disabled (SCR:TXE = 0)

Figure 4-7 Flow Chart of Initialization of Transmission Synchronized with Timer

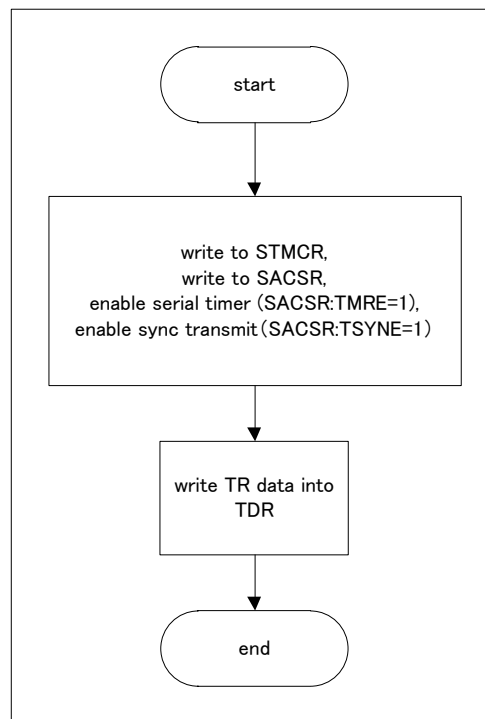

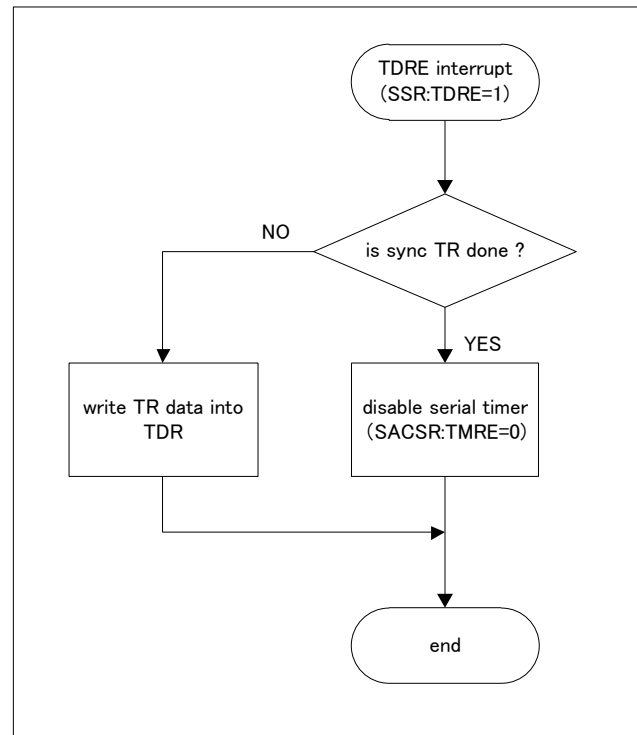

Figure 4-8 Flow Chart of Interrupt Processing in Transmission Synchronized with Timer**Notes:**

- If synchronous transmission is enabled (SACSR:TSYNE = 1), external triggers are enabled (SACSR:TRGE = 1), and (0000) H is set in the timer comparison register (STMCR), transmission synchronized with the timer is not performed, but transmission operation synchronized with an external trigger is performed.
- If the transmission data register (TDR) does not contain valid transmission data (SSR:TDRE = 1) before transmitting a data frame of the size specified by TBYTE0, transmission is suspended until the transmission data is written to the transmission data register (TDR). Writing transmission data to the transmission data register (TDR) restarts transmission.

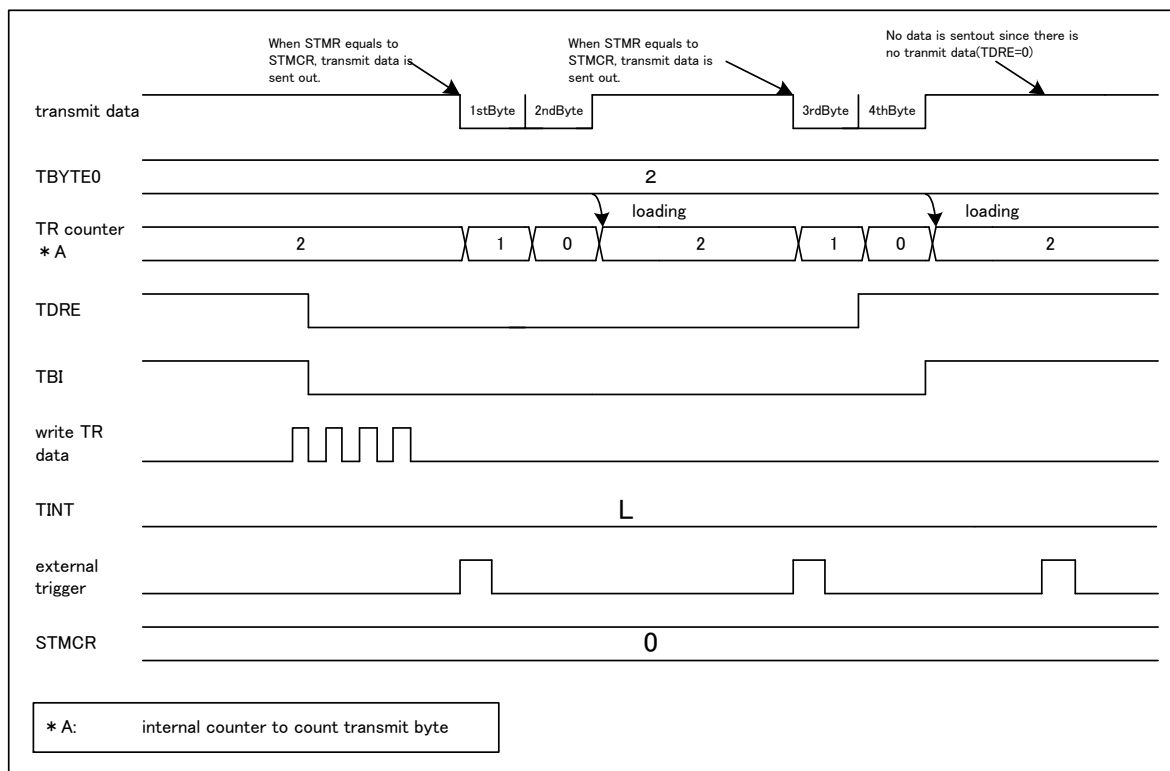

Transmission Operation Synchronized with an External Trigger

If synchronous transmission is enabled (SACSR:TSYNE = 1), external triggers are enabled (SACSR:TRGE = 1), (0000) H is set in the timer comparison register (STMCR), transmission is enabled (SCR:TXE = 1), and there is valid transmission data (SSR:TDRE = 0), transmission operation synchronized with an external trigger is started.

The start of transmission synchronized with an external trigger is performed as described below.

1. The operation starts immediately upon the detection of an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0). Data transmission is performed for the data count specified in TBYTE0.
2. After the completion of the transmission of the data count specified by TBYTE0, transmission is suspended until an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) is next detected.

Figure 4-9 External-Trigger-Synchronized Transmission (SACSR:TSYNE = 1, TRG1 = 0, TRG0 = 0)

During external-trigger-synchronized transmission, the detection of an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) does not start transmission under the following conditions:

- Transmission is disabled (SCR:TXE = 0).
- The transmission data register does not contain valid data (SSR:TDRE = 1).

However, writing transmission data to the transmission data register starts transmission immediately provided all of the following are satisfied: 1. The external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) is detected. 2. The transmission data register does not contain valid data (SSR:TDRE = 1).

If the transmission data register (TDR) contains valid data (SSR:TDRE = 0) after transmission of the data count specified by TBYTE0, the following occurs: The remaining data is not transmitted until an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) is next detected.

However, when an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) is detected during transmission (SSR:TBI = 0) with synchronous transmission enabled (SACSR:TSYNE = 1), transmission reservation is performed. If transmission reservation has been performed, transmission does not stop after transmission of the data count specified by TBYTE0, and the subsequent transmission occurs.

Transmission reservation is released under one of the conditions below.

- Programmable reset (SCR:UPCL = 1)
- Transmission disabled (SCR:TXE = 0)

Figure 4-10 Flow Chart of Initialization of Transmission Synchronized with External Trigger

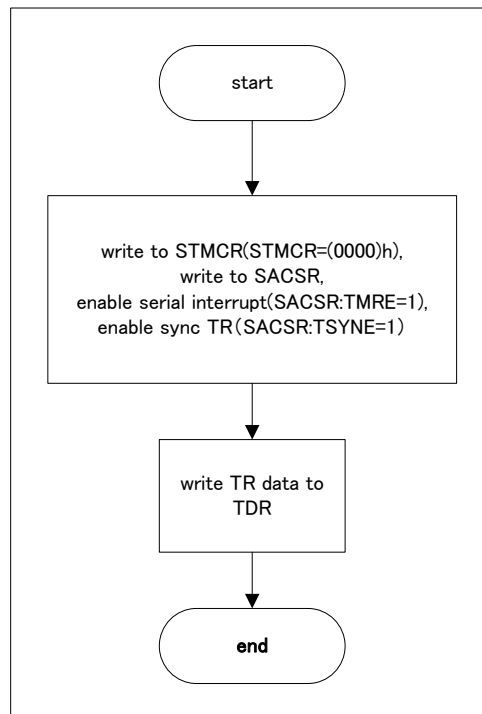

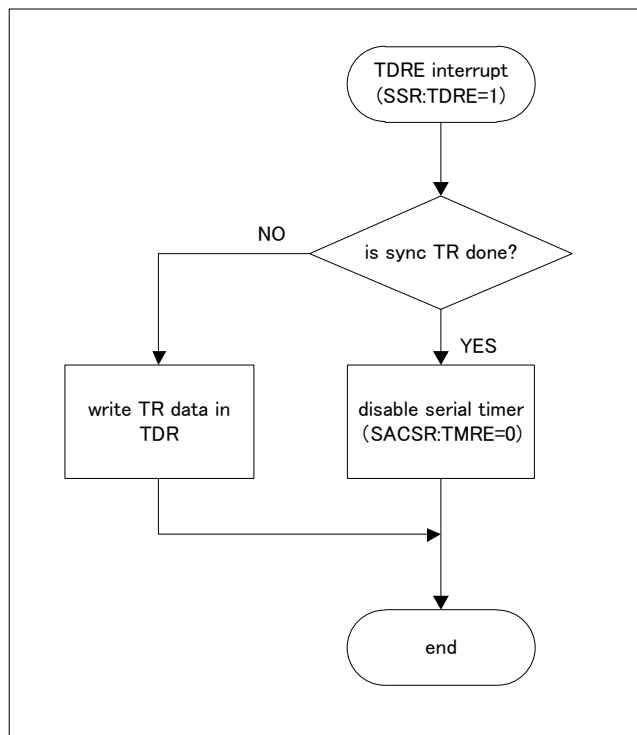

Figure 4-11 Flow Chart of Interrupt Processing in Transmission Synchronized with External Trigger

Note:

- If the transmission data register (TDR) does not contain valid transmission data (SSR:TDRE = 1) before transmitting a data frame of the size specified by TBYTE0, transmission is suspended until the transmission data is written to the transmission data register (TDR). Writing transmission data to the transmission data register (TDR) restarts transmission.

5. Test Mode

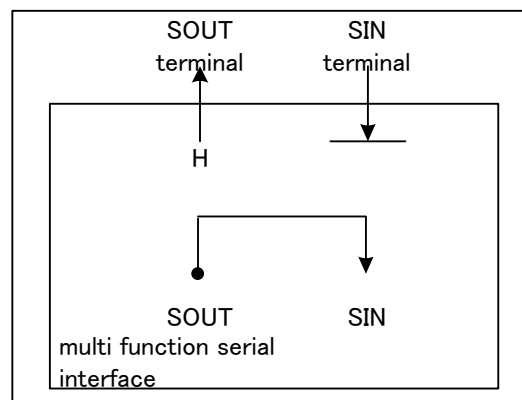

This section describes operation in a test mode.

Serial Test Mode

When serial test mode is enabled ($SACSR:STST = 1$), SOUT and SIN are connected together inside the multi-function serial interface, so that the data transmitted from SOUT can be received from SIN directly.

When serial test mode is enabled ($SACSR:STST = 1$), the SOUT pin is fixed to "H", and the data input to the SIN pin is ignored.

Figure 5-1 Serial Test Mode

Note:

- The value of the serial test mode enable bit ($SACSR:STST$) can be changed only when transmission and reception are prohibited ($SCR:TXE = RXE = 0$).

6. Dedicated Baud Rate Generator

A transmission and reception clock source for the UART can be selected from the following:

- Dedicated baud rate generator (reload counter)
- Input of an external clock to the baud rate generator (reload counter)

UART Baud Rate Selection

A baud rate can be selected from the following 2 types:

Baud Rate Obtained by Dividing the Internal Clock by the Dedicated Baud Rate Generator (Reload Counter)

There are 2 internal reload counters, each of which corresponds to the transmission or reception serial clock. A baud rate can be selected by setting a 15-bit reload value in baud rate generator register 1 or 0 (BGR1, BGR0).

The reload counters divide the internal clock according to the setting value.

Set the clock source by selecting an internal clock (BGR1:EXT = 0).

Baud Rate Obtained by Dividing an External Clock by the Dedicated Baud Rate Generator (Reload Counter)

An external clock is used as the clock source of the reload counter.

A baud rate can be selected by setting a 15-bit reload value in baud rate generator register 1 or 0 (BGR1, BGR0).

The reload counters divide the external clock according to the setting value.

Set a clock source by selecting an external clock and using a baud rate generator clock (BGR1:EXT = 1).

This mode is provided for dividing and using a special-frequency oscillator.

Notes:

- Set the external clock (BGR1:EXT = 1) under the condition whereby the reload counter is stopped (BGR1/0 = 0x0000).
- When the external clock setting is specified (BGR1:EXT = 1), the "H" width and "L" width of the external clock must be 2 bus clocks or more.

6.1. Setting the Baud Rate

This section describes baud rate setting. This section also describes the result of calculating the serial clock frequency.

Calculation of Baud Rate

The 2 15-bit reload counters are set by baud rate generator register 1, 0 (BGR1, BGR0).

The baud rate calculation formulas are shown below.

(1) Reload value:

$$V = \Phi / b - 1$$

V : reload value b : baud rate Φ : frequency of bus clock or that of external clock

(2) Calculation example

When bus clock is 16MHz, using internal clock, baud rate is 19200 bps, the reload value can be calculated as follows.

reload value :

$$V = (16 \times 1000000) / 19200 - 1 = 832$$

then baud rate will be

$$b = (16 \times 1000000) / (832 + 1) = 19208\text{bps}$$

(3) Baud rate error

The baud rate error is obtained using the following formula:

$$\text{error rate (\%)} = (\text{calculated value} - \text{target value}) / \text{target value} \times 100$$

(ex. When bus clock is 20MHz, target baud rate is 153600 bps,

the result will be as follows.

$$\text{reload value} = (20 \times 1000000) / 153600 - 1 = 129$$

$$\text{calculated baud rate} = 20 \times 1000000 / (129 + 1) = 153846 \text{ (bps)}$$

$$\text{error rate (\%)} = (153846 - 153600) / 153600 \times 100 = 0.16 \text{ (\%)}$$

Notes:

- Setting the reload value to "0" stops the reload counter.
- When the reload value is even, the "L" width of the reception serial clock is 1-bus-clock-cycle longer than the "H" width. When the reload value is odd, the "L" width and the "H" width of the serial clock are equal.
- Set the reload value to 4 or larger. However, data may not be received normally depending on baud rate errors and the reload value setting.
- When considering the tolerable baud rate range, also consider the impact of the jitter of the clock input to the macro.

Example of Reload Values and Baud Rate Settings for Individual Bus Clock Frequencies

The following table lists example reload values and baud rate settings.

Table 6-1 Example Reload Values and Baud Rate Settings

Baud Rate (bps)	8 MHz		10 MHz		16 MHz		20 MHz		24 MHz		32 MHz	
	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR
4 M	-	-	-	-	-	0	4	0	5	0	7	0
2.5 M	-	-	-	-	-	-	7	0	-	-	-	-
2 M	-	0	4	0	7	0	9	0	11	0	15	0
1 M	7	0	9	0	15	0	19	0	23	0	31	0
500000	15	0	19	0	31	0	39	0	47	0	63	0
460800	-	-	-	-	-	-	-	-	51	0.16	-	-
250000	31	0	39	0	63	0	79	0	95	0	127	0
230400	-	-	-	-	-	-	86	-0.22	103	0.16	138	-0.08
153600	51	0.16	64	0.16	103	0.16	129	0.16	155	0.16	207	0.16

Reception Baud Rate Tolerance

The following describes the degree of error in the receiver baud rate that is tolerable during reception.

Use the following formula to ensure that the baud rate errors during data reception fall within the tolerable range.

Figure 6-1 Reception Baud Rate Tolerance

After the detection of a start bit, the sampling timing of the reception data is determined by the counters set in registers BGR1/0, as shown in the figure. The data can be received normally provided all the data up to the last data (stop bit) is included within this sampling timing.

This theoretically gives the following for 11-bit data reception.

For a sampling timing margin of 1 bus clock cycle (Φ), the tolerable minimum transfer rate (FL_{min}) will be as follows:

$$FL_{min} = (11 \text{ bits} * (V + 1) - (V + 1) / 2 + 2) / \Phi = (21V + 25) / 2 \Phi \text{ (s)} \quad V: \text{Reload value}, \Phi: \text{Bus clock}$$

Therefore, the maximum receiver baud rate (BG_{max}) receivable will be as follows:

$$BG_{max} = 11 / FL_{min} = 22 \Phi / (21V + 25) \text{ (bps)} \quad V: \text{Reload value}, \Phi: \text{Bus clock}$$

When receiving data at the tolerable maximum transfer rate (FL_{max}), sampling is performed at the first point of the 11th-bit in the reception data.

Therefore, the tolerable maximum transfer rate (FL_{max}) will be as follows:

$$10 / 11 * FL_{max} = (11 \text{ bits} * (V + 1) - (V + 1) / 2) / \Phi \quad V: \text{Reload value}, \Phi: \text{Bus clock}$$

$$FL_{max} = (21 / 20 * 11 * (V + 1)) / \Phi$$

For a sampling timing margin (Φ) of 2 clock cycles, the tolerable maximum transfer rate (FL_{max}) will be as follows:

$$FL_{max} = (21 / 20 * 11 * (V + 1) - 2) / \Phi = (231V + 191) / 20 \Phi \text{ (s)} \quad V: \text{Reload value}, \Phi: \text{Bus clock}$$

Therefore, the minimum receiver baud rate (BG_{min}) receivable will be as follows:

$$BG_{min} = 11 / FL_{max} = 220 \Phi / (231V + 191) \text{ (bps)} \quad V: \text{Reload value}, \Phi: \text{Bus clock}$$

The tolerable baud rate errors for the UART and the receiver will be as follows, given the calculation formulas for the minimum and maximum baud rate values.

Reload Value (V)	Tolerable Maximum Baud Rate Error	Tolerable Minimum Baud Rate Error
3	0%	0
10	+2.98%	-3.24%
50	+4.37%	-4.44%
100	+4.56%	-4.60%
200	+4.66%	-4.68%
32767	+4.76%	-4.76%

Note:

- The receiving accuracy depends on the number of bits in a frame, the bus clock, and the reload value. A higher accuracy is achieved with a higher bus clock and a higher division ratio.

External Clock

Writing "1" to the EXT bit in the baud rate generator register (BGR1) causes the baud rate generator to divide the external clock.

Note:

- The external clock synchronizes with the internal clock of the UART. Therefore, the existence of an external clock that cannot be synchronized makes this operation unstable.

Reload Counter Function

There is both a transmission reload counter and a reception reload counter, which function as dedicated baud rate generators. These feature 15-bit registers for the reload values. They generate a transmission clock and a reception clock from either an external or internal clock.

Start of Counting

When a reload value is written to the baud rate generator registers (BGR1 and BGR0), the reload counters start counting.

Restarting

A reload counter restarts under the following conditions:

For both the Transmission and Reception Reload Counters

- Programmable reset (SCR:UPCL bit)

For the Reception Reload Counter

- Detection of the falling edge of the start bit in the asynchronous mode

7. Block Transfer

This section describes the operation of block transfer.

Setting Block Transfer

Block transfer can be performed for reception by setting RXBLKEN in the extended control register (ECR) to 1 and for transmission by setting TXBLKEN to 1.

Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).

The block size can be set with the transmission block size register and the FBYTE register (reception side).

The threshold at which to output a block transfer request can be set with the FBYTE register for reception and with the FTICR register for transmission. When the amount of data in the reception FIFO exceeds the setting made for the FBYTE register, a reception block transfer request is output. When the amount of free space in the transmission FIFO exceeds the setting made for the FTICR register, a transmission block transfer request is output.

7.1. RW Access Mode

This section describes block transfer in RW access mode.

Reception Block Transfer

Reception block transfer is performed as described below.

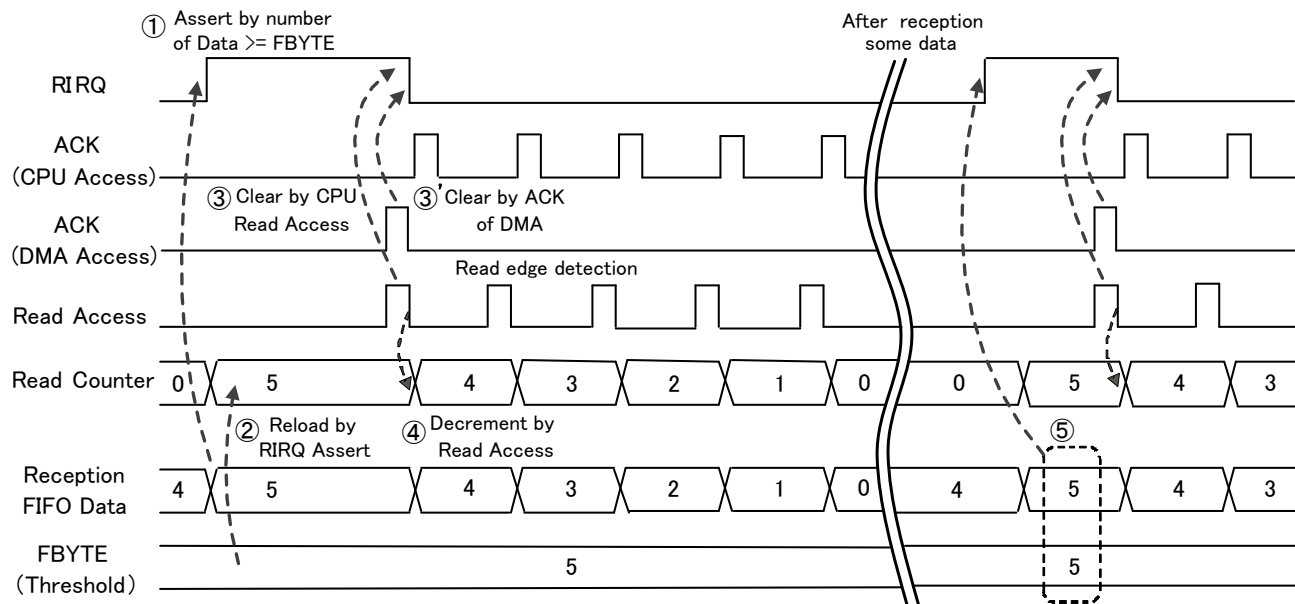

If the amount of data in the reception FIFO is same or more than the threshold (FBYTE), a reception block transfer request (RIRQ) is asserted. At this time, the value of the reception block size is reloaded from the FBYTE register to the Read counter. When the reception FIFO is not used, the value of the reception block size is "1".

After the reception block transfer request, if a read to the reception data occurs, the reception block transfer request (RIRQ) is cleared. With a read to the reception data, the Read counter is decremented.

When the Read counter becomes "0", if the amount of data in the reception FIFO is same or more than the threshold (FBYTE), the reception block transfer request (RIRQ) is asserted again. With the assertion of the reception block transfer request (RIRQ), the Read counter is reloaded.

During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Figure 7-1 Reception Block Transfer in RW Access Mode

Transmission Block Transfer

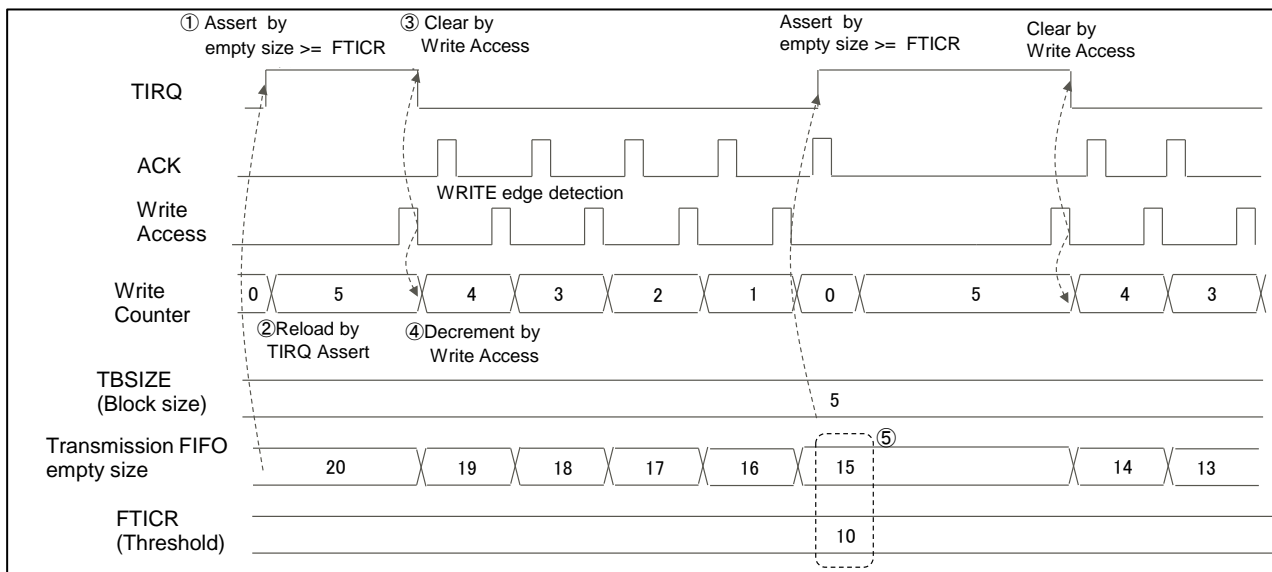

Transmission block transfer is performed as described below.

If the amount of free space in the transmission FIFO exceeds the threshold (FTICR), a transmission block transfer request (TIRQ) is asserted. At this time, the value of the transmission block size is reloaded from the TBSIZE register to the Write counter. When the transmission FIFO is not used, the value of the transmission block size is "1".

After the transmission block transfer request, if a write to the transmission data occurs, the transmission block transfer request (TIRQ) is cleared. With a write to the transmission data, the Write counter is decremented.

When the Write counter becomes "0", if the amount of free space in the transmission FIFO exceeds the threshold (FTICR), the transmission block transfer request (TIRQ) is asserted again. With the assertion of the transmission block transfer request (TIRQ), the Write counter is reloaded.

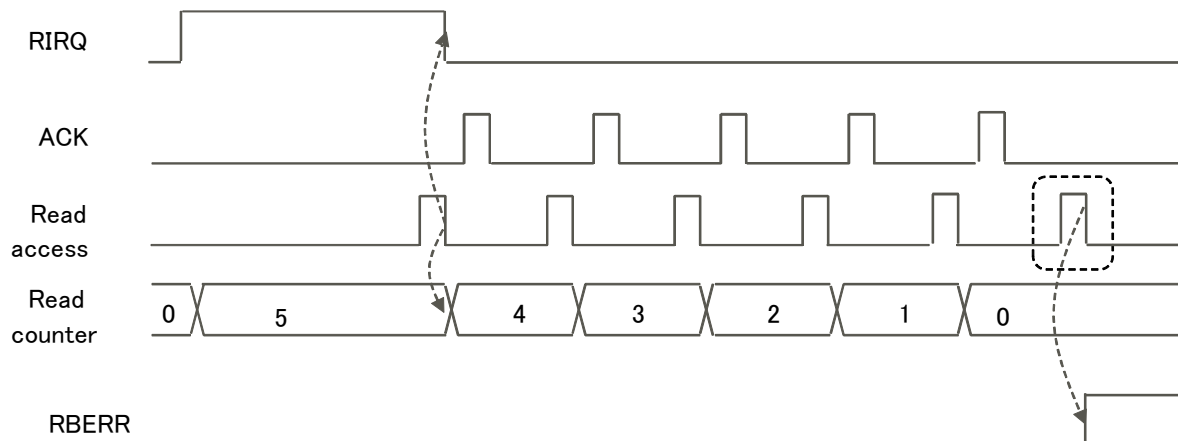

Figure 7-2 Transmission Block Transfer in RW Access Mode

Reception Block Transfer Error

If, while the Read counter is "0", a read access occurs before the next reception block transfer request (RIRQ) is asserted, a reception block transfer error occurs, and the ESR:RBERR bit is asserted.

Figure 7-3 Reception Block Transfer Error in RW Access Mode

Transmission Block Transfer Error

If, while the Write counter is "0", a write access occurs before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the ESR:TBERR bit is asserted.

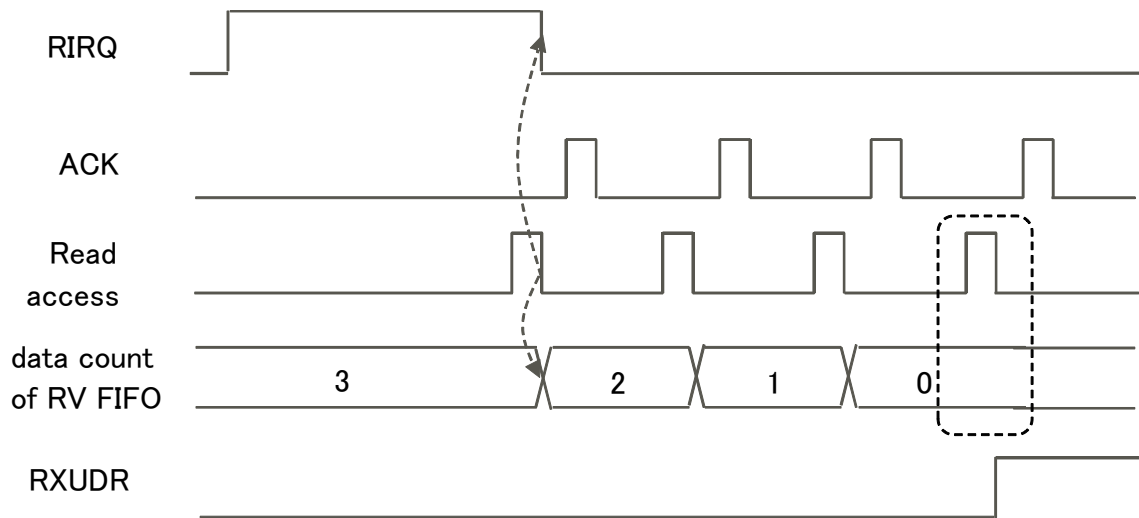

Figure 7-4 Transmission Block Transfer Error in RW Access Mode

Reception FIFO under Run

If, while the amount of data in the reception FIFO is "0", reception data is read from the reception FIFO, a reception FIFO under run occurs, and the ESR:RXUDR bit is asserted.

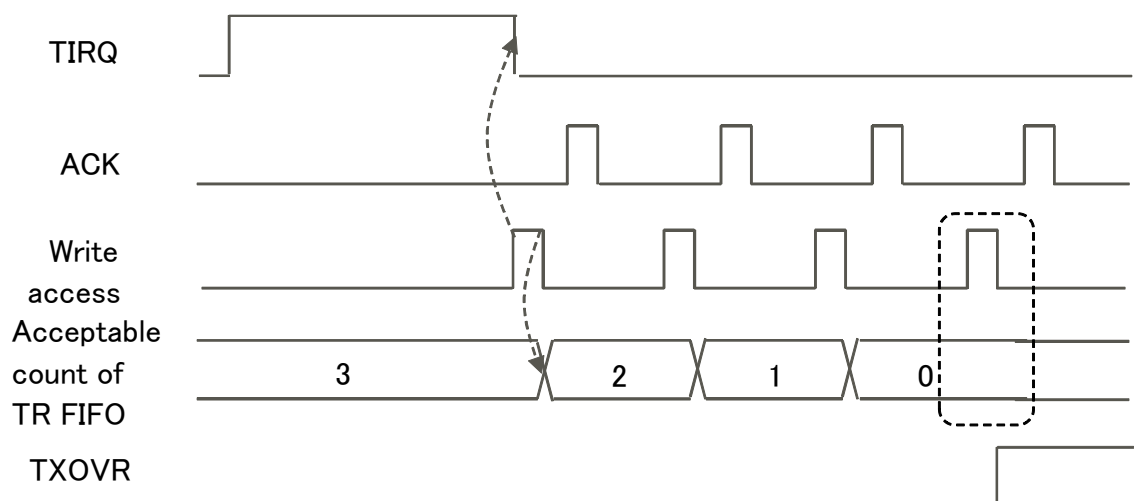

Figure 7-5 Reception FIFO Under Run in RW Access Mode

Transmission FIFO Overrun

If, while the amount of free space in the transmission FIFO is "0", transmission data is written to the transmission FIFO, a transmission FIFO overrun occurs, and the ESR:TXOVR bit is asserted.

Figure 7-6 Transmission FIFO Overrun in RW Access Mode

8. Setup Procedure and Program Flow for Operation Mode 0 (Asynchronous Normal Mode)

Operation mode 0 allows asynchronous serial bidirectional communication.

Connection between MCUs

Select bidirectional communication for operation mode 0 (normal mode). As shown in Figure 8-1, interconnect two MCUs.

Figure 8-1 Example of Bidirectional Communication Connection for UART Operation Mode 0 (Flow Control Prohibited)

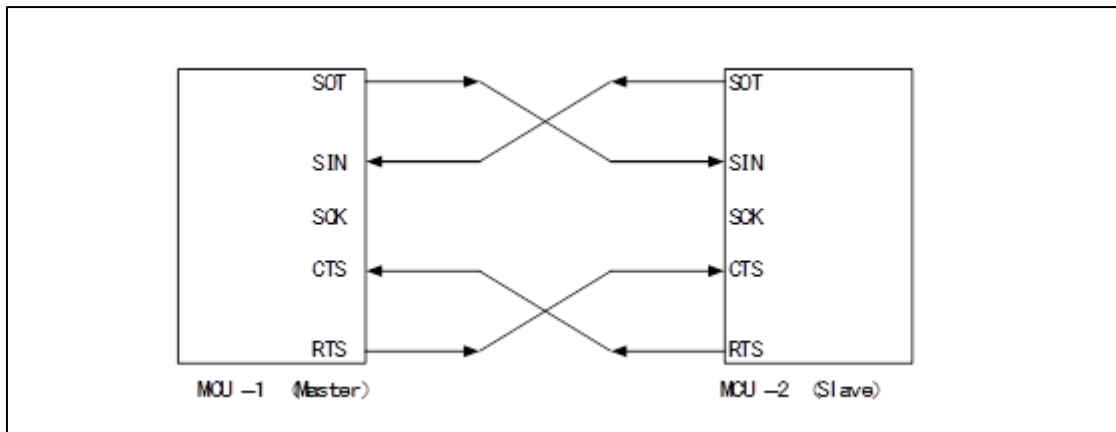

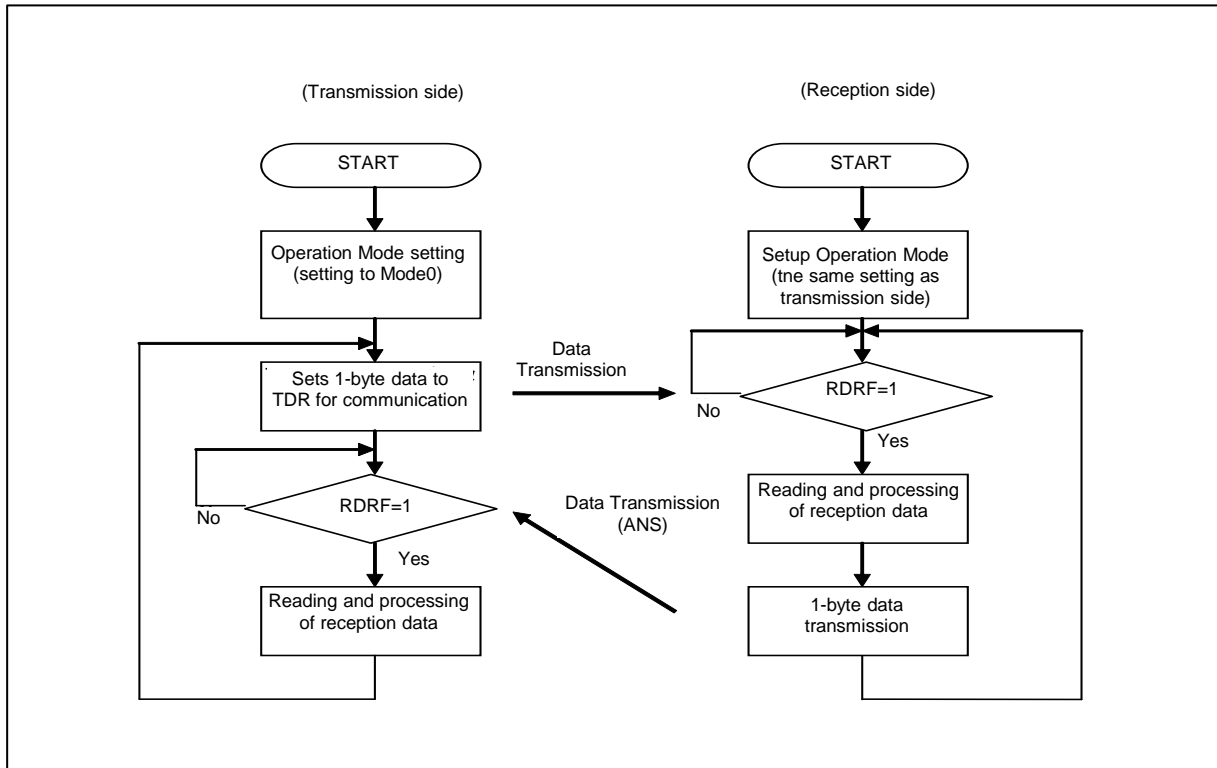

Figure 8-2 Example of Bidirectional Communication Connection for UART Operation Mode 0 (Flow Control)

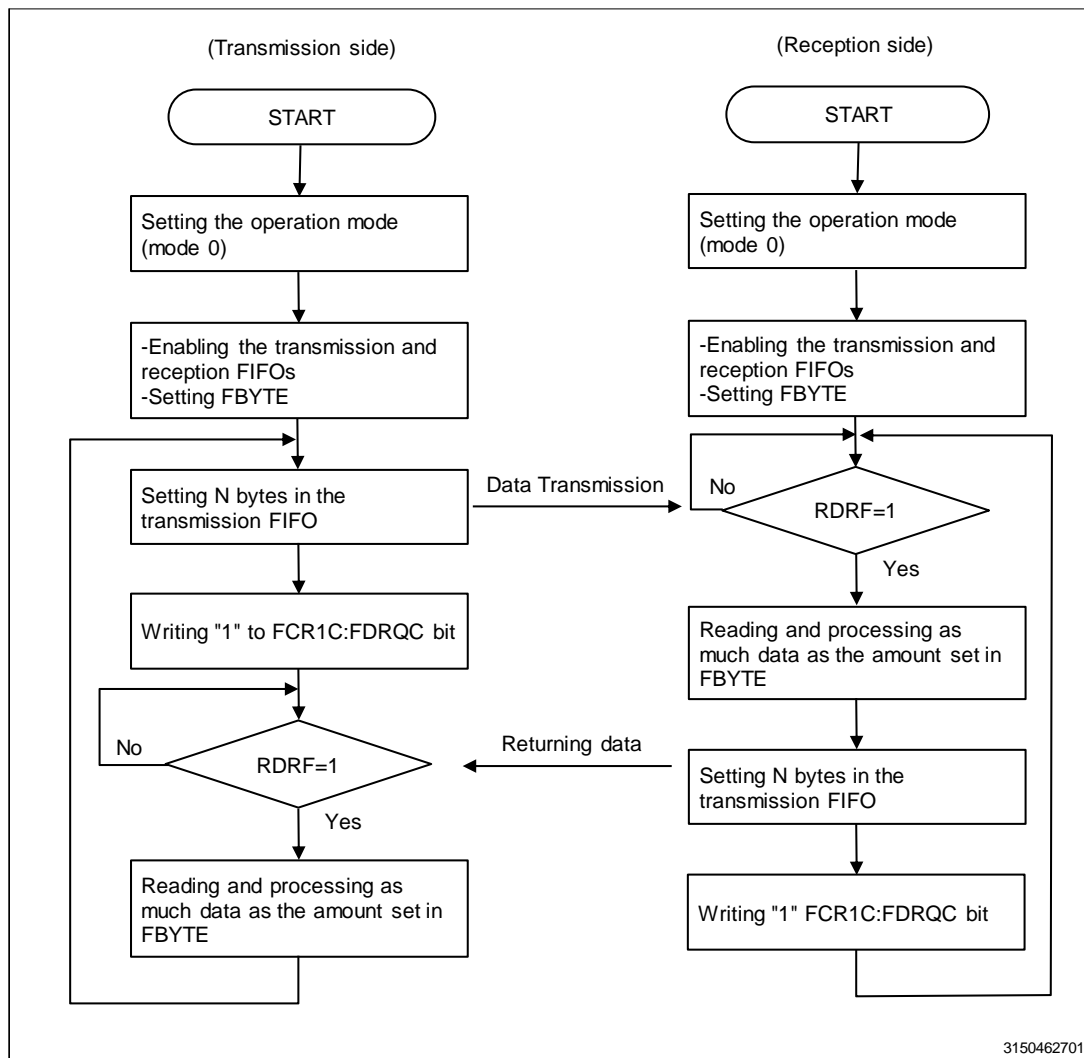

Flow Chart

FIFO Not Used

Figure 8-3 Example of Bidirectional Communication Flow Chart (FIFO Not Used)

FIFO Used**Figure 8-4 Example of Bidirectional Communication Flow Chart (FIFO Used)**

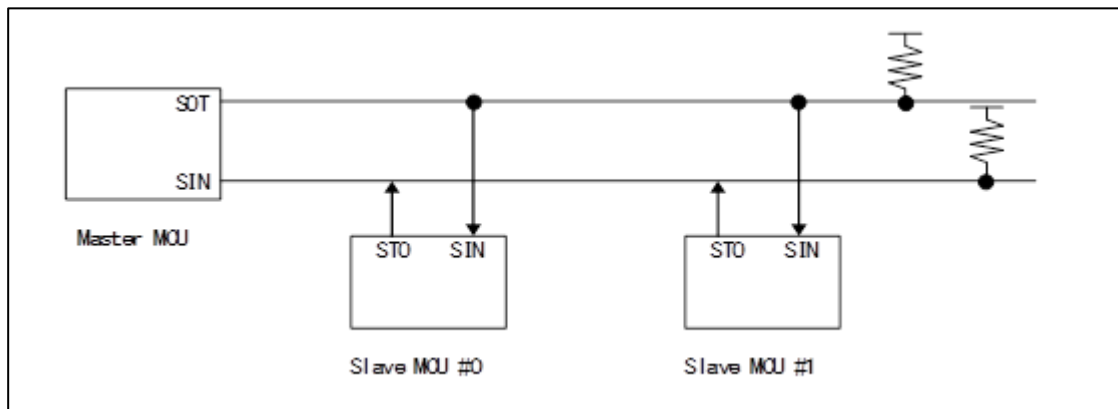

9. Setup Procedure and Program Flow for Operation Mode 1 (Asynchronous Multi-processor Mode)

Operation mode 1 (multi-processor mode) allows communication in master/slave connections of multiple MCUs. This mode can be used for master/slave-type communication.

Connection between MCUs

Master/slave-type communication enables a communication system that has 2 shared communication lines connecting 1 master MCU and multiple slave MCUs, as shown in the figure. The UART can be used either as a master or a slave.

Figure 9-1 Connection Example for UART Master/Slave-Type Communication

Function Selection

Select an operation mode and a data transfer method for master/slave-type communication as shown in Table 9-1.

Table 9-1 Selection of Master/Slave-Type Communication Function

	Operation Mode		Data	Parity	Stop Bit	Bit Direction
	Master MCU	Slave MCU				
Address Transmission/Reception	Mode 1 (A/D bit transmission)	Mode 1 (A/D bit reception)	AD = 1 + 7-bit or 8-bit address	None	1 bit or 2 bits	LSB or MSB first
Data Transmission/Reception			AD = 0 + 7-bit or 8-bit data			

Note:

- Access the transmission/reception data (TDR/RDR) in word units for operation mode 1.

Communication Procedure

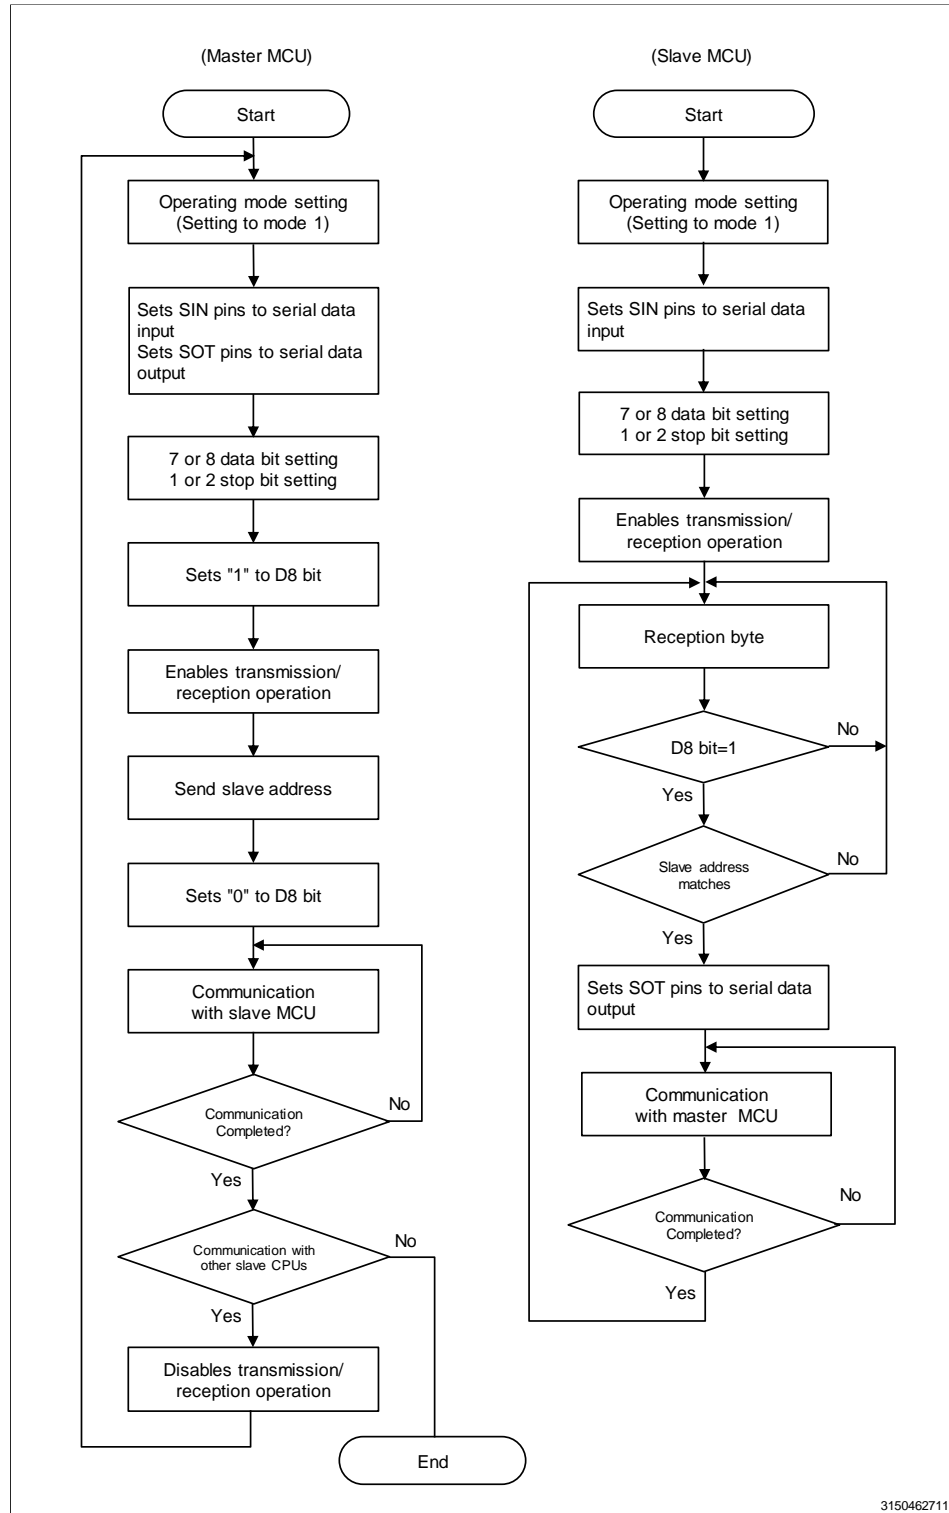

Communication starts when the master MCU transmits address data. Address data, for which the D8 bit is set to "1", selects the destination slave MCU. Each slave CPU checks the address data by its program, and if it coincides with the allocated address, the MCU communicates (by normal data) with the master MCU.

Figure 9-2 and Figure 9-3 provide flow charts of master/slave-type communication (multi-processor mode).

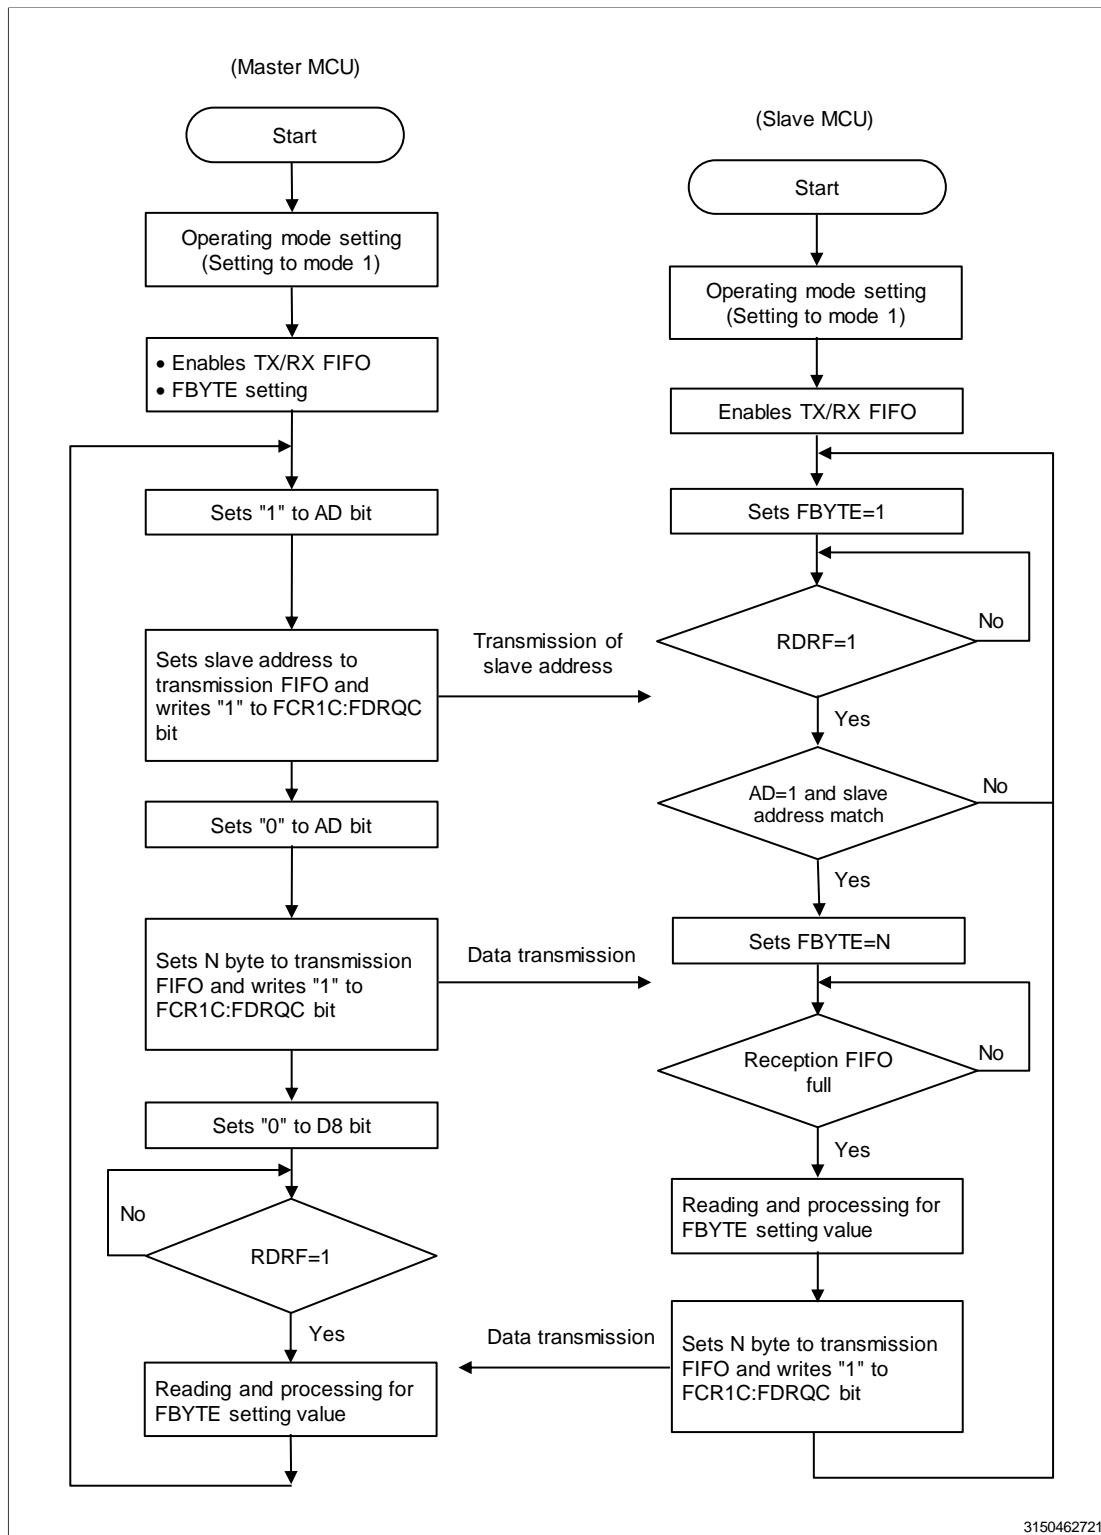

Flow Chart

FIFO Not Used

Figure 9-2 Example of Flow Chart of Master/Slave-Type Communication (FIFO Not Used)

*1: Access with a mirror address area

Operation Mode

The UART (Asynchronous Serial Interface) can operate in either of 2 modes. The operation mode is determined by MD2, MD1, and MD0 in the serial mode register (SMR).

Table 10-2 Operation Modes of UART (Asynchronous Serial Interface)

Operation Mode	MD2	MD1	MD0	Type
0	0	0	0	UART0 (asynchronous normal mode)
1	0	0	1	UART1 (asynchronous multi-processor mode)

10.1. Serial Control Register (SCR)

The serial control register (SCR) can be used for permission/prohibition of transmission and reception, permission/prohibition of transmission and reception interrupts, permission/prohibition of transmission bus idle interrupts, and UART reset.

Serial Control Register (SCR)

Figure 10-1 shows the bit configuration of the serial control register (SCR).

Figure 10-1 Bit Configuration of Serial Control Register (SCR)

Bit	15	14	13	12	11	10	9	8
Field	UPCL	Reserved		RIE	TIE	TBIE	RXE	TXE
R/W Attribute	R0,W	R0,W0		R/W	R/W	R/W	R/W	R/W
Protection attribute	-							
Initial Value	0	00		0	0	0	0	0

Lower byte [bit7:0] of this register is Serial Mode Register (SMR)

[bit15] UPCL: Programmable Clear Bit

This bit initializes the UART's internal status.

When "1" is set:

- UART is directly reset (software reset). However, the register settings are retained. At this time, transmission and reception communications are immediately disconnected.
- The baud rate generator reloads the setting values for the BGR1/0 registers and restarts.
- All transmission and reception communications and status interrupt factors (SSR:PE, FRE, ORE, RDRF, TDRE, TBI, SACS: TINT) are initialized to 0b0000110.
- The \overline{RTS} signal is cleared to "L".

When "0" is set:

There is no effect.

When it is read, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Programmable clear	

Notes:

- Execute programmable clear immediately after setting interrupt prohibition.
- When FIFO is used, prohibit FIFO (FCR0:FE2, FE1 = 0) before executing programmable clear.
- Executing programmable clear (SCR:UPCL = 1) does not clear the value of the serial timer register (STMR).

[bit14:13] Reserved: Reserved Bits

[bit12] RIE: Reception Interrupt Enable Bit

- This bit enables/disables reception interrupt request output to the CPU.
- When ECR:EISEL = 0, and the RIE bit and the reception data flag bit (SSR:RDRF) are "1" or one of the error flag bits (SSR:PE, ORE, FRE, ESR:RXUDR, and RBERR) is "1", a reception interrupt request is issued.
- When ECR:EISEL = 1, and the RIE bit and the reception data flag bit (SSR:RDRF) are "1", a reception interrupt request is issued.

Bit	Description
0	Disable reception interrupts.
1	Enable reception interrupts.

[bit11] TIE: Transmission Interrupt Enable Bit

- This bit enables/disables transmission interrupt request output to the CPU.
- When ECR:EISEL = 0, and the TIE bit and the SSR:TDRE bit are "1" or one of the error flag bits (ESR:TXOVR and TBERR) is "1", a transmission interrupt request is issued.
- When ECR:EISEL = 1, and the TIE bit and the SSR:TDRE bit are "1", a transmission interrupt request is issued.

Bit	Description
0	Disable transmission interrupts.
1	Enable transmission interrupts.

[bit10] TBIE: Transmission Bus Idle Interrupt Enable Bit

- This bit enables/disables transmission bus idle interrupt request output to the CPU.
- A transmission bus idle interrupt request is issued when the TBIE bit and the TBI bit are "1".

Bit	Description
0	Disable transmission bus idle interrupts.
1	Enable transmission bus idle interrupts.

[bit9] RXE: Reception Operation Enable Bit

This bit enables/disables UART reception operation.

- "0": Disable reception operation.
- "1": Enable reception operation.

Bit	Description
0	Disable reception.
1	Enable reception.

Note:

- Even if reception operation is enabled (RXE = 1), reception does not start unless there is a falling edge of a start bit (for NRZ format (ESCR:INV = 0)). (For inverted NRZ format (ESCR:INV = 1), reception does not start unless there is a rising edge.)

- If reception operation is disabled ($RXE = 0$) during reception, the operation is stopped immediately.
- When reception operation is disabled ($RXE = 0$), the \overline{RTS} signal is fixed to "L".

[bit8] TXE: Transmission Operation Enable Bit

This bit enables/disables UART transmission operation.

- "0": Disable transmission operation.
- "1": Enable transmission operation.

Bit	Description
0	Disable transmission.
1	Enable transmission.

Note:

- If transmission operation is disabled ($TXE = 0$) during transmission, the operation is stopped immediately.

10.2. Serial Mode Register (SMR)

The serial mode register (SMR) is responsible for the following: 1. Operation mode setting, 2. Selection of the transfer direction, the data length, and the stop bit length, and 3. Settings of enabling/disabling of output on the serial data and clock pins.

Serial Mode Register (SMR)

Figure 10-2 shows the bit configuration of the serial mode register (SMR).

Figure 10-2 Bit Configuration of Serial Mode Register (SMR)

Bit	7	6	5	4	3	2	1	0
Field	MD2	MD1	MD0	WUCR	SBL	BDS	Reserved	SOE
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R0,W0	R/W
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit7:5] MD[2:0]: Operation Mode Setting Bits

These bits set the operation mode of the Asynchronous Serial Interface.

Bits			Description
0	0	0	Operation mode 0 (asynchronous normal mode)
0	0	1	Operation mode 1 (asynchronous multi-processor mode)
0	1	0	Operation mode 2 (clock synchronous mode)
0	1	1	Operation mode 3 (LIN communication mode)
1	0	0	Operation mode 4 (I2C mode)

* This section describes the registers and their operations in operation mode 0 and operation mode 1.

Notes:

- Settings other than those described above are prohibited.
- To switch the operation mode, execute programmable clear (SCR:UPCL = 1) and then switch the operation mode.
- Set the registers after setting the operation mode.

[bit4] WUCR: WAKE UP Control Bit

WUCR is not supported

This bit selects the pin to be used for external interrupts.

"0": Set the INT pin for external interrupts.

"1": Set the SIN pin for external interrupts.

Bit	Description
0	Disable the WAKE UP function.
1	Enable the WAKE UP function.

Note:

- The WAKE UP function is not supported.

[bit3] SBL: Stop Bit Length Selection Bit

This bit sets the length of the stop bits (the frame end mark of the transmission data).

Settings for which SBL is "0" and ESCR:ESBL is "0": The stop bit length is set to 1 bit.

Settings for which SBL is "1" and ESCR:ESBL is "0": The stop bit length is set to 2 bits.

Settings for which SBL is "0" and ESCR:ESBL is "1": The stop bit length is set to 3 bits.

Settings for which SBL is "1" and ESCR:ESBL is "1": The stop bit length is set to 4 bits.

Bit	Description	
0	ESCR.ESBL = 0	1 bit
	ESCR.ESBL = 1	3 bits
1	ESCR.ESBL = 0	2 bits
	ESCR.ESBL = 1	4 bits

Notes:

- Reception always detects only the first stop bit.
- Set this bit when transmission is disabled (SCR:TXE = 0).

[bit2] BDS: Transfer Direction Selection Bit

This bit selects between whether the lowest bit is transferred first (LSB first, BDS = 0) or the highest bit is transferred first (MSB first, BDS = 1), for transfer serial data.

Bit	Description
0	LSB first (lowest bit transferred first)
1	MSB first (highest bit transferred first)

Note:

- Set this bit when transmission and reception are disabled (SCR:TXE = SCR:RXE = 0).

[bit1] Reserved: Reserved Bit**[bit0] SOE: Serial Data Output Enable Bit**

This bit enables/stops the output of serial data.

Bit	Description
0	Stop the serial data output.
1	Enable the serial data output.

10.3. Serial Status Register (SSR)

The serial status register (SSR) checks the transmission and reception status, checks the reception error flag, and clears the reception error flag.

Serial Status Register (SSR)

Figure 10-3 shows the bit configuration of the serial status register (SSR).

Figure 10-3 Bit Configuration of Serial Status Register (SSR)

Bit	15	14	13	12	11	10	9	8
Field	REC	Reserved	PE	FRE	ORE	RDRF	TDRE	TBI
R/W Attribute	R0,W	R0,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-							
Initial Value	0	0	0	0	0	0	1	1

* Lower byte [bit7:0] of this register is Extended Communication Control Register (ESCR)

[bit15] REC: Reception Error Flag Clear Bit

This bit clears the PE, FRE, and ORE flags in the serial status register (SSR).

- Writing "1" clears the error flags.
- Writing "0" does not have any effect.

If it is read, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Clear the reception error flags (PE, FRE, and ORE).	

[bit14] Reserved: Reserved Bit

[bit13] PE: Parity Error Flag Bit (Effective Only in Operation Mode 0)

- This bit is set to "1" when a parity error occurs in data reception with ESCR:PEN = 1, and is cleared when writing "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is issued when the PE bit and the SCR:RIE bit are both "1".
- For details on the output of interrupt requests, see Table 2-3.
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when the reception FIFO is used, the reception FIFO enable bits will be cleared, and no reception data will be stored in the reception FIFO.

Bit	Description
0	No parity error
1	Parity error found

Note:

- This bit is reset by the Software reset (SCR:UPCL=1).

[bit12] FRE: Framing Error Flag Bit

- This bit is set to "1" when a framing error occurs in data reception, and is cleared when writing "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is issued when the FRE bit and the SCR:RIE bit are both "1".
- For details on the output of interrupt requests, see Table 2-3.
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when the reception FIFO is used, the reception FIFO enable bits will be cleared, and no reception data will be stored in the reception FIFO.

Bit	Description
0	No framing error
1	Framing error found

Note:

- This bit is reset by the Software reset (SCR:UPCL=1).

[bit11] ORE: Overrun Error Flag Bit

- This bit is set to "1" when an overrun error occurs in data reception, and is cleared when writing "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is issued when the ORE bit and the SCR:RIE bit are both "1".
- For details on the output of interrupt requests, see Table 2-3.
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when the reception FIFO is used, the reception FIFO enable bits will be cleared, and no reception data will be stored in the reception FIFO.

Bit	Description
0	No overrun error
1	Overrun error found

Note:

- This bit is reset by the Software reset (SCR:UPCL=1).

[bit10] RDRF: Reception Data Full Flag Bit

- This flag indicates the status of the reception data register (RDR).
- This flag is set to "1" when reception data is loaded to RDR, and is cleared to "0" when the data in the reception data register (RDR) is read.
- A reception interrupt request is issued when the RDRF bit and the SCR:RIE bit are both "1".
- When the reception FIFO is used, if the reception FIFO receives a prescribed data count, RDRF is set to "1".
- When the reception FIFO is used, if both of the conditions below are satisfied, and the reception idle state continues for at least 8 clock pulses of the baud rate clock, RDRF is set to "1".
 - The reception FIFO idle detection enable bit (FCR1:FRIIE) is "1".
 - The reception FIFO has not received a prescribed data count, and data remains in the reception FIFO.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again.

- When ECR:RXBLKEN = 0, and the reception FIFO is used, this bit is cleared to "0" when the reception FIFO becomes empty by reading data from it.
- When ECR:RXBLKEN = 1, and the reception FIFO is used, this bit is cleared to "0" when the data count in the reception FIFO becomes equal to or less than the setting of the FBYTE register.

Bit	Description
0	The reception data register (RDR) is empty.
1	The reception data register RDR contains data.

Notes:

- When the reception FIFO is used and RDRF has become "1", resetting the reception FIFO (FCR0:FCL2, FCL1 = 1) does not result in RDRF being set to "0". Therefore, in order to set RDRF to "0" after resetting the reception FIFO, perform a dummy read of the reception data register during the reception disable status (SCR:RXE = 0).
- This bit is reset by the Software reset (SCR:UPCL=1).

[bit9] TDRE: Transmission Data Empty Flag Bit

- This flag indicates the status of the transmission data register (TDR).
- Writing transmission data to TDR sets this bit to "0", indicating that TDR contains valid data. Loading the data to the transmission shift register to start transmission sets this bit to "1", indicating that TDR does not contain valid data.
- A transmission interrupt request is issued when the TDRE bit and the SCR:TIE bit are both "1".
- The TDRE bit is set to "1" by the programmable clear (SCR:UPCL=1) is executed.
- For set/reset timing of the TDRE bit when the transmission FIFO is used, see "CHAPTER 36:2.4 Occurrence of Interrupts and Flag Set Timing When the Transmission FIFO Is Used."

Bit	Description
0	The transmission data register (TDR) contains data.
1	The transmission data register is empty.

[bit8] TBI: Transmission Bus Idle Flag Bit

- This bit indicates that the UART is not performing transmission.
- This bit is set to "0" when transmission data is written to the transmission data register (TDR).
- This bit is set to "1" during periods in which the transmission data register is empty (TDRE = 1) and transmission is not being performed.
- The TBI bit is set to "1" by the programmable clear (SCR:UPCL=1) is executed.
- A transmission interrupt request is issued if this bit is set to "1" and a transmission bus idle interrupt is enabled (SCR:TBIE = 1).

Bit	Description
0	Transmission in progress
1	No transmission operation

10.4. Extended Communication Control Register (ESCR)

The extended communication control register (ESCR) sets the transmission and reception data length, enables/disables the parity bits, selects a parity bit, inverts the serial data format, and selects a stop bit length.

Bit Configuration of the Extended Communication Control Register (ESCR)

Figure 10-4 shows the bit configuration of the extended communication control register (ESCR).

Figure 10-4 Bit Configuration of Extended Communication Control Register (ESCR)

Bit	7	6	5	4	3	2	1	0
Field	FLWEN	ESBL	INV	PEN	P	L2	L1	L0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit7] FLWEN: Flow Control Enable Bit

This bit enables or disables hardware flow control.

- "0": Disable hardware flow control.
- "1": Enable hardware flow control.

Bit	Description
0	Disable hardware flow control.
1	Enable hardware flow control.

Notes:

- Set this bit when transmission and reception are disabled (SCR:TXE = 0, RXE = 0).
- Set this bit to "1" only when performing hardware flow control.

[bit6] ESBL: Extended Stop Bit Length Selection Bit

This bit sets the length of the stop bits (the frame end mark of the transmission data).

Settings for which SBL is "0" and ESCR:ESBL is "0": The stop bit length is set to 1 bit.

Settings for which SBL is "1" and ESCR:ESBL is "0": The stop bit length is set to 2 bits.

Settings for which SBL is "0" and ESCR:ESBL is "1": The stop bit length is set to 3 bits.

Settings for which SBL is "1" and ESCR:ESBL is "1": The stop bit length is set to 4 bits.

Bit	Extended Stop Bit Length	
0	SMR.SBL = 0	1 bit
	SMR.SBL = 1	2 bits
1	SMR.SBL = 0	3 bits
	SMR.SBL = 1	4 bits

Notes:

- Reception always detects only the first stop bit.
- Set this bit when transmission is disabled (SCR:TXE = 0).

[bit5] INV: Inverted Serial Data Format Bit

This bit selects the NRZ format or the inverted NRZ format as the serial data format.

Bit	Description
0	NRZ format
1	Inverted NRZ format

[bit4] PEN: Parity Enable Bit (Effective Only in Operation Mode 0)

This bit specifies whether to append (in transmission) and detect (in reception) parity bits.

- "0": Parity bits are not appended.
- "1": Parity bits are appended.

Bit	Description
0	Disable parity.
1	Enable parity.

Note:

- This bit is internally fixed to "0" in operation mode 1.

[bit3] P: Parity Selection Bit (Effective Only in Operation Mode 0)

This bit selects the odd parity "1" or the even parity "0" when parity check is enabled (ESCR:PEN = 1).

- "0": Set even parity.
- "1": Set odd parity.

Bit	Description
0	Even parity
1	Odd parity

[bit2:0] L[2:0]: Data Length Selection Bits

These bits specify the data length of the transmission/reception data.

- 0b000: The data length is 8 bits.
- 0b001: The data length is 5 bits.
- 0b010: The data length is 6 bits.
- 0b011: The data length is 7 bits.
- 0b100: The data length is 9 bits.

Bits			Data Length
0	0	0	8-bit length
0	0	1	5-bit length
0	1	0	6-bit length
0	1	1	7-bit length
1	0	0	9-bit length

Notes:

- Values other than the above are prohibited.
- Change these bits when transmission and reception are disabled (SCR:TXE = RXE = 0).
- Set the data length to 7 or 8 bits for operation mode 1. Other values are prohibited.

10.5. Reception Data Register/Transmission Data Register (RDR/TDR)

The reception data register and the transmission data register are placed at the same address. If read, the register functions as a reception data register, and if written to, it functions as a transmission register. When FIFO operation is enabled, the RDR/TDR address is the FIFO read/write address.

Reception Data Register (RDR)

Figure 10-5 shows the bit configuration of the serial reception register (RDR).

Figure 10-5 Bit Configuration of Reception Data Register (RDR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved							D8
R/W Attribute	R0							R
Protection attribute	-							
Initial Value	00000000							0

Bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute	R	R	R	R	R	R	R	R
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

The reception data register (RDR) is a 9-bit data buffer register for serial data reception.

- Serial data signals transmitted to the serial input pin (SIN pin) are converted by the shift register, and are stored in the reception data register (RDR).
- Higher bits are padded with "0s" depending on the data length, as follows:

Data Length	D8	D7	D6	D5	D4	D3	D2	D1	D0
9 bits	X	X	X	X	X	X	X	X	X
8 bits	0	X	X	X	X	X	X	X	X
7 bits	0	0	X	X	X	X	X	X	X
6 bits	0	0	0	X	X	X	X	X	X
5 bits	0	0	0	0	X	X	X	X	X

(X represents a reception data bit.)

- The reception data full flag bit (SSR:RDRF) is set to "1" when reception data is stored in the reception data register (RDR). A reception interrupt request occurs if the reception interrupt is enabled (SCR:RIE = 1).
- Read the reception data register (RDR) when the reception data full flag bit (SSR:RDRF) is "1". The reception data full flag bit (SSR:RDRF) is automatically cleared to "0" when reading data from the reception data register (RDR).
- If a reception error occurs (when SSR:PE, ORE, or FRE becomes "1"), the data in the reception data register (RDR) will be invalid.
- In operation mode 1 (multi-processor mode), the data length is 7 or 8 bits, and the received AD bit is stored in the D8 bit.
- In the case of 9-bit transfer or in operation mode 1, RDR is read in 16-bit access.

Notes:

- *When the reception FIFO is used, SSR:RDRF is set to "1" when a predefined amount of data is received by the reception FIFO.*
- *When the reception FIFO is used, SSR:RDRF is cleared to "0" when the reception FIFO becomes empty.*
- *When a reception error occurs (when SSR:PE, ORE, or FRE becomes "1") during use of the reception FIFO, the enable bit in the reception FIFO is cleared and the reception data is not stored in the reception FIFO.*

Transmission Data Register (TDR)

Figure 10-6 shows the bit configuration of the transmission data register.

Figure 10-6 Bit Configuration of Transmission Data Register (TDR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved							D8
R/W Attribute	WX							W
Protection attribute	-							
Initial Value	0000000							1

Bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute	W	W	W	W	W	W	W	W
Protection attribute	-							
Initial Value	1	1	1	1	1	1	1	1

The transmission data register (TDR) is a 9-bit data buffer register for serial data transmission.

- When data to be transmitted is written to the transmission data register (TDR) while transmission is enabled (SCR:TXE = 1), the transmission data is transferred to the transmission shift register. The transmission data is converted to serial data and sent out from the serial data output pin (SOUT pin).
- Bits are invalidated in descending order depending on the data length, as follows:

Data Length	D8	D7	D6	D5	D4	D3	D2	D1	D0
9 bits	X	X	X	X	X	X	X	X	X
8 bits	Invalid	X	X	X	X	X	X	X	X
7 bits	Invalid	Invalid	X	X	X	X	X	X	X
6 bits	Invalid	Invalid	Invalid	X	X	X	X	X	X
5 bits	Invalid	Invalid	Invalid	Invalid	X	X	X	X	X

- The transmission data empty flag (SSR:TDRE) is cleared to "0" when transmission data is written to the transmission data register (TDR).
- If the transmission FIFO is disabled or empty, the transmission data empty flag (SSR:TDRE) is set to "1" when transmission data is transferred to the transmission shift register to start transmission.
- When the transmission data empty flag (SSR:TDRE) is "1", transmission data can be written. A transmission interrupt occurs if the transmission interrupt is enabled. Write transmission data after the occurrence of a transmission interrupt or when the transmission data empty flag (SSR:TDRE) is "1".
- When the transmission data empty flag (SSR:TDRE) is "0" and the transmission FIFO is disabled or full, transmission data cannot be written.
- In operation mode 1 (multi-processor mode), the data length is 7 or 8 bits, and the AD bit is transmitted by writing it to the D8 bit.
- In the case of 9-bit transfer or in operation mode 1, write data to TDR by 16-bit access.

Notes:

- The transmission data register is a write-only register, and the reception data register is a read-only register. Because the transmission and reception registers are allocated at the same address, the write value and the read value are different.

- *For the set timing for the transmission data empty flag (SSR:TDRE) when the transmission FIFO is used, see "CHAPTER 36:2.4 Occurrence of Interrupts and Flag Set Timing When the Transmission FIFO Is Used."*

10.6. Serial Auxiliary Control Status Register (SACSR)

The serial auxiliary control status register (SACSR) performs the following: 1. Controlling serial test operation, 2. selecting a serial timer activation method, 3. enabling/disabling timer interrupts, 4. enabling/disabling synchronous transmission, 5. setting division value of the serial timer operation clock, and 6. enabling/disabling the serial timer.

Bit Configuration of the Serial Auxiliary Control Status Register (SACSR)

Figure 10-7 shows the bit configuration of the serial auxiliary control status register (SACSR).

Figure 10-7 Bit Configuration of Serial Auxiliary Control Status Register (SACSR)

Bit	15	14	13	12	11	10	9	8
Field	STST	Reserved				TRG1	TRG0	TINT
R/W Attribute	R/W	RX,WX				R/W	R/W	R
Protection attribute	-							
Initial Value	0	0000				0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TINTE	TSYNE	TRGE	TDIV3	TDIV2	TDIV1	TDIV0	TMRE
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit15] STST: Serial Test Bit

This bit enables or disables serial test mode.

When serial test mode is enabled, SOUT and SIN are connected together inside the multi-function serial interface, so that the data transmitted from SOUT can be received from SIN directly.

When serial test mode is enabled, the SOUT pin is fixed to "H", and any data input to the SIN pin is ignored.

- This bit is reset when the SACSRC:STSTC bit in the clear register is set to "1".
- This bit is set when the SACSRS:STSTS bit in the set register is set to "1".

Bit	Serial Test Bit
0	Disable the serial test mode.
1	Enable the serial test mode.

Note:

- This bit can be changed only when transmission/reception are disabled (SCR:TXE = 0, SCR:RXE = 0).

[bit14:11] Reserved: Reserved Bits

[bit10:9] TRG[1:0]: Trigger Selection Bits

These bits select the method for detecting external trigger edges for activating the serial timer.

Bits		Edge Detection Method for External Trigger
0	0	Rising edge detection
0	1	Falling edge detection
1	0	Both edge detection
1	1	Setting prohibited

Notes:

- These bits are invalid if the external trigger enable bit (TRGE) is "0".
- These bits can be changed only when the serial timer enable bit (TMRE) is "0".

[bit8] TINT: Timer Interrupt Flag

If the serial timer register (STMR) and the serial timer comparison register (STMCR) match, the serial timer register (STMR) is set to "0", and this bit is set to "1".

When this bit is "1" and the timer interrupt enable bit (TINTE) is "1", a status interrupt request is issued.

Writing to this bit is invalid.

- This bit is reset when the SACSRC:TINTC bit in the clear register is set to "1".

Bit	Description
0	No timer interrupt request
1	Timer interrupt request issued

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is not set to "1" when the synchronous transmission enable bit (TSYNE) is "1".

[bit7] TINTE: Timer Interrupt Enable Bit

This bit enables/disables timer interrupts to the CPU.

When this bit is "1" and the timer interrupt flag (TINT) is "1", a status interrupt request is issued.

- This bit is reset when the SACSRC:TINTEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TINTES bit in the set register is set to "1".

Bit	Description
0	Disable interrupts triggered by the serial timer.
1	Enable interrupts triggered by the serial timer.

[bit6] TSYNE: Synchronous Transmission Enable Bit

This bit enables or disables synchronous transmission.

Transmission is activated if this bit is "1" and in any of the cases below.

- The serial timer register (STMR) and the serial timer comparison register (STMCR) coincide at the time of timer-synchronized transmission.
- An external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) is detected at the time of external-trigger-synchronized transmission.
- This bit is reset when the SACSRC:TSYNEC bit in the clear register is set to "1".
- This bit is set when the SACSRC:TSYNEC bit in the set register is set to "1".

Bit	Description
0	Disable synchronous transmission. The serial timer is used as a timer.
1	Enable synchronous transmission. The serial timer is not used as a timer.

Notes:

- This bit can be changed only when the serial timer enable bit (TMRE) is "0".
- When synchronous transmission is enabled (TSYNE = 1), if transmission is disabled (SCR:TXE = 0), transmission is not activated even in any of the following cases.
 - The serial timer register (STMR) and the serial timer comparison register (STMCR) coincide at the time of timer-synchronized transmission.
 - An external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) is detected at the time of external-trigger-synchronized transmission.

[bit5] TRGE: External Trigger Enable Bit

This bit selects a way to activate the serial timer.

- This bit is reset when the SACSRC:TRGEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TRGES bit in the set register is set to "1".

Bit	Description
0	The serial timer starts when the serial timer enable bit (TMRE) is changed from "0" to "1".
1	If the serial timer enable bit (TMRE) is set to "1", the detection of an external trigger edge specified by the trigger selection bits (TRG1, 0) starts the serial timer.

Notes:

- This bit can be changed only when the serial timer enable bit (TMRE) is "0".
- If the serial timer enable bit (TMRE) is set to "0", the detection of an external trigger edge specified by the trigger selection bits (TRG1, 0) does not start the serial timer.
- When synchronous transmission is enabled (SACSR:TSYNE = 1), external triggers are enabled (SACSR:TRGE = 1), the timer comparison register (STMCR) is set to 0x0000, and the serial timer is enabled (SACSR:TMRE = 1), transmission is activated in synchronization with an external trigger.

[bit4:1] TDIV3, TDIV2, TDIV1, TDIV0: Timer Operation Clock Division Bits

These bits set the division ratio of the serial timer.

TDIV3	TDIV2	TDIV1	TDIV0	Timer Operation Clock						
				Division Ratio	Φ = 8 MHz	Φ = 10 MHz	Φ = 16 MHz	Φ = 20 MHz	Φ = 24 MHz	Φ = 32 MHz
0	0	0	0	Φ	125 ns	100 ns	62.5 ns	50 ns	41.67 ns	31.25 ns
0	0	0	1	$\Phi/2$	250 ns	200 ns	125 ns	100 ns	83.33 ns	62.5 ns
0	0	1	0	$\Phi/4$	500 ns	400 ns	250 ns	200 ns	166.67 ns	125 ns
0	0	1	1	$\Phi/8$	1 μ s	800 ns	500 ns	400 ns	333.33 ns	250 ns
0	1	0	0	$\Phi/16$	2 μ s	1.6 μ s	1 μ s	800 ns	666.67 ns	500 ns
0	1	0	1	$\Phi/32$	4 μ s	3.2 μ s	2 μ s	1.6 μ s	1.33 μ s	1 μ s
0	1	1	0	$\Phi/64$	8 μ s	6.4 μ s	4 μ s	3.2 μ s	2.67 μ s	2 μ s
0	1	1	1	$\Phi/128$	16 μ s	12.8 μ s	8 μ s	6.4 μ s	5.33 μ s	4 μ s
1	0	0	0	$\Phi/256$	32 μ s	25.6 μ s	16 μ s	12.8 μ s	10.67 μ s	8 μ s

Φ : Bus clock

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is "0".
- Settings other than the above are prohibited.

[bit0] TMRE: Serial Timer Enable Bit

This bit enables or disables the serial timer operation.

- This bit is reset when the SACSRC:TMREC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TMRES bit in the set register is set to "1".

Bit	Description
0	Stop the serial timer operation. When stopped, the value of the serial timer register (STMR) is retained.
1	Changing this bit from "0" to "1" initializes the serial timer register (STMR) to "0" and starts the operation of the serial timer.

Notes:

- If the external trigger is enabled ($TRGE = 1$), setting this bit to "1" does not start the serial timer until the detection of an external trigger edge as specified by the trigger selection bits (SACSR:TRG1, 0).
- For serial timer synchronous transmission or external trigger transmission, change this bit from "0" to "1" if transmission is disabled.

10.7. Serial Timer Register (STMR)

The serial timer register (STMR) represents the timer value of the serial timer.

Bit Configuration of the Serial Timer Register (STMR)

Figure 10-8 shows the bit configuration of the serial timer register (STMR).

Figure 10-8 Bit Configuration of Serial Timer Register (STMR)

Bit	15	14	13	12	11	10	9	8
Field	TM15	TM14	TM13	TM12	TM11	TM10	TM9	TM8
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TM7	TM6	TM5	TM4	TM3	TM2	TM1	TM0
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TM15-0: Timer Data Bits

These bits indicate the timer value of the serial timer.

During timer operation, the timer value of the serial timer is incremented by 1 for each timer operation clock (specified by SACSr:TDIV3 to TDIV0).

Note:

- These bits are initialized to "0" when the timer operation starts.

10.8. Serial Timer Comparison Register (STMCR)

The serial timer comparison register (STMCR) sets the timer comparison value for the serial timer.

Bit Configuration of the Serial Timer Comparison Register (STMCR)

Figure 10-9 shows the bit configuration of the serial timer comparison register (STMCR).

Figure 10-9 Bit Configuration of Serial Timer Comparison Register (STMCR)

Bit	15	14	13	12	11	10	9	8
Field	TC15	TC14	TC13	TC12	TC11	TC10	TC9	TC8
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TC7	TC6	TC5	TC4	TC3	TC2	TC1	TC0

Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TC15-0: Compare Bits

These bits set a comparison value for the serial timer.

These bits are compared with the serial timer register (STMR). If the serial timer register (STMR) coincides with these bits when the serial timer register is updated, the serial timer register is set to "0". At that time, if synchronous transmission is disabled (SACSR:TSYNE = 0), the timer interrupt flag (SACSR:TINT) is set to "1". If synchronous transmission is enabled (SACSR:TSYNE = 1), transmission is activated.

The interval of the operations below is (STMCR:TC + 1) * timer operation clock (specified by SACSR:TDIV3 to TDIV0).

- SACSR:TINT is set to "1".
- Serial-timer-synchronized transmission is activated.

Notes:

- The timer interrupt flag (SACSR:TINT) is fixed to "1" when all of the following conditions are satisfied.
 - Synchronous transmission is disabled (SACSR:TSYNE = 0).
 - 0x0000 is set in this register.
 - Timer operating
 - Set the timer operating clock division value (SACSR:TDIV[3:0]) to 0b0000.
- When all of the following conditions are satisfied, transmission starts immediately upon the detection of an edge of the external trigger specified by the trigger selection bits (SACSR:TRG1, 0).

- Synchronous transmission is enabled (SACSR:TSYNE = 1).
- External trigger is enabled (SACSR:TRGE = 1).
- 0x0000 is set in this register.
- Transmission is enabled (SCR:TXE = 1), and transmission data exists (SSR:TDRE = 0).
- *This register can be changed only when the serial timer is disabled (SACSR:TMRE = 0).*

10.9. Transfer Byte Register (TBYTE0)

The transfer byte (TBYTE0) represents the transfer data amount when synchronous transmission or external trigger transmission starts.

Bit Configuration of the Transfer Byte Register (TBYTE0)

Figure 10-10 shows the bit configuration of the transfer byte register (TBYTE0).

Figure 10-10 Bit Configuration of Transfer Byte Register (TBYTE0)

Bit	7	6	5	4	3	2	1	0
Field	TBYTE0							
R/W Attribute	R/W							
Protection attribute	-							
Initial Value	00000000							

[bit7:0] TBYTE0: Transfer Byte Register

The transfer byte register 0 (TBYTE0) is used for synchronous transmission or external trigger transmission. The data amount set in TBYTE0 is transferred when synchronous transmission or external trigger transmission starts.

TBYTE0	Description
Write	Writing to TBYTE0
Read	Setting of TBYTE0

Note:

- If one of these bits is set to 0x00, the transfer count is 8.

10.10. Baud Rate Generator Register 1, 0 (BGR1, BGR0)

The baud rate generator register 1, 0 (BGR1, BGR0) set the division ratio of the serial clock. An external clock can also be selected as the clock source of the reload counter.

Bit Configuration of the Baud Rate Generator Register 1, 0 (BGR1, BGR0)

Figure 10-11 shows the bit configuration of baud rate generator register 1, 0 (BGR1, BGR0).

Figure 10-11 Bit Configuration of Baud Rate Generator Register 1, 0 (BGR1, BGR0)

Bit	15	14	13	12	11	10	9	8
Field	EXT	BGR1						
R/W Attribute	R/W	R/W						
Protection attribute	-							
Initial Value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	BGR0							
R/W Attribute	R/W							
Protection attribute	-							
Initial Value	00000000							

- The baud rate generator registers set the division ratio of the serial clock.
- BGR1 represents the higher bits while BGR0 represents the lower bits. The reload value for counting can be written to these registers, while the currently set reload values can be read from these registers.
- The reload counter starts counting when a reload value is written to baud rate generator register 0, 1 (BGR1, BGR0).
- The EXT bit, bit15, selects the internal clock or an external clock as the clock source of the reload counter. EXT = 0 selects the internal clock. EXT = 1 selects an external clock.

[bit15] EXT: External Clock Selection Bit

Bit	Description
0	Use the internal clock.
1	Use an external clock.

[bit14:8] BGR1: Baud Rate Generator Register 1

BGR1	Description
Write	Write to reload counter bits 8 to 14.
Read	Read the setting value of BGR1.

[bit7:0] BGR0: Baud Rate Generator Register 0

BGR0	Description
Write	Write to reload counter bits 0 to 7.
Read	Read the setting value of BGR0.

Notes:

- Use 16-bit access for writing a value to the baud rate generator register (BGR1, BGR0).
- If the setting values of the baud rate generator registers (BGR1, BGR0) are changed, the new values are not reloaded until the counter value becomes 0x0000. Therefore, in order to enable the new value immediately, execute programmable clear (UPCL) after changing the values of BGR1/0.
- When the reload value is even, the "L" width of the reception serial clock is 1-bus-clock-cycle longer than the "H" width. When the reload value is odd, the "L" width and the "H" width of the serial clock are equal.
- Set a reload value of 4 or larger in BGR1/0. However, data may not be received normally depending on baud rate errors and the reload value setting.
- To change the clock setting to that of the external clock (EXT = 1) when the baud rate generator is operating, perform the following: 1. Write "0" to baud rate generators 1, 0 (BGR1, BGR0). 2. Execute programmable clear (UPCL). 3. Set the external clock mode (EXT = 1).

10.11. FIFO Control Register 1 (FCR1)

FIFO control register 1 (FCR1) sets the FIFO test, selects transmission and reception FIFOs, enables transmission FIFO interrupts, and controls the interrupt flag.

Bit Configuration of FIFO Control Register 1 (FCR1)

Figure 10-12 shows the bit configuration of FIFO control register 1 (FCR1).

Figure 10-12 Bit Configuration of FIFO Control Register 1 (FCR1)

Bit	15	14	13	12	11	10	9	8
Field	Reserved			FLSTE	FRIIE	FDRQ	FTIE	FSEL
R/W Attribute	R0,W0			R/W	R/W	R	R/W	R/W
Protection attribute	-							
Initial Value	000			0	0	1	0	0

*: Lower byte of this register [bit7:0] is FIFO Control Register 0 (FCR0)

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTE: Retransmission Data Lost Detection Enable Bit

This bit enables the detection of the FIFO retransmission data lost flag (FLST).

- This bit is reset when the FCR1C:FLSTEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FLSTES bit in the set register is set to "1".

"0": Disable FLST bit detection.

"1": Enable FLST bit detection.

Bit	Description
0	Disable data lost detection.
1	Enable data lost detection.

Note:

- To set this bit to "1", set the FSET bit to "1" first and then set this bit to "1".

[bit11] FRIIE: Reception FIFO Idle Detection Enable Bit

When the reception FIFO contains valid data, this bit enables or disables the detection of continuation of reception idle status for the 8-bit time or longer. If the reception interrupt is enabled (SCR:RIE = 1), detection of reception idle status triggers a reception interrupt.

- This bit is reset when the FCR1C:FRIIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FRIIES bit in the set register is set to "1".

"0": Disable detection of reception idle status.

"1": Enable detection of reception idle status.

Bit	Description
0	Disable detection of reception FIFO idle.
1	Enable detection of reception FIFO idle.

Note:

- To use the reception FIFO, set this bit to "1".

[bit10] FDRQ: Transmission FIFO Data Request Bit

This bit requests transmission FIFO data.

Value "1" of this bit indicates that transmission data is requested. At that time, a FIFO transmission interrupt request is issued if the transmission FIFO interrupt is enabled (FTIE = 1).

FDRQ set conditions

- When transmission FIFO interrupt control is not used
 - FBYTE (for transmission) = 0 (Transmission FIFO is empty.)
 - Reset of the transmission FIFO
- When transmission FIFO interrupt control is used
 - When ECR:TXBLKEN = 0
 - FTICR setting value \geq FTICR read value (The amount of data in the transmission FIFO at the interrupt trigger level or lower.)
 - When ECR:TXBLKEN = 1
 - FTICR setting value \leq Free space in the transmission FIFO
 - Reset of the transmission FIFO

FDRQ reset conditions

- "1" is written to FCR1C:FDRQC.
- When ECR:TXBLKEN = 0
 - The transmission FIFO is full.
- When ECR:TXBLKEN = 1
 - FTICR setting value \geq Free space in the transmission FIFO

Bit	Description
0	No transmission FIFO data request
1	Transmission FIFO data request issued

Notes:

- Writing to this bit is invalid.
- The FSEL bit cannot be changed when this bit is "0".
- When you write the necessary data to the transmission FIFO after a transmission interrupt occurs, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.

[bit9] FTIE: Transmission FIFO Interrupt Enable Bit

This bit enables a transmission FIFO interrupt. If this bit is set to "1", an interrupt occurs when the FDRQ bit is "1".

- This bit is reset when the FCR1C:FTIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FTIES bit in the set register is set to "1".

Bit	Description
0	Disable transmission FIFO interrupts.
1	Enable transmission FIFO interrupts.

Note:

- Set FTIE=0 if FIFO is not used when block transfer.

[bit8] FSEL: FIFO Selection Bit

This bit selects the transmission and reception FIFOs.

- This bit is reset when the FCR1C:FSELC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FSELS bit in the set register is set to "1".

"0": Allocation is made as a transmission FIFO: FIFO1 and reception FIFO: FIFO2.

"1": Allocation is made as a transmission FIFO: FIFO2 and reception FIFO: FIFO1.

Bit	Description
0	Transmission FIFO: FIFO1, reception FIFO: FIFO2
1	Transmission FIFO: FIFO2, reception FIFO: FIFO1

Notes:

- This bit is not cleared by a FIFO reset (FCR0:FCL2, FCL1 = 1).
- To change the value of this bit, disable the FIFO operation (FCR0:FE2, FE1 = 0) first.
- This bit cannot be changed when FDRQ = 0.
- Set this bit before setting the FIFO byte register(FBYTE) and the transmission FIFO interrupt control register(FTICR).
- This bit and the FIFO byte register(FBYTE) cannot be accessed at the same time.

10.12. FIFO Control Register 0 (FCR0)

FIFO control register 0 (FCR0) enables/disables the FIFO operation, resets FIFO, saves the read pointer, and makes the retransmission setting.

Bit Configuration of FIFO Control Register 0 (FCR0)

Figure 10-13 shows the bit configuration of FIFO control register 0 (FCR0).

Figure 10-13 Bit Configuration of FIFO Control Register 0 (FCR0)

Bit	7	6	5	4	3	2	1	0
Field	Reserved	FLST	FLD	FSET	FCL2	FCL1	FE2	FE1
R/W Attribute	R0,W0	R,WX	R,W	R0,W	R0,W	R0,W	R/W	R/W
Protection attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

[bit6] FLST: FIFO Retransmission Data Lost Flag Bit

This bit indicates that the retransmission data of the transmission FIFO has been lost.

FLST set condition

- Data is written in the FIFO (overwriting the contents) when the FLSTE bit in the FIFO control register 1 (FCR1) is "1" and the write pointer of the transmission FIFO and the read pointer saved by the FSET bit coincide.

FLST reset conditions

- The transmission FIFO reset
 - set "1" to FCR0:FCL1 when FCR1:FSEL=0
 - set "1" to FCR0:FCL2 when FCR1:FSEL=1
- Writing "1" to the FSET bit

If "1" is set in this bit, the data pointed to by the read pointer saved with the FSET bit is overwritten. For this reason, retransmission with the FLD bit cannot be set even if an error occurs. When performing retransmission with this bit set to "1", resets the FIFO and then writes the data to the FIFO again.

Bit	Description
0	Data has not been lost.
1	Data has been lost.

[bit5] FLD: FIFO Pointer Reload Bit

This bit reloads, to the read pointer, the data saved to the transmission FIFO by the FSET bit. This bit is used for retransmission in cases such as communication errors.

This bit is set to "0" when the retransmission setting has been completed.

- This bit is set when the FCR0S:FLDS bit in the set register is set to "1".

Bit	Description
0	Do not execute reload.
1	Execute reload.

Notes:

- While this bit is set to "1", reloading to the read pointer is in progress, so writing is prohibited except in the case of a FIFO reset.
- Setting this bit to "1" is prohibited when FIFO is enabled or transmission is in progress.
- To set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then enable the transmission FIFO and set the SCR:TIE and SCR:TBIE bits to "1".

[bit4] FSET: FIFO Pointer Saving Bit

This bit stores the read pointer for the transmission FIFO.

If the read pointer is saved before transmission starts and then a communication error occurs, retransmission is possible if the FLST bit is "0".

- This bit is set when the FCR0S:FSETS bit in the set register is set to "1".

"1": Save the current read pointer value.

"0": No effect.

Bit	Description	
	Write	Read
0	Do not save.	"0" is always read.
1	Save the read pointer value.	

Note:

- Set this bit to "1" when the transmission byte count (FBYTE) is 0.

[bit3] FCL2: FIFO2 Reset Bit

This bit resets FIFO2.

If this bit is set to "1", the internal status of FIFO2 is initialized.

Only the FCR0:FLST bit is initialized and the values of the other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL2S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO2.	

Notes:

- Disable transmission/reception first and then execute a FIFO2 reset.
- Execute the reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE2 register is set to 0.
- The TDR register and the RDR register are not initialized.

[bit2] FCL1: FIFO1 Reset Bit

This bit resets FIFO1.

If this bit is set to "1", the internal status of FIFO1 is initialized.

Only the FCR0:FLST bit is initialized and the values of the other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL1S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO1.	

Notes:

- Disable transmission/reception first and then execute a FIFO1 reset.
- Execute the reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE1 register is set to 0.
- The TDR register and the RDR register are not initialized.

[bit1] FE2: FIFO2 Operation Enable Bit

This bit enables or disables the operation of FIFO2.

- Set this bit to "1" when using FIFO2.
- When FIFO2 is specified as the transmission FIFO (FCR1:FSEL = 1) and "1" is written to this bit, transmission starts immediately if FIFO2 contains data and UART transmission is enabled (SCR:TXE = 1). At that time, to set the SCR:TIE and SCR:TBIE bits to "1", first set them to "0", write "1" to this bit, and then set the SCR:TIE and SCR:TBIE bits to "1".

- A reception error clears this bit to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. After that, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO2 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO2 as the reception FIFO, first disable reception (SCR:RXE = 0) and then change the setting of this bit when the reception buffer is empty (SSR:RDRF = 0) and the reception FIFO does not contain valid data (FBYTE2 = 0).
- To use FIFO2 as the reception FIFO, first disable reception (SCR:RXE = 0) and then set this bit to "1" when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO2 does not change the state of FIFO2.
- This bit is reset when the FCR0C:FE2C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE2S bit in the set register is set to "1".

Bit	Description
0	Disable FIFO2 operation.
1	Enable FIFO2 operation.

[bit0] FE1: FIFO1 Operation Enable Bit

This bit enables or disables the operation of FIFO1.

- Set this bit to "1" when using FIFO1.
- When FIFO1 is specified as the transmission FIFO (FCR1:FSEL = 0) and "1" is written to this bit, transmission starts immediately if FIFO1 contains data and UART transmission is enabled (SCR:TXE = 1). At that time, to set the SCR:TIE and SCR:TBIE bits to "1", first set them to "0", write "1" to this bit, and then set the TIE and SCR:TBIE bits to "1".
- A reception error clears this bit to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. After that, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO1 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO1 as the reception FIFO, first disable reception (SCR:RXE = 0) and then change the setting of this bit when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO1 does not change the state of FIFO1.
- This bit is reset when the FCR0C:FE1C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE1S bit in the set register is set to "1".

Bit	Description
0	Disable FIFO1 operation.
1	Enable FIFO1 operation.

10.13. FIFO Byte Register (FBYTE)

The FIFO byte register (FBYTE) indicates the valid data count of the FIFO. This register also specifies whether a reception interrupt is generated when the predefined amount of data is received by the reception FIFO.

Bit Configuration of the FIFO Byte Register (FBYTE)

Figure 10-14 shows the bit configuration of the FIFO byte register (FBYTE).

Figure 10-14 Bit Configuration of FIFO Byte Register (FBYTE)

Bit	15	14	13	12	11	10	9	8
Field	FBYTE2							
R/W Attribute	R,W							
Protection attribute	-							
Initial Value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	FBYTE1							
R/W Attribute	R,W							
Protection attribute	-							
Initial Value	00000000							

The FBYTE register indicates the valid count for the data that has been written or received by the FIFO. Settings with the FCR1:FSEL bit are listed below.

Table 10-3 Data Count Indication

FSEL	FIFO Selection	Data Count Indication
0	FIFO2: Reception FIFO, FIFO1: Transmission FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1
1	FIFO2: Transmission FIFO, FIFO1: Reception FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1

- The initial transfer count value of the FBYTE register is 0x08.
- The FBYTE for the reception FIFO contains the data count for setting the reception interrupt flag. When the transferred data count and the data count indication in the FBYTE register coincide, the interrupt flag (SSR:RDRF) is set to "1".
- When both of the following conditions are satisfied, the continuation of reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1".
 - The reception FIFO idle detection enable bit (FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system then starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, the counting restarts.
- Whenever transmission data is written to TDR, the FBYTE of the transmission FIFO is incremented by 1.
- Whenever reception data is read from RDR, the FBYTE of the reception FIFO is decremented by 1.
- During block transfer, the value in this register is the block transfer count.

[bit15:8] FBYTE2: FIFO2 Data Count Indication byte
[bit7:0] FBYTE1: FIFO1 Data Count Indication Byte

FBYTE2, FBYTE1	Description
Write	Set the transfer count.
Read	Read valid data count.

Read (valid data count)

Transmission: Data count written in the FIFO and not yet transmitted

Reception: Data count that has been received but not read by the reception FIFO

Write (transfer count)

Transmission: Set 0x00.

Reception: Set the data count that triggers reception interrupts.

Table 10-4 Data Count Stored in FIFO

FIFO Capacity	Operation Mode	Data Length	Max FBYTE Count	Data Count That Can Be Stored
16 bytes	Mode 0	5 to 8 bits	16	16
	Mode 0	9 bits	8	8
	Mode 1	All		
32 bytes	Mode 0	5 to 8 bits	32	32
	Mode 0	9 bits	16	16
	Mode 1	All		
64 bytes	Mode 0	5 to 8 bits	64	64
	Mode 0	9 bits	32	32
	Mode 1	All		

Notes:

- Set 0x00 in the FBYTE register for the transmission FIFO.
- When the reception FIFO is not used, the reception block size during block transfer will be "1" regardless of the setting of this register.
- Change the value of the FBYTE of the reception FIFO after disabling the reception operation.
- Any setting that exceeds the FIFO capacity is prohibited.
- Set the FIFO byte register (FBYTE) after setting the FIFO selection bit (FCR1:FSEL).
- The FIFO selection bit (FCR1:FSEL) and the FIFO byte register (FBYTE) cannot be set at the same time.
- As the FIFO data count for transmission, the transmission data count that has been written, minus 1, is displayed as the valid data count. This is because an attempt to write transmission data to the TDR register stores the data in the transmission FIFO if the TDR register contains data that has not been transmitted yet. When the data in the TDR register is transmitted, the data in the transmission FIFO that has not been transmitted is transferred to the TDR register.
- The FIFO data count for reception represents the data count received by the reception FIFO but which has not yet been read. The data count does not include the data being received by the RDR register.

10.14. Transmission FIFO Interrupt Control Register (FTICR)

The transmission FIFO interrupt control register (FTICR) sets the condition for interrupts triggered by the valid data count of the FIFO transmission.

Transmission FIFO Interrupt Control Register (FTICR)

Figure 10-15 shows the bit configuration of the transmission FIFO interrupt control register (FTICR).

Figure 10-15 Bit Configuration of Transmission FIFO Interrupt Control Register (FTICR)

Bit	15	14	13	12	11	10	9	8
Field	FTICR2							
R/W Attribute	R,W							
Protection attribute	-							
Initial Value	00000000							

Bit	7	6	5	4	3	2	1	0
Field	FTICR1							
R/W Attribute	R,W							
Protection attribute	-							
Initial Value	00000000							

These bits have different functions depending on the setting of the ECR:TXBLKEN bit. The details are as shown below.

■ ECR:TXBLKEN = 0

The FTICR register sets the trigger level for interrupts by the valid transmission data count (remaining amount) in the transmission FIFO.

■ ECR:TXBLKEN = 1

The FTICR register sets the trigger level for interrupts by the amount of free space in the transmission FIFO.

The table below shows the setting conditions for different FCR1:FSEL bit values.

Table 10-5 Transmission FIFO Setting by FCR1:FSEL

FSEL	Selection of Transmission FIFO	Transmission FIFO Interrupt Control Register
0	FIFO1	FTICR1
1	FIFO2	FTICR2

■ The initial value of the valid data count for triggering interrupts of the FTICR register is 0x00.

■ Set the number of data items that generate a transmission interrupt to FTICR of the transmission FIFO.

- When ECR:TXBLKEN = 0, if the set number of data items matches, or becomes smaller than, the indication of the number of valid data items in the transmission FIFO (FTICR or FBYTE), the interrupt flag (FDRQ) is set to "1".
- When ECR:TXBLKEN = 1, if the set number of data items matches, or becomes smaller than, the amount of free space in the transmission FIFO, the interrupt flag (FDRQ) is set to "1". If the

number of data items that is set in this bit becomes larger than the amount of free space in the transmission FIFO, the interrupt flag (FDRQ) is set to "0".

- Set FTICR so that it satisfies: $FTICR \leq \text{FIFO capacity} - 2$.
- The read value indicates the valid data count of the FIFO.
- Transmission FIFO: Data count written to the transmission FIFO that has not yet been transmitted.
- Reception FIFO: Data count received by the reception FIFO that has not yet been read.

[bit15:8] FTICR2: FIFO2 Data Count Indication byte

[bit7:0] FTICR1:FIFO1 Data Count Indication Byte

FTICR2, FTICR1	Description
Write	Set the number of valid data items that generates an interrupt.
Read	Read valid data count.

Notes:

- Any setting that exceeds the FIFO capacity is prohibited.
- The setting value cannot be read.
- As the FIFO data count for transmission, the transmission data count that has been written, minus 1, is displayed as the valid data count. This is because an attempt to write data to the TDR register stores the data in the transmission FIFO if the TDR register contains data that is yet to be transmitted. When the data in the TDR register is transmitted, the data in the transmission FIFO that has not yet been transmitted is transferred to the TDR register.
- The FIFO data count for reception represents the data count received by the reception FIFO but which has not yet been read. The data count does not include the data that has been received by the RDR register.
- For $ECR:TXBLKEN = 0$, if block transfer is performed during DMA transfer, only 1 can be set as the block size.
- To perform block transfer with $ECR:TXBLKEN = 1$, set the value of the block size to this register.

10.15. Extended Control Register (ECR)

The extended control register (ECR) can set block transfer.

Bit Configuration of the Extended Control Register (ECR)

Figure 10-16 shows the bit configuration of the extended control register (ECR).

Figure 10-16 Bit Configuration of Extended Control Register (ECR)

Bit Field	7	6	5	4	3	2	1	0

Protection Attribute	-			-	-	-	-	-
Initial Value	000			0	0	0	0	0

[bit7:5] Reserved: Reserved Bits

[bit4] EISEL: Error Interrupt Request Output Selection Bit

This bit selects between the output of an error interrupt from an interrupt request pin and output from an error interrupt request pin. For details on interrupt output selection, see Table 2-2 and Table 2-3.

Bit	Description
0	Output a reception error interrupt request from a reception interrupt request pin. Output a transmission error interrupt request from a transmission interrupt request pin.
1	Output a reception error interrupt request from a reception error interrupt request pin. Output a transmission error interrupt request from a transmission error interrupt request pin.

[bit3] REIE: Reception Error Interrupt Enable Bit

This bit enables/disables reception error interrupt request output. For details on the target interrupt factors, see Table 2-3.

Bit	Description
0	Disable reception error interrupts.
1	Enable reception error interrupts.

[bit2] TEIE: Transmission Error Interrupt Enable Bit

This bit enables/disables transmission error interrupt request output. For details on the target interrupt factors, see Table 2-2.

Bit	Description
0	Disable transmission error interrupts.
1	Enable transmission error interrupts.

[bit1] RXBLKEN: Reception Block Transfer Setting Bit

This bit sets the reception DMA transfer mode.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

[bit0] TXBLKEN: Transmission Block Transfer Setting Bit

This bit sets the transmission DMA transfer mode.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

10.16. Extended Status Register (ESR)

The extended status register (ESR) verifies the reception block transfer error flag and the transmission block transfer error flag.

Extended Status Register (ESR)

Figure 10-17 shows the bit configuration of the extended status register (ESR).

Figure 10-17 Bit Configuration of Extended Status Register (ESR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved				RXUDR	TXOVR	RBERR	TBERR
R/W Attribute	R0,W0				R,WX	R,WX	R,WX	R,WX
Protection Attribute	-				-	-	-	-
Initial Value	0000				0	0	0	0

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDR: Reception FIFO under Run Flag Bit

This bit is set to "1" if the reception FIFO becomes empty due to block transfer, and then a read occurs.

- This bit is reset when the ESRC:RXUDRC bit in the clear register is set to "1".
- For details on the output of interrupt requests, see Table 2-3.

Bit	Description
0	No reception FIFO under run has occurred.
1	A reception FIFO under run has occurred.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" if reception block transfer enable (ECR:RXBLKEN) is "0".
- This bit is set only when the reception FIFO is used.
- If Reception FIFO is disabled, this bit is set to "0".

[bit10] TXOVR: Transmission FIFO Overflow Flag Bit

This bit is set to "1" if the transmission FIFO becomes full due to block transfer, and then a write occurs.

- This bit is reset when the ESRC:TXOVR bit in the clear register is set to "1".
- For details on the output of interrupt requests, see Table 2-2.

Bit	Description
0	No transmission FIFO overflow has occurred.
1	A transmission FIFO overflow has occurred.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" if transmission block transfer enable (ECR:TXBLKEN) is "0".
- This bit is set only when the transmission FIFO is used.

- If Transmission FIFO is disabled, this bit is set to "0".

[bit9] RBERR: Reception Block Transfer Error Bit

This bit indicates that a block transfer error has occurred during reception.

If block transfer is executed with a value greater than the threshold set in the FBYTE register, "1" is set in this bit as a block transfer error. A reception interrupt occurs if reception interrupts are enabled (SCR:RIE = 1).

- This bit is reset when the ESRC:RBERRC bit in the clear register is set to "1".
- For details on the output of interrupt requests, see Table 2-3.

Bit	Description
0	No reception block transfer error has occurred.
1	A reception block transfer error has occurred.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" if reception block transfer enable (ECR:RXBLKEN) is "0" or reception interrupt enable (SCR:RIE) is "0".

[bit8] TBERR: Transmission Block Transfer Error Bit

This bit indicates that a block transfer error has occurred during transmission.

If block transfer is executed with a value greater than the threshold set in the FTICR register, "1" is set in this bit as a block transfer error. A transmission interrupt occurs if transmission interrupts are enabled (SSR:TIE=1).

- This bit is reset when the ESRC:TBERRC bit in the clear register is set to "1".
- For details on the output of interrupt requests, see Table 2-2.

Bit	Description
0	No transmission block transfer error has occurred.
1	A transmission block transfer error has occurred.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" if transmission block transfer enable (ECR:TXBLKEN) is "0".
- If the transmission FIFO is OFF, this bit is set to "1" as a block transfer error if block transfer is executed under one of the conditions below.
 - Transmission interrupts are enabled (SCR:TIE = 1) and data exists in the transmission data register (SSR:TDRE = 0).
 - Transmission interrupts are disabled (SCR:TIE = 0), transmission bus idle interrupts are enabled (SCR:TBIE = 1), and transmission is in progress (SSR:TBI = 0).
- If transmission interrupts are enabled (SCR:TIE = 1) and transmission bus idle interrupts are enabled (SCR:TBIE = 1), the transmission interrupt enable (SCR:TIE = 1) condition is given priority.

10.17. Transmission Block Size Register (TBSIZE)

This register sets the block size for transmission block transfer.

Bit Configuration of the Transmission Block Size Register (TBSIZE)

Figure 10-18 shows the bit configuration of the transmission block size register (TBSIZE).

Figure 10-18 Bit Configuration of Transmission Block Size Register (TBSIZE)

Bit	7	6	5	4	3	2	1	0
Field	TBSIZE							
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

The TBSIZE register sets the block size for transmission block transfer.

[bit7:0] TBSIZE: Transmission Block Size byte

TBSIZE	Description
Write	Set the number of transmission blocks.
Read	Read the setting.

Notes:

- Any setting that exceeds the FIFO capacity is prohibited.
- It is prohibited to set "0" in these bits.
- It is prohibited to make a setting that exceeds the setting of the transmission FIFO interrupt control register (FTICR).
- In this register, set the same value as the transmission block size set in the DMA controller.
- When the transmission FIFO is not used, the transmission block size during block transfer will be "1" regardless of the setting of this register.

10.18. Serial Auxiliary Control Status Clear Register (SACSRC)

The serial auxiliary control status clear register (SACSRC) can clear the bits in the serial auxiliary control status register (SACSR).

Note:

- For operations on this register, also see the description of target register SACSR.

Bit Configuration of Serial Auxiliary Control Status Clear Register (SACSRC)

Figure 10-19 shows the bit configuration of the serial auxiliary control status clear register (SACSRC).

Figure 10-19 Bit Configuration of Serial Auxiliary Control Status Clear Register (SACSRC)

Bit	15	14	13	12	11	10	9	8
Field	STSTC	Reserved						TINTC
R/W Attribute	R0,W	R0,W0						R0,W
Protection Attribute	-							
Initial Value	0	000000						0

Bit	7	6	5	4	3	2	1	0
Field	TINTEC	TSYNEC	TRGEC	Reserved			TMREC	
R/W Attribute	R0,W	R0,W	R0,W	R0,W0			R0,W	
Protection Attribute	-							
Initial Value	0	0	0	0000			0	

[bit15] STSTC: Clearing the Serial Test Bit

Writing "1" to this bit resets SACSR:STST to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14:9] Reserved: Reserved Bits

[bit8] TINTC: Clearing the Timer Interrupt Flag

Writing "1" to this bit resets SACSR:TINT to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7] TINTEC: Clearing the Timer Interrupt Enable Bit

Writing "1" to this bit resets SACSR:TINTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] TSYNEC: Clearing the Synchronous Transmission Enable Bit

Writing "1" to this bit resets SACSR:TSYNE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] TRGEC: Clearing the External Trigger Enable Bit

Writing "1" to this bit resets SACS:TRGE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved: Reserved Bits

[bit0] TMREC: Clearing the Serial Timer Enable Bit

Writing "1" to this bit resets SACS:TMRE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.19. FIFO Control Clear Register 1 (FCR1C)

FIFO control clear register 1 (FCR1C) can clear a bit in FIFO control register 1 (FCR1).

Note:

- For operations on this register, also see the description of target register FCR1.

Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Figure 10-20 shows the bit configuration of FIFO control clear register 1 (FCR1C).

Figure 10-20 Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Bit	15	14	13	12	11	10	9	8
Field	Reserved			FLSTEC	FRIIEC	FDRQC	FTIEC	FSELC
R/W Attribute	R0,W0			R0,W	R0,W	R0,W	R0,W	R0,W
Protection	-							
Attribute								
Initial Value	000			0	0	0	0	0

* Lower byte [bit7:0] of this register is FIFO Control Clear Register 0 (FCR0C)

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTEC: Clearing the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit resets FCR1:FLSTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIEC: Clearing the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit resets FCR1:FRIIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] FDRQC: Clearing the Transmission FIFO Data Request Bit

Writing "1" to this bit resets FCR1:FDRQ to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] FTIEC: Clearing the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit resets FCR1:FTIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELC: Clearing the FIFO Selection Bit

Writing "1" to this bit resets FCR1:FSEL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.20. FIFO Control Clear Register 0 (FCR0C)

FIFO control clear register 0 (FCR0C) can clear a bit in FIFO control register 0 (FCR0).

Note:

- For operations on this register, also see the description of target register FCR0.

Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Figure 10-21 shows the bit configuration of FIFO control clear register 0 (FCR0C).

Figure 10-21 Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Bit	7	6	5	4	3	2	1	0
Field	Reserved						FE2C	FE1C
R/W Attribute	R0,W0						R0,W	R0,W
Protection Attribute	-							
Initial Value	00000						0	0

[bit7:2] Reserved: Reserved Bits

[bit1] FE2C: Clearing the FIFO2 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE2 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1C: Clearing the FIFO1 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE1 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.21. Extended Status Clear Register (ESRC)

The extended status clear register (ESRC) can clear a bit in the extended status register (ESR).

Extended Status Clear Register (ESRC)

Figure 10-22 shows the bit configuration of the extended status clear register (ESRC).

Figure 10-22 Bit Configuration of Extended Status Clear Register (ESRC)

Bit	15	14	13	12	11	10	9	8
Field	Reserved				RXUDRC	TXOVR	RBERRC	TBERRC
R/W Attribute	R0,W0				R0,W	R0,W	R0,W	R0,W
Protection	-							
Attribute								
Initial Value	0000				0	0	0	0

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDRC: Reception FIFO under Run Flag Clear Bit

Writing "1" to this bit resets ESR:RXUDR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TXOVR: Transmission FIFO Overrun Flag Clear Bit

Writing "1" to this bit resets the ESR:TXOVR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RBERRC: Reception Block Transfer Error Clear Bit

Writing "1" to this bit resets the ESR:RBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TBERRC: Transmission Block Transfer Error Clear Bit

Writing "1" to this bit resets the ESR:TBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.22. Serial Auxiliary Control Status Set Register (SACSRS)

The serial auxiliary control status set register (SACSRS) can set the bits in the serial auxiliary control status register (SACSR).

Note:

- For operations on this register, also see the description of target register SACSR.

Bit Configuration of the Serial Auxiliary Control Status Set Register (SACSRS)

Figure 10-23 shows the bit configuration of the serial auxiliary control status register (SACSRS).

Figure 10-23 Bit Configuration of Serial Auxiliary Control Status Set Register (SACSRS)

Bit	15	14	13	12	11	10	9	8
Field	STSTS	Reserved						
R/W Attribute	R0,W	R0,W0						
Protection Attribute	-							
Initial Value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	TINTES	TSYNES	TRGES	Reserved				TMRES
R/W Attribute	R0,W	R0,W	R0,W	R0,W0				R0,W
Protection Attribute	-							
Initial Value	0	0	0	0000				0

[bit15] STSTS: Setting the Serial Test Bit

Writing "1" to this bit sets the SACSR:STST to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14:8] Reserved: Reserved Bits

[bit7] TINTES: Setting the Timer Interrupt Enable Bit

Writing "1" to this bit sets SACSR:TINTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] TSYNES: Setting the Synchronous Transmission Enable Bit

Writing "1" to this bit sets SACSR:TSYNE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] TRGES: Setting the External Trigger Enable Bit

Writing "1" to this bit sets SACSR:TRGE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved: Reserved Bits

[bit0] TMRES: Setting the Serial Timer Enable Bit

Writing "1" to this bit sets SACSr:TMRE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.23. FIFO Control Set Register 1 (FCR1S)

FIFO control set register 1 (FCR1S) can set a bit in FIFO control register 1 (FCR1).

Note:

- For operations on this register, also see the description of target register FCR1.

Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Figure 10-24 shows the bit configuration of FIFO control set register 1 (FCR1S).

Figure 10-24 Bit Configuration of FIFO Control Set Register 1 (FCR1S)

* Lower byte [bit7:0] of this register is FIFO Control Set Register 0 (FCR0S)

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTES: Setting the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit sets FCR1:FLSTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIES: Setting the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit sets FCR1:FRIIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] Reserved: Reserved Bit

[bit9] FTIES: Setting the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit sets FCR1:FTIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELS: Setting the FIFO Selection Bit

Writing "1" to this bit sets FCR1:FSEL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

10.24. FIFO Control Set Register 0 (FCR0S)

FIFO control set register 0 (FCR0S) can set a bit in FIFO control register 0 (FCR0).

Note:

- For operations on this register, also see the description of target register FCR0.

Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Figure 10-25 shows the bit configuration of FIFO control set register 0 (FCR0S).

Figure 10-25 Bit Configuration of FIFO Control Set Register 0 (FCR0S)

[bit7:6] Reserved: Reserved Bits

[bit5] FLDS: Setting the FIFO Pointer Reload Bit

Writing "1" to this bit sets FCR0:FLD to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4] FSETS: Setting the FIFO Pointer Saving Bit

Writing "1" to this bit sets FCR0:FSET to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] FCL2S: Setting the FIFO2 Reset Bit

Writing "1" to this bit sets FCR0:FCL2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] FCL1S: Setting the FIFO1 Reset Bit

Writing "1" to this bit sets FCR0:FCL1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] FE2S: Setting the FIFO2 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1S: Setting the FIFO1 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

CHAPTER 37: CSIO (Clock Synchronous Serial Interface)

This chapter explains the CSIO functions of the multi-function serial interface, supported by operating mode 2.

1. Overview of the CSIO (Clock Synchronous Serial Interface)
2. Interrupts of the CSIO (Clock Synchronous Serial Interface)
3. Operation of the CSIO (Clock Synchronous Serial Interface)
4. Serial Timer Operation
5. Operation of Serial Chip Select
6. Test Mode
7. Dedicated Baud Rate Generator
8. Block Transfer
9. Registers of the CSIO (Clock Synchronous Serial Interface)

CSIO-TXXPT03P01R01L13-E1-XX

1. Overview of the CSIO (Clock Synchronous Serial Interface)

The CSIO (Clock Synchronous Serial Interface) is a general-purpose serial data communication interface for performing synchronous communication with an external machine (supports SPI). In addition, this interface incorporates transmission/reception FIFOs (64 bytes each).

Functions of the CSIO (Clock Synchronous Serial Interface)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Transfer format	<ul style="list-style-type: none"> Clock synchronization (no start bits/stop bits) Master/slave function Supports SPI (supports both master and slave)
3	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter during master operation). External clock input is enabled (during slave operation).
4	Data length	<ul style="list-style-type: none"> Variable to 5 to 16, 20, 24, and 32 bits.
5	Reception error detection	<ul style="list-style-type: none"> Overrun error
6	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, overrun error, and reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, chip error interrupt, and transmission block transfer error) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA transfer is supported for both transmission and reception. Status interrupt (serial timer interrupt)
7	Serial chip select	<ul style="list-style-type: none"> 4-channel control (independent control, round control) The setup/hold/deselect times can be set to variable. The active level can be selected for each channel.
8	Synchronous transmission function	<ul style="list-style-type: none"> Can automatically transmit data periodically in synchronization with the serial timer. Can transmit in synchronization with an external trigger.
9	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. <ul style="list-style-type: none"> A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
10	Synchronous mode	<ul style="list-style-type: none"> Master or slave function
11	Pin access	<ul style="list-style-type: none"> The serial data output pin can be set to "1".
12	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

2. Interrupts of the CSIO (Clock Synchronous Serial Interface)

The CSIO (Clock Synchronous Serial Interface) interrupts include reception interrupts, transmission interrupts, and status interrupts. Interrupt requests can be generated according to the factors described below.

- When reception data is set in the reception data register (RDR), or when a reception error occurs
- When transmission data is transferred from the transmission data register (TDR) to the transmission shift register, causing transmission to start
- Transmission bus idle (no transmission)
- Transmission FIFO data request
- When the serial timer comparison value (STMCR) and the serial timer value (STMR) coincide.
- A chip select error occurs.

CSIO Interrupts

Table 2-1 lists the CSIO interrupt control bits and interrupt factors.

Table 2-1 CSIO Interrupt Control Bits and Interrupt Factors

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL=1)
			Reception of as much data as the value set in FBYTE		- Reading of reception data until the reception FIFO is empty - Software reset (SCR:UPCL=1)
			Detection of reception idle for the 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overflow error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL=1)
	RXUDR	ESR	Reception FIFO under run	ECR:REIE	- Writing "1" to the transmission FIFO under run flag clear bit (ESRC:RXUDRC) - Software reset (SCR:UPCL=1) - Disable reception FIFO (1) When FCR1:FSEL=0, set FCR0:FE2=0 (2) When FCR1:FSEL=1, set FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit (ESRC:RBERRC) - Software reset (SCR:UPCL=1) - Disable reception block transfer mode (ECR:RXBLKEN=0)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data register (TDR) or writing "1" to the transmission FIFO operation enable bit (retransmission) when the transmission FIFO operation enable bit is "0" and the transmission FIFO contains valid data*1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data register (TDR) or writing "1" to the transmission FIFO operation enable bit (retransmission) when the transmission FIFO operation enable bit is "0" and the transmission FIFO contains valid data*1
	FDRQ	FCR1	The amount of data stored in the transmission FIFO is equal to or smaller than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC), or the transmission FIFO full condition
	CSE	SACSR	In slave mode (SCR:MS = 1), the serial chip select pin is inactive during transmission. In master mode (SCR:MS = 0), the transmission count is equal to or less than the TBYTE setting and the next transmission data is not written to TDR (SSR:TDRE = 1).	SACSR:CSEIE	<ul style="list-style-type: none"> - Writing "1" to the serial chip select flag clear bit (SACSRC:CSEC) - Software reset (SCR:UPCL=1)
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVR) - Software reset(SCR:UPCL=1) - Disable transmission FIFO <ul style="list-style-type: none"> (1) When FCR1:FSEL=0, set FCR0:FE1=0 (2) When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission block transfer error clear bit (ESRC:TBERR) - Software reset(SCR:UPCL=1) - Disable transmission block transfer(ECR:TXBLKEN=0)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
Status	TINT	SACSR	Coincidence of the serial timer register (STMR) and the serial timer comparison register (STMCR) values	SACSR:TINTE	<ul style="list-style-type: none"> - Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset(SCR:UPCL=1)

*1: Set the TIE bit to "1" after the TDRE bit becomes "0".

Switching of Error Interrupt Output

The error interrupt request output method depends on the setting of the error interrupt request output switching bit (ECR:EISEL), the transmission and reception error interrupt enable bits (SACSR:CSEIE, ECR:REIE, TEIE) or the transmission and reception interrupt enable bits (SCR:RIE, TIE, TBIE, FCR1:FTIE).

Table 2-2 How to Output Transmission Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
		SACSR:CSEIE	Chip select error (SACSR:CSE)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)
	Transmission error interrupt request output	-	No interrupt factor
1	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
	Transmission error interrupt request output	SACSR:CSEIE	Chip select error (SACSR:CSE)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)

Table 2-3 How to Output Reception Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF) Overrun error (SSR:ORE)
		ECR:REIE	Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)
	Reception error interrupt request output	-	No interrupt factor
1	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF)
	Reception error interrupt request output	ECR:REIE	Overrun error (SSR:ORE) Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)

2.1. Reception Interrupt Generation and Flag Set Timing

Reception-time interrupts include reception completion (SSR:RDRF) and reception error occurrence (SSR:ORE).

Reception Interrupt Generation and Flag Set Timing

Upon the detection of the last data bit, reception data is stored in the reception data register (RDR). Once reception is completed (SSR:RDRF = 1) or when a reception error occurs (SSR:ORE = 1), each flag is set. At this time, if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt is generated.

Note:

- If a reception error occurs, the data in the reception data register (RDR) will be invalid.

Figure 2-1 Reception Operation and Flag Set Timing

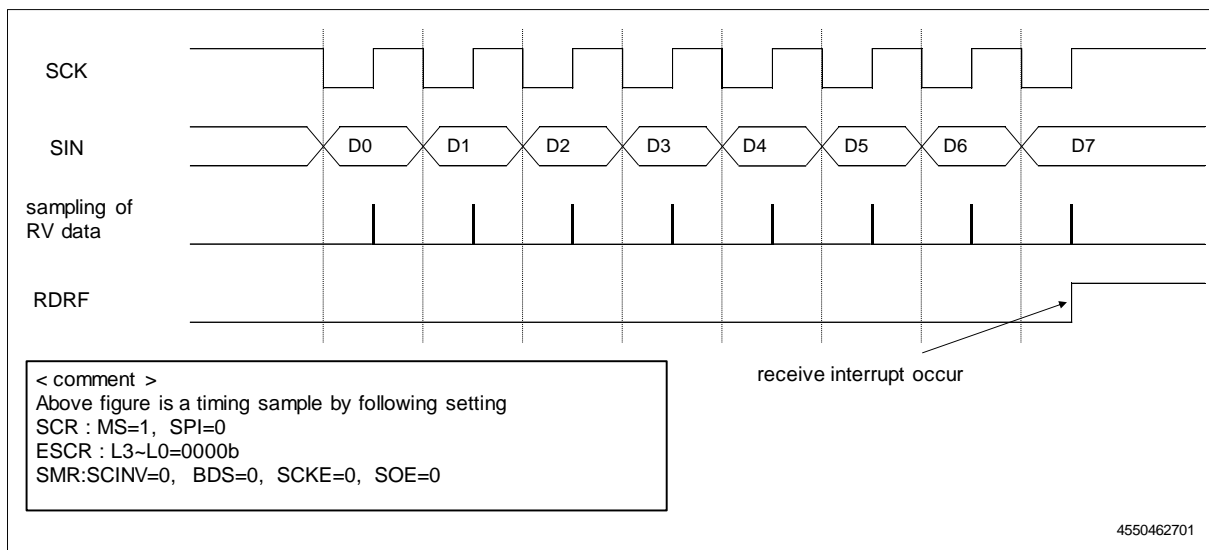

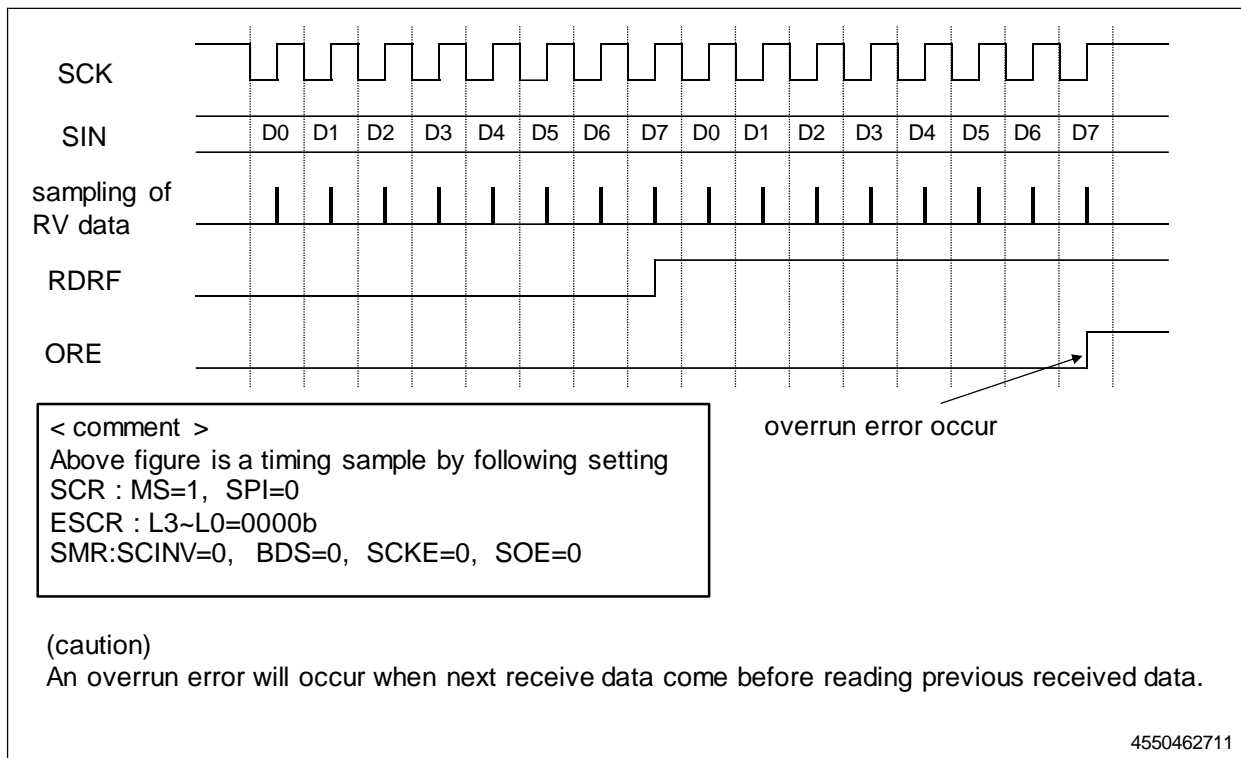

Figure 2-2 ORE (Overrun Error) Flag Set Timing

2.2. Interrupt Generation and Flag Set Timing When the Reception FIFO Is Used

When the reception FIFO is used, an interrupt is generated if as many data items as the setting in the FBYTE register (FBYTE) are received.

Reception Interrupt Generation and Flag Set Timing When the Reception FIFO is Used

The occurrence of interrupts during the use of the reception FIFO is determined by the value set in the FBYTE register.

- If as much transfer data as the amount set in the FBYTE register is received, the reception data full flag (SSR:RDRF) in the serial status register will be set to "1". At this time, if reception interrupts are enabled (SCR:RIE), a reception interrupt will be generated.
- When both of the following conditions are satisfied, continuation of reception idle status for 8 baud rate clocks or longer will set the interrupt flag (RDRF) to "1".
 - The reception FIFO idle detection enable bit (FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, so that the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when there is remaining data in the reception FIFO, counting restarts.

- Once the reception FIFO becomes empty through reading of the reception data (RDR), the reception data full flag (SSR:RDRF) is cleared.
- If the reception valid data count becomes equal to the value of the FIFO capacity, reception of the next data triggers an overrun error (SSR:ORE = 1).

Figure 2-3 Reception Interrupt Generation Timing When Reception FIFO Is Used

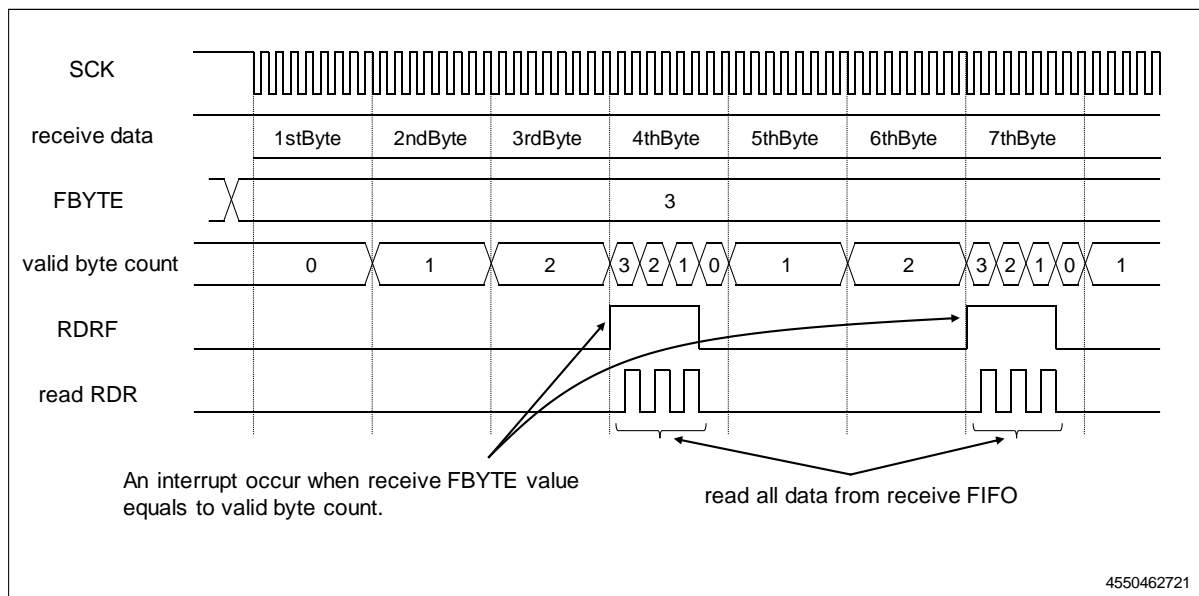

Figure 2-4 Set Timing of ORE (Overrun Error) Flag Bit

2.3. Transmission Interrupt Generation and Flag Set Timing

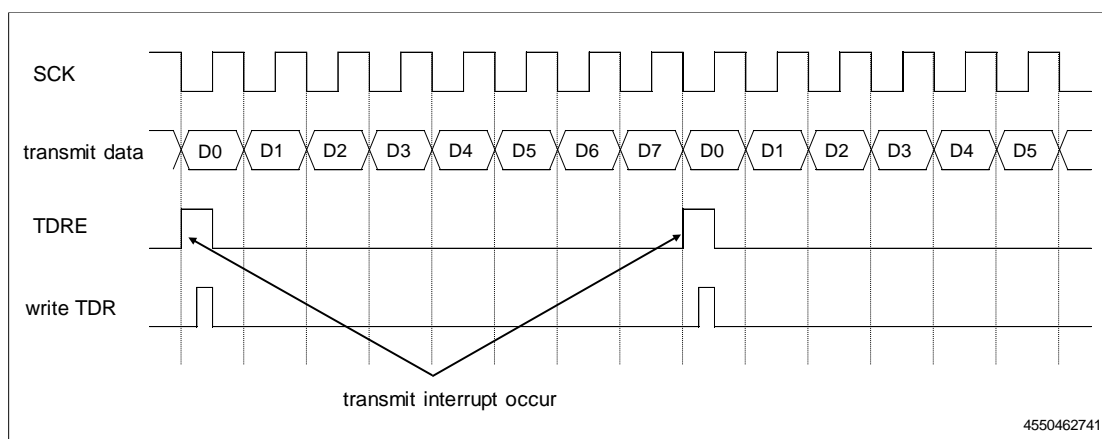

An interrupt during transmission is generated if transmission data is transferred from the transmission data register (TDR) to the transmission shift register (SSR:TDRE = 1) and transmission is started, or if transmission is not being performed (SSR:TBI = 1).

Transmission Interrupt Generation and Flag Set Timing

Set Timing of the Transmission Data Empty Flag (SSR:TDRE)

When the data written to the transmission data register (TDR) is transferred to the transmission shift register, the system enters the state in which the next data can be written (SSR:TDRE = 1). At this time, if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt is generated. The SSR:TDRE bit is a read only bit, so the SSR:TDRE bit is cleared to "0" with the writing of data to the transmission data register (TDR).

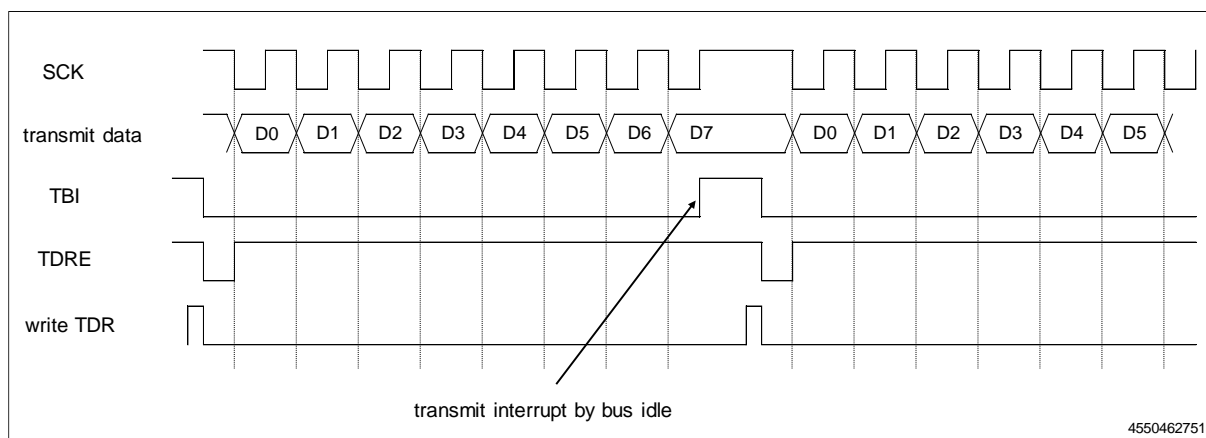

Figure 2-5 Set Timing of Transmission Data Empty Flag (SSR:TDRE) (SCR:MS = 0, SCR:SPI = 0)

Set Timing of the Transmission Bus Idle Flag (SSR:TBI)

The SSR:TBI bit is set to "1" during those periods in which the transmission data register is empty (SSR:TDRE = 1) and transmission is not being performed. At that time, a transmission interrupt occurs if the transmission bus idle interrupt is enabled (SCR:TBIE = 1). If transmission data is set in the transmission data register (TDR), the SSR:TBI bit and the transmission interrupt request are cleared.

Figure 2-6 Set Timing of Transmission Bus Idle Flag (TBI)
 (SCSCR: CSEN3 to CSEN0 = 0b0000, SACSR:TSYNE = 0)

2.4. Interrupt Generation and Flag Set Timing When the Transmission FIFO Is Used

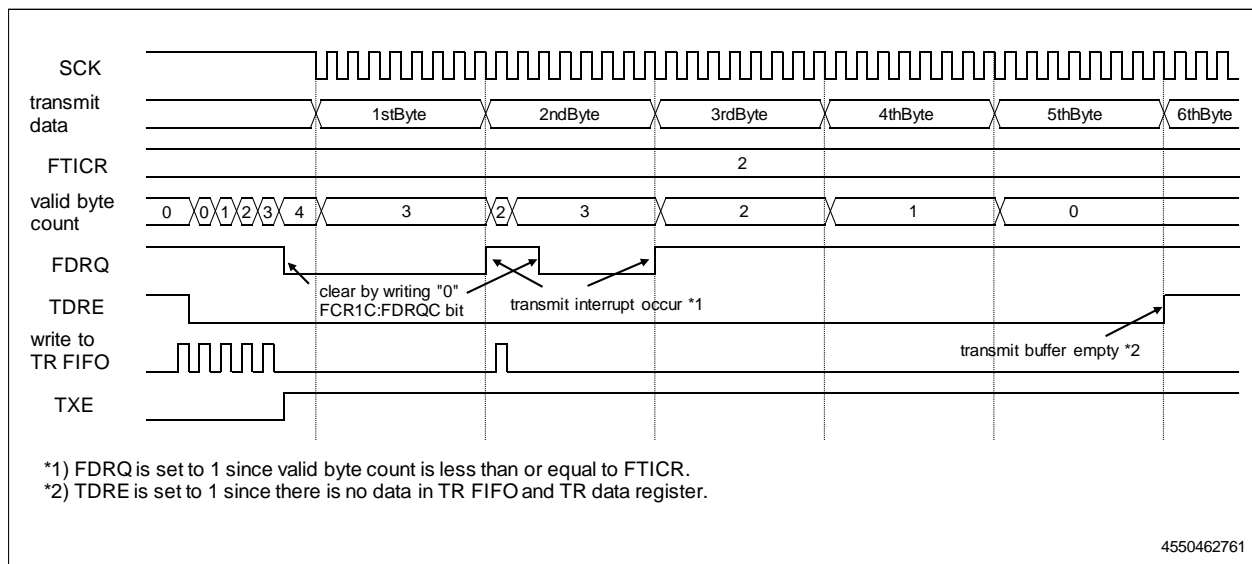

When the transmission FIFO is used, an interrupt is generated if the number of data items stored in the transmission FIFO is equal to or less than the setting made for the FTICR register (FTICR).

Transmission Interrupt Generation and Flag Set Timing When the Transmission FIFO is Used

The occurrence of interrupts during the use of the transmission FIFO is determined by the value set in the FTICR register.

- When the data count in the transmission FIFO is equal to or less than the set value in the FTICR register, the FIFO transmission data request bit (FCR1:FDRQ) is set to "1".
At this time, a transmission interrupt occurs if the FIFO transmission interrupt is enabled (FCR1:FTIE = 1).
- After a transmission interrupt is generated, write the necessary data to the transmission FIFO, and then clear the interrupt request by writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC).
- The FIFO transmission data request bit (FCR1:FDRQ) is set to "0" once the transmission FIFO becomes full.
- The existence of data in the transmission FIFO can be verified by reading the FIFO byte register (FBYTE) or the transmission FIFO interrupt control register (FTICR).
FBYTE = 0x00 and FTICR = 0x00 indicate that the transmission FIFO does not contain data.

Figure 2-7 Occurrence Timing of Transmission Interrupt When Transmission FIFO Is Used

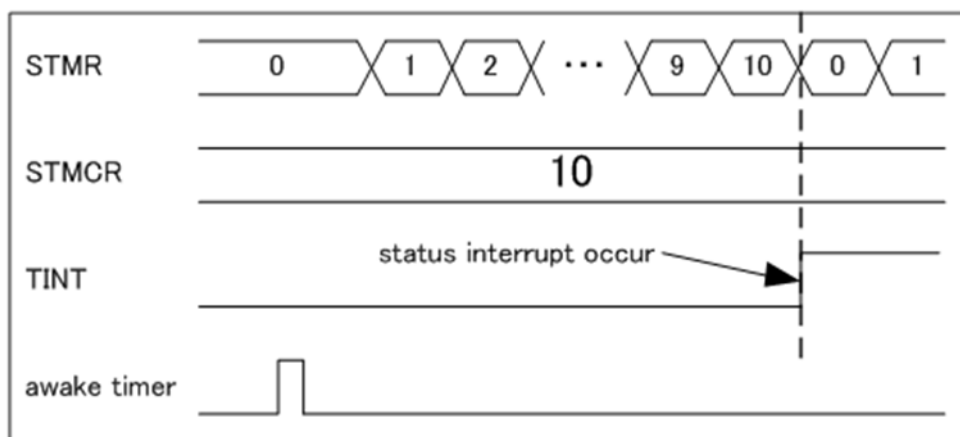

2.5. Timer Interrupt Generation and Flag Set Timing

A timer interrupt occurs when the serial timer register (STMR) coincides with the serial timer comparison register (STMCR).

Timer Interrupt Generation and Flag Set Timing

- The timer interrupt flag (SACSR:TINT) is set to "1" when the serial timer register (STMR) coincides with the serial timer comparison register.
- At this time, a status interrupt occurs if the timer interrupt is enabled (SACSR:TINTE = 1).

Figure 2-8 Occurrence Timing of Timer Interrupt

2.6. Chip Select Error Occurrence and Flag Set Timing

A chip select error occurs in master mode (SCR:MS = 0) if fewer frames than the value set in TBYTE have been transmitted, and the transmission data register (TDR) contains no valid data (SSR:TDRE = 1). A chip select error also occurs during transmission in slave mode (SCR:MS = 1) if the serial chip select pin becomes inactive.

Chip Select Error Occurrence and Flag Set Timing

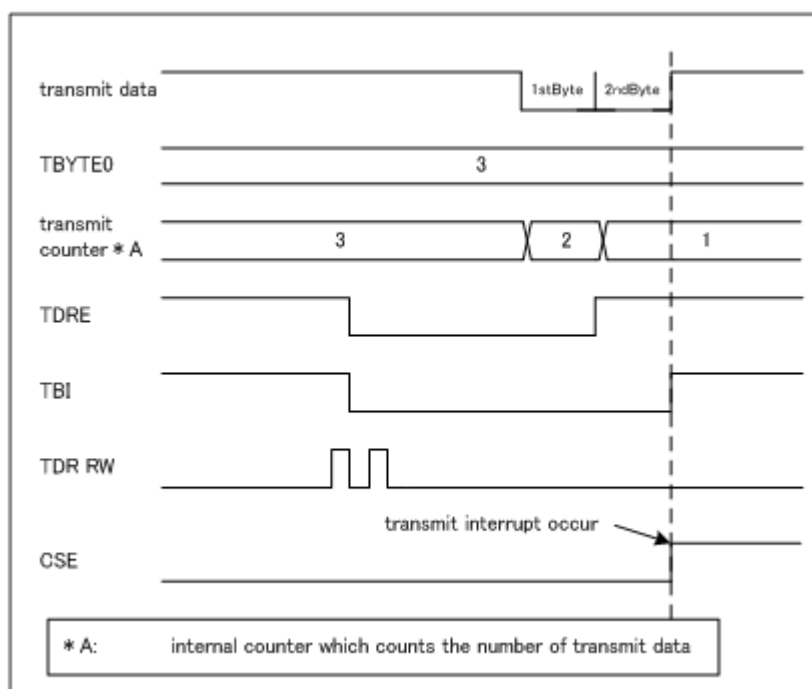

Master Mode (SCR:MS = 0)

A chip select error occurs when transfer byte errors are enabled (TBEEN = 1) in any of the following cases, if the transmission data register (TDR) contains no valid transmission data (SSR:TDRE = 1) before as many data frames as the setting of TBYTE are transmitted.

- When chip select is used
- When synchronous transmission with the serial timer is used
- When transmission activation with an external trigger is used

At this time, if chip select error interrupts are enabled (SACSR:CSEIE = 1), a transmission interrupt is generated.

Figure 2-9 Chip Select Error Occurrence Timing (SCSCR:CSEN3 to CSEN0 = 0b0000, SACSR:TSYNE = 1)

Notes:

- When serial chip select is used, the chip select error flag (SACSR:CSE) is set to "1" after the elapse of the deselect time from the occurrence of a chip select error. Even if transmission data is written to the transmission data register (TDR) within the hold delay time, transmission operation does not start, and the chip select error flag (SACSR:CSE) is set to "1" after the elapse of the deselect time.

- If "1" is set in the chip select error flag (SACSR:CSE), transmission does not start even if transmission data is written to the transmission data register (TDR).
- If "1" is set in the chip select error flag (SACSR:CSE) when synchronous transmission is used, transmission operation does not start under the conditions described below.
 - The serial timer register (STMR) and the serial timer comparison register match during transmission in synchronization with the serial timer.
 - During transmission in synchronization with an external trigger, an edge of the external trigger that is set with the trigger select bits (TRG1, TRG0) is detected.

Slave Mode (SCR:MS = 1)

A chip select error occurs if chip select becomes inactive in any of the following cases.

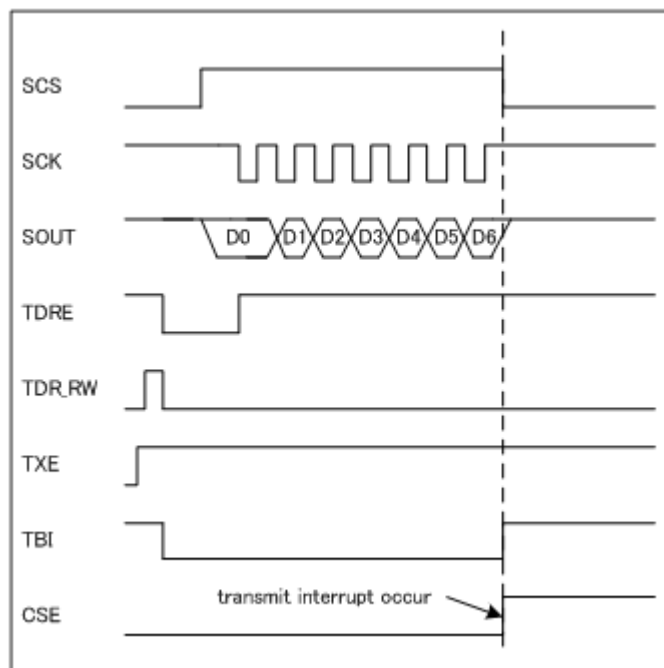

■ Serial clock in operation

■ The transmission module is not idle and the serial clock has changed.

*If the transmission module is not idle, this means that the transmission data has been prepared and that transmission starts when the serial clock is entered.

At this time, if chip select error interrupts are enabled (SACSR:CSEIE = 1), a transmission interrupt is generated.

Figure 2-10 Chip Select Error Occurrence Timing (CSLVL = 0, SCR:SPI = 0)

Note:

- When the transmission data register (SSR:TDR) is empty (TDRE = 1), if a serial chip select error (SACSR:CSE = 1) occurs, this bit is set to "1" within the baud rate period.

3. Operation of the CSIO (Clock Synchronous Serial Interface)

Clock synchronization is used as the transfer method.

3.1. Normal Transfer (I)

Features

	Item	Description
1	Serial clock (SCK) mark level	"H"
2	Transmission data output timing	SCK falling edge
3	Reception data sampling	SCK rising edge
4	Data length	5 to 16, 20, 24 and 32 bits

Register Setting

The register settings needed for normal transfer (I) are listed below.

SCR:SPI = 0*1, SMR:MD2 = 0, MD1 = 1, MD0 = 0, SCINV = 0*1

During master operation: SCR:MS = 0, SMR:SCKE = 1

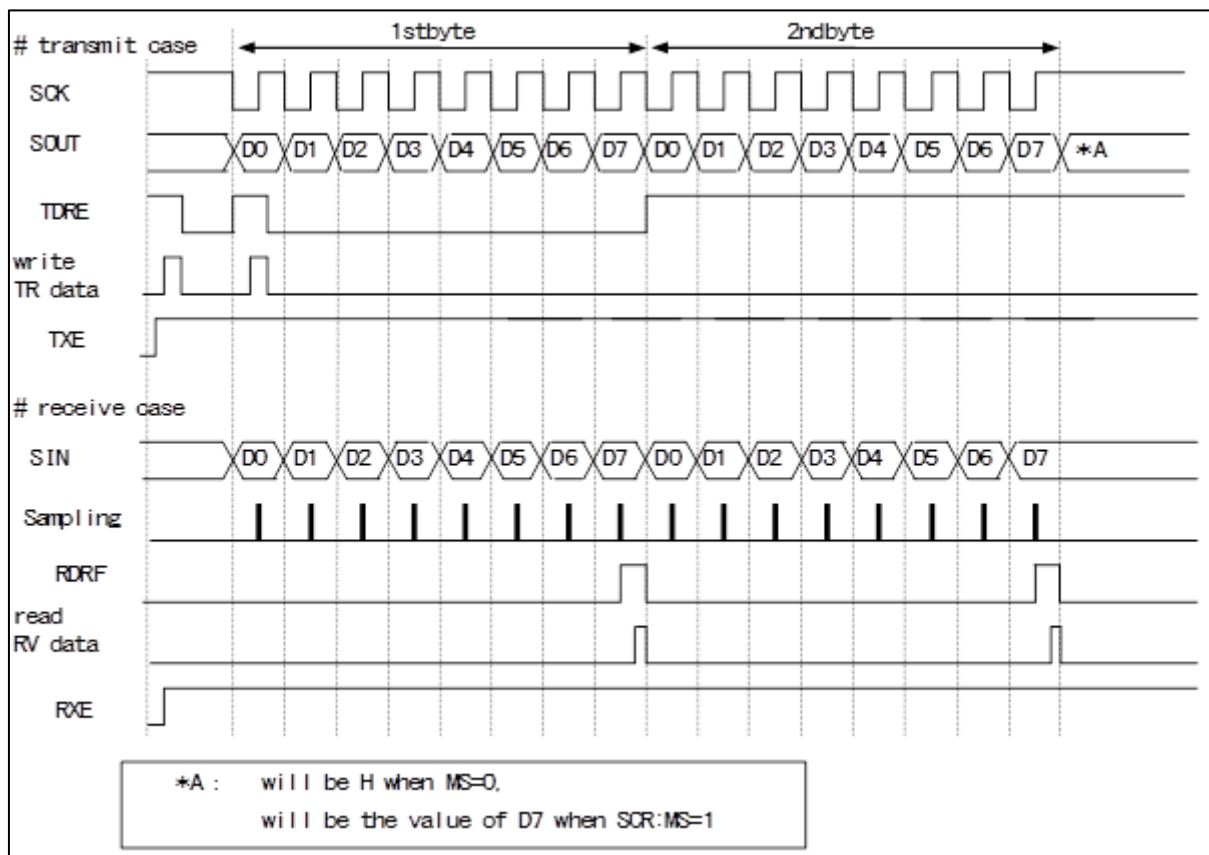

During slave operation: SCR:MS = 1, SMR:SCKE = 0

*1) The bit to be set differs depending on the condition. See Table 5-2.

Note:

- Except for the bits described above, set the registers according to their use.

Normal Transfer (I) Timing Chart (When the Serial Chip Select Pin is Not Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSEN3 to CSEN0 = 0b0000)

Transmission Operation

1. After serial data output is enabled (SMR:SOE = 1), transmission operation is enabled (SCR:TXE = 1), and reception operation is disabled (SCR:RXE = 0), the writing of transmission data to TDR causes SSR:TDRE to be set to 0. In this way, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output.
2. When the first 1 bit of the transmission data is output, SSR:TDRE is set to 1. Thus, if the transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) and transmission operation is enabled (SCR:TXE = 1) while reception operation is enabled (SCR:RXE = 1), writing dummy data to TDR causes the reception data to be sampled at a rising edge of the serial clock output (SCK).
2. When the last bit is received, SSR:RDRF is set to 1. At this time, if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Notes:

- If performing reception operation only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and enable transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and transmission data is output in synchronization with a falling edge of the serial clock (SCK) output. When the first 1 bit of the transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of the transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) output. When the last bit of the reception data is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

ESCR.WT1=0, ESCR.WT0=1 (master mode)

ESCR.WT1=1, ESCR.WT0=0 (master mode)

ESCR.WT1=1, ESCR.WT0=1 (master mode)

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN0 = 0)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) as well as transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. For this reason, transmission data is output in synchronization with a falling edge of the serial clock (SCK) input.
2. When the first 1 bit of the transmission data is output, SSR:TDRE is set to 1. If transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of the transmission data can be written.

Note:

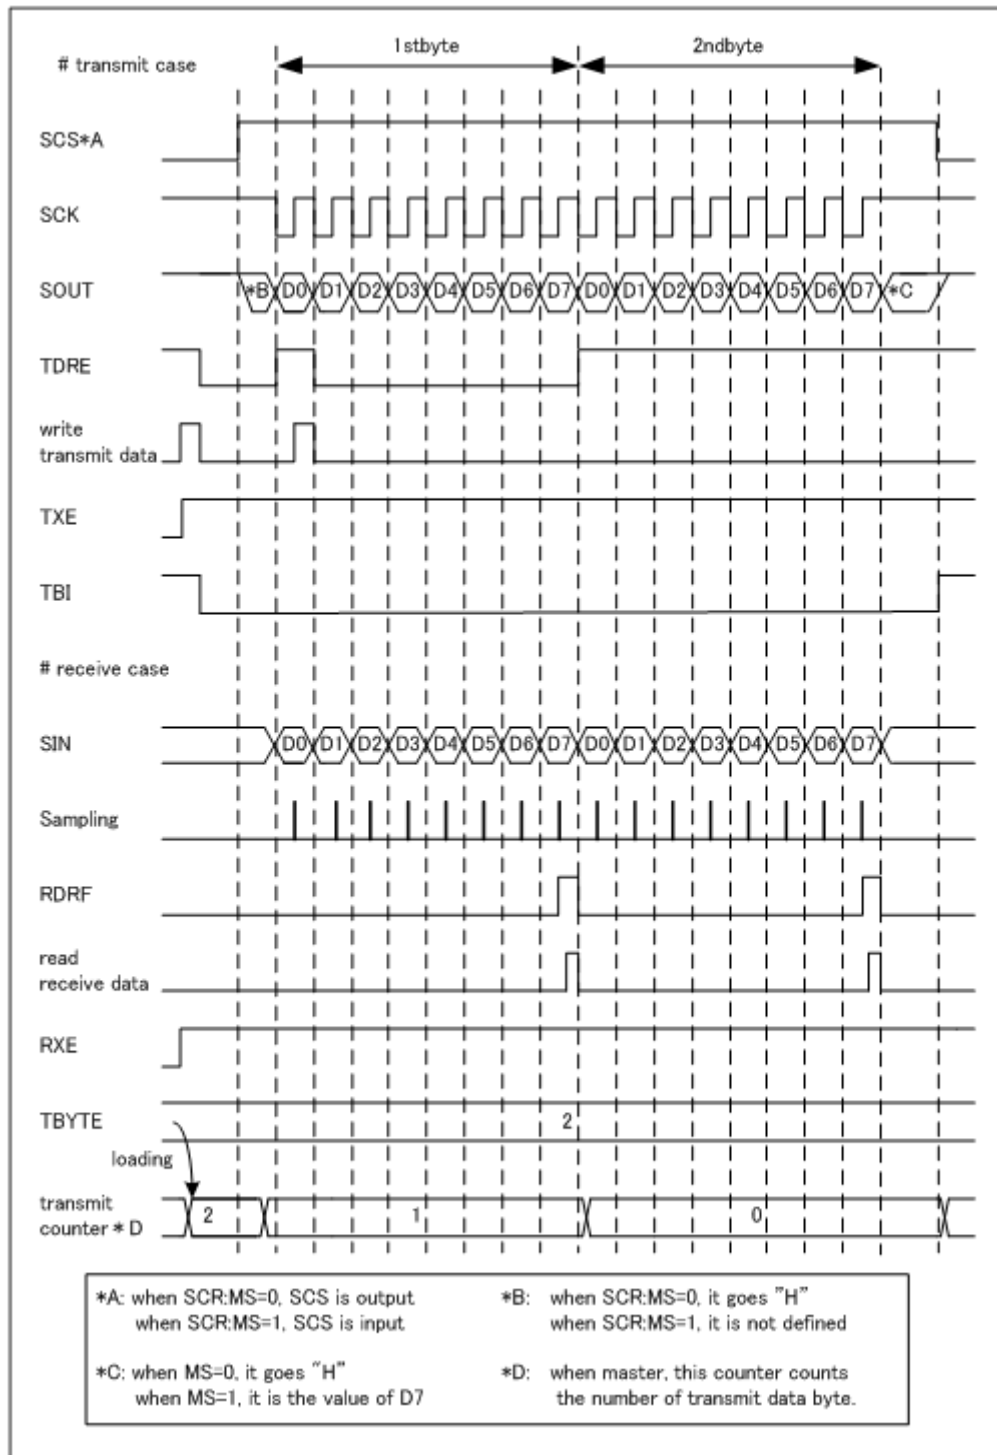

- After transmission operation is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed while the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission operation is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) and reception operation is enabled (SCR:RXE = 1), reception data is sampled at a rising edge of the serial clock input (SCK).
2. If the last bit is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and enable transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and transmission data is output in synchronization with a falling edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) input. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Normal Transfer (I) Timing Chart (When the Serial Chip Select Pin is Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSOE = 1, SCSCR:CSENn* = 1)

*: n is replaced by the serial chip select pin number used.

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission operation (SCR:TXE = 1), while disabling reception operation (SCR:RXE = 0), and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Later, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. After the end of data transmission for which the count is set in TBYTE, the serial clock stops.
4. After the serial clock stops, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Reception Operation

1. Disabling serial data output (SMR:SOE = 0), enabling transmission operation (SCR:TXE = 1), and enabling reception operation (SCR:RXE = 1), and then writing dummy data to TDR, causes the serial chip select pin (SCS) to become active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, reception data is sampled at a rising edge of the serial clock output (SCK).
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
4. After the end of data reception for which the count is set in TBYTE, the serial clock stops.
5. After the serial clock stops, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Notes:

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) as well as transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. During transmission/reception, reception data is sampled at a rising edge of the serial clock (SCK) output. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. After the end of data transmission/reception for which the count is set in TBYTE, the serial clock stops.

5. After the serial clock stops, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

ESCR.WT1=0, ESCR.WT0=1 (master mode)

ESCR.WT1=1, ESCR.WT0=0 (master mode)

ESCR.WT1=1, ESCR.WT0=1 (master mode)

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN0 = 1, SCSCR:CISOE = 0, SCSCR:SCAM = 0)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and enabling transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0.
2. If the serial chip select pin (SCS) becomes active, transmission is started, and transmission data is output in synchronization with a falling edge of the serial clock (SCK) input.
3. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
4. If the serial chip select pin (SCS) becomes inactive, transmission operation is ended, and the serial output pin (SOUT) becomes "H".

Note:

- After transmission operation is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission operation is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) and reception is enabled (SCR:RXE = 1), and if the serial chip select pin (SCS) becomes active, reception starts, and reception data is sampled at a rising edge of the serial clock input (SCK).
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
3. At this time, reception data (RDR) can be read.
4. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
5. If the serial chip select pin (SCS) becomes inactive, reception operation is ended.

Transmission/Reception Operations

1. To perform transmission/reception operations at the same time, enable serial data output (SMR:SOE = 1) and enable transmission/reception operations (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, if the serial chip select pin (SCS) becomes active, transmission/reception operations are started, and transmission data is output in synchronization with a falling edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. During transmission/reception, reception data is sampled at a rising edge of the serial clock (SCK) input. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. If the serial chip select pin (SCS) becomes inactive, transmission/reception operations stop, and the serial output pin (SOUT) becomes "H".

3.2. Normal Transfer (II)

Features

	Item	Description
1	Serial clock (SCK) mark level	"L"
2	Transmission data output timing	SCK rising edge
3	Reception data sampling	SCK falling edge
4	Data length	5 to 16, 20, 24 and 32 bits

Register Setting

The register settings necessary for normal transfer (II) are listed below.

SCR:SPI*1 = 0, SMR:MD2 = 0, MD1 = 1, MD0 = 0, SCINV*1 = 1

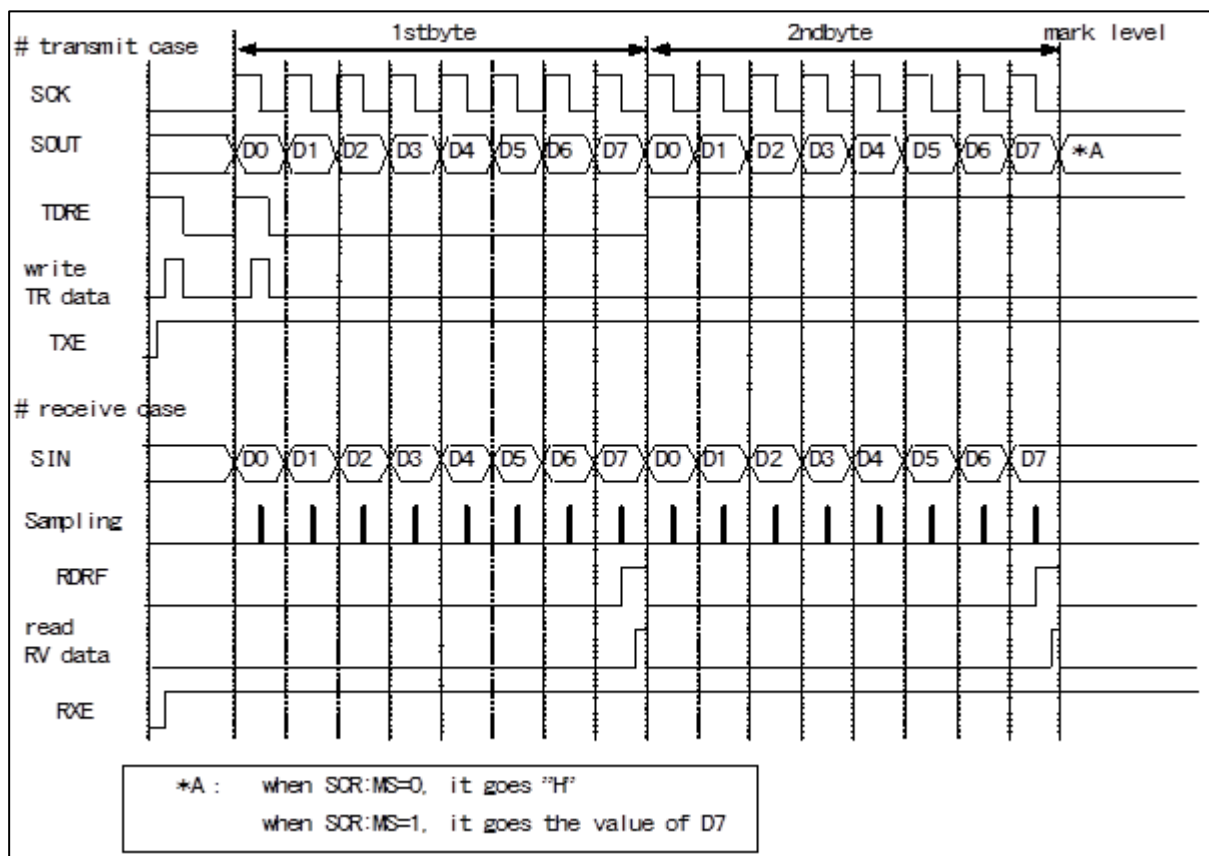

During master operation: SCR:MS = 0, SMR:SCKE = 1

During slave operation: SCR:MS = 1, SMR:SCKE = 0

*1) The bit to be set differs depending on the condition. See Table 5-2.

Note:

- Except for the above, set registers according to their use.

Normal Transfer (II) Timing Chart (When the Serial Chip Select Pin is Not Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSEN3 to CSEN0 = 0b0000)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission operation (SCR:TXE = 1), while disabling reception operation (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. With this, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1. Thus, if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0), transmission is enabled (SCR:TXE = 1), and reception is enabled (SCR:RXE = 1), writing dummy data to TDR causes reception data to be sampled at a falling edge of the serial clock output (SCK).
2. If the last bit is received, SSR:RDRF is set to 1. At this time, if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Notes:

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and transmission data is output in synchronization with a rising edge of the serial clock (SCK) output. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) output. If the last bit of reception data is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN0 = 0)
Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and also transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. For this reason, transmission data is output in synchronization with a rising edge of the serial clock (SCK) input.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1. If transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Note:

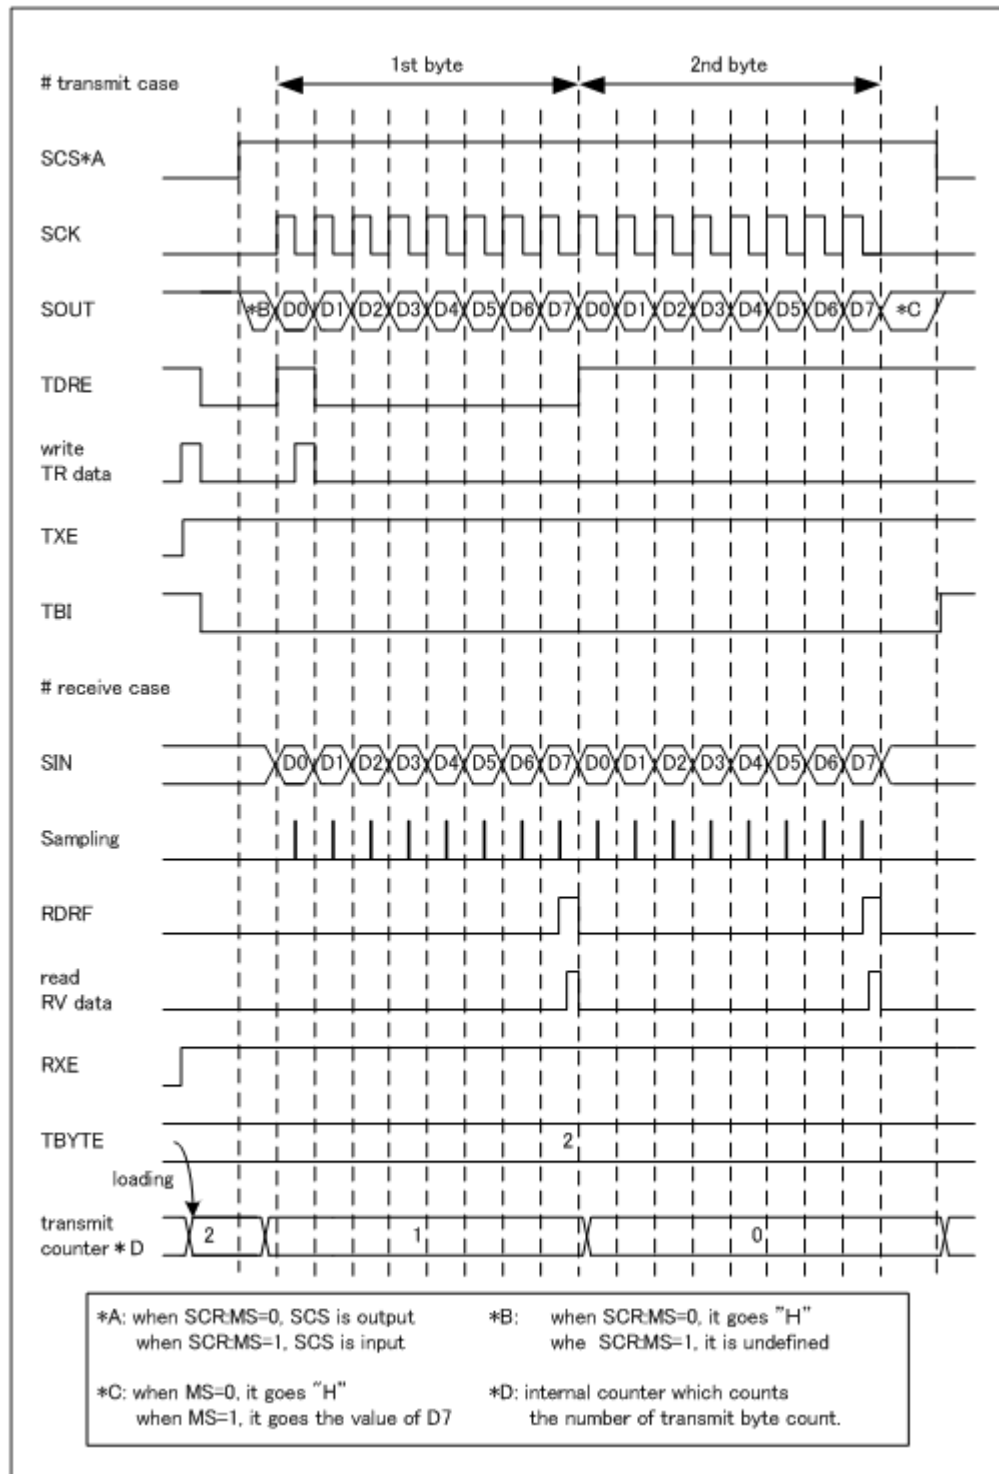

- After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) but reception is enabled (SCR:RXE = 1), reception data is sampled at a falling edge of the serial clock input (SCK).
2. If the last bit is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and transmission data is output in synchronization with a rising edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) input. If the last bit of reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Normal Transfer (II) Timing Chart (When the Serial Chip Select Pin is Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSCOE = 1, SCSCR:CSENn = 1)

*: n is replaced by the serial chip select pin number used.

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission (SCR:TXE = 1), while disabling reception (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Later, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. After the end of data transmission for which the count is set in TBYTE, the serial clock is stopped.
4. After the serial clock stops, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Reception Operation

1. Disabling serial data output (SMR:SOE = 0) while enabling transmission (SCR:TXE = 1) and also reception (SCR:RXE = 1), and then writing dummy data to TDR, causes the serial chip select pin (SCS) to become active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output starts, reception data is sampled at a falling edge of the serial clock output (SCK).
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
4. After the end of data reception for which the count is set in TBYTE, the serial clock is stopped.
5. After the serial clock stops, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Notes:

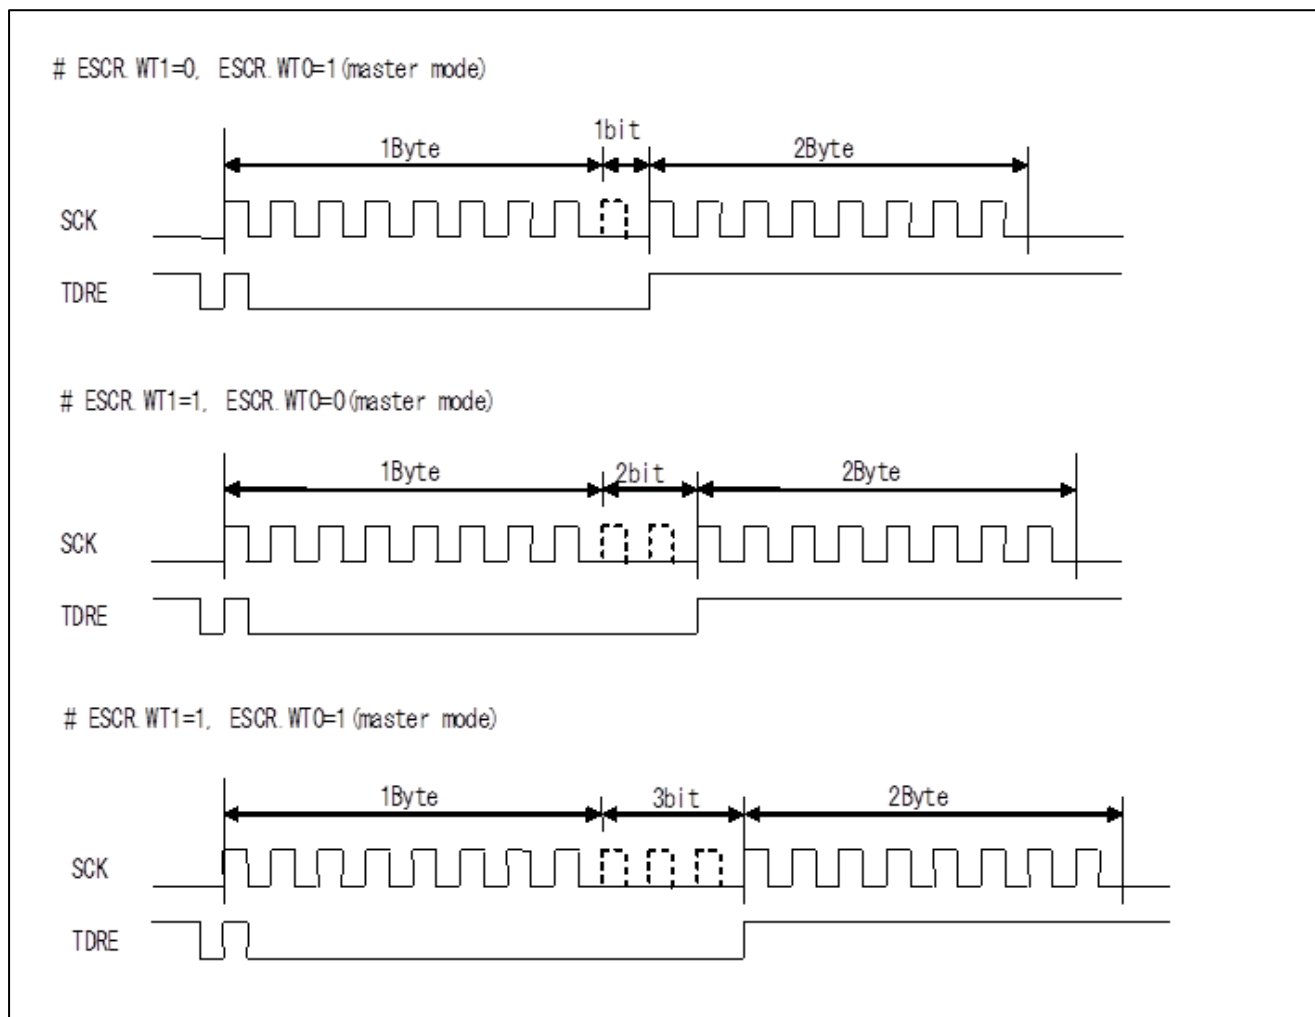

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. During transmission/reception, reception data is sampled at a falling edge of the serial clock (SCK) output. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. After the end of data transmission/reception for which the count is set in TBYTE, serial clock output is stopped.

5. After serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN0 = 1, SCSCR:CISOE = 0, SCSCR:SCAM = 0)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and also transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0.
2. If the serial chip select pin (SCS) becomes active, transmission is started, and transmission data is output in synchronization with a rising edge of the serial clock (SCK) input.
3. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
4. If the serial chip select pin (SCS) becomes inactive, transmission operation is stopped, and the serial output pin (SOUT) becomes "H".

Note:

- After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) but reception is enabled (SCR:RXE = 1), and the serial chip select pin (SCS) becomes active, reception starts, and reception data is sampled at a falling edge of the serial clock input (SCK).
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
3. At this time, reception data (RDR) can be read.
4. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
5. If the serial chip select pin (SCS) becomes inactive, reception is stopped.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, if the serial chip select pin (SCS) becomes active, transmission/reception operations are started, and transmission data is output in synchronization with a rising edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. During transmission/reception, reception data is sampled at a falling edge of the serial clock (SCK) input. When the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. If the serial chip select pin (SCS) becomes inactive, transmission/reception operations stop, and the serial output pin (SOUT) becomes "H".

3.3. SPI Transfer (I)

Features

	Item	Description
1	Serial clock (SCK) mark level	"H"
2	Transmission data output timing	SCK rising edge
3	Reception data sampling	SCK falling edge
4	Data length	5 to 16, 20, 24 and 32 bits

Register Setting

The register settings necessary for SPI transfer (I) are listed below.

SCR:SPI*1 = 1, SMR:MD2 = 0, MD1 = 1, MD0 = 0, SCINV*1 = 0

During master operation: SCR:MS = 0, SMR:SCKE = 1

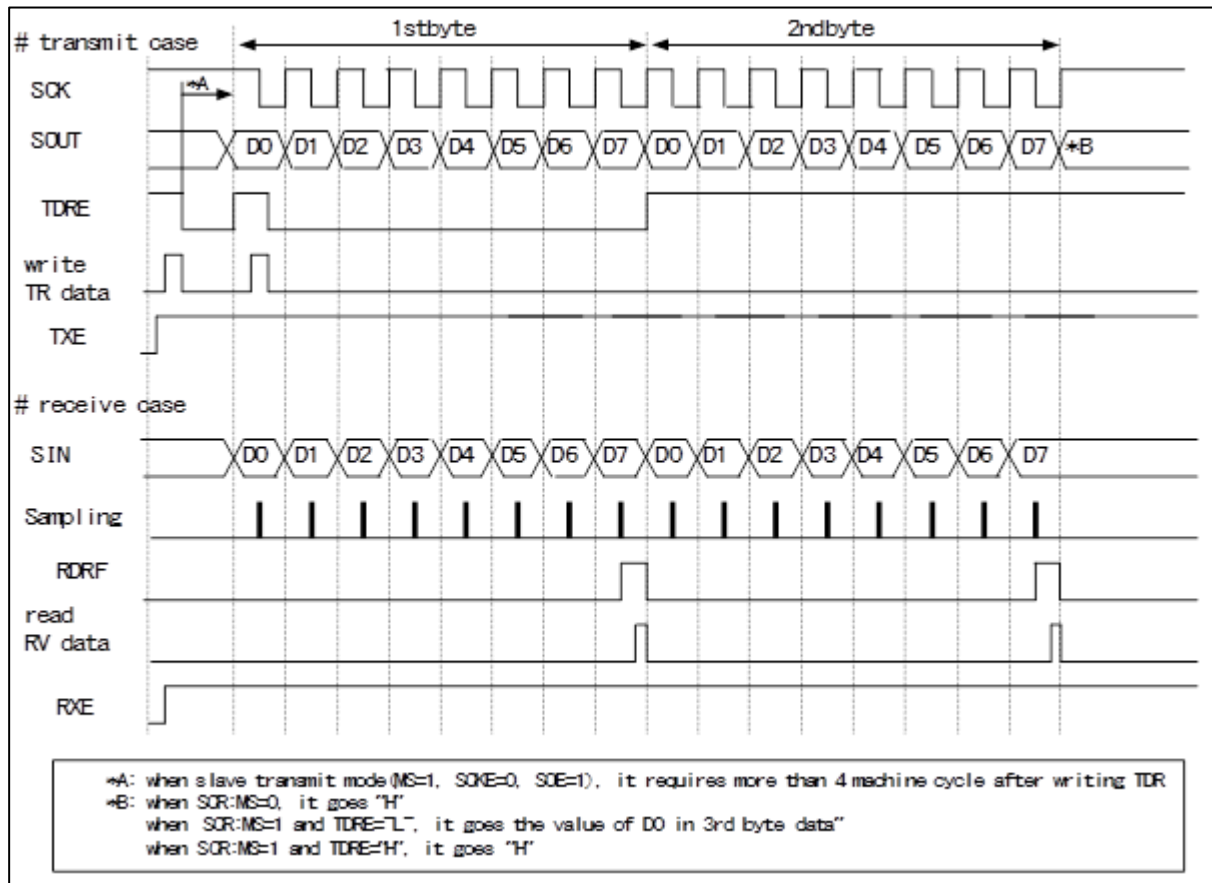

During slave operation: SCR:MS = 1, SMR:SCKE = 0

*1) The bit to be set differs depending on the condition. See Table 5-2.

Note:

- Except for those above, set registers according to their use.

SPI Transfer (I) Timing Chart (When the Serial Chip Select Pin is Not Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSEN3 to CSEN0 = 0x0000)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1), and also transmission operation (SCR:TXE = 1), while disabling reception operation (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. This causes the first bit to be output. Later, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.
2. Half a cycle before a falling edge of the first serial clock (SCK) output, SSR:TDRE is set to 1. Thus, if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0), and transmission is enabled (SCR:TXE = 1), and also reception (SCR:RXE = 1), writing dummy data to TDR causes reception data to be sampled at a falling edge of the serial clock (SCK) output.
2. When the last bit is received, SSR:RDRF is set to 1. At this time, if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Notes:

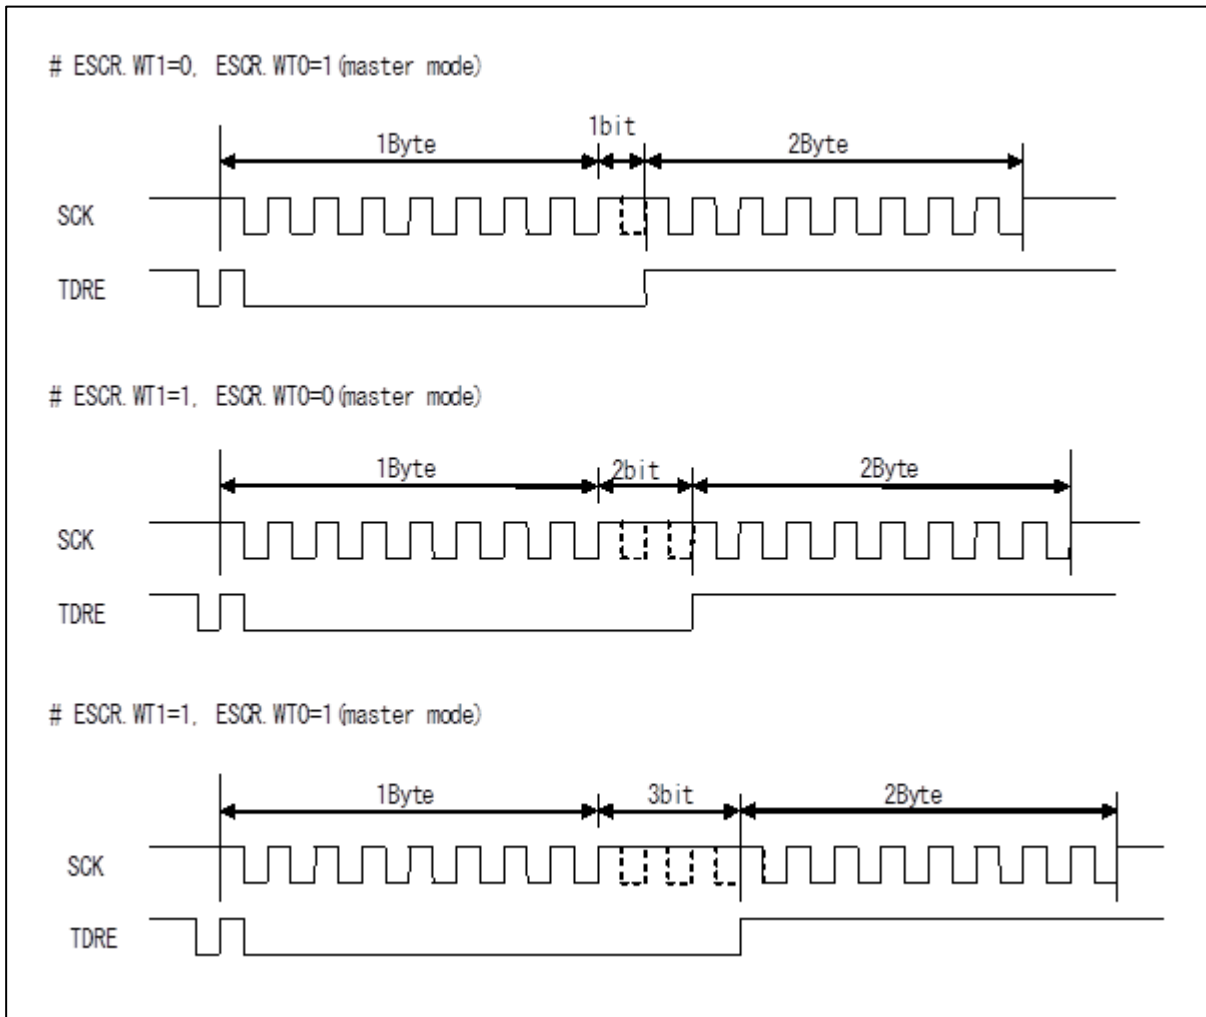

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and the first bit is output. Later, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output. Half a cycle before a falling edge of the first serial clock, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) output. When the last bit of reception data is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN0 = 0)
Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and also transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Thus, the first bit is output. Later, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1. If transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Note:

- After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) but reception is enabled (SCR:RXE = 1), reception data is sampled at a falling edge of the serial clock input (SCK).
2. When the last bit is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

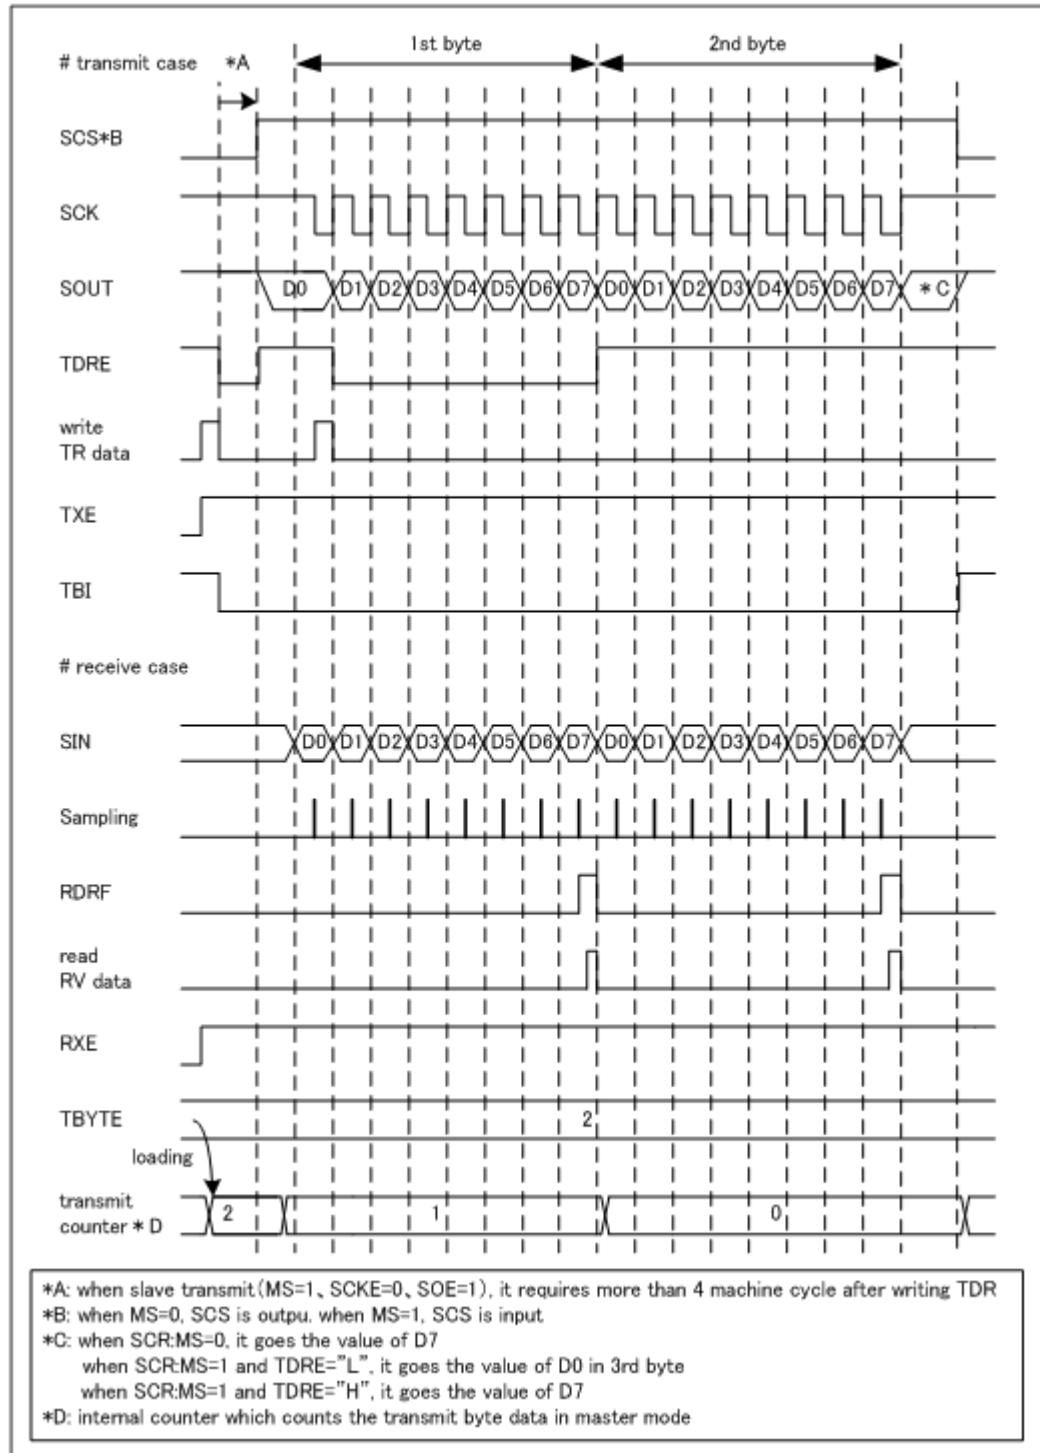

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and the first bit is output. Later, transmission data is output in synchronization with a rising edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) input. When the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Switching from Reception Operation to Transmission Operation

1. Disable serial data output (SMR:SOE = 0), enable reception interrupts (SCR:RIE = 1) and reception operation (SCR:RXE = 1), and also transmission operation (SCR:TXE = 1). If dummy data is written to TDR when the serial clock (SCK) is at the mark level, reception data is sampled at a falling edge of the serial clock input (SCK).
2. To continue reception, write dummy data to TDR between a reception interrupt request and the next rising edge of the serial clock (SCK).
3. To switch from reception to transmission, enable serial data output (SMR:SOE = 1), disable reception interrupts (SCR:RIE = 0), and also reception (SCR:RXE = 0) between a reception interrupt request and the next rising edge of the serial clock (SCK), and write transmission data to TDR; after the end of reception, transmission data is output in synchronization with a rising edge of the serial clock.

SPI Transfer (I) Timing Chart (When the Serial Chip Select Pin is Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CISOE = 1, SCSCR:CSENn* = 1)

*: n is replaced by the serial chip select pin number used.

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and also transmission operation (SCR:TXE = 1), while disabling reception (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Later, at the same time as the first bit is output, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After the start of serial clock output, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.
2. Half a cycle before a falling edge of the first serial clock (SCK) output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. After the end of data transmission for which the count is set in TBYTE, serial clock output is stopped.
4. After the serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Reception Operation

1. Disabling serial data output (SMR:SOE = 0), while enabling transmission (SCR:TXE = 1) and also reception (SCR:RXE = 1), and then writing dummy data to TDR causes the serial chip select pin (SCS) to become active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output starts, reception data is sampled at a falling edge of the serial clock (SCK) output.
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
4. After the end of data reception for which the count is set in TBYTE, serial clock output is stopped.
5. After serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Notes:

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

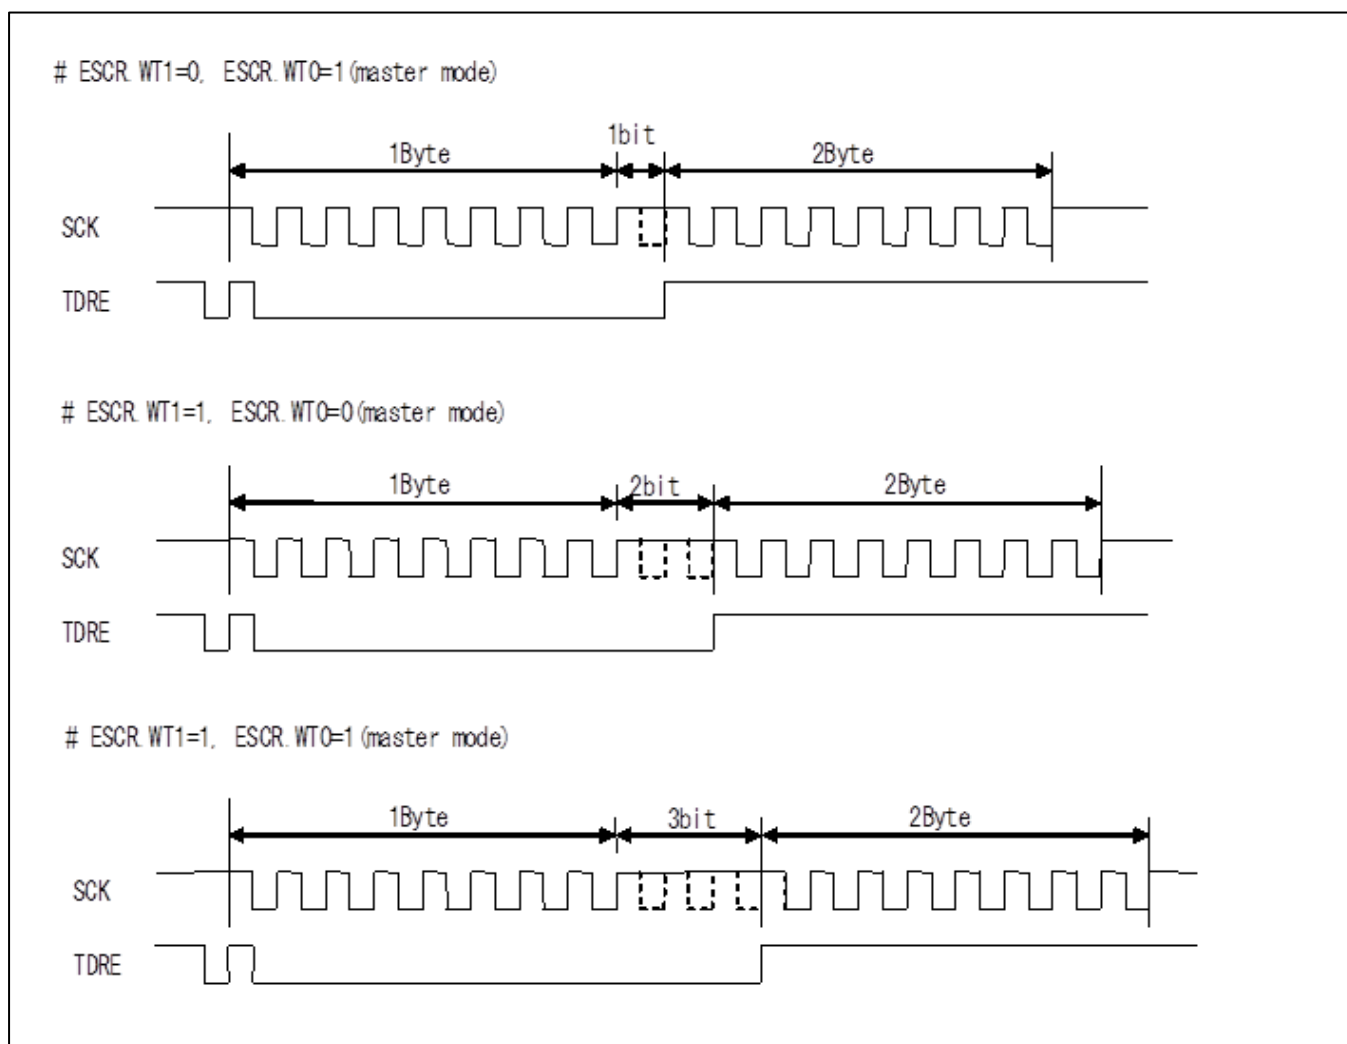

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, at the same time as the first bit is output, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After the start of serial clock output, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output. Half a cycle before a falling edge of the first serial clock, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) output. When the last bit of reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

4. After the end of data transmission/reception for which the count is set in TBYTE, serial clock output is stopped.
5. After serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN = 1, SCSCR:SCAM = 0)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and also transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0.
2. If the serial chip select pin (SCS) becomes active, transmission is started, and the first bit is output. After the start of transmission, transmission data is output in synchronization with a rising edge of the serial clock (SCK) output.

3. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
4. If the serial chip select pin (SCS) becomes inactive, transmission is stopped, and the serial output pin (SOUT) becomes "H".

Note:

- *After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR when the serial clock (SCK) is at the mark level.*

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) and reception is enabled (SCR:RXE = 1), if the serial chip select pin (SCS) becomes active, reception starts, and reception data is sampled at a falling edge of the serial clock input (SCK).
2. If the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
3. At this time, reception data (RDR) can be read.
4. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
5. If the serial chip select pin (SCS) becomes inactive, reception is stopped.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. If the serial chip select pin (SCS) becomes active, transmission/reception starts, and the first bit is output. After the start of transmission/reception, transmission data is output in synchronization with a rising edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a falling edge of the serial clock (SCK) input. When the last bit of reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. If the serial chip select pin (SCS) becomes inactive, transmission/reception stops, and the serial output pin (SOUT) becomes "H".

3.4. SPI Transfer (II)

Features

	Item	Description
1	Serial clock (SCK) mark level	"L"
2	Transmission data output timing	SCK falling edge
3	Reception data sampling	SCK rising edge
4	Data length	5 to 16, 20, 24 and 32 bits

Register Setting

The register settings necessary for SPI transfer (II) are listed below.

SCR:SPI*1 = 1, SMR:MD2 = 0, MD1 = 1, MD0 = 0, SCINV*1 = 1

During master operation: SCR:MS = 0, SMR:SCKE = 1

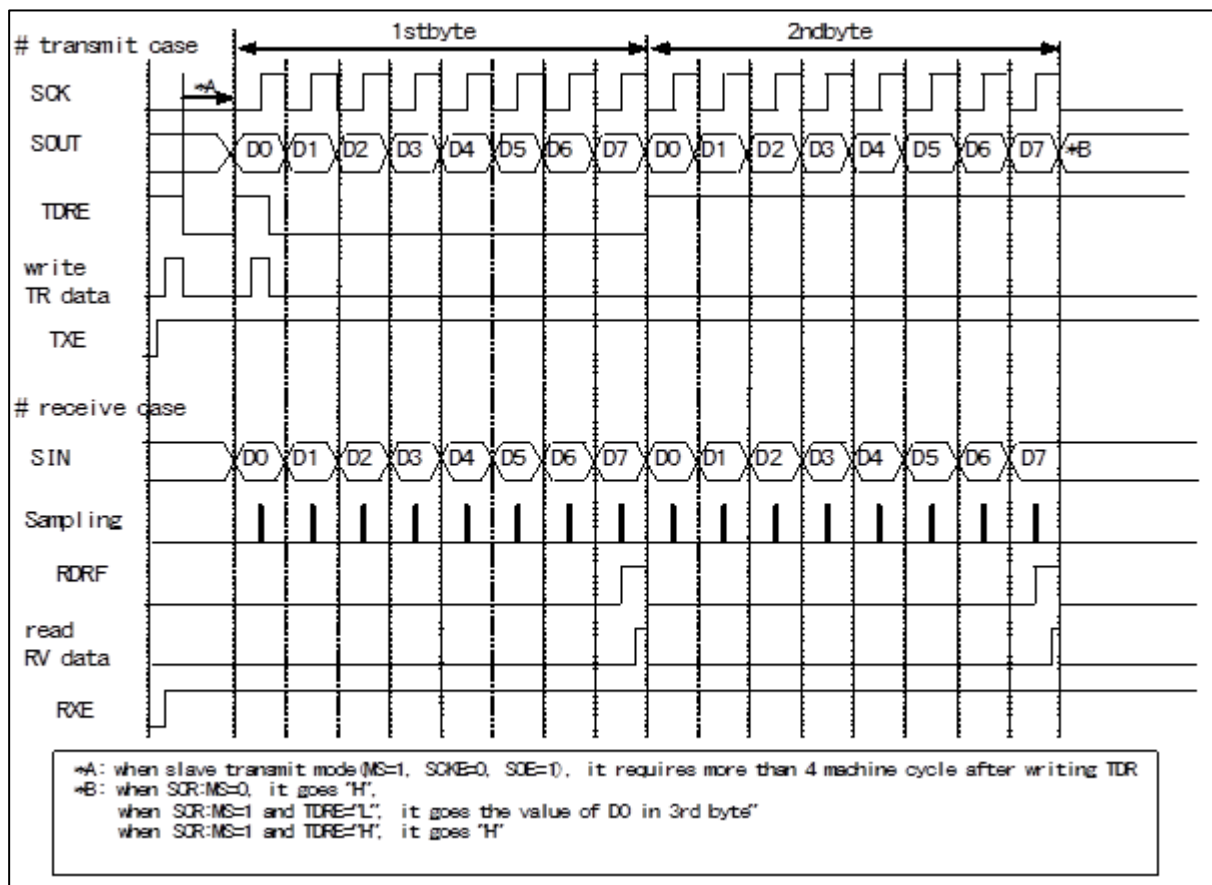

During slave operation: SCR:MS = 1, SMR:SCKE = 0

*1) The bit to be set differs depending on the condition. See Table 5-2.

Note:

- Except for those described above, set the registers according to their use.

SPI Transfer (II) Timing Chart (When the Serial Chip Select Pin is Not Used)

Master Operation (Setting to SCR:MS = 0, SMR:SCKE = 1)
Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission (SCR:TXE = 1), while disabling reception (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. With this, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output.
2. Half a cycle before a rising edge of the first serial clock (SCK) output, SSR:TDRE is set to 1. Thus, if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0), while transmission (SCR:TXE = 1) and reception (SCR:RXE = 1) are enabled, writing dummy data to TDR causes reception data to be sampled at a rising edge of the serial clock output (SCK).
2. When the last bit is received, SSR:RDRF is set to 1. At this time, if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

Notes:

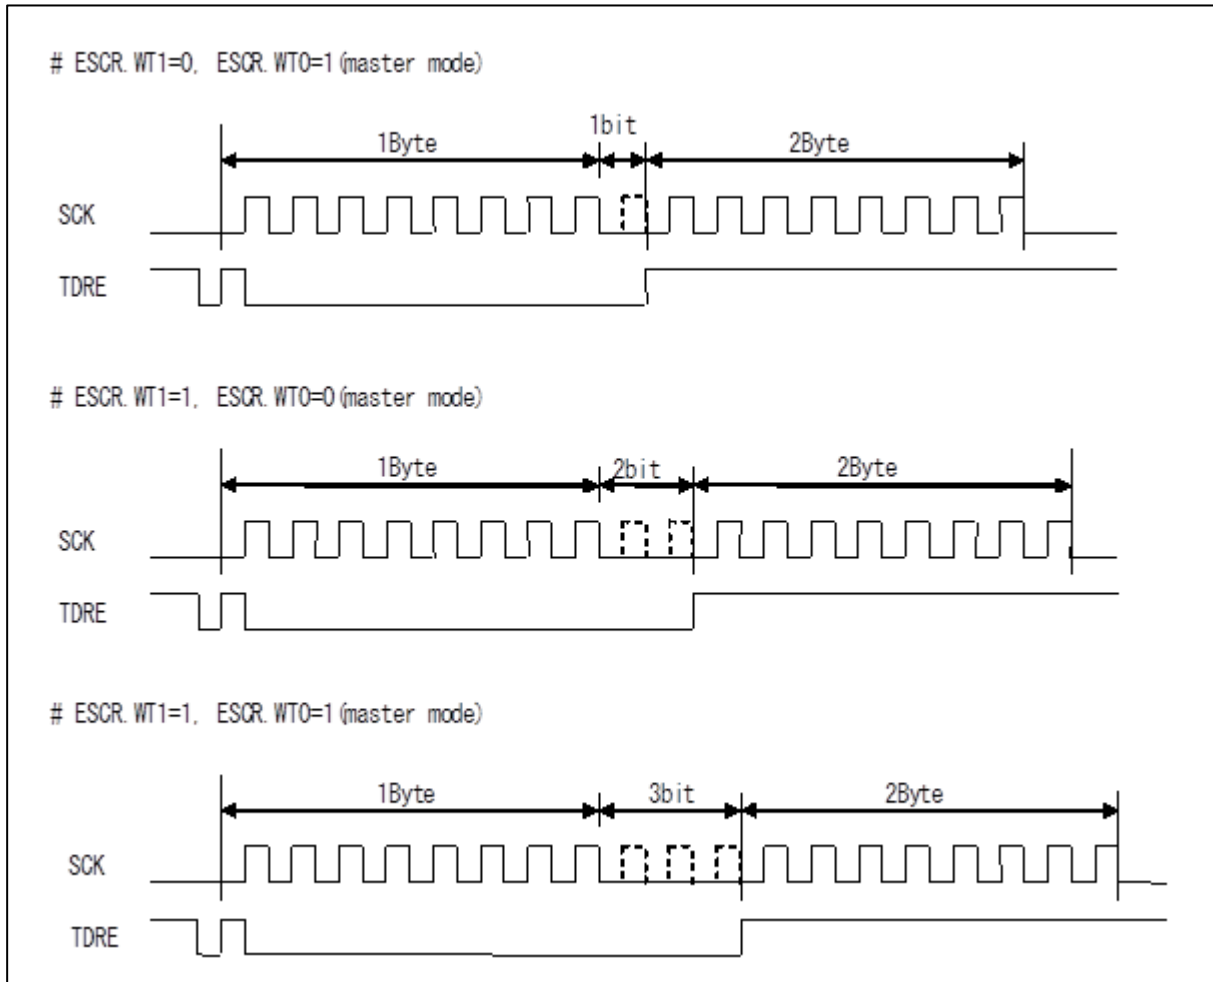

- When performing reception only, write dummy data to TDR to output the serial clock (SCK).
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and the first bit is output. Later, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output. Half a cycle before a rising edge of the first serial clock, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) output. When the last bit of reception data is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

Slave Operation (Setting to SCR:MS = 1, SMR:SCKE = 0)

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Thus, the first bit is output. Later, transmission data is output in synchronization with a falling edge of the serial clock (SCK) input.
2. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1. If transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.

Note:

- After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR with SSR:TBI = 1 when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) and reception operation is enabled (SCR:RXE = 1), reception data is sampled at a rising edge of the serial clock input (SCK).
2. When the last bit is received, SSR:RDRF is set to 1. If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".

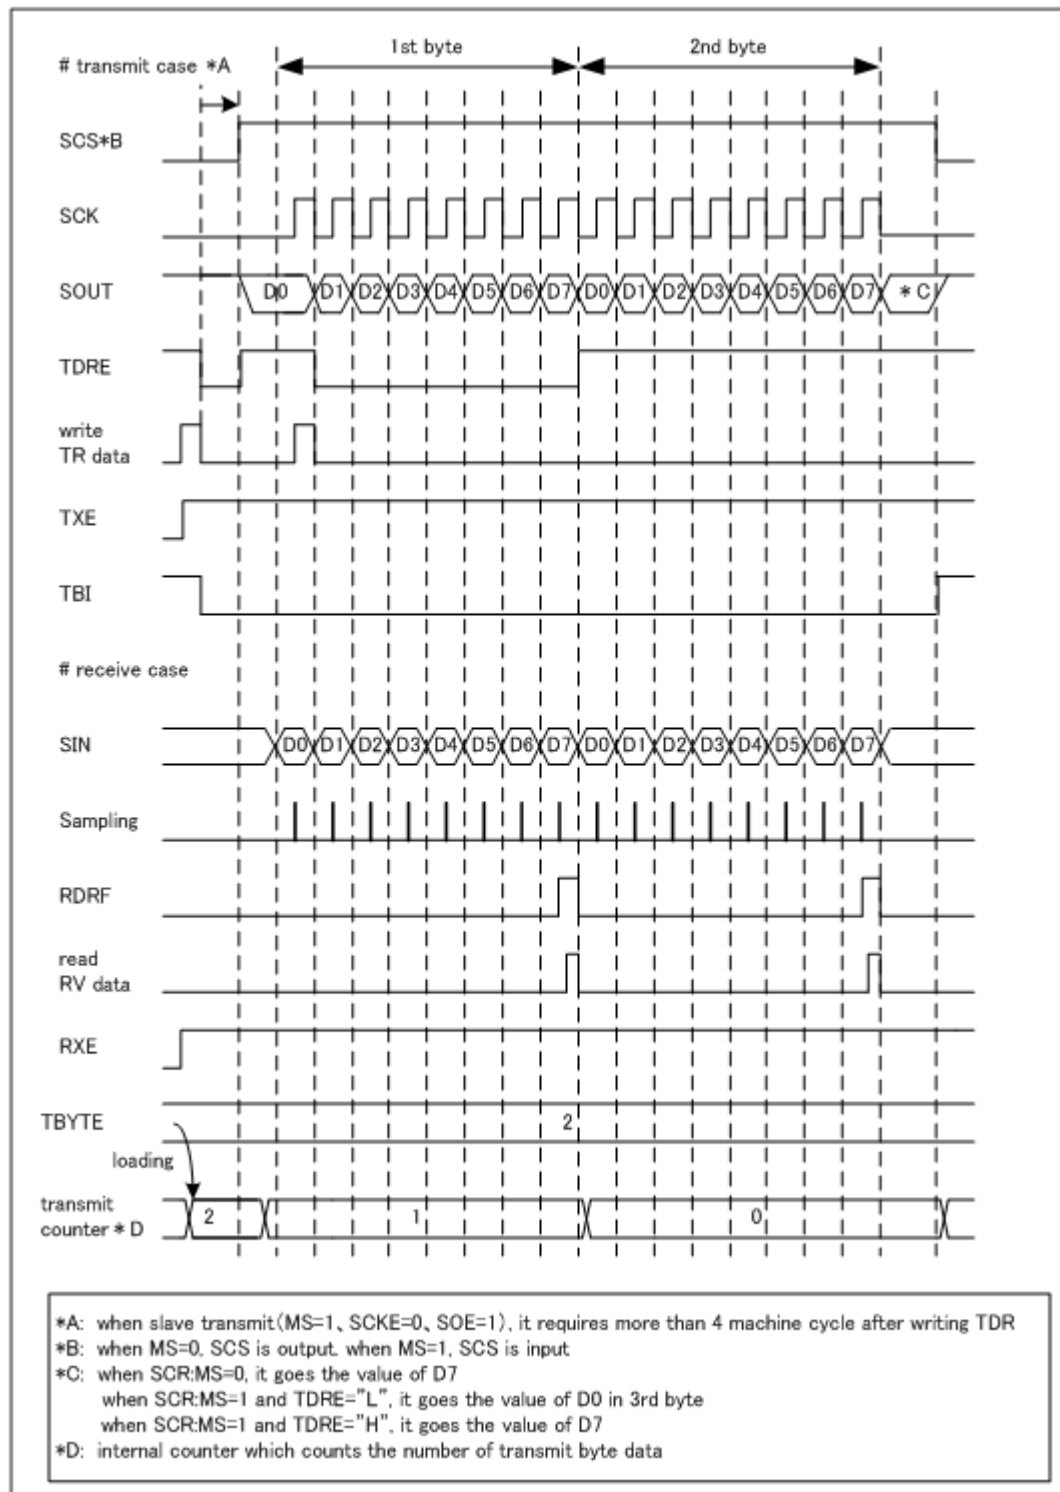

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0, and the first bit is output. Later, transmission data is output in synchronization with a falling edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) input. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".

Continuous Switching from Reception Operation to Transmission Operation

1. Disable serial data output (SMR:SOE = 0), enable reception interrupts (SCR:RIE = 1), enable reception (SCR:RXE = 1) and also transmission (SCR:TXE = 1). If dummy data is written to TDR when the serial clock (SCK) is at the mark level, reception data is sampled at a falling edge of the serial clock input (SCK).
2. To continue reception, write dummy data to TDR between a reception interrupt request and the next rising edge of the serial clock (SCK).
3. To switch from reception to transmission, enable serial data output (SMR:SOE = 1), disable reception interrupts (SCR:RIE = 0), and disable reception (SCR:RXE = 0) between a reception interrupt request and the next rising edge of the serial clock (SCK), and write transmission data to TDR; after the end of reception, transmission data is output in synchronization with a rising edge of the serial clock.

SPI Transfer (II) Timing Chart (When the Serial Chip Select Pin is Used)

Master Operation (SCR:MS = 0, SMR:SCKE = 1, SCSCR:CSCOE = 1, SCSCR:CSENⁿ* = 1)

*: n is replaced by the serial chip select pin number used.

Transmission Operation

1. Enabling serial data output (SMR:SOE = 1) and transmission (SCR:TXE = 1), while disabling reception (SCR:RXE = 0) and then writing transmission data to TDR causes SSR:TDRE to be set to 0. Later, at the same time as the output of the first bit, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After the start of serial clock output, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output.
2. Half a cycle before a falling edge of the first serial clock (SCK) output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. After the end of data transmission for which the count is set in TBYTE, serial clock output is stopped.
4. After the serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Reception Operation

1. Disabling serial data output (SMR:SOE = 0), while enabling transmission (SCR:TXE = 1) and also reception (SCR:RXE = 1) and then writing dummy data to TDR causes the serial chip select pin (SCS) to become active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After serial clock output is started, reception data is sampled at a rising edge of the serial clock (SCK) output.
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
4. After the end of data reception for which the count is set in TBYTE, the serial clock output is stopped.
5. After the serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Notes:

- When performing only reception, write dummy data to TDR to cause the serial clock (SCK) to be output.
- When the transmission/reception FIFOs are enabled, setting the number of frames to transfer in the FBYTE register causes as many serial clock (SCK) pulses as the number of frames to be output.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable both serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. Later, at the same time as the output of the first bit, the serial chip select pin (SCS) becomes active, and after the elapse of the serial chip select pin setup time, serial clock output is started. After the start of serial clock output, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output. Half a cycle before a rising edge of the first serial clock, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) output. When the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When the reception data is read, SSR:RDRF is cleared to "0".
4. After the end of data transmission/reception for which the count is set in TBYTE, the serial clock output is stopped.
5. After serial clock output is stopped, the serial chip select pin (SCS) becomes inactive after the elapse of the serial chip select pin hold time. At this time, however, if the serial chip select active level (SCSCR:SCAM = 1) is retained, the serial chip select pin (SCS) retains the active state.

Continuous Data Transmission or Reception Wait Operation

If settings other than (ESCR:WT1, ESCR.WT0) = (0, 0) are set for continuous data transmission or reception, a wait is inserted between the frames.

ESCR.WT1=0, ESCR.WT0=1 (master mode)

ESCR.WT1=1, ESCR.WT0=0 (master mode)

ESCR.WT1=1, ESCR.WT0=1 (master mode)

Slave Operation (SCR:MS = 1, SMR:SCKE = 0, SCSCR:CSEN = 1, SCSCR:SCAM = 0)

Transmission Operation

1. Enabling both serial data output (SMR:SOE = 1) and transmission (SCR:TXE = 1) and then writing transmission data to TDR causes SSR:TDRE to be set to 0.
2. If the serial chip select pin (SCS) becomes active, transmission operation is started, and the first bit is output. After the start of transmission, transmission data is output in synchronization with a falling edge of the serial clock (SCK) output.
3. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
4. If the serial chip select pin (SCS) becomes inactive, transmission operation is ended, and the serial output pin (SOUT) becomes "H".

Note:

- After transmission is enabled (SCR:TXE = 1), if the first writing of transmission data to TDR is performed when the serial clock (SCK) is not at the mark level, the first 1 bit of data is not output, and transmission is not performed normally. After transmission is enabled (SCR:TXE = 1), perform the first writing of transmission data to TDR when the serial clock (SCK) is at the mark level.

Reception Operation

1. If serial data output is disabled (SMR:SOE = 0) but reception is enabled (SCR:RXE = 1), and if the serial chip select pin (SCS) becomes active, reception operation starts, and reception data is sampled at a rising edge of the serial clock input (SCK).
2. When the last bit is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output.
At this time, reception data (RDR) can be read.
3. When reception data (RDR) is read, SSR:RDRF is cleared to "0".
4. If the serial chip select pin (SCS) becomes inactive, reception is stopped.

Transmission/Reception Operations

1. To perform transmission/reception at the same time, enable both serial data output (SMR:SOE = 1) and also transmission/reception (SCR:TXE, RXE = 1).
2. When transmission data is written to TDR, SSR:TDRE is set to 0. If the serial chip select pin (SCS) becomes active, transmission/reception starts, and the first bit is output. After the start of transmission, transmission data is output in synchronization with a falling edge of the serial clock (SCK) input. When the first 1 bit of transmission data is output, SSR:TDRE is set to 1, and if transmission interrupts are enabled (SCR:TIE = 1), a transmission interrupt request is output. At this time, the second byte of transmission data can be written.
3. Reception data is sampled at a rising edge of the serial clock (SCK) input. If the last bit of the reception data is received, SSR:RDRF is set to 1, and if reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is output. At this time, reception data (RDR) can be read. When reception data is read, SSR:RDRF is cleared to "0".
4. If the serial chip select pin (SCS) becomes inactive, transmission/reception operations are stopped, and the serial output pin (SOUT) becomes "H".

4. Serial Timer Operation

The serial timer can be used as either a timer function or as a synchronous transmission function.

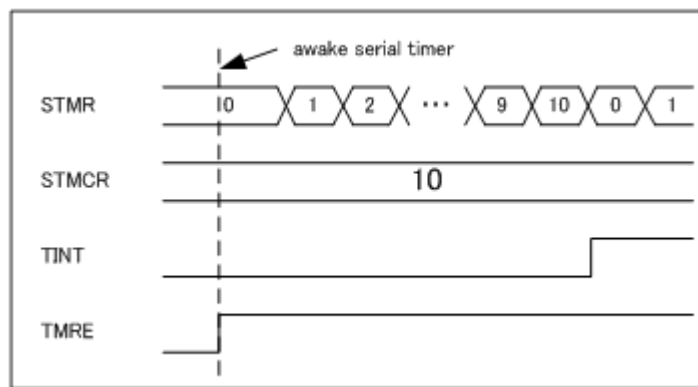

Activating the Serial Timer

The serial timer can be activated either by setting the serial timer enable bit (SACSR:TMRE) to "1" or by using an external trigger.

■ Activation by the serial timer enable bit (SACSR:TMRE)

Provided that the external trigger enable bit (SACSR:TRGE) is set to "0", if the serial timer enable bit (SACSR:TMRE) is set to "1", the serial timer is activated, and the serial timer register (STMR) starts counting from 0.

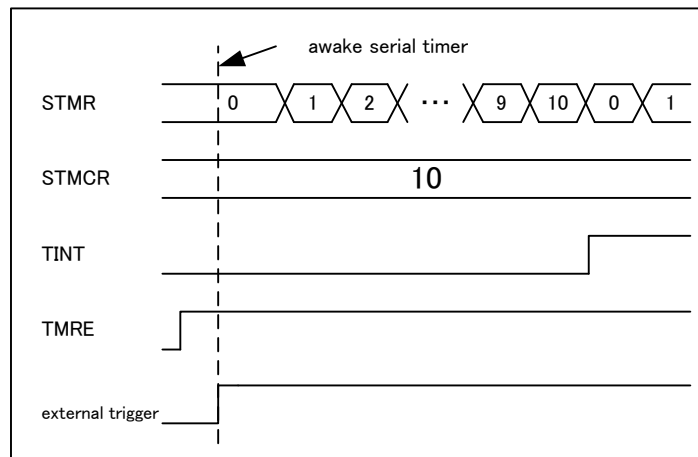

Figure 4-1 Activation by Serial Timer Enable Bit (STMCR = 10, SACSR:TRGE = 0, TSYNE = 0)

■ Activation by an external trigger

The serial timer is activated and counting of the serial timer register (STMR) starts from 0 when all of the following are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is set to "1". 2. An external trigger edge specified by the trigger selection bit (TRG1, 0) is detected. 3. The serial timer enable bit (SACSR:TMRE) is set to "1".

Figure 4-2 Activation by an External Trigger (STMCR = 10, SACSR:TRGE = 1, TSYNE = 0, TRG1 = 0, TRG0 = 0)

Note:

- Detection of an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) does not start the serial timer if both of the following are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is "1". 2. The serial timer enable bit (SACSR:TMRE) is "0".

Stopping the Serial Timer

The serial timer stops when the serial timer enable bit (SACSR:TMRE) is set to "0". At this time, the value of the serial timer register (STMR) is retained.

Timer Operation

When the synchronous transmission enable bit (SACSR:TSYNE) is "0", the serial timer operates as a timer.

The timer interrupt flag (SACSR:TINT) is set to "1" and the serial timer register (STMR) is reset to 0 when the serial timer register (STMR) coincides with the serial timer comparison register (STMCR).

Figure 4-3 Timer Operation (STMCR = 10, SACSR:TSYNE = 0)

Figure 4-4 Flow Chart of Serial Timer Initialization

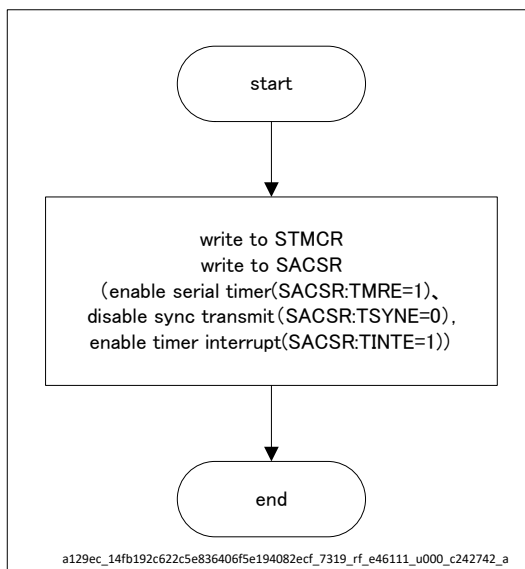

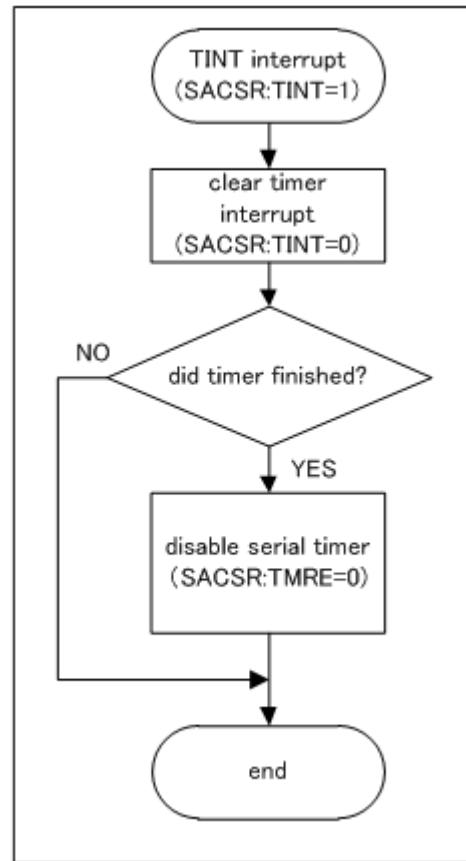

Figure 4-5 Flow Chart of Serial Timer Interrupt Processing**Note:**

- In the state in which synchronous transmission is disabled ($SACSR:TSYNE = 0$) while $0x0000$ is set in the timer comparison register ($STMCR$), if the timer is operating and the division value ($SACSR:TDIV3-0$) of the timer operation clock is set to $0b0000$, the timer interrupt flag ($SACSR:TINT$) is fixed to "1".

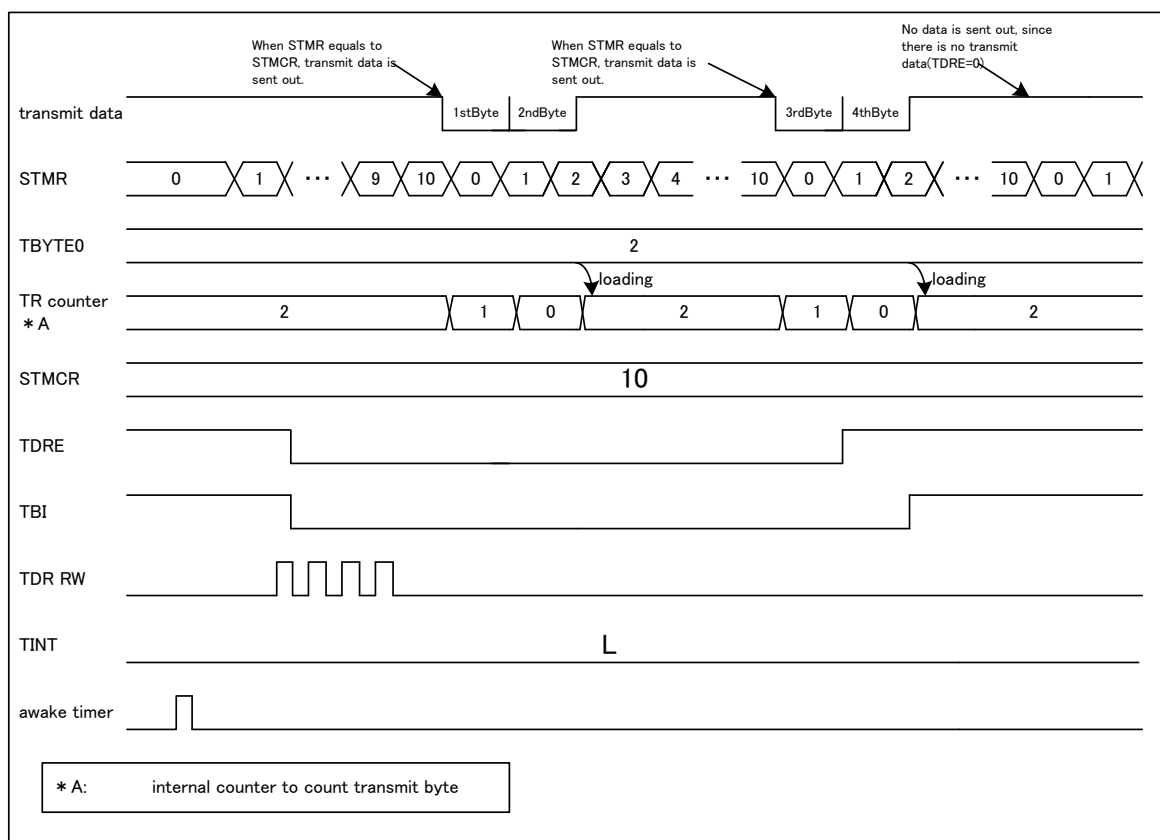

Transmission Operation Synchronized with the Timer

The serial timer is used for synchronous transmission when the synchronous transmission enable bit (SACSR:TSYNE) is set to "1".

Timer-synchronized transmission operates in the following manner:

1. If the transmission data register contains data (SSR:TDRE = 0) and if the contents of the serial timer register (STMR) and the serial timer comparison register (STMCR) match, transmission operation starts, and the serial timer register (STMR) is reset to 0. Data transmission is performed for the data count specified in TBYTE0.
2. After transmitting the data count as specified by TBYTE0, transmission is suspended until the next time the serial timer register (STMR) and serial timer comparison register (STMCR) coincide.

Figure 4-6 Transmission Operation Synchronized with the Timer (STMR = 10, TBYTE0 = 2, SACSR:TSYNE = 1)

When synchronous transmission is enabled (SACSR:TSYNE = 1) and the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide, transmission is not activated under the following conditions:

- Transmission is disabled (SCR:TXE = 0).
- In slave mode (SCR:MS = 1)
- When a chip select error (SACSR:CSE = 1) occurs
- The transmission data register does not contain valid data (SSR:TDRE = 1).

However, writing transmission data to the transmission data register instantly starts transmission when all of the following are satisfied: 1. The transmission data register does not contain valid data (SSR:TDRE = 1). 2. Synchronous transmission is enabled (SACSR:TSYNE = 1). 3. The serial timer register (STMR) and serial timer comparison register (STMCR) coincide.

If the transmission data register (TDR) contains valid data (SSR:TDRE = 0) after transmission of the data count specified by TBYTE, the data is not transmitted until the next time the serial timer register (STMR) and the serial timer comparison register (STMCR) coincide.

If, however, synchronous transmission is enabled (SACSR:TSYNE = 1), transmission is in progress (SSR:TBI = 0), and the serial timer register (STMR) and the serial timer comparison register (STMCR) match, transmission is reserved. When transmission reservation has been made, transmission does not stop after transmission of the data count specified by TBYTE0, and any subsequent transmission is performed.

Transmission reservation is released under one of the conditions below.

- Programmable reset (SCR:UPCL = 1)
- Transmission disabled (SCR:TXE = 0)
- Chip select error (SACSR:CSE = 1)

To perform synchronous reception, disable serial data output (SMR:SOE = 0), enable transmission (SCR:TXE = 1) and also reception (SCR:RXE = 1) and then write dummy data to TDR for the reception count.

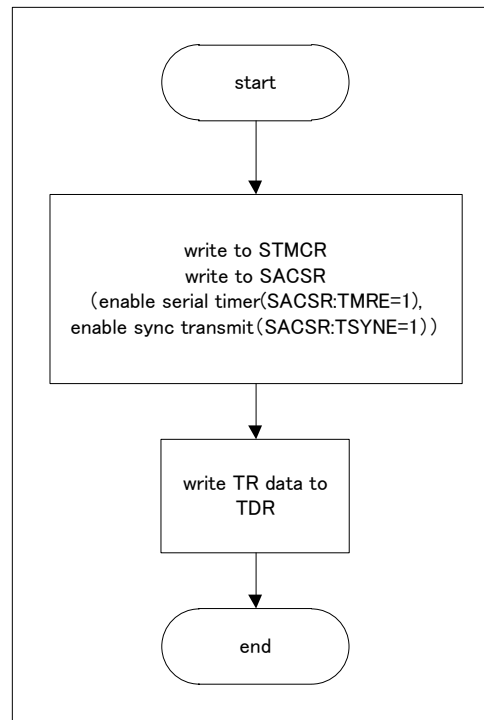

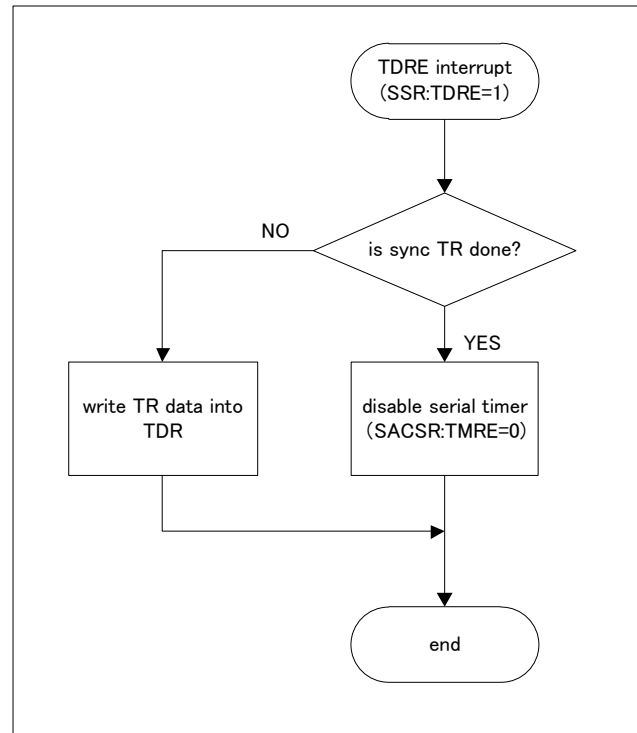

Figure 4-7 Flow Chart of Initialization of Transmission Synchronized with Timer

Figure 4-8 Flow Chart of Interrupt Processing in Transmission Synchronized with Timer**Notes:**

- If synchronous transmission is enabled ($SACSR:TSYNE = 1$), external triggers are enabled ($SACSR:TRGE = 1$), and $0x0000$ is set in the timer comparison register ($STMCR$), transmission synchronized with the timer is not performed, but transmission synchronized with an external trigger is performed.
- If the transmission data register (TDR) contains no valid transmission data ($SSR:TDRE = 1$) before the transmission of as many data frames as the setting made for $TBYTE$, the following operation is performed.
 - If transfer byte errors are enabled ($TBEEN = 1$), a chip select error ($SACSR:CSE = 1$) occurs. If "1" is set in the chip select error flag ($SACSR:CSE$), transmission is not started even if transmission data is written to the transmission data register (TDR).
 - If transfer byte errors are disabled ($TBEEN = 0$), transmission is stopped until transmission data is written to the transmission data register (TDR). Writing transmission data to the transmission data register (TDR) restarts the transmission operation.

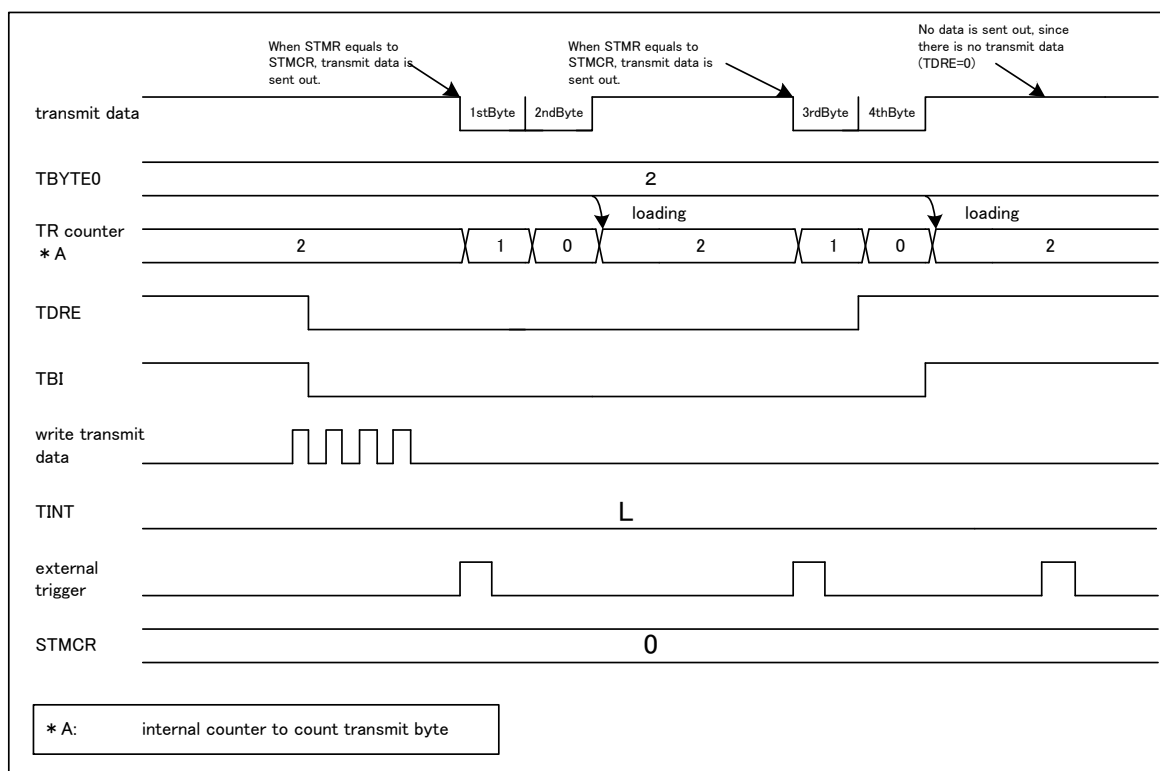

Transmission Operation Synchronized with an External Trigger

If synchronous transmission is enabled (SACSR:TSYNE = 1), external triggers are enabled (SACSR:TRGE = 1), 0x0000 is set in the timer comparison register (STMCR), transmission is enabled (SCR:TXE = 1), and there is valid transmission data (SSR:TDRE = 0), transmission synchronized with an external trigger is started.

The start of transmission synchronized with an external trigger is performed as described below.

1. The operation starts immediately when an external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) is detected. Data transmission is performed for the data count specified in TBYTE0.
2. After the completion of data transmission for the number of data items that is set in TBYTE0, transmission stops until the next time an external trigger edge that is set in the trigger select bits (SACSR:TRG1, 0) is detected.

Figure 4-9 Transmission Operation Synchronized with External Trigger (TRG1 = 0, TRG0 = 0, SACSR:TSYNE = 1)

During external-trigger-synchronized transmission, the detection of an external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) does not start transmission under the following conditions:

- Transmission is disabled (SCR:TXE = 0).
- In slave mode (SCR:MS = 1)
- When a chip select error (SACSR:CSE = 1) occurs
- The transmission data register does not contain valid data (SSR:TDRE = 1).

If, however, the transmission data register contains no valid data (SSR:TDRE = 1), and an external trigger edge that is set in the trigger selection bits (SACSR:TRG1, 0) is detected, transmission starts as soon as transmission data is written to the transmission data register.

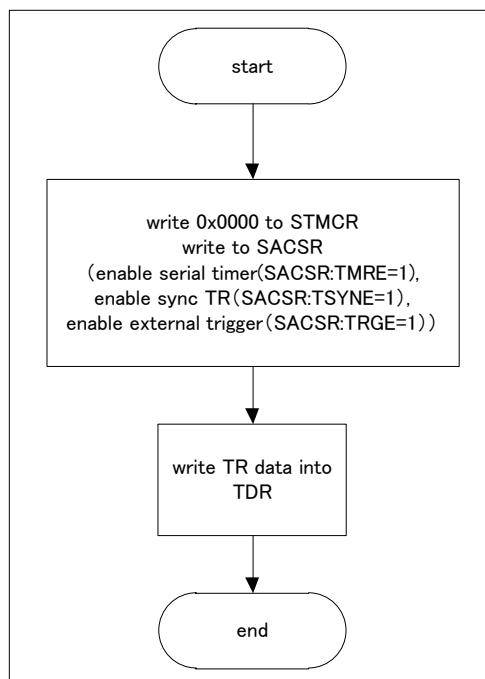

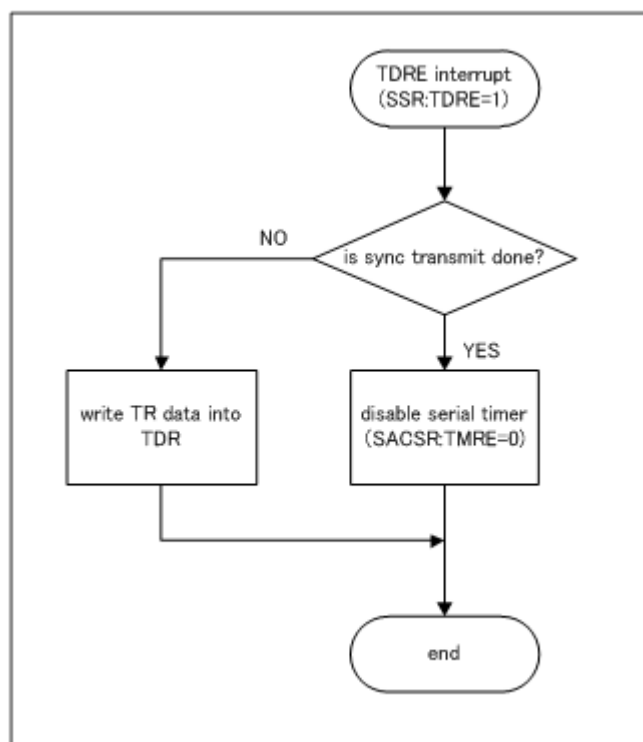

If the transmission data register (TDR) contains valid transmission data (SSR:TDRE = 0) after transmission of the data count specified by TBYTE, the following occurs: The remaining data is not transmitted until an external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) is next detected.

However, when an external trigger edge specified by the trigger selection bits (SACSR:TRG1, 0) is detected during a transmission operation (SSR:TBI = 0) with synchronous transmission enabled (SACSR:TSYNE = 1), a transmission reservation takes place. If transmission reservation has been performed, transmission does not stop after transmission of the data count specified by TBYTE0, and the subsequent transmission is performed.

Transmission reservation is released under one of the conditions below.

- Programmable reset (SCR:UPCL = 1)
- Transmission disabled (SCR:TXE = 0)
- Chip select error (SACSR:CSE = 1)

To perform reception operation synchronized with an external trigger, disable serial data output (SMR:SOE = 0), enable both transmission (SCR:TXE = 1) and reception (SCR:RXE = 1) and then write dummy data to TDR for the reception count.

Figure 4-10 Flow Chart of Initialization of Transmission Synchronized with External Trigger

Figure 4-11 Flow Chart of Interrupt Processing in Transmission Synchronized with External Trigger

Notes:

- If the transmission data register (TDR) contains no valid transmission data (SSR:TDRE = 1) before the transmission of as many data frames as the setting made for TBYTE, the operation described below is performed.

- If transfer byte errors are enabled (TBEEN = 1), a chip select error (SACSR:CSE = 1) occurs. If "1" is set in the chip select error flag (SACSR:CSE), transmission is not started even if transmission data is written to the transmission data register (TDR).
- If transfer byte errors are disabled (TBEEN = 0), transmission is stopped until transmission data is written to the transmission data register (TDR). Writing transmission data to the transmission data register (TDR) restarts transmission.

5. Operation of Serial Chip Select

This section explains serial chip select operation.

Operation in Master Mode (SCR:MS = 0)

In master mode (SCR:MS = 0), the serial chip select pin operates as described below.

1. If you enable both serial chip select (SCSCR:CSENn = 1) and transmission (SCR:TXE = 1), the serial chip select pin becomes active when transmission data is written.
2. After the elapse of the serial chip select pin setup time, transmission/reception operations are started.
3. After data transmission/reception for which the count is set in TBYTE, the serial clock stops.
4. After the serial clock is stopped, the serial chip select pin becomes inactive after the elapse of the serial chip select pin hold time.

Figure 5-1 Serial Chip Select Operation (Master Transmission (MS = 0), Normal Transfer (SPI = 0), SCINV = 0)

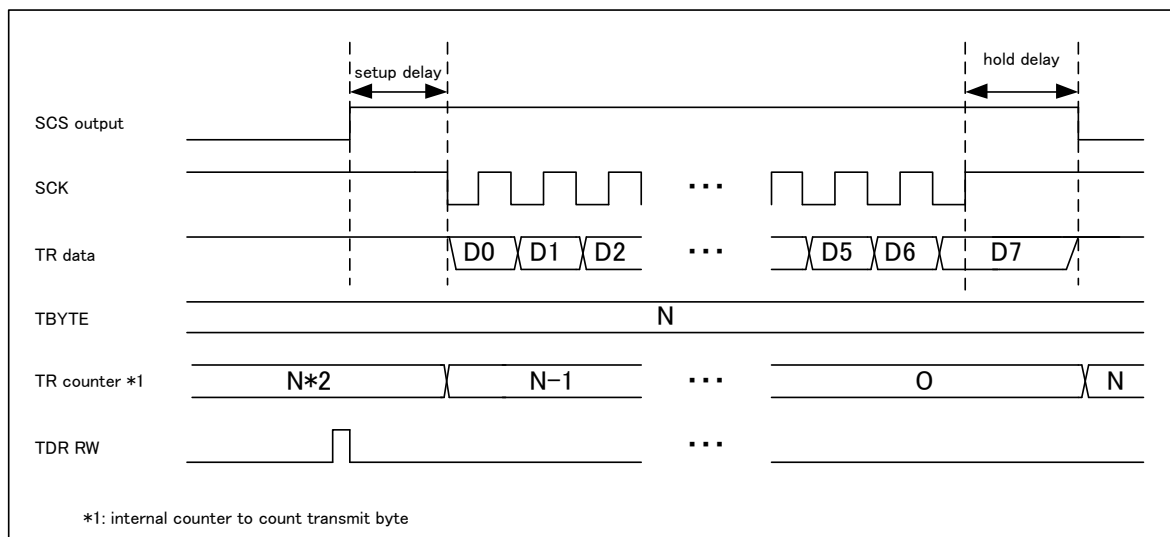

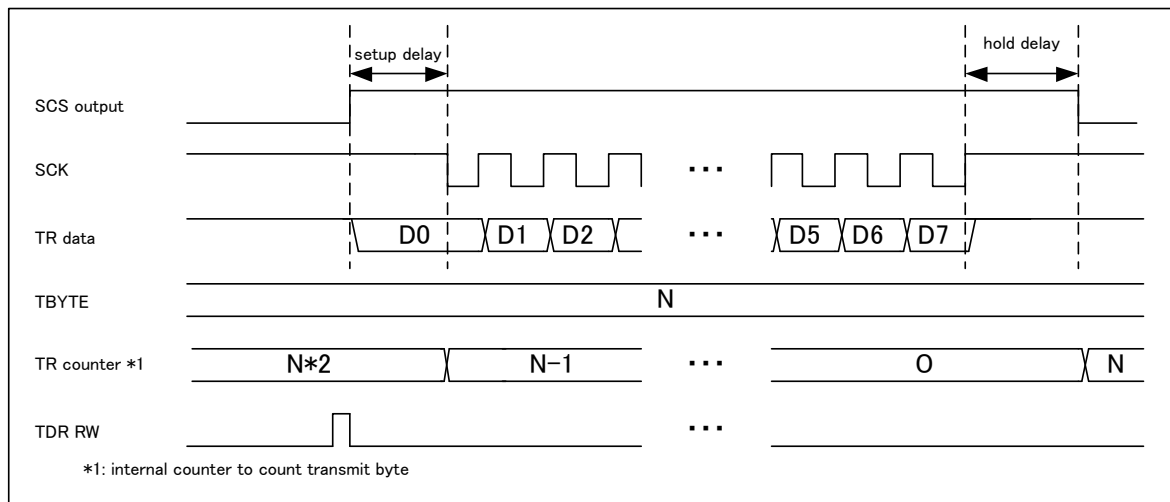

Figure 5-2 Serial Chip Select Operation (Master Transmission (MS = 0), SPI Transfer (SPI = 1), SCINV = 0)

Notes:

- While the serial chip select pin is active, if transmission is disabled ($SCR:TXE = 0$) and software is reset ($SCR:UPCL = 1$), the serial chip select pin becomes inactive.
- If the active state of the serial chip select pin is not retained ($SCSCR:SCAM = 0$), the serial chip select pin becomes inactive, and if there is no transmission data ($SSR:TDRE = 1$) after the elapse of the deselect time, the transmission bus idle state ($SSR:TBI = 1$) is assumed.
- In master mode ($SCR:MS = 0$), if $SCSCR:CSEN3$ to $CSEN0$ is set to $0b0000$, transmission/reception operations are performed regardless of the status of the serial chip select pin.
- When fewer frames than the number set in $TBYTE$ have been transmitted, if the transmission data register (TDR) contains no valid transmission data at the time of completion of 1-frame transmission ($SSR:TDRE = 1$), the operation described below is performed.
 - If transfer byte errors are enabled ($TBEEN = 1$), a chip select error ($SACSR:CSE = 1$) occurs. Once the hold delay time elapses after the occurrence of a chip select error ($SACSR:CSE = 1$), the serial chip select pin becomes inactive. If "1" is set in the chip select error flag ($SACSR:CSE$), transmission is not started even if transmission data is written to the transmission data register (TDR).
 - If transfer byte errors are disabled ($TBEEN = 0$), transmission is stopped until transmission data is written to the transmission data register (TDR). At this time, the serial chip select pin is active. Writing transmission data to the transmission data register (TDR) restarts the transmission operation.

Serial Chip Select Timing Adjustment

If, in master mode (SCR:MS = 0), serial chip select operation is enabled (SCSCR:CSENn = 1), by adjusting the serial chip select timing registers (SCSTR3 to SCSTR0), setup delay, hold delay, and deselect time can be adjusted.

■ Setup delay time

Time from the instant at which the serial chip select pin becomes active until the serial clock is output.

For details on the regulations governing the setup delay time, see Figure 5-3 and Figure 5-4.

This can be adjusted with the chip select setup delay bits (SCSTR1:CSSU7 to CSSU0).

■ Hold delay time

Time from the instant at which the output of the serial clock ends until the serial chip select pin becomes inactive. For details on the regulations governing the hold delay time, see Figure 5-3 and Figure 5-4.

This can be adjusted with the chip select hold delay bits (SCSTR0:CSHD7 to CSHD0).

■ Deselect time

Minimum time from the instant at which the serial chip select pin becomes inactive until the next time that the serial chip select pin becomes active. Even if transmission data is written to the transmission data register (TDR) within the deselect time, the serial chip select pin does not become active until the end of the deselect time. For details on the regulations governing the deselect time, see Figure 5-3 and Figure 5-4.

This can be adjusted with the chip select/deselect bits (SCSTR3 to SCSTR2:CSDS15 to CSDS0).

Figure 5-3 Timing Adjustment (Normal Transfer (SPI = 0), SCINV = 0)

Figure 5-4 Timing Adjustment (Normal Transfer (SPI = 1), SCINV = 0)**Notes:**

- During normal transfer (SCR:SPI = 0) with no hold delay time (SCSTR0:CSHD7 to CSHD0 = 0x00), the chip select pin may become inactive before the sampling of the last bit. In this case, perform adjustments by increasing the values of SCSTR0:CSHD7 to CSHD0.
- During SPI transfer (SCR:SPI = 1) with no setup delay time (SCSTR1:CSSU7 to CSSU0 = 0x00), the chip select pin may become active after the sampling of the first bit. In this case, perform adjustments by increasing the values of SCSTR1:CSSU7 to CSSU0.

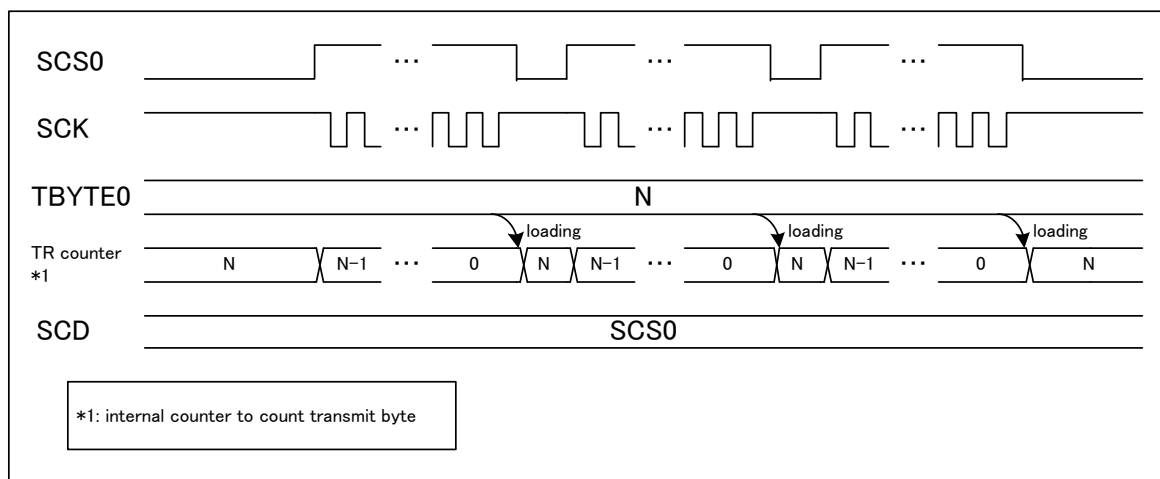

Independent Operation of the Chip Select Pin (Valid Only in Master Mode (SCR:MS = 0))

If the serial chip select start bits (SCSCR:SST1 and SST0) and the serial chip select end bits (SCSCR:SED1 and SED0) are equal, operation is performed based on only the set serial chip select pin.

When the active level of serial chip select is not retained (SCSCR:SCAM = 0), the serial chip select pin becomes inactive for each data transmission/reception for which the count is set in TBYTE.

For details on the serial chip select pin operation performed if the active level of serial chip select is retained (SCSCR:SCAM = 1), see "Serial chip select active level retention operation."

Figure 5-5 Independent Operation of Chip Select (SST1 and SST0 = 0, SED1 and SED0 = 0, CSEN0 = 1, SCAM = 0)

Note:

- During independent operation, serial chip select pin timing adjustment (setup time, hold time, and deselect time) is valid.

Rounding Operation of the Chip Select Pin (Valid Only in Master Mode (SCR:MS = 0))

If the serial chip select start bits (SCSCR:SST1 and SST0) and the serial chip select end bits (SCSCR:SED1 and SED0) differ, multiple serial chip select pins become active sequentially.

1. If transmission data is written when you enable both serial chip select output (SCSCR:CSOE = 1) and transmission (SCR:TXE = 1), the serial chip select pins become active, starting with that specified with the serial chip select start bits (SCSCR:SST1 and SST0).
2. When the active level of serial chip select is not retained (SCSCR:SCAM = 0), the serial chip select pin becomes inactive after the end of data transmission/reception for which the count is set in TBYTE. Later, the serial chip select pin with the pin number equal to the number of the last active serial chip select pin + 1 becomes active.* 1

If the next serial chip select pin to become active is disabled (SCSCR:CSENN = 0), the serial chip select pin does not become active but is instead skipped.

3. If the active serial chip select pin number matches the serial chip select pin specified with the serial chip select end bits (SCSCR:SED1 and SED0), the serial chip select pin specified with the serial chip select start bits (SCSCR:SST1 and SST0) becomes active next.

*1: If the last active serial chip select pin is pin 0, pin 1 becomes active; if it is pin 1, pin 2 becomes active; if it is pin 2, pin 3 becomes active; and if it is pin 3, pin 0 becomes active.

For details on the serial chip select pin operation performed if the active level of serial chip select is retained (SCSCR:SCAM = 1), see "Serial chip select active level retention operation."

Figure 5-6 shows the timing chart that is assumed if the serial chip select start pin is SCS0 (SST1 and SST0 = 0) and the end pin is SCS3 (SED1 and SED0 = 3).

Figure 5-6 Rounding Operation of Chip Select (SST1=0 = 0, SED1=0 = 3, CSEN3 = 1, CSEN2 = 1, CSEN1 = 1, CSEN0 = 1, SCAM = 0)

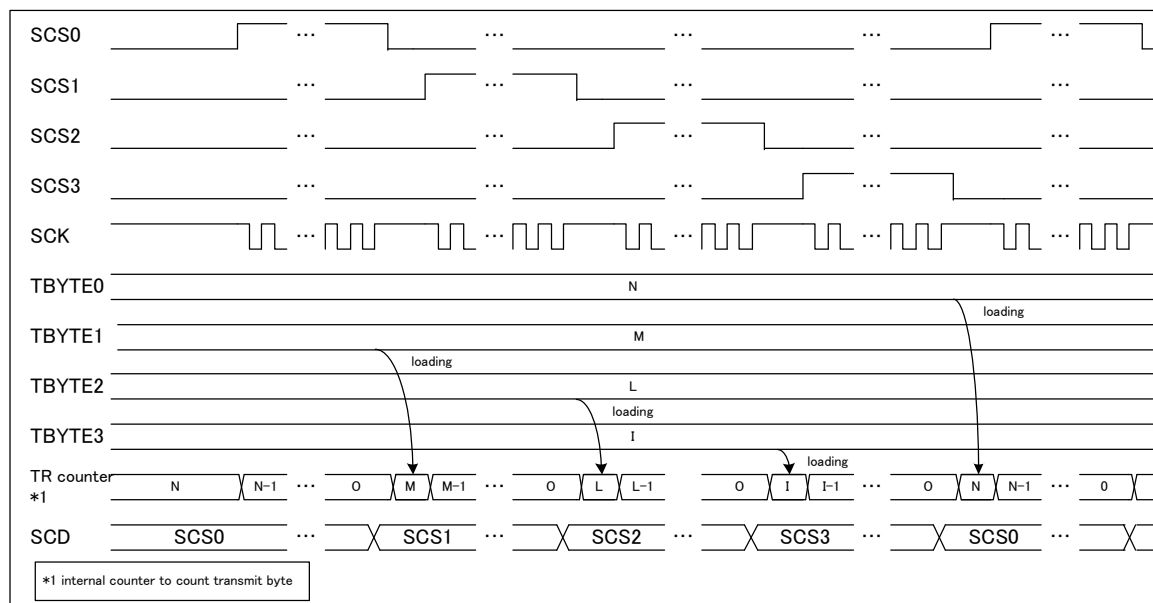

Figure 5-7 shows the timing chart that is assumed if the serial chip select start pin is SCS1 (SST1 and SST0 = 1) and the end pin is SCS2 (SED1 and SED0 = 2).

Figure 5-7 Rounding Operation of Chip Select (SST1-0 = 1, SED1-0 = 2, CSEN3 = 0, CSEN2 = 1, CSEN1 = 1, CSEN0 = 0, SCAM = 0)

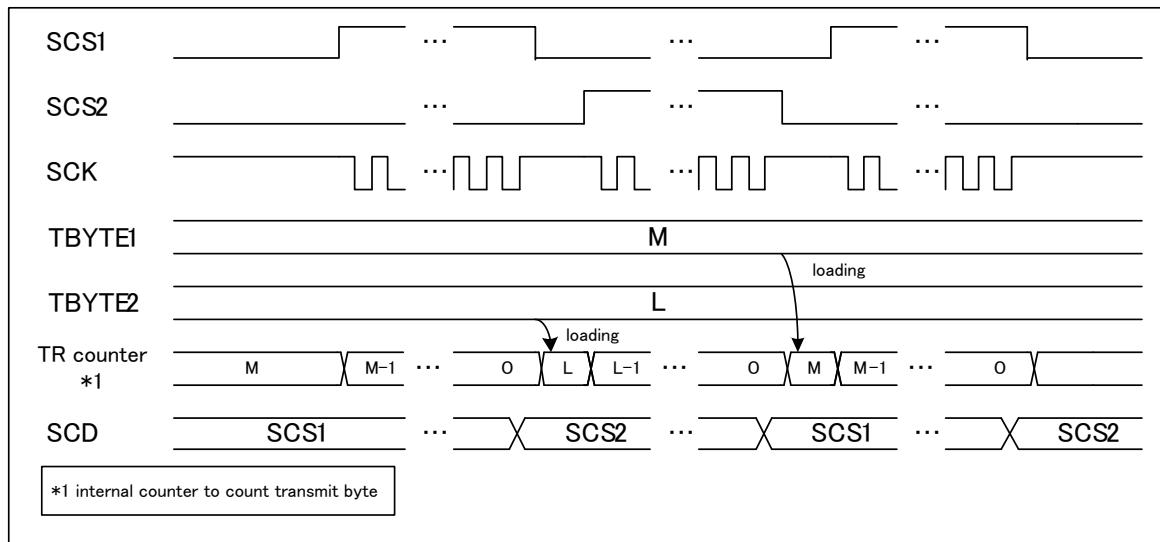

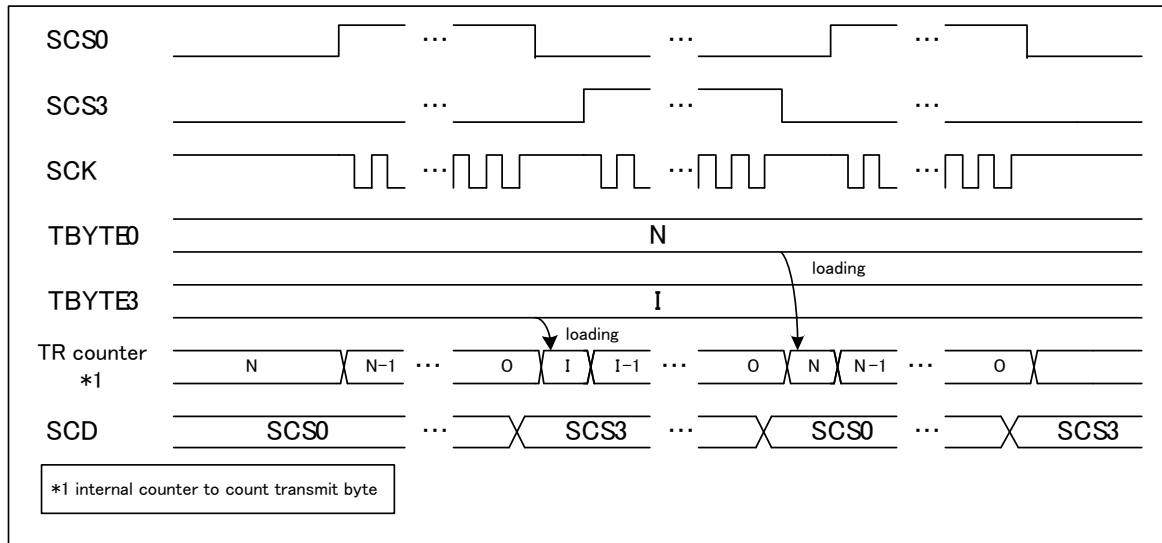

Figure 5-8 shows the timing chart that is assumed if the serial chip select start pin is SCS0 (SST1 and SST0 = 0), the end pin is SCS3 (SED1 and SED0 = 3), and chip select pins 1 and 2 are disabled (CSEN1 and CSEN2 = 0b00). After serial chip select pin 0 becomes active, pins 1 and 2 are skipped, and pin 3 becomes active.

Figure 5-8 Rounding Operation of Chip Select (SST1-0 = 0, SED1-0 = 3, CSEN3 = 1, CSEN2 = 0, CSEN1 = 0, CSEN0 = 1, SCAM = 0)

Notes:

- Serial chip select pins become active starting with that specified with the serial chip select start bits (SCSCR:SST1 and SST0) in any of the following cases:
 - If a change is made from transmission operation disable (SCR:TXE = 0) to transmission operation enable (SCR:TXE = 1)
 - If a software reset (SCR:UPCL = 1) is performed
- During a rounding operation, serial chip select pin timing adjustment (setup time, hold time, and deselect time) is valid.

Serial Chip Select Active Level Retention Operation (SCSCR:SCAM = 1) (Valid Only in Master Mode (SCR:MS = 0))

If the serial chip select active level retention bit (SCSCR:SCAM) is set to "1" and transmission is started, the serial chip select pin is retained in the active state.

Table 5-1 Serial Chip Select Active Level Retention Bit (SCSCR:SCAM)

Current State	Current SCSCR:SCAM Bit	Current SSR:TDRE Bit	Next State
Transmitting (Transmission count < TBYTE)	0	—	Until as many frames as the value set for TBYTE have been transmitted, the serial chip select pin remains active.
	1		
End of transmission of as many frames as the setting of TBYTE	0	0	After the hold delay time, the serial chip select pin is deactivated. After the elapse of the deselect time, the next transmission is started.
		1	After the hold delay time, the serial chip select pin is deactivated. After the elapse of the deselect time, transmission is stopped until the next transmission is written.
	1	1	The active level of the serial chip select is retained.
		0	With serial chip select being in the active level, transmission operation continues. Until as many frames as the value set for TBYTE have been transmitted, the serial chip select pin remains active.
A chip select error (SACSR:CSE = 1) occurs.	—	—	Regardless of the setting of SCAM, the serial chip select pin is deactivated after the hold delay time.
A software reset is executed (SCR:UPCL = 1).	—	—	Regardless of the setting of SCAM, the serial chip select pin is deactivated immediately.
Transmission disabled (SCR:TXE = 0)			

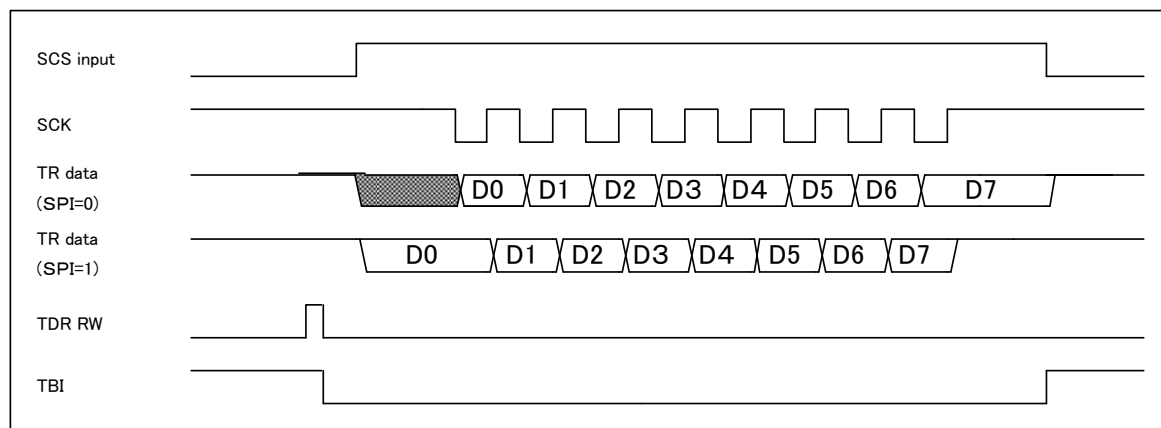

Notes:

- If the conditions described below are all satisfied, the serial chip select pin is not retained, and after the elapse of the hold delay time, the serial chip select pin becomes inactive, causing a chip select error (SACSR:CSE = 1) to occur.
 - Transfer byte errors are enabled (SACSR:TBEEN = 1).
 - If data transmission/reception for which the count is set in TBYTE has not ended.
 - If the transmission data register (TDR) is empty (SSR:TDRE = 1).

Operation in Slave Mode (SCR:MS = 1)

If serial chip select pin 0 (SCS0) is enabled (SCSCR:CSEN0 = 1) and the serial chip select pin input becomes active, transmission or reception is performed in synchronization with the serial clock (SCK). Later, if the serial chip select pin input becomes inactive, transmission or reception is ended.

Figure 5-9 Serial Chip Select Operation in Slave Mode (Slave Transmission, SCINV = 0)

Notes:

- When the serial chip select pin input is inactive, operation is not performed even if the serial clock is input.
- If the serial chip select input becomes inactive before bits are last sampled during reception, the data being received is erased.
- If the serial chip select input becomes inactive during transmission, the data being transmitted is erased and a chip select error occurs (SACSR:CSE).
- If TDR is empty (SSR:TDRE = 1) and the serial chip select pin input becomes inactive, transmission bus idle state (SSR:TBI = 1) is assumed.
- In slave mode (SCR:MS = 1), if SCSCR:CSEN0 is set to "0", transmission/reception operations are performed regardless of the status of the serial chip select pin.

Serial Chip Select Pin Format Setting

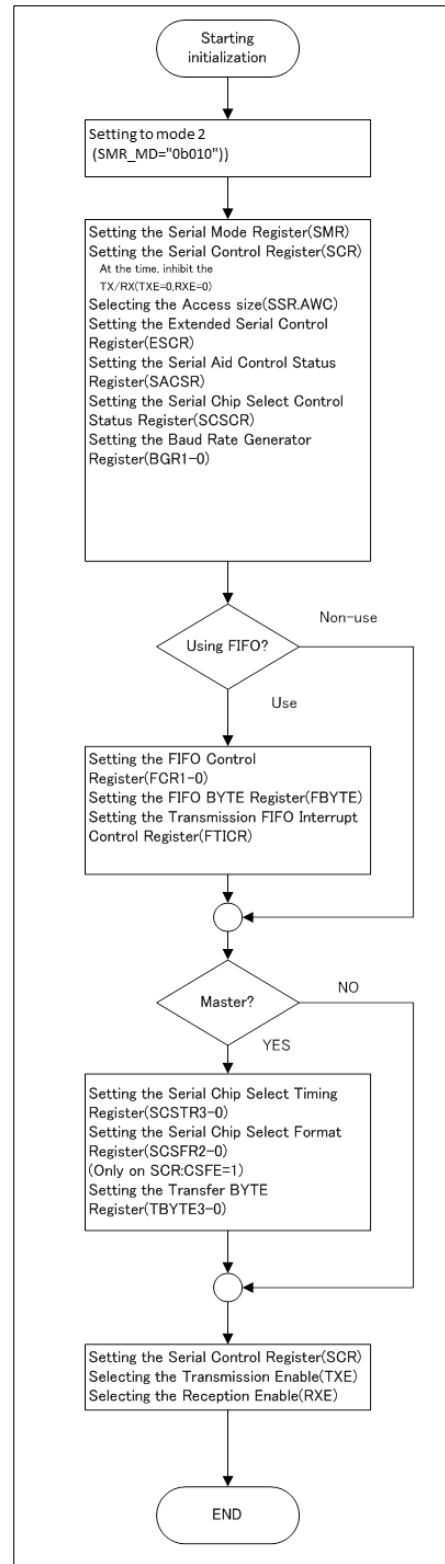

The active level of chip select of each serial chip select pin, mark level of the serial clock, SPI mode enabling and disabling, and data direction and data length of serial data output can be set with the bits listed in Table 5-2.

Table 5-2 Serial Chip Select Pin Format Setting

Conditions		Chip Select Active Level	Serial Clock Inversion	SPI Setting	Data Direction	Data Length
Chip select format is enabled (SCR:CSFE = 1) and master mode (SCR:MS = 0)	Serial chip select pin 0 output	SCSCR0:CSLVL	SMR:SCINV	SCR:SPI	SMR:BDS	ESCR:L3 to L0
	Serial chip select pin 1 output	SCSFR0:CS1CSLVL	SCSFR0:CS1SCINV	SCSFR0:CS1SPI	SCSFR0:CS1BDS	SCSFR0:CS1L3 to CS1L0
	Serial chip select pin 2 output	SCSFR1:CS2CSLVL	SCSFR1:CS2SCINV	SCSFR1:CS2SPI	SCSFR1:CS2BDS	SCSFR1:CS2L3 to CS2L0
	Serial chip select pin 3 output	SCSFR2:CS3CSLVL	SCSFR2:CS3SCINV	SCSFR2:CS3SPI	SCSFR2:CS3BDS	SCSFR2:CS3L3 to CS3L0
Chip select format disable (SCR:CSFE = 0)		SCSCR0:CSLVL	SMR:SCINV	SCR:SPI	SMR:BDS	ESCR:L3 to L0
Slave mode (MS = 1)						
When chip select is not used (CSEN3 to CSEN0 = 0b0000)						

Initialization Flow

Figure 5-10 Chip Select Initialization Flow

6. Test Mode

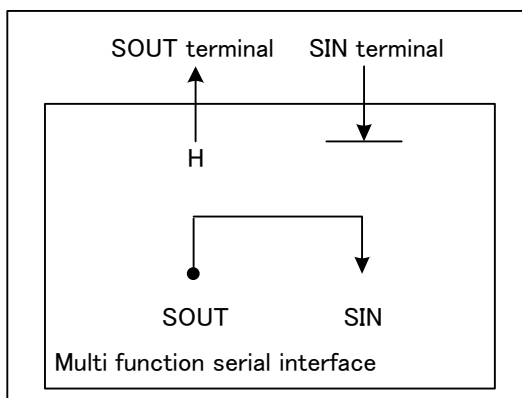

This section describes operation in test mode.

Serial Test Mode

When serial test mode is enabled ($SACSR:STST = 1$), SOUT and SIN are connected together inside the multi-function serial interface, so that the data transmitted from SOUT can be received from SIN directly.

When serial test mode is enabled ($SACSR:STST = 1$), the SOUT pin is fixed to "H", and the data input to the SIN pin is ignored.

Figure 6-1 Serial Test Mode

Note:

- The value of the serial test mode enable bit ($SACSR:STST$) can be changed only when transmission and reception are prohibited ($SCR:TXE = RXE = 0$).

7. Dedicated Baud Rate Generator

The dedicated baud rate generator functions during master operation only. When using the reception FIFO, however, set the dedicated baud rate generator even during slave operation.

CSIO (Clock Synchronous Serial Interface) Baud Rate Selection

The dedicated baud rate generator must be set differently for master operation and slave operation.

[1] During Master Operation

Use the Dedicated Baud Rate Generator to Divide the Internal Clock and Select a Baud Rate.

- There are 2 internal reload counters, each of which corresponds to the transmission or reception serial clock. A baud rate can be selected by setting a 15-bit reload value in baud rate generator register 1 or 0 (BGR1, BGR0).
- The reload counters divide the internal clock by the value that is set.

[2] During Slave Operation

- During slave operation (SCR:MS = 1), the dedicated baud rate generator does not function. (Instead, the external clock, input from clock input pin SCK, is input directly.)

Note:

- *When using the reception FIFO, set the dedicated baud rate generator even during slave operation.*

7.1. Setting the Baud Rate

This section describes the baud rate setting. It also describes the results of calculating serial clock frequencies.

Baud Rate Calculation

The 2 15-bit reload counters are set by baud rate generator registers 1, 0 (BGR1, BGR0).

The baud rate is calculated using the formula given below.

(1) Reload value:

$$V = \text{Phy} / b - 1$$

V : reload value b : baud rate Phy : bus clock frequency

(2) Calculation example

When bus clock is 16MHz, using internal clock, baud rate is 19200 bps, the reload value can be calculated as follows.

reload value :

$$V = (16 * 1000000) / 19200 - 1 = 832$$

and then baud rate will be

$$b = (16 * 1000000) / (832 + 1) = 19208 \text{ bps}$$

6e9f8f_ef8b95fa570a507b8b91fc169c501b19_7320_rf_96ff61_u000_c242742_a

(3) Baud rate error

The baud rate error is obtained by using the following formula.

$$\text{error rate(\%)} = (\text{calculated value} - \text{target value}) / \text{target value} * 100$$

(ex. When bus clock is 20MHz, target baud rate is 153600 bps,

the result will be as follows.

$$\text{reload value} = (20 * 1000000) / 153600 - 1 = 129$$

$$\text{calculated baud rate} = 20 * 1000000 / (129 + 1) = 153846 \text{ (bps)}$$

$$\text{error rate (\%)} = (153846 - 153600) / 153600 * 100 = 0.16 \text{ (\%)}$$

Notes:

- *Setting the reload value to "0" stops the reload counter.*
- *If the reload value is even-numbered, the "H" width and "L" width of the serial clock will be as described below, depending on the settings made for the SMR:SCINV bit and SCR:SPI bit. If the reload value is odd-numbered, the "H" width and the "L" width of the serial clock will be the same.*
 - For normal transfer (SCR:SPI = 0) when the mark level of the serial clock is "H" (SMR:SCINV = 0) or for SPI transfer (SCR:SPI = 1) when the mark level of the serial clock is "L" (SMR:SCINV = 1), the "H" width of the serial clock will be longer by 1 bus clock cycle.
 - For normal transfer (SCR:SPI = 0) when the mark level of the serial clock is "L" (SMR:SCINV = 1) or for SPI transfer (SCR:SPI = 1) when the mark level of the serial clock is "H" (SMR:SCINV = 0), the "L" width of the serial clock will be longer by 1 bus clock cycle.
- *Set the reload value to 2 or more in master mode, or to 3 or more in slave mode.*

- When considering the tolerable baud rate range, also consider the impact of the jitter in the clock input on the macro.

Example Reload Values and Baud Rate Settings for Individual Bus Clock Frequencies

The following table contains example reload values and baud rate settings.

Table 7-1 Example Reload Values and Baud Rate Settings

Baud Rate (bps)	8 MHz		10 MHz		16 MHz		20 MHz		24 MHz		32 MHz	
	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR

Functions of the Reload Counters

The reload counters include the transmission reload counter and the reception reload counter. They function as a dedicated baud rate generator. They consist of 15-bit registers for reload values, and generate transmission/reception clocks from their internal clocks.

Start of Counting

When a reload value is written to the baud rate generator registers (BGR1 and BGR0), the reload counters start counting.

Restarting

The reload counter restarts under the conditions described below.

For both Transmission and Reception Reload Counters

Programmable reset (SCR:UPCL bit)

7.2. Setup Procedure and Program Flow for the CSIO (Clock Synchronous Serial Interface)

The CSIO (Clock Synchronous Serial Interface) can perform serial bidirectional transmission.

Connection Between MCUs

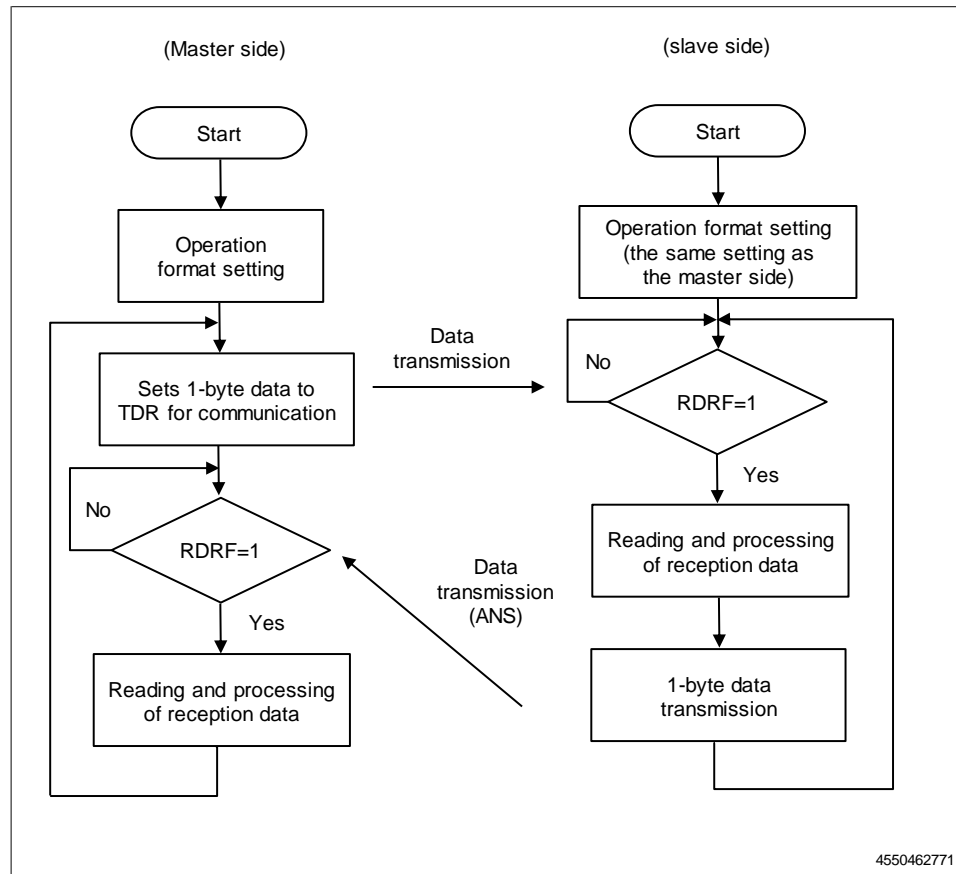

For the CSIO (Clock Synchronous Serial Interface), select bidirectional communication. As shown in Figure 7-1, 2 MCUs are interconnected.

Figure 7-1 Connection Example for CSIO (Clock Synchronous Serial Interface) Bidirectional Communication

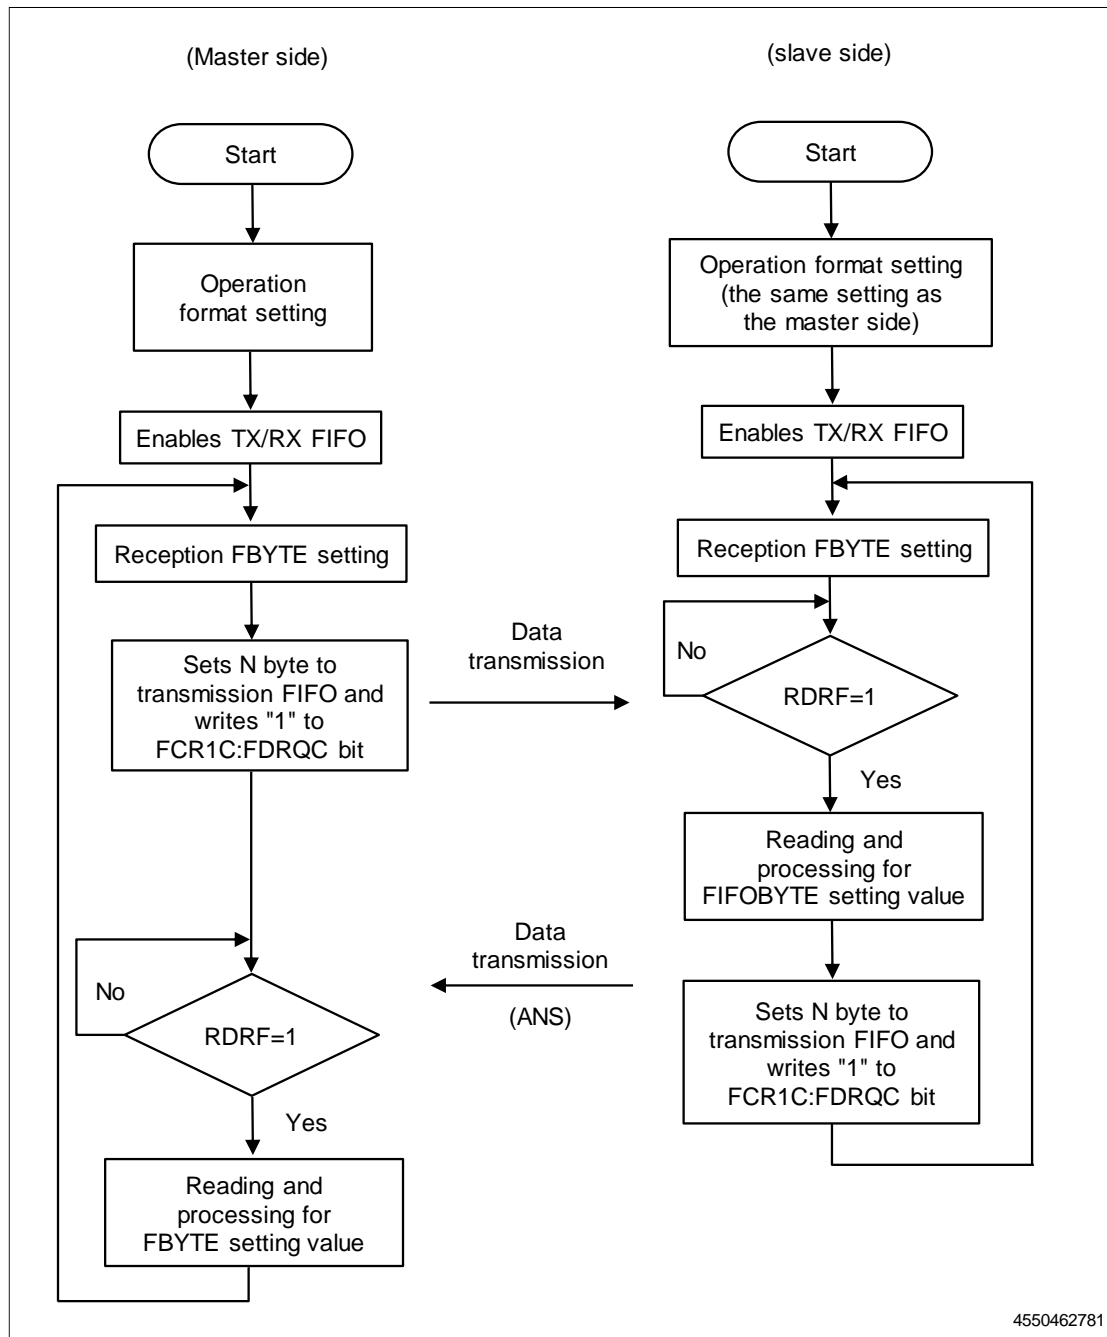

■ FIFO not used

Figure 7-2 Example of Bidirectional Communication Flow Chart (FIFO Not Used)

■ FIFO used

Figure 7-3 Example of Bidirectional Communication Flow Chart (FIFO Used)

8. Block Transfer

This section describes the operation of block transfer.

Setting Block Transfer

Block transfer can be performed for reception by setting RXBLKEN in the extended control register (ECR) to 1 and for transmission by setting TXBLKEN to 1.

Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).

The block size can be set with the transmission block size register and the FBYTE register (for reception).

The threshold at which to output a block transfer request can be set with the FBYTE register for reception and with the FTICR register for transmission. When the amount of data in the reception FIFO exceeds the setting made for the FBYTE register, a reception block transfer request is output. When the amount of free space in the transmission FIFO exceeds the setting made for the FTICR register, a transmission block transfer request is output.

8.1. RW Access Mode

This section describes block transfer in RW access mode.

Reception Block Transfer

Reception block transfer is performed as described below.

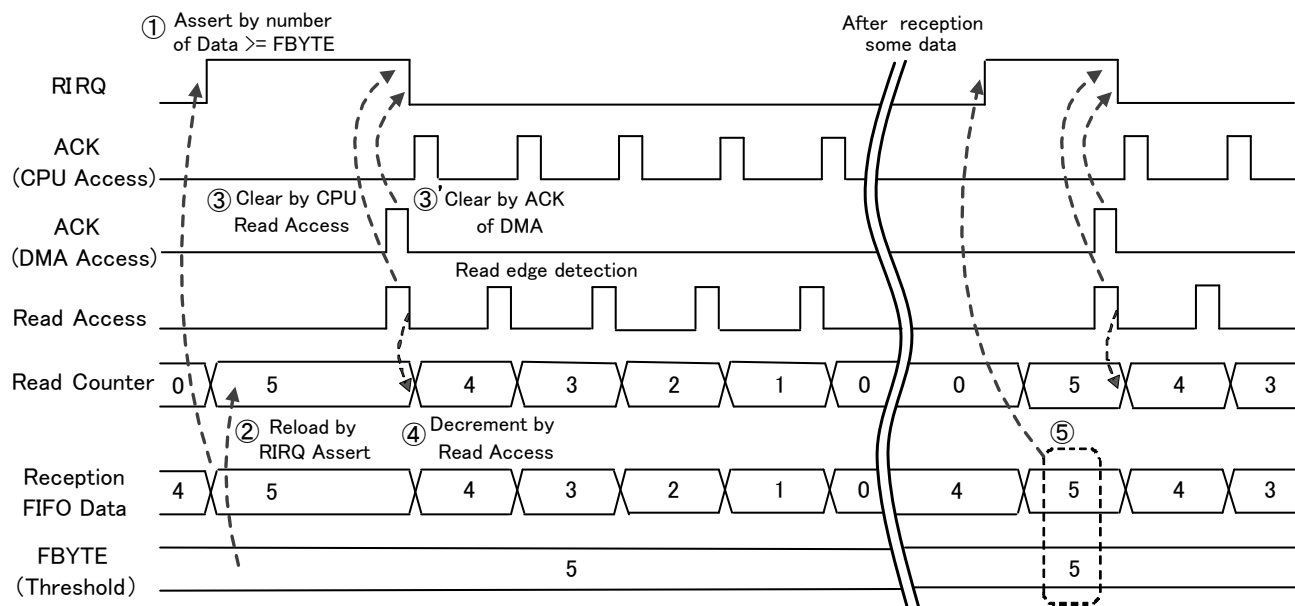

If the amount of data in the reception FIFO is same or more than the threshold (FBYTE), a reception block transfer request (RIRQ) is asserted. At this time, the value of the reception block size is reloaded from the FBYTE register to the Read counter. When the reception FIFO is not used, the value of the reception block size is "1".

After the reception block transfer request, if a reading a reception data occurs, the reception block transfer request (RIRQ) is cleared. With a reading a reception data, the Read counter is decremented.

When the Read counter becomes "0", if the amount of data in the reception FIFO is same or more than the threshold (FBYTE), the reception block transfer request (RIRQ) is asserted again. With the assertion of the reception block transfer request (RIRQ), the Read counter is reloaded.

During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Figure 8-1 Reception Block Transfer in RW Access Mode

Transmission Block Transfer

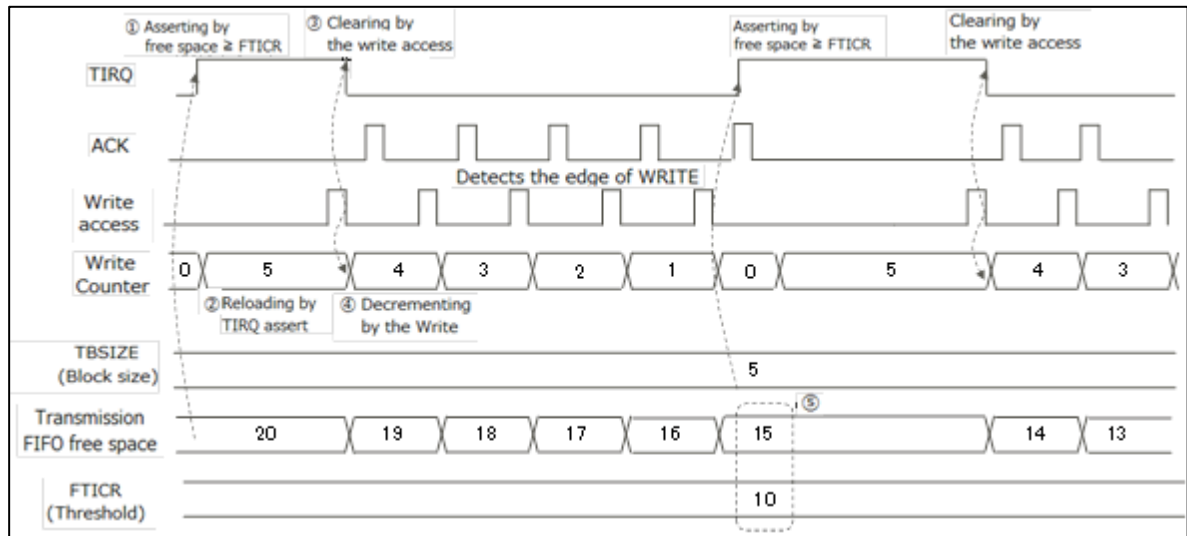

Transmission block transfer is performed as described below.

If the amount of free space in the transmission FIFO exceeds the threshold (FTICR), a transmission block transfer request (TIRQ) is asserted. At this time, the value of the transmission block size is reloaded from the TBSIZE register to the Write counter. When the transmission FIFO is not used, the value of the transmission block size is "1".

After the transmission block transfer request, if a writing a transmission data occurs, the transmission block transfer request (TIRQ) is cleared. With a writing a transmission data, the Write counter is decremented.

When the Write counter becomes "0", if the amount of free space in the transmission FIFO exceeds the threshold (FTICR), the transmission block transfer request (TIRQ) is asserted again. With the assertion of the transmission block transfer request (TIRQ), the Write counter is reloaded.

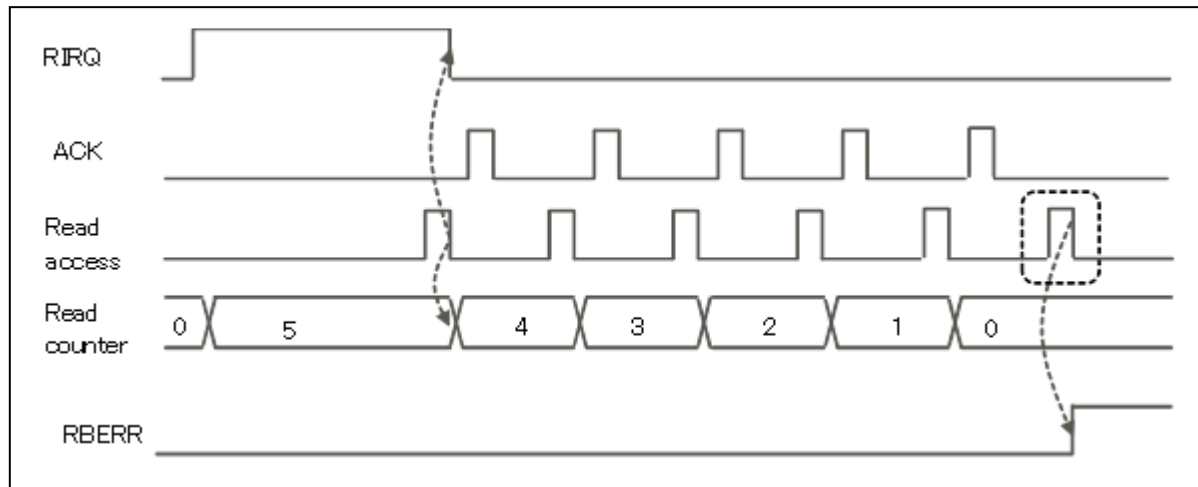

Figure 8-2 Transmission Block Transfer in RW Access Mode

Reception Block Transfer Error

If, while the Read counter is "0", a read access occurs before the next reception block transfer request (RIRQ) is asserted, a reception block transfer error occurs, and the ESR:RBERR bit is asserted.

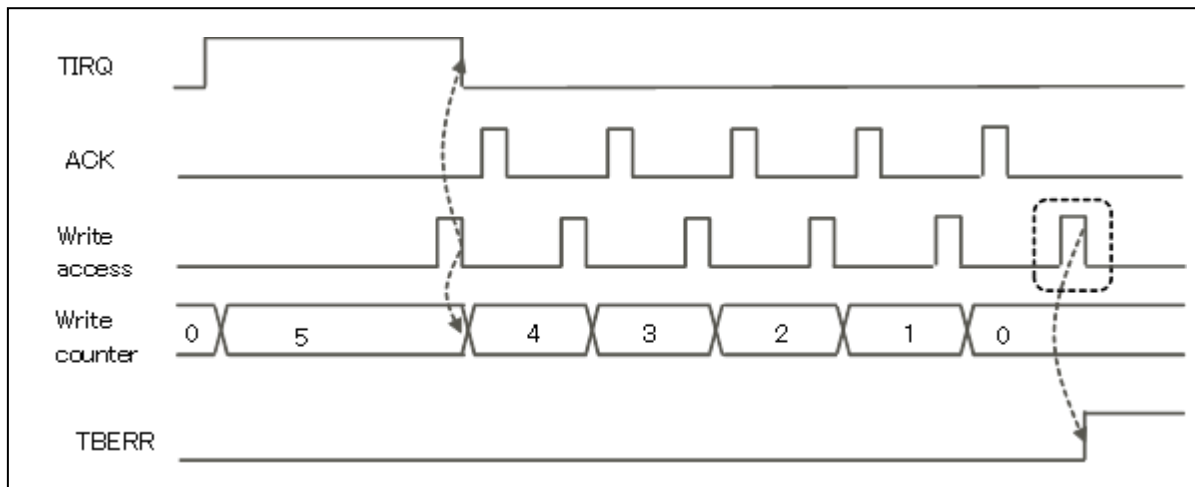

Figure 8-3 Reception Block Transfer Error in RW Access Mode

Transmission Block Transfer Error

If, while the Write counter is "0", a write access occurs before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the ESR:TBERR bit is asserted.

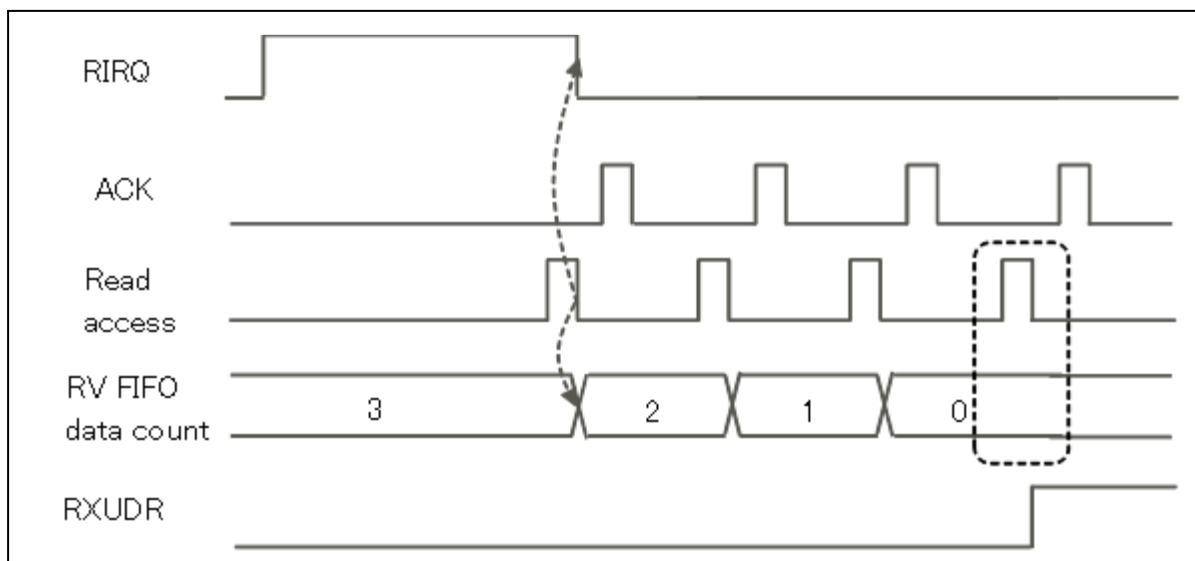

Figure 8-4 Transmission Block Transfer Error in RW Access Mode

Reception FIFO under Run

If, while the amount of data in the reception FIFO is "0", reception data is read from the reception FIFO, a reception FIFO under run occurs, and the ESR:RXUDR bit is asserted.

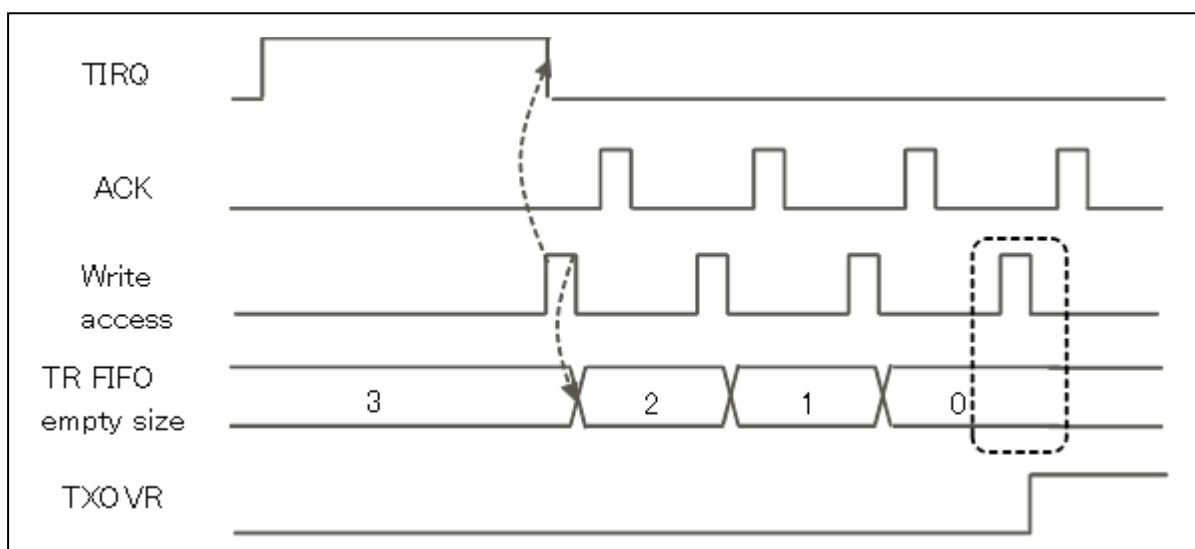

Figure 8-5 Reception FIFO Under Run in RW Access Mode

Transmission FIFO Overrun

If, while the amount of free space in the transmission FIFO is "0", transmission data is written to the transmission FIFO, a transmission FIFO overrun occurs, and the ESR:TXOVR bit is asserted.

Figure 8-6 Transmission FIFO Overrun in RW Access Mode

9. Registers of the CSIO (Clock Synchronous Serial Interface)

This section lists the registers of the CSIO (Clock Synchronous Serial Interface).

CSIO (Clock Synchronous Serial Interface) Register List

Table 9-1 CSIO (Clock Synchronous Serial Interface) Register List

	bit15	bit8	bit7	bit0
CSIO	SCR (serial control register)		SMR (serial mode register)

*1: Access by the mirror address area

9.1. Serial Control Register (SCR)

The serial control register (SCR) is used to enable/disable transmission/reception interrupts, enable/disable transmission idle interrupts, and enable/disable transmission/reception operations. It can also be used to make settings for connection to SPI and to reset the CSIO.

Serial Control Register (SCR)

Figure 9-1 shows the bit configuration of the serial control register (SCR).

Figure 9-1 Bit Configuration of Serial Control Register (SCR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	UPCL	MS	SPI	RIE	TIE	TBIE	RXE	TXE	(SMR)		
R/W Attribute	R0,W	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] UPCL: Programmable Clear Bit

This bit initializes the internal state of the CSIO.

When "1" is set:

- Resets the CSIO directly (software reset). However, the register setting is retained. At this time, anything in the transmission/reception state is disconnected immediately.
- The baud rate generator reloads the setting of the BGR1/0 register and then restarts.
- All transmission/reception and status interrupt factors (SSR:TDRE, TBI, RDRF, ORE, SACS:R:TINT, CSE[*]) are initialized.
- All serial chip select pins become inactive.

When "0" is set:

Does not have any effect on the operation.

At reading, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Programmable clear	

Notes:

- Execute programmable clear (SCR:UPCL = 1) after disabling interrupts.
- When FIFOs are used, execute programmable clear after disabling the FIFOs (FCR0:FE2, FE1 = 0).
- Executing programmable clear (SCR:UPCL = 1) does not clear the value of the serial timer register (STMR).

[bit14] MS: Master/Slave Function Selection Bit

This bit selects either master or slave mode.

- 0: Set master mode.
- 1: Set slave mode.

Bit	Description
0	Master mode
1	Slave mode

Notes:

- If slave mode is selected, an external clock is input directly, provided that SMR:SCKE = 0.
- Change this bit when transmission and reception are disabled (SCR:TXE = RXE = 0).
- After setting the MS bit, enable reception (RXE = 1).

[bit13] SPI: SPI-Supporting Bit

This bit is for performing communication that supports SPI. When chip select is used in master mode (SCR:MS = 0), the bit is used for communication with serial chip select pin 0.

- 0: Perform normal synchronous communication.
- 1: Support SPI.

Bit	Description
0	Normal synchronous transfer
1	SPI support

Notes:

- Set this bit when transmission and reception are disabled (TXE = RXE = 0).
- This bit is used in any of the following cases:
 - The chip select pins are disabled (SCSCR:CSEN3 to CSEN0 = 0b0000).
 - In slave mode (SCR:MS = 1).
 - When the chip select data format is disabled (ESCR:CSFE = 0).
 - When the chip select data format is enabled (ESCR:CSFE = 1) and serial chip select pin 0 is active.

[bit12] RIE: Reception Interrupt Enable Bit

- This bit enables/disables reception interrupt request output to the CPU.
- For ECR:EISEL = 0, a reception interrupt request is issued when the RIE bit and the reception data flag bit (SSR:RDRF) are "1" or when one of the error flag bits (SSR:ORE, ESR:RXUDR, RBERR) is "1".
- For ECR:EISEL = 1, a reception interrupt request is issued when the SMR:RIE bit and the reception data flag bit (SSR:RDRF) are both "1".

Bit	Description
0	Disable reception interrupts.
1	Enable reception interrupts.

[bit11] TIE: Transmission Interrupt Enable Bit

- This bit enables/disables transmission interrupt request output to the CPU.
- For ECR:EISEL = 0, a transmission interrupt request is issued when the TIE bit and the SSR:TDRE bit are set to "1" or when one of the error flag bits (ESR:TXOVR, TBERR) is set to "1".
- For ECR:EISEL = 1, a transmission interrupt request is issued when the TIE bit and the SSR:TDRE bit are both "1" or when one of the error flag bits (ESR:TXOVR, TBERR) is "1".

Bit	Description
0	Disable transmission interrupts.
1	Enable transmission interrupts.

[bit10] TBIE: Transmission Bus Idle Interrupt Enable Bit

- This bit enables/disables transmission bus idle interrupt request output to the CPU.
- A transmission bus idle interrupt request is output when the TBIE bit and the SSR:TBI bit are both "1".

Bit	Description
0	Disable transmission bus idle interrupts.
1	Enable transmission bus idle interrupts.

[bit9] RXE: Reception Operation Enable Bit

This bit enables/disables CSIO reception.

- 0: Disable data frame reception.
- 1: Enable data frame reception.

Bit	Description
0	Disable reception.
1	Enable reception.

Notes:

- If reception is disabled (RXE = 0) during reception, reception is stopped immediately.
- After setting the MS bit and the SMR:SCINV bit, enable reception (RXE = 1).

[bit8] TXE: Transmission Operation Enable Bit

This bit enables/disables CSIO transmission.

- 0: Disable data frame transmission.
- 1: Enable data frame transmission.

Bit	Description
0	Disable transmission.
1	Enable transmission.

Notes:

- If transmission is disabled (TXE = 0) during transmission, transmission is stopped immediately.
- When serial chip select is used (SCSCR:CSEN = 1) in master mode (SCR:MS = 0), perform a programmable reset (SCR:UPCL = 1) after disabling transmission.

9.2. Serial Mode Register (SMR)

The serial mode register (SMR) is used to set the operating mode, transfer direction, and data length, invert the serial clock, and enable/disable the output of serial data and clocks to pins.

Serial Mode Register (SMR)

Figure 9-2 shows the bit configuration of the serial mode register (SMR).

Figure 9-2 Bit Configuration of Serial Mode Register (SMR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SCR)			MD2	MD1	MD0	WUCR	SCINV	BDS	SCKE	SOE
R/W Attribute				R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] MD[2:0]: Operation Mode Setting Bits

These bits set the operation modes.

Bits			Description
0	0	0	Operation mode 0 (asynchronous normal mode)
0	0	1	Operation mode 1 (asynchronous multi-processor mode)
0	1	0	Operation mode 2 (clock synchronous mode)
0	1	1	Operation mode 3 (LIN communication mode)
1	0	0	Operation mode 4 (I2C mode)

* This section describes the registers and their operations in operation mode 2.

Notes:

- Settings other than above are prohibited.
- To switch the operation mode, execute programmable clear (SCR:UPCL = 1) and then switch the operation mode.
- Set the registers after setting an operation mode.

[bit4] WUCR: WAKE UP Control Bit

WUCR is not supported

This bit selects the pin used for external interrupts.

0: The pin used for external interrupts is the INT pin.

1: The pin used for external interrupts is the SCK pin.

Bit	Description
0	Disable the WAKE UP function.
1	Enable the WAKE UP function.

Note:

- The WAKE UP function is not supported.

[bit3] SCINV: Serial Clock Invert Bit

This bit inverts the serial clock format. When chip select is used in master mode (SCR:MS = 0), this bit is used for communication with serial chip select pin 0.

0:

- The mark level of serial clock output is set to "H".
- During normal transfer, transmission data is output in synchronization with a falling edge of the serial clock. In SPI transfer, it is output in synchronization with a rising edge of the serial clock.
- During normal transfer, reception data is sampled at a rising edge of the serial clock. In SPI transfer, it is sampled at a falling edge of the serial clock.

1:

- The mark level of serial clock output is set to "L".
- During normal transfer, transmission data is output in synchronization with a rising edge of the serial clock. During SPI transfer, it is output in synchronization with a falling edge of the serial clock.
- During normal transfer, reception data is sampled at a falling edge of the serial clock. In SPI transfer, it is sampled at a rising edge of the serial clock.

Bit	Description
0	Mark level "H" format
1	Mark level "L" format

Notes:

- Set this bit when the serial clock output is disabled (SCKE = 0).
- After setting the SCINV bit, enable reception (SCR:RXE = 1).
- Set this bit when transmission and reception are disabled (SCR:TXE = RXE = 0).
- This bit is used in any of the following cases:
 - The chip select pins are disabled (SCSCR:CSEN3 to CSEN0 = 0b0000).
 - In slave mode (SCR:MS = 1).
 - When the chip select data format is disabled (ESCR:CSFE = 0).
 - When the chip select data format is enabled (ESCR:CSFE = 1) and serial chip select pin 0 is active.
- Set this bit to "0" when serial test mode is enabled (SACSR:STST = 1).

[bit2] BDS: Transfer Direction Selection Bit

This bit selects whether the lowest bit is transferred first (LSB first, BDS = 0) or the highest bit is transferred first (MSB first, BDS = 1), when transferring serial data. When chip select is used in master mode (SCR:MS = 0), the bit is used for communication with serial chip select pin 0.

Bit	Description
0	LSB first (lowest bit is transferred first)
1	MSB first (highest bit is transferred first)

Notes:

- Set this bit when transmission and reception are disabled (SCR:TXE = RXE = 0).
- This bit is used in any of the following cases:
 - The chip select pins are disabled (SCSCR:CSEN3 to CSEN0 = 0b0000).
 - In slave mode (SCR:MS = 1).
 - When the chip select data format is disabled (ESCR:CSFE = 0).
 - When the chip select data format is enabled (ESCR:CSFE = 1) and serial chip select pin 0 is active.

[bit1] SCKE: Serial Clock Input/Output Enable Bit

This bit enables the input or output of the serial clock.

Bit	Description
0	Enable the Serial clock input.
1	Enable the Serial clock output.

Notes:

- Set this bit to "0" in slave mode (SCR:MS = 1) and set this bit to "1" in master mode (SCR:MS = 0).
- Enable serial clock output (SCKE = 1) after setting the SCINV bit.

[bit0] SOE: Serial Data Output Enable Bit

This bit enables/stops the output of serial data.

Bit	Description
0	Stop the serial data output.
1	Enable the serial data output.

Note:

- In the case of serial data output (SOE = 1), the SOUT pin operates as the SOUT pin regardless of the setting of the general-purpose I/O port (DDR).

9.3. Serial Status Register (SSR)

The serial status register (SSR) is used to verify the transmission/reception state, verify the reception error flag, or clear the reception error flag.

Serial Status Register (SSR)

Figure 9-3 shows the bit configuration of the serial status register (SSR).

Figure 9-3 Bit Configuration of Serial Status Register (SSR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	REC	Reserved	Reserved	AWC	ORE	RDRF	TDRE	TBI	(ESCR)		
R/W Attribute	R0,W	R0, W0	R0, W0	R/W	R, WX	R, WX	R, WX	R, WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	1	1			

[bit15] REC: Reception Error Flag Clear Bit

This bit clears the ORE flag of the serial status register (SSR).

- Writing "1" clears the error flag.
- Writing "0" does not have any effect.

Upon reading, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Clear the reception error flag (ORE).	

[bit14:13] Reserved: Reserved Bits

[bit12] Access width Control Bit

This bit selects between 16- and 32-bit access when accessing the transmission data register (TDR) and the reception data register (RDR).

Bit	Description
0	16-bit access
1	32-bit access

Notes:

- Change this bit only when transmission and reception are disabled (SCR:TXE = RXE = 0) and TDR and RDR are empty (SSR:TDRE = 1, SSR:RDRF = 0).
- If the data length is 20, 24, or 32 bits, set "1" in this bit.
- If the data length is 8 bits or less, the TDR and RDR registers can be byte-accessed.

[bit11] ORE: Overrun Error Flag Bit

- This bit is set to "1" when an overrun error occurs during data reception, and is cleared when "1" is written to the REC bit of the serial status register (SSR).
- A reception interrupt request is issued when the ORE bit and the SCR:RIE bit are "1".
- Please refer to "CHAPTER: INTERRUPT CONTROLLER" for interrupt request output
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when the reception FIFO is used, the reception FIFO enable bits are cleared, and no reception data is stored in the reception FIFO.

Bit	Description
0	No overrun error
1	Overrun error found

Note:

- This bit is cleared by the Software reset (SCR:UPCL=1).

[bit10] RDRF: Reception Data Full Flag Bit

- This flag indicates the status of the reception data register (RDR).
- This flag is set to "1" when reception data is loaded to the RDR, and is cleared to "0" when the data in the reception data register (RDR) is read.
- A reception interrupt request is issued when the RDRF bit and the SCR:RIE bit are both "1".
- When the reception FIFO is used, if the reception FIFO receives a prescribed number of data items, RDRF is set to "1".
- When the reception FIFO is used, both of the following conditions are satisfied, and the reception idle state continues for at least 8 clock pulses of the baud rate clock, RDRF is set to "1".
 - The reception FIFO idle detection enable bit (FCR1:FRIIE) is set to "1".
 - The reception FIFO has not received the prescribed number of data items, and data remains in the reception FIFO.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again.
- For ECR:RXBLKEN = 0, when the reception FIFO is used, this bit is cleared to "0" when the reception FIFO empties as a result of data being read from it.
- For ECR:RXBLKEN = 1, when the reception FIFO is used, this bit is cleared to "0" when the number of data items in the reception FIFO becomes equal to or less than the value set for the FBYTE register.

Bit	Description
0	The reception data register RDR is empty.
1	The reception data register RDR contains data.

Note:

- When the reception FIFO is used and RDRF has become "1", resetting the reception FIFO (FCR0:FCL2, FCL1 = 1) does not cause RDRF to be set to "0". Therefore, in order to set RDRF to "0" after resetting the reception FIFO, perform a dummy reading of the reception data register during the reception disable status (SCR:RXE = 0).

- This bit is cleared by the Software reset (SCR:UPCL=1).

[bit9] TDRE: Transmission Data Empty Flag Bit

- This bit indicates the status of the transmission data register (TDR).
- Writing transmission data to the TDR sets this bit to "0", indicating that the TDR contains valid data. Loading the data into the transmission shift register to start transmission sets this bit to "1", indicating that the TDR does not contain valid data. A transmission interrupt request is issued when the TDRE bit and the SCR:TIE bit are both "1".
- The TDRE bit is set to "1" when programmable reset is executed (SCR:UPCL=1).
- For the set/reset timing of the TDRE bit when using the transmission FIFO, see "2.4 Interrupt Generation and Flag Set Timing When the Transmission FIFO Is Used."

Bit	Description
0	The transmission data register (TDR) contains data.
1	The transmission data register is empty.

[bit8] TBI: Transmission Bus Idle Flag Bit

- This bit indicates that the CSIO is not performing transmission.
- If data is written to the transmission data register (TDR), this bit is set to "0".
- When the transmission data register (TDR) is empty (TDRE = 1), if the serial chip select pin is deselected and transmission is not being performed, this bit is set to "1".
- The TBI bit is set to "1" when programmable reset is executed (SCR:UPCL=1).
- When this bit is "1", if transmission bus idle interrupts are enabled (SCR:TBIE = 1), a transmission interrupt request is output.

Bit	Description
0	Transmission in progress
1	No transmission

Note:

- When the transmission data register (TDR) is empty (TDRE = 1), if a serial chip select error (CSE = 1) occurs, this bit is set to "1" within the baud rate period.

9.4. Extended Communication Control Register (ESCR)

The extended communication control register (ESCR) can be used to set the transmission/reception data length and fix the serial output to "H".

Bit Configuration of the Extended Communication Register (ESCR)

Figure 9-4 shows the bit configuration of the extended communication control register (ESCR).

Figure 9-4 Bit Configuration of Extended Communication Control Register (ESCR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-			SOP	L3	CSFE	WT1	WT0	L2	L1	L0
R/W Attribute				R0,W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7] SOP: Serial Output Pin Set Bit

- This bit sets the serial output pin to "H". When "1" is written to this bit, the SOUT pin is set to "H". Later, "0" need not be written to this bit.
- When this bit is read, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Set the SOUT pin to "H".	

Note:

- Do not set this bit while transmitting serial data.
- To set Serial output (SOT) pin to "High", follow one of the below mentioned methods.
 1. Execute programmable clear. (Set SCR.UPCL="1")
 - After disabling interrupt, execute programmable clear. (Set SCR.UPCL="1")
 - When FIFOs are used, execute programmable clear after disabling the FIFOs (FCR0:FE2, FE1 = 0).
 2. Disable transmission. (Set SCR.TXE="0")
 - When serial chip select is used (SCSCR:CSEN = 1) in master mode (SCR:MS = 0), perform a programmable reset (SCR:UPCL = 1) after disabling transmission.
 3. Use Bit Band Unit to set ESCR.SOP bit.

[bit5] CSFE: Serial Chip Select Format Enable Bit

This bit enables or disables the setting of a format for each serial chip select pin.

When this bit is set to "1", make the settings described below for each serial chip select pin.

- Inactive level of serial chip select
- Mark level of the serial clock
- Selection between SPI transfer and normal transfer
- Serial data transfer direction
- Data length of serial data

Bit	Description
0	Set the same data format and clock format for all of the serial chip select pins.
1	Set a data format and clock format for each serial chip select pin.

Notes:

- The setting of this bit is invalid in any of the cases described below.
 - The chip select pins are disabled (SCSCR0: CSEN3 to CSEN0 = 0b0000).
 - In slave mode (SCR:MS = 1).
- Set this bit when transmission is disabled (SCR:TXE = 0).

[bit4:3] WT[1:0]: Data Transmission/Reception Wait Select Bits

These bits specify the number of waits for the transmission or reception of continuous data in master mode. In slave mode, the operation is that for "00".

- "00": Output SCK continuously.
- "01": Output SCK after a 1-bit time wait.
- "10": Output SCK after a 2-bit time wait.
- "11": Output SCK after a 3-bit time wait.

Bits		Description
0	0	0 bit
0	1	1 bit
1	0	2 bits
1	1	3 bits

[bit6, bit2:0] L3, L2, L1, L0: Data Length Selection Bits

These bits specify the data length of the transmission/reception data. When chip select is used in master mode (SCR:MS = 0), this bit is used for communication with serial chip select pin 0.

L3	L2	L1	L0	Data Length
0	0	0	0	8-bit length
0	0	0	1	5-bit length
0	0	1	0	6-bit length
0	0	1	1	7-bit length
0	1	0	0	9-bit length
0	1	0	1	10-bit length
0	1	1	0	11-bit length
0	1	1	1	12-bit length
1	0	0	0	13-bit length
1	0	0	1	14-bit length
1	0	1	0	15-bit length
1	0	1	1	16-bit length
1	1	0	0	20-bit length
1	1	0	1	24-bit length
1	1	1	0	32-bit length

Notes:

- Settings other than those described above are prohibited.
- Change these bits when transmission and reception are disabled (SCR:TXE = RXE = 0).
- These bits are used for any of the following:
 - The chip select pins are disabled (SCSCR:CSEN3 to CSEN0 = 0b0000).
 - In slave mode (SCR:MS = 1).
 - When the chip select data format is disabled (ESCR:CSFE = 0).
 - When the chip select data format is enabled (ESCR:CSFE = 1) and serial chip select pin 0 is active.

9.5. Reception Data Register/Transmission Data Register (RDR/TDR)

The reception data register and transmission data register are placed at the same address. If read, the register functions as a reception data register, while if written to, it functions as a transmission data register. When FIFO operation is enabled, the RDR/TDR address is the FIFO read/write address.

Reception data register (RDR)

Figure 9-5 shows the bit configuration of the serial reception register (RDR).

Figure 9-5 Bit Configuration of Reception Data Register (RDR)

Bit	31	30	29	28	27	26	25	24
Field	D31	D30	D29	D28	D27	D26	D25	D24
R/W Attribute	R	R	R	R	R	R	R	R
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	D23	D22	D21	D20	D19	D18	D17	D16
R/W Attribute	R	R	R	R	R	R	R	R
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Field	D15	D14	D13	D12	D11	D10	D9	D8
R/W Attribute	R	R	R	R	R	R	R	R
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute	R	R	R	R	R	R	R	R
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

The reception data register (RDR) is a 32-bit data buffer register that is used for serial data reception.

- Serial data signals transmitted to the serial input pin (SIN pin) is converted by the shift register, and the result is stored in the reception data register (RDR).
According to the data length, the reception data is stored, starting with the lower bits, while the other bits are set to "0". Example: D7 to D0 = 0x45, D31 to D8 = 0x000000 if the data length is 8 bits, and 0x45 is received.
- The reception data full flag bit (SSR:RDRF) is set to "1" when reception data is stored to the reception data register (RDR). If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is generated.
- Read the reception data register (RDR) when the reception data full flag bit (SSR:RDRF) is "1". The reception data full flag bit (SSR:RDRF) is such that if the reception data register (RDR) is read, it is automatically cleared to "0".
- If a reception error occurs (SSR:ORE), the data in the reception data register (RDR) will be invalid.
- To read the RDR, access it as described below.
 - If SSR:AWC = 0, perform 16-bit access to the lower 16 bits of the RDR.
 - If SSR:AWC = 1, perform 32-bit access.

Notes:

- When the reception FIFO is used, RDRF is set to "1" when a predefined amount of data has been received by the reception FIFO.
- When the reception FIFO is used, RDRF is cleared to "0" once the reception FIFO is empty.
- If, while the reception FIFO is being used, a reception error occurs (SSR:ORE), the reception FIFO enable bit is cleared, and reception data is not stored in the reception FIFO.
- When AWC = 0, do not access D31 to D16.

Transmission Data Register (TDR)

Figure 9-6 shows the bit configuration of the transmission data register.

Figure 9-6 Bit Configuration of Transmission Data Register (TDR)

Bit	31	30	29	28	27	26	25	24
Field	D31	D30	D29	D28	D27	D26	D25	D24
R/W Attribute	W	W	W	W	W	W	W	W

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1

Bit	15	14	13	12	11	10	9	8
Field	D15	D14	D13	D12	D11	D10	D9	D8
R/W Attribute	W	W	W	W	W	W	W	W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1

Bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute	W	W	W	W	W	W	W	W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1

The transmission data register (TDR) is a 32-bit data buffer register that is used for serial data transmission.

- If transmission is enabled (SCR:TXE = 1), and the data to be transmitted is written to the transmission data register (TDR), the transmission data is transferred to the transmission shift register, converted into serial data, and is sent out from the serial data output pin (SOUT pin).
- According to the data length, the transmission data is stored, starting with the lower bits, while the other bits are "invalid". Example: If the data length is 8 bits, and 0x45 is transmitted, D7 to D0 = 0x45 and D31 to D8 will be invalid.
- The transmission data empty flag (SSR:TDRE) is cleared to "0" when transmission data is written to the transmission data register (TDR).
- If the transmission FIFO is disabled or empty, the transmission data empty flag (SSR:TDRE) is set to "1" when transmission data is transferred to the transmission shift register to start transmission.
- When the transmission data empty flag (SSR:TDRE) is set to "1", the next transmission data can be written. A transmission interrupt occurs if the transmission interrupt is enabled. Write the next transmission data after the occurrence of a transmission interrupt or when the transmission data empty flag (SSR:TDRE) is set to "1".
- When the transmission data empty flag (SSR:TDRE) is set to "0", and the transmission FIFO is disabled or the transmission FIFO is full, transmission data cannot be written to the transmission data register (TDR).

- To write to the TDR, perform access as described below.
 - If SSR:AWC = 0, perform 16-bit access to the lower 16 bits of the TDR.
 - If SSR:AWC = 1, perform 32-bit access.

Notes:

- *The transmission data register is a write-only register, while the reception data register is a read-only register. The two registers are placed at the same address, so the written value differs from that which is read.*
- *For details on the set timing of the transmission data empty flag (SSR:TDRE) when the transmission FIFO is used, see "2.4 Interrupt Generation and Flag Set Timing When the Transmission FIFO Is Used."*
- *When AWC = 0, do not access D31 to D16.*

Relationship between the Transmission Data Register (TDR) and the Transmission Data Empty Flag

For 16-bit access (SSR:AWC = 0), the TDR register has a 16-bit boundary, so that, with a single write, transmission data is stored in blocks of 16 bits. If the TDR register contains 32-bit transmission data, the transmission data empty flag (SSR:TDRE) is set to "0".

For 32-bit access (SSR:AWC = 1), the TDR register has a 32-bit boundary, so that, with a single write, transmission data is stored in blocks of 32 bits.

Table 9-2 Relationship between the Transmission Data Register (TDR) and the Transmission Data Empty Flag

Data Access Width	Number of Data Items Stored in the TDR Register	TBI Flag	TDRE Flag	Transmission
16-bit access (SSR:AWC = 0)	0 bit	1	1 *1	Transmission not possible
	16 bits	0		Transmission possible
	32 bits		0	
32-bit access (SSR:AWC = 1)	0 bit	1	1	Transmission not possible
	32 bits	0	0	Transmission possible

*1: For SSR:AWC = 0, when the number of storage data items in the TDR register is 0, if 16-bit data is written, TDRE is first set to 0 and then to 1.

9.6. Serial Auxiliary Control Status Register (SACSR)

The serial auxiliary control status register (SACSR) performs the following: 1. Controls serial test operation, 2. Selects a serial timer activation method, 3. Enables/disables timer interrupts, 4. Enables/disables synchronous transmission, 5. Sets the division value for the serial timer operation clock, and 6. Enables/disables the serial timer.

Bit Configuration of the Serial Auxiliary Control Status Register (SACSR)

Figure 9-7 shows the bit configuration of the serial auxiliary control status register (SACSR).

Figure 9-7 Bit Configuration of Serial Auxiliary Control Status Register (SACSR)

Bit	15	14	13	12	11	10	9	8
Field	STST	Reserved	TBEEN	CSEIE	CSE	TRG1	TRG0	TINT
R/W Attribute	R/W	R0,W0	R/W	R/W	R,WX	R/W	R/W	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TINTE	TSYNE	TRGE	TDIV3	TDIV2	TDIV1	TDIV0	TMRE
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] STST : Serial test bit

This bit enables or disables serial test mode.

When serial test mode is enabled, SOUT and SIN are connected together within the multi-function serial interface, so that the data transmitted from SOUT can be received from SIN directly.

When serial test mode is enabled, the SOUT pin is fixed to "H", and any data input to the SIN pin is ignored.

- This bit is reset when the SACSRC:STSTC bit in the clear register is set to "1".
- This bit is set when the SACSRS:STSTS bit in the set register is set to "1".

Bit	Description
0	Disable serial test mode.
1	Enable serial test mode.

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = 0, SCR:RXE = 0).
- Set this bit to "0" in slave mode (SCR:MS = 1).

[bit14] Reserved : Reserved Bit

[bit13] TBEEN: Transfer Byte Error Enable Bit

In master mode (SCR:MS = 0), this bit enables/disables the occurrence of serial chip select errors.

For details, see "2.6 Chip Select Error Occurrence and Flag Set Timing".

- This bit is reset when the SACSRC:TBEENC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TBEENS bit in the set register is set to "1".

Bit	Description
0	In master mode (SCR:MS = 0), disable the occurrence of chip select errors.
1	In master mode (SCR:MS = 0), enable the occurrence of chip select errors.

Note:

- Change this bit when transmission and reception are disabled (SCR:TXE = RXE = 0).

[bit12] CSEIE: Chip Select Error Interrupt Enable Bit

- This bit enables/disables the output of chip select error interrupt requests.
- If the CSEIE bit and the chip select error flag bit (CSE) are "1", a transmission interrupt request is output.
- This bit is reset when the SACSRC:CSEIEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:CSEIES bit in the set register is set to "1".

Bit	Description
0	Disable chip select error interrupts.
1	Enable chip select error interrupts.

[bit11] CSE: Chip Select Error Flag Bit

This bit indicates whether a chip select error has occurred.

For details, see "2.6 Chip Select Error Occurrence and Flag Set Timing".

When this bit is "1" and the chip select error interrupt enable bit (CSEIE) is also "1", a transmission interrupt request is output.

Writing to this bit is invalid.

- This bit is reset when the SACSRC:CSEC bit in the clear register is set to "1".

Bit	Description
0	No chip select error has occurred.
1	A chip select error has occurred.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- When serial chip select is not used (SCSCR:CSEN0 = 0) in slave mode (SCR:MS = 1), this bit is not set to "1".
- When a chip select error occurs (CSE = 1), disable transmission (SCR:TXE = 0), and then write "1" to SACSRC:CSEC. To restart transmission, write "1" to SACSRC:CSEC, enable transmission (SCR:TXE = 1), and then write transmission data to the transmission data buffer (TDR).
- If noise of 1 bus clock or greater is generated in the serial chip select input during slave transmission, this bit may be set to "1". Should this occur, restart transmission after the end of master transfer.

[bit10:9] TRG[1:0] : Trigger selection bits

These bits select the method for detecting the external trigger edges for activating the serial timer.

Bits		Edge Detection Method for External Trigger
0	0	Rising edge detection
0	1	Falling edge detection
1	0	Both edge detection
1	1	Setting prohibited

Notes:

- These bits are invalid if the external trigger enable bit (TRGE) is "0".
- These bits can be changed only when the serial timer enable bit (TMRE) is "0".

[bit8] TINT : Timer interrupt flag

If the serial timer register (STMR) and the serial timer comparison register (STMCR) match, the serial timer register (STMR) is set to "0", and this bit is set to "1".

When this bit is "1" and the timer interrupt enable bit (TINTE) is "1", a status interrupt request is issued.

Writing to this bit is invalid.

- This bit is reset when the SACSRC:TINTC bit in the clear register is set to "1".

Bit	Description
0	No timer interrupt request
1	Timer interrupt request issued

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is not set to "1" when the synchronous transmission enable bit (TSYNE) is "1".

[bit7] TINTe : Timer interrupt enable bit

This bit enables/disables timer interrupts to the CPU.

When this bit is "1" and the timer interrupt flag (TINT) is "1", a status interrupt request is issued.

- This bit is reset when the SACSRC:TINTEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TINTES bit in the set register is set to "1".

Bit	Description
0	Disable interrupts triggered by the serial timer.
1	Enable interrupts triggered by the serial timer.

[bit6] TSYNE : Synchronous transmission enable bit

This bit enables or disables synchronous transmission.

Transmission is activated if this bit is set to "1", as well as in any of the cases described below.

- The serial timer register (STMR) and the serial timer comparison register (STMCR) values coincide at the time of timer-synchronized transmission.
- An external trigger edge specified by the trigger selection bits (SACSR:TRG1, TRG0) is detected at the time of external-trigger-synchronized transmission.
- This bit is reset when the SACSRC:TSYNEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TSYNES bit in the set register is set to "1".

Bit	Description
0	Disable synchronous transmission. The serial timer is used as a timer.
1	Enable synchronous transmission. The serial timer is not used as a timer.

Notes:

- This bit can be changed only when the serial timer enable bit (TMRE) is set to "0".
- When synchronous transmission is enabled (TSYNE = 1) and transmission is disabled (SCR:TXE = 0), transmission is not activated, even in any of the cases below.
 - The serial timer register (STMR) and the serial timer comparison register (STMCR) values coincide at the time of timer-synchronized transmission.
 - An external trigger edge specified by the trigger selection bits (SACSR:TRG1, TRG0) is detected at the time of external-trigger-synchronized transmission.
- In slave mode (SCR:MS = 1), this bit is internally fixed to "0".

[bit5] TRGE: External trigger enable bit

This bit selects the method used to activate the serial timer.

- This bit is reset when the SACSRC:TRGEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TRGES bit in the set register is set to "1".

Bit	Description
0	The serial timer starts when the setting of the serial timer enable bit (TMRE) is changed from "0" to "1".
1	If the serial timer enable bit (TMRE) is set to "1", the detection of an external trigger edge specified by the trigger selection bits (TRG1, TRG0) starts the serial timer.

Notes:

- This bit can be changed only when the serial timer enable bit (TMRE) is set to "0".
- If the serial timer enable bit (TMRE) is set to "0", the detection of an external trigger edge specified by the trigger selection bits (TRG1, TRG0) does not start the serial timer.
- When synchronous transmission is enabled (SACSR:TSYNE = 1), external triggers are enabled (SACSR:TRGE = 1), the timer comparison register (STMCR) is set to 0x0000, and the serial timer is enabled (SACSR:TMRE = 1), transmission is activated in synchronization with an external trigger.

[bit4:1] TDIV[3:0]: Timer operation clock division bits

These bits set the division ratio for the serial timer.

TDIV3	TDIV2	TDIV1	TDIV0	Timer Operation Clock						
				Division Ratio	Φ = 8 MHz	Φ = 10 MHz	Φ = 16 MHz	Φ = 20 MHz	Φ = 24 MHz	Φ = 32 MHz
0	0	0	0	Φ	125 ns	100 ns	62.5 ns	50 ns	41.67 ns	31.25 ns
0	0	0	1	$\Phi/2$	250 ns	200 ns	125 ns	100 ns	83.33 ns	62.5 ns
0	0	1	0	$\Phi/4$	500 ns	400 ns	250 ns	200 ns	166.67 ns	125 ns
0	0	1	1	$\Phi/8$	1 μ s	800 ns	500 ns	400 ns	333.33 ns	250 ns
0	1	0	0	$\Phi/16$	2 μ s	1.6 μ s	1 μ s	800 ns	666.67 ns	500 ns
0	1	0	1	$\Phi/32$	4 μ s	3.2 μ s	2 μ s	1.6 μ s	1.33 μ s	1 μ s
0	1	1	0	$\Phi/64$	8 μ s	6.4 μ s	4 μ s	3.2 μ s	2.67 μ s	2 μ s
0	1	1	1	$\Phi/128$	16 μ s	12.8 μ s	8 μ s	6.4 μ s	5.33 μ s	4 μ s
1	0	0	0	$\Phi/256$	32 μ s	25.6 μ s	16 μ s	12.8 μ s	10.67 μ s	8 μ s

Φ : Bus clock

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is set to "0".
- Settings other than the above are prohibited.

[bit0] TMRE: Serial timer enable bit

This bit enables or disables serial timer operation.

- This bit is reset when the SACSRC:TMREC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TMRES bit in the set register is set to "1".

Bit	Description
0	Stop the serial timer operation. When stopped, the value of the serial timer register (STMR) is retained.
1	Changing the setting of this bit from "0" to "1" initializes the serial timer register (STMR) to "0" and starts the serial timer operation.

Notes:

- If the external trigger is enabled ($TRGE = 1$), setting this bit to "1" does not start the serial timer until detection of an external trigger edge specified by the trigger selection bits (SACSR:TRG1, TRG0).
- For serial timer synchronous transmission or external trigger transmission, change the setting of this bit from "0" to "1" if transmission is disabled.

9.7. Serial Timer Register (STMR)

The serial timer register (STMR) represents the timer value of the serial timer.

Bit Configuration of the Serial Timer Register (STMR)

Figure 9-8 shows the bit configuration of the serial timer register (STMR).

Figure 9-8 Bit Configuration of Serial Timer Register (STMR)

Bit	15	14	13	12	11	10	9	8
Field	TM15	TM14	TM13	TM12	TM11	TM10	TM9	TM8
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TM7	TM6	TM5	TM4	TM3	TM2	TM1	TM0
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15-0] TM[15:0]: Timer Data Bits

These bits indicate the timer value of the serial timer.

During timer operation, the timer value of the serial timer is incremented by 1 for each timer operation clock (specified by SACSr:TDIV3 to TDIV0).

Note:

- These bits are initialized to "0" when the timer operation starts.

9.8. Serial Timer Comparison Register (STMCR)

The serial timer comparison register (STMCR) sets the timer comparison value for the serial timer.

Bit Configuration of the Serial Timer Comparison Register (STMCR)

Figure 9-9 shows the bit configuration of the serial timer comparison register (STMCR).

Figure 9-9 Bit Configuration of Serial Timer Comparison Register (STMCR)

Bit	15	14	13	12	11	10	9	8
Field	TC15	TC14	TC13	TC12	TC11	TC10	TC9	TC8
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TC7	TC6	TC5	TC4	TC3	TC2	TC1	TC0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TC[15:0]: Compare bits

These bits set a comparison value for the serial timer.

These bits are compared with the serial timer register (STMR). If the serial timer register (STMR) coincides with these bits when the serial timer register is updated, the serial timer register is set to "0". At this time, if synchronous transmission is disabled (SACSR:TSYNE = 0), the timer interrupt flag (SACSR:TINT) is set to "1". If synchronous transmission is enabled (SACSR:TSYNE = 1), the transmission is activated.

The interval for the operations described below is (STMCR:TC + 1) * timer operation clock (specified by SACSR:TDIV3 to TDIV0).

- SACSR:TINT is set to "1".
- Serial-timer-synchronized transmission is activated.

Notes:

- The timer interrupt flag (SACSR:TINT) is fixed to "1" when all of the following conditions are satisfied.
 - Synchronous transmission is disabled (SACSR:TSYNE = 0).
 - 0x0000 is set in this register.
 - The timer is operating.
 - 0b0000 is set as the timer operating clock division value (SACSR:TDIV3-0).
- When all of the following conditions are satisfied, transmission starts immediately upon the detection of an external trigger edge specified by the trigger selection bits (SACSR:TRG1, TRG0).
 - Synchronous transmission is enabled (SACSR:TSYNE = 1).

- External trigger is enabled (SACSR:TRGE = 1).
- 0x0000 is set in this register.
- Transmission is enabled (SCR:TXE = 1), and transmission data exists (SSR:TDRE = 0).
- *This register can be changed only when the serial timer is disabled (SACSR:TMRE = 0).*

9.9. Serial Chip Select Control Status Register (SCSCR)

The serial chip select control register (SCSCR) is used to select the serial chip select start and end pins, display a serial chip select output pin, retain the active level of serial chip select, invert serial chip select, and enable/disable the output of the serial chip select pins.

Bit Configuration of the Serial Chip Select Control Status Register (SCSCR)

Figure 9-10 shows the bit configuration of the serial chip select control status register (SCSCR).

Figure 9-10 Bit Configuration of Serial Chip Select Control Status Register (SCSCR)

Bit	15	14	13	12	11	10	9	8
Field	SST1	SST0	SED1	SED0	SCD1	SCD0	SCAM	CDIV2
R/W Attribute	R/W	R/W	R/W	R/W	R,WX	R,WX	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	CDIV1	CDIV0	CSLVL	CSEN3	CSEN2	CSEN1	CSEN0	CSOE
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	1	0	0	0	0	0

[bit15:14] SST[1:0]: Serial chip select start bits

These bits select the pin at which serial chip select is to start.

If transmission is changed from the disabled state (SCR:TXE = 0) to the enabled state (SCR:TXE = 1), and transmission data is written to TDR, the serial chip select pins become active sequentially, starting with the one set with these bits.

Bits		Start Pin
0	0	SCS0
0	1	SCS1
1	0	SCS2
1	1	SCS3

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- If the serial chip select start bits (SST1, SST0) and the serial chip select end bits (SED1, SED0) are set to the same values, only the set serial chip select pin becomes active.
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- Only those serial chip select pins for which serial chip select is enabled (SCSCR:CSEN3, CSEN2, CSEN1, CSEN0=1) become active.

- When using serial chip select in master mode ($SCR:MS = 0$), enable serial chip select ($SCSCR:CSEN3, CSEN2, CSEN1, CSEN0 = "1"$) for the serial chip select pin that is set with these bits.

[bit13:12] SED[1:0]: Serial chip select end bits

These bits select the pin at which serial chip select is to end.

If the serial chip select pins become active, up to the serial chip select pin that is set with these bits, the next serial chip select pin to become active is that specified with the serial chip select start bits (SST1, SST0).

Bits		End Pin
0	0	SCS0
0	1	SCS1
1	0	SCS2
1	1	SCS3

Notes:

- These bits can be changed only when transmission and reception are disabled ($SCR:TXE = RXE = 0$).
- If the serial chip select start bits (SST1, SST0) and the serial chip select end bits (SED1, SED0) are set to the same values, only the set serial chip select pin becomes active.
- Only those serial chip select pins for which serial chip select is enabled ($SCSCR:CSEN3, CSEN2, CSEN1, CSEN0 = "1"$) become active.
- In slave mode ($SCR:MS = 1$), the settings of these bits are invalid.
- When serial chip select is used in master mode ($SCR:MS = 0$), enable serial chip select ($SCSCR:CSEN3, CSEN2, CSEN1, CSEN0 = "1"$) for the serial chip select pin that is set with these bits.

[bit11:10] SCD[1:0]: Serial chip select display bits

These bits display the active serial chip select pin.

Bits		Display Pin
0	0	SCS0
0	1	SCS1
1	0	SCS2
1	1	SCS3

Notes:

- If the serial chip select pins are inactive, these bits display the next serial chip select pin to become active.
- These bits are set to 0b00 in slave mode ($SCR:MS = 1$), at a software reset ($SCR:UPCL = 1$), or when transmission is disabled ($SCR:TXE = 0$).

[bit9] SCAM: Serial chip select Active retention bit

This bit selects whether to retain the active state of the serial chip select pin.

For details, see "5 Operation of Serial Chip Select," "Serial Chip Select Active Level Retention Operation (SCSCR:SCAM = 1) (Valid Only in Master Mode (SCR:MS = 0))."

Bit	Description
0	Do not retain the active state of the serial chip select pin.
1	Retain the active state of the serial chip select pin.

Notes:

- If transmission is disabled (SCR:TXE = 0) and a software reset is performed (SCR:UPCL = 1), the serial chip select pin will be inactive regardless of the value of this bit.
- When a serial chip select error occurs (SACSR:CSE = 1), the serial chip select pin will be inactive regardless of the value of this bit.

[bit8:6] CDIV[2:0]: Serial chip select timing operating clock division bits

These bits set the division ratio of the serial chip select timing operating clock.

Bits			Serial Chip Select Timing Operating Clock						
			Division Ratio	Φ = 8 MHz	Φ = 10 MHz	Φ = 16 MHz	Φ = 20 MHz	Φ = 24 MHz	Φ = 32 MHz
0	0	0	Φ	125 ns	100 ns	62.5 ns	50 ns	41.67 ns	31.25 ns
0	0	1	$\Phi/2$	250 ns	200 ns	125 ns	100 ns	83.33 ns	62.5 ns
0	1	0	$\Phi/4$	500 ns	400 ns	250 ns	200 ns	166.67 ns	125 ns
0	1	1	$\Phi/8$	1 μ s	800 ns	500 ns	400 ns	333.33 ns	250 ns
1	0	0	$\Phi/16$	2 μ s	1.6 μ s	1 μ s	800 ns	666.67 ns	500 ns
1	0	1	$\Phi/32$	4 μ s	3.2 μ s	2 μ s	1.6 μ s	1.33 μ s	1 μ s
1	1	0	$\Phi/64$	8 μ s	6.4 μ s	4 μ s	3.2 μ s	2.67 μ s	2 μ s

Φ : Bus clock

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- Settings other than those above are prohibited.

[bit5] CSLVL: Serial chip select level set bit

This bit switches the inactive-time level of the serial chip select pin between "H" and "L".

This bit is used for chip select pin 0.

Bit	Description
0	Set the inactive level to "L".
1	Set the inactive level to "H".

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- This bit setting is used in any of the following:
 - In slave mode (SCR:MS = 1).
 - The chip select data format is disabled (ESCR:CSFE = 0).
 - The chip select data format is enabled (ESCR:CSFE = 1) and serial chip select pin 0 is active.

[bit4:1] CSEN3, CSEN2, CSEN1, CSEN0: Serial chip select enable bits

These bits enable or disable each serial chip select pin.

The CSEN3 bit corresponds to the SCS3 pin, the CSEN2 bit to the SCS2 pin, the CSEN1 bit to the SCS1 pin, and the CSEN0 bit to the SCS0 pin.

In slave mode (SCR:MS = 1), only the CSEN0 bit is used to enable or disable serial chip pins.

Bit	Description
0	Disable the operation of the serial chip select pin.
1	Enable the operation of the serial chip select pin.

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In master mode (SCR:MS = 0), if CSEN3 to CSEN0 are set to 0b0000, transmission/reception operations are performed regardless of the status of the serial chip select pin.
- In slave mode (SCR:MS = 1), if CSEN0 is set to "0", transmission/reception operations are performed regardless of the status of the serial chip select pin.
- Disable any serial chip select pins that are not used.

[bit0] CSOE: Serial chip select output enable bit

This bit enables or disables the output of serial chip select pins.

Bit	Description
0	Disable the output of all serial chip select pins.
1	Enable the output of all serial chip select pins.

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), set this bit to "0".

9.10. Serial Chip Select Timing Registers (SCSTR3 to SCSTR0)

The serial chip select timing registers (SCSTR3 to SCSTR0) are used to set the serial chip select setup delay time, serial chip select hold delay time, and serial chip select deselect time.

Bit Configuration of the Serial Chip Select Timing Registers (SCSTR3 to SCSTR0)

Figure 9-11 and

Figure 9-12 show the bit configuration of the serial chip select timing registers (SCSTR3 to SCSTR0).

Figure 9-11 Bit Configuration of Serial Chip Select Timing Registers (SCSTR1, SCSTR0)

Bit	15	14	13	12	11	10	9	8

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:8] CSSU[7:0]: Serial chip select setup delay bits

These bits set the time from the instant that the serial chip select pin becomes active until the serial clock is output. If 0x00 is set in these bits, the serial clock is output at the same time as the serial chip select pin becomes active.

Bits								Setup Delay Time
0	0	0	0	0	0	0	0	The output of the serial clock is started at the same time as the serial chip select pin becomes active.
0	0	0	0	0	0	0	1	1x Serial chip select timing operating clock
0	0	0	0	0	0	1	0	2x Serial chip select timing operating clock
-	-	-	-	-	-	-	-	-
-	-	-	-	-	-	-	-	-
1	1	1	1	1	1	1	0	254x Serial chip select timing operating clock
1	1	1	1	1	1	1	1	255x Serial chip select timing operating clock

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.

[bit7:0] CSHD[7:0]: Serial chip select hold delay bits

These bits set the time from the instant that the output of the serial clock ends until the serial chip select pin becomes inactive.

If these bits are set to 0x00, the output of the serial clock ends at the same time as the serial chip select pin becomes inactive.

Bits								Hold Delay Time
0	0	0	0	0	0	0	0	The output of the serial clock ends at the same time as the serial chip select pin becomes inactive.
0	0	0	0	0	0	0	1	1x Serial chip select timing operating clock
0	0	0	0	0	0	1	0	2x Serial chip select timing operating clock
-	-	-	-	-	-	-	-	-
-	-	-	-	-	-	-	-	-
1	1	1	1	1	1	1	0	254x Serial chip select timing operating clock
1	1	1	1	1	1	1	1	255x Serial chip select timing operating clock

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.

-	-	-	-	-	-	-	-
1	1	1	...	1	1	0	65534x Serial chip select timing operating clock
1	1	1	...	1	1	1	65535x Serial chip select timing operating clock

Notes:

- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- Regardless of the deselect time setting, a minimum time of at least 5 bus clocks is required from the time the serial chip select pin becomes inactive until the next time it becomes active.
- Do not make the settings: SCSTR3-2:CSDS = 0x0001 and SCSCR:CDIV2-0 = "000".

9.11. Serial Chip Select Format Registers (SCSFR2 to SCSFR0)

The serial chip select format registers (SCSFR2 to SCSFR0) are used to select the chip select active level of each serial chip select, invert the serial clock, make the settings for connecting to SPI, and set the data direction and data length of serial data output.

Bit Configuration of the Serial Chip Select Format Registers (SCSFR2 to SCSFR0)

Figure 9-13 and

Figure 9-14 show the bit configuration of the serial chip select format registers (SCSFR2 to SCSFR0).

Figure 9-13 Bit Configuration of Serial Chip Select Format Registers 1/0 (SCSFR1, SCSFR0)

[bit15] CS2CSLVL: Bit for Setting the Serial Chip Select Level of Chip Select 2

When the chip select data format is enabled (ESCR:CSFE = 1), this bit selects the inactive-time level of serial chip select pin 2.

Bit	Description
0	Set the inactive level to "L".
1	Set the inactive level to "H".

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit14] CS2SCINV: Bit for Inverting the Serial Clock of Chip Select 2

When the chip select data format is enabled (ESCR:CSFE = 1), this bit sets the serial clock format to be assumed when serial chip select pin 2 is active.

0:

- Set the mark level of serial clock output to "H".
- In normal transfer, transmission data is output in synchronization with a falling edge of the serial clock. In SPI transfer, it is output in synchronization with a rising edge of the serial clock.
- In normal transfer, reception data is sampled at a rising edge of the serial clock. In SPI transfer, it is sampled at a falling edge of the serial clock.

1:

- Set the mark level of serial clock output to "L".
- In normal transfer, transmission data is output in synchronization with a rising edge of the serial clock. In SPI transfer, it is output in synchronization with a falling edge of the serial clock.
- In normal transfer, reception data is sampled at a falling edge of the serial clock. In SPI transfer, it is sampled at a rising edge of the serial clock.

Bit	Description
0	Mark level "H" format
1	Mark level "L" format

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit13] CS2SPI: Bit for Making Serial Chip Select Pin 2 Support SPI

When the chip select data format is enabled (ESCR:CSFE = 1), this bit is used for performing communication supporting SPI when serial chip select pin 2 is active.

- 0: Perform normal synchronous communication.
- 1: Support SPI.

Bit	Description
0	Normal synchronous transfer
1	SPI support

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit12] CS2BDS: Bit for Selecting the Transfer Direction of Chip Select Pin 2

When the chip select data format is enabled (ESCR:CSFE = 1), this bit selects the transfer of transfer serial data when serial chip select pin 2 is active, setting either transfer of the lowest bit first (LSB first, SCSFR1:CS2BDS = 0) or transfer of the highest bit first (MSB first, SCSFR1:CS2BDS = 1).

Bit	Description
0	LSB first (lowest bit transferred first)
1	MSB first (highest bit transferred first)

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit11:8] CS2L[3:0]: Bits for Selecting the Data Length of Serial Chip Select Pin 2

When the chip select data format is enabled (ESCR:CSFE = 1), these bits specify the data length of the transmission/reception data to be assumed when serial chip select pin 2 is active.

Bits				Data Length
0	0	0	0	8-bit length
0	0	0	1	5-bit length
0	0	1	0	6-bit length
0	0	1	1	7-bit length
0	1	0	0	9-bit length
0	1	0	1	10-bit length
0	1	1	0	11-bit length
0	1	1	1	12-bit length
1	0	0	0	13-bit length
1	0	0	1	14-bit length
1	0	1	0	15-bit length
1	0	1	1	16-bit length
1	1	0	0	20-bit length
1	1	0	1	24-bit length
1	1	1	0	32-bit length

Notes:

- Settings other than those above are prohibited.
- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the settings of these bits are invalid.

[bit7] CS1CSLVL: Bit for Setting the Serial Chip Select Level of Chip Select 1

When the chip select data format is enabled (ESCR:CSFE = 1), this bit selects the inactive-time level of serial chip select pin 1.

Bit	Description
0	Set the inactive level to "L".
1	Set the inactive level to "H".

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit6] CS1SCINV: Bit for Inverting the Serial Clock of Chip Select 1

When the chip select data format is enabled (ESCR:CSFE = 1), this bit sets the serial clock format to be assumed when serial chip select pin 1 is active.

0:

- Set the mark level of serial clock output to "H".
- In normal transfer, transmission data is output in synchronization with a falling edge of the serial clock. In SPI transfer, it is output in synchronization with a rising edge of the serial clock.
- In normal transfer, reception data is sampled at a rising edge of the serial clock. In SPI transfer, it is sampled at a falling edge of the serial clock.

1:

- Set the mark level of serial clock output to "L".
- In normal transfer, transmission data is output in synchronization with a rising edge of the serial clock. In SPI transfer, it is output in synchronization with a falling edge of the serial clock.
- In normal transfer, reception data is sampled at a falling edge of the serial clock. In SPI transfer, it is sampled at a rising edge of the serial clock.

Bit	Description
0	Mark level "H" format
1	Mark level "L" format

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit5] CS1SPI: Bit for Making Serial Chip Select Pin 1 Support SPI

When the chip select data format is enabled (ESCR:CSFE = 1), this bit is used for performing communication supporting SPI when serial chip select pin 1 is active.

- 0: Perform normal synchronous communication.
- 1: Support SPI.

Bit	Description
0	Normal synchronous transfer
1	SPI support

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit4] CS1BDS: Bit for Selecting the Transfer Direction of Chip Select Pin 1

When the chip select data format is enabled (ESCR:CSFE = 1), this bit selects the transfer of transfer serial data when serial chip select pin 1 is active, setting either transfer of the lowest bit first (LSB first, SCSFR0:CS1BDS = 0) or transfer of the highest bit first (MSB first, SCSFR0:CS1BDS = 1).

Bit	Description
0	LSB first (lowest bit transferred first)
1	MSB first (highest bit transferred first)

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit3:0] CS1L[3:0]: Bits for Selecting the Data Length of Serial Chip Select Pin 1

When the chip select data format is enabled (ESCR:CSFE = 1), these bits specify the data length of the transmission/reception data to be assumed when serial chip select pin 1 is active.

Bits				Data Length
0	0	0	0	8-bit length
0	0	0	1	5-bit length
0	0	1	0	6-bit length
0	0	1	1	7-bit length
0	1	0	0	9-bit length
0	1	0	1	10-bit length
0	1	1	0	11-bit length
0	1	1	1	12-bit length
1	0	0	0	13-bit length
1	0	0	1	14-bit length
1	0	1	0	15-bit length
1	0	1	1	16-bit length
1	1	0	0	20-bit length
1	1	0	1	24-bit length
1	1	1	0	32-bit length

Notes:

- Settings other than above are prohibited.
- These bits can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the settings of these bits are invalid.

[bit7] CS3CSLVL: Bit for Setting the Serial Chip Select Level of Chip Select 3

When the chip select data format is enabled (ESCR:CSFE = 1), this bit selects the inactive-time level of serial chip select pin 3.

Bit	Description
0	Set the inactive level to "L".
1	Set the inactive level to "H".

Notes:

- This bit can be changed only when transmission and reception are disabled (SCR:TXE = RXE = 0).
- In slave mode (SCR:MS = 1), the setting of this bit is invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the setting of this bit is invalid.

[bit6] CS3SCINV: Bit for Inverting the Serial Clock of Chip Select 3

When the chip select data format is enabled (ESCR:CSFE = 1), this bit sets the serial clock format to be assumed when serial chip select pin 3 is active.

0:

- Set the mark level of the serial clock output to "H".
- In normal transfer, transmission data is output in synchronization with a falling edge of the serial clock. In SPI transfer, it is output in synchronization with a rising edge of the serial clock.
- In normal transfer, reception data is sampled at a rising edge of the serial clock. In SPI transfer, it is sampled at a falling edge of the serial clock.

1:

- Set the mark level of the serial clock output to "L".
- In normal transfer, transmission data is output in synchronization with a rising edge of the serial clock. In SPI transfer, it is output in synchronization with a falling edge of the serial clock.
- In normal transfer, reception data is sampled at a falling edge of the serial clock. In SPI transfer, it is sampled at a rising edge of the serial clock.

Bit	Description
0	Mark level "H" format
1	Mark level "L" format

Notes:

- This bit can be changed only when transmission and reception are disabled ($SCR:TXE = RXE = 0$).
- In slave mode ($SCR:MS = 1$), the setting of this bit is invalid.
- When the chip select data format is disabled ($ESCR:CSFE = 0$), the setting of this bit is invalid.

[bit5] CS3SPI: Bit for Making Serial Chip Select Pin 3 Support SPI

When the chip select data format is enabled ($ESCR:CSFE = 1$), this bit is used for performing communication supporting SPI when serial chip select pin 3 is active.

- 0: Perform normal synchronous communication.
- 1: Support SPI.

Bit	Description
0	Normal synchronous transfer
1	SPI support

Notes:

- This bit can be changed only when transmission and reception are disabled ($SCR:TXE = RXE = 0$).
- In slave mode ($SCR:MS = 1$), the setting of this bit is invalid.
- When the chip select data format is disabled ($ESCR:CSFE = 0$), the setting of this bit is invalid.

[bit4] CS3BDS: Bit for Selecting the Transfer Direction of Chip Select Pin 3

When the chip select data format is enabled ($ESCR:CSFE = 1$), this bit selects the transfer of transfer serial data when serial chip select pin 3 is active, setting either transfer of the lowest bit first (LSB first, $SCSFR2.CS3BDS = 0$) or transfer of the highest bit first (MSB first, $SCSFR2.CS3BDS = 1$).

Bit	Description
0	LSB first (lowest bit transferred first)
1	MSB first (highest bit transferred first)

Notes:

- This bit can be changed only when transmission and reception are disabled ($SCR:TXE = RXE = 0$).
- In slave mode ($SCR:MS = 1$), the setting of this bit is invalid.
- When the chip select data format is disabled ($ESCR:CSFE = 0$), the setting of this bit is invalid.

[bit3:0] CS3L[3:0]: Bits for Selecting the Data Length of Serial Chip Select Pin 3

When the chip select data format is enabled ($ESCR:CSFE = 1$), these bits specify the data length of the transmission/reception data to be assumed when serial chip select pin 3 is active.

Bits				Data Length
0	0	0	0	8-bit length
0	0	0	1	5-bit length
0	0	1	0	6-bit length
0	0	1	1	7-bit length
0	1	0	0	9-bit length
0	1	0	1	10-bit length
0	1	1	0	11-bit length
0	1	1	1	12-bit length
1	0	0	0	13-bit length
1	0	0	1	14-bit length
1	0	1	0	15-bit length
1	0	1	1	16-bit length
1	1	0	0	20-bit length
1	1	0	1	24-bit length
1	1	1	0	32-bit length

Notes:

- Settings other than above are prohibited.
- These bits can be changed only when transmission and reception are disabled (SCR:TXE=RXE = 0).
- In slave mode (SCR:MS = 1), the settings of these bits are invalid.
- When the chip select data format is disabled (ESCR:CSFE = 0), the settings of these bits are invalid.

9.12. Transfer Byte Registers (TBYTE3 to TBYTE0)

The transfer byte registers (TBYTE3 to TBYTE0) are used to set the number of transfer data items when the respective serial chip select pins are active.

Bit Configuration of the Transfer Bytes (TBYTE3 to TBYTE0)

Figure 9-15 shows the bit configuration of the transfer byte register (TBYTE).

Figure 9-15 Bit Configuration of Transfer Byte Register (TBYTE)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	TBYTE1								TBYTE0							
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	TBYTE3								TBYTE2							
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The transfer byte registers can set the number of transfer data items when the respective serial chip select pins are active. After a serial chip select pin becomes active, if the transfer of data items for which a number is set in the corresponding one of these bits is completed, the serial chip select pin becomes inactive.

Serial chip select pin 0 (SCS0) corresponds to TBYTE0, serial chip select pin 1 (SCS1) to TBYTE1, serial chip select pin 2 (SCS2) to TBYTE2, and serial chip select pin 3 (SCS3) to TBYTE3.

When serial chip select is disabled (SCSCR: CSEN3-0 = 0b0000), transfer byte register 0 (TBYTE0) is used for transmission synchronized with the timer or transmission synchronized with an external trigger. After the start of transmission due to transmission being synchronized with the timer, or transmission synchronized with an external trigger, data items for which a number is set in TBYTE0 are transferred.

If the value of one of these bits is changed during transmission (SSR: TBI = 0), the new number of transfer data items becomes valid after the end of transmission with the old number of transfer data items.

[bit15] TBYTE: Transfer Byte

TBYTE	Description
Write	Writing to TBYTE
Read	Setting of TBYTE

Notes:

- If one of these bits is set to 0x00, the transfer count will be 8.
- In slave mode (SCR: MS = 1), the setting of this bit is invalid.

9.13. Baud Rate Generator Registers 1, 0 (BGR1, BGR0)

The baud rate generator registers 1, 0 (BGR1 and BGR0) are used to set the division ratio of the serial clock.

Bit Configuration of Baud Rate Generator Registers 1, 0 (BGR1, BGR0)

Figure 9-16 shows the bit configuration of baud rate generator registers 1, 0 (BGR1, BGR0).

Figure 9-16 Bit Configuration of Baud Rate Generator Registers 1, 0 (BGR1, BGR0)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	Reserved	BGR1							BGR0							
R/W Attribute	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- These registers are set the value of the division ratio of the serial clock.
- BGR1 represents the upper bits while BGR0 represents the lower bits. The reload value for counting can be written to these registers, and the setting values can be read from these registers.
- The reload counter starts counting when a reload value is written to baud rate generator registers 1, 0 (BGR1, BGR0).

[bit15] Reserved: Reserved Bit

[bit14:8] BGR1: Baud Rate Generator Register 1

BGR1	Description
Write	Write to reload counter bits 8 to 14.
Read	Read the setting value of BGR1.

[bit7:0] BGR0: Baud Rate Generator Register 0

BGR0	Description
Write	Write to reload counter bits 0 to 7.
Read	Read the setting value of BGR0.

Notes:

- Use 16-bit access for writing a value to baud rate generator register (BGR1, BGR0).
- If the reload value is even-numbered, the "H" width and the "L" width of the serial clock will be as described below, depending on the setting of the SCINV bit. If it is odd-numbered, the "H" width and the "L" width of the serial clock will be the same.
 When SMR:SCINV = 0, the "H" width of the serial clock will be longer by 1 cycle of the bus clock.
 When SMR:SCINV = 1, the "L" width of the serial clock will be longer by 1 cycle of the bus clock.
- Set the reload value to 2 or more in master mode and to 3 or more in slave mode.
- If the set values of the baud rate generator registers (BGR1, BGR0) are changed, the new values are reloaded when the counter value becomes 0x00000. Thus, to have the new settings take effect immediately, execute a CSIO reset (SCR:UPCL) after changing the settings of BGR1/0.
- When the reception FIFO is used, set the reception FIFO idle detection enable bit (FCR1:FRIDE) to "1", and if performing operation in slave mode, set baud rates in BGR1/0.

9.14. FIFO Control Register 1 (FCR1)

FIFO control register 1 (FCR1) sets the FIFO test, selects the transmission and reception FIFOs, enables the transmission FIFO interrupts, and controls the interrupt flag.

Bit Configuration of FIFO Control Register 1 (FCR1)

Figure 9-17 shows the bit configuration of FIFO control register 1 (FCR1).

Figure 9-17 Bit Configuration of FIFO Control Register 1 (FCR1)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	FLSTE	FRIIE	FDRQ	FTIE	FSEL	(FCR0)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R/W	R/W	R,WX	R/W	R/W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	1	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTE: Retransmission Data Lost Detection Enable Bit

This bit enables FIFO Retransmission Data Lost Flag Bit (FCR0:FLST) detection.

- This bit is reset when the FCR1C:FLSTEC bit in the clear register is set to "1".

- This bit is set when the FCR1S:FLSTES bit in the set register is set to "1".

"0": Disable FLST bit detection.

"1": Enable FLST bit detection.

Bit	Description
0	Disable data lost detection.
1	Enable data lost detection.

Note:

- To set this bit to "1", first set the FSET bit to "1" and then set this bit to "1".

[bit11] FRIIE: Reception FIFO Idle Detection Enable Bit

When the reception FIFO contains valid data, this bit enables or disables the detection of the continuation of reception idle status for the 8-bit time or longer. If the reception interrupt is enabled (SCR:RIE = 1), detection of the reception idle status triggers a reception interrupt.

- This bit is reset when the FCR1C:FRIIEC bit in the clear register is set to "1".

- This bit is set when the FCR1S:FRIIES bit in the set register is set to "1".

"0": Disable the detection of reception idle status.

"1": Enable the detection of reception idle status.

Bit	Description
0	Disable the detection of reception FIFO idle.
1	Enable the detection of reception FIFO idle.

Note:

- To use the reception FIFO, set this bit to "1".

[bit10] FDRQ: Transmission FIFO Data Request Bit

This bit requests transmission FIFO data.

Value "1" of this bit indicates that transmission data is requested. At this time, if transmission FIFO interrupts are enabled (FTIE = 1), a transmission FIFO interrupt request is output.

ECR.TXBLKEN=0

	FTICR=0	FTICR>0
Setting FDRQ	If transmission FIFO is empty	$FTICR \geq$ the number of valid data of transmitting FIFO
Clearing FDRQ	If transmission FIFO is full	If transmitting FIFO is full.

ECR.TXBLKEN=1

	FTICR=0	FTICR>0
Setting FDRQ	If transmission FIFO is empty	$FTICR \leq$ empty data of transmitting FIFO
Clearing FDRQ	If transmission FIFO is full	$FTICR >$ empty data of transmitting FIFO

Regardless of the setting value of ECR.TXBLKEN, the FDRQ bit is cleared by writing "1" to the FCR1C.FDRQC bit.

Regardless of the setting value of ECR.TXBLKEN, the FDRQ bit is set by resetting the transmission FIFO.

Bit	Description
0	No transmission FIFO data request
1	Transmission FIFO data request issued

Notes:

- The FSEL bit cannot be changed when this bit is "0".
- Writing to this bit is invalid.
- If a transmission interrupt is generated, and the necessary data is written to the transmission FIFO, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.

[bit9] FTIE: Transmission FIFO Interrupt Enable Bit

This bit enables a transmission FIFO interrupt. If this bit is set to "1", an interrupt occurs when the FDRQ bit is "1".

- This bit is reset when the FCR1C:FTIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FTIES bit in the set register is set to "1".

Bit	Description
0	Disable transmission FIFO interrupts.
1	Enable transmission FIFO interrupts.

Note:

- Set FTIE=0 if FIFO is not used when block transfer.

[bit8] FSEL: FIFO Selection Bit

This bit selects the transmission and reception FIFO.

- This bit is reset when the FCR1C:FSELC bit in the clear register is set to "1".
 - This bit is set when the FCR1S:FSELS bit in the set register is set to "1".
- "0": Allocate as the transmission FIFO: FIFO1, and as the reception FIFO: FIFO2.
 "1": Allocate as the transmission FIFO: FIFO2, and as the reception FIFO: FIFO1.

Bit	Description
0	Transmission FIFO: FIFO1, reception FIFO: FIFO2
1	Transmission FIFO: FIFO2, reception FIFO: FIFO1

Notes:

- This bit is not cleared by a FIFO reset ($FCL2, FCL1 = 1$).
- To change this bit, first disable FIFO operation ($FCR0:FE2, FE1 = 0$).
- When $FDRQ = 0$, the changing of this bit is prohibited.
- Set this bit before setting the FIFO Byte Register(FBYTE) and the Transmission FIFO Interrupt Control Register(FTICR).
- This bit can't be accessed with the FIFO Byte Register(FBYTE) at the same time.

9.15. FIFO Control Register 0 (FCR0)

FIFO control register 0 (FCR0) enables/disables FIFO operation, resets the FIFO, saves the read pointer, and makes the retransmission setting.

Bit Configuration of FIFO Control Register 0 (FCR0)

Figure 9-18 shows the bit configuration of FIFO control register 0 (FCR0).

Figure 9-18 Bit Configuration of FIFO Control Register 0 (FCR0)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(FCR1)			Reserved	FLST	FLD	FSET	FCL2	FCL1	FE2	FE1
R/W Attribute				R0,W0	R,WX	R,W	R0,W	R0,W	R0,W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

[bit6] FLST: FIFO Retransmission Data Lost Flag Bit

This bit indicates that the retransmission data of the transmission FIFO has been lost.

FLST set condition

- Data is written in the FIFO when the FLSTE bit in FIFO control register 1 (FCR1) is "1" and the write pointer of the transmission FIFO and the read pointer saved by the FSET bit coincide.

FLST reset conditions

- The transmission FIFO reset(When FCR1:FSEL=0, set "1" to the FCR0:FCL1. When FCR1:FSEL=1, set "1" to the FCR0:FCL2.)
- Writing "1" to the FSET bit

If "1" is set in this bit, the data pointed to by the read pointer saved with the FSET bit is overwritten. For this reason, re-transmission with the FLD bit cannot be set even if an error occurs. When performing retransmission with this bit set to "1", reset the FIFO and then write the data to the FIFO again.

Bit	Description
0	Data has not been lost.
1	Data has been lost.

[bit5] FLD: FIFO Pointer Reload Bit

This bit reloads, to the read pointer, the data saved in the transmission FIFO by the FSET bit. This bit is used for retransmission in cases such as communication errors.

This bit is set to "0" when the retransmission setting has been completed.

- This bit is set when the FCR0S:FLDS bit in the set register is set to "1".

Bit	Description
0	Do not execute reload.
1	Execute reload.

Notes:

- While this bit is set to "1", reloading to the read pointer is in progress, so writing of other than a FIFO reset is prohibited.
- Setting this bit to "1" is prohibited when a FIFO is enabled or transmission is in progress.
- First set the SCR:TIE bit and the SCR:TBIE bit to "0" and then write "1" to this bit, and after the transmission FIFO is enabled, set the SCR:TIE and SCR:TBIE bits to "1".

[bit4] FSET: FIFO Pointer Saving Bit

This bit stores the read pointer of the transmission FIFO.

If the read pointer is saved before transmission starts and then a communication error occurs, retransmission is possible if the FLST bit is "0".

- This bit is set when the FCR0S:FSETS bit in the set register is set to "1".

"1": Save the current read pointer value.

"0": No effect.

Bit	Description	
	Write	Read
0	Do not save.	Always read "0".
1	Save the read pointer value.	

Note:

- Set this bit to "1" when the transmission byte count (FBYTE) is 0.

[bit3] FCL2: FIFO2 Reset Bit

This bit resets FIFO2.

If this bit is set to "1", the internal status of FIFO2 is initialized.

Only the FCR0:FLST bit is initialized and the values of other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL2S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO2.	

Notes:

- Disable transmission/reception first and then execute a FIFO2 reset.
- Execute the reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE2 register is set to 0.
- Neither TDR register nor the RDR register is initialized.

[bit2] FCL1: FIFO1 Reset Bit

This bit resets FIFO1.

If this bit is set to "1", the internal status of FIFO1 is initialized.

Only the FCR0:FLST bit is initialized and the values of other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL1S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO1.	

Notes:

- Disable transmission/reception first and then execute a FIFO1 reset.
- Execute this reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE1 register is set to 0.
- Neither TDR register nor the RDR register is initialized.

[bit1] FE2: FIFO2 Operation Enable Bit

This bit enables or disables the operation of FIFO2.

- Set this bit to "1" when using FIFO2.
- When FIFO2 is set as the transmission FIFO (FCR1:FSEL = 1), FIFO2 contains data when "1" is written to this bit, and CSIO is transmission-enabled (SCR:TXE = 1), transmission is started immediately. At this time, to set the SCR:TIE and SCR:TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the SCR:TIE and SCR:TBIE bits to "1".
- A reception error clears this bit to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. After this, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO1 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO1 as a reception FIFO, first disable reception (SCR:RXE = 0) and then change the setting of this bit when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO2 does not change the state of FIFO2.
- This bit is reset when the FCR0C:FE2C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE2S bit in the set register is set to "1".

Bits	Description
0	Disable FIFO2 operation.
1	Enable FIFO2 operation.

[bit0] FE1: FIFO1 Operation Enable Bit

This bit enables or disables the operation of FIFO1.

- Set this bit to "1" when using FIFO1.
- When FIFO1 is set as the transmission FIFO (FCR1:FSEL = 0), FIFO1 contains data when "1" is written to this bit, and CSIO is transmission-enabled (SCR:TXE = 1), transmission is started immediately. At this time, to set the SCR:TIE and SCR:TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the TIE and TBIE bits to "1".

- A reception error clears this bit to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. Subsequently, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO1 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO1 as a reception FIFO, first disable reception (SCR:RXE = 0) and then change the setting of this bit when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO1 does not change the state of FIFO1.
- This bit is reset when the FCR0C:FE1C bit in the clear register is set to "1".
- This bit is set when bit FCR0S:FE1S in the set register is set to "1".

Bit	Description
0	Disable FIFO1 operation.
1	Enable FIFO1 operation.

9.16. FIFO Byte Register (FBYTE)

The FIFO byte register (FBYTE) indicates the valid data count of the FIFO. This register also specifies whether a reception interrupt is generated when the predefined amount of data is received by the reception FIFO.

Bit Configuration of the FIFO Byte Register (FBYTE)

Figure 9-19 shows the bit configuration of the FIFO byte register (FBYTE).

Figure 9-19 Bit Configuration of FIFO Byte Register (FBYTE)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FBYTE2								FBYTE1							
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FBYTE register indicates the valid data count for the FIFO. The settings made with the FCR1:FSEL bit are listed below.

Table 9-3 Data Count Indication

FSEL	FIFO Selection	Data Count Indication
0	FIFO2: Reception FIFO, FIFO1: Transmission FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1
1	FIFO2: Transmission FIFO, FIFO1: Reception FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1

- The initial transfer count value of the FBYTE register is 0x08.
- The FBYTE for the reception FIFO contains the data count for setting the reception interrupt flag. If the transfer count that is set matches the data display of the FBYTE register, the interrupt flag (SSR:RDRF) is set to "1".
- When both of the following conditions are satisfied, the continuation of reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1".
 - The reception FIFO idle detection enable bit (FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled while there is data remaining in the reception FIFO, counting restarts.
- To receive data with the master operation (master reception), set the SCR:TIE bit and the SCR:TBIE bit to "0", set the number of reception data items in the FBYTE register of the transmission FIFO, and write "1" to the FCR1C:FDRQC bit. Later, when the SCR:TXE bit is "1", the serial clock pulses needed for the data items that have been set are output, and as many data items as set can be received. To set the SCR:TIE bit and the SCR:TBIE bit to "1", set them to "1" after FCR1:FDRQ is set to "1".
- Whenever transmission data is written to TDR, the FBYTE of the transmission FIFO is incremented by 1.
- Whenever reception data is read from RDR, the FBYTE of the reception FIFO is decremented by 1.
- During block transfer, the value of this register is the block transfer count.

[bit15:8] FBYTE2: FIFO2 Data Count Indication Bit
[bit7:0] FBYTE1: FIFO1 Data Count Indication Bit

FBYTE2, FBYTE1	Description
Write	Set the transfer count.
Read	Read valid data count.

Read (valid data count)

Transmission: Data count written to the FIFO but not yet transmitted

Reception: Data count that has been received but not read by the reception FIFO

Write (transfer count)

Transmission: Set 0x00.

Reception: Set the data count that triggers reception interrupts.

Table 9-4 Data Count Stored in FIFO

FIFO Capacity	Data Length	SSR:AWC	Maximum FBYTE Value	Number of Data Items That Can Be Stored
16 bytes	5 to 16 bits	0	8	8
		1	4	4
	20, 24, and 32 bits	1	4	
32 bytes	5 to 16 bits	0	16	16
		1	8	8
	20, 24, and 32 bits	1	8	
64 bytes	5 to 16 bits	0	32	32
		1	16	16
	20, 24, and 32 bits	1	16	

Notes:

- Set the FBYTE of the transmission FIFO to 0x00, When only transmitting data during master operation..
- When receiving data during master operation, set the number of transmission data items when the transmission FIFO is empty and the SCR:TIE and SSR:TBIE bits are both "0".
- To disable reception (SCR:RXE = 0) while receiving data during master operation, disable the transmission FIFO first and then disable transmission/reception.
- When the reception FIFO is not used, the reception block size to be assumed during block transfer is set to "1", regardless of the setting of this register.
- To change the FBYTE of the reception FIFO, first disable reception and then change the setting.
- Any setting that exceeds the FIFO capacity is prohibited.
- Set the FIFO byte register (FBYTE) after setting the FIFO selection bit (FCR1:FSEL).
- The FIFO selection bit (FCR1:FSEL) and the FIFO byte register (FBYTE) cannot be set at the same time.
- When transmitting, FBYTE shows the value of the number of writing the TDR register times minus 1. This is the reason that the data to transmit written to the TDR register is stored to the FIFO when a previous data to transmit is remained in the TDR register. When the data in the

TDR register is transmitted, the data not transmitted in the FIFO is transferred to the TDR register.

- *When receiving, FBYTE shows the value of the number of the received data in the FIFO not read from the RDR register. The data that has not received yet to the RDR register is not included.*

9.17. Transmission FIFO Interrupt Control Register (FTICR)

The transmission FIFO interrupt control register (FTICR) sets the condition for interrupts triggered by the valid data count of FIFO transmission.

Transmission FIFO Interrupt Control Register (FTICR)

Figure 9-20 shows the bit configuration of the transmission FIFO interrupt control register (FTICR).

Figure 9-20 Bit Configuration of Transmission FIFO Interrupt Control Register (FTICR)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FTICR2								FTICR1							
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The function of this bit depends on the setting of the ECR:TXBLKEN bit. The details are as follows:

- ECR:TXBLKEN = 0
The FTICR register sets the trigger level for interrupts according to the valid transmission data count (remaining amount) of the transmission FIFO.
- FCR:TXBLKEN = 1
The FTICR register sets the trigger level for interrupts according to the vacant data count of the transmission FIFO.

The table below lists the settings made by the FCR1:FSEL bit.

Table 9-5 Transmission FIFO Setting by FCR1:FSEL

FSEL	Selection of Transmission FIFO	Transmission FIFO Interrupt Control Register
0	FIFO1	FTICR1
1	FIFO2	FTICR2

- The initial valid data count for triggering interrupts of the FTICR register is 0x00.
- Set the number of data items that generate a transmission interrupt in the FTICR of the transmission FIFO.
 - For ECR:TXBLKEN = 0, if the data count that was set becomes equal to or smaller than the valid data count of the transmission FIFO (FTICR or FBYTE), the interrupt flag (FDRQ) is set to "1".
 - For ECR:TXBLKEN = 1, if the data count that was set becomes equal to or smaller than the vacant data count of the transmission FIFO, the interrupt flag (FDRQ) is set to "1". If the data count that was set in this bit is greater than the vacant data count of the transmission FIFO, the interrupt flag (FDRQ) is set to "0".
- Set FTICR so that it satisfies: $FTICR \leq \text{FIFO capacity} - 2$.
- The read value indicates the valid data count of the FIFO.
- Transmission FIFO: Data count written to the transmission FIFO that has not yet been transmitted.
- Reception FIFO: Data count received by in the reception FIFO that has not yet been read.

FTICR2: FIFO2 Data Count Indication Bit**FTICR1: FIFO1 Data Count Indication Bit**

FTICR2, FTICR1	Description
Write	Set the number of valid data items that generate an interrupt.
Read	Read valid data count.

Notes:

- Any setting that would exceed the FIFO capacity is prohibited.
- The setting value cannot be read.
- As the FIFO data count for transmission, the transmission data count that has been written, minus 1, is displayed as the valid data count. This is because any attempt to write data to the TDR register stores the data in the transmission FIFO if the TDR register contains data that has yet to be transmitted. When the data in the TDR register is transmitted, data in the transmission FIFO that has yet to be transmitted is transferred to the TDR register.
- The FIFO data count for reception represents the data count received by the reception FIFO and which has not yet been read. The data count does not include the data being received by the RDR register.
- For ECR:TXBLKEN = 0, if block transfer is performed during DMA transfer, only 1 can be set as the block size.
- To perform block transfer with ECR:TXBLKEN = 1, set the value of the block size to this register.

9.18. Extended Control Register (ECR)

The extended control register (ECR) can be used to set block transfer.

Bit Configuration of the Extended Control Register (ECR)

Figure 9-21 shows the bit configuration of the extended control register (ECR).

Figure 9-21 Bit Configuration of Extended Control Register (ECR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(ESR)			Reserve d	Reserve d	Reserve d	EISEL	REIE	TEIE	RX BLKEN	TX BLKEN
R/W Attribute				R0,W0	R0,W0	R0,W0	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved: Reserved Bits

[bit4] EISEL: Error Interrupt Request Output Selection Bit

This bit selects the output of the error interrupts from the interrupt request pin or outputs them through the error interrupt request pin. For details on interrupt output selection, see Table 2-2 and Table 2-3.

Bit	Description
0	Output a reception error interrupt request from the reception interrupt request pin. Output a transmission error interrupt request from the transmission interrupt request pin.
1	Output a reception error interrupt request from the reception error interrupt request pin. Output a transmission error interrupt request from the transmission error interrupt request pin.

[bit3] REIE: Reception Error Interrupt Enable Bit

This bit enables/disables reception error interrupt request output.

For details on the target interrupt factors, see Table 2-3.

Bit	Description
0	Disable reception error interrupts.
1	Enable reception error interrupts.

[bit2] TEIE: Transmission Error Interrupt Enable Bit

This bit enables/disables transmission error interrupt request output.

For details on the target interrupt factors, see Table 2-2.

Bit	Description
0	Disable transmission error interrupts.
1	Enable transmission error interrupts.

[bit1] RXBLKEN: Reception Block Transfer Set Bit

This bit sets reception-side DMA transfer mode.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

[bit0] TXBLKEN: Transmission Block Transfer Set Bit

This bit sets transmission-side DMA transfer mode.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

9.19. Extended Status Register (ESR)

The extended status register (ESR) checks the reception block transfer error flag and transmission block transfer error flag.

Extended Status Register (ESR)

Figure 9-22 shows the bit configuration of the extended status register (ESR).

Figure 9-22 Bit Configuration of Extended Status Register (ESR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	Reserved	RXUDR	TXOVR	RBERR	TBERR	(ECR)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R0,W0	R,WX	R,WX	R,WX	R,WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDR: Reception FIFO under Run Flag Bit

If the reception FIFO becomes empty as a result of block transfer and reading is generated, this bit is set to "1".

- This bit is reset when the ESRC:RXUDRC bit in the clear register is set to "1".
- Please refer to Table 2-3 for output of interrupt request.

Bit	Description
0	Indicate that reception FIFO under run is not occurring.
1	Indicate that reception FIFO under run is occurring.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- If reception block transfer enable (ECR:RXBLKEN) is "0", this bit is set to "0".
- This bit is set only when the reception FIFO is used.
- This bit is set to "0" when Reception FIFO is disabled.

[bit10] TXOVR: Transmission FIFO Overrun Flag Bit

If the transmission FIFO becomes full by block transfer and writing occurs, this bit is set to "1".

- This bit is reset when the ESRC:TXOVRC bit in the clear register is set to "1".
- Please refer to Table 2-2 for output of interrupt request.

Bit	Description
0	Indicate that transmission FIFO overrun is not occurring.
1	Indicate that transmission FIFO overrun is occurring.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- If transmission block transfer enable (ECR:TXBLKEN) is "0", this bit is set to "0".
- This bit is set only when the transmission FIFO is used.
- This bit is set to "0" when Transmission FIFO is disabled.

[bit9] RBERR: Reception Block Transfer Error Bit

This bit indicates that a block transfer error has occurred on the reception side.

If block transfer is performed with a value greater than the threshold set in the FBYTE register, this bit is set to "1" to indicate a block transfer error. A reception interrupt occurs if reception interrupts are enabled (SCR:RIE = 1).

- This bit is reset when the ESRC:RBERRC bit in the clear register is set to "1".
- Please refer to Table 2-3 for output of interrupt request.

Bit	Description
0	Indicate that a reception block transfer error is not occurring.
1	Indicate that a reception block transfer error is occurring.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- If reception block transfer enable (ECR:RXBLKEN) is "0", or if reception interrupt enable (SCR:RIE) is "0", this bit is set to "0".

[bit8] TBERR: Transmission Block Transfer Error Bit

This bit indicates that a block transfer error has occurred on the transmission side.

If block transfer is performed with a value greater than the threshold set in the FTICR register, this bit is set to "1" to indicate a block transfer error. At that time, a transmission interrupt occurs if transmission interrupt is enabled (SCR:TIE = 1).

- This bit is reset when the ESRC:TBERRC bit in the clear register is set to "1".
- Please refer to Table 2-2 for output of interrupt request.

Bit	Description
0	Indicate that a transmission block transfer error is not occurring.
1	Indicate that a transmission block transfer error is occurring.

Notes:

- Software reset (SCR:UPCL = 1) resets this bit to "0".
- If transmission block transfer enable (ECR:TXBLKEN) is "0", this bit is set to "0".
- When the transmission FIFO is OFF and block transfer is performed under one of the following conditions, this bit is set to "1" to indicate a block transfer error.
 - A transmission interrupt is enabled (SCR:TIE = 1) and the transmission data register contains data (SSR:TDRE = 0).
 - Transmission is in progress (SSR:TBI = 0) with transmission interrupt disabled (SCR:TIE = 0) and with transmission bus idle interrupt enabled (SCR:TBIE = 1).
 - If transmission interrupt is enabled (SCR:TIE = 1) and transmission bus idle interrupt is enabled (SCR:TBIE = 1), the condition for enabling transmission interrupt (SCR:TIE = 1) is given priority.

9.20. Transmission Block Size Register (TBSIZE)

This register sets the block size for transmission block transfer.

Bit Configuration of the Transmission Block Size Register (TBSIZE)

Figure 9-23 shows the bit configuration of the transmission block size register (TBSIZE).

Figure 9-23 Bit Configuration of Transmission Block Size Register (TBSIZE)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-										
R/W Attribute	R/W										
Protection Attribute	-										
Initial Value	0										

The TBSIZE register sets the block size of the transmission block transfer.

: [bit7:0] TBSIZE: Transmission Block Size byte

TBSIZE	Description
Write	Sets the number of transmission blocks.
Read	Read the setting value.

Notes:

- Any setting that would exceed the FIFO capacity is prohibited.
- Setting this bit to "0" is prohibited.
- Any setting that would exceed the value set in the transmission FIFO interrupt control register (FTICR) is prohibited.
- In this register, set the same value as the transmission block size set in the DMA controller.
- When the transmission FIFO is not used, the transmission block size to be assumed at block transfer is "1", regardless of the setting of this register.

9.21. Serial Auxiliary Control Status Clear Register (SACSRC)

The serial auxiliary control status clear register (SACSRC) can clear the bits in the serial auxiliary control status register (SACSR).

Note:

- For details on the operations that can be performed on this register, also see the description of the target register SACSR.

Bit Configuration of the Serial Auxiliary Control Status Clear Register (SACSRC)

Figure 9-24 shows the bit configuration of the serial auxiliary control status clear register (SACSRC).

Figure 9-24 Bit Configuration of Serial Auxiliary Control Status Clear Register (SACSRC)

Bit	15	14	13	12	11	10	9	8
Field	STSTC	Reserved	TBEENC	CSEIEC	CSEC	Reserved		TINTC
R/W Attribute	R0,W	R0,W0	R0,W	R0,W	R0,W	R0,W0		R0,W
Protection Attribute	-	-	-	-	-	-		-
Initial Value	0	0	0	0	0	00		0

Field	TINTEC	TSYNEC	TRGEC		Reserved			TMREC
R/W Attribute	R0,W	R0,W	R0,W		R0,W0			R0,W
Protection Attribute	-	-	-		-			-
Initial Value	0	0	0		0000			0

[bit15] STSTC: Clearing the Serial Test Bit

Writing "1" to this bit resets the SACSR:STST to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] Reserved: Reserved Bit

[bit13] TBEENC: Clearing the Transfer Byte Error Enable Bit

If "1" is written to this bit, SACSR:TBEEN is reset to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] CSEIEC: Clearing the Chip Select Error Interrupt Enable Bit

If "1" is written to this bit, SACSR:CSEIE is reset to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] CSEC: Clearing the Chip Select Error Flag

If "1" is written to this bit, SACSR:CSE is reset to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10:9] Reserved: Reserved Bits**[bit8] TINTC: Clearing the Timer Interrupt Flag**

Writing "1" to this bit resets SACSR:TINT to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7] TINTEC: Clearing the Timer Interrupt Enable Bit

Writing "1" to this bit resets SACSR:TINTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] TSYNEC: Clearing the Synchronous Transmission Enable Bit

Writing "1" to this bit resets SACSR:TSYNE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] TRGEC: Clearing the External Trigger Enable Bit

Writing "1" in this bit resets the SACSR:TRGE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved: Reserved Bits**[bit0] TMREC: Clearing the Serial Timer Enable Bit**

Writing "1" to this bit resets SACSR:TMRE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.22. FIFO Control Clear Register 1 (FCR1C)

FIFO control clear register 1 (FCR1C) can clear a bit in FIFO control register 1 (FCR1).

Note:

- For operations on this register, also see the description of the target register FCR1.

Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Figure 9-25 shows the bit configuration of FIFO control clear register 1 (FCR1C).

Figure 9-25 Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Bit	15	14	13	12	11	10	9	8	7	...	0

Initial Value	0	0	0	0	0	0	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTEC: Clearing the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit resets FCR1:FLSTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIEC: Clearing the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit resets FCR1:FRIIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] FDRQC: Clearing the Transmission FIFO Data Request Bit

Writing "1" to this bit resets FCR1:FDRQ to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] FTIEC: Clearing the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit resets FCR1:FTIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELC: Clearing the FIFO Selection Bit

Writing "1" to this bit resets FCR1:FSEL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.23. FIFO Control Clear Register 0 (FCR0C)

FIFO control clear register 0 (FCR0C) can clear a bit in FIFO control register 0 (FCR0).

Note:

- For details on the operations that can be performed on this register, also see the description of target register FCR0.

Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Figure 9-26 shows the bit configuration of FIFO control clear register 0 (FCR0C).

Figure 9-26 Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(FCR1C)			Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	FE2C	FE1C
R/W Attribute				R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W	R0,W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:2] Reserved: Reserved Bits

[bit1] FE2C: Clearing the FIFO2 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE2 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1C: Clearing the FIFO1 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE1 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.24. Extended Status Clear Register (ESRC)

The extended status clear register (ESRC) can clear a bit in the extended status register (ESR).

Extended Status Clear Register (ESRC)

Figure 9-27 shows the bit configuration of the extended status clear register (ESRC).

Figure 9-27 Bit Configuration of Extended Status Clear Register (ESRC)

Bit	15	14	13	12	11	10	9	8	7	...	0

R/W Attribute	R0,W0	R0,W0	R0,W0	R0,W0	R0,W	R0,W	R0,W	R0,W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDRC: Reception FIFO underrun flag clear bit

Writing "1" to this bit resets ESR:RXUDR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TXOVR: Transmission FIFO overrun flag clear bit

Writing "1" to this bit resets ESR:TXOVR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RBERRC: Reception Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:RBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TBERRC: Transmission Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:TBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.25. Serial Auxiliary Control Status Set Register (SACSR)

The serial auxiliary control status set register (SACSR) can clear a bit in the serial auxiliary control status register (SACSR).

Note:

- For operations on this register, also see the description of the target register SACSR.

Bit Configuration of Serial Auxiliary Control Status Set Register (SACSR)

Figure 9-28 shows the bit configuration of the serial auxiliary control status set register (SACSR).

Figure 9-28 Bit Configuration of Serial Auxiliary Control Status Set Register (SACSR)

Bit	15	14	13	12	11	10	9	8
Field	STSTS	Reserved	TBEENS	CSEIES	Reserved

Initial Value	0	0	0	0000			0	

[bit15] STSTS: Setting the Serial Test Bit

Writing "1" to this bit sets the SACSR:STST to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] Reserved: Reserved Bit

[bit13] TBEENS: Transfer Byte Error Enable Set Bit

Writing "1" to this bit sets SACSR:TBEEN to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] CSEIES: Chip Select Error Interrupt Enable Set Bit

Writing "1" to this bit sets SACSR:CSEIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11:8] Reserved: Reserved Bits

[bit7] TINTES: Setting the Timer Interrupt Enable Bit

Writing "1" to this bit sets SACSR:TINTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] TSYNES: Setting the Synchronous Transmission Enable Bit

Writing "1" to this bit sets SACSR:TSYNE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] TRGES: Setting the External Trigger Enable Bit

Writing "1" to this bit sets SACSR:TRGE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved: Reserved Bits

[bit0] TMRES: Setting the Serial Timer Enable Bit

Writing "1" to this bit sets SACSR:TMRE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.26. FIFO Control Set Register 1 (FCR1S)

FIFO control set register 1 (FCR1S) can set a bit in FIFO control register 1 (FCR1).

Note:

- For details on the operations that can be performed on this register, also see the description of target register FCR1.

Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Figure 9-29 shows the bit configuration of FIFO control set register 1 (FCR1S).

Figure 9-29 Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Bit	15	14	13	12	11	10	9	8	7	...	0

Initial Value	0	0	0	0	0	0	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTES: Setting the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit sets FCR1:FLSTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIES: Setting the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit sets FCR1:FRIIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] Reserved: Reserved Bit

[bit9] FTIES: Setting the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit sets FCR1:FTIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELS: Setting the FIFO Selection Bit

Writing "1" to this bit sets FCR1:FSEL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.27. FIFO Control Set Register 0 (FCR0S)

FIFO control set register 0 (FCR0S) can set a bit in FIFO control register 0 (FCR0).

Note:

- For details on the operations that can be performed on this register, also see the description of target register FCR0.

Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Figure 9-30 shows the bit configuration of FIFO control set register 0 (FCR0S).

Figure 9-30 Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Initial Value				0	0	0	0	0	0	0	0

[bit7:6] Reserved: Reserved Bits

[bit5] FLDS: Setting the FIFO Pointer Reload Bit

Writing "1" to this bit sets FCR0:FLD to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4] FSETS: Setting the FIFO Pointer Saving Bit

Writing "1" to this bit sets FCR0:FSET to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] FCL2S: Setting the FIFO2 Reset Bit

Writing "1" to this bit sets FCR0:FCL2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] FCL1S: Setting the FIFO1 Reset Bit

Writing "1" to this bit sets FCR0:FCL1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] FE2S: Setting the FIFO2 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1S: Setting the FIFO1 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

CHAPTER 38: I²C Interface (I²C Communication Control Interface)

This chapter explains the I²C function supported by operation mode 4 of the multi-function serial interface.

1. Overview of the I²C Interface (I²C Communication Control Interface)
2. I²C Interface Interrupts
3. I²C Interface Operation
4. Serial Timer Operation
5. Dedicated Baud Rate Generator
6. Block Transfer
7. I²C Communication Operation Flowchart Examples
8. I²C Interface Registers

I2C-TXXPT03P01R01L08-E1-XX

1. Overview of the I²C Interface (I²C Communication Control Interface)

The I²C interface (I²C communication control interface) supports the I²C bus and operates as a master/slave device on the I²C bus. Also, this interface has transmission and reception FIFOs (64 bytes each).

I²C Interface (I²C Communication Control Interface) Functions

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> For serial clock and data input, noise from 2 to 38 bus clocks is filtered out.
3	Transfer mode	<ul style="list-style-type: none"> Synchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter).
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Interrupt request	<ul style="list-style-type: none"> Reception interrupt Transmission interrupt Status interrupt (INT interrupt, stop condition interrupt, repeated start detection interrupt, and serial timer interrupt) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, reception FIFO under run) Reception FIFO interrupt (reception FIFO under run) DMA transfer is supported for both transmission and reception.
8	I ² C	<ul style="list-style-type: none"> Master/slave transmission and reception function Arbitration function Clock synchronization function Transfer direction detection function Function to generate and detect the repeated start condition Bus error detection function General call addressing function 7-bit addressing as master and slave An interrupt can be generated upon transfer and bus error occurrence. 10-bit addressing function can be supported by program. Standard-mode and Fast-mode are supported. Fast-mode Plus, High-speed mode, and Ultra Fast-mode are not supported.
9	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
10	FIFO	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

2. I²C Interface Interrupts

The following factors may generate an interrupt request for an I²C interface interrupt:

- After the 1st byte is transmitted and received / After data is transmitted and received
- Stop condition
- Repeated start condition
- FIFO transmission data request
- FIFO reception data completion
- When the serial timer comparison value (STMCR) matches the serial timer value (STMR)

I²C Interface Interrupts

Table 2-1 lists the interrupt control bits and interrupt factors of the I²C interface.

Table 2-1 Interrupt Control Bits and Interrupt Factors of the I²C Interface

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
Status	INT	IBCR	After 1st byte is transmitted and received*1 (except when master is operating with SSR:DMA= 1)	IBCR:INTE	Writing "1" to interrupt flag clear bit (IBCR:INTC)
			After data is transmitted and received*1 (where SSR:DMA= 0)		
			Bus error (EIBCR:BEC= 0)		
			Arbitration lost detected		
			Reserved address detected		
			NACK received		
			Reception FIFO full during slave reception operation (where SSR:DMA= 0)		Writing "1" to IBCRC:INTC, after reception data is read until reception FIFO is empty
	SPC	IBSR	Stop condition	IBCR:CNDE	Writing "1" to interrupt flag clear bit IBSRC:SPCC
	RSC		Repeated start detected		Writing "1" to interrupt flag clear bit IBSRC:RSCC
	TINT	SACSR	When serial timer register (STMR) matches serial timer comparison register (STMCR)	SACSR:TINTE	Writing "1" to timer interrupt flag clear bit (SACSRC:TINTC)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Interrupt Request Flag Clearing
Reception	RDRF	SSR	Reserved address received	SMR:RIE	Reading reception data (RDR)
			After receiving data		Reading reception data until reception FIFO is empty
			Receiving as much data as FBYTE setting value		
			Reception idle detected when FRIIE= 1		
	ORE	SSR	Overflow error	SMR:RIE ECR:REIE	Writing "1" to reception error flag bit (SSR:REC)
Transmission	RXUDR	ESR	Reception FIFO under run	ECR:REIE	- Writing "1" to reception FIFO under run flag clear bit (ESRC:RXUDRC) - Disable reception FIFO 1)When FCR1:FSEL=0, FCR0:FE2=0 2)When FCR1:FSEL=1, FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to reception block transfer error clear bit (ESRC:RBERRC) - Disable Block transfer mode (ECR:RXBLKEN=0)
	TDRE	SSR	Transmission register is empty	SMR:TIE	Writing to transmission data register (TDR), or writing "1" to transmission FIFO operation enable bit (retransmission) when bit is "0" and transmission FIFO has valid data*2
			Writing "1" to transmission buffer empty flag set bit (SSR:TSET)		
	FDRQ	FCR1	Transmission FIFO stores data count equal to or less than FTICR setting value or is empty	FCR1:FTIE	Writing "1" to FIFO transmission data request clear bit (FCR1C:FDRQC), or transmission FIFO is full
Transmission	TBI (SSR:DMA=1)	SSR	No transmission operation	SSR:TBIE	Writing to transmission data register (TDR), or writing "1" to transmission FIFO operation enable bit (retransmission) when bit is "0" and transmission FIFO has valid data*3
			Writing "1" to transmission buffer empty flag set bit (SSR:TSET)		
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	- Writing "1" to transmission FIFO overrun flag clear bit (ESRC:TXOVRRC) - Disable transmission FIFO 1)When FCR1:FSEL=0, FCR0:FE1=0 2)When FCR1:FSEL=1, FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	- Writing "1" to transmission block transfer error clear bit (ESRC:TBERRC) - Disable Block transfer mode (ECR:TXBLKEN=0)

*1: If normal data can be transmitted and received and SSR:TDRE is "0", no interrupt is generated. The purpose is to support DMA transfer.

If you want to generate an IBCR:INT flag when transmitting and receiving data, the SSR:TDRE bit must be "1" before the time that the IBCR:INT flag is set.

*2 After the SSR:TDRE bit becomes "0", set the SMR:TIE bit to "1".

*3 After the SSR:TBI bit becomes "0", set the SSR:TBIE bit to "1".

Switching of Error Interrupt Request Output

The error interrupt request output method varies depending on the setting of the error interrupt request output switch bit (ECR:EISEL), the transmission/reception error interrupt enable bit (ECR:REIE, TEIE), or the transmission/reception interrupt enable bit (SMR:RIE, TIE, SSR:TBIE, FCR1:FTIE).

Table 2-2 Transmission Interrupt Request Output Methods

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Transmission interrupt request output	SMR:TIE	Transmission data empty (SSR:TDRE)
		SSR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)
	Transmission error interrupt request output	-	No interrupt factor
1	Transmission interrupt request output	SMR:TIE	Transmission data empty (SSR:TDRE)
		SSR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
	Transmission error interrupt request output	ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)

Table 2-3 Reception Interrupt Request Output Methods

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Reception interrupt request output	SMR:RIE	Reception FIFO full (SSR:RDRF) Overrun error (SSR:ORE)
		ECR:REIE	Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)
	Reception error interrupt request output	-	No interrupt factor
1	Reception interrupt request output	SMR:RIE	Reception FIFO full (SSR:RDRF)
	Reception error interrupt request output	ECR:REIE	Overrun error (SSR:ORE) Reception FIFO under run (ESR:RXUDR) Reception block transfer error (ESR:RBERR)

2.1. Timer Interrupt Generation and Flag Set Timing

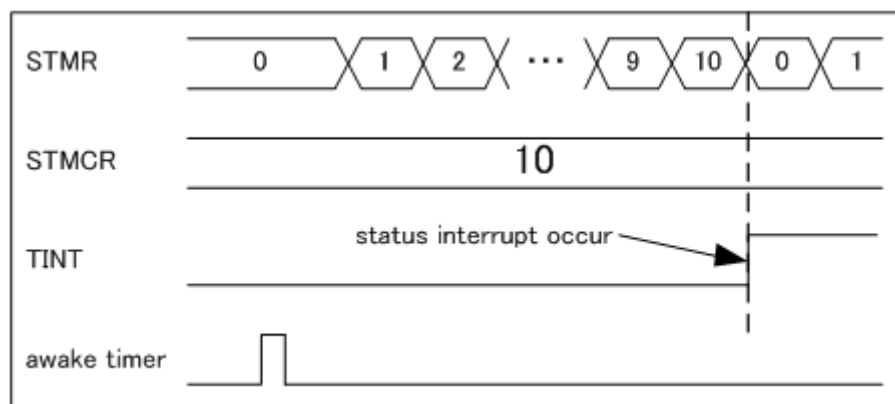

A timer interrupt is generated when the serial timer register (STMR) and the serial timer comparison register (STMCR) match.

Timer Interrupt Generation and Flag Set Timing

- The timer interrupt flag (SACSR:TINT) is set to "1" when the serial timer register (STMR) matches the serial timer comparison register.

If timer interrupts are enabled (SACSR:TINTE= 1) at this time, a status interrupt is generated.

Figure 2-1 Timer Interrupt Generation Timing

3. I²C Interface Operation

The I²C interface communicates using two bidirectional bus lines: a serial data line (SDA) and a serial clock line (SCL).

I²C Bus Start Condition

The following figure shows the start condition of the I²C bus.

Figure 3-1 Start Condition

I²C Bus Stop Condition

The following figure shows the stop condition of the I²C bus.

Figure 3-2 Stop Condition

I²C Bus Repeated Start Condition

The following figure shows the repeated start condition of the I²C bus.

Figure 3-3 Repeated Start Condition

3.1. Master Mode

In master mode, the clock is output to the I²C bus upon the occurrence of the start condition for the I²C bus. Master mode is selected and the ACT bit in the IBCR register is set to "1" when the I²C bus is in the idle state (SCL="H" and SDA="H") and the MSS bit in the IBCR register is set to "1".

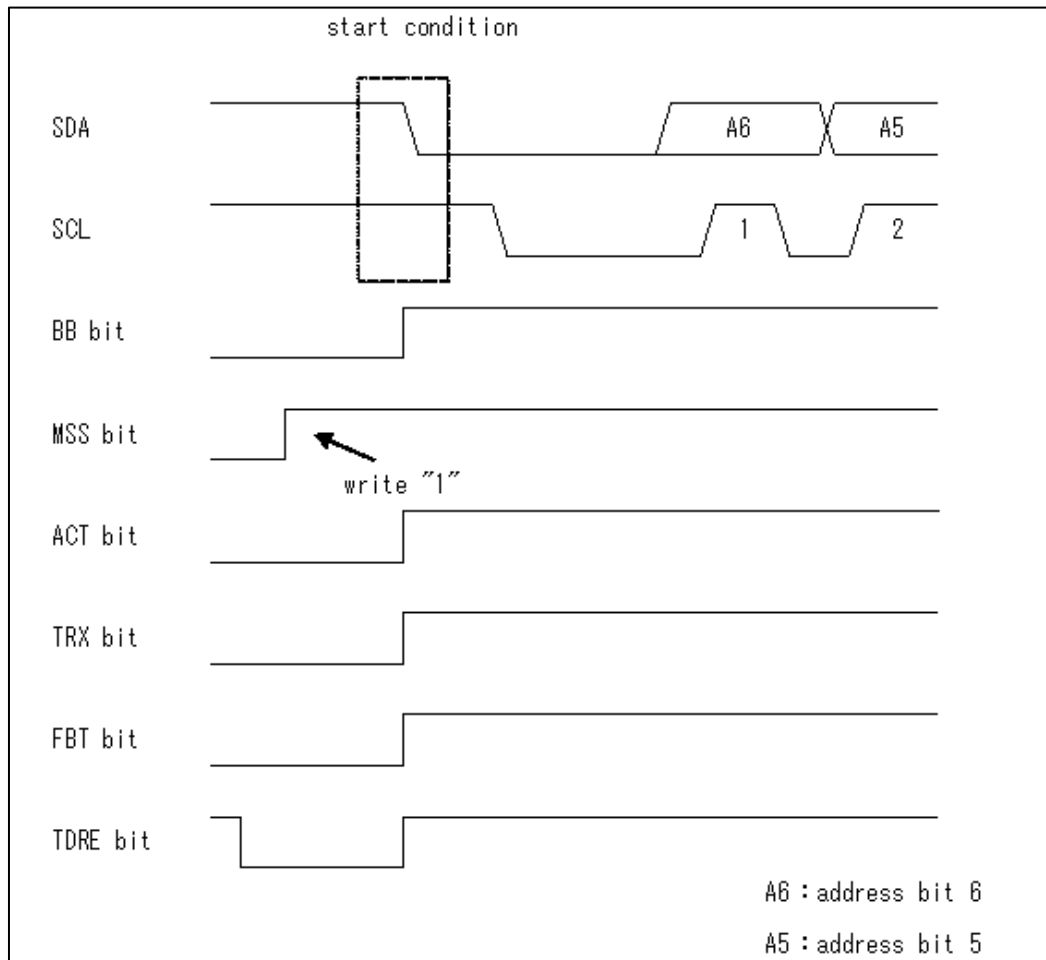

Start Condition Occurrence

The start condition is output under the following condition.

- "1" is written to the IBCR:MSS bit when SDA="H", SCL="H", ISMK:EN=1, and IBSR:BB=0.

The IBCR:ACT bit is set to "1" when the start condition is output to the I²C bus. Then, the IBSR:BB bit is set to "1" when the start condition is received, indicating that communication with the I²C bus is in progress (see Figure 3-4).

Figure 3-4 Relationship between Start Condition Output and Individual Bits

Note:

- In operation mode 4 (I²C mode), use the bus clock at 8 MHz or more. A baud rate generator setting exceeding 400 kbps is prohibited in this mode.

Slave Address Output

After the start condition is output, the set data in the TDR register is output as the address, beginning with bit7. If FIFO is enabled, the data written first in the TDR register is output. bit0 is used as a data direction bit (R/W). When the data direction bit (R/W) is "0", the data indicates the write direction (from master to slave). Set the address in the TDR register before writing IBCR:MSS= 1 or IBCR:SCC= 1.

Figure 3-5 and Figure 3-6 show the output timing of the address and data direction.

Figure 3-5 Address and Data Direction (When FIFO Is Disabled)

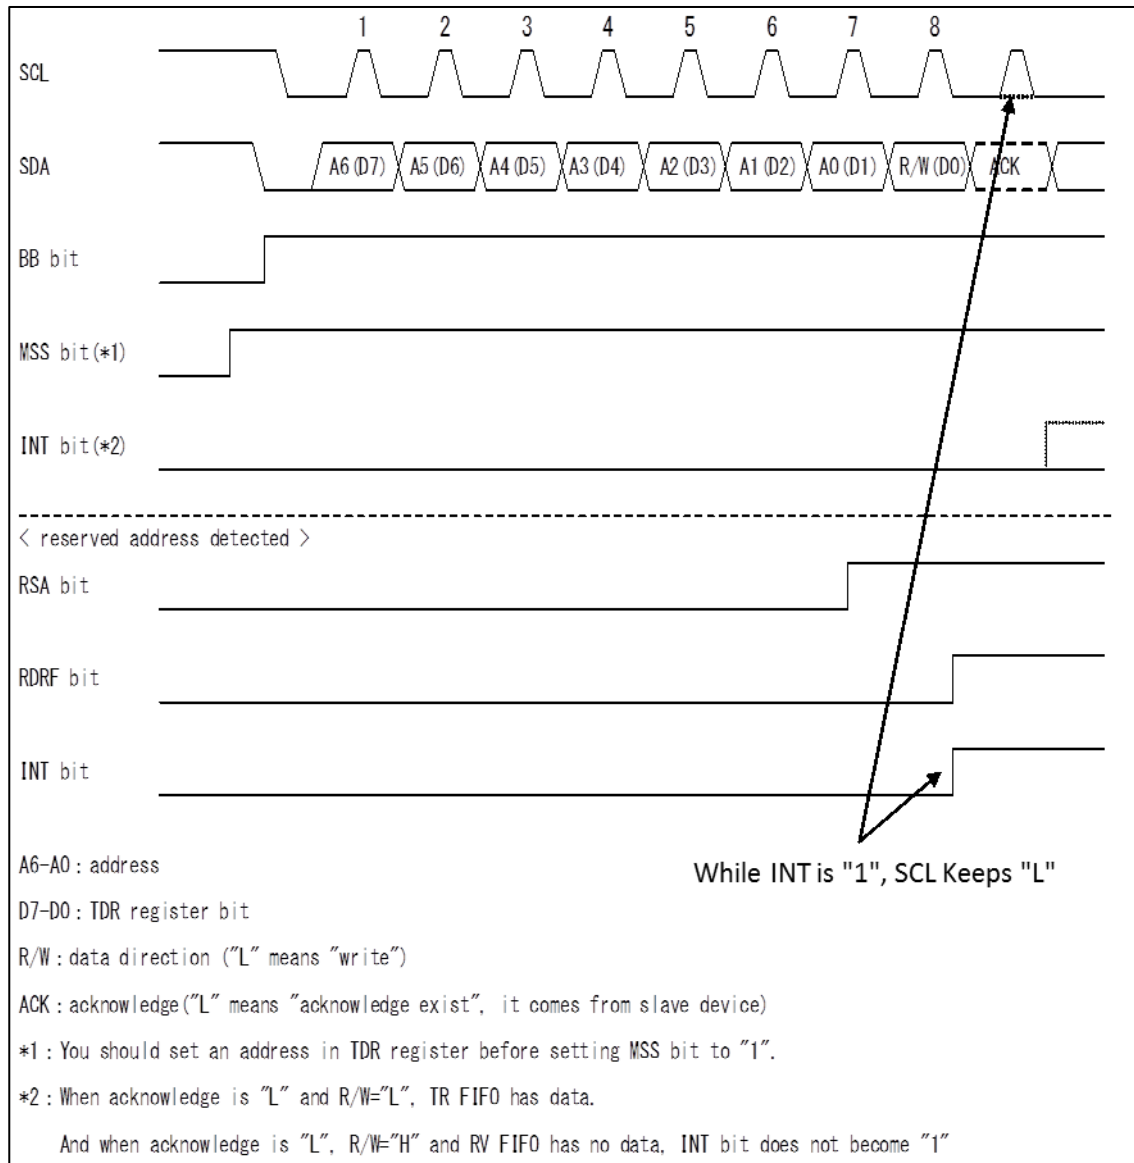

Figure 3-6 Address and Data Direction (When the Transmission and Reception FIFOs Are Enabled)

Acknowledgment Reception by Transmission of the 1st Byte

After the data direction bit (R/W) is output, the I²C interface receives an acknowledgment from the slave.

The following tables describe the operations when FIFO is enabled or disabled.

Table 3-1 Operations after Acknowledgment Reception When DMA Mode Is Disabled
 (IBSR:RSA Bit = 0 and SSR:DMA Bit = 0)

Transmission FIFO	Reception FIFO	Transmission FIFO State	Reception FIFO State	Data Direction Bit (R/W)	Operation Immediately after Acknowledgment Reception	
					Acknowledgment Is ACK	Acknowledgment Is NACK
Disabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
				1		
Disabled	Enabled	-	Without data	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
			-	1	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	
Enabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
				1	If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	
Enabled	Enabled	-	Without data	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
			-	1	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	

Table 3-2 Operations after Acknowledgment Reception When DMA Mode Is Enabled
(IBSR:RSA Bit = 0 and SSR:DMA Bit = 1)

Transmission FIFO	Reception FIFO	Transmission FIFO State	Reception FIFO State	Data Direction Bit (R/W)	Operation Immediately after Acknowledgment Reception	
					Acknowledgment Is ACK	Acknowledgment Is NACK
Disabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
				1		
Disabled	Enabled	-	Without data	0	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
			-	1	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	
Enabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
				1		

Transmission FIFO	Reception FIFO	Transmission FIFO State	Reception FIFO State	Data Direction Bit (R/W)	Operation Immediately after Acknowledgment Reception	
					Acknowledgment Is ACK	Acknowledgment Is NACK
Enabled	Enabled	-	Without data	0	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
Enabled	Enabled	-		1	If the SSR:TDRE bit is "1", the SSR:TBI bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the SSR:TBI bit remains "0", and no wait is performed.	The IBCR:INT bit is set to "1", and a wait is performed.

When DMA Mode is Disabled (SSR:DMA = 0)

FIFO disabled (transmission and reception FIFOs both disabled)

- If the IBSR:RSA bit is "0" and if the SSR:TDRE bit is "1" after acknowledgment reception, the interrupt flag (IBCR:INT) is set to "1", the SCL remains "L", and a wait is performed. For the wait, the interrupt flag is set to "0" and the wait is released by writing "1" to the interrupt flag clear bit (IBCR:INTC). If the SSR:TDRE bit is "0" and ACK is received, a clock is generated on the SCL without setting the interrupt flag to "1".
- If the IBSR:RSA bit is "1", the interrupt flag (IBCR:INT) is set to "1" after the reserved address is received (before acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set and "1" is written to the interrupt flag clear bit (IBCR:INTC). This sets the interrupt flag to "0" and releases the wait.
- The received acknowledgment is set in the IBSR:RACK bit. The IBSR:RACK bit is verified during the wait. If the acknowledgment is NACK, "0" is written to the IBCR:MSS bit to generate the stop condition, or "1" is written to the IBCR:SCC bit to generate the repeated start condition. At this time, the IBCR:INT bit is automatically cleared to "0".

FIFO enabled

- The following settings are required for the FIFOs before the IBCR:MSS bit is set to "1".
 - To transmit to a slave (data direction bit = 0), set the data including the slave address for the transmission FIFO.
 - To receive data from a slave (data direction bit = 1), set the number of bytes to be received in the FIFO byte count register. Also, write to the transmission data register by using the slave address, the data direction bit, and as many dummies as the desired quantity of data to be received.
- If the IBSR:RSA bit is "0" and the received acknowledgment is ACK, the interrupt flag (IBCR:INT) is not set to "1", and data is transmitted and received according to the data direction bit (without a wait). If the acknowledgment is NACK, the interrupt flag (IBCR:INT) is set to "1", the SCL remains "L", and a wait is performed.
- The IBSR:RACK bit stores the received acknowledgment. The IBSR:RACK bit is verified during the wait. If the acknowledgment is NACK, "0" is written to the IBCR:MSS bit to generate the stop condition, or "1" is written to the IBCR:SCC bit to generate the repeated start condition. At this time, the IBCR:INT bit is automatically cleared to "0".

When DMA Mode is Enabled (SSR:DMA = 1)

FIFO disabled (transmission and reception FIFOs both disabled)

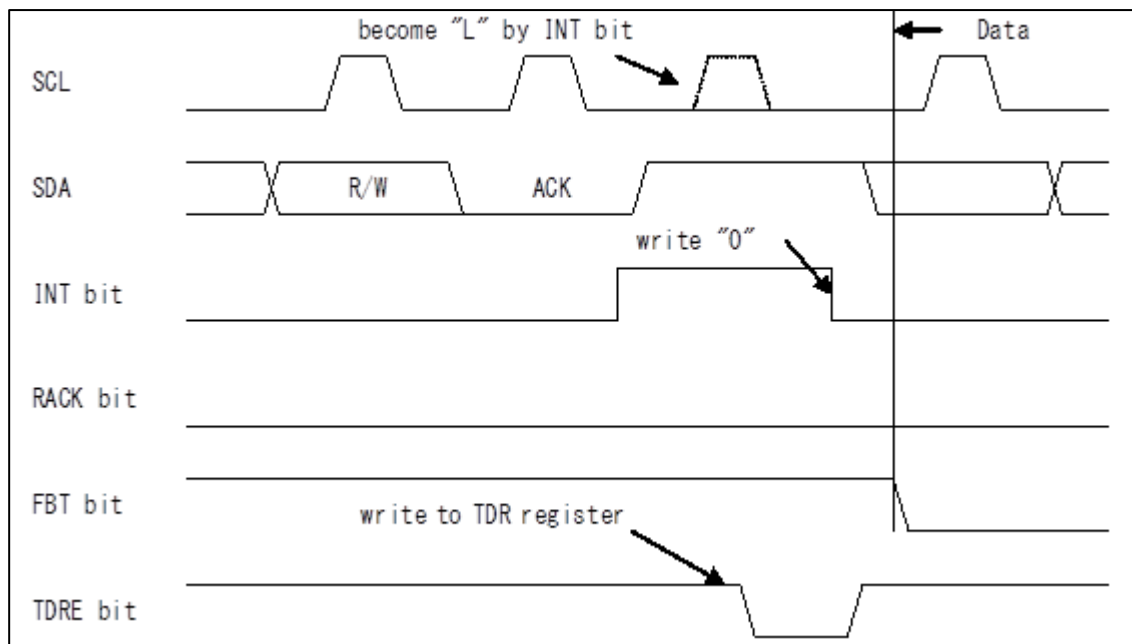

- If the IBSR:RSA bit is "0" and if the SSR:TDRE bit is "1" after an acknowledgment is received, the transmission bus idle flag (SSR:TBI) is set to "1", the SCL remains "L", and a wait is performed. The transmission bus idle flag is set to "0", which releases the wait, when the data to be transmitted is written to the TDR register. If the SSR:TDRE bit is "0" and ACK is received, a clock is generated on the SCL without setting the transmission bus idle flag (SSR:TBI) to "1".
- If the IBSR:RSA bit is "1", the interrupt flag (IBCR:INT) is set to "1" after the reserved address is received (before an acknowledgment), the SCL remains "L", and a wait is performed. After the RDR register is read, the IBCR:ACKE bit and transmission data are set, the writing "1" to the IBCR:INTC sets the interrupt flag to "0", which releases the wait.
- The received acknowledgment is set in the IBSR:RACK bit. The IBSR:RACK bit is verified during the wait. If the acknowledgment is NACK, "0" is written to the IBCR:MSS bit to generate the stop condition, or "1" is written to the IBCR:SCC bit to generate the repeated start condition. At this time, the IBCR:INT bit is automatically cleared to "0".

FIFO enabled

- The following settings are required for the FIFOs before the IBCR:MSS bit is set to "1".
 - To transmit to a slave (data direction bit = 0), set the data including the slave address for the transmission FIFO.
 - To receive data from a slave (data direction bit = 1), set the number of bytes to be received in the FIFO byte count register. Also, write to the transmission data register by using the slave address, the data direction bit, and as many dummies as the desired quantity of data to be received.
- If the IBSR:RSA bit is "0" and the received acknowledgment is ACK, the interrupt flag (IBCR:INT) is not set to "1", and data is transmitted and received according to the data direction bit (without a wait). If the acknowledgment is NACK, the interrupt flag (IBCR:INT) is set to "1", the SCL remains "L", and a wait is performed.
- The IBSR:RACK bit stores the received acknowledgment. The IBSR:RACK bit is verified during the wait. If the acknowledgment is NACK, "0" is written to the IBCR:MSS bit to generate the stop condition,

or "1" is written to the IBCR:SCC bit to generate the repeated start condition. At this time, the IBCR:INT bit is automatically cleared to "0".

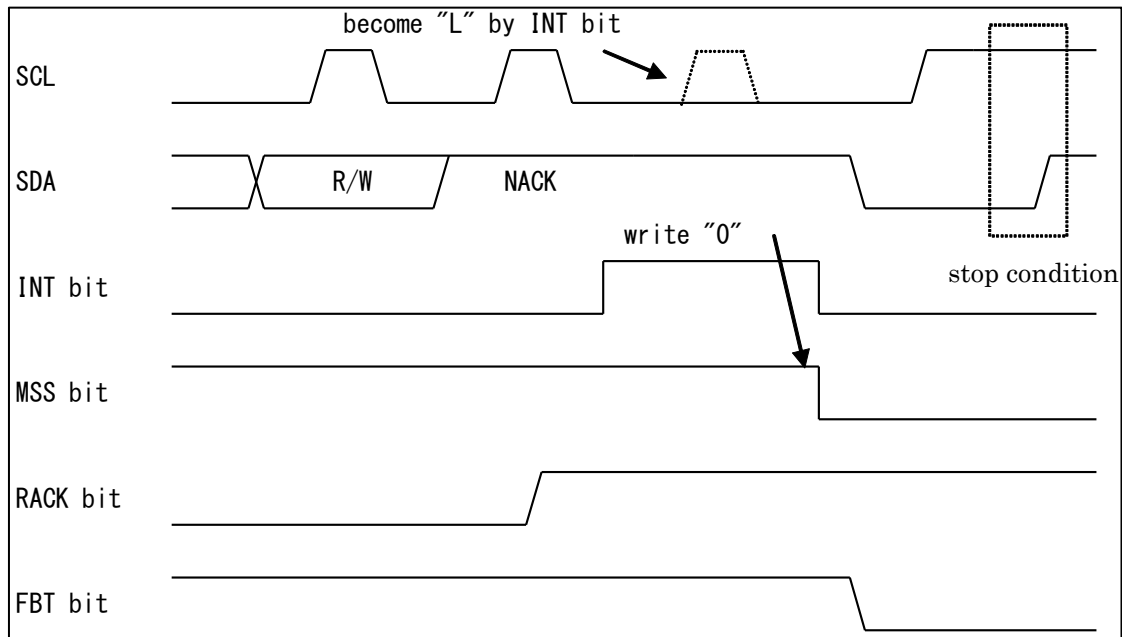

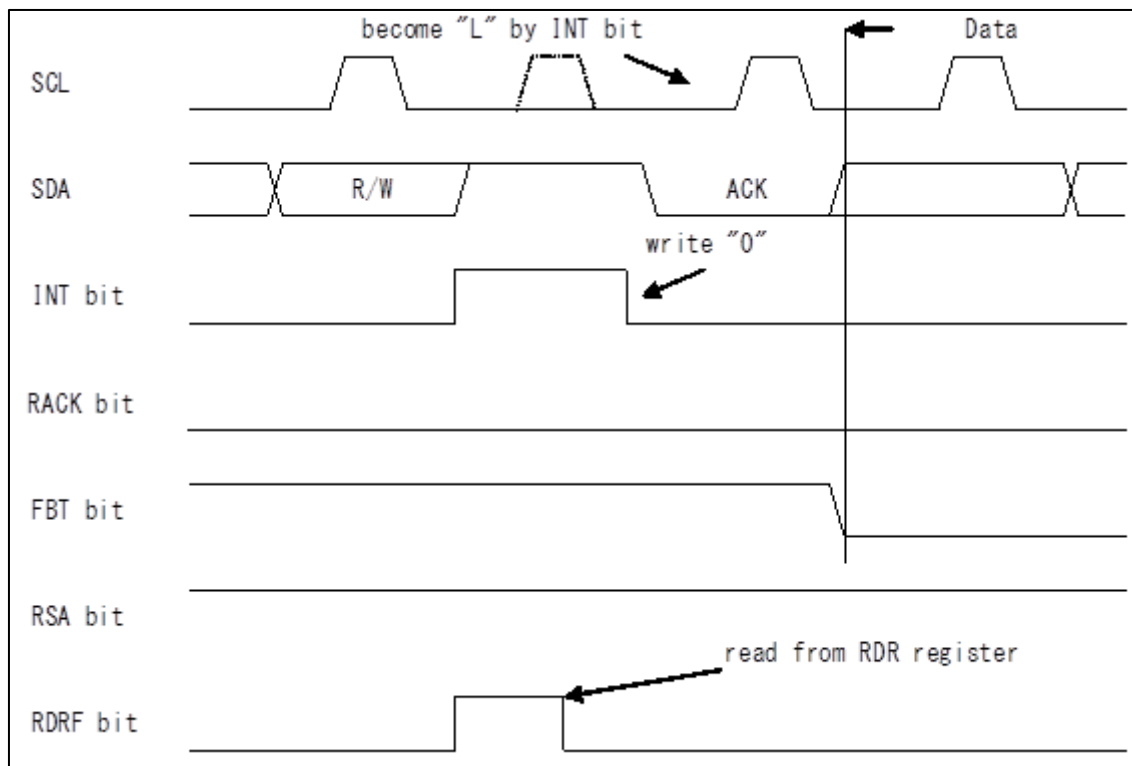

Figure 3-7 Acknowledgment (with FIFO Disabled, IBSR:RSA= 0, DMA= 0, and an ACK Response)

The wait for an address is as follows:

- Wait after acknowledgment reception if the IBSR:RSA bit is "0"
- Wait before acknowledgment reception if the IBSR:RSA bit is "1"

It does not depend on the IBCR:WSEL setting.

Figure 3-8 Acknowledgment (with FIFO Disabled, IBSR:RSA= 0, and a NACK Response)**Figure 3-9 Acknowledgment (with FIFO Disabled, IBSR:RSA= 1, and an ACK Response)**

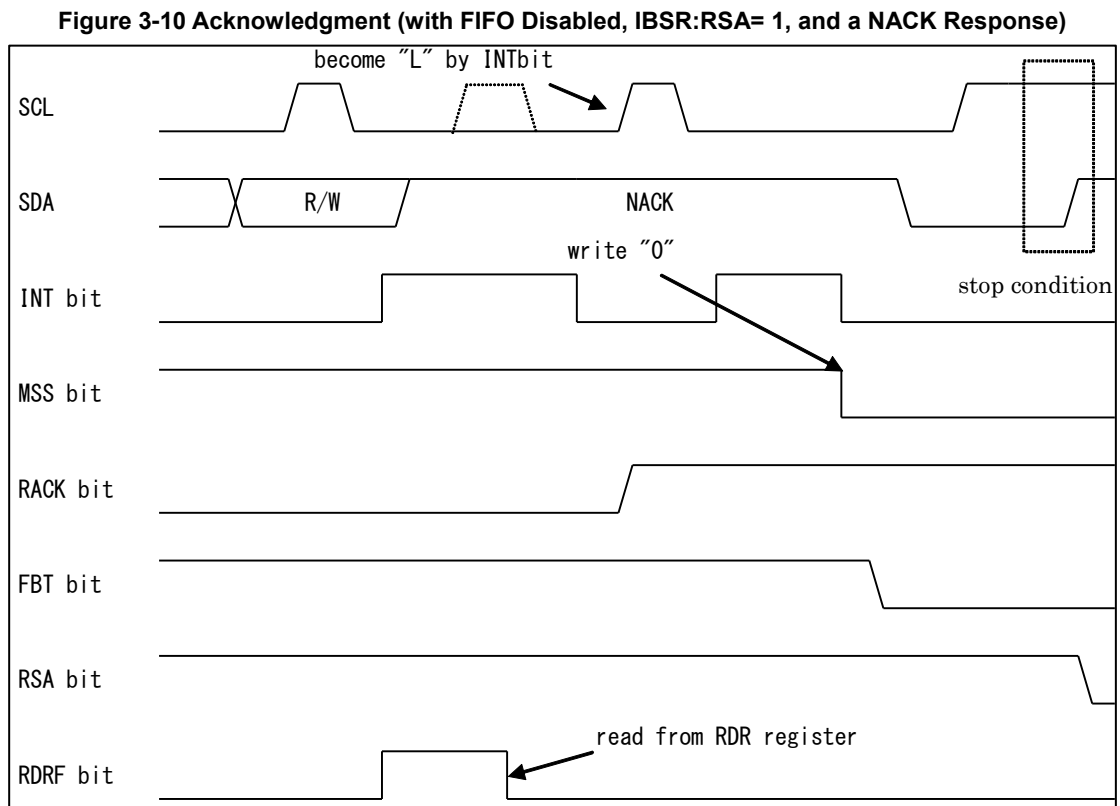

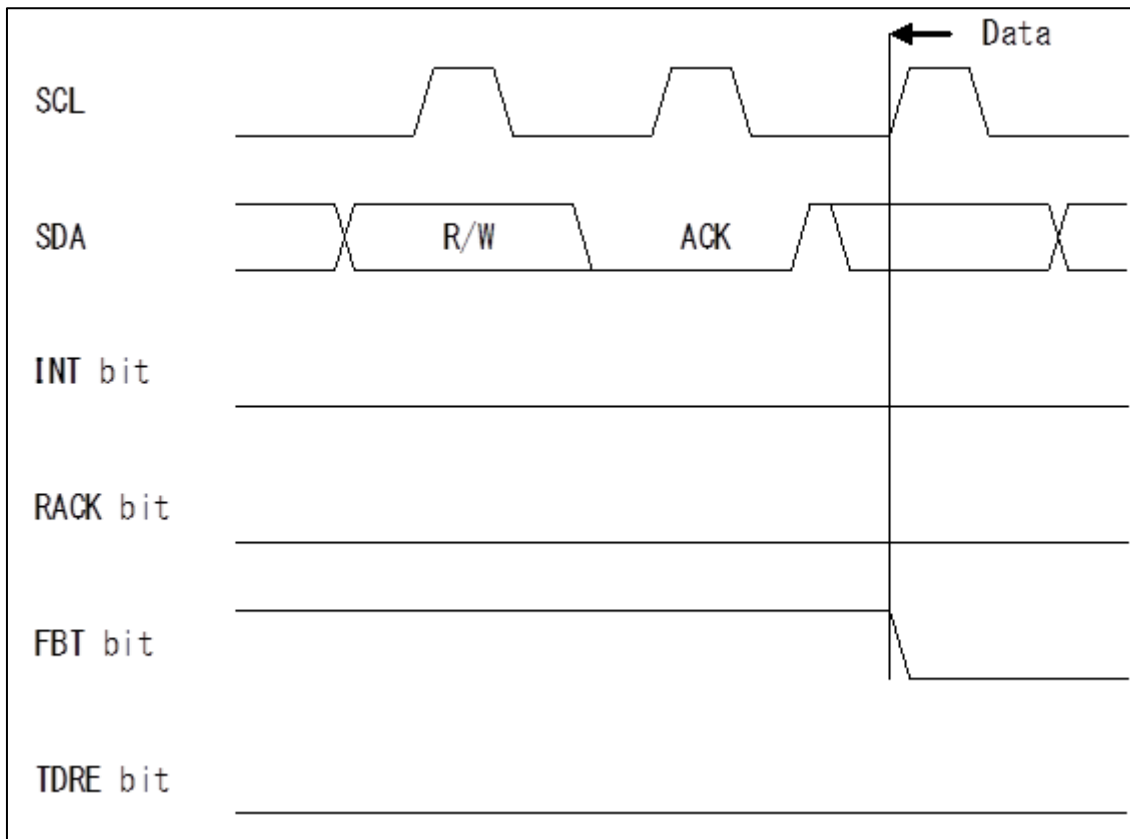

Figure 3-11 Acknowledgment (with FIFO Enabled, the Transmission FIFO with Data, the Reception FIFO without Data, IBSR:RSA= 0, and an ACK Response)

Data Transmission by the Master

If the data direction bit (R/W) is "0", data is transmitted from the master. The slave responds with ACK or NACK each time that 1 byte is transmitted.

The following tables describe the location where a wait is generated, which varies depending on the setting of the IBCR:WSEL bit.

Table 3-3 IBCR:WSEL Bit for Master Data Transmission When DMA Mode Is Disabled (SSR:DMA= 0)

WSEL Bit	Operation
0	<p><FIFO not used></p> <p>At the 2nd or subsequent byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL is set to "L" after an acknowledgment when the SSR:TDRE bit is "1" or arbitration lost is detected. Then, the wait state is entered.</p>

However, in the following case, the interrupt flag (IBCR:INT) is set after an acknowledgment, regardless of the IBCR:WSEL setting.

- NACK is received at a time other than when the stop condition is set (IBCR:MSS= 0 and ACT= 1).

The following procedures are examples showing how to transmit data to a slave.

Data Transmission to a Slave When DMA Mode is Disabled (SSR:DMA= 0)

1. Transmission to a non-reserved address

- When the transmission FIFO is disabled
 - Set the slave address (including the data direction bit) in the TDR register, and write "1" to the IBCR:MSS bit.
 - Transmit the slave address, and then receive ACK. The interrupt flag (IBCR:INT) is set to "1".
 - Write the data to be transmitted, to the TDR register.
 - To update the IBCR:WSEL bit, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus.

5. After the transmission of 1 byte, set the interrupt flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission. Repeat steps 3. to 5. until the predefined quantity of data has been transmitted. However, suppose NACK is received after the release of the wait when IBCR:WSEL= 1. In that case, after an acknowledgment is received, an interrupt is generated once again to wait for the bus.
 6. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.
- When the transmission FIFO is enabled
1. Write the slave address (including the data direction bit) and transmission data to the TDR register.
 2. Set the IBCR:WSEL bit, and write "1" to the IBCR:MSS bit.
 3. If NACK is received during transmission, set the interrupt flag (IBCR:INT) to "1" immediately after the reception, and wait for the I²C bus. If all received responses are ACK, set the interrupt flag to "1" after the last byte is transmitted according to the IBCR:WSEL setting, and wait for the I²C bus.
 4. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.
2. Transmission to the reserved address
- When the transmission FIFO is disabled
1. Set the reserved address as the slave address in the TDR register, and write "1" to the IBCR:MSS bit.
 2. Transmit the slave address. Then, the interrupt flag (IBCR:INT) is set to "1".
 3. Read the RDR register, and verify the reserved address. (*1)
 4. Write the data to be transmitted, to the TDR register.
 5. To update the IBCR:WSEL bit, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus.
 6. After the transmission of 1 byte, set the interrupt flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission. Repeat steps 4. to 6. until the predefined quantity of data has been transmitted. However, suppose NACK is received after the release of the wait when IBCR:WSEL= 1. In that case, after an acknowledgment is received, an interrupt is generated once again to wait for the bus.
 7. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.
- When the transmission FIFO is enabled
1. Set the reserved address as the slave address in the TDR register, and write "1" to the IBCR:MSS bit.
 2. Transmit the slave address. Then, the interrupt flag (IBCR:INT) is set to "1".
 3. Read the RDR register, and verify the reserved address. (*1)
 4. Write all transmission data to the TDR register (until the transmission FIFO is as full as possible).
 5. If NACK is received during the transmission, set the interrupt flag (IBCR:INT) to "1" immediately after the reception, and wait for the I²C bus.
If all received responses are ACK, set the interrupt flag to "1" after the last byte is transmitted according to the IBCR:WSEL setting, and wait for the I²C bus.
 6. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.

*1 If either of the following conditions is satisfied, the IBCR:ACK bit and the IBCR:WSEL bit must both be set to "1". Verification that the device operates as the master or a slave for the next data is also necessary.

- In a multi-master configuration, the reserved address is a general call address.
- The device is likely operating as a slave due to arbitration lost.

Data Transmission to a Slave When DMA Mode is Enabled (SSR:DMA=1)

1. Transmission to a non-reserved address

■ When the transmission FIFO is disabled

1. Set the slave address (including the data direction bit) in the TDR register, and write "1" to the IBCR:MSS bit.
2. Transmit the slave address, and then receive ACK. The transmission bus idle flag (SSR:TBI) is set to "1".
3. Write the data to be transmitted, to the TDR register to release the wait for the I²C bus.
4. After the transmission of 1 byte, set the transmission bus idle flag (SSR:TBI) to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission.
5. Write the data to be transmitted, to the TDR register to release the wait for the I²C bus.
6. After the transmission of 1 byte, set the transmission bus idle flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission. Repeat steps 5. to 6. until the predefined quantity of data has been transmitted. However, suppose NACK is received after the release of the wait when IBCR:WSEL= 1. In that case, after an acknowledgment is received, the interrupt flag (IBCR:INT) is set to "1" to wait for the bus.
7. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1"*2 to generate the repeated start condition.

■ When the transmission FIFO is enabled

1. Write the slave address (including the data direction bit) and transmission data to the TDR register.
2. Set the IBCR:WSEL bit, and write "1" to the IBCR:MSS bit.
3. If NACK is received during the transmission, set the interrupt flag (IBCR:INT) to "1" immediately after the reception, and wait for the I²C bus. If all received responses are ACK, set the transmission bus idle flag (SSR:TBI) to "1" after the last byte is transmitted according to the IBCR:WSEL setting, and wait for the I²C bus.
4. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1"*2 to generate the repeated start condition.

2. Transmission to the reserved address

■ When the transmission FIFO is disabled

1. Set the reserved address as the slave address in the TDR register, and write "1" to the IBCR:MSS bit.
2. Transmit the slave address. Then, the interrupt flag (IBCR:INT) is set to "1".
3. Read the RDR register, and verify the reserved address. (*1)
4. Write the data to be transmitted, to the TDR register.

5. To update the IBCR:WSEL bit, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus.
6. After the transmission of 1 byte, set the transmission bus idle flag (SSR:TBI) to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission.
7. Write the data to be transmitted, to the TDR register to release the wait for the I²C bus.
8. After the transmission of 1 byte, set the transmission bus idle flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL= 0, set it after receiving an acknowledgment. If IBCR:WSEL= 1, set it immediately after the 1-byte transmission. Repeat steps 7. to 8. until the predefined quantity of data has been transmitted. However, suppose NACK is received after the release of the wait when IBCR:WSEL= 1. In that case, after an acknowledgment is received, the interrupt flag (IBCR:INT) is set to "1" to wait for the bus.
9. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1"*2 to generate the repeated start condition.

■ When the transmission FIFO is enabled

1. Set the reserved address as the slave address in the TDR register, and write "1" to the IBCR:MSS bit.
2. Transmit the slave address. Then, the interrupt flag (IBCR:INT) is set to "1".
3. Read the RDR register, and verify the reserved address. (*1)
4. Write all transmission data to the TDR register (until the transmission FIFO is as full as possible).
5. If NACK is received during the transmission, set the interrupt flag (IBCR:INT) to "1" immediately after the reception, and wait for the I²C bus. If all received responses are ACK, set the transmission bus idle flag (SSR:TBI) to "1" after the last byte is transmitted according to the IBCR:WSEL setting, and wait for the I²C bus.
6. Set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1"*2 to generate the repeated start condition.

*1 If either of the following conditions is satisfied, the IBCR:ACK bit and the IBCR:WSEL bit must both be set to "1". Verification that the device operates as the master or a slave for the next data is also necessary.

- In a multi-master configuration, the reserved address is a general call address.
- The device is likely operating as a slave due to arbitration lost.

*2 To issue the repeated start condition when DMA mode is enabled (SSR:DMA= 1), the SSR:TBI bit is "1", and the IBCR:INT bit is "0", perform the following procedure.

1. Write "1" to the IBCR:INT bit.
2. Verify that the IBCR:INT bit is set to "1".
3. Write the slave address to the TDR.
4. Set the IBCR:SCC bit to "1".

Notes:

- Specifying a 7-bit slave address in master mode is prohibited when 7-bit slave address detection is enabled (ISBA:SAEN= 1).
- To change the IBCR register during transmission and reception, do so when the interrupt flag (IBCR:INT) is "1".

- If the IBCR:WSEL bit is changed, it is used as a generation condition for the interrupt flag (IBCR:INT) of the next data and the transmission bus idle flag (SSR:TBI) when DMA mode is enabled (SSR:DMA= 1).
- If transmission data is written to the TDR when an ACK response is detected and SSR:TDRE is "1" during data transmission, operation is as follows.
 - When DMA mode is disabled (SSR:DMA= 0), the interrupt flag (IBCR:INT) is not set to "1", and the written data is transmitted.
 - When DMA mode is enabled (SSR:DMA= 1), the transmission bus idle flag (SSR:TBI) is not set to "1", and the written data is transmitted.
- If transmission data is written to the TDR and an ACK response is returned when SSR:TDRE is "1" while data is being received, operation is as follows.
 - When DMA mode is disabled (SSR:DMA= 0), the interrupt flag (IBCR:INT) is not set to "1" and only SSR:RDRF is set to "1". (If the reception FIFO is enabled, this is done when as much data as set by the FBYTE register is received.)
 - When DMA mode is enabled (SSR:DMA= 1), the transmission bus idle flag (SSR:TBI) is not set to "1" and only SSR:RDRF is set to "1". (If the reception FIFO is enabled, this is done when as much data as set by the FBYTE register is received.)

Data Reception by the Master

When DMA Mode is Disabled (SSR:DMA= 0)

If the data direction bit (R/W) is "1", the master receives data from a slave.

If FIFO is disabled, the master operates as follows.

- If the SSR:TDRE bit is "1", a wait is generated each time that 1 byte is received (IBCR:INT = 1 and SSR:RDRF = 1). At this time, the master returns an ACK or NACK response based on the setting of the ACKE bit in the IBCR register as follows. If the IBCR:WSEL bit is "0", it does so before the wait. If the IBCR:WSEL bit is "1", it does so after the wait.
- If the SSR:TDRE bit is "0", the master receives the next data with a response based on the setting of the ACKE bit in the IBCR register. If the response is ACK, no wait is generated (IBCR:INT = 0). If the response is NACK, a wait is generated (IBCR:INT = 1).

If FIFO is enabled, the SSR:RDRF bit is set to "1" when the master receives the same number of bytes as the reception byte count setting. The interrupt flag is set to "1" when the SSR:TDRE bit is "1", to wait for the I²C bus. At this time, the acknowledgment operates as follows. Note that even if NACK is output, data is stored as reception data in the reception FIFO.

- If IBCR:WSEL = 0, the master returns a NACK response based on the setting of the ACKE bit, when the SSR:TDRE bit is set to "1".
- If IBCR:WSEL = 1, the interrupt flag is set to "1" after the last byte is received, generating a wait. The IBCR:ACKE bit is set and the interrupt flag is cleared to "0" during the wait. Then, the master returns an ACK or NACK response based on the IBCR:ACKE setting.

For details on the wait due to an interrupt, see the following table.

Table 3-5 IBCR:WSEL Bit for Master Data Reception When DMA Mode Is Disabled (SSR:DMA= 0)

WSEL Bit	Operation
0	At the 2nd or subsequent byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL is set to "L" after an acknowledgment when the SSR:TDRE bit is "1". Then, the wait state is entered.
1	At the 2nd or subsequent byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL is set to "L" after the master receives 1-byte data when the SSR:TDRE bit is "1". Then, the wait state is entered.

The following procedures are examples showing how to receive data from a slave.

- When the reception FIFO is disabled
 1. Set the slave address (including the data direction bit) in the TDR register, and write "1" to the IBCR:MSS bit.
 2. Transmit the slave address, and then receive ACK. The interrupt flag (IBCR:INT) is set to "1".
 3. To update the IBCR:WSEL bit, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus.
 4. After receiving 1 byte, set the interrupt flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL = 0, set it after transmitting an acknowledgment. If IBCR:WSEL = 1, set it immediately after the reception of 1 byte. Repeat steps 3. to 4. until the predefined quantity of data has been received.
 5. After receiving the last data, output NACK. Then, set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.

- When the transmission and reception FIFOs are enabled
 1. Set the number of bytes to be received in the FBYTE register.
 2. Write the following to the TDR register: the slave address (including the data direction bit) and as much dummy data as the quantity to be received.
 3. Write "1" to the IBCR:MSS bit.
 4. While the SSR:TDRE bit is "0", return an ACK response and continue to receive data. During reception, if the received data reaches the set count in FBYTE, set SSR:RDRF to "1". Read the RDR register when SSR:RDRF is set to "1".
 5. When the SSR:TDRE bit is set to "1", set the interrupt flag to "1" as follows to wait for the I²C bus. If IBCR:WSEL = 0, set it after NACK output. If IBCR:WSEL = 1, set it immediately after the reception of 1 byte.
 6. If IBCR:WSEL = 1, set the IBCR:ACE bit to "0". If IBCR:WSEL = 0, this IBCR:ACE bit setting is not necessary, but either set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC bit to "1" to generate the repeated start condition.

When DMA Mode is Enabled (SSR:DMA= 1)

If the data direction bit (R/W) is "1", the master receives data from a slave.

If FIFO is disabled, the master operates as follows.

- If the SSR:TDRE bit is "1", a wait is generated each time that 1 byte is received (SSR:TBI= 1 and SSR:RDRF= 1). At this time, the master returns an ACK or NACK response based on the setting of the ACE bit in the IBCR register as follows. If the IBCR:WSEL bit is "0", it does so before the wait. If the IBCR:WSEL bit is "1", it does so after the wait.
- If the SSR:TDRE bit is "0", a wait is generated each time that 1 byte is received (SSR:RDRF = 1). At this time, the master returns an ACK or NACK response based on the setting of the ACE bit in the IBCR register as follows. If the IBCR:WSEL bit is "1", it does so before the wait. If the IBCR:WSEL bit is "0", it does so after the wait.

If FIFO is enabled, the SSR:RDRF bit is set when the master receives the same number of bytes as the reception byte count setting. When the SSR:TDRE bit is "1", the transmission bus idle flag (SSR:TBI) is set to "1" to wait for the I²C bus. At this time, the acknowledgment operates as follows. Note that even if NACK is output, data is stored as reception data in the reception FIFO.

- If IBCR:WSEL = 0, the master returns a NACK response based on the setting of the ACE bit, when the SSR:TDRE bit is set to "1".
- If IBCR:WSEL = 1, a wait is generated (SSR:TBI = 1) after the last byte is received. During the wait, the IBCR:ACE bit is set, and the transmission bus idle flag (SSR:TBI) is cleared. Then, the master returns an ACK or NACK response based on the IBCR:ACE setting.

For details on the wait due to an interrupt, see the following table.

Table 3-6 IBCR:WSEL Bit for Master Data Reception When DMA Mode Is Enabled (SSR:DMA= 1)

WSEL Bit	Operation
0	<p>At the 2nd or subsequent byte, the transmission bus idle flag (SSR:TBI) is set to "1" and the SCL is set to "L" after an acknowledgment when the SSR:TDRE bit is "1". Then, a wait state is entered.</p> <p>At the 2nd or subsequent byte, if "1" is set for the reception data full flag (SSR:RDRF) after an acknowledgment when the reception FIFO is not used, the SCL is set to "L". Then, the wait state is entered.</p>
1	<p>At the 2nd or subsequent byte, the interrupt flag (SSR:TBI) is set to "1" and the SCL is set to "L" after the master receives 1-byte data when the SSR:TDRE bit is "1". Then, the wait state is entered.</p> <p>At the 2nd or subsequent byte, after data is received when the reception data full flag (SSR:RDRF) is set to "1" and the reception FIFO is not used, the SCL is set to "L". Then, the wait state is entered.</p>

The following procedures are examples showing how to receive data from a slave.

■ When the reception FIFO is disabled

1. Set the slave address (including the data direction bit) in the TDR register, and write "1" to the IBCR:MSS bit.
2. Transmit the slave address, and then receive ACK. The transmission bus idle flag (SSR:TBI) is set to "1".
3. Write the data to be transmitted, to the TDR register to release the wait for the I²C bus.
4. After receiving 1 byte, set the transmission bus idle flag (SSR:TBI) and the reception data full flag (SSR:RDRF)*2 to "1" under the following conditions to wait for the I²C bus:
 - After acknowledgment transmission if IBCR:WSEL = 0
 - Immediately after reception of 1 byte if IBCR:WSEL = 1
5. Update the IBCR:WSEL bit, and read the RDR register. Then, write dummy data to the TDR register, and release the wait.
6. After receiving 1 byte, set the transmission bus idle flag (SSR:TBI) and the reception data full flag (SSR:RDRF)*2 to "1" under the following conditions to wait for the I²C bus:
 - After acknowledgment transmission if IBCR:WSEL = 0
 - Immediately after reception of 1 byte if IBCR:WSEL = 1
 Repeat steps 5. to 6. until the predefined quantity of data has been received.
7. After receiving the last data, output NACK. Then, set the IBCR:MSS bit to "0" generate the stop condition, or set the IBCR:SCC*1 bit to "1" to generate the repeated start condition.

■ When the transmission and reception FIFOs are enabled

1. Set the number of bytes to be received in the FBYTE register.
2. Write the following to the TDR register: the slave address (including the data direction bit) and as much dummy data as the quantity to be received.
3. If IBCR:WSEL= 0, set NACK with the ACKE bit setting, and write "1" to the IBCR:MSS bit.
4. While the SSR:TDRE bit is "0", return an ACK response and continue to receive data. During reception, if the received data reaches the set count in FBYTE, set SSR:RDRF to "1". Read the RDR register when SSR:RDRF is set to "1".
5. If IBCR:WSEL = 0 when the SSR:TDRE bit is set to "1", set the interrupt flag to "1" after NACK output, and wait for the I²C bus. If IBCR:WSEL = 1, set the transmission bus idle flag (SSR:TBI) to "1" immediately after receiving 1 byte, and wait for the I²C bus.

6. If IBCR:WSEL = 1, set the IBCR:ACE bit to "0". If IBCR:WSEL = 0, this IBCR:ACE bit setting is not necessary, but either set the IBCR:MSS bit to "0" to generate the stop condition, or set the IBCR:SCC*1 bit to "1" to generate the repeated start condition.

*1 To issue the repeated start condition when DMA mode is enabled (SSR:DMA= 1), the SSR:TBI bit is "1", and the IBCR:INT bit is "0", perform the following procedure.

1. Write "1" to the IBCR:INT bit.
2. Verify that the IBCR:INT bit is set to "1".
3. Write the slave address to the TDR.
4. Set the IBCR:SCC bit to "1".

*2 Regardless of the IBCR:WSEL setting, the reception data full flag (SSR:RDRF) is set to "1" immediately after the reception of 1 byte. For the 2nd or subsequent byte, there is the following wait for the I²C bus when the reception data full flag (SSR:RDRF) is set to "1". If IBCR:WSEL = 0, the wait is performed after the transmission of an acknowledgment. If IBCR:WSEL = 1, the wait is performed immediately after the reception of 1 byte.

Notes:

- Specifying a 7-bit slave address in master mode is prohibited when 7-bit slave address detection is enabled (ISBA:SAEN = 1).
- When SSR:TDRE is "0", an acknowledgment is output according to the setting of the IBCR:ACE bit, and the next processing is performed even if an overrun error occurs.
- To change the IBCR register during transmission and reception, do so when the interrupt flag (IBCR:INT) is "1" or when the transmission bus idle flag is "1" (SSR:TBI = 1) and DMA mode is enabled (SSR:DMA = 1).
- During master reception with DMA mode disabled (SSR:DMA = 0), the SSR:TDRE bit may be "0" at the time that the interrupt flag (IBCR:INT) is set to "1" after dummy data is written to the TDR register. If so, the interrupt flag (IBCR:INT) remains "0", and the next data is received.
- During master reception with DMA mode enabled (SSR:DMA = 1), the SSR:TDRE bit may be "0" at the time that the transmission bus idle flag (SSR:TBI) is set to "1" after dummy data is written to the TDR register. If so, the transmission bus idle flag (SSR:TBI) remains "0", and the next data is received.
- If data is received while the reception FIFO is enabled and IBCR:WSEL is "0", the SSR:RDRF bit is set to "1" after the last bit is received. Then, after ACK transmission, the interrupt flag (IBCR:INT) is set to "1".

Figure 3-37 Master Reception Interrupts 8 When FIFO Is Enabled (SSR:DMA= 1, IBCR:WSEL= 1, and IBSR:RSA= 0)

Arbitration Lost

Arbitration lost is determined as a case where data from one master conflicts with data from another master and the received data differs from the transmitted data. At this time, the IBCR:MSS bit is set to "0" and the IBSR:AL bit to "1", enabling the master to operate in slave mode.

The IBSR:AL bit can be cleared to "0" under the following conditions.

- "1" is written to the IBCR:MSS bit.
- "0" is written to the IBCR:INT bit.
- "1" is written to the IBSRC:SPCC bit when the IBSR:AL bit is "1" and the IBSR:SPC bit is "1".
- I²C interface operation is disabled (ISMK:EN bit = 0).

If arbitration lost occurs, the interrupt flag (IBCR:INT) is set to "1" according to the IBCR:WSEL setting, and the SCL of the I²C bus is set to "L".

Wait for Master Mode

If both of the following conditions are satisfied, a wait for master mode is performed while the IBSR:BB bit is "1", and the start condition is transmitted when the IBSR:BB bit is set to "0".

- The IBCR:MSS bit is set to "1" when the IBSR:BB bit is "1".
- The device does not operate in slave mode.

To determine whether a wait for master mode is in progress, check the IBCR:MSS and IBCR:ACT bits (the wait state if IBCR:MSS = 1 and IBCR:ACT = 0). If the device operates in slave mode after the IBCR:MSS bit is set to "1", set the IBSR:AL bit to "1", the IBCR:MSS bit to "0", and the IBCR:ACT bit to "1".

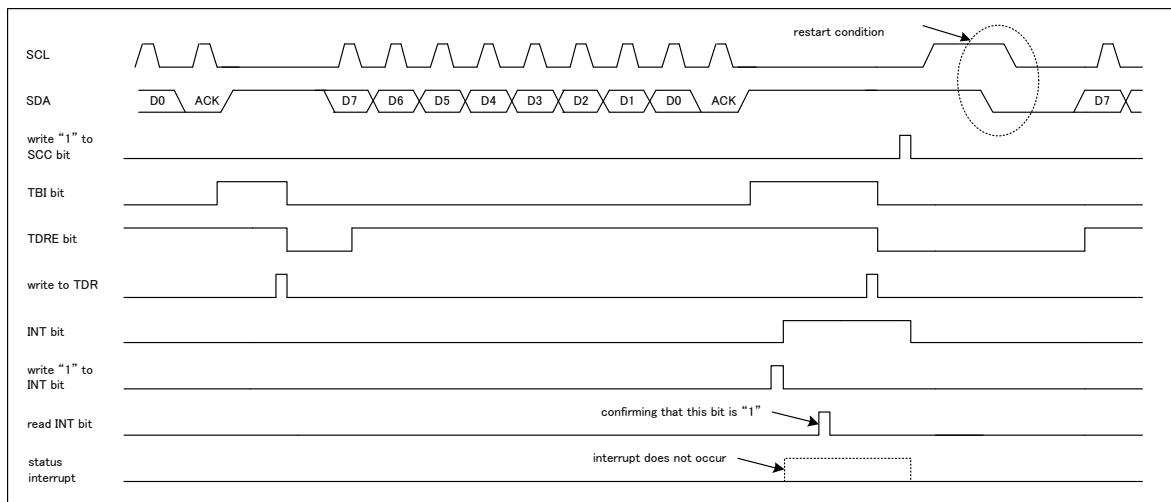

Issuing the Repeated Start Condition When DMA Mode is Enabled (SSM:DMA=1)

If a slave address is written to the TDR register when the transmission bus is idle (SSR:TBI = 1) and the interrupt flag (IBCR:INT) is "0", the transmission operation begins, and the repeated start condition cannot be issued.

Therefore, to issue the repeated start condition when the transmission bus is idle (SSR:TBI = 1) and the interrupt flag (IBCR:INT) is "0", perform the following procedure.

1. Write "1" to the IBCR:INT bit. No status interrupt is generated at this time.
2. Verify that the IBCR:INT bit is set to "1".
3. Write the slave address to the TDR.
4. Issue the repeated start (IBCR:SCC = 1).

Figure 3-38 Issuing the Repeated Start Condition When DMA Mode Is Enabled (SSR:DMA= 1, IBCR:WSEL= 0, IBSR:RSA= 0, and ACK Response)

3.2. Slave Mode

Operation is in slave mode after the start condition or the repeated start condition is detected and an ACK response is returned when the combination of the ISBA register and the ISMK register matches the received address.

Notes:

- When $EIBCR:BE C=0$, if 2nd start condition is detected after 1st start condition is detected (during transfer of bit2 to bit9), a bus error is detected ($IBCR:BER=1$) and reception is stopped.
- In this case, after the interrupt flag ($IBCR:INT$) is cleared, retransmission of the start condition from the master is necessary.

Slave Address Match Detection

The 1st receiving data after the start condition or the repeated start condition is detected contains 7-bit slave address and the bit that shows the direction of the data transmission. The ISMK register is set the value that masks the slave address of the ISBA register. The bit value "0" means "don't care", and "1" means that it needs that the bit value of address corresponds with the data of received slave address. That is, the bit whose the value is set to "0" in the ISMK register is not compared to the bit of the address.

When SAEN is set to "1", it enables the slave address detection.

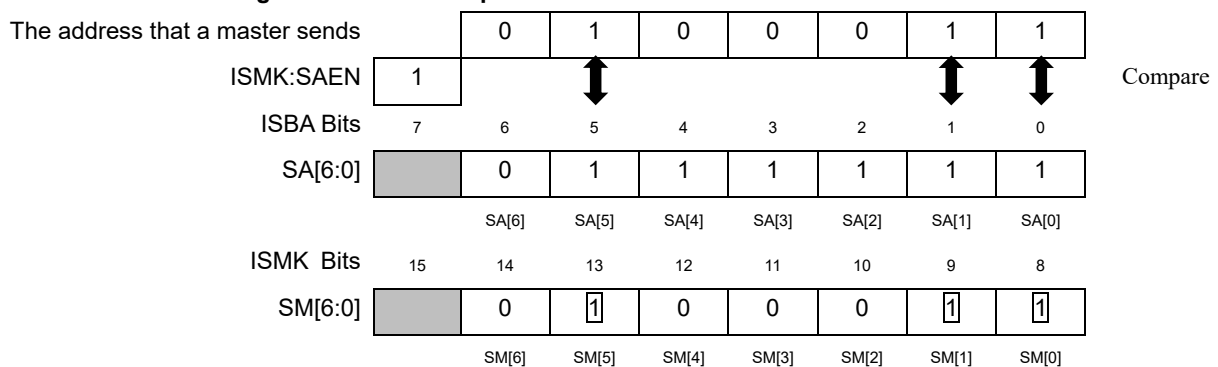

The data as the address sent by a master is compared with some slave address bits(SA[6:0]) that mask bits(SM[6:0]) corresponded to is set to "1".

If they match, ACK is output. If not, ACK is not output.

Example of the address detection

For example, a master send the slave address 0x23.

Figure 3-39 The example of the slave address detection

Just SA5, SA1, SA0 are compared the data as the address sent by the master. Because SM[6], SM[4:2] are set to "0", those bits are "don't care". As a result, the Multi-function serial interface outputs the ACK response.

Table 3-7 Operations Immediately after Acknowledgment Output for a Slave Address

Transmission FIFO	Reception FIFO	Transmission FIFO State	Reception FIFO State	Data Direction Bit (R/W)	Operation Immediately after Acknowledgment	
					Acknowledgment Is ACK	Acknowledgment Is NACK
Disabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed.	The IBCR:INT bit remains "0", and no wait is performed.
				1	If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	
Disabled	Enabled	-	Without data	0	The IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit remains "0", and no wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
			-	1	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	

Transmission FIFO	Reception FIFO	Transmission FIFO State	Reception FIFO State	Data Direction Bit (R/W)	Operation Immediately after Acknowledgment	
					Acknowledgment Is ACK	Acknowledgment Is NACK
Enabled	Disabled	-	-	0	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit remains "0", and no wait is performed.
				1		
Enabled	Enabled	-	Without data	0	The IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit remains "0", and no wait is performed.
			With data		The IBCR:INT bit is set to "1", and a wait is performed.	
Enabled	Enabled	-	-	1	If the SSR:TDRE bit is "1", the IBCR:INT bit is set to "1", and a wait is performed. If the SSR:TDRE bit is "0", the IBCR:INT bit remains "0", and no wait is performed.	The IBCR:INT bit remains "0", and no wait is performed.

■ Reserved address detection

If the 1st byte matches the reserved address (0b0000xxxx or 0b1111xxxx), the IBCR:INT bit is set to "1" after the 8th bit of data is received, regardless of whether the transmission and reception FIFOs are enabled, to wait for the I²C bus. After reading the reception data at this time, set the following.

- If you want the device to operate as a slave, set IBCR:ACKE to "1", and check the data direction bit (IBSR:TRX). If the bit indicates the transmission direction, write transmission data to the TDR, and clear the IBCR:INT bit. Then, the device operates as a slave.
- If you do not want the device to operate as a slave, set IBCR:ACKE to "0", and clear the IBCR:INT bit. After acknowledgment output, the device does not operate as a slave.

Data Direction Bit

After receiving an address, the interface receives the data direction bit that determines whether data is transmitted or received. When this bit is "0", it indicates transmission from the master, and the slave receives the data.

Reception by a Slave

A matching slave address and "0" in the data direction bit together indicate reception in slave mode. The following procedures are examples for reception in slave mode.

When DMA Mode is Disabled (SSR:DMA = 0)

- When the reception FIFO is disabled
 1. After ACK transmission, set the interrupt flag (IBCR:INT) to "1" to wait for the I²C bus. An interrupt due to a slave address match is determined from the IBCR:MSS, IBCR:ACT, and IBSR:FBT bits. Write "1" to the IBCR:ACE bit and "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus. (See Table 3-7.)
 2. After transmitting 1-byte data, set the interrupt flag (IBCR:INT) to "1" according to the IBCR:WSEL setting to wait for the I²C bus.
 3. Read the received data from the RDR register, and set the IBCR:ACE bit. After that, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus.
 4. Repeat steps 2. to 3. until the stop condition or the repeated start condition is detected.
- When the reception FIFO is enabled
 1. When NACK is detected or the reception FIFO is full, the interrupt flag (IBCR:INT) is set to "1" to wait for the I²C bus. If the stop condition or the repeated start condition is detected, the IBSR:SPC bit or the IBSR:RSC bit is set to "1", and the interrupt flag (IBCR:INT) is not set to "1" (no wait for the I²C bus). The reception FIFO sets the SSR:RDRF bit to "1" when the received data count matches the FBYTE register setting value. If the SMR:RIE bit is "1" at this time, a reception interrupt is generated.
 1. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0".

When DMA Mode is Enabled (SSR:DMA=1)

- When the reception FIFO is disabled
 1. After ACK transmission, set the interrupt flag (IBCR:INT) to "1" to wait for the I²C bus. An interrupt due to a slave address match is determined from the IBCR:MSS, IBCR:ACT, and IBSR:FBT bits. Write "1" to the IBCR:ACE bit and "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus. (See Table 3-7.)
 2. After receiving 1-byte data or immediately after receiving 1 byte, set the reception data full flag (SSR:RDRF) to "1". There is the following wait for the I²C bus when the reception data full flag (SSR:RDRF) is set to "1". If IBCR:WSEL = 0, the wait is performed after the transmission of an acknowledgment. If IBCR:WSEL = 1, the wait is performed immediately after the reception of 1 byte.
 3. After setting the IBCR:ACE bit, read the received data from the RDR register. Then, clear the reception data full flag (SSR:RDRF) to "0" to release the wait for the I²C bus.
 4. Repeat steps 2. to 3. until the stop condition or the repeated start condition is detected.

■ When the reception FIFO is enabled

1. The detection of NACK sets the interrupt flag (IBCR:INT) to "1" to wait for the I²C bus. Also, when the reception FIFO is full, wait for the I²C bus. If the stop condition or the repeated start condition is detected, the IBSR:SPC bit or the IBSR:RSC bit is set to "1", and the interrupt flag (IBCR:INT) is not set to "1" (no wait for the I²C bus). The reception FIFO sets the SSR:RDRF bit to "1" when the received data count matches the FBYTE register setting value. If the SMR:RIE bit is "1" at this time, a reception interrupt is generated.
2. If the interrupt flag (IBCR:INT) was set to "1", read the received data from the RDR register. After reading all the data, write "1" to the interrupt flag clear bit (IBCR:INTC) to release the wait for the I²C bus. If the reception FIFO is full, read the received data from the RDR register at least once to release the wait for the I²C bus. If the stop condition or the repeated start condition was detected, read all the received data from the RDR register, and clear the IBSR:SPC bit or the IBSR:RSC bit to "0".

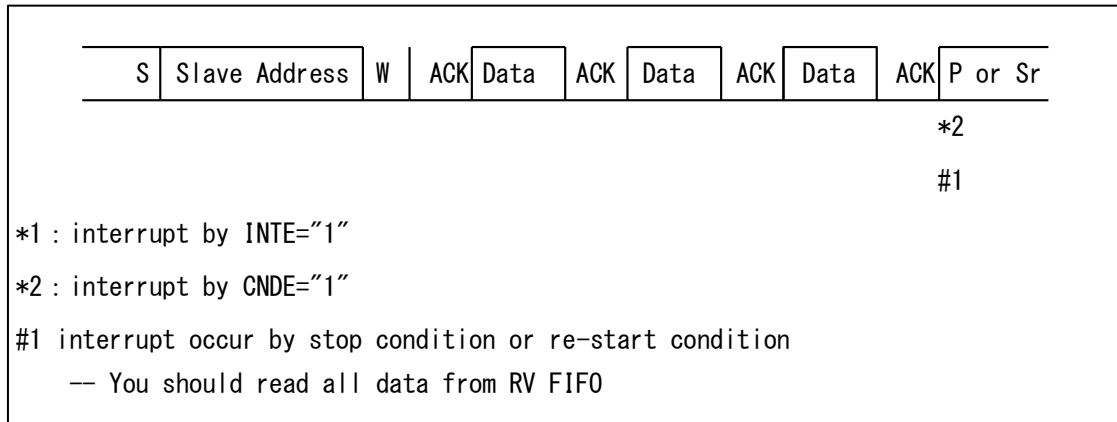

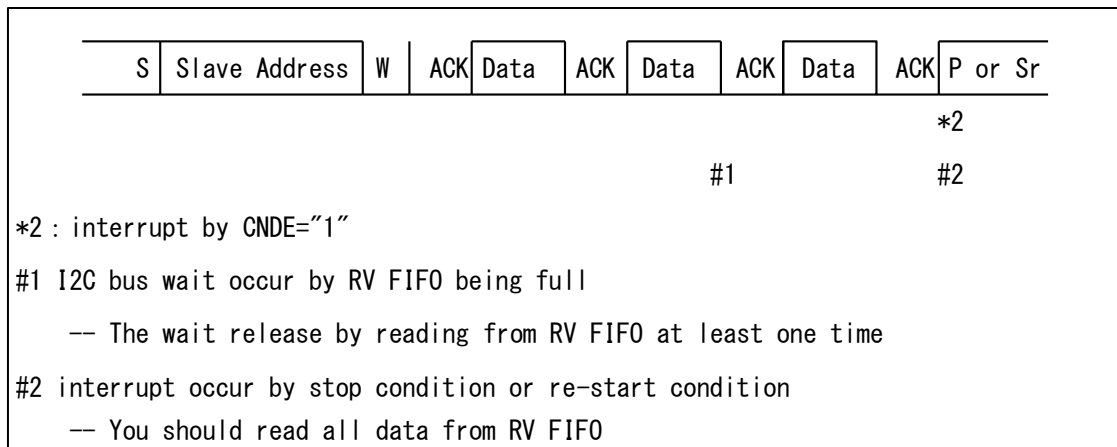

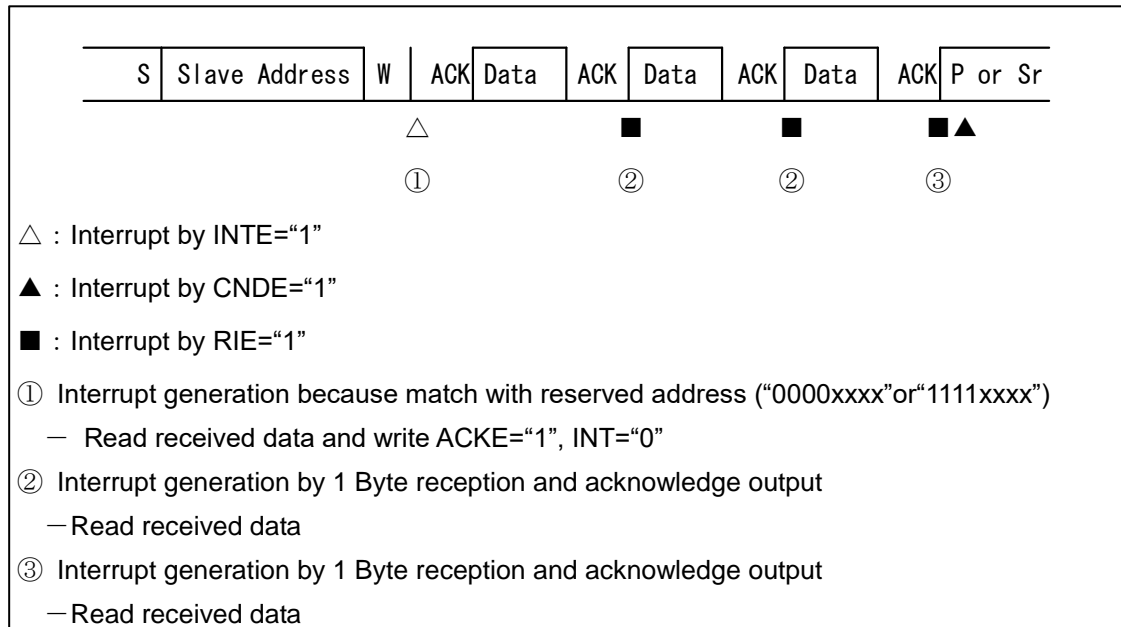

Figure 3-49 Slave Reception Interrupts 10 When the Reception FIFO Is Enabled (SSR:DMA= 1 and IBSR:RSA= 0)**Figure 3-50 Slave Reception Interrupts 11 When the Reception FIFO Is Enabled (SSR:DMA= 1 and IBSR:RSA= 0)**

Figure 3-51 Slave Reception Interrupts 12 When FIFO Is Disabled (SSR:DMA= 1, IBCR:WSEL= 0, and IBSR:RSA= 1)

Transmission by a Slave

A matching slave address and "1" in the data direction bit together indicate transmission by a slave. If FIFO is disabled, the interrupt flag (IBCR:INT) is set to "1" according to the IBCR:WSEL setting, to generate a wait after the transmission of 1 byte or after an acknowledgment response. (See Table 3-7.)

You can verify acknowledgment output from the master by checking the IBSR:RACK bit. A NACK response from the master indicates that the master could not receive data correctly or that data reception ended. If NACK is detected when IBCR:WSEL = 1, an interrupt is generated and a wait is performed.

3.3. Bus Error

The detection of the stop or (repeated) start condition on the I²C bus during data transmission or reception is handled as a bus error.

Bus Error Occurrence Conditions

For a bus error, the IBCR:BER bit is set to "1" under the following conditions.

- The (repeated) start or stop condition is detected during transfer of the 1st byte.
- The (repeated) start or stop condition is detected in the 2nd to 9th (acknowledgment) bits of data.

Bus Error Operation

When EIBCR:BEC=0

Check the IBCR:BER bit when the interrupt flag (IBCR:INT) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by writing "1" to the interrupt flag clear bit (IBCRC:INTC).

If a bus error occurs, the IBCR:INT bit is set to "1", but the SCL of the I²C bus is not set to "L". Then, the wait state is entered.

When EIBCR:BEC=1

Check the IBCR:BER bit when the interrupt flag (IBSR:SPC or IBSR:RSC) is set to "1" according to the status. If the IBCR:BER bit is "1", take action against the error. The IBCR:BER bit is cleared by the following operations:

- Writing "1" to the IBCRC:INTC bit when IBCR:INT = 1
- Writing "1" to the IBSRC:SPCC bit when IBSR:SPC = 1
- Writing "1" to the IBSRC:RSCC bit when IBSR:RSC = 1

4. Serial Timer Operation

The serial timer can be used for timer functions.

Serial Timer Operation

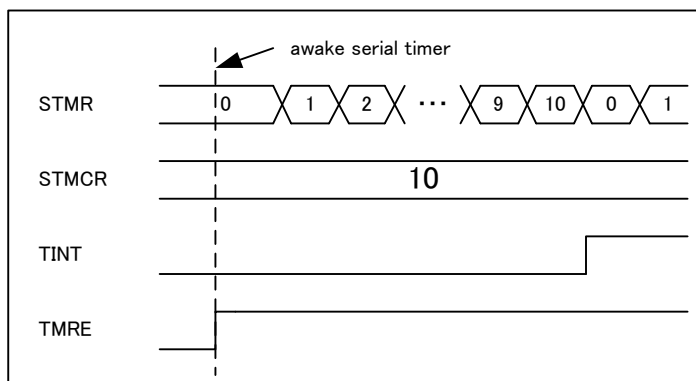

Activating the Serial Timer

There are two ways to activate the serial timer: setting the serial timer enable bit (SACSR:TMRE) to "1", and activation by external trigger.

■ Activation by the serial timer enable bit (SACSR:TMRE)

If the external trigger enable bit (SACSR:TRGE) is set to "0", the serial timer is activated after the serial timer enable bit (SACSR:TMRE) is set to "1". Then, the serial timer register (STMR) starts counting from 0.

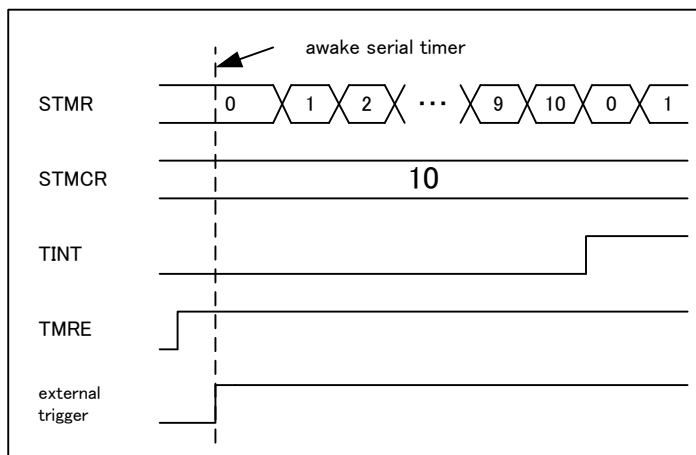

Figure 4-1 Activation by the Serial Timer Enable Bit (STMCR=10, SACSR:TRGE=0)

■ Activation by external trigger

If the external trigger enable bit (SACSR:TRGE) is set to "1", the serial timer is activated after the edge of the set external trigger in the trigger selection bits (TRG1,0) is detected when the serial timer enable bit (SACSR:TMRE) is "1". Then, the serial timer register (STMR) starts counting from 0.

Figure 4-2 Activation by External Trigger (STMCR=10, SACSR:TRGE=1, TRG1=0, TRG0=0)

Note:

- If the external trigger enable bit (SACSR:TRGE) is "1" and the serial timer enable bit (SACSR:TMRE) is "0", even the detection of the edge of the external trigger that is set in the trigger selection bits (SACSR:TRG1,0) does not start the operation of the serial timer.

Stopping the Serial Timer

The serial timer stops when the serial timer enable bit (SACSR:TMRE) is set to "0". The value of the serial timer register (STMR) at this time is retained.

Timer Operation

The serial timer operates as the timer.

If the serial timer register (STMR) matches the serial timer comparison register (STMCR), the timer interrupt flag (SACSR:TINT) is set to "1", and the serial timer register (STMR) is reset to 0.

Figure 4-3 Timer Operation (STMCR=10)

Figure 4-4 Serial Timer Initialization Flowchart

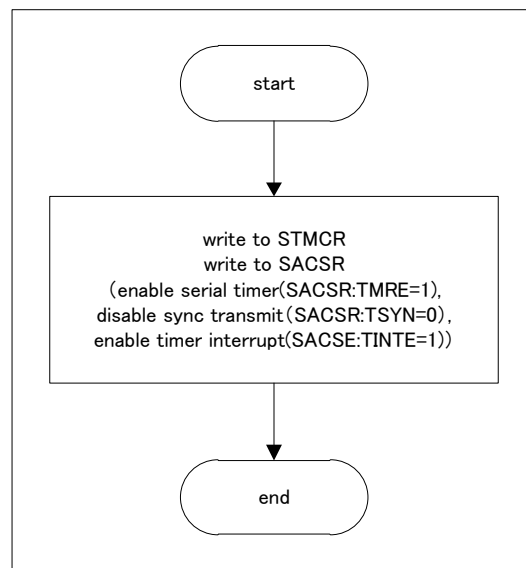

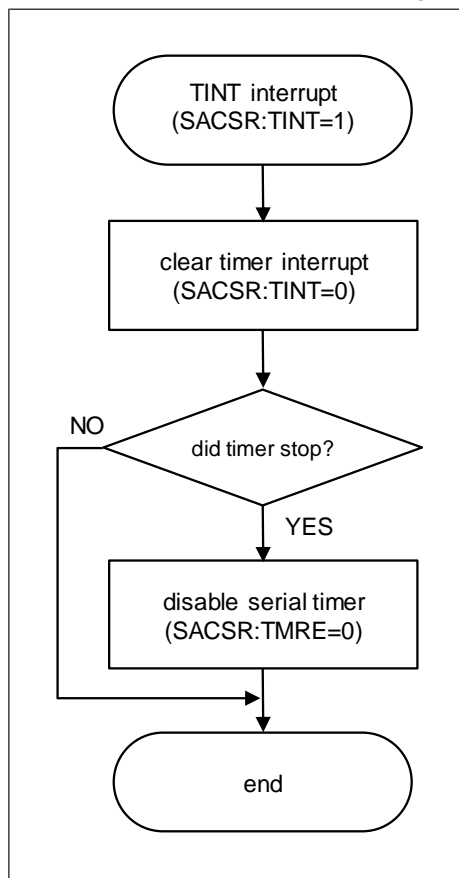

Figure 4-5 Serial Timer Interrupt Processing Flowchart

Note:

- If the setting of the timer comparison register (STMCR) is 0x0000, the timer is operating, and the timer operation clock divider value (SACSR:TDIV) is set to 0b0000, the timer interrupt flag (SACSR:TINT) is fixed at "1".

5. Dedicated Baud Rate Generator

A dedicated baud rate generator sets the frequency of the serial clock.

Baud Rate Selection

Baud Rate Obtained by Dividing the Internal Clock by a Dedicated Baud Rate Generator (Reload Counter)

There are two internal reload counters, with each corresponding to the transmission or reception serial clock. A baud rate can be selected with the setting of a 15-bit reload value in baud rate generator registers 1 and 0 (BGR1, BGR0).

The reload counters divide the internal clock according to the set value.

Baud Rate Calculation

The two 15-bit reload counters are set by baud rate generator registers 1 and 0 (BGR1, BGR0).

The following shows the baud rate calculation formulas.

(1) Reload value

$$V = \text{Phy} / b - 1$$

V : reload value b : baud rate Phy : frequency of bus clock or that of external clock

If baud rate is affected by the rising time of I2C bus, you should make a cut-and-try to the reload value.

(2) Calculation example

When bus clock is 16MHz, baud rate is 400k bps, the reload value can be calculated as follows.

reload value :

$$V = (16 \times 1000000) / 400000 - 1 = 39$$

then baud rate will be

$$b = (16 \times 1000000) / (39 + 1) = 400k \text{ bps}$$

Notes:

- Use 16-bit access when writing values to baud rate generator registers 1 and 0 (BGR1, BGR0).
- Set the baud rate generator registers when the ISMK:EN bit in the ISMK register is "0".
- In operation mode 4 (I²C mode), use the bus clock at 8 MHz or more. A baud rate generator setting exceeding 400 kbps is prohibited in this mode.
- Setting the reload value to "0" stops the reload counter.
- When considering the allowable baud rate range, also consider the impact of the jitter of the input clock to the macro.

Examples of Reload Values and Baud Rate Settings for Each Bus Clock Frequency

The following table shows examples of reload values and baud rate settings.

Table 5-1 Examples of Reload Values and Baud Rate Settings

Baud Rate [bps]	8 MHz	10 MHz	16 MHz	20 MHz	24 MHz	32 MHz
	Value	Value	Value	Value	Value	Value
400000	19	24	39	49	59	79
200000	39	49	79	99	119	159
100000	79	99	159	199	239	319

Baud Rate [bps]	40 MHz	48 MHz	72 MHz	80 MHz
	Value	Value	Value	Value
400000	99	119	179	199
200000	199	239	359	399
100000	399	479	719	799

These numerical values assume that the SCL rising of the I²C bus is 0 s. If the SCL rising of the I²C bus is slower, the resulting baud rates are slower than the above numerical values.

Reload Counter Function

The reload counters consist of 15-bit registers for reload values, and they generate transmission/reception clocks from internal clocks. Also, the count value of the transmission reload counter can be read from the baud rate generator registers (BGR1, BGR0).

Start of Counting

A reload counter starts counting when a reload value is written to a baud rate generator register (BGR1, BGR0).

6. Block Transfer

This section explains the block transfer operation.

Block Transfer Setting

The setting of RXBLKEN= 1 in the extended control register (ECR) enables reception block transfer.

The setting of TXBLKEN= 1 in the ECR enables transmission block transfer.

The block size is set in the transmission block size register or FBYTE register(reception side).

The threshold values used to output block transfer requests are set in the FBYTE register for reception and in the FTICR register for transmission. A reception block transfer request is output when the data count in the reception FIFO exceeds the FBYTE register setting value. A transmission block transfer request is output when the available capacity of the transmission FIFO exceeds the FTICR register setting value.

6.1. RW Access Mode

This section explains operation in RW access mode for block transfer.

Reception Block Transfer

Reception block transfer operates as follows.

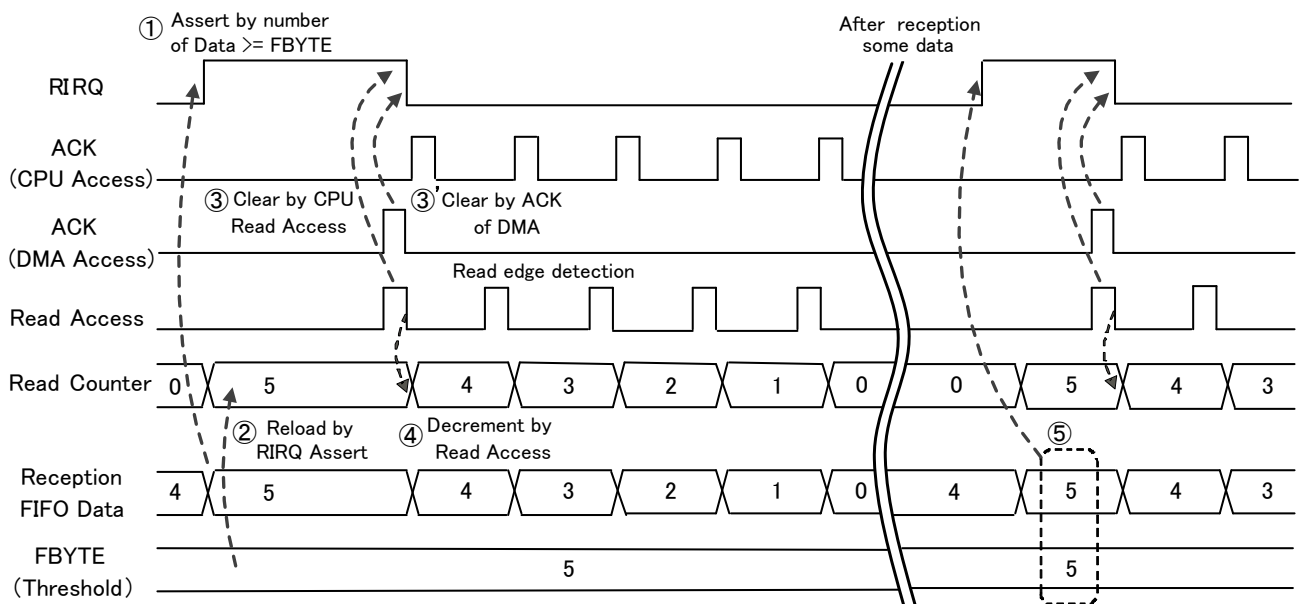

A reception block transfer request (RIRQ) is asserted when the data count in the reception FIFO exceeds the threshold value (FBYTE). At this time, the reception block size value is reloaded from the FBYTE register to the Read counter. The reception block size value is "1" when the reception FIFO is not used.

After the reception block transfer is requested, the reception block transfer request (RIRQ) is cleared when a read access to the reception data occurs. The read access to the reception data decrements the Read counter.

If the data count in the reception FIFO exceeds the threshold value (FBYTE) when the Read counter becomes "0", the reception block transfer request (RIRQ) is asserted again. Asserting the reception block transfer request (RIRQ) reloads the Read counter.

During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Figure 6-1 Reception Block Transfer in RW Access Mode

Transmission Block Transfer

Transmission block transfer operates as follows.

A transmission block transfer request (TIRQ) is asserted when the available capacity in the transmission FIFO exceeds the threshold value (FTICR). At this time, the transmission block size value is reloaded from the TBSIZE register to the Write counter. The transmission block size value is "1" when the transmission FIFO is not used.

After the transmission block transfer is requested, the transmission block transfer request (TIRQ) is cleared when write access to the transmission FIFO occurs. The write access to the transmission FIFO decrements the Write counter.

If the available capacity in the transmission FIFO exceeds the threshold value (FTICR) when the Write counter becomes "0", the transmission block transfer request (TIRQ) is asserted again. Asserting the transmission block transfer request (TIRQ) reloads the Write counter.

Figure 6-2 Transmission Block Transfer in RW Access Mode

Reception Block Transfer Error

The occurrence of read access before the assertion of the next reception block transfer request (RIRQ) while the Read counter is "0" causes a reception block transfer error. Then, the ESR:RBERR bit is asserted.

Figure 6-3 Reception Block Transfer Error in RW Access Mode

Transmission Block Transfer Error

The occurrence of write access before the assertion of the next transmission block transfer request (TIRQ) while the Write counter is "0" causes a transmission block transfer error. Then, the ESR:TBERR bit is asserted.

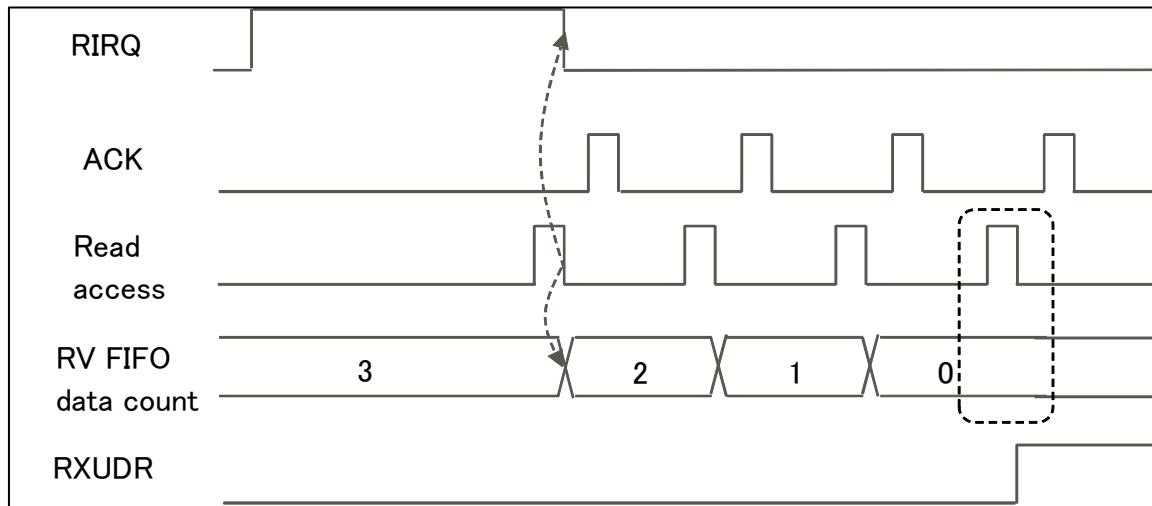

Figure 6-4 Transmission Block Transfer Error in RW Access Mode

Reception FIFO under run

Reading reception data from the reception FIFO while the data count in the reception FIFO is "0" causes a reception FIFO under run. Then, the ESR:RXUDR bit is asserted.

Figure 6-5 Reception FIFO Under run in RW Access Mode

Transmission FIFO overrun

Writing transmission data to the transmission FIFO while the available capacity of the transmission FIFO is "0" causes a transmission FIFO overrun. Then, the ESR:TXOVR bit is asserted.

Figure 6-6 Transmission FIFO Overrun in RW Access Mode

7. I²C Communication Operation Flowchart Examples

This section shows examples of flowcharts of I²C communication operations.

I²C Flowchart Examples When DMA Mode is Disabled (SSR:DMA=0) (FIFO is Not Used)

Figure 7-1 I²C Flowchart Example Where DMA Mode Is Disabled (SSR:DMA=0) (FIFO Not Used) 1/3

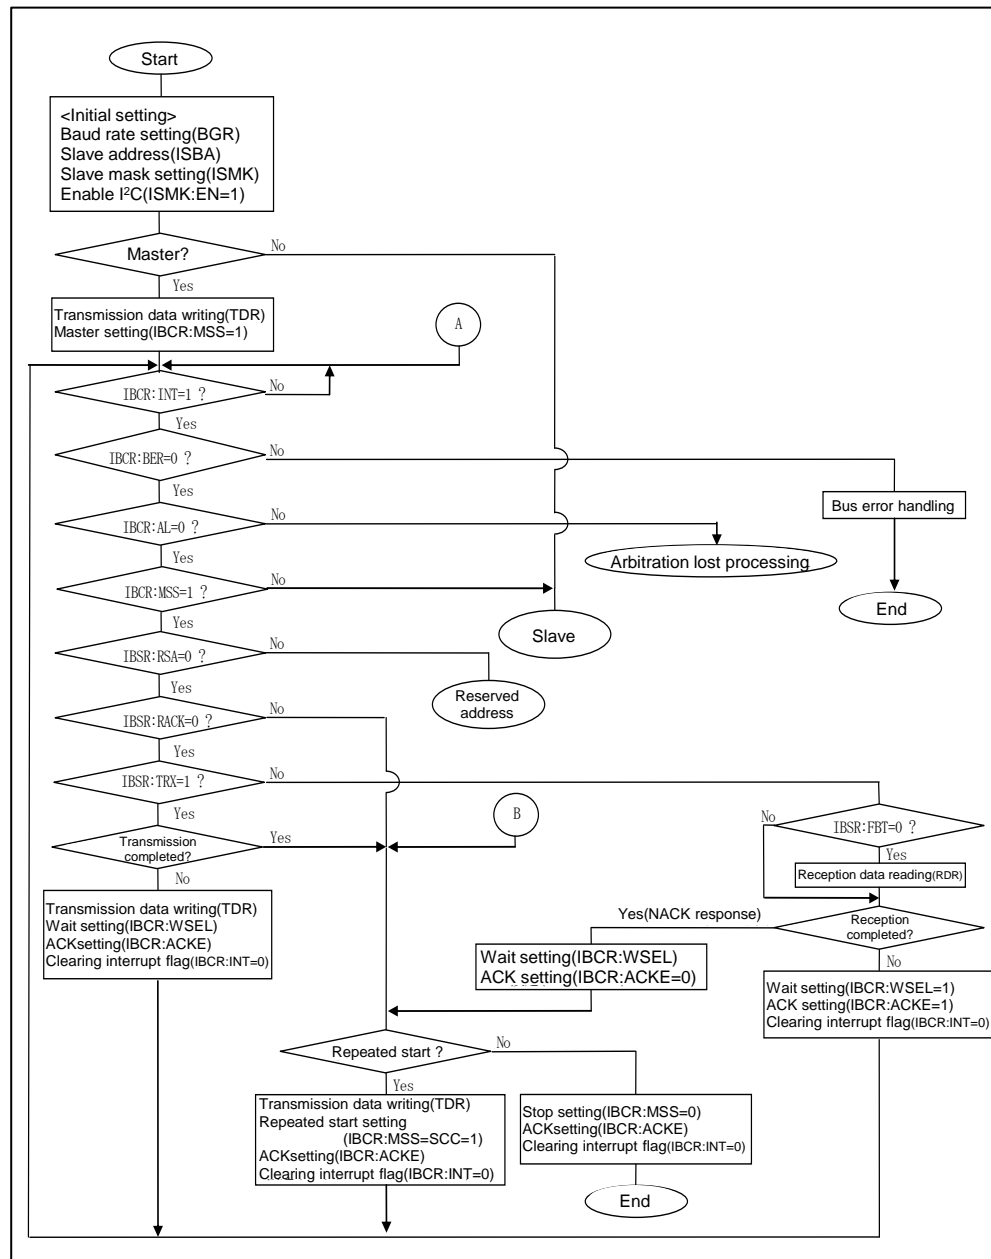

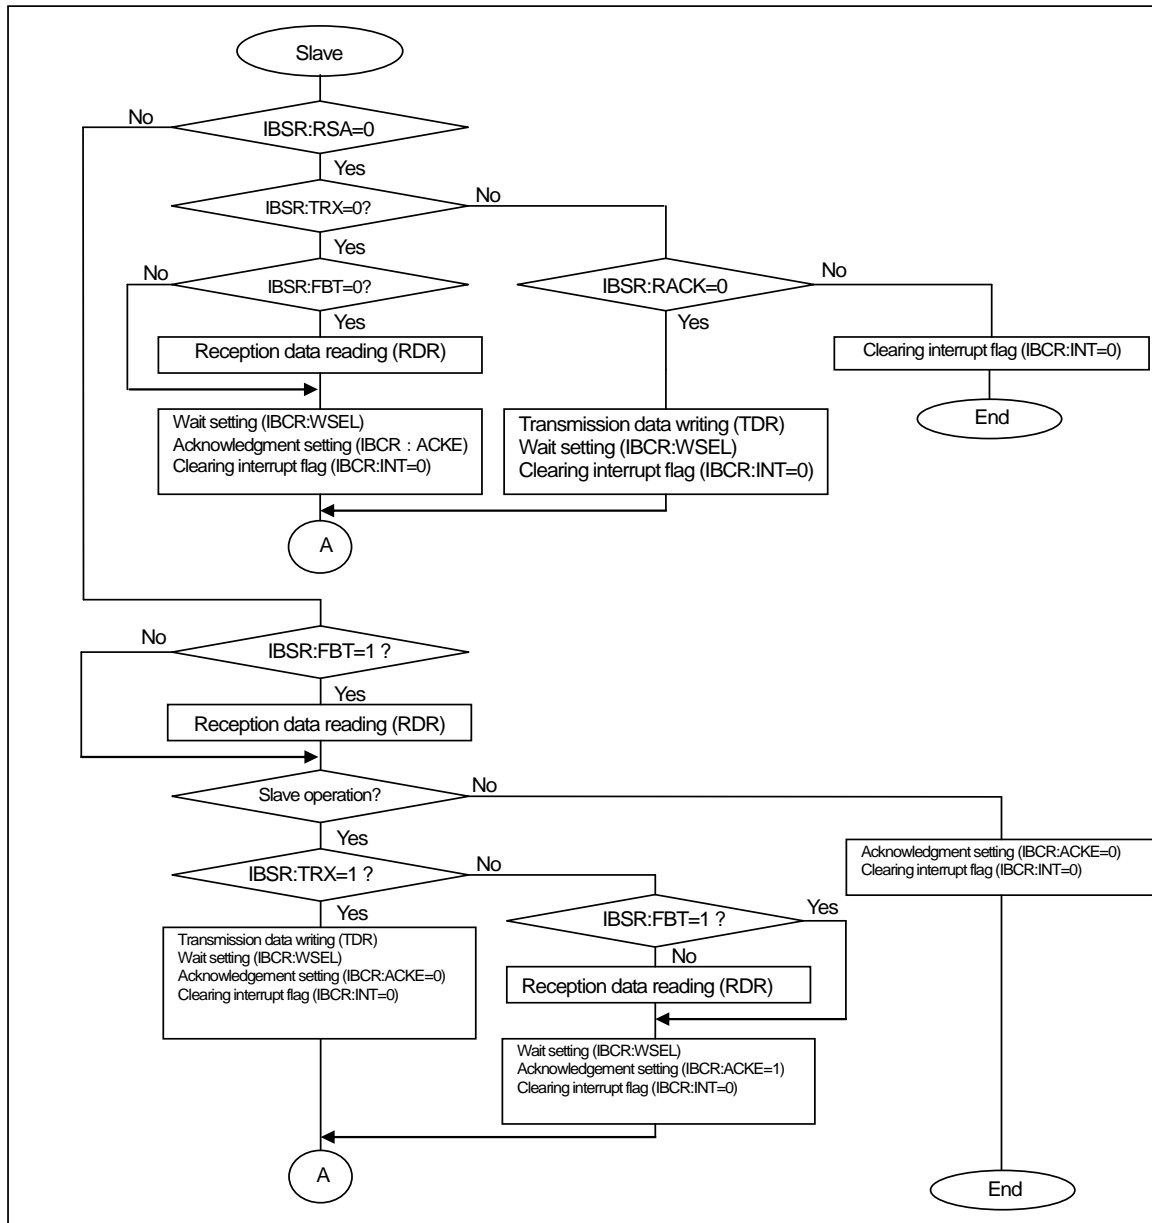

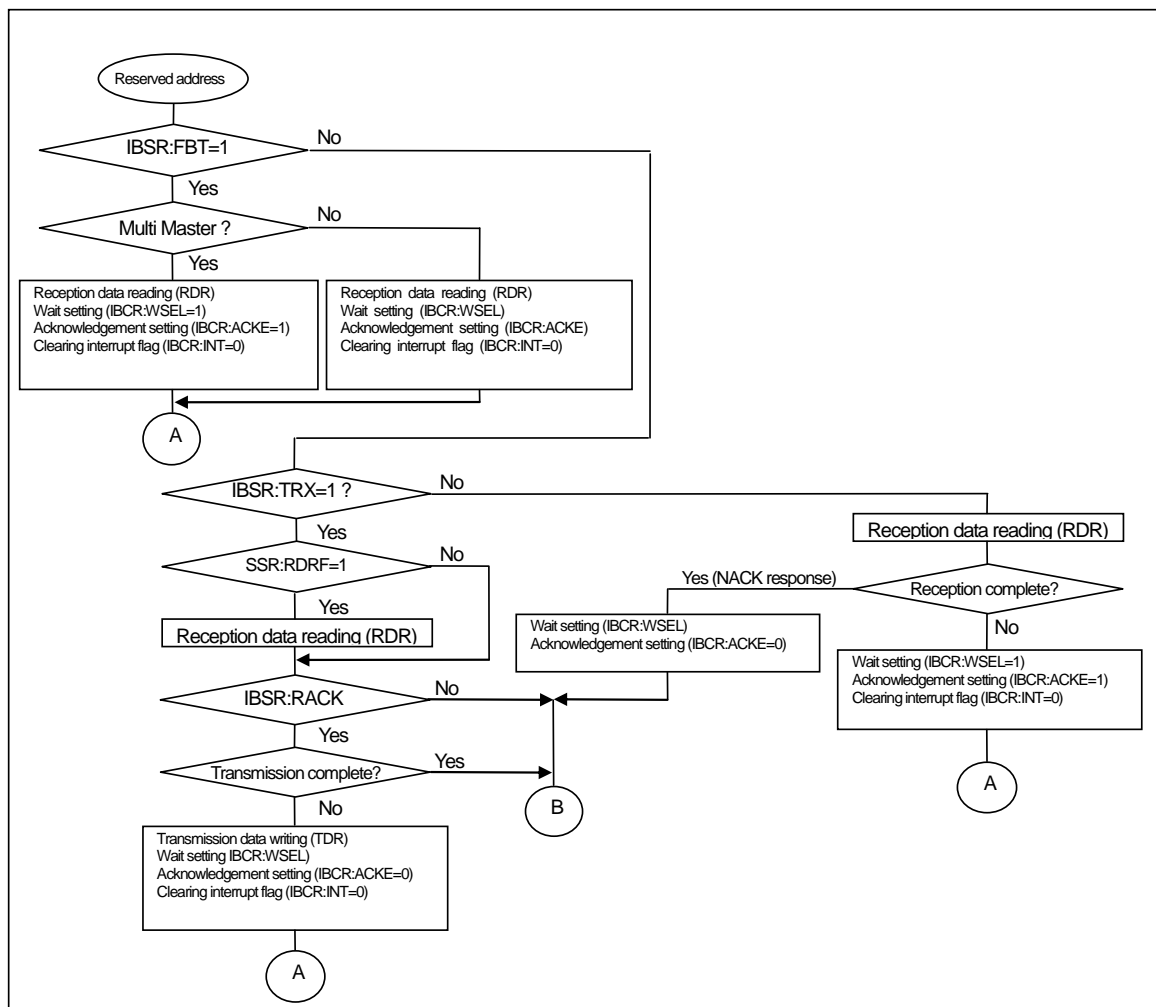

Figure 7-2 I²C Flowchart Example Where DMA Mode Is Disabled (SSR:DMA=0) (FIFO Not Used) 2/3

Figure 7-3 I²C Flowchart Example Where DMA Mode Is Disabled (SSR:DMA=0) (FIFO Not Used) 3/3

I²C Flowchart Example Where DMA Mode is Enabled (SSR:DMA=1) (FIFO Not Used)
Figure 7-4 I²C Flowchart Example Where DMA Mode Is Enabled (SSR:DMA=1) (FIFO Not Used) 1/5

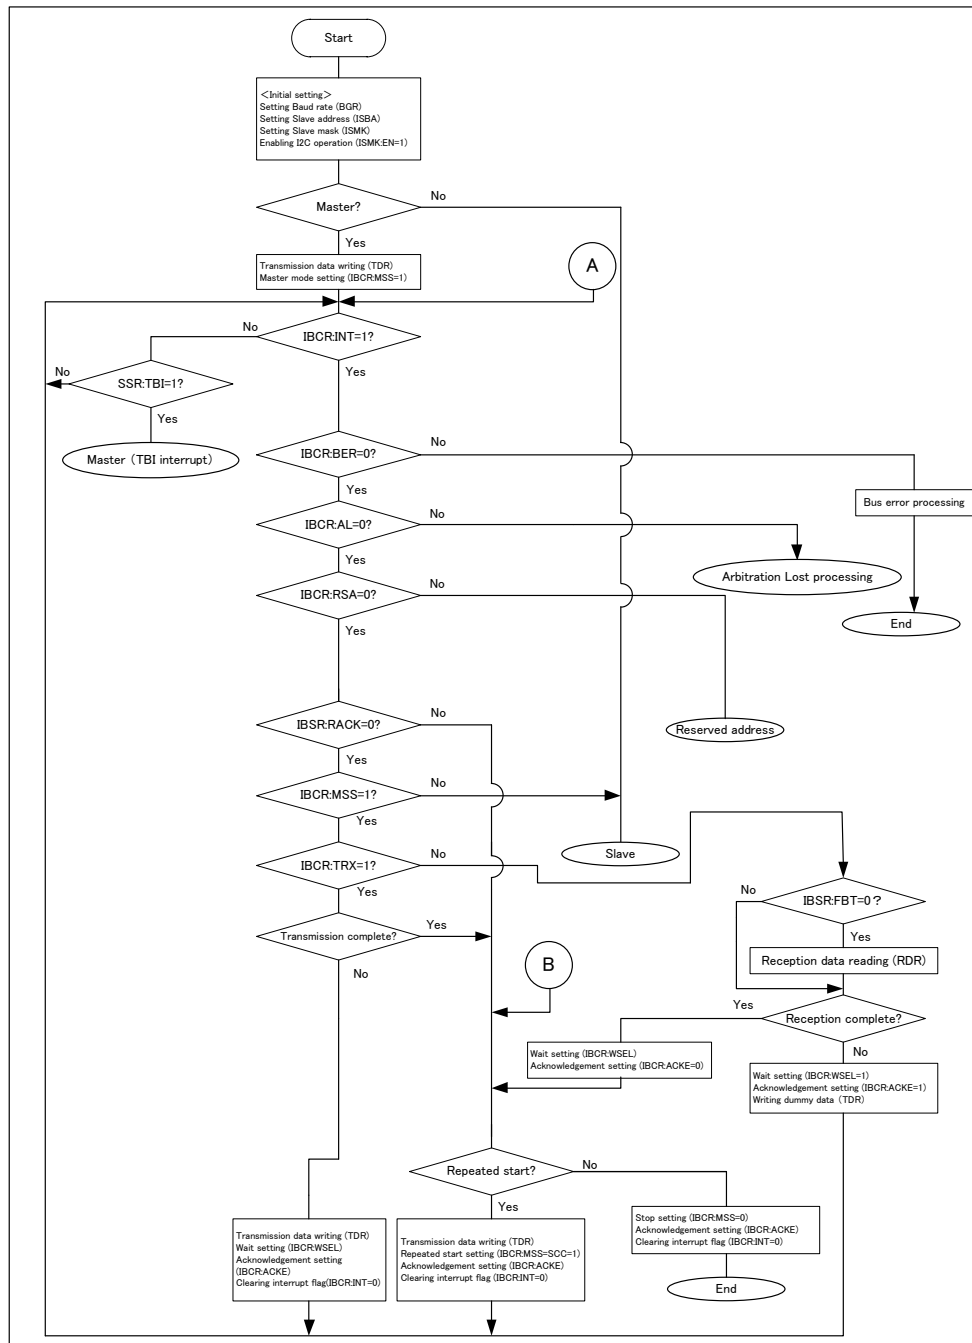

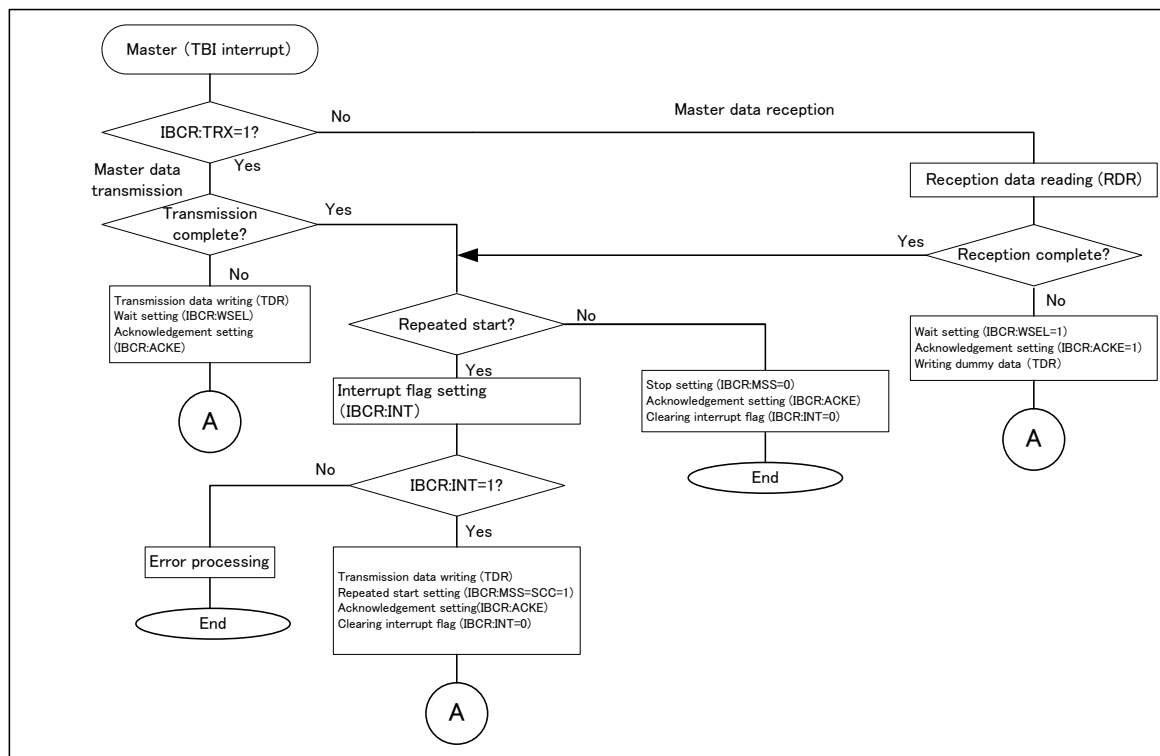

Figure 7-5 I²C Flowchart Example Where DMA Mode Is Enabled (SSR:DMA=1) (FIFO Not Used) 2/5

Figure 7-6 I²C Flowchart Example Where DMA Mode Is Enabled (SSR:DMA=1) (FIFO Not Used) 3/5

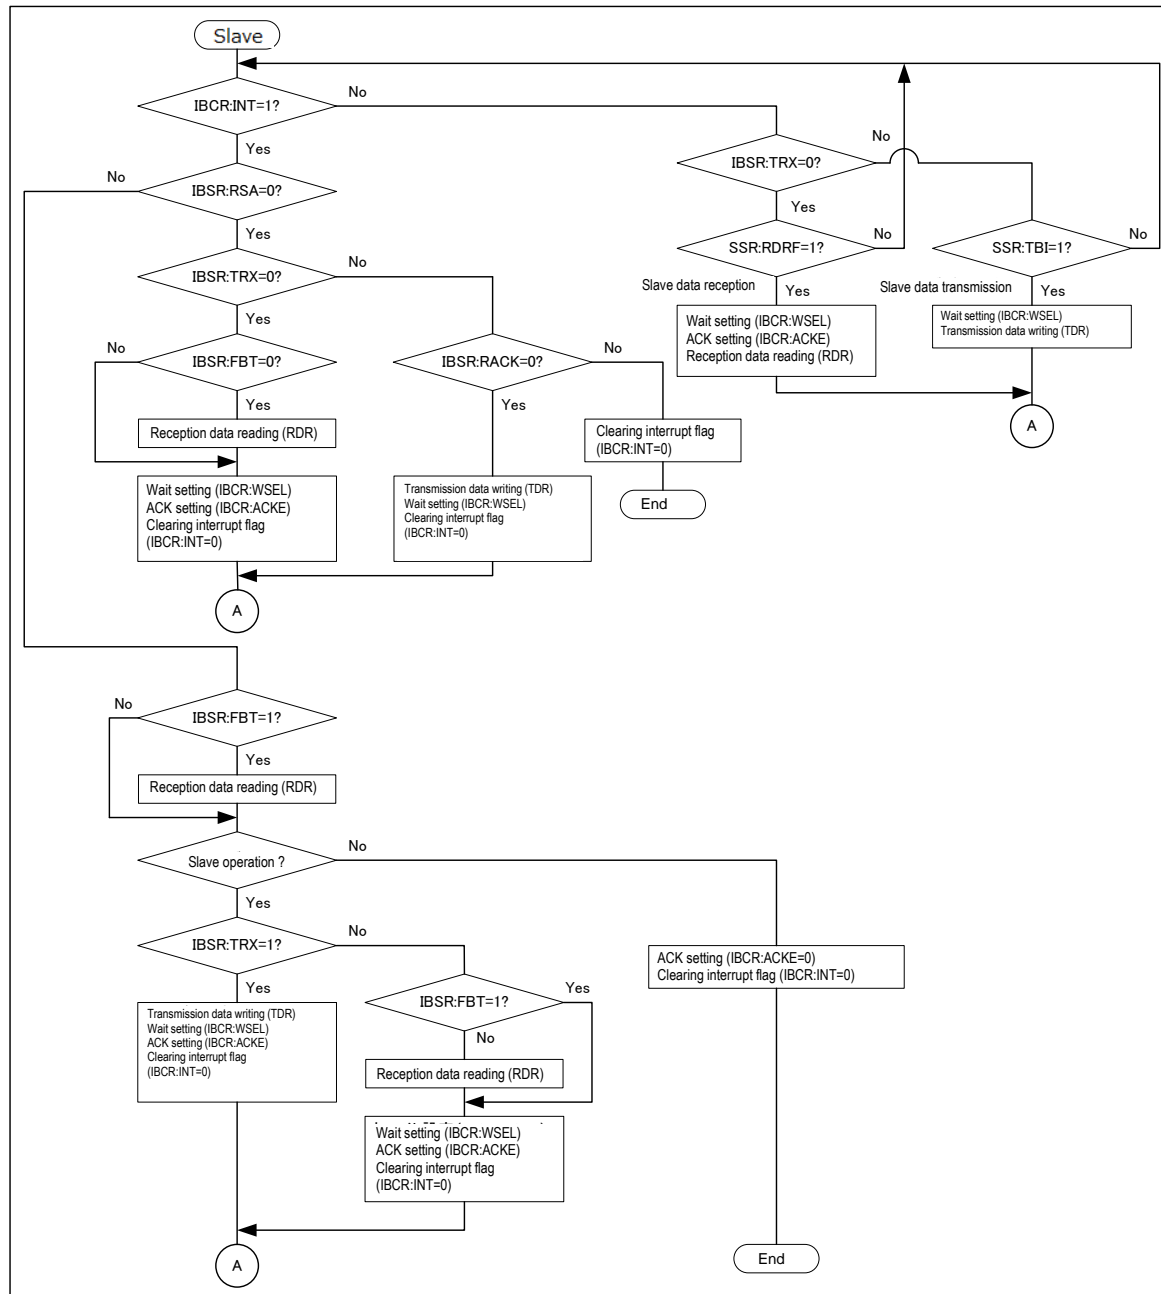

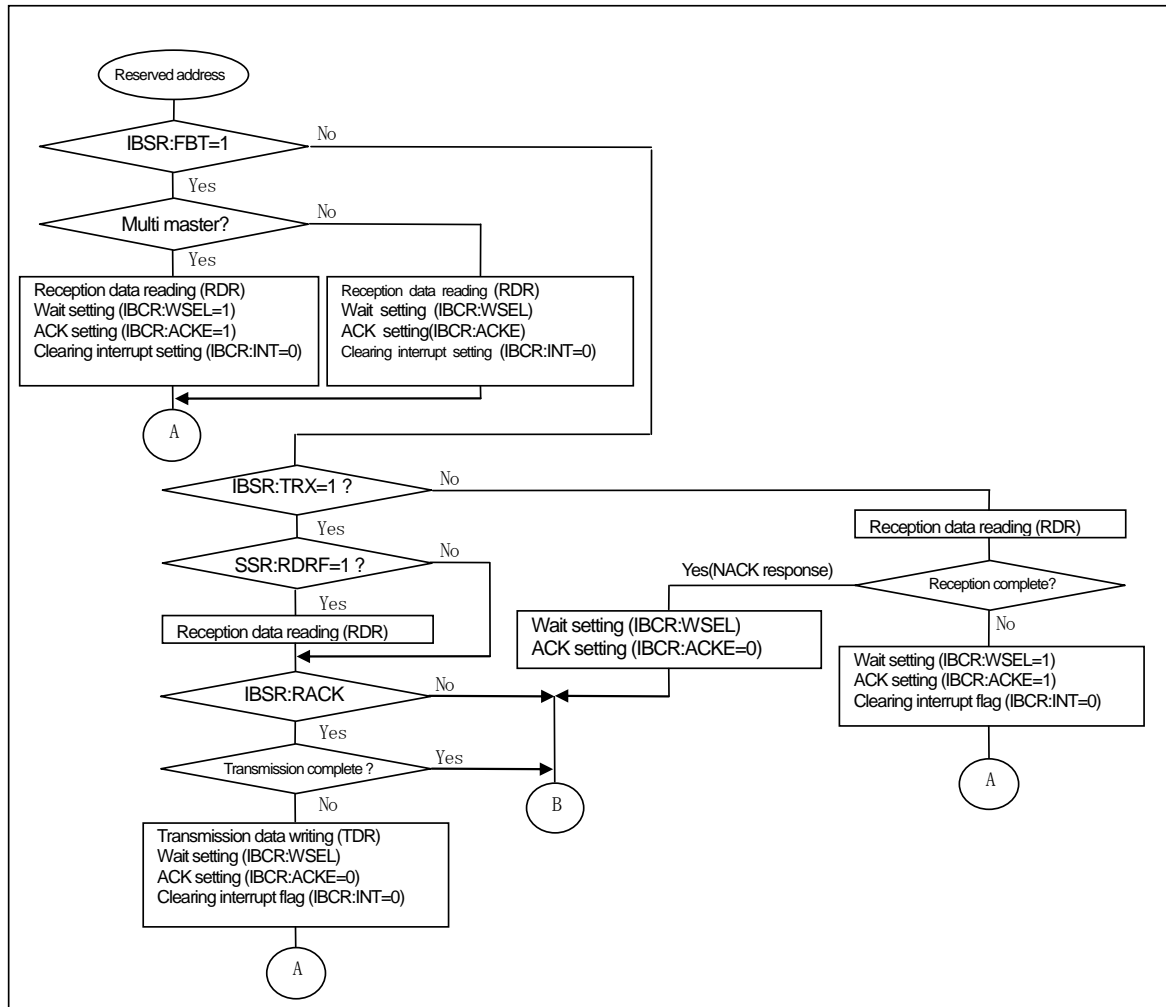

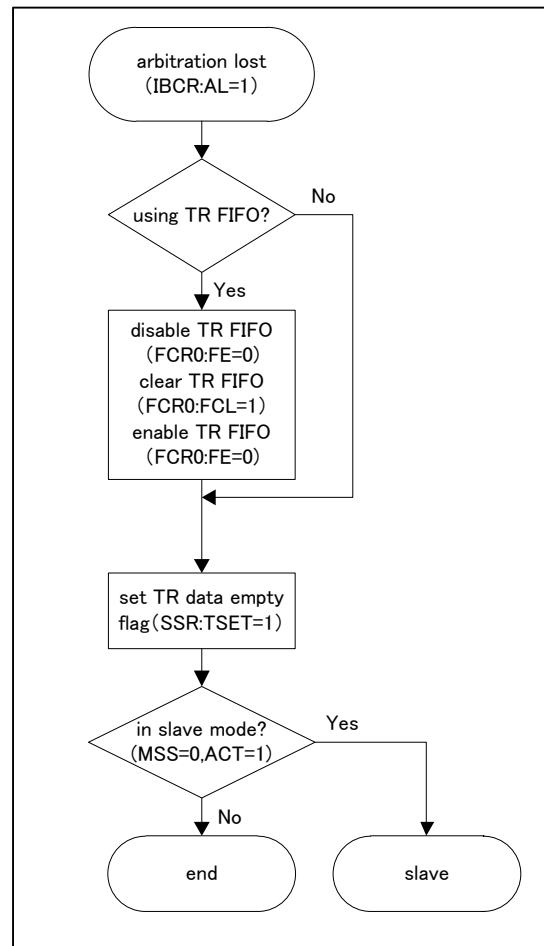

Figure 7-7 I²C Flowchart Example Where DMA Mode Is Enabled (SSR:DMA=1) (FIFO Not Used) 4/5

Figure 7-8 Arbitration Lost Processing Flowchart Example 5/5**Note:**

- The flows roughly show the settings for operation in I²C mode. Processing must take into account error handling, etc. according to the application.

8. I²C Interface Registers

This section lists the I²C interface registers.

I²C Interface Registers

Table 8-1 I²C Interface Registers

	bit15	bit8	bit7	bit0
I ² C	IBCR (I ² C bus control register)		SMR (serial mode register)	
	SSR (serial status register)		IBSR (I ² C bus status register)	
	-		RDR/TDR (reception data register/transmission data register)	
	-		-	
	SACSR1 (serial auxiliary control status register 1)		SACSR0 (serial auxiliary control status register 0)

Set	IBCRS (I ² C bus control set register)		SMRS (serial mode set register)	

*1 Access via a mirror address area

8.1. I²C Bus Control Register (IBCR)

The I²C bus control register (IBCR) sets the selection of master/slave mode, generation of the repeated start condition, enabling of acknowledgments, and enabling of interrupts. The IBCR also displays an interrupt flag.

I²C Bus Control Register (IBCR)

Figure 8-1 shows the bit configuration of the I²C bus control register (IBCR).

Figure 8-1 Bit Configuration of the I²C Bus Control Register (IBCR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	MSS	ACT/ SCC	ACKE	WSEL	CNDE	INTE	BER	INT	(SMR)		
R/W	R/W	R,W	R/W	R/W	R/W	R/W	R,WX	R,WX			
Attribute											
Protection	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] MSS : Master/Slave Selection Bit

- If this bit is set to "1" when the I²C bus is in the idle state (ISMK:EN= 1 and IBSR:BB= 0), the mode is set to master mode.
- After this bit is set to "1" when the BB bit in the IBSR register is "1", a wait for start condition generation is performed until the IBSR:BB bit is set to "0". If a slave address is found to match during this wait and the device operates as a slave, this bit is set to "0" and the AL bit in the IBSR register is set to "1".
- Writing "0" to this bit during master operation (MSS= 1 and ACT= 1) when the interrupt flag (INT) is "1" generates the stop condition.
- This bit is reset when the IBCRC:MSSC bit in the clear register is set to "1".
- This bit is set when the IBCRS:MSSS bit in the set register is set to "1".

MSS is cleared under the following conditions.

1. I²C interface operation is disabled (ISMK:EN bit = 0).
2. Arbitration lost occurs.
3. A bus error is detected (BER bit = 1) (except in cases where the stop condition is detected in the acknowledgment field during master operation).
4. "0" is written to the MSS bit when INT= 1.
5. "0" is written to the MSS bit when DMA mode is enabled (SSR:DMA= 1) and SSR:TBI= 1.

The following table shows the relationship between the MSS bit and the ACT bit.

MSS Bit	ACT Bit	State
0	0	Idle
0	1	Slave operation in progress (slave mode) after ACK response*1 is returned for slave address match or reserved address
1	0	Master operation waiting
1	1	Master operation in progress (master mode)

*1 ACK response: Indicates that the SDA of the I²C bus is "L" during the acknowledgment interval.

MSS Bit	Description
0	Select slave mode.
1	Select master mode.

Notes:

- To change the MSS bit to "0" when DMA mode is disabled (SSR:DMA= 0) and the MSS bit is set to "1", do so when the MSS bit is "1" and the INT bit is "1". Writing "0" to the MSS bit when the ACT bit is "1" also clears the INT bit to "0".
- To change the MSS bit to "0" when DMA mode is enabled (SSR:DMA= 1) and the MSS bit is set to "1", do so when the MSS bit is "1" and the INT bit is "1" or the SSR:TBI bit is "1". Writing "0" to the MSS bit when the ACT bit is "1" also clears the INT bit to "0".
- During master operation, "1" is read while the ACT bit is "1", even if "0" is written to the MSS bit.
- If "1" is written to the MSS bit during slave operation, this bit is set to "0" and the AL bit in the IBSR register is set to "1". If you want the device to operate in master mode after slave operation ends, perform the following procedure.
 1. Verify the end of slave operation through detection of the stop condition (IBCR:SPC= 1).
 2. Write the slave address and transmission data (only when the transmission FIFO is used).
 3. Write "1" to this bit.

[bit14] ACT/SCC: Operation Flag/Repeated Start Condition Generation Bit

The meaning of this bit varies depending on whether the operation is read or write.

ACT/SCC	Description
Write	SCC bit
Read	ACT bit

The ACT bit indicates whether the device is operating in master or slave mode.

- This bit is set when the IBCRS:ACTS bit in the set register is set to "1".

ACT bit set conditions:

1. The start condition is output to the I²C bus (master mode).
2. The slave address matches the address transmitted by the master (slave mode).
3. The reserved address is detected, and an acknowledgment response to the detection is returned (slave mode is selected when MSS= 0).

ACT bit reset conditions:

<Master mode>

1. The stop condition is detected (except in cases where the stop condition is detected in the acknowledgment field).

2. Arbitration lost is detected.
3. A bus error is detected (BER bit = 1) (except in cases where the stop condition is detected in the acknowledgment field).
4. I²C interface is operation disabled (ISMK:EN bit = 0).

<Slave mode>

1. The (repeated) start condition is detected.
2. The stop condition is detected.
3. No acknowledgment response is returned in the detection of the reserved address (IBSR:RSA= 1).
4. I²C interface operation is disabled (ISMK:EN bit = 0).
5. A bus error is detected (BER bit = 1).

Writing "1" to this bit in master mode executes a repeated start. Writing "0" is invalid.

Bit	Description	
	Write	Read
0	No effect	No operation
1	Generate the repeated start condition.	The I ² C is operating.

Notes:

- When writing "1" to the SCC bit, do so during an interrupt in master mode (MSS= 1, ACT= 1, and INT= 1). Writing "1" to the SCC bit when the ACT bit is "1" clears the INT bit to "0".
- Writing "1" to this bit in slave mode (MSS= 0 and ACT= 1) is prohibited.
- If "1" is written to the SCC bit and "0" to the MSS bit, the MSS bit takes priority.
- If both of the following conditions are satisfied, the INT bit is set to "1" to wait for the I²C bus (SCL="L"). To generate the repeated start condition, it is necessary to write "1" to the SCC bit again and clear the INT bit.
 - "1" is written to the SCC bit when a master mode interrupt (MSS= 1, ACT= 1, INT= 1, and WSEL= 1) is generated at the 8th bit.
 - NACK is received as the 9th bit.
- To issue the repeated start condition when DMA mode is enabled (SSR:DMA= 1), the SSR:TBI bit is "1", and the IBCR:INT bit is "0", perform the following procedure.
 - 1 Write "1" to the IBCR:INT bit.
 - 2 Verify that the IBCR:INT bit is set to "1".
 - 3 Write the slave address to the TDR.
 4. Set this bit to "1".

[bit13] ACKE : Data Byte acknowledgment Enable Bit

- If this bit is set to "1", "L" is output at the acknowledgment timing.
- Under any of the following conditions, change this bit.
 - The INT bit is "1" when ACT= 1.
 - DMA mode is enabled (SSM:DMA= 1) and the SSR:TBI bit is "1" when ACT= 1.

- DMA mode is enabled (SSM:DMA= 1) and SSR:RDRF is "1" during slave reception when ACT= 1.
- ACT is "0".
- This bit is reset when the IBCRC:ACKEC bit in the clear register is set to "1".
- This bit is set when the IBCRS:ACKES bit in the set register is set to "1".

This bit is invalid under the following conditions.

1. There is an acknowledgment for an address field for other than the reserved address (automatic generation).
2. Data is being transmitted (IBSR:RSA= 0, IBSR:TRX= 1, and IBSR:FBT= 0).
3. An ACK response is always returned during slave reception when the reception FIFO is enabled (FCR0:FE= 1, MSS= 0, and ACT= 1).
4. The response during master reception when the reception FIFO is enabled and WSEL is "0" (FCR0:FE= 1, MSS= 1, ACT= 1, and WSEL= 0) is as follows. If the SSR:TDRE bit is "0", an ACK response is returned. If the SSR:TDRE bit is "1", a NACK response is returned.
5. An ACK response is always returned during slave transmission when the reception FIFO is enabled, WSEL= 0, and the reserved address is detected (IBSR:RSA= 1, IBSR:TRX= 1, IBSR:FBT= 1). If a NACK response is returned, disable the reception FIFO and set ACKE= 0 at the interrupt time after the reserved address is detected.
6. The transmission data register has data during master reception when the reception FIFO is enabled and WSEL is "1" (FCR0:FE= 1, MSS= 1, ACT= 1, WSEL= 1, and SSR:TDRE= 0).

Bit	Description
0	Disable acknowledgment.
1	Enable acknowledgment.

[bit12] WSEL : Wait Selection Bit

- When DMA mode is disabled (SSR:DMA= 0), this bit generates an interrupt (INT= 1) before or after acknowledgment and selects whether to wait for the I²C bus.
- When DMA mode is enabled (SSR:DMA= 1), this bit selects whether to wait for the I²C bus before or after an acknowledgment.
- The WSEL bit is invalid under the following conditions.
 1. An interrupt for the 1st byte*1 is generated (INT= 1).
 2. The reserved address is detected (IBSR:FBT= 1 and IBSR:RSA= 1).
 3. A NACK response*2 is detected during data transmission with FIFO used (FCR0:FE= 1, IBSR:RACK= 1, and ACT= 1).
 4. The reception FIFO becomes full during use.

*1 1st byte: Indicates the data after the (repeated) start condition.

*2 NACK response: Indicates that the SDA of the I²C bus is "H" during an acknowledgment period.

- This bit is reset when the IBCRC:WSELC bit in the clear register is set to "1".
- This bit is set when the IBCRS:WSELS bit in the set register is set to "1".

Bit	Description
0	Wait after acknowledgment (9th bit).
1	Wait after data transmission is completed (8th bit).

[bit11] CNDE : Condition Detection Interrupt Enable Bit

This bit enables interrupt generation when the stop or repeated start condition is detected in master or slave mode (ACT= 1). An interrupt is generated when the RSC or SPC bit in the IBSR register is "1" and this bit is "1".

- This bit is reset when the IBCRC:CNDEC bit in the clear register is set to "1".
- This bit is set when the IBCRS:CNDEN bit in the set register is set to "1".

Bit	Description
0	Disable repeated start or stop condition interrupts.
1	Enable repeated start or stop condition interrupts.

[bit10] INTE : Interrupt Enable Bit

This bit enables interrupts (INT= 1) for data transmission and reception and for bus errors in master or slave mode.

- This bit is reset when the IBCRC:INTEC bit in the clear register is set to "1".
- This bit is set when the IBCRS:INTES bit in the set register is set to "1".

Bit	Description
0	Disable interrupts.
1	Enable interrupts.

[bit9] BER : Bus Error Flag Bit

This bit indicates that an error has been detected on the I²C bus.

BER bit set conditions:

1. The start or stop condition is detected during transfer of the 1st byte*1.
2. At the 2nd or subsequent byte, the (repeated) start or stop condition is detected in the 2nd to 9th (acknowledgment) bits of data.

BER bit reset conditions:

1. "1" is written to the IBCRC:INTC bit when EIBCR:BEC= 0 and BER= 1.
2. I2C interface operation is disabled (ISMK:EN= 0).
3. "1" is written to the IBCRC:INTC bit when EIBCR:BEC= 1 and IBCR:INT= 1.
4. "1" is written to the IBSRC:SPCC bit when EIBCR:BEC= 1 and IBSR:SPC= 1.
5. "1" is written to the IBSRC:RSCC bit when EIBCR:BEC= 1 and IBSR:RSC= 1.

*1 1st byte: Indicates the data after the (repeated) start condition.

Bit	Description
0	There is no error.
1	An error is detected.

Notes:

- Check this bit in the following cases. If it is "1", data was either not transmitted or received correctly. Perform retransmission or other processing accordingly.
 - When EIBCR:BEC= 0, the interrupt flag (INT bit) was set to "1".
 - When EIBCR:BEC= 1, the repeated start condition check bit (IBSR:RSC bit) was set to "1".
 - When EIBCR:BEC= 1, the stop condition check bit (IBSR:SPC bit) was set to "1".
- If all of the following conditions are true when EIBCR:BEC= 1, issue the stop condition:

- IBCR:BER=1
- IBCR:INT=1
- IBCR:ACT=1
- IBCR:MSS=1

[bit8] INT : Interrupt Flag Bit

This bit sets the flag to "1" in master or slave mode when a bus error occurs or after 8 or 9 bits (ACK) of data are transmitted or received. The SCL is set to "L" when the INT bit is set to "1" and released from the "L" state when the INT bit is set to "0", although this does not apply when a bus error occurs.

INT bit set conditions:

<8th bit>

<When DMA mode is not involved>

1. Write "1" to IBCR:INTS.
2. The reserved address is detected in the 1st byte.
3. Arbitration lost is detected in the 2nd or subsequent byte when WSEL is "1".

<When DMA mode is disabled (SSR:DMA=0)>

1. The SSR:TDRE bit is "1" at the 2nd or subsequent byte during master operation when WSEL is "1".
2. The SSR:TDRE bit is "1" at the 2nd or subsequent byte during slave operation when WSEL is "1" and the reception FIFO is disabled.
3. The SSR:TDRE bit is "1" at the 2nd or subsequent byte during slave transmission when WSEL is "1".
4. Slave reception occurs when the reception FIFO is disabled and WSEL is "1".

<When DMA mode is enabled (SSR:DMA=1)>

1. "1" is written to the INT bit at the 2nd or subsequent byte during master operation when WSEL is "1" and the SSR:TBI bit is "1".

<9th bit>

<When DMA mode is not involved>

1. Arbitration lost is detected in the 1st byte.
2. A NACK is received at a time other than when stop condition output is set ("0" is written to the MSS bit during master operation).
3. Arbitration lost is detected in the 2nd or subsequent byte when WSEL is set to "0".
4. The reserved address is not detected in the 1st byte, and the reception FIFO has data in the reception direction (IBSR:TRX= 0) in master or slave mode when the reception FIFO is enabled.
5. IBSR:BER is "1" during master operation (MSS= 1 and ACT= 1) when EIBCR:BEC= 1.

<When DMA mode is disabled (SSR:DMA=0)>

1. The reserved address is not detected in the 1st byte, and the SSR:TDRE bit is "1" in the transmission direction (IBSR:TRX= 1) in master or slave mode.
2. The reserved address is not detected in the 1st byte, and the SSR:TDRE bit is "1" in the reception direction (IBSR:TRX= 0) in master or slave mode when the reception FIFO is disabled.

3. The SSR:TDRE bit at the 2nd or subsequent byte is "1" during operation in master mode when WSEL is set to "0".
4. The SSR:TDRE bit at the 2nd or subsequent byte is "1" during slave transmission when WSEL is set to "0".
5. The reception FIFO is disabled during slave reception when WSEL is set to "0". However, an interrupt is not generated in the 9th bit during slave reception of the 1st byte where the reserved address has been detected.
6. The reception FIFO becomes full during slave reception with the reception FIFO enabled.

<When DMA mode is enabled (SSR:DMA=1)>

1. The reserved address is not detected in the 1st byte, and the SSR:TDRE bit is "1" in the transmission direction (IBSR:TRX= 1) in slave mode.
2. The reserved address is not detected in the 1st byte, and the SSR:TDRE bit is "1" in the reception direction (IBSR:TRX= 0) in slave mode with the reception FIFO disabled.
3. "1" is written to the INT bit at the 2nd or subsequent byte during operation in master mode, where the SSR:TBI bit is "1" when WSEL is set to "0".

<Other>

1. A bus error is detected when IBCR:BEC= 0.

INT bit reset conditions:

1. "1" is written to the IBCRC:INTC bit.
2. "0" is written to the MSS bit when the INT bit is "1" and the ACT bit is "1".
3. "1" is written to the SCC bit when the INT bit is "1" and the ACT bit is "1".

Writing "1" to the INT bit is invalid when DMA mode is disabled (SSR:DMA= 0).

Bit	Description	
	Write	Read
0	No effect	No interrupt request
1	No effect	Interrupt request

Notes:

- If "1" is written to the INT bit at the 2nd or subsequent byte during operation in master mode when DMA mode is enabled (SSR:DMA= 1) and the SSR:TBI bit is "1", a status interrupt is not generated.
- To issue the repeated start condition when DMA mode is enabled (SSR:DMA= 1), the SSR:TBI bit is "1", and the IBCR:INT bit is "0", perform the following procedure.
 1. Write "1" to the IBCR:INT bit.
 2. Verify that the IBCR:INT bit is set to "1".
 3. Write the slave address to the TDR.
 4. Set the IBCR:SCC bit to "1".
- When "1" is set to INT flag, write "1" to IBCRC:INTC to release the wait for the I²C bus.
- If the ISMK:EN bit is set to "0", the SSR:RDRF and INT bits may be set to "1" depending on the reception timing. In this case, read the reception data, and clear the INT bit.

- Even if the reception FIFO becomes full during master reception operation when the reception FIFO is enabled, the INT bit is not set to "1".
- Write "1" to this bit when the start condition is issued (IBCR:MSS= 1).

8.2. Serial Mode Register (SMR)

The serial mode register (SMR) sets the operation mode and enables/disables transmission and reception interrupts.

Serial Mode Register (SMR)

Figure 8-2 shows the bit configuration of the serial mode register (SMR).

Figure 8-2 Bit Configuration of the Serial Mode Register (SMR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(IBCR)			MD2	MD1	MD0	WUCR	RIE	TIE	Reserved	Reserved
R/W Attribute				R/W	R/W	R/W	R/W	R/W	R/W	R0,W0	R0,W0
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] MD[2:0] : Operation Mode Setting Bits

These bits set the operation mode.

Bits			Description
0	0	0	Operation mode 0 (asynchronous normal mode)
0	0	1	Operation mode 1 (asynchronous multi-processor mode)
0	1	0	Operation mode 2 (clock synchronous mode)
0	1	1	Operation mode 3 (LIN communication mode)
1	0	0	Operation mode 4 (I ² C mode)

* This section explains the register and its operations in operation mode 4.

Notes:

- Settings other than above are prohibited.
- To switch the operation mode, disable the I²C (ISMK:EN= 0), and then switch the operation mode without a break.
- After setting the operation mode, set each register.

[bit4] WUCR: WAKE UP Control Bit

WUCR is not supported

This bit selects the pin used for external interrupts.

- This bit is reset when the SMRC:WUCRC bit in the clear register is set to "1".
- This bit is set when the SMRS:WUCRS bit in the set register is set to "1".

"0": Set the INT pin for external interrupts.

"1": Set the SDA or SCL pin for external interrupts.

Bit	Description
0	Disable the WAKE UP function.
1	Enable the WAKE UP function.

Note:

- The WAKE UP function is not supported.

[bit3] RIE: Reception Interrupt Enable Bit

- This bit enables/disables reception interrupt request output to the CPU.
- A reception interrupt request is output when the RIE bit and the reception data flag bit (SSR:RDRF) are "1" or when any of the error flag bits (SSR:ORE) is "1".
- This bit is reset when the SMRC:RIEC bit in the clear register is set to "1".
- This bit is set when the SMRS:RIES bit in the set register is set to "1".

Bit	Description
0	Disable reception interrupts.
1	Enable reception interrupts.

Note:

- To receive data using the INT bit in the I²C bus control register (IBCR) when DMA mode is disabled (SSR:DMA= 0), set this bit to "0".

[bit2] TIE: Transmission Interrupt Enable Bit

- This bit enables/disables transmission interrupt request output to the CPU.
- A transmission interrupt request is output when the TIE bit and the SSR:TDRE bit are "1".
- This bit is reset when the SMRC:TIEC bit in the clear register is set to "1".
- This bit is set when the SMRS:TIES bit in the set register is set to "1".

Bit	Description
0	Disable transmission interrupts.
1	Enable transmission interrupts.

Note:

- To transmit data using the INT bit in the I²C bus control register (IBCR) when DMA mode is disabled (SSR:DMA= 0), set this bit to "0".

[bit1:0]Reserved : Reserved Bits

8.3. I²C Bus Status Register (IBSR)

The I²C bus status register (IBSR) indicates whether the repeated start, an acknowledgment, the data direction, arbitration lost, the stop condition, the I²C bus status, and a bus error have been detected.

I²C Bus Status Register (IBSR)

Figure 8-3 shows the bit configuration of the I²C bus status register (IBSR).

Figure 8-3 Bit Configuration of the I²C Bus Status Register (IBSR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SSR)			FBT	RACK	RSA	TRX	AL	RSC	SPC	BB
R/W				R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Attribute				-	-	-	-	-	-	-	-
Protection				-	-	-	-	-	-	-	-
Attribute				-	-	-	-	-	-	-	-
Initial				0	0	0	0	0	0	0	0
Value				0	0	0	0	0	0	0	0

[bit7] FBT : First Byte Bit

This bit indicates the 1st byte.

FBT bit set condition:

1. The (repeated) start condition is detected.

FBT bit clear conditions:

1. The 2nd byte starts to be transmitted and received.
2. The stop condition is detected (except in cases where the stop condition is detected in the acknowledgment field during master operation).
3. I²C interface operation is disabled (ISMK:EN bit= 0).
4. A bus error is detected (IBCR:BER bit= 1) when EIBCR:BEC= 0.

Bit	Description
0	Not the 1st byte
1	The 1st byte is being transmitted and received.

[bit6] RACK : Acknowledgment Flag Bit

This bit indicates an acknowledgment received for the 1st byte, in master or slave mode.

RACK bit update conditions:

1. Acknowledgment for the 1st byte
2. Acknowledgment of data in master or slave mode

RACK bit clear conditions(RACK bit = 0):

1. The (repeated) start condition is detected.
2. I²C interface operation is disabled (ISMK:EN bit = 0).
3. A bus error is detected (IBCR:BER bit = 1) when EIBCR:BEC= 0.

Bit	Description
0	"L" reception
1	"H" reception

[bit5] RSA : Reserved Address Detection Bit

This bit indicates that the reserved address has been detected.

RSA bit set condition (RSA= 1):

1. The 1st byte is (0000xxxx) or (1111xxxx). The letter "x" represents "0" or "1".

RSA bit reset conditions (RSA= 0)

1. The (repeated) start condition is detected.
2. The stop condition is detected (except in cases where the stop condition is detected in the acknowledgment field during master operation).
3. I²C interface operation is disabled (ISMK:EN bit = 0).
4. A bus error is detected (IBCR:BER bit = 1) (except in cases where the stop condition is detected in the acknowledgment field during master operation).

If the RSA bit is set to "1" in the 1st byte, the interrupt flag (IBCR:INT) is set to "1" and the SCL to "L" at the SCL falling of the 8th bit in the 1st byte. This occurs regardless of whether FIFO is enabled or disabled. To read reception data and have the device operate as a slave at this time, set IBCR:ACKE to "1", and clear the interrupt flag (IBCR:INT) to "0". After that, if the TRX bit is "0", the device receives data as a slave. To prevent the device from receiving data in midstream, set the IBCR:ACKE bit to "0". Then, the device does not receive subsequent data.

Bit	Description
0	Reserved address not detected
1	Reserved address detected

Notes:

- If IBCR:ACKE is set to "0" during data transmission, "1" is a prohibited setting for IBCR:ACKE until the stop or repeated start condition is detected.
- If slave transmission has been confirmed at the time of an interrupt due to the detection of the reserved address, an ACK response is returned when the reception FIFO is enabled. Therefore, disable the reception FIFO and set IBCR:ACKE= 0.

[bit4] TRX : Data Direction Bit

This bit indicates the direction of data.

TRX bit set conditions:

1. The (repeated) start condition is transmitted in master mode.
2. The 8th bit in the 1st byte in slave mode is "1" (transmission direction as a slave).

TRX bit reset conditions:

1. Arbitration lost occurs (AL= 1).
2. The 8th bit in the 1st byte in slave mode is "0" (reception direction as a slave)
3. The 8th bit in the 1st byte in master mode is "1" (reception direction as a master).
4. The stop condition is detected (except in cases where the stop condition is detected in the acknowledgment field during master operation).
5. The (repeated) start condition is detected in a mode other than master mode.
6. I²C interface operation is disabled (ISMK:EN bit = 0).
7. A bus error is detected (IBCR:BER bit = 1) (except in cases where the stop condition is detected in the acknowledgment field during master operation).

Bit	Description
0	Reception direction
1	Transmission direction

[bit3] AL: Arbitration Lost Bit

This bit indicates arbitration lost.

AL bit set conditions:

1. The data output in master mode differs from the received data.
2. The IBCR:MSS bit is set to "1" but the device operates as a slave.
3. The repeated start condition is detected in the 1st bit of the 2nd or subsequent byte of data in master mode when EIBCR:BEC= 0.
4. The repeated start condition is detected in master mode when EIBCR:BEC= 1.
5. The stop condition is detected in the 1st bit of the 2nd or subsequent byte of data in master mode when EIBCR:BEC= 0.
6. The stop condition is detected in master mode when EIBCR:BEC= 1 (except in cases where the stop condition is detected in the acknowledgment field).
7. Generation of the repeated start condition is attempted in master mode but fails.
8. Generation of the stop condition is attempted in master mode but fails.

AL bit reset conditions:

1. "1" is written to the IBCR:MSS bit.
2. "1" is written to the IBCRC:INTC bit.
3. "1" is written to the IBSRC:SPCC bit when the AL bit is "1" and the SPC bit is "1".
4. I²C interface operation is disabled (ISMK:EN bit= 0).
5. A bus error is detected (IBCR:BER bit= 1) when EIBCR:BEC= 0.

Bit	Description
0	No arbitration lost occurred.
1	Arbitration lost occurred.

[bit2] RSC: Repeated Start Condition Check Bit

This bit indicates that the repeated start condition has been detected in master or slave mode.

RSC bit set conditions:

1. The repeated start condition is detected after an acknowledgment during operation in slave or master mode when EIBCR:BEC= 0.
2. The repeated start condition is detected in the 1st byte during operation in slave or master mode when EIBCR:BEC= 1.

RSC bit reset conditions:

1. "1" is written to the IBSRC:RSCC bit.
2. "1" is written to the IBCR:MSS bit.
3. I²C interface operation is disabled (ISMK:EN bit = 0).

Writing to this bit is invalid.

Bit	Description
0	The repeated start condition was not detected.
1	The repeated start condition was detected.

Note:

- If no acknowledgment response is returned during the reception operation in slave mode following the detection of the reserved address, slave mode ends. Consequently, even when the repeated start condition is next detected, this bit is not set to "1".

[bit1] SPC: Stop Condition Check Bit

This bit indicates that the stop condition has been detected in master or slave mode.

SPC bit set conditions:

1. The stop condition is detected after an acknowledgment during operation in slave or master mode when EIBCR:BEC= 0.
2. The stop bit is detected in any of the following cases when EIBCR:BEC= 1:
 - During transfer of the 1st byte
 - Slave mode operation in progress
 - Master mode operation in progress (except in cases where the stop condition is detected in the acknowledgment field)
3. Arbitration lost occurs in the stop condition generation operation in master mode.

SPC bit reset conditions:

1. "1" is written to the IBSRC:SPCC bit.
2. "1" is written to the IBCR:MSS bit.
3. I²C interface operation is disabled (ISMK:EN bit = 0).

Writing to this bit is invalid.

Bit	Description	
0	The stop condition was not detected.	
1	Master	The stop condition was detected, or arbitration lost occurred when the stop condition was output.
	Slave	The stop condition was detected.

Notes:

- If no acknowledgment response is returned during the reception operation in slave mode following the detection of the reserved address, slave mode ends. Consequently, even when the stop condition is next detected, this bit is not set to "1".
- If all of the following conditions are true, this bit is not set to "1", and master operation continues even when the stop condition is detected:
 - EIBCR:BEC=1
 - Master operation in progress
 - Acknowledgment field transfer in progress

[bit0] BB : Bus Status Bit

This bit indicates the bus status.

BB bit set condition:

1. "L" is detected in the SDA or SCL of the I²C bus.

BB bit reset conditions:

1. The stop condition is detected (except in cases where the stop condition is detected in the acknowledgment field during master operation).
2. I²C interface operation is disabled (ISMK:EN bit = 0).
3. A bus error is detected (IBCR:BER bit = 1) when EIBCR:BEC= 0.

Bit	Description
0	Bus idle state
1	Bus transmission and reception state

8.4. Serial Status Register (SSR)

The serial status register (SSR) is used to check the transmission and reception status.

Serial Status Register (SSR)

Figure 8-4 shows the bit configuration of the serial status register (SSR).

Figure 8-4 Bit Configuration of the Serial Status Register (SSR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	REC	TSET	DMA	TBIE	ORE	RDRF	TDRE	TBI	(IBSR)		
R/W	R0,W	R0,W	R/W	R/W	R,WX	R,WX	R,WX	R,WX			
Attribute											
Protection	-	-	-	-	-	-	-	-			
Attribute											
Initial Value	0	0	0	0	0	0	1	1			

[bit15] REC : Reception Error Flag Clear Bit

This bit clears the ORE bit in the serial status register (SSR).

- This bit is set when the SSRS:RECS bit in the set register is set to "1".
- Writing "1" clears the ORE bit.
- Writing "0" does not have any effect.

If it is read, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Clear the reception error flag (ORE).	

[bit14] TSET : Transmission Buffer Empty Flag Set Bit

This bit sets the TDRE bit in the serial status register (SSR).

- Writing "1" sets the TDRE bit. This also sets the TBI bit when DMA mode is enabled (DMA= 1).
- Writing "0" does not have any effect.
- This bit is set when the SSRS:TSETS bit in the set register is set to "1".

If it is read, "0" is always read.

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Set the TDRE bit.	

Note:

- Write "1" to this bit when the IBCR:INT bit is "1".

[bit13] DMA: DMA Mode Enable Bit

This bit disables/enables DMA mode.

- This bit is reset when the SSRC:DMAC bit in the clear register is set to "1".
- This bit is set when the SSRS:DMAS bit in the set register is set to "1".
- If this bit is set to "1", it means interrupt conditions corresponding to DMA transfer.
- If this bit is set to "0", it means interrupt conditions for cases where DMA transfer is not performed.

For details, see Table 2-1.

Bit	Description
0	Disable DMA mode.
1	Enable DMA mode.

Notes:

- This bit can be changed only when ISMK:EN= 0.
- If block transfer is performed during DMA transfer, the only block size that can be set is 1.

[bit12] TBIE : Transmission Bus Idle Interrupt Enable Bit (Valid Only when DMA Mode is Enabled)

- This bit enables/disables transmission bus idle interrupt request output to the CPU.
- A transmission bus idle interrupt request is output when DMA mode is enabled (DMA= 1) and the TBIE and TBI bits are "1".
- This bit is set to "0" when DMA mode is disabled (DMA= 0), even during writing, in which case the writing is ignored and the "0" state is retained.
- This bit is reset when the SSRC:TBIEC bit in the clear register is set to "1".
- This bit is set when the SSRS:TBIES bit in the set register is set to "1".

Bit	Description
0	Disable transmission bus idle interrupts.
1	Enable transmission bus idle interrupts.

[bit11] ORE : Overrun Error Flag Bit

- This bit is set to "1" when an overrun occurs in reception, and it is cleared by the writing of "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is output when the ORE bit and the SMR:RIE bit are "1".
- For details on interrupt request output, see Table 2-3.
- If this flag is set, the reception data register (RDR) is invalid.
- If this flag is set, no reception data is stored in the reception FIFO when used.

Bit	Description
0	No overrun error
1	Overrun error found

[bit10] RDRF : Reception Data Full Flag Bit

- This flag indicates the status of the reception data register (RDR).
- A reception interrupt request is output when the SMR:RIE bit and the reception data flag bit (RDRF) are "1".
- This flag is set to "1" when reception data is loaded into the reception data register (RDR), and it is cleared to "0" when the data in the RDR is read.
- This bit is set at the SCL falling time of the 8th bit of data.
- This bit is also set when a NACK response*1 is returned.
- RDRF is set to "1" when the predefined quantity of data is received by the reception FIFO in use.
- When ECR:RXBLKEN=0 and reading of the reception FIFO empties it during use, this bit is cleared to "0".
- When ECR:RXBLKEN=1 and using reception FIFO, this bit is clear to "0" when the number of the data in the reception FIFO is less than or equal to the value of the FBYTE register.
- If all of the following conditions are satisfied and the reception idle state continues for 8 or more clocks of the baud rate clock, the interrupt flag (SSR:RDRF) is set to "1".
 - The reception FIFO idle detection enable bit (FCR:FRIDE) is "1".
 - The data count in the reception FIFO has not reached the transfer count.
 - The IBCR:BER bit is "0".

During an 8-clock count, the counter is reset to 0 when the RDR is read, and the system starts counting the 8 clocks again.

*1 NACK response: Indicates that the SDA of the I²C bus is "H" during an acknowledgment period.

Bit	Description
0	The reception data register (RDR) is empty.
1	The reception data register RDR contains data.

Notes:

- After RDRF becomes "1" when the reception FIFO is used, resetting the reception FIFO (FCR0:FCL2,FCL1= 1) does not cause RDRF to become "0". Therefore, to set RDRF to "0" after resetting the reception FIFO, perform a dummy read on the reception data register while I2C mode is disabled (ISMK.I2CEN=0).
- If all of the following conditions are satisfied, the SCL is set to "L" after ACK transmission. The SCL is released from the "L" state when the RDRF bit is set to "0".
 - The reception FIFO is not used.
 - DMA mode is enabled (IBCR:DMA= 1).
 - The RDRF bit is "1" during the reception operation (IBSR:TRX= 0) for the 2nd or subsequent byte.
 - IBCR:WSEL=0
- If all of the following conditions are satisfied, the SCL is set to "L" after the reception of 1-byte data. The SCL is released from the "L" state when the RDRF bit is set to "0".
 - The reception FIFO is not used.
 - DMA mode is enabled (IBCR:DMA= 1).
 - The RDRF bit is "1" during the reception operation (IBSR:TRX= 0) for the 2nd or subsequent byte.

- IBCR:WSEL=1
- *If the reception FIFO is used to receive data with DMA mode enabled (DMA= 1), the SCL is set to "L" when the reception FIFO becomes full. The SCL is released from the "L" state when data is read from the RDR at least once.*

[bit9] TDRE : Transmission Data Empty Flag Bit

- This bit indicates the status of the transmission data register (TDR).
- A transmission interrupt request is output when the SMR:TIE bit and the TDRE bit are "1".
- Writing transmission data in the TDR sets this bit to "0", which indicates that the TDR contains valid data. Loading the data into the transmission shift register to start transmission sets this bit to "1", which indicates that TDR does not contain valid data.
- This bit is set when "1" is written to the TSET bit in the serial status register (SSR). Use it when the desired setting for the TDRE bit is "1" at the detection time of arbitration lost, a bus error, etc.

Bit	Description
0	The transmission data register (TDR) contains data.
1	The transmission data register is empty.

[bit8] TBI: Transmission Bus Idle Flag Bit (Valid Only when DMA Mode is Enabled)

This bit indicates that the I²C does not perform the transmission operation when DMA mode is enabled (DMA= 1). The SCL is set to “L” when DMA mode is enabled (DMA= 1) and the TBI bit is set to “1”. Writing transmission data to the TDR sets the TBI bit to “0” and releases the SCL from the “L” state.

TBI bit set conditions:

<8th bit>

1. The SSR:TDRE bit is “1” at the 2nd or subsequent byte during master operation when WSEL is “1”.
2. The SSR:TDRE bit is “1” at the 2nd or subsequent byte during slave transmission when WSEL is “1”.

<9th bit>

1. The reserved address is not detected in the 1st byte and the SSR:TDRE bit is “1” during master operation.
2. The SSR:TDRE bit is “0” at the 2nd or subsequent byte during master operation when WSEL is “1”.
3. The SSR:TDRE bit is “0” at the 2nd or subsequent byte during slave transmission when WSEL is “1”.

<Other>

“1” is written to the transmission buffer empty flag set bit (TSET).

TBI bit reset condition:

1. Transmission data is written to the transmission data register (TDR).

A transmission interrupt request is output when this bit is set to “1” and transmission bus idle interrupts are enabled (SSR:TBIE= 1).

■ This bit is “1” when DMA mode is disabled (DMA= 0).

Bit	Description
0	Transmission in progress
1	No transmission

8.5. Reception Data Register/Transmission Data Register (RDR/TDR)

The reception and transmission data registers are allocated to the same address. This register functions as the reception data register when data is read, and as the transmission data register when data is written. When the FIFO mode is enabled, RDR/TDR register address is the address of reading/writing of the FIFO.

Reception Data Register (RDR)

Figure 8-5 shows the bit configuration of the register for serial data reception (RDR).

Figure 8-5 Bit Configuration of the Reception Data Register (RDR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-			D7	D6	D5	D4	D3	D2	D1	D0
R/W				R	R	R	R	R	R	R	R
Attribute											
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

The reception data register (RDR) is the data buffer register used to receive serial data.

- The shift register converts serial data signals transmitted to the serial data line (SDA pin), and they are stored in the reception data register (RDR).
- When the 1st byte*1 is received, the lowest bit (RDR:D0) indicates the data direction.
- The reception data full flag bit (SSR:RDRF) is set to "1" when reception data is stored in the reception data register (RDR).
- The reception data full flag bit (SSR:RDRF) is automatically cleared to "0" when the data in the reception data register (RDR) is read.
- *1 1st byte: Indicates the data after the (repeated) start condition.

Notes:

- SSR:RDRF is set to "1" when the predefined quantity of data is received by the reception FIFO in use.
- SSR:RDRF is cleared to "0" when the reception FIFO becomes empty during use.

Transmission Data Register (TDR)

Figure 8-6 shows the bit configuration of the transmission data register.

Figure 8-6 Bit Configuration of the Transmission Data Register (TDR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-			D7	D6	D5	D4	D3	D2	D1	D0
R/W				W	W	W	W	W	W	W	W
Attribute				-	-	-	-	-	-	-	-
Protection				-	-	-	-	-	-	-	-
Initial Value				1	1	1	1	1	1	1	1

The transmission data register (TDR) is the data buffer register used to transmit serial data.

- The transmission data register (TDR) value is output MSB first to the serial data line (SDA pin).
- When the 1st byte*1 is transmitted, the lowest bit (TDR:D0) indicates the data direction.
- The transmission data empty flag (SSR:TDRE) is cleared to "0" when transmission data is written to the transmission data register (TDR).
- The transmission data empty flag (SSR:TDRE) is set to "1" when data is transferred to the transmission shift register.
- Transmission data cannot be written to the transmission data register (TDR) when the transmission FIFO is disabled and the data empty flag (SSR:TDRE) is "0".
- Transmission data can be written to the transmission FIFO in use until the transmission FIFO capacity is reached, even when the data empty flag (SSR:TDRE) is "0".

Note:

- The transmission data register is a write-only register, and the reception data register is a read-only register. The two registers are located at the same address, so the written value differs from the read one.

8.6. Serial Auxiliary Control Status Register (SACSR)

The serial auxiliary control status register (SACSR) can select the method of serial timer activation, enable/disable timer interrupts, set the division value of the serial timer operation clock, and enable/disable the serial timer.

Bit Configuration of the Serial Auxiliary Control Status Register (SACSR)

Figure 8-7 shows the bit configuration of the serial auxiliary control status register (SACSR).

Figure 8-7 Bit Configuration of the Serial Auxiliary Control Status Register (SACSR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved	Reserved	Reserved	Reserved	Reserved	TRG1	TRG0	TINT
R/W	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R/W	R/W	R,WX
Protection	-	-	-	-	-	-	-	-
Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TINTE	Reserved	TRGE	TDIV3	TDIV2	TDIV1	TDIV0	TMRE
R/W	R/W	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W
Protection	-	-	-	-	-	-	-	-
Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:11] Reserved : Reserved Bits

[bit10:9] TRG[1:0] : Trigger Selection Bits

These bits select the method of detecting the edge for an external trigger of serial timer activation.

Bits		Description
0	0	Rising edge detection
0	1	Falling edge detection
1	0	Both edge detection
1	1	Setting prohibited

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is "0".
- These bits are invalid when the external trigger enable bit (TRGE) is "0".

[bit8] TINT : Timer Interrupt Flag

If the serial timer register (STMR) and the serial timer comparison register (STMCR) match, the serial timer register (STMR) is set to "0", and this bit is set to "1".

A status interrupt request is output when this bit is "1" and the timer interrupt enable bit (TINTE) is "1".

Writing "0" to this bit resets it to "0".

Writing "1" to this bit is invalid.

- This bit is reset when the SACSRC:TINTC bit in the clear register is set to "1".

Bit	Description
0	No timer interrupt request
1	Timer interrupt request issued

[bit7] TINTE : Timer Interrupt Enable Bit

This bit enables/disables timer interrupts to the CPU.

A status interrupt request is output when this bit is "1" and the timer interrupt flag (TINT) is "1".

- This bit is reset when the SACSRC:TINTEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TINTES bit in the set register is set to "1".

Bit	Description
0	Disable interrupts triggered by the serial timer.
1	Enable interrupts triggered by the serial timer.

[bit6] Reserved : Reserved Bit
[bit5] TRGE : External Trigger Enable Bit

This bit selects the method of activating the serial timer.

- This bit is reset when the SACSRC:TRGEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TRGES bit in the set register is set to "1".

Bit	Description
0	The serial timer starts when the serial timer enable bit (TMRE) changes from "0" to "1".
1	If the serial timer enable bit (TMRE) is set to "1", the detection of the edge of the external trigger that is set in the trigger selection bits (TRG1, 0) starts the serial timer.

Notes:

- This bit can be changed only when the serial timer enable bit (TMRE) is "0".
- If the serial timer enable bit (TMRE) is set to "0", even the detection of the edge of the external trigger that is set in the trigger selection bits (TRG1, 0) does not start the serial timer.

[bit4-1] TDIV[3:0] : Timer Operation Clock Division Bits

These bits set the division ratio of the serial timer.

Bits				Timer Operation Clock						
				Division Ratio	Φ = 8 MHz	Φ = 10 MHz	Φ = 16 MHz	Φ = 20 MHz	Φ = 24 MHz	Φ = 32 MHz
0	0	0	0	Φ	125 ns	100 ns	62.5 ns	50 ns	41.67 ns	31.25 ns
0	0	0	1	$\Phi/2$	250 ns	200 ns	125 ns	100 ns	83.33 ns	62.5 ns
0	0	1	0	$\Phi/4$	500 ns	400 ns	250 ns	200 ns	166.67 ns	125 ns
0	0	1	1	$\Phi/8$	1 μ s	800 ns	500 ns	400 ns	333.33 ns	250 ns
0	1	0	0	$\Phi/16$	2 μ s	1.6 μ s	1 μ s	800 ns	666.67 ns	500 ns
0	1	0	1	$\Phi/32$	4 μ s	3.2 μ s	2 μ s	1.6 μ s	1.33 μ s	1 μ s
0	1	1	0	$\Phi/64$	8 μ s	6.4 μ s	4 μ s	3.2 μ s	2.67 μ s	2 μ s
0	1	1	1	$\Phi/128$	16 μ s	12.8 μ s	8 μ s	6.4 μ s	5.33 μ s	4 μ s
1	0	0	0	$\Phi/256$	32 μ s	25.6 μ s	16 μ s	12.8 μ s	10.67 μ s	8 μ s

Φ : Bus clock

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is "0".
- Settings other than the above are prohibited.

[bit0] TMRE : Serial Timer Enable Bit

This bit enables or disables serial timer operation.

- This bit is reset when the SACSRC:TMREC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TMRES bit in the set register is set to "1".

Bit	Description
0	Stop the operation of the serial timer. The value of the serial timer register (STMR), when stopped, is retained.
1	Initialize the serial timer register (STMR) to "0" and start the operation of the serial timer when this bit changes from "0" to "1".

Note:

- When external triggers are enabled (TRGE= 1), setting this bit to "1" does not start the serial timer until the detection of the edge of the external trigger that is set in the trigger selection bits (SACSR:TRG1, 0).

8.7. Serial Timer Register (STMR)

The serial timer register (STMR) represents the timer value of the serial timer.

Bit Configuration of the Serial Timer Register (STMR)

Figure 8-8 shows the bit configuration of the serial timer register (STMR).

Figure 8-8 Bit Configuration of the Serial Timer Register (STMR)

Bit	15	14	13	12	11	10	9	8
Field	TM15	TM14	TM13	TM12	TM11	TM10	TM9	TM8
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection	-	-	-	-	-	-	-	-
Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TM7	TM6	TM5	TM4	TM3	TM2	TM1	TM0
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection	-	-	-	-	-	-	-	-
Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TM15-0 : Timer Data Bits

These bits indicate the timer value of the serial timer.

While the timer is operating, the timer value of the serial timer is incremented by 1 for every timer operation clock (as set in SACSr:TDIV3 to 0).

Note:

- These bits are initialized to "0" when timer operation starts.

8.8. Serial Timer Comparison Register (STMCR)

The serial timer comparison register (STMCR) sets the timer comparison value of the serial timer.

Bit Configuration of the Serial Timer Comparison Register (STMCR)

Figure 8-9 shows the bit configuration of the serial timer comparison register (STMCR).

Figure 8-9 Bit Configuration of the Serial Timer Comparison Register (STMCR)

Bit	15	14	13	12	11	10	9	8
Field	TC15	TC14	TC13	TC12	TC11	TC10	TC9	TC8
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TC7	TC6	TC5	TC4	TC3	TC2	TC1	TC0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TC15-0 : Compare Bits

These bits set the comparison value of the serial timer.

These bits are compared with the serial timer register (STMR). If the serial timer register (STMR) matches these bits when updated, the serial timer register is set to "0". At this time, the timer interrupt flag (SACSR:TINT) is set to "1".

The interval of the following operation is (STMCR:TC + 1) * timer operation clock (as set in SACSR:TDIV3 to 0):

- Setting SACSR:TINT to "1"

Notes:

- If this register is set to 0x0000, the timer is operating, and the division value (SACSR:TDIV) of the timer operation clock is set to 0b0000, the timer interrupt flag (SACSR:TINT) is fixed at "1".
- This register can be changed only when the serial timer is disabled (SACSR:TMRE= 0).

8.9. Noise Filter Control Register (NFCR)

The noise filter control register (NFCR) sets the noise filter time.

Noise Filter Control Register (NFCR)

Figure 8-10 shows the bit configuration of the noise filter control register (NFCR).

Figure 8-10 Bit Configuration of the Noise Filter Control Register (NFCR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(EIBCR)			Reserved	Reserved	Reserved	NFT4	NFT3	NFT2	NFT1	NFT0
R/W Attribute				R0,W0	R0,W0	R0,W0	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved : Reserved Bits

[bit4:0] NFT : Noise Filter Time Selection Bits

These bits select the noise filter time for serial clock input (SCL) and serial data input (SDA).

The calculation formula for the noise filter time is as follows:

$$\text{Noise filter time} = (\text{NFT} + 1) * 2 * \text{bus clock cycle time}$$

Table 8-2 shows the relationship between the noise filter time selection bits and bus clock frequency. Adjust the noise filter time selection bits according to the bus clock frequency.

Notes:

- Set these bits when the EN bit in the ISMK register is "0".
- Combinations not listed in Table 8-2 are prohibited.

Table 8-2 Relationship between the Noise Filter Time Selection Bits and Bus Clock Frequency

Bits					Bus Clock Frequency [MHz]
0	0	0	0	0	8 MHz to less than 40 MHz*1
0	0	0	0	1	40 MHz to less than 60 MHz
0	0	0	1	0	60 MHz to less than 80 MHz
0	0	0	1	1	80 MHz to less than 100 MHz
0	0	1	0	0	100 MHz to less than 120 MHz
0	0	1	0	1	120 MHz to less than 140 MHz
0	0	1	1	0	140 MHz to less than 160 MHz
0	0	1	1	1	160 MHz to less than 180 MHz
0	1	0	0	0	180 MHz to less than 200 MHz
0	1	0	0	1	200 MHz to less than 220 MHz
0	1	0	1	0	220 MHz to less than 240 MHz
0	1	0	1	1	240 MHz to less than 260 MHz
0	1	1	0	0	260 MHz to less than 280 MHz
0	1	1	0	1	280 MHz to less than 300 MHz
0	1	1	1	0	300 MHz to less than 320 MHz
0	1	1	1	1	320 MHz to less than 340 MHz
1	0	0	0	0	340 MHz to less than 360 MHz
1	0	0	0	1	360 MHz to less than 380 MHz
1	0	0	1	0	380 MHz to less than 400 MHz

*1 In standard mode, this is 2 MHz to less than 40 MHz.

8.10. Extended I²C Bus Control Register (EIBCR)

The extended I²C bus control register (EIBCR) controls SDA/SCL output and sets whether to continue operation after a bus error occurs.

Extended I²C Bus Control Register (EIBCR)

Figure 8-11 shows the bit configuration of the extended I²C bus control register (EIBCR).

Figure 8-11 Bit Configuration of the Extended I²C Bus Control Register (EIBCR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	SDAS	SCLS	SDAC	SCLC	SOCE	BEC	(NFCR)		
R/W	R0,W0	R0,W0	R,WX	R,WX	R/W	R/W	R/W	R/W			
Initial Value	0	0	0	0	1	1	0	0			

[bit15-14] Reserved : Reserved Bits

[bit13] SDAS : SDA Status Bit

This bit indicates the signal level of the SDA line after a signal passes through the noise filter.

Bit	Description
0	The SDA line is "L".
1	The SDA line is "H".

Note:

- This bit is valid only when the I²C is enabled (ISMK:EN= 1). When the I²C is disabled (ISMK:EN= 0), this bit always reads "0".

[bit12] SCLS : SCL Status Bit

This bit indicates the signal level of the SCL line after a signal passes through the noise filter.

Bit	Description
0	The SCL line is "L".
1	The SCL line is "H".

Note:

- This bit is valid only when the I²C is enabled (ISMK:EN= 1). When the I²C is disabled (ISMK:EN= 0), this bit always reads "0".

[bit11] SDAC : SDA Output Control Bit

This bit controls SDA output when serial output control is enabled (SOCE= 1).

Bit	Description
0	SDA output is "L".
1	SDA output is "H".

[bit10] SCLC : SCL Output Control Bit

This bit controls SCL output when serial output control is enabled (SOCE= 1).

Bit	Description
0	SCL output is "L".
1	SCL output is "H".

[bit9] SOCE : Serial Output Enable Bit

This bit enables serial output control.

If this bit is set to "1", operation is as follows.

- The SDA output control bit (SDAC) controls SDA output.
- The SCL output control bit (SCLC) controls SCL output.

Bit	Description
0	Disable serial output control.
1	Enable serial output control.

Note:

- Set this bit to "1" only when IBCR:MSS= 0 and IBCR:ACT= 0.

[bit8] BEC : Bus Error Control Bit

This bit selects whether to continue or stop I²C operation after a bus error occurs (IBSR:BER= 1).

Bit	Description
0	Stop I ² C operation.
1	Continue I ² C operation.

Note:

- If the start condition is detected again during address data transfer after the start condition was detected or during transfer of bit2 to bit9 (acknowledgment bits) when EIBCR:BEC= 0, a bus error is detected (IBCR:BER= 1) and reception is stopped. Consequently, the next data cannot be received.
In this case, after the interrupt flag (IBCR:INT) is cleared, retransmission of the start condition from the master is necessary.

8.11. 7-Bit Slave Address Mask Register (ISMK)

The 7-bit slave address mask register (ISMK) specifies whether to compare slave address bits.

7-Bit Slave Address Mask Register (ISMK)

Figure 8-12 shows the bit configuration of the 7-bit slave address mask register (ISMK).

Figure 8-12 Bit Configuration of the 7-Bit Slave Address Mask Register (ISMK)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	EN	SM6	SM5	SM4	SM3	SM2	SM1	SM0	(ISBA)		
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W			
Protection	-	-	-	-	-	-	-	-			
Attribute											
Initial Value	0	1	1	1	1	1	1	1			

[bit15] EN : I2C Interface Operation Enable Bit

This bit enables/disables I2C interface operation.

"0": Disable I2C interface operation.

"1": Enable I2C operation.

Bit	Description
0	Disable
1	Enable

Notes:

- This bit is not cleared to "0" even when the BER bit in the IBCR register is set to "1".
- Set the baud rate generator when this bit is "0".
- Set the 7-bit slave address and 7-bit slave address mask registers when this bit is "0".
- Transmission and reception are disabled immediately after the I2C interface is disabled (EN=0).
- If you want to disable I2C interface operation after generating the stop condition by writing "0" to the IBCR:MSS bit, verify that the stop condition is generated, and then disable operation (EN=0).
- If the EN bit is set to "0" during transmission, a pulse may be generated on the SDA/SCL of the I2C bus.

[bit14:8] SM[n] n=6 to 0 : Slave Address Mask Bits

These bits specify whether a 7-bit slave address and the received address are excluded from comparison.

Bits set to "1": Compare them.

Bits set to "0": Handle them as a match.

SM[n] n=6 to 0	Description
0	Do not compare bits.
1	Compare bits.

Note:

- Set this register when the EN bit is "0".

8.12. 7-Bit Slave Address Register (ISBA)

The 7-bit slave address register (ISBA) sets a slave address.

7-Bit Slave Address Register (ISBA)

Figure 8-13 shows the bit configuration of the 7-bit slave address register (ISBA).

Figure 8-13 Bit Configuration of the 7-Bit Slave Address Register (ISBA)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(ISMK)			SAEN	SA6	SA5	SA4	SA3	SA2	SA1	SA0
R/W				R/W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Attribute											
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

[bit7] SAEN : Slave Address Enable Bit

This bit enables slave address detection.

"0": Do not detect the slave address.

"1": Compare the ISBA and ISMK settings with the 1st byte received.

Bit	Description
0	Disable
1	Enable

[bit6:0] SA[6:0] : 7-Bit Slave Address

- If slave address detection is enabled (SAEN= 1), the 7-bit slave address register (ISBA) compares the 7-bit data received after the detection of the (repeated) start condition with this register. If all bits match, the device operates in slave mode, and ACK is output. Then, the received slave address is set in this register. (If SAEN= 0, ACK is not output.)
- The 1st received data after detecting the (repeated) start condition consists of 7-bit slave address and the bit that specifies the direction of data transfer. It compares the slave address included in the received data to these bits.
- The address bit for which "0" is set in ISMK is excluded from the comparison.

Figure 8-14 The 1st byte format after detecting the (repeated) start condition

Compare the slave address with the 7-bit slave address register (ISBA)

SA[6:0]	Description
Write / Read	7-bit slave address

Notes:

- *Setting the reserved address is prohibited.*
- *Set this register when the EN bit in the ISMK register is "0".*

8.13. Baud Rate Generator Registers 1, 0 (BGR1, BGR0)

Baud rate generator registers 1, 0 (BGR1, BGR0) set the division ratio of the serial clock.

Bit Configuration of Baud Rate Generator Registers 1 and 0 (BGR1, BGR0)

Figure 8-15 shows the bit configuration of baud rate generator registers 1 and 0 (BGR1, BGR0).

Figure 8-15 Bit Configuration of Baud Rate Generator Registers 1 and 0 (BGR1, BGR0)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	Reserved	BGR1							BGR0							
R/W Attribute	R0, W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The baud rate generator registers set the division ratio of the serial clock.

BGR1 represents the upper bits, and BGR0 represents the lower bits. The reload value for counting can be written to these registers, and the setting value can be read.

The reload counter starts counting when a reload value is written to baud rate generator registers 0 and 1 (BGR1, BGR0).

[bit15] Reserved : Reserved Bit

[bit14:8] BGR1 : Baud Rate Generator Register 1

BGR1	Description
Write	Write a value to reload counter bit8 to 14.
Read	Read the BGR1 setting value.

[bit7:0] BGR0 : Baud Rate Generator Register 0

BGR0	Description
Write	Write a value to reload counter bit0 to 7.
Read	Read the BGR0 setting value.

Notes:

- Use 16-bit access when writing a value to the baud rate generator registers (BGR1, BGR0).
- Set the baud rate generator registers when the EN bit in the ISMK register is "0".
- Set a baud rate regardless of whether the mode is master or slave.
- In operation mode 4 (I²C mode), use the bus clock at 8 MHz or more. A baud rate generator setting exceeding 400 kbps is prohibited in this mode.

8.14. FIFO Control Register 1 (FCR1)

FIFO control register 1 (FCR1) sets the FIFO test, selects the transmission and reception FIFOs, enables transmission FIFO interrupts, and controls the interrupt flag.

Bit Configuration of FIFO Control Register 1 (FCR1)

Figure 8-16 shows the bit configuration of FIFO control register 1 (FCR1).

Figure 8-16 Bit Configuration of FIFO Control Register 1 (FCR1)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	FLSTE	FRIIE	FDRQ	FTIE	FSEL	(FCR0)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R/W	R/W	R,WX	R/W	R/W			
Protection	-	-	-	-	-	-	-	-			
Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	1	0	0			

[bit15:13] Reserved : Reserved Bits

[bit12] FLSTE : Retransmission Data Lost Detection Enable Bit

This bit enables the detection of the FIFO Retransmission Data Lost Flag Bit (FCR0:FLST).

- This bit is reset when the FCR1C:FLSTEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FLSTES bit in the set register is set to "1".

"0": Disable FCR0:FLST bit detection.

"1": Enable FCR0:FLST bit detection.

Bit	Description
0	Disable data lost detection.
1	Enable data lost detection.

Note:

- To set this bit to "1", set the FSET bit to "1" first, and then set this bit to "1".

[bit11] FRIIE : Reception FIFO Idle Detection Enable Bit

When the reception FIFO has valid data, this bit enables or disables detection of the reception idle state that continues for an 8-bit time or longer. If reception interrupts are enabled (SMR:RIE= 1), the detection of the reception idle state generates a reception interrupt.

- This bit is reset when the FCR1C:FRIIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FRIIES bit in the set register is set to "1".

"0": Disable detection of the reception idle state.

"1": Enable detection of the reception idle state.

Bit	Description
0	Disable detection of reception FIFO idle.
1	Enable detection of reception FIFO idle.

Note:

- To use the reception FIFO, set this bit to "1".

[bit10] FDRQ : Transmission FIFO Data Request Bit

This bit requests transmission FIFO data.

"1" in this bit indicates that transmission data is requested. At this time, if transmission interrupts are enabled (FTIE= 1), a transmission FIFO interrupt request is output .

FDRQ set conditions

- When transmission FIFO interrupt control is not used
 - FBYTE (for transmission) = 0 (The transmission FIFO is empty.)
 - The transmission FIFO is reset.
- When transmission FIFO interrupt control is used
 - When ECR:TXBLKEN= 0
 - FTICR setting value \geq FTICR read value (The data count stored in the transmission FIFO is at the interrupt trigger level or lower.)
 - When ECR:TXBLKEN= 1
 - FTICR setting value \leq Free data count in transmission FIFO
 - The transmission FIFO is reset.

FDRQ reset conditions

- "1" is written to the FCR1C:FDRQC bit.
- When ECR:TXBLKEN= 0
 - The transmission FIFO becomes full.
- When ECR:TXBLKEN= 1
 - FTICR setting value \geq Free data count in transmission FIFO

Bit	Description
0	No transmission FIFO data request
1	Transmission FIFO data request issued

Notes:

- Writing "0" to this bit is inhibited when FBYTE(for transmission) = "0".
- The FSEL bit cannot be changed when this bit is "0".
- Writing to this bit is invalid.
- If a transmission interrupt is generated, and the necessary data is written to the transmission FIFO, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.

[bit9] FTIE : Transmission FIFO Interrupt Enable Bit

This bit enables a transmission FIFO interrupt. If this bit is set to "1" when the FDRQ bit is "1", an interrupt is generated.

- This bit is reset when the FCR1C:FTIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FTIES bit in the set register is set to "1".

Bit	Description
0	Disable transmission FIFO interrupts.
1	Enable transmission FIFO interrupts.

Note:

- Set FTIE=0 if FIFO is not used when block transfer.

[bit8] FSEL : FIFO Selection Bit

This bit selects the transmission and reception FIFOs.

- This bit is reset when the FCR1C:FSELC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FSELS bit in the set register is set to "1".

"0": Allocate FIFO1 as the transmission FIFO and FIFO2 as the reception FIFO.

"1": Allocate FIFO2 as the transmission FIFO and FIFO1 as the reception FIFO.

Bit	Description
0	Transmission FIFO: FIFO1; reception FIFO: FIFO2
1	Transmission FIFO: FIFO2; reception FIFO: FIFO1

Notes:

- This bit is not cleared by a FIFO reset (FCL2, FCL1= 1).
- To change the value of this bit, disable FIFO operation (FCR0:FE2, FE1= 0) first.
- This bit cannot be changed when FDRQ= 0.
- Set the FIFO Selection Bit (FCR1:FSEL) before setting the FIFO byte register (FBYTE) and the Transmission FIFO Interrupt Control Register (FTICR).
- It can not access the FIFO byte register (FBYTE) at the same access.

8.15. FIFO Control Register 0 (FCR0)

FIFO control register 0 (FCR0) enables/disables FIFO operation, performs a FIFO reset, saves the read pointer, and sets retransmission.

Bit Configuration of FIFO Control Register 0 (FCR0)

Figure 8-17 shows the bit configuration of FIFO control register 0 (FCR0).

Figure 8-17 Bit Configuration of FIFO Control Register 0 (FCR0)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(FCR1)			Reserved	FLST	FLD	FSET	FCL2	FCL1	FE2	FE1
R/W Attribute				R0,W0	R,WX	R,W	R0,W	R0,W	R0,W	R/W	R/W
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved : Reserved Bit

[bit6] FLST : FIFO Retransmission Data Lost Flag Bit

This bit indicates that the retransmission data of the transmission FIFO has been lost.

FLST set condition

- Data is written to the FIFO when the FLSTE bit in FIFO control register 1 (FCR1) is "1" and the write pointer of the transmission FIFO coincides with the read pointer saved by the FSET bit.

FLST reset conditions

- Transmission FIFO reset.
 - When FCR1:FSEL="0", set "1" to the FCR0:FCL1.
 - When FCR1:FSEL="1", set "1" to the FCR0:FCL2.
- "1" is written to the FSET bit.

When this bit is set to "1", the data pointed to by the read pointer stored by the FSET bit is overwritten. Also, the FLD bit cannot set retransmission even if an error occurs. To perform retransmission with this bit set to "1", perform a FIFO reset, and write data to the FIFO again.

Bit	Description
0	Data has not been lost.
1	Data has been lost.

[bit5] FLD : FIFO Pointer Reload Bit

This bit reloads the data saved in the transmission FIFO by the FSET bit, into the read pointer. This bit is used for retransmission in such cases as communication errors.

This bit is set to "0" when retransmission setting is completed.

- This bit is set when the FCR0S:FLDS bit in the set register is set to "1".

Bit	Description
0	Do not reload.
1	Reload.

Notes:

- Since a reload to the read pointer is in progress while this bit is "1", operations other than FIFO reset are prohibited.
- Setting this bit to "1" is prohibited while FIFO is enabled or transmission is in progress.
- To set the SMR:TIE bit to "1", first set it to "0", write "1" to this bit, and enable the transmission FIFO. Then, set the SMR:TIE bit to "1".

[bit4] FSET : FIFO Pointer Saving Bit

This bit stores the read pointer of the transmission FIFO.

With the read pointer saved before transmission, retransmission is possible in such cases as communication errors, provided that the FLST bit is "0".

- This bit is set when the FCR0S:FSETS bit in the set register is set to "1".

"1": Save the current read pointer value.

"0": No effect

Bit	Description
0	Do not save.
1	Save.

Note:

- Set this bit to "1" when the transmission byte count (FBYTE) is 0.

[bit3] FCL2 : FIFO2 Reset Bit

This bit resets FIFO2.

If this bit is set to "1", the internal status of FIFO2 is initialized.

Only the FCR0:FLST bit is initialized, and the values of other bits in the FCR1/0 register are retained.

- This bit is set when the FCR0S:FCL2S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO2.	

Notes:

- After disabling FIFO2, reset FIFO2.
- Before performing the reset, set the transmission FIFO interrupt enable bit to "0".

- The valid data count of the FBYTE2 register is set to 0.
- TDR register and RDR register are not initialized.

[bit2] FCL1 : FIFO1 Reset Bit

This bit resets FIFO1.

If this bit is set to "1", the internal status of FIFO1 is initialized.

Only the FCR0:FLST bit is initialized, and the values of other bits in the FCR1/0 register are retained.

- This bit is set when the FCR0S:FCL1S bit in the set register is set to "1".

Bit	Description	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO1.	

Notes:

- After disabling FIFO1, reset FIFO1.
- Before performing the reset, set the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE1 register is set to 0.
- TDR register and RDR register are not initialized.

[bit1] FE2 : FIFO2 Operation Enable Bit

This bit enables or disables FIFO2 operation.

- Set this bit to "1" when using FIFO2.
- If a reception error occurs when this FIFO is selected as the reception FIFO by the FCR1:FSEL bit, this bit is cleared to "0". After that, this bit cannot be set to "1" until the reception error is cleared.
- To use FIFO2 as the transmission FIFO, set this bit to "1" when the transmission buffer is empty (SSR:TDRE= 1). To use it as the reception FIFO, set this bit to "0" when the reception buffer is empty (SSR:RDRF= 0).
- Disabling FIFO2 does not change the state of FIFO2.
- This bit is reset when the FCR0C:FE2C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE2S bit in the set register is set to "1".

Bit	Description
0	Disable FIFO2 operation.
1	Enable FIFO2 operation.

Notes:

- When the IBSR:BB bit is "0" or the IBCR:INT bit is "1", change the enable/disable setting accordingly.
- If this FIFO is selected as the reception FIFO and operates for slave transmission after the reserved address is detected, set this bit to "0" upon an interrupt triggered by the detection of the reserved address. Also set IBCR:ACE= 0.

- If the SSR:RDRF bit is "1" when this FIFO is used as the reception FIFO and this bit changes from "1" to "0", the reception FIFO is not disabled until the SSR:RDRF bit is set to "0".
- To change this bit from "0" to "1" when FIFO2 is used as the transmission FIFO and contains data, set the SMR:TIE bit to "0" before writing "1" to this bit. Then, set the SMR:TIE bit to "1".

[bit0] FE1 : FIFO1 Operation Enable Bit

This bit enables or disables FIFO1 operation.

- Set this bit to "1" when using FIFO1.
- If a reception error occurs when this FIFO is selected as the reception FIFO by the FCR1:FSEL bit, this bit is cleared to "0". After that, this bit cannot be set to "1" until the reception error is cleared.
- To use FIFO1 as the transmission FIFO, set this bit to "1" when the transmission buffer is empty (SSR:TDRE= 1). To use it as the reception FIFO, set this bit to "0" when the reception buffer is empty (SSR:RDRF= 0).
- Disabling FIFO1 does not change the state of FIFO1.
- This bit is reset when the FCR0C:FE1C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE1S bit in the set register is set to "1".

Bit	Description
0	Disable FIFO1 operation.
1	Enable FIFO1 operation.

Notes:

- When the IBSR:BB bit is "0" or the IBCR:INT bit is "1", change the enable/disable setting accordingly.
- If this FIFO is selected as the reception FIFO and operates for slave transmission after the reserved address is detected, set this bit to "0" upon an interrupt triggered by the detection of the reserved address. Also set IBCR:ACKE= 0.
- If the SSR:RDRF bit is "1" when this FIFO is used as the reception FIFO and this bit changes from "1" to "0", the reception FIFO is not disabled until the SSR:RDRF bit is set to "0".
- To change this bit from "0" to "1" when FIFO1 is used as the transmission FIFO and contains data, set the SMR:TIE bit to "0" before writing "1" to this bit. Then, set the SMR:TIE bit to "1".

8.16. FIFO Byte Register (FBYTE)

The FIFO byte register (FBYTE) indicates the valid data count of the FIFO. This register can also specify whether to generate a reception interrupt when the reception FIFO receives the predefined quantity of data.

Bit Configuration of the FIFO Byte Register (FBYTE)

Figure 8-18 shows the bit configuration of the FIFO byte register (FBYTE).

Figure 8-18 Bit Configuration of the FIFO Byte Register (FBYTE)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FBYTE2								FBYTE1							
R/W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Protection	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FBYTE register indicates the valid data count of the FIFO. Table 8-3 shows the relationship between the FCR1:FSEL bit settings and FBYTE.

Table 8-3 Data Count Indication

FSEL	FIFO Selection	Data Count Indication
0	FIFO2: Reception FIFO; FIFO1: Transmission FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1
1	FIFO2: Transmission FIFO; FIFO1: Reception FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1

- The initial transfer count value of the FBYTE register is 0x08.
- In FBYTE of the reception FIFO, set the data count that generates a reception interrupt flag. The interrupt flag (SSR:RDRF) is set to "1" when this set transfer count matches the data count indication in the FBYTE register.
- If both of the following conditions are satisfied and the reception idle state continues for 8 or more clocks of the baud rate clock, the interrupt flag (SSR:RDRF) is set to "1".
 - The reception FIFO idle detection enable bit (FCR:FRIIE) is "1".
 - The data count in the reception FIFO has not reached the transfer count.

During an 8-clock count, the counter is reset to 0 when the RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, the counting resumes.

- To receive data during master operation (master reception), set the SMR:TIE bit to "0", set the reception data count in the FBYTE register of the transmission FIFO, and write "0" to the FCR1:FDRQ bit. SCL clocks equivalent to the set data are output. Then, the IBCR:INT bit is set to "1". If you want to set the SMR:TIE bit to "1", do so after the FCR1:FDRQ is set to "1".
- When writing a transmission data to the TDR register one time, the FBYTE of the transmission FIFO is incremented by one (" +1").
- When reading a reception data from the RDR register one time, the FBYTE of the reception FIFO is decremented by one (" -1").
- During block transfer, the value of this register is the block transfer count.

[bit15:8] FBYTE2: FIFO2 Data Count Indication byte
[bit7:0] FBYTE1: FIFO1 Data Count Indication Byte

FBYTE2, FBYTE1	Description
Write	Set the transfer count.
Read	Read the valid data count.

Read (valid data count)

Transmission: Data count that was written but not sent to the transmission FIFO

Reception: Data count that has been received but not read by the reception FIFO

Write (transfer count)

Transmission: Set 0x00.

Reception: Set the data count that generates a reception interrupt.

Table 8-4 FIFO-Stored Data Count

FIFO Capacity	Maximum FBYTE Count	Data Count That Can Be Stored
16 bytes	16	16
32 bytes	32	32
64 bytes	64	64

Notes:

- Set FBYTE of the transmission FIFO to 0x00, except when receiving data during master operation.
- For the transmission data count for data reception during master operation, set the count when the transmission FIFO is empty and the SMR:TIE bit is "0".
- Before disabling the I²C interface (ISMK:EN= 0) while data is being received in master operation, first disable the transmission and reception FIFOs.
- When the reception FIFO is not used, the reception block size is "1" for block transfer regardless of the setting of this register.
- Under any of the following conditions, change the setting.
 - The I2C interface is disabled (ISMK:EN= 0).
 - IBCR:INT is "1" during master reception when SSR:DMA= 0.
 - SSR:TBI is "1" during master reception when SSR:DMA= 1.
- Settings that exceed the FIFO capacity are prohibited.
- To receive data during master operation (master reception), set the SMR:TIE bit to "0", and do not write dummy data to the transmission data register (TDR) when setting the reception data count in the FBYTE register of the transmission FIFO.
- After setting the FIFO Selection Bit (FCR1:FSEL), set the FIFO byte register (FBYTE).
- The FIFO Selection Bit and the FIFO byte register can not be set at the same time.
- The indication of transmission FIFO data number is indicated as the valid value that is the number of writing times of the transmission data decremented by one. This is the reason that a transmission data written is transferred to transmission FIFO when TDR register has a data not transmitted. When the data in TDR register is transmitted, the data not transmitted in transmission FIFO is transferred to TDR register.

- *The indication of reception FIFO data number is indicated the number of the data received to reception FIFO and not read from reception FIFO. The data receiving in RDR register is not included.*

8.17. Transmission FIFO Interrupt Control Register (FTICR)

The transmission FIFO interrupt control register (FTICR) is used to set the interrupts triggered by the valid data count for FIFO transmission.

Transmission FIFO Interrupt Control Register (FTICR)

Figure 8-19 shows the bit configuration of the transmission FIFO interrupt control register (FTICR).

Figure 8-19 Bit Configuration of the Transmission FIFO Interrupt Control Register (FTICR)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FTICR2								FTICR1							
R/W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The function of this bit is changed by the value of ECR:TXBLKEN.

- ECR:TXBLKEN="0"

The FTICR register sets the interrupt trigger level by the valid transmission data count (remaining amount) of the transmission FIFO.

- ECR:TXBLKEN="1"

The FTICR register sets the interrupt trigger level by the number of the empty data in transmission FIFO.

Table 8-5 Transmission FIFO Setting by FCR1:FSEL

FSEL	Selection of Transmission FIFO	Transmission FIFO Interrupt Control Register
0	FIFO1	FTICR1
1	FIFO2	FTICR2

- The initial value of the valid data count for generating interrupts is 0x00 in the FTICR register.
- Set the data count that generates a transmission interrupt in FTICR of the transmission FIFO.
- When ECR:TXBLKEN="0", the interrupt flag (FDRQ) is set to "1" when the set data count matches or is smaller than the valid data count of the transmission FIFO (FTICR or FBYTE).
- When ECR:TXBLKEN="1", the interrupt flag (FDRQ) is set to "1" when the set data count matches or is smaller than the number of the empty data in transmission FIFO. When the number of data set to this register is bigger than the number of the empty data in transmission FIFO, the interrupt flag (FCR1:FDRQ) is set to "0".
- Set FTICR such that the setting satisfies $FTICR \leq \text{FIFO capacity} - 2$.
- The read value shows the valid data count of the FIFO.
- Transmission FIFO: Quantity of written but not-yet-transmitted data in the transmission FIFO
- Reception FIFO: Quantity of received but unread data in the reception FIFO

[bit15:8] FTICR2: FIFO2 Data Count Indication byte**[bit7:0] FTICR1: FIFO1 Data Count Indication Byte**

FTICR2, FTICR1	Description
Write	Set the valid data count that generates an interrupt.
Read	Read the valid data count.

Notes:

- Settings that exceed the FIFO capacity are prohibited.
- The setting value cannot be read.
- For the display of the FIFO data count for transmission, the written count for transmission data minus 1 is displayed as the valid data count. This is because the transmission FIFO stores any transmission data written to the TDR register that still contains data not yet transmitted. When the data in the TDR register is transmitted, the not-yet-transmitted data in the transmission FIFO is transferred to the TDR register.
- For the display of the FIFO data count for reception, the quantity of received but unread data in the reception FIFO is displayed. The data count does not include the data being received in the RDR register.
- For ECR:TXBLKEN = 0, if block transfer is performed during DMA transfer, only 1 can be set as the block size.
- To perform block transfer with ECR:TXBLKEN = 1, set the value of the block size to this register.

8.18. Extended Control Register (ECR)

The extended control register (ECR) can be used to set block transfer.

Bit Configuration of the Extended Control Register (ECR)

Figure 8-20 shows the bit configuration of the extended control register (ECR).

Figure 8-20 Bit Configuration of the Extended Control Register (ECR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(ESR)			Reserved	Reserved	Reserved	EISEL	REIE	TEIE	RX BLKEN	TX BLKEN
R/W Attribute				R0,W0	R0,W0	R0,W0	R/W	R/W	R/W	R/W	R/W
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved : Reserved Bits

[bit4] EISEL : Error Interrupt Request Output Selection Bit

This error interrupt output bit selects output from an interrupt request pin or output from an error interrupt request pin. For details on the interrupt output selection, see Table 2-2 and Table 2-3.

Bit	Description
0	Output a reception error interrupt request from the reception interrupt request pin. Output a transmission error interrupt request from the transmission interrupt request pin.
1	Output a reception error interrupt request from the reception error interrupt request pin. Output a transmission error interrupt request from the transmission error interrupt request pin.

[bit3] REIE : Reception Error Interrupt Enable Bit

This bit enables/disables reception error interrupt request output. For details on the target interrupt factors, see Table 2-3.

Bit	Description
0	Disable reception error interrupts.
1	Enable reception error interrupts.

[bit2] TEIE : Transmission Error Interrupt Enable Bit

This bit enables/disables transmission error interrupt request output. For details on the target interrupt factors, see Table 2-2.

Bit	Description
0	Disable transmission error interrupts.
1	Enable transmission error interrupts.

[bit1] RXBLKEN : Reception Block Transfer Setting Bit

This bit sets the DMA transfer mode for reception.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

[bit0] TXBLKEN : Transmission Block Transfer Setting Bit

This bit sets the DMA transfer mode for transmission.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Description
0	Demand transfer mode
1	Block transfer mode

8.19. Extended Status Register (ESR)

The extended status register (ESR) is used to check the reception block transfer error flag and transmission block transfer error flag.

Extended Status Register (ESR)

Figure 8-21 shows the bit configuration of the extended status register (ESR).

Figure 8-21 Bit Configuration of the Extended Status Register (ESR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	Reserved	RXUDR	TXOVR	RBERR	TBERR	(ECR)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R0,W0	R,WX	R,WX	R,WX	R,WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved : Reserved Bits

[bit11] RXUDR : Reception FIFO under Run Flag Bit

If the reception FIFO is read when empty due to a block transfer, this bit is set to "1".

- This bit is reset when the ESRC:RXUDRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-3.

Bit	Description
0	No reception FIFO under run has occurred.
1	A reception FIFO under run has occurred.

Notes:

- This bit is "0" when the reception block transfer enable (ECR:RXBLKEN) is "0".
- This bit is set only when the reception FIFO is used.
- This bit is "0" when the reception FIFO is disabled.

[bit10] TXOVR : Transmission FIFO Overrun Flag Bit

If the transmission FIFO is written when full due to a block transfer, this bit is set to "1".

- This bit is reset when the ESRC:TXOVR bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-2.

Bit	Description
0	No transmission FIFO overrun has occurred.
1	A transmission FIFO overrun has occurred.

Notes:

- This bit is "0" when the transmission block transfer enable (ECR:TXBLKEN) is "0".
- This bit is set only when the transmission FIFO is used.
- This bit is "0" when the transmission FIFO is disabled.

[bit9] RBERR : Reception Block Transfer Error Bit

This bit indicates that a block transfer error occurred during reception.

If a block transfer is performed using a value larger than the set threshold value in the FBYTE register, it is handled as a block transfer error. If reception interrupts are enabled (SMR:RIE= 1), a reception interrupt is generated.

- This bit is reset when the ESRC:RBERRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-3.

Bit	Description
0	No reception block transfer error has occurred.
1	Reception block transfer error has occurred.

Notes:

- This bit is "0" when the reception block transfer enable (ECR:RXBLKEN) is "0" or when the reception interrupt enable bit is "0".

[bit8] TBERR : Transmission Block Transfer Error Bit

This bit indicates that a block transfer error occurred during transmission.

If a block transfer is performed using a value larger than the set threshold value in the FTICR register, it is handled as a block transfer error. Then, this bit is set to "1". If transmission interrupts are enabled (SMR:TIE= 1), a transmission interrupt is generated.

- This bit is reset when the ESRC:TBERRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-2.

Bit	Description
0	No transmission block transfer error has occurred.
1	A transmission block transfer error has occurred.

Notes:

- If the transmission block transfer enable (ECR:TXBLKEN) is "0", this bit is "0".
- This bit is set "1" as the block transfer error when the transmission FIFO is OFF and the block transfer is executed under either the condition:
 - The transmission interrupt is enabled (SMR:TIE="1") and the TDR register has a data (SSR:TDRE="0")
 - The transmission interrupt is disabled (SMR:TIE="0") and the transmission bus idle interrupt is enabled (SSR:TBIE="1") and in transmitting (SSR:TBI="0")
- When the transmission interrupt is enabled (SMR:TIE="1") and the transmission bus idle interrupt is enabled (SSR:TBIE="1"), the condition of the transmission interrupt enabled (SMR:TIE="1") is prior.

8.20. Transmission Block Size Register (TBSIZE)

This register is used to set the block size for transmission block transfer.

Bit Configuration of the Transmission Block Size Register (TBSIZE)

Figure 8-22 shows the bit configuration of the transmission block size register (TBSIZE).

Figure 8-22 Bit Configuration of the Transmission Block Size Register (TBSIZE)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-										
R/W	R/W										
Attribute	-										
Protection	-										
Attribute	-										
Initial Value	0										

The TBSIZE register sets the block size for transmission block transfer.

[bit7:0] TBSIZE : Transmission Block size byte

TBSIZE	Description
Write	Set the number of transmission blocks.
Read	Read the setting value.

Notes:

- Settings that exceed the FIFO capacity are prohibited.
- Setting "0" to this bit is prohibited.
- Settings that exceed the setting value in the transmission FIFO interrupt control register (FTICR) are prohibited.
- Set the same value in this register as the transmission block size that is set for the DMA controller.
- When the transmission FIFO is not used, the transmission block size is "1" for block transfer regardless of the register setting.

8.21. I²C Bus Control Clear Register (IBCRC)

The I²C bus control clear register (IBCRC) can clear a bit in the I²C bus control register (IBCR).

Note:

- For details on operations of this register, see also the descriptions of IBCR, which is the targeted register.

I²C Bus Control Clear Register (IBCRC)

Figure 8-23 shows the bit configuration of the I²C bus control clear register (IBCRC).

Figure 8-23 Bit Configuration of the I²C Bus Control Clear Register (IBCRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	MSSC	Reserved	ACKEC	WSEL	CNDEC	INTEC	Reserved	INTC	SMRC		
R/W Attribute	R0,W	R0,W0	R0,W	R0,W	R0,W	R0,W	R0,W0	R0,W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] MSSC : Clearing the Master/Slave Selection Bit

Writing "1" to this bit resets IBCR:MSS to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] Reserved : Reserved Bit

[bit13] ACKEC : Clearing the Data Byte acknowledgment Enable Bit

Writing "1" to this bit resets IBCR:ACKE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] WSEL : Clearing the Wait Selection Bit

Writing "1" to this bit resets IBCR:WSEL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] CNDEC : Clearing the Condition Detection Interrupt Enable Bit

Writing "1" to this bit resets IBCR:CNDE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] INTEC : Clearing the Interrupt Enable Bit

Writing "1" to this bit resets IBCR:INTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] Reserved : Reserved Bit**[bit8] INTC : Clearing the Interrupt Flag**

Writing "1" to this bit resets IBCR:INT to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.22. Serial Mode Clear Register (SMRC)

The serial mode clear register (SMRC) can clear a bit in the serial mode register (SMR).

Note:

- For details on operations of this register, see also the descriptions of SMR, which is the targeted register.

Bit Configuration of the Serial Mode Clear Register (SMRC)

Figure 8-24 shows the bit configuration of the serial mode clear register (SMRC).

Figure 8-24 Bit Configuration of the Serial Mode Clear Register (SMRC)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(IBCRC)			Reserved	Reserved	Reserved	WUCRC	RIEC	TIEC	Reserved	Reserved
R/W				R0,W0	R0,W0	R0,W0	R0,W	R0,W	R0,W	R0,W0	R0,W0
Attribute				-	-	-	-	-	-	-	-
Protection				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved : Reserved Bits

[bit4] WUCRC : Clearing the WAKE UP Control Bit

Writing "1" to this bit resets SMR:WUCR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] RIEC : Clearing the Reception Interrupt Enable Bit

Writing "1" to this bit resets SMR:RIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] TIEC : Clearing the Transmission Interrupt Enable Bit

Writing "1" to this bit resets SMR:TIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1:0] Reserved ; Reserved Bits

8.23. Serial Status Clear Register (SSRC)

The serial status clear register (SSRC) can clear a bit in the serial status register (SSR).

Note:

- For details on operations of this register, see also the descriptions of SSR, which is the targeted register.

Bit Configuration of the Serial Status Clear Register (SSRC)

Figure 8-25 shows the bit configuration of the serial status clear register (SSRC).

Figure 8-25 Bit Configuration of the Serial Status Clear Register (SSRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	DMAC	TBIEC	Reserved	Reserved	Reserved	Reserved	(IBSRC)

Protection	-	-	-	-	-	-	-	-			
Attribute											
Initial Value	0	0	0	0	0	0	0	0			

[bit15:14] Reserved : Reserved Bits

[bit13] DMAC : Clearing the DMA Mode Enable Bit

Writing "1" to this bit resets SSR:DMA to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] TBIEC : Clearing the Transmission Bus Idle Interrupt Enable Bit (Valid Only when DMA Mode is Enabled)

Writing "1" to this bit resets SSR:TBIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11:8] Reserved : Reserved Bits

8.24. I²C Bus Status Clear Register (IBSRC)

The I²C bus status clear register (IBSRC) can clear a corresponding bit in the I²C bus status register (IBSR).

Note:

- For details on operations of this register, see also the descriptions of IBSR, which is the targeted register.

I²C Bus Status Clear Register (IBSRC)

Figure 8-26 shows the bit configuration of the I²C bus status clear register (IBSRC).

Figure 8-26 Bit Configuration of the I²C Bus Status Clear Register (IBSRC)

Bit	15	...	8	7	6	5	4	3	2	1	0

Attribute											
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

[bit7:3] Reserved : Reserved Bits

[bit2] RSCC : Clearing the repeated Start Condition Check Bit

Writing "1" to this bit resets IBSR:RSC to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] SPCC : Clearing the Stop Condition Check Bit

Writing "1" to this bit resets IBSR:SPC to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] Reserved : Reserved Bit

8.25. Serial Auxiliary Control Status Clear Register(SACSRC)

The serial auxiliary control status clear register (SACSRC) can clear a corresponding bit in the serial auxiliary control status register (SACSR).

Note:

- For details on operations of this register, see also the descriptions of SACSR, which is the targeted register.

Bit Configuration of the Serial Auxiliary Control Status Clear Register (SACSRC)

Figure 8-27 Bit Configuration of the Serial Auxiliary Control Status Register (SACSRC)

Protection	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:9] Reserved : Reserved Bits

[bit8] TINTC : Clearing the Timer Interrupt Flag

Writing "1" to this bit resets SACSR:TINT to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7] TINTEC : Clearing the Timer Interrupt Enable Bit

Writing "1" to this bit resets SACSR:TINTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] Reserved : Reserved Bit

[bit5] TRGEC : Clearing the External Trigger Enable Bit

Writing "1" to this bit resets SACSR:TINTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved : Reserved Bits

[bit0] TMREC : Clearing the Serial Timer Enable Bit

Writing "1" to this bit resets SACSr:TMRE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.26. FIFO Control Clear Register 1 (FCR1C)

FIFO control clear register 1 (FCR1C) can clear a bit in FIFO control register 1 (FCR1).

Note:

- For details on operations of this register, see also the descriptions of FCR1, which is the targeted register.

8.26.1.1 Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Figure 8-28 Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Bit	15	14	13	12	11	10	9	8	7	...	0

Initial Value	0	0	0	0	0	0	0	0			

[bit15:13] Reserved : Reserved Bits

[bit12] FLSTEC : Clearing the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit resets FCR1:FLSTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIEC : Clearing the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit resets FCR1:FRIIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] FDRQC : Clearing the Transmission FIFO Data Request Bit

Writing "1" to this bit resets FCR1:FDRQ to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] FTIEC : Clearing the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit resets FCR1:FTIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELC : Clearing the FIFO Selection Bit

Writing "1" to this bit resets FCR1:FSEL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.27. FIFO Control Clear Register 0 (FCR0C)

FIFO control clear register 0 (FCR0C) can clear a bit in FIFO control register 0 (FCR0).

Note:

- For details on operations of this register, see also the descriptions of FCR0, which is the targeted register.

Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Figure 8-29 Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Bit	1	..	8	7	6	5	4	3	2	1	0

Protection Attribute			-		-		-		-		-
Initial Value			0		0		0		0		0

[bit7:2] Reserved : Reserved Bits

[bit1] FE2C : Clearing the FIFO2 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE2 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1C : Clearing the FIFO1 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE1 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.28. Extended Status Clear Register (ESRC)

The extended status clear register (ESRC) can be used to clear a bit in the extended status register (ESR).

Extended Status Clear Register (ESRC)

Figure 8-30 shows the bit configuration of the extended status clear register (ESRC).

Figure 8-30 Bit Configuration of the Extended Status Clear Register (ESRC)

Bit	15	14	13	12	11	10	9	8	7	...	0

Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved : Reserved Bits

[bit11] RXUDRC : Reception FIFO under Run Flag Clear Bit

Writing "1" to this bit resets ESR:RXUDR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TXOVR : Transmission FIFO Overrun Flag Clear Bit

Writing "1" to this bit resets ESR:TXOVR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RBERR : Reception Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:RBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TBERR : Transmission Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:TBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.29. I²C Bus Control Set Register (IBCRS)

The I²C bus control set register (IBCRS) can set a bit in the I²C bus control register (IBCR).

Note:

- For details on operations of this register, see also the descriptions of IBCR, which is the targeted register.

I²C Bus Control Set Register (IBCRS)

Figure 8-31 shows the bit configuration of the I²C bus control set register (IBCRS).

Figure 8-31 Bit Configuration of the I²C Bus Control Set Register (IBCRS)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	MSSS	ACTS	ACKES	WSEL S	CNDES	INTES	Reserved	INTS	(SMRS)		
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W0	R0,W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] MSSS : Setting the Master/Slave Selection Bit

Writing "1" to this bit sets IBCR:MSS to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] ACTS : Setting the repeated Start Condition Generation Bit

Writing "1" to this bit sets IBCR:ACT to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] ACKES : Setting the Data Byte acknowledgment Enable Bit

Writing "1" to this bit sets IBCR:ACE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] WSELS : Setting the Wait Selection Bit

Writing "1" to this bit sets IBCR:WSEL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] CNDES : Setting the Condition Detection Interrupt Enable Bit

Writing "1" to this bit sets IBCR:CNDE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] INTES : Setting the Interrupt Enable Bit

Writing "1" to this bit sets IBCR:INTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] Reserved : Reserved Bit

[bit8] INTS : Setting the Interrupt Flag

Writing "1" to this bit sets IBCR:INT to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.30. Serial Mode Set Register (SMRS)

The serial mode set register (SMRS) can set a bit in the serial mode register (SMR).

Note:

- For details on operations of this register, see also the descriptions of SMR, which is the targeted register.

Bit Configuration of the Serial Mode Set Register (SMRS)

Figure 8-32 Bit Configuration of the Serial Mode Set Register (SMRS)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(IBCRS)			Reserved	Reserved	Reserved	WUCRS	RIES	TIES	Reserved	Reserved
R/W				R0,W0	R0,W0	R0,W0	R0,W	R0,W	R0,W	R0,W0	R0,W0
Attribute											
Protection				-	-	-	-	-	-	-	-
Attribute											
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved : Reserved Bits

[bit4] WUCRS : Setting the WAKE UP Control Bit

Writing "1" to this bit sets SMR:WUCR to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] RIES : Setting the Reception Interrupt Enable Bit

Writing "1" to this bit sets SMR:RIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] TIES : Setting the Transmission Interrupt Enable Bit

Writing "1" to this bit sets SMR:TIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1:0] Reserved : Reserved Bits

8.31. Serial Status Set Register (SSRS)

The serial status set register (SSRS) can set a bit in the serial status register (SSR).

Note:

- For details on operations of this register, see also the descriptions of SSR, which is the targeted register.

Bit Configuration of the Serial Status Set Register (SSRS)

Figure 8-33 Bit Configuration of the Serial Status Set Register (SSRS)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	RECS	TSETS	DMAS	TBIES	Reserved	Reserved	Reserved	Reserved			-
R/W	R0,W	R0,W	R0,W	R0,W	R0,W0	R0,W0	R0,W0	R0,W0			
Attribute											
Protection	-	-	-	-	-	-	-	-			
Attribute											
Initial Value	0	0	0	0	0	0	0	0			

[bit15] RECS : Setting the Reception Error Flag Clear Bit

Writing "1" to this bit sets SSR:REC to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] TSETS : Setting the Transmission Buffer Empty Flag Set Bit

Writing "1" to this bit sets SSR:TSET to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] DMAS : Setting the DMA Mode Enable Bit

Writing "1" to this bit sets SSR:DMA to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] TBIES : Setting the Transmission Bus Idle Interrupt Enable Bit (Valid Only when DMA Mode is Enabled)

Writing "1" to this bit sets SSR:TBIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11:8] Reserved : Reserved Bits

8.32. Serial Auxiliary Control Status Set Register (SACSRS)

The serial auxiliary control status set register (SACSRS) can set a bit in the serial auxiliary control status register (SACSR).

Note:

- For details on operations of this register, see also the descriptions of SACSR, which is the targeted register.

Bit Configuration of the Serial Auxiliary Control Status Set Register (SACSRS)

Figure 8-34 Bit Configuration of the Serial Auxiliary Control Status Set Register (SACSRS)

Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:8] Reserved : Reserved Bits

[bit7] TINTES : Setting the Timer Interrupt Enable Bit

Writing "1" to this bit sets SACSRS:TINTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] Reserved : Reserved Bit

[bit5] TRGES : Setting the External Trigger Enable Bit

Writing "1" to this bit sets SACSRS:TRGE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved : Reserved Bits

[bit0] TMRES : Setting the Serial Timer Enable Bit

Writing "1" to this bit sets SACSRS:TMRE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.33. FIFO Control Set Register 1 (FCR1S)

FIFO control set register 1 (FCR1S) can set a bit in FIFO control register 1 (FCR1).

Note:

- For details on operations of this register, see also the descriptions of FCR1, which is the targeted register.

Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Figure 8-35 Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Bit	15	14	13	12	11	10	9	8	7	...	0

[bit15:13] Reserved : Reserved Bits

[bit12] FLSTES : Setting the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit sets FCR1:FLSTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIES : Setting the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit sets FCR1:FRIIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] Reserved : Reserved Bit

[bit9] FTIES : Setting the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit sets FCR1:FTIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELS : Setting the FIFO Selection Bit

Writing "1" to this bit sets FCR1:FSEL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

8.34. FIFO Control Set Register 0 (FCR0S)

FIFO control set register 0 (FCR0S) can set a bit in FIFO control register 0 (FCR0).

Note:

- For details on operations of this register, see also the descriptions of FCR0, which is the targeted register.

Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Figure 8-36 Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Bit	15	...	8	7	6	5	4	3	2	1	0

[bit7:6] Reserved : Reserved Bits

[bit5] FLDS : Setting the FIFO Pointer Reload Bit

Writing "1" to this bit sets FCR0:FLD to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4] FSETS : Setting the FIFO Pointer Saving Bit

Writing "1" to this bit sets FCR0:FSET to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] FCL2S : Setting the FIFO2 Reset Bit

Writing "1" to this bit sets FCR0:FCL2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] FCL1S : Setting the FIFO1 Reset Bit

Writing "1" to this bit sets FCR0:FCL1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] FE2S : Setting the FIFO2 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1S : Setting the FIFO1 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

CHAPTER 39: LIN Interface (V2.1) (LIN Communication Control Interface (V2.1))

This chapter describes the LIN communication function supported by operation mode 3 of the multi-function serial interface functions.

1. LIN Interface (V2.1) (LIN Communication Control Interface (V2.1))
2. LIN Interface (v2.1) Interrupts
3. Serial Timer Operation
4. Test Mode
5. Dedicated Baud Rate Generator
6. Block Transfer
7. LIN Interface (V2.1) Operation
8. Setup Procedure and Program Flow for Operation Mode 3 (LIN Communication Mode)
9. Interface (V2.1) Registers

LIN-TXXPT03P01R01L09-E1-XX

1. LIN Interface (V2.1) (LIN Communication Control Interface (V2.1))

1.1. Manual Mode

The LIN interface (v2.1) (LIN communication control interface (v2.1)) provides the functions to support the LIN bus.

In addition, this interface incorporates transmission/reception FIFOs (64 bytes each).

LIN interface (v2.1) (LIN communication control interface (v2.1)) functions (manual mode)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed 3 times by the bus clock. The reception value is determined by majority decision.
3	Transfer mode	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter). The external clock can be adjusted by the reload counter. Auto baud rate adjustment with Sync Field reception.
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error
9	Interrupt request	<ul style="list-style-type: none"> Reception interrupt (reception completion, framing error, overrun error, and reception block transfer error) Reception FIFO interrupt (reception FIFO under run) Transmission interrupt (transmission data empty, transmission bus idle, and transmission block transfer error) Status interrupt (LIN Break field detection and serial timer interrupt) Interrupt request to ICU (LIN Sync field detection: LSYN) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) DMA transfer is supported for both transmission and reception.
10	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.
11	LIN bus option	<ul style="list-style-type: none"> Support for LIN Protocol Revision 2.1 Master device operation Slave device operation LIN Break field generation (changeable from 13 to 16 bits) LIN Break delimiter generation (changeable from 1 to 4 bits) LIN Break field detection Detection of the start/stop edge of the LIN Sync field connected to an input capture
12	FIFO option	<ul style="list-style-type: none"> Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). Transmission FIFO and reception FIFO can be selected. Transmission data can be retransmitted. The timing of the reception FIFO interrupt can be changed by software. Independent FIFO reset is supported.

Note:

- The LIN Wake Up function is not supported.

1.2. Assist Mode

The LIN interface (v2.1) (LIN communication control interface (v2.1)) provides functions for supporting the LIN bus. The header section can be automatically transmitted/detected in LIN communication.

In addition, this interface incorporates transmission/reception FIFOs (64 bytes each).

LIN Interface (v2.1) (LIN Communication Control Interface (v2.1)) Functions (Assist Mode)

	Function	Description
1	Data buffer	<ul style="list-style-type: none"> Full duplex, double buffering (when FIFOs are not used) Transmission and reception FIFOs (64 bytes each) (when FIFOs are used)
2	Serial input	<ul style="list-style-type: none"> Oversampling is performed 3 times by the bus clock. The reception value is determined by majority decision.
3	Transfer mode	<ul style="list-style-type: none"> Asynchronous
4	Baud rate	<ul style="list-style-type: none"> Dedicated baud rate generator is provided (configured from a 15-bit reload counter). The external clock can be adjusted by the reload counter. Auto baud rate adjustment with Sync Field reception.
5	Data length	<ul style="list-style-type: none"> 8 bits
6	Signaling method	<ul style="list-style-type: none"> NRZ (Non Return to Zero)
7	Start bit detection	<ul style="list-style-type: none"> Synchronized to falling edges of the start bit
8	Reception error detection	<ul style="list-style-type: none"> Framing error Overrun error LIN bus error LIN ID parity error LIN checksum error
9	Interrupt request	<ul style="list-style-type: none"> Transmission interrupt <ul style="list-style-type: none"> Data transmission interrupt (transmission data empty, transmission bus idle, and transmission block transfer error) Transmission FIFO interrupt (when the transmission FIFO is not higher than the interrupt trigger level or when the transmission FIFO is empty, transmission FIFO overrun) Reception interrupt <ul style="list-style-type: none"> Data reception interrupt (reception completion and reception block transfer error) Reception FIFO interrupt (when the reception FIFO is higher than the interrupt threshold, reception FIFO under run) Various types of error interrupts (LIN bus error, LIN Sync Data error, LIN ID parity error, framing error, overrun error, and LIN checksum error) Status interrupt <ul style="list-style-type: none"> Auto header completion interrupt Sync Field detection interrupt Checksum calculation completion interrupt DMA transfer is supported for both transmission and reception.
10	Timer function	<ul style="list-style-type: none"> A 16-bit serial timer is provided. A division value can be selected for the operation clock (division by 1 to 256). Activation by external trigger is available.

11	LIN bus option	<ul style="list-style-type: none"> - Support for LIN Protocol Revision 2.1 - Automatic transmission/reception of the header of the master/slave device <ul style="list-style-type: none"> ➤ LIN Break field generation (changeable from 13 to 20 bits) ➤ LIN Break delimiter generation (changeable from 1 to 4 bits) ➤ Automatic generation of the Sync Field and automatic check of data value (0x55) ➤ Automatic generation/check of the parity value of the ID Field ➤ Automatic generation/check of a checksum (support for standard/extended checksum)
12	FIFO option	<ul style="list-style-type: none"> - Transmission and reception FIFOs are provided (64 bytes for the transmission FIFO and 64 bytes for the reception FIFO). - Transmission FIFO and reception FIFO can be selected. - Transmission data can be retransmitted. - The timing of the transmission/reception FIFO interrupt can be changed by software. - Independent FIFO reset is supported.
13	LIN communication test function	<ul style="list-style-type: none"> - Serial communication test function - Pseudo error generation functions (LIN bus error, LIN ID parity error, LIN checksum error, LIN Sync Field error, and framing error)

Note:

- *The LIN Wake Up function is not supported.*

2. LIN Interface (v2.1) Interrupts

2.1. Manual Mode

The LIN interface (v2.1) can generate reception interrupts, transmission interrupts, and status interrupts. In manual mode, an interrupt request can be generated by any of the following factors.

- When reception data is set in the reception data register (RDR) or when a reception error occurs.
- When transmission is started after transmission data is transferred from the transmission data register (TDR) to the transmission shift register.
- Transmission bus idle (no transmission operation)
- Transmission FIFO data request
- LIN Break Field detection
- LIN Sync Field detection
- The serial timer comparison value (STMCR) matches the serial timer value (STMR).

LIN interface (v2.1) interrupts (manual mode)

Table 2-1 shows the interrupt control bits of the LIN interface (v2.1), together with the interrupt factors in manual mode.

Table 2-1 Interrupt Control Bits and Interrupt Factors of LIN Interface (v2.1) (Manual Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL = 1)
			Reception of as much data as the amount set in FBYTE		- Reading of reception data until the reception FIFO becomes empty - Software reset (SCR:UPCL = 1)
			Detection of reception idle for 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overflow error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL = 1)
	FRE	SSR	Framing error		
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	- Writing "1" to the reception FIFO underrun clear flag bit (ESRC:RXUDRC) - Software reset (SCR:UPCL = 1) - Disable reception FIFO - When FCR1:FSEL=0, set FCR0:FE2=0 - When FCR1:FSEL=1, set FCR0:FE1=0
	RBERR	ESR	Reception block transfer error	ECR:REIE	- Writing "1" to the reception block transfer error clear bit (ESRC:RBERRC) - Software reset(SCR:UPCL=1) - Disable Block transfer mode (ECR:RXBLKEN=0)
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data *1

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) while the bit value is "0" and the transmission FIFO contains valid data*1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or smaller than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or transmission FIFO full
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVR) - Software reset (SCR:UPCL = 1) - Disable transmission FIFO <ul style="list-style-type: none"> - When FCR1:FSEL=0, set FCR0:FE1=0 - When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission block transfer error clear bit (FSRC:TBERRC) - Software reset (SCR:UPCL=1) - Disable Block transfer mode (ECR:TXBLKEN=0)
Status (Manual Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	<ul style="list-style-type: none"> - Writing "1" to the SSRC:LBDC bit - Software reset (SCR:UPCL = 1)
	SFD	SACSR	Sync Field detection	SACSR:SFD E	<ul style="list-style-type: none"> - Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC) - Software reset (SCR:UPCL=1)
	TINT	SACSR	Coincidence of the serial timer register (STMR) and the serial timer comparison register (STMCR) values	SACSR:TINT E	<ul style="list-style-type: none"> - Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset (SCR:UPCL=1)
Input Capture	ICP0	ICS0	1st falling edge of the LIN Sync Field	ICS0:ICE0	Disabling the ICP0
	ICP0	ICS0	5th falling edge of the LIN Sync Field		

*1: Set the TIE bit to "1" after the TDRE bit becomes "0".

*2: When auto baud rate adjustment is enabled (SACSR:AUTE = 1),this interrupt by input capture is not generated.

Switching of Error Interrupt Request Output

The method of outputting an error interrupt request varies depending on the settings of the error interrupt request output switching bit (ECR:EISEL), transmission/reception error interrupt enable bits (ECR:REIE, TEIE), and transmission/reception interrupt enable bits (SCR:RIE, TIE, TBIE, FCR1:FTIE).

Table 2-2 Method of Outputting Transmission Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)
	Transmission error interrupt request output	-	No interrupt factor
1	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
	Transmission error interrupt request output	ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)

Table 2-3 Method of Outputting Reception Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF) Framing error (SSR:FRE) Overrun error (SSR:ORE)
		ECR:REIE	Reception FIFO underrun (ESR:RXUDR) Reception block transfer error (ESR:RBERR)
	Reception error interrupt request output	-	No interrupt factor
1	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF)
	Reception error interrupt request output	ECR:REIE	Framing error (SSR:FRE) Overrun error (SSR:ORE) Reception FIFO underrun (ESR:RXUDR) Reception block transfer error (ESR:RBERR)

2.1.1. Occurrence of Reception Interrupts and Flag Set Timing

There are 2 reception interrupt types: reception completion (SSR:RDRF) and reception error (SSR:ORE, FRE).

Occurrence of Reception Interrupts and Flag Set Timing

Detection of the first stop bit stores the reception data to the reception data register (RDR). Related flags are set upon the completion of reception (SSR:RDRF = 1) or upon a reception error (SSR:ORE, FRE = 1). At this time, a reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1).

Note:

- If a reception error occurs, the data of the reception data register (RDR) is invalid.

Figure 2-1 Set Timing of RDRF (Reception Data Full) Flag Bit

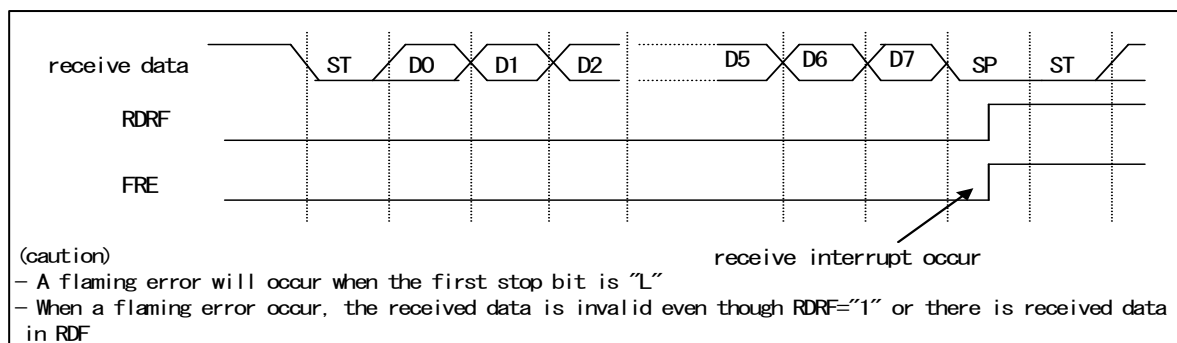

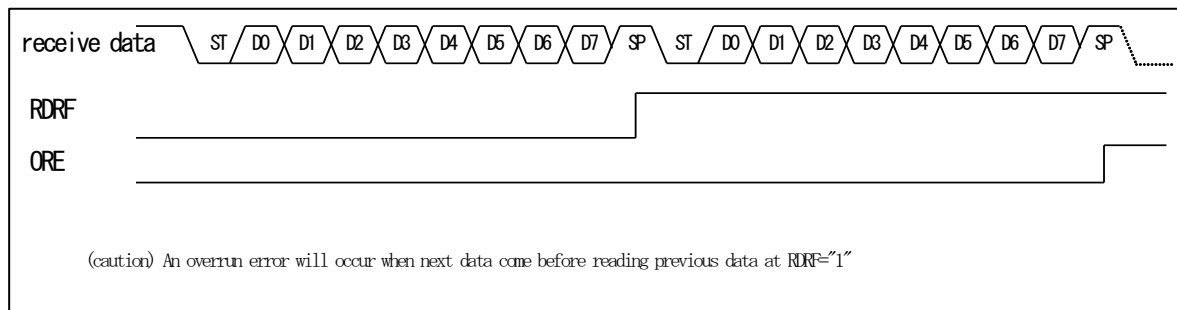

Figure 2-2 Set Timing of FRE (Framing Error) Flag Bit

Note:

- During data reception, the following occurs if a falling edge of serial data is detected at the same time as, or 1 or 2 bus clocks earlier than, the sampling point: The edge becomes invalid and the data that follows may not be received normally. Consecutive frames must have intervals between them.

Figure 2-3 Set Timing of ORE (Overrun Error) Flag Bit

2.1.2. Occurrence of Interrupts and Flag Set Timing When Using Reception FIFO

An interrupt occurs during the use of the reception FIFO when as much data as the amount set in the FIFO byte register (FBYTE) is received.

Occurrence of Reception Interrupts and Flag Set Timing When Using Reception FIFO

The occurrence of interrupts during the use of the reception FIFO is determined by the value set in the FBYTE register.

- If as much transfer data as the amount set in the FBYTE register is received, the reception data full flag (SSR:RDRF) in the serial status register is set to "1". At this time, if reception interrupts are enabled (SCR:RIE), a reception interrupt is generated.
- When the amount of data in the reception FIFO is "1" or greater and both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (SSR:RDRF) to "1".
 - The reception FIFO idle detection enable bit (FCR1:FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. After the reception FIFO is enabled while there is still data in the reception FIFO, counting restarts.

- When the reception FIFO becomes empty as a result of reading the reception data (RDR), the reception data full flag (SSR:RDRF) is cleared.
- If the reception valid data count becomes equal to the value of the FIFO capacity, the reception of the next data triggers an overrun error (SSR:ORE = 1).

Figure 2-4 Occurrence Timing of Reception Interrupt When Reception FIFO Is Used

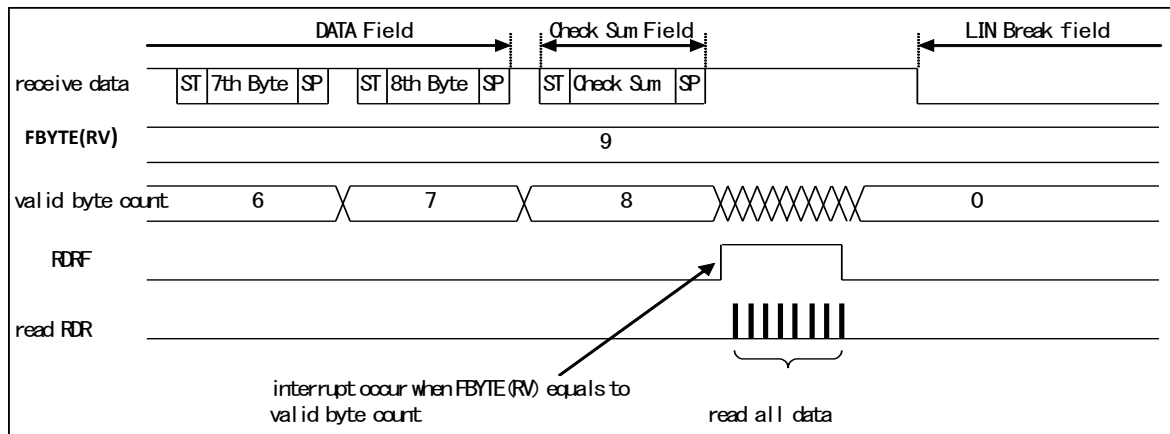

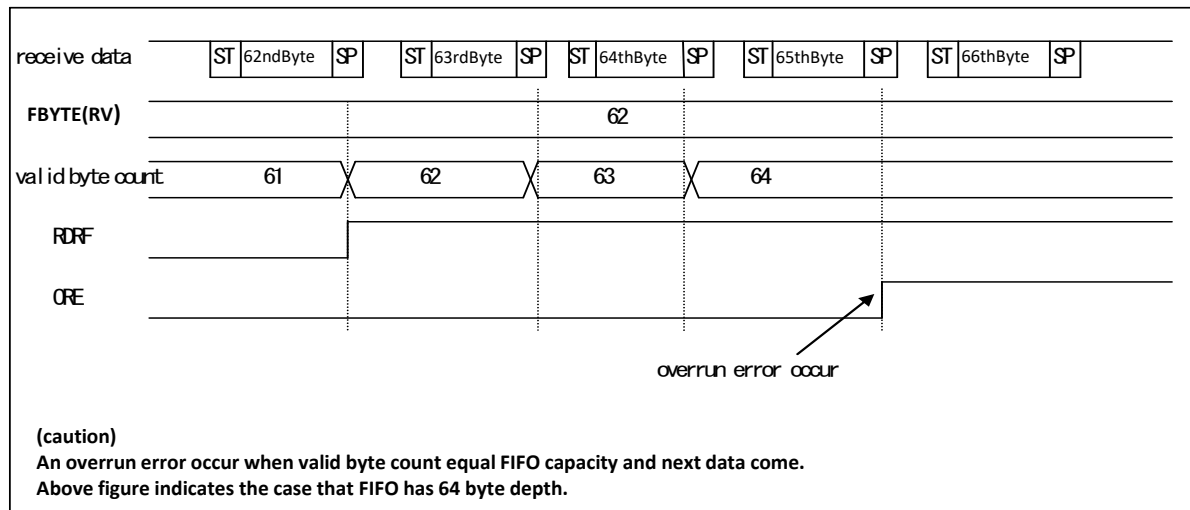

Figure 2-5 Set Timing of ORE (Overrun Error) Flag Bit

2.1.3. Occurrence of Transmission Interrupts and Flag Set Timing

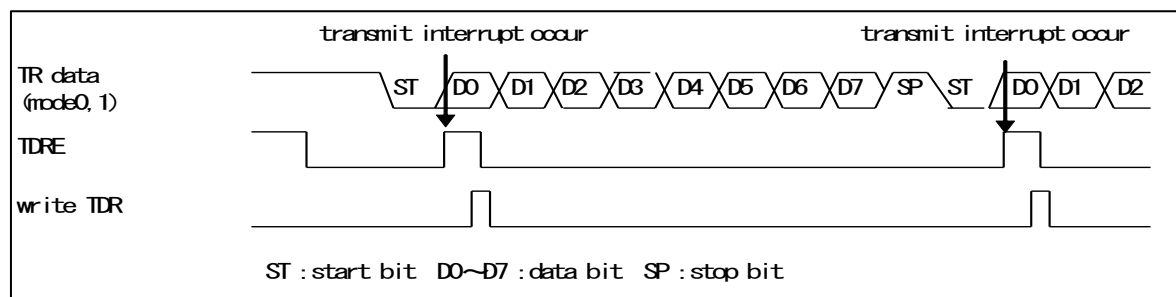

A data transmission interrupt occurs in the following cases: 1. The transmission data is transferred from the transmission data register (TDR) to the transmission shift register (SSR:TDRE = 1) to start data transmission. 2. Transmission is not performed (SSR:TBI = 1).

Occurrence of Transmission Interrupts and Flag Set Timing

Set Timing of Transmission Data Empty Flag (TDRE)

The transfer of data from the transmission data register (TDR) to the transmission shift register allows the next data to be written (SSR:TDRE = 1). At this time, a transmission interrupt occurs if transmission interrupt is enabled (SCR:TIE = 1). The TDRE bit is a read-only bit, and the SSR:TDRE bit is cleared to "0" when data is written to the transmission data register (TDR).

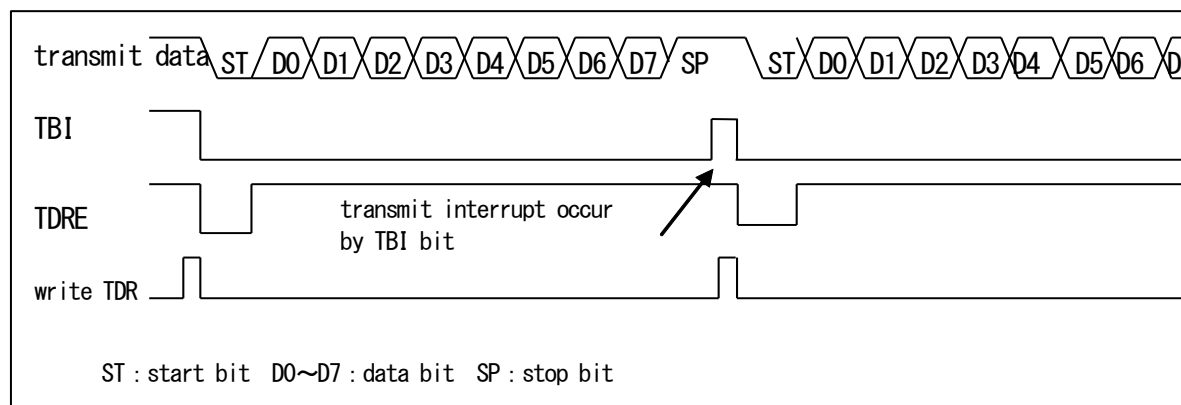

Figure 2-6 Set Timing of Transmission Data Empty Flag (SSR:TDRE)

Set Timing of Transmission Bus Idle Flag (TBI)

The SSR:TBI bit is set to "1" during those periods in which the transmission data register is empty (SSR:TDRE = 1) and transmission is not performed. At this time, a transmission interrupt occurs if transmission bus idle interrupt is enabled (SCR:TBIE = 1). Setting transmission data to the transmission data register (TDR) clears the TBI bit and the transmission interrupt request.

Figure 2-7 Set Timing of Transmission Bus Idle Flag (TBI)

2.1.4. Occurrence of Interrupts and Flag Set Timing When Using Transmission FIFO

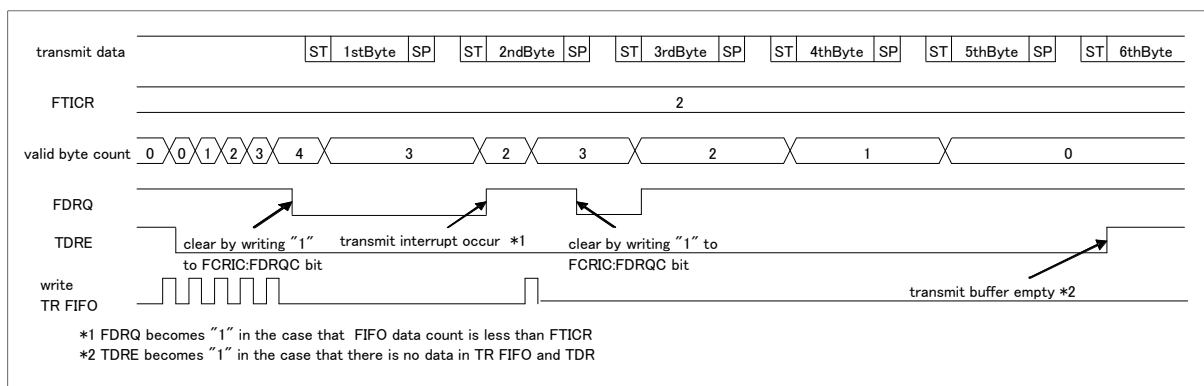

An interrupt occurs during the use of the transmission FIFO when the data count in the transmission FIFO is equal to or less than the value set in the transmission FIFO interrupt control register (FTICR).

Occurrence of Transmission Interrupts and Flag Set Timing When Using Transmission FIFO

The occurrence of interrupts during the use of the transmission FIFO is determined by the value set in the FTICR register.

- When the data count in the transmission FIFO is equal to or less than the value set in the FTICR register, the FIFO transmission data request bit (FCR1:FDRQ) is set to "1".
At this time, a transmission interrupt occurs if the FIFO transmission interrupt is enabled (FCR1:FTIE = 1).
- When you write the necessary data to the transmission FIFO after a transmission interrupt occurs, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.
- The FIFO transmission data request bit (FCR1:FDRQ) is set to "0" when the transmission FIFO becomes full.
- Whether data is present in the transmission FIFO can be checked by reading the FIFO byte register (FBYTE). This can also be checked by reading the transmission FIFO interrupt control register (FTICR).
FBYTE = 0x00 indicates that the transmission FIFO does not contain data.

Figure 2-8 Timing of Transmission Interrupt Occurrence When Transmission FIFO Is Used

2.1.5. Occurrence of Timer Interrupts and Flag Set Timing

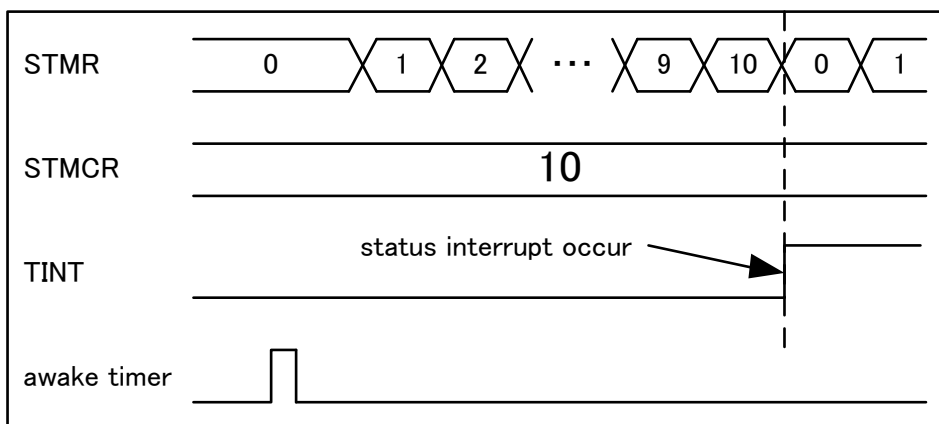

A timer interrupt occurs when the value of the serial timer register (STMR) coincides with that of the serial timer comparison register (STMCR).

Timer Interrupt Generation and Flag Set Timing

The timer interrupt flag (SACSR:TINT) is set to "1" when the value of the serial timer register (STMR) coincides with that of the serial timer comparison register.

At this time, a status interrupt occurs if the timer interrupt is enabled (SACSR:TINTE = 1).

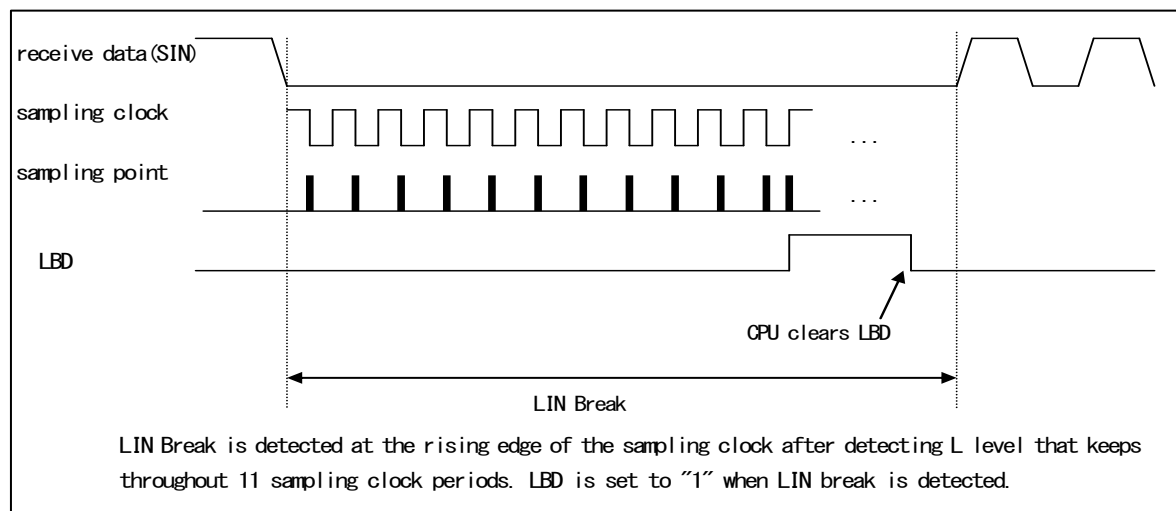

Figure 2-9 Occurrence Timing of Timer Interrupt

2.1.6. Set Timing of LIN Break Field Detection Flag (LBD)

The LBD bit is set to "1" when the serial input (SIN) has "0" input for an interval of 11 bits or more. At this time, a status interrupt occurs if the LIN Break Field interrupt is enabled (ESCR:LBIE = 1).

Figure 2-10 Set Timing of LBD (LIN Break Field Detection) Flag

Note:

- During the reception of a LIN Break Field, a framing error (SSR:FRE=1) is detected before the detection of a LIN Break Field if reception is enabled (SCR:RXE=1).

2.1.7. Occurrence of Sync Field Detection Interrupt and Flag Set Timing

A Sync Field detection interrupt occurs if the detection of the Sync Field is complete.

Occurrence of Sync Field Detection Interrupt and Flag Set Timing

The Sync Field detection flag (SACSR:SFD) is set to "1" once the 5th falling edge of the LIN bus is detected in the SyncField when auto baud rate adjustment is enabled (SACSR:AUTE = 1).

At this time, a status interrupt occurs if the Sync Field interrupt is enabled (SACSR:SFDE = 1).

Figure 2-11 Timing of Sync Field Detection Interrupt

2.2. Assist Mode

The LIN interface (v2.1) can generate reception interrupts, transmission interrupts, and status interrupts. In assist mode, an interrupt request can be generated due to the following factors:

- When reception data is set in the reception data register (RDR) or when a reception error occurs.
- When transmission is started after transmission data is transferred from the transmission data register (TDR) to the transmission shift register.
- Transmission bus idle (no transmission operation)
- Transmission FIFO data request
- LIN Break Field detection
- LIN Sync Field detection
- The serial timer comparison value (STMCR) matches the serial timer value (STMR)
- Detection of the completion of the LIN auto header or the checksum calculation

LIN Interface (v2.1) Interrupts (Assist Mode)

Table 2-4 shows the interrupt control bits of the LIN interface (v2.1) and the interrupt factors in assist mode.

Table 2-4 LIN Interface (v2.1) Interrupt Control Bits and Interrupt Factors (Assist Mode)

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
Reception	RDRF	SSR	1-byte reception	SCR:RIE	- Reading of reception data (RDR) - Software reset (SCR:UPCL = 1)
			Reception of as much data as the amount set in FBYTE		- Reading of reception data (RDR) until the reception FIFO becomes empty - Software reset (SCR:UPCL = 1)
			Detection of reception idle for the 8-bit time or longer while the FRIIE bit is "1" and the reception FIFO contains valid data		
	ORE	SSR	Overrun error	SCR:RIE ECR:REIE	- Writing "1" to the reception error flag clear bit (SSR:REC) - Software reset (SCR:UPCL = 1)
	FRE	SSR	Framing error		
	LBSE	LAMESR	LIN bus error detection	LAMIER: LBSEIE	- Writing "1" to LAMESRC:LBSERC - Software reset (SCR:UPCL = 1)
	LSFER	LAMESR	LIN Sync Data error detection	LAMIER: LSFERIE	- Writing "1" to LAMESRC:LSFERC - Software reset (SCR:UPCL = 1)
	LPTE	LAMESR	LIN ID parity error detection	LAMIER: LPTEIE	- Writing "1" to LAMESRC:LPTEC - Software reset (SCR:UPCL = 1)
	LCSE	LAMESR	LIN checksum error detection	LAMIER: LCSEIE	- Writing "1" to LAMESRC:LCSERC - Software reset (SCR:UPCL = 1)
	RXUDR	ESR	Reception FIFO underrun	ECR:REIE	- Writing "1" to the reception FIFO underrun flag clear bit (ESRC:RXUDRC) - Software reset (SCR:UPCL = 1) - Disable reception FIFO - When FCR1:FSEL=0, set FCR0:FE2=0 - When FCR1:FSEL=1, set FCR0:FE1=0

Interrupt Type	Interrupt Request Flag Bit	Flag Register	Interrupt Factor	Interrupt Factor Enable Bit	Clearing of Interrupt Request Flag
	RBERR	ESR	Reception block transfer error	ECR:REIE	<ul style="list-style-type: none"> - Writing "1" to the reception block transfer error clear bit - Software reset (SCR:UPCL=1) - Disable Block transfer mode (ECR:RXBLKEN=0)
Transmission	TDRE	SSR	The transmission register is empty.	SCR:TIE	Writing to the transmission data (TDR) , or writing "1" to the transmission FIFO operation enable bit (FCR0:FE1 or FCR0:FE2) (retransmission) when the bit value is "0" and the transmission FIFO contains valid data*1
	TBI	SSR	No transmission operation	SCR:TBIE	Writing to the transmission data (TDR), writing "1" to the LIN Break Field setting bit (LBR), or writing "1" to the transmission FIFO operation enable bit (retransmission) when the bit value is "0" and the transmission FIFO contains valid data *1
	FDRQ	FCR1	The amount of data in the transmission FIFO is equal to or less than the FTICR setting value or it is empty.	FCR1:FTIE	Writing "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) , or the transmission FIFO is full
	TXOVR	ESR	Transmission FIFO overrun	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission FIFO overrun flag clear bit (ESRC:TXOVR) - Software reset (SCR:UPCL=1) - Disable transmission FIFO - When FCR1:FSEL=0, set FCR0:FE1=0 - When FCR1:FSEL=1, set FCR0:FE2=0
	TBERR	ESR	Transmission block transfer error	ECR:TEIE	<ul style="list-style-type: none"> - Writing "1" to the transmission block transfer error clear bit (ESRC:TBERR) - Software reset (SCR:UPCL=1) - Disable Block transfer (ECR:TXBLKEN=0)
Status (Assist Mode)	LBD	SSR	LIN Break Field detection	ESCR:LBIE	<ul style="list-style-type: none"> - Writing "1" to the SSRC:LBDC bit - Software reset (SCR:UPCL=1)
	SFD	SACSR	Sync Field detection	SACSR:SFDE	<ul style="list-style-type: none"> - Writing "1" to the Sync Field detection flag clear bit (SACSRC:SFDC) - Software reset (SCR:UPCL=1)
	TINT	SACSR	Coincidence of the value in the serial timer register (STMR) and that in the serial timer comparison register (STMCR)	SACSR:TINTE	<ul style="list-style-type: none"> - Writing "1" to the timer interrupt flag clear bit (SACSRC:TINTC) - Software reset (SCR:UPCL=1)
	LAHC	LAMSR	Completion of auto header	LAMIER:LAHCIE	<ul style="list-style-type: none"> - Writing "1" to LAMSRC:LAHCC - Reading from the ID register (LAMRID) - Software reset (SCR:UPCL = 1)
	LCSC	LAMSR	Completion of checksum calculation	LAMIER:LCSCIE	<ul style="list-style-type: none"> - Writing "1" to LAMSRC:LCSCC - Software reset (SCR:UPCL = 1)

*1: Set the TIE bit to "1" after the TDRE bit becomes "0".

Switching of Error Interrupt Request Output

The method of outputting an error interrupt request varies depending on the setting of the error interrupt request output switching bit (ECR:EISEL), transmission/reception error interrupt enable bits (ECR:REIE, TEIE), and transmission/reception interrupt enable bits (SCR:RIE, TIE).

Table 2-5 Method of Outputting Transmission Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
		ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)
	Transmission error interrupt request output	-	No interrupt factor
1	Transmission interrupt request output	SCR:TIE	Transmission data empty (SSR:TDRE)
		SCR:TBIE	No transmission operation (SSR:TBI)
		FCR1:FTIE	Transmission FIFO empty (FCR1:FDRQ)
	Transmission error interrupt request output	ECR:TEIE	Transmission FIFO overrun (ESR:TXOVR) Transmission block transfer error (ESR:TBERR)

Table 2-6 Method of Outputting Reception Interrupt Requests

ECR:EISEL	Interrupt Output	Target Interrupt Enable Bit	Interrupt Factor
0	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF) Framing error (SSR:FRE) Overrun error (SSR:ORE)
		LAMIER:LBSERIE	LIN bus error (LAMESR:LBSEr)
		LAMIER:LSFERIE	LIN Sync Data error (LAMESR:LSFER)
		LAMIER:LPTERIE	LIN ID parity error (LAMESR:LPTER)
		LAMIER:LCSERIE	LIN Check Sum error (LAMESR:LCSEr)
		ECR:REIE	Reception FIFO underrun (ESR:RXUDR) Reception block transfer error (ESR:RBERR)
	Reception error interrupt request output	-	No interrupt factor
1	Reception interrupt request output	SCR:RIE	Reception full (SSR:RDRF)
	Reception error interrupt request output	LAMIER:LBSERIE	LIN bus error (LAMESR:LBSEr)
		LAMIER:LSFERIE	LIN Sync Data error (LAMESR:LSFER)
		LAMIER:LPTERIE	LIN ID parity error (LAMESR:LPTER)
		LAMIER:LCSERIE	LIN Check Sum error (LAMESR:LCSEr)
		ECR:REIE	Framing error (SSR:FRE) Overrun error (SSR:ORE) Reception FIFO underrun (ESR:RXUDR) Reception block transfer error (ESR:RBERR)

2.2.1. Occurrence of Reception Interrupts and Flag Set Timing in Assist Mode

There are 2 reception interrupt types: Reception completion (SSR:RDRF) and reception error (SSR:ORE, FRE, LAMESR:LBSE, LSFER, LPTER, LCSER).

Occurrence of Reception Completion Interrupts and Flag Set Timing

In assist mode (LAMCR:LAMEN = 1), reception data is stored in the reception data register (RDR) every time the stop bit of each of the following fields is detected. A flag is set (SSR:RDRF = 1) once reception is complete. At this time, a reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1).

- Data Field for Response
- ID Field when the ID register is not used (LAMCR:LIDEN = 0)

The timing at which the reception data full flag bit (SSR:RDRF) is set is the same as that in manual mode, as described in "2.1.1 Occurrence of Reception Interrupts and Flag Set Timing." See "Figure 2-1 Set Timing of RDRF (Reception Data Full) Flag Bit."

Notes:

- *If a reception error occurs, the data in the reception data register (RDR) will be invalid.*
- *Suppose that the setting is such that the LIN assist mode reception ID register is used for the reception of ID Fields (LAMCR:LIDEN = 1). Then, when an ID Field is received, the received ID value is not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.*
- *In slave operation, suppose that the setting is such that the reception data register (RDR) is used for the reception of ID Fields (LAMCR:LIDEN = 0). Then, when an ID Field is received, the received ID value is stored to the reception data register (RDR) and the reception data full flag bit is set (SSR:RDRF = 1). Check the ID value after the LIN auto header completion flag is set (LAMSR:LAHC = 1).*
- *Neither the Sync Field nor the checksum are stored to the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.*

Occurrence of Framing Error Interrupt and Flag Set Timing

In assist mode (LAMCR:LAMEN = 1), a framing error is detected and the framing error flag is set (SSR:FRE = 1) if the "L" level is detected on the stop bit when the Sync Field, ID Field, data, and checksum are received. A reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1). The master node that transmits the Sync Field and ID Field or the master/slave node that transmits the checksum executes self-check on the transmitted data. If the "L" level is detected on the stop node, then a framing error is detected and the framing error flag is set (SSR:FRE = 1). A reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1).

Transmission/reception processing of a header and response in assist mode stops once a framing error is detected.

The operation enable bit for the reception FIFO is cleared (FCR0:FE1 = 0 or FCR0:FE2 = 0) while the framing error flag is set (SSR:FRE = 1).

The timing at which the framing error flag bit (SSR:FRE) is set is the same as that in manual mode, as described in "2.1.1 Occurrence of Reception Interrupts and Flag Set Timing." See "Figure 2-2 Set Timing of FRE (Framing Error) Flag Bit."

Occurrence of Overrun Error Interrupt and Flag Set Timing

An overrun error is detected if the following data reception has been detected before reading of the reception data (SSR:RDRF = 1). The overrun error flag is set (SSR:ORE = 1) when reception is complete (SSR:RDRF = 1). A reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1).

The reception processing of a header section and response section in assist mode stops once an overrun error is detected.

The operation enable bit for the reception FIFO is cleared (FCR0:FE1 = 0 or FCR0:FE2 = 0) while the overrun error flag is set (SSR:ORE = 1).

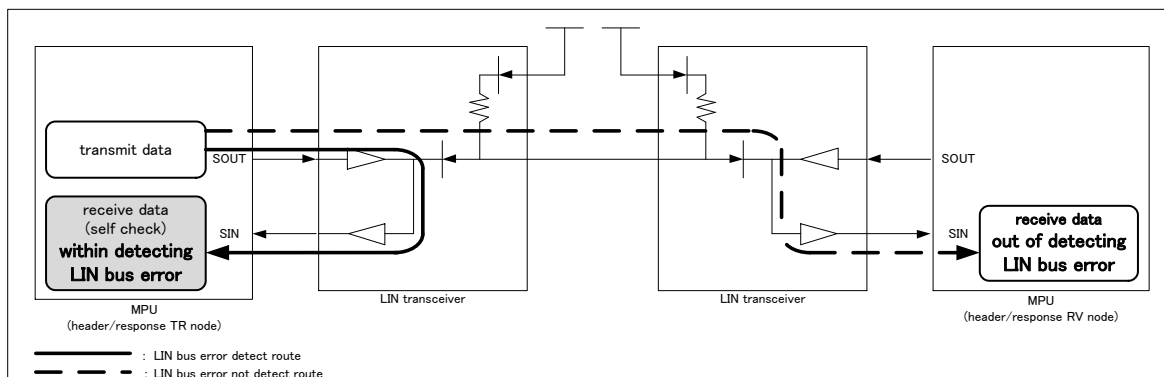

The timing at which the overrun error flag bit (SSR:ORE) is set is the same as that in manual mode, as described in "2.1.1 Occurrence of Reception Interrupts and Flag Set Timing." See "Figure 2-3 Set Timing of ORE (Overrun Error) Flag Bit."

Occurrence of LIN Bus Error Detection Interrupt and Flag Set Timing

In assist mode (LAMCR:LAMEN = 1), LIN bus error detection is executed by the self-check on the side that transmits the header/response. The side that receives the header/response cannot execute LIN bus error detection.

Figure 2-12 shows the LIN bus error detection target.

Figure 2-12 LIN BUS Error Detection Target

The target range of the LIN bus error detection is the start bit and byte data of the LIN Break and Sync Field/ID Field/Data Field/Check Sum Field. The stop bit is not included in the LIN bus error detection target. A framing error (SSR:FRE = 1) is detected when the "L" level is detected on the stop bit.

The transmission processing of a header section and response section in assist mode stops once a LIN bus error is detected.

The LIN auto header completion flag (LAMSR:LAHC = 1) is set even if a LIN bus error occurs when the ID Field transmission is complete.

Occurrence of LIN Bus Error Detection Interrupt and Flag Set Timing on the Master Side

The master side (SCR:MS = 0) performs LIN bus error detection when transmitting a header/response.

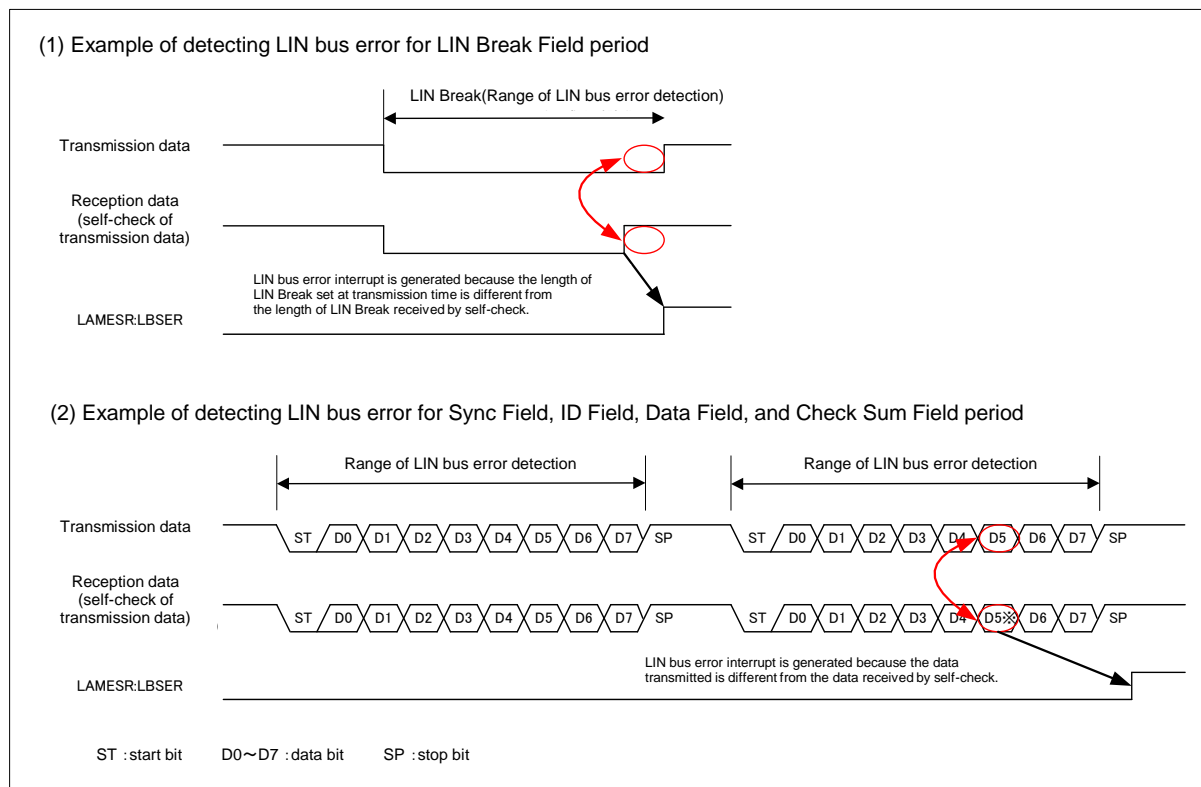

If an abnormality is detected as a result of comparing the transmission LIN Break length and the reception LIN Break length or the transmission data and reception data, then a LIN bus error is detected and a flag is set (LAMESR:LBSE = 1). A reception interrupt occurs if the interrupt is enabled (LAMIER:LBSEIE = 1).

Occurrence of LIN Bus Error Detection Interrupt and Flag Set Timing on the Slave Side

The slave side (SCR:MS = 1) performs LIN bus error detection when transmitting a response.

If an abnormality is detected as a result of comparing transmission data and reception data, then a LIN bus error is detected and a flag is set (LAMESR:LBSE = 1). A reception interrupt occurs if the interrupt is enabled (LAMIER:LBSEIE = 1).

Figure 2-13 Set Timing of LIN Bus Error Detection Flag (LAMESR:LBSE)

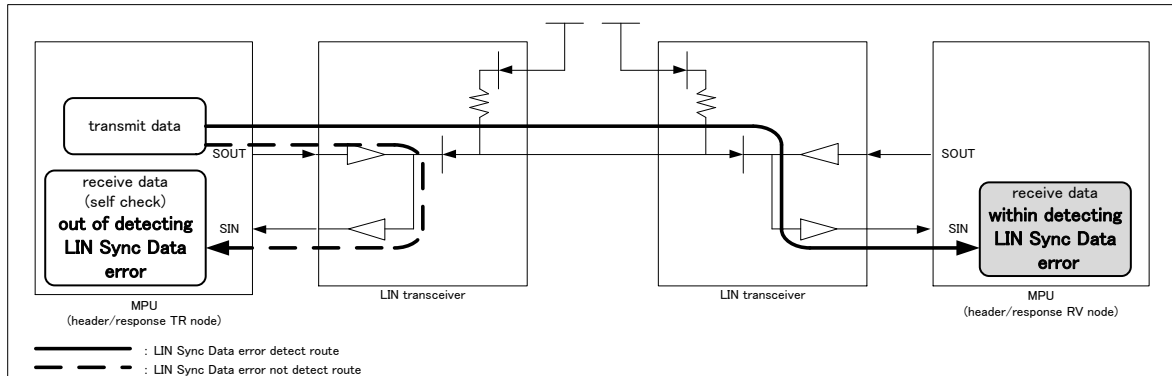

Occurrence of LIN Sync Data Error Detection Interrupt and Flag Set Timing

The LIN Sync Data error detection is executed if the auto baud rate adjustment (SACSR:AUTE = 0) is disabled when slave mode (SCR:MS = 1) is set in assist mode (LAMCR:LAMEN = 1).

Figure 2-14 shows the LIN Sync Data error detection target.

Figure 2-14 LIN Sync Data Error Detection Target

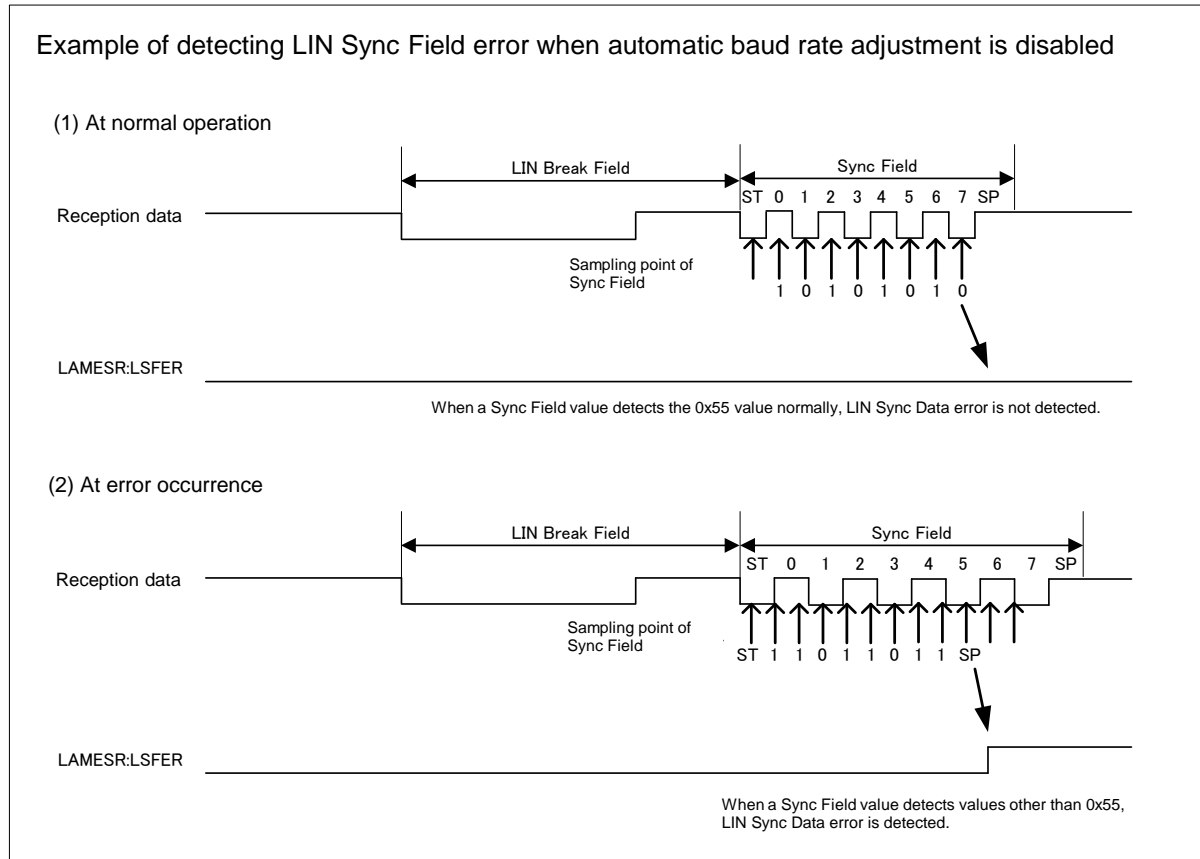

The target range of LIN Sync Data error detection is the start bit and byte data of the Sync Field. The stop bit is not included in the LIN Sync Data error detection target. A framing error (SSR:FRE = 1) is detected when the "L" level is detected on the stop bit.

Occurrence of LIN Sync Data Error Eetection Interrupt and Flag Set Timing When the Auto Baud Rate Adjustment is Disabled

In slave mode (SCR:MS = 1) when auto baud rate adjustment is disabled (SACSR:AUTE = 0), the data value of the Sync Field is checked. If any value other than 0x55 is detected, then a LIN Sync Data error is detected and a flag is set (LAMESR:LSFER = 1). At this time, a reception interrupt occurs if the interrupt is enabled (LAMIER:LSFERIE = 1).

Figure 2-15 Set Timing of LIN Sync Data Error Detection Flag (LAMESR:LSFER) (When Auto Baud Rate Adjustment is Disabled)

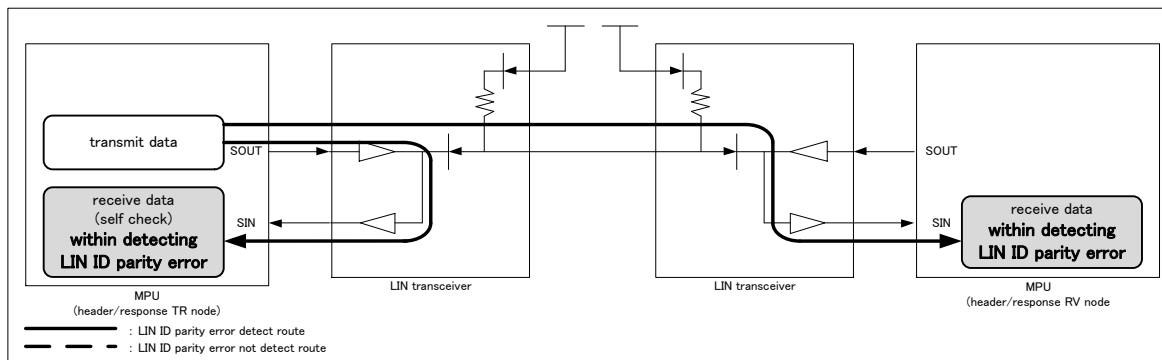

Occurrence of LIN ID Parity Error Detection Flag Interrupt and Flag Set Timing

In assist mode (LAMCR:LAMEN = 1), the LIN ID parity error detection is executed on the slave that receives the ID Field and the self-check is performed on the master that transmits the ID Field.

Figure 2-16 shows the LIN ID parity error detection target.

Figure 2-16 LIN ID Parity Error Detection Target

The target range of LIN ID parity error detection is the ID data and the byte data of the parity. The start and stop bits are not included in the LIN ID parity error detection target. A framing error occurs (SSR:FRE = 1) if the "L" level is detected on the stop bit.

In LIN assist mode (LAMCR:LAMEN = 1), the auto header completion flag is set (LAMSR:LAHC = 1) if a LIN ID parity error occurs during auto header transmission/reception.

Transmission/reception processing for a response in assist mode stops once a LIN ID parity error is detected.

Occurrence of LIN ID Parity Error Detection Interrupt and Flag Set Timing on the Master Side

The master (SCR:MS = 0) set in assist mode (LAMCR:LAMEN = 1) performs LIN ID parity error detection when transmitting the ID Field. The master executes a parity operation for the 6-bit Frame ID set in the transmission data register (TDR) or the LIN assist mode transmission ID register (LAMTID). Then, the master automatically creates and transmits an ID Field.

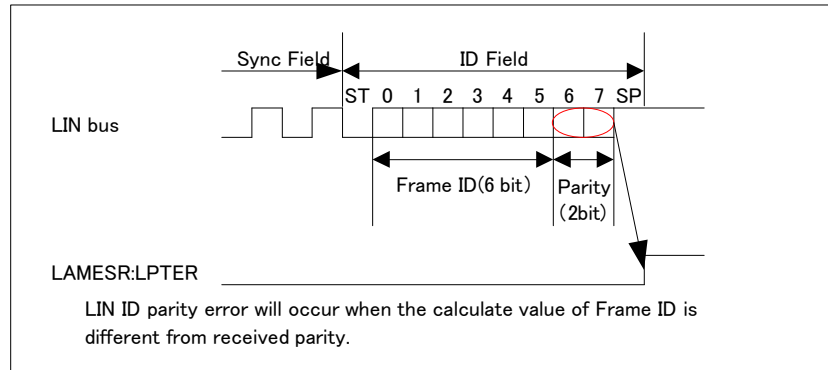

If an ID Field is received for self-check and if the parity operation result of the Frame ID value differs from the received parity value, then a LIN ID parity error is detected and a flag is set (LAMESR:LPTER = 1).

At this time, a reception interrupt occurs if the interrupt is enabled (LAMIER:LPTERIE = 1).

Occurrence of LIN ID Parity Error Detection Interrupt and Flag Set Timing on the Slave Side

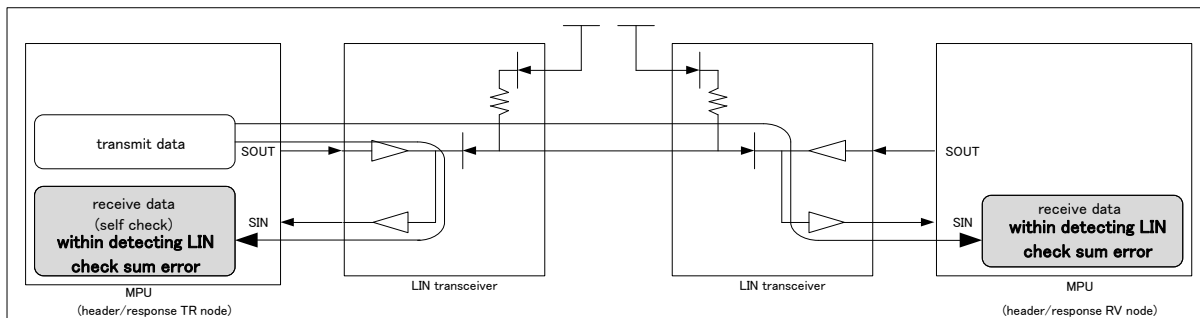

The slave (SCR:MS = 1) set in assist mode (LAMCR:LAMEN = 1) performs LIN ID parity error detection when it receives the ID Field. If the ID Field is received and if the parity operation result of the Frame ID value differs from the received parity value, then a LIN ID parity error is detected and a flag is set (LAMESR:LPTER = 1).

At this time, a reception interrupt occurs if the interrupt is enabled (LAMIER:LPTERIE = 1).

Figure 2-17 Set Timing of LIN ID Parity Error Detection Flag (LAMESR:LPTER)**Occurrence of LIN Checksum Error Detection Flag Interrupt and Flag Set Timing**

In assist mode (LAMCR:LAMEN = 1), LIN checksum error detection is executed by the self-check on the side that transmits the checksum and is also executed by the side that receives the checksum.

Figure 2-18 shows the LIN checksum error detection target.

Figure 2-18 LIN Checksum Error Detection Target

As the calculation method for the checksum that is automatically transmitted, select standard (target: data) or extended (target: ID Field + data) checksum with the LAMCR:LCSTYP bit.

Occurrence of LIN Checksum Error Detection Interrupt and Flag Set Timing When Setting Standard Checksum Calculation

When the standard checksum calculation is set (LAMCR:LCSTYP = 0), the side that transmits a response (data and checksum) performs the checksum calculation based on the transmission data for the specified LIN data length (LAMCR:LDL3-0). Then, after transmitting the last data, the transmission side automatically transmits the checksum.

The side that receives a response (data and checksum) executes the checksum calculation based on the reception data for the specified LIN data length (LAMCR:LDL3-0). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1).

At this time, a reception interrupt occurs if the interrupt is enabled (LAMIER:LCSERIE = 1).

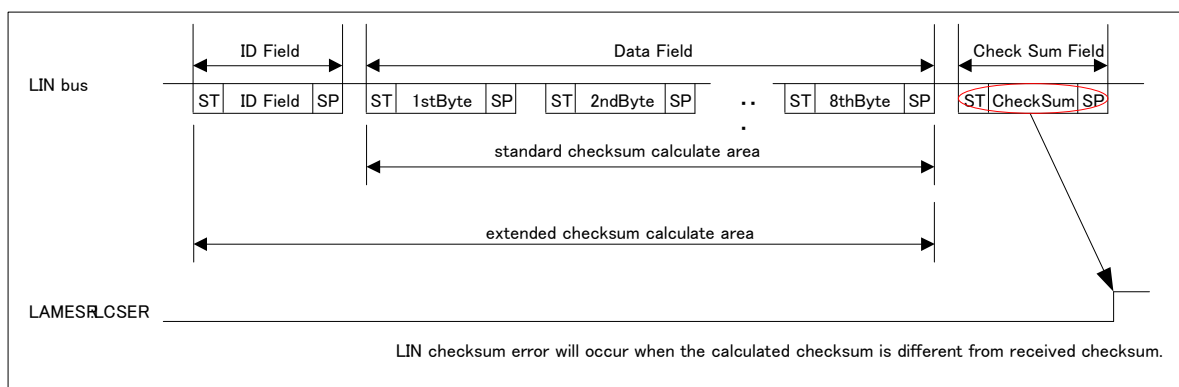

Occurrence of LIN Checksum Error Detection Interrupt and Flag Set Timing When Setting Extended Checksum Calculation

When extended checksum calculation is set (LAMCR:LCSTYP = 1), the side that transmits a response (data and checksum) performs the checksum calculation based on the ID Field value and the transmission data for the specified LIN data length (LAMCR:LDL3-0). Then, after transmitting the last data, the transmission side automatically transmits the checksum.

The side that receives a response (data and checksum) executes the checksum calculation based on the ID Field value and the reception data for the specified LIN data length (LAMCR:LDL3-0). If the received checksum differs from the calculation result value, then a LIN checksum error is detected and a flag is set (LAMESR:LCSER = 1).

At this time, a reception interrupt occurs if the interrupt is enabled (LAMIER:LCSERIE = 1).

Figure 2-19 Set Timing of LIN Checksum Error Detection Flag (LAMESR:LCSER)

Note:

- Regardless of the standard/extended checksum calculation setting, the processing performed in assist mode stops and checksum calculation is not executed if an error (LIN bus error, LIN ID parity error, LIN Sync Data error, or framing error) is detected in the data of the header section and the response section.

2.2.2. Occurrence of Interrupts and Flag Set Timing When Using Reception FIFO

The timing is the same as that in manual mode, as described in "2.1.2 Occurrence of Interrupts and Flag Set Timing When Using Reception FIFO"

2.2.3. Occurrence of Transmission Interrupts and Flag Set Timing

An interrupt occurs by the SSR:TDRE flag and the SSR:TBI flag at transmission.

Occurrence of Transmission Interrupts and Flag Set Timing

Set Timing of Transmission Data Empty Flag (TDRE)

The timing is the same as that in manual mode, as described in "2.1.3 Occurrence of Transmission Interrupts and Flag Set Timing."

Set Timing of Transmission Bus Idle Flag (TBI)

The transmission bus idle flag bit (SSR:TBI) is set to "1" when all the following conditions are satisfied. At this time, a transmission interrupt occurs if the transmission bus idle interrupt is enabled (SCR:TBIE = 1).

- The transmission data register is empty (SSR:TDRE = 1) and transmission is not performed.
- A header (LIN Break Field, Sync Field, or ID Field) has not been transmitted when the master operation (SCR:MS = 0) is used in assist mode (LAMCR:LAMEN = 1).
- A response (data and checksum) has not been transmitted in assist mode (LAMCR:LAMEN = 1).

The transmission bus idle flag bit (SSR:TBI) and a transmission interrupt request are cleared in any of the following cases.

- When writing transmission data to the transmission data register (TDR)
(The transmission data register is not empty (SSR:TDRE = 0))
- When a header (LIN Break Field, Sync Field, or ID Field) is being transmitted while the master is being used (SCR:MS = 0) in assist mode (LAMCR:LAMEN = 1).
- A response (data and checksum) is being transmitted in assist mode (LAMCR:LAMEN = 1)

Figure 2-20 Set Timing of Transmission Bus Idle Flag (TBI) (When Master Response Is Transmitted and ID Register Is Used)

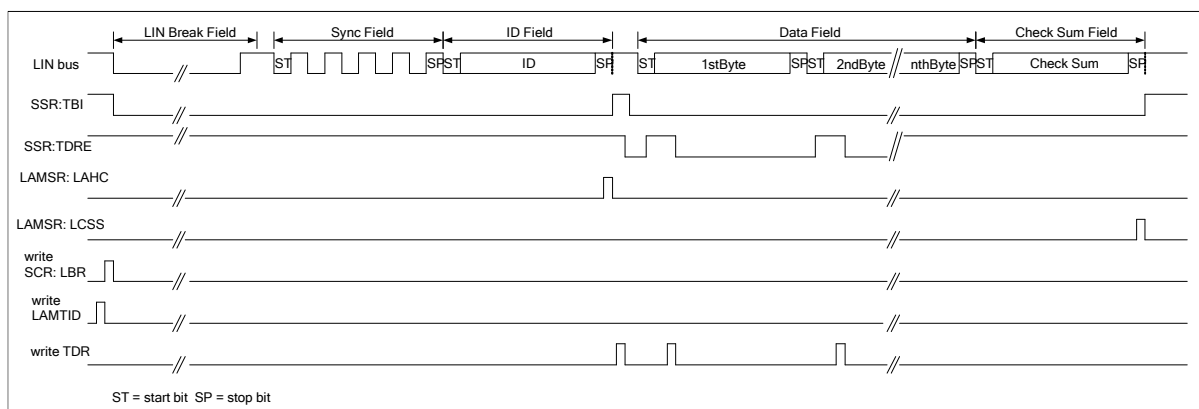

Figure 2-21 Set Timing of Transmission Bus Idle Flag (TBI) (When Master Response Is Transmitted and ID Register Is Not Used)

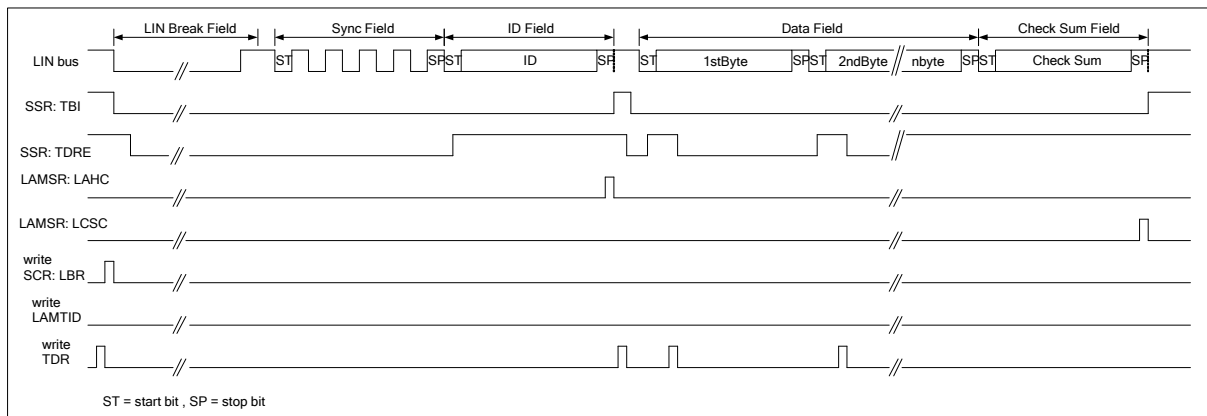

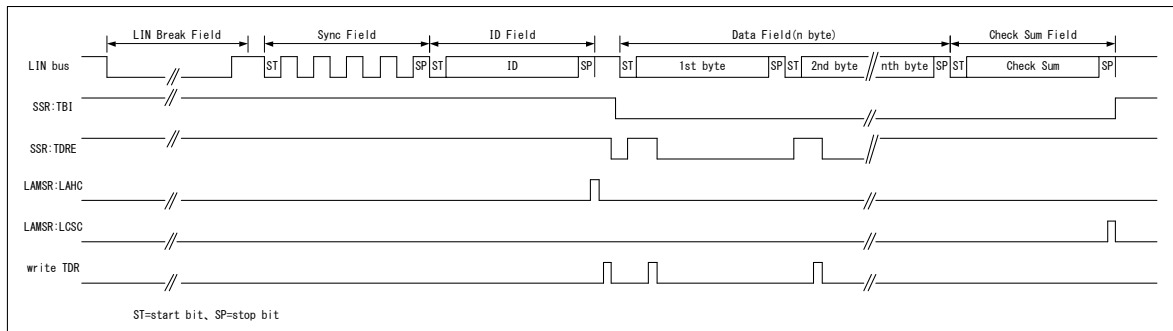

Figure 2-22 Set Timing of Transmission Bus Idle Flag (TBI) (When Slave Response Is Transmitted)

2.2.4. Occurrence of Interrupts and Flag Set Timing When Using Transmission FIFO

The timing is the same as that in manual mode, as described in "2.1.4 Occurrence of Interrupts and Flag Set Timing When Using Transmission FIFO."

2.2.5. Occurrence of Timer Interrupts and Flag Set Timing

The timing is the same as that in manual mode, as described in "2.1.5 Occurrence of Timer Interrupts and Flag Set Timing"

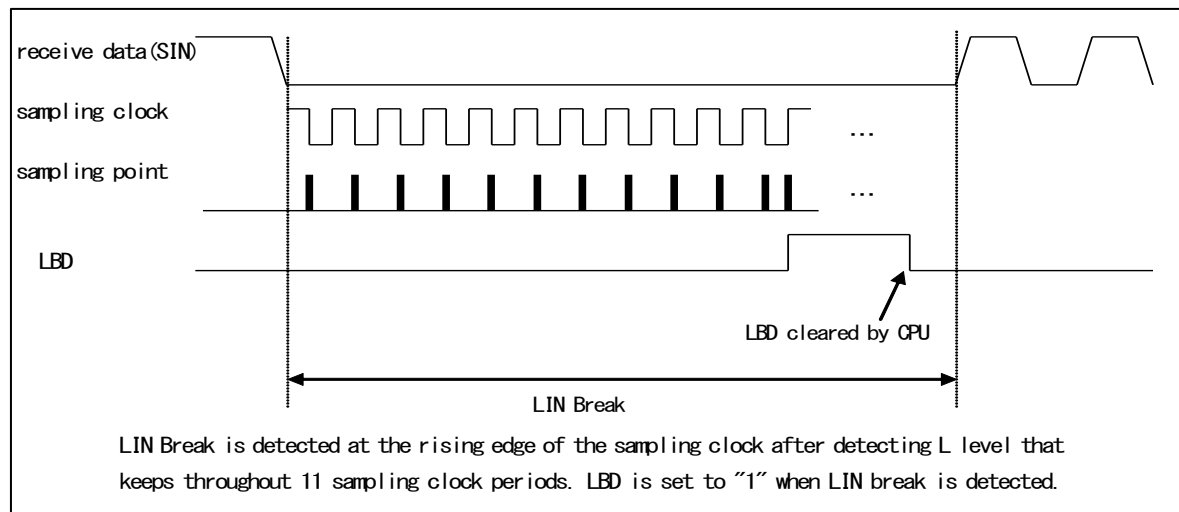

2.2.6. Occurrence of Status Interrupt and Flag Set Timing in Assist Mode

In assist mode, a status interrupt occurs when the LIN Break Field (SSR:LBD) is detected, the Sync Field is detected (SACSR:SFD), the auto header is complete (LAMSR:LAHC), or checksum calculation is complete (LAMSR:LCSC).

Set Timing of LIN Break Field Detection Flag (LBD)

The LBD bit is set to "1" when the serial input (SIN) has "0" input for an interval of 11 bits or more. At this time, a status interrupt occurs if the LIN Break Field interrupt is enabled (ESCR:LBIE = 1).

Figure 2-23 Set Timing of LBD (LIN Break Field Detection) Flag

Note:

- During the reception of a LIN Break Field, a framing error is detected before the detection of a LIN Break Field if reception is enabled (SCR:RXE = 1).

Sync Field Detection Interrupt and Flag Set Timing

The Sync Field detection interrupt and flag set timing varies as follows based on the setting value of the auto baud rate adjustment bit (SACSR:AUTE).

- When auto baud rate adjustment is enabled (SACSR:AUTE = 1)

The timing is the same as that in manual mode, as described in "2.1.7 Occurrence of Sync Field Detection Interrupt and Flag Set Timing."

■ When auto baud rate adjustment is disabled (SACSR:AUTE = 0)

The Sync Field detection flag is set (SACSR:SFD = 1) when the stop bit of the Sync Field is detected.

A status interrupt occurs if the interrupt is enabled (SACSR:SFDE = 1).

Figure 2-24 Set Timing of Sync Field Detection Flag (SACSR:SFD) When Auto Baud Rate Adjustment is Disabled (SACSR:AUTE = 0)

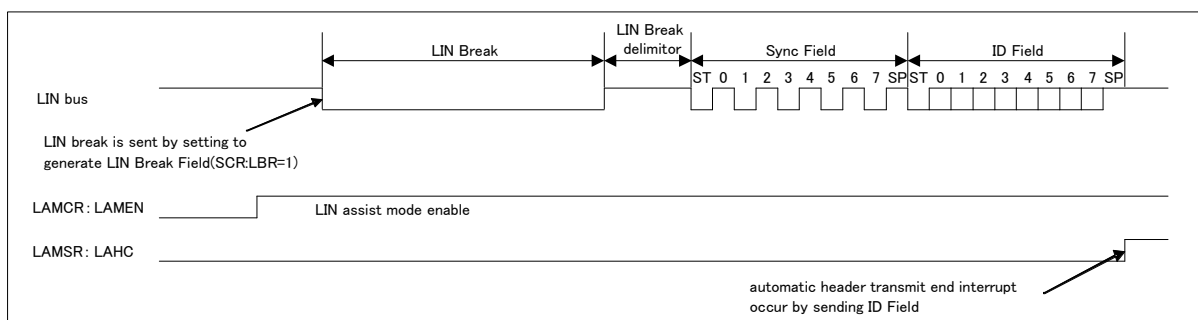

Auto Header Completion Interrupt and Flag Set Timing at Transmission

When the master is set in LIN assist mode (LAMCR:LAMEN = 1), a flag is set (LAMSR:LAHC = 1) once transmission of the headers from the LIN Break to the ID Field is complete. A status interrupt occurs if the interrupt is enabled (LAMIER:LAHCIE = 1).

In LIN assist mode, the auto header completion flag is set (LAMSR:LAHC = 1) even when a LIN bus error/LIN ID parity error/framing error occurs in the ID Field. However, the transmission/reception processing of the response section stops in LIN assist mode.

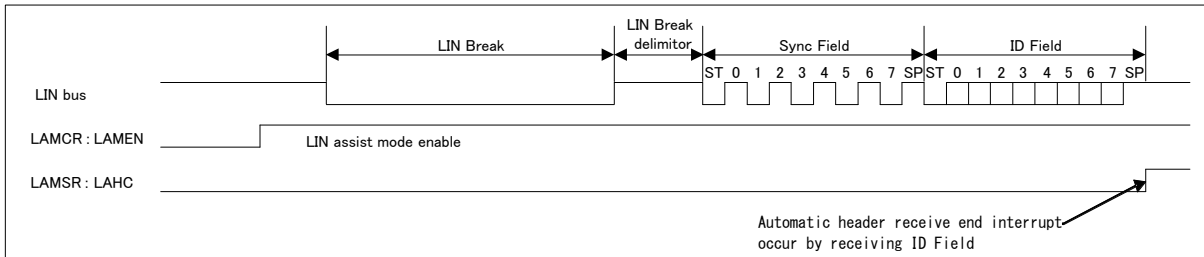

Figure 2-25 Set Timing of Auto Header Completion Flag (LAMSR:LAHC)

Auto Header Reception Completion Interrupt and Flag Set Timing at Reception

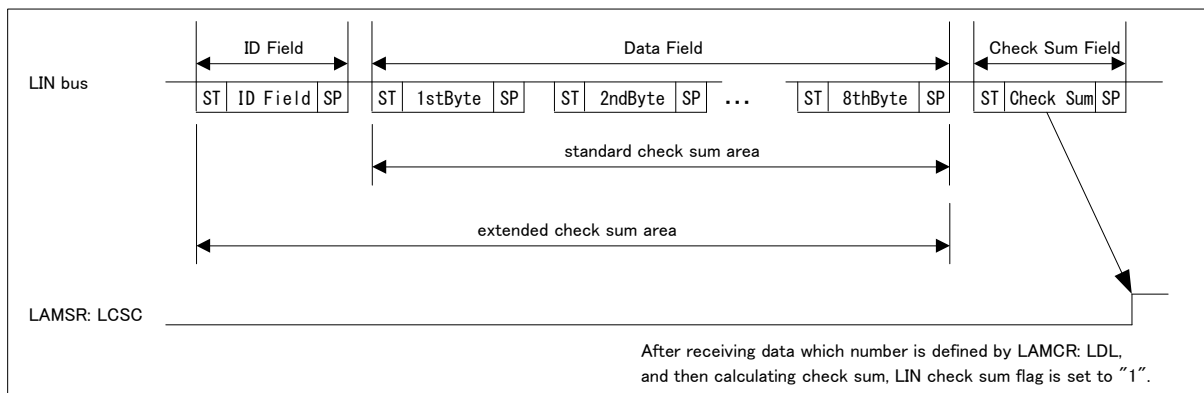

When the slave is set in LIN assist mode (LAMCR:LAMEN = 1), a flag is set (LAMSR:LAHC = 1) once reception of the headers from the LIN Break to the ID Field is complete. A status interrupt occurs if the interrupt is enabled (LAMIER:LAHCIE = 1).

In LIN assist mode, the auto header completion flag is set (LAMSR:LAHC = 1) even if a LIN bus error/LIN ID parity error/framing error occurs in the ID Field. However, transmission/reception processing for the response section stops in LIN assist mode.

Figure 2-26 Set Timing of Auto Header Completion Flag (LAMSR:LAHC)**Occurrence of LIN Checksum Detection Completion Flag Interrupt and Flag Set Timing**

When assist mode is set (LAMCR:LAMEN = 1), checksum detection is executed by the self-check performed on the side that transmits the checksum, and is also executed by the side that receives the checksum. When the data for the specified data length (LAMCR:LDL3 to LDL0) and checksum are received, the checksum calculation is complete so a flag is set (LAMSR:LCSC = 1). A status interrupt occurs if the interrupt is enabled (LAMIER:LCSCIE = 1).

When checksum reception is complete, the received checksum value is not stored in the RDR register and the SSR:RDRF is not set to "1". When a FIFO is used, the value is not stored in the reception FIFO.

Figure 2-27 Set Timing of LIN Checksum Detection Completion Flag (LAMSR:LCSC)**Notes:**

- The checksum calculation stops as soon as a framing error is detected in the last data of the specified data length (LAMCR:LDL3 to LDL0).
- If a framing error is detected in the checksum, the calculation result is not guaranteed.

3. Serial Timer Operation

The serial timer provides timer functions.

Serial Timer Operation

Activating Serial Timer

The serial timer can be activated by setting the serial timer enable bit (SACSR:TMRE) to "1", either by an external trigger or by the Sync Field.

■ Activation by the serial timer enable bit (SACSR:TMRE)

When the external trigger enable bit (SACSR:TRGE) is set to "0", setting the serial timer enable bit (SACSR:TMRE) to "1" activates the serial timer and starts counting of the serial timer register (STMR) from 0.

Figure 3-1 Activation by Serial Timer Enable Bit (STMCR = 10, SACSR:TRGE = 0)

■ Activation by an external trigger

The serial timer is activated and counting of the serial timer register (STMR) starts from 0 when all of the following are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is set to "1". 2. An external trigger edge specified by the trigger selection bit (TRG1, 0) is detected. 3. The serial timer enable bit (SACSR:TMRE) is set to "1".

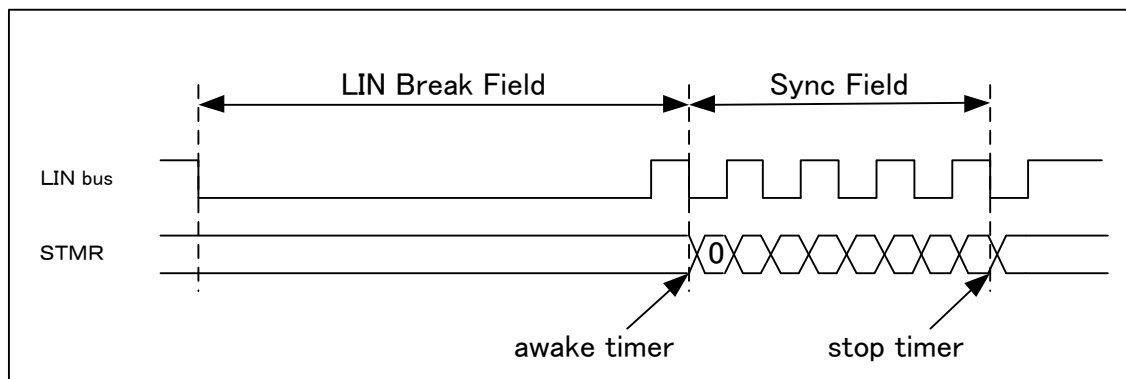

Figure 3-2 Activation by an External Trigger (STMCR = 10, SACSR:TRGE = 1, TRG1 = 0, TRG0 = 0)

■ Activation by Sync Field reception

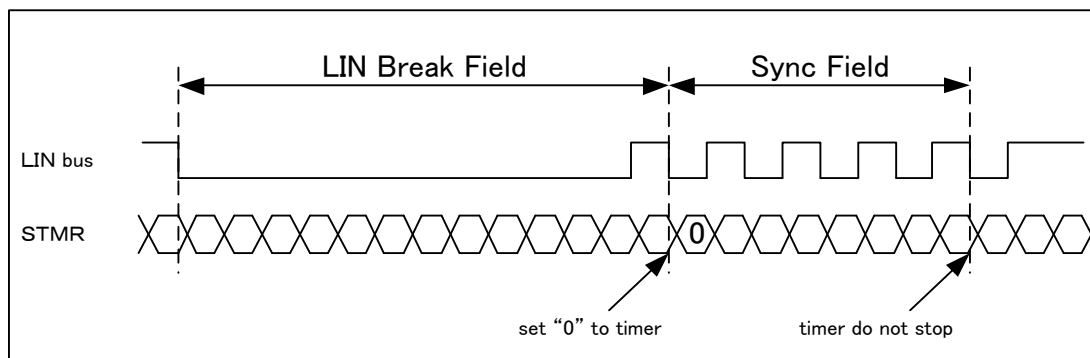

The serial timer is activated and counting of the serial timer register (STMR) starts from 0 when all of the following are satisfied: 1. The serial timer is stopped. 2. The auto baud rate adjustment bit (SACSR:AUTE) is set to "1". 3. The LIN interface (v2.1) detects the first falling edge of the Sync Field.

Figure 3-3 Reception of Sync Field While Serial Timer Is Stopped (SACSR:AUTE = 1, TMRE = 0)

Counting of the serial timer register (STMR) starts from 0 when all of the following are satisfied: 1. The serial timer is operating. 2. The auto baud rate adjustment bit (SACSR:AUTE) is set to "1". 3. The LIN interface (v2.1) detects the first falling edge of the Sync Field.

Figure 3-4 Reception of Sync Field While Serial Timer Is Operating (SACSR:AUTE = 1, TMRE = 1)

Note:

- Detection of an external trigger edge specified by the trigger selection bit (SACSR:TRG1, 0) does not start the serial timer when both of the following are satisfied: 1. The external trigger enable bit (SACSR:TRGE) is set to "1". 2. The serial timer enable bit (SACSR:TMRE) is set to "0".

Stopping the Serial Timer

The serial timer stops under the following conditions.

- The serial timer stops when both of the following are satisfied: 1. The auto baud rate adjustment bit (SACSR:AUTE) is set to "0". 2. The serial timer enable bit (SACSR:TMRE) is reset to "0". At this time, the value of the serial timer register (STMR) is retained.
- The serial timer stops when all of the following are satisfied: 1. The auto baud rate adjustment bit (SACSR:AUTE) is set to "1". 2. The serial timer enable bit (SACSR:TMRE) is set to "1". 3. The serial timer enable bit (SACSR:TMRE) is reset to "0" in any status other than that indicating that the Sync Field is being received. At this time, the value of the serial timer register (STMR) is retained.
- The serial timer stops and the value of the serial timer register (STMR) is retained if the LIN interface (v2.1) detects the 5th falling edge of the Sync Field, when both of the following are satisfied: 1. The auto baud rate adjustment bit (SACSR:AUTE) is set to "1". 2. The serial timer enable bit (SACSR:TMRE) is set to "0".

Note:

- *The serial timer does not stop and continues operating even if the LIN interface (v2.1) detects the 5th falling edge of the Sync Field, when both of the following are satisfied: 1. The auto baud rate adjustment bit (SACSR:AUTE) is set to "1". 2. The serial timer enable bit (SACSR:TMRE) is set to "1".*

Timer Operation

If the serial timer register (STMR) and the serial timer comparison register (STMCR) match, the timer interrupt flag (SACSR:TINT) is set to "1", and the serial timer register (STMR) is reset to "0".

Figure 3-5 Timer Operation (STMCR = 10)

Figure 3-6 Serial Timer Initialization

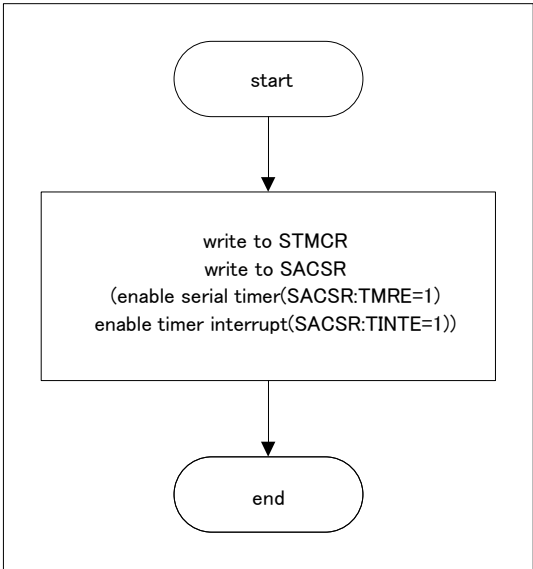

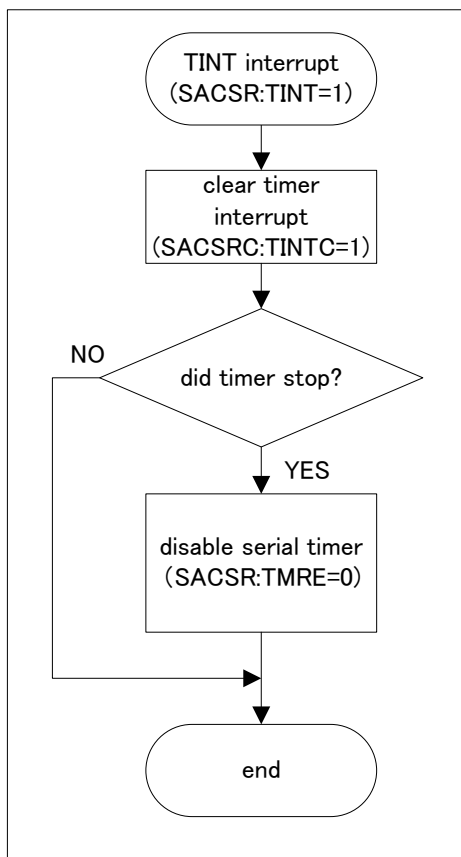

Figure 3-7 Serial Timer Interrupt

Notes:

- The timer interrupt flag (SACSR:TINT) is fixed to "1" when the timer comparison register (STMCR) is set to 0x0000, the timer is operating, and the division value (SACSR:TDIV) of the timer operation clock is set to 0b0000.
- The serial timer register (STMR) is reset to "0" after receiving the Sync Field when the auto baud rate adjustment bit (SACSR:AUTE) is set to "1".

4. Test Mode

This chapter describes the operation in test mode.

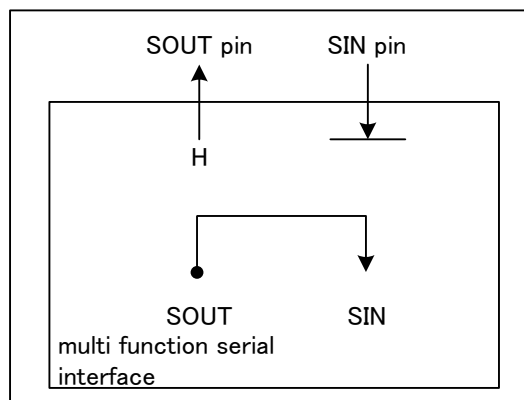

4.1. Manual Mode

Serial Test Mode

When serial test mode is enabled ($SACSR:STST = 1$), SOUT and SIN are connected together within the multi-function serial interface, so that the data transmitted from SOUT can be received through SIN directly.

When serial test mode is enabled ($SACSR:STST = 1$), the SOUT pin is fixed to "H", and the data input to the SIN pin is ignored.

Figure 4-1 Serial Test Mode

Notes:

- The value of the serial test mode enable bit ($SACSR:STST$) can be changed only when transmission and reception are prohibited ($SCR:TXE = RXE = 0$).
- In manual mode ($LAMCR:LAMEN = 0$), do not set the pseudo error test mode.

4.2. Assist Mode

Serial test mode

This mode is the same as Serial Test Mode in manual mode.

However, in LIN assist mode (LAMCR:LAMEN = 1), the serial test can be executed only on the master node (SCR:MS = 0). The serial test result is checked by the transmission/reception flag and the status flag. For the transmission/reception flag and status flag, see "Table 2-4 LIN Interface (v2.1) Interrupt Control Bits and Interrupt Factors (Assist Mode)."

Notes:

- In LIN assist mode (LAMCR:LAMEN = 1), the serial test cannot be executed on the slave node (SCR:MS = 1).
- When the serial test is executed on the master node (SCR:MS = 0) in LIN assist mode (LAMCR:LAMEN = 1), transmission data (the Sync Field, ID Field, and response data, as well as the checksum) cannot be read by the reception data register (RDR).

Pseudo Error Test Mode

In assist mode (LAMCR:LAMEN = 1), a LIN bus error, LIN Sync Data error, LIN ID parity error, LIN checksum error, and framing error can be generated as a pseudo error. More than one of these errors can be generated at the same time.

Any of the following self-diagnostics can be executed by implementing serial test mode together.

- Pseudo LIN bus error test mode
- Pseudo LIN ID parity error test mode
- Pseudo LIN checksum error test mode
- Pseudo framing error test mode

Activating Pseudo Error Test Mode

To activate pseudo error test mode, it is necessary to enable the pseudo error setting by writing values to the key code control bit (LAMERT:KEY1, KEY0) according to the following procedure.

- KEY1, KEY0 = 0b00 + write a pseudo error setting value
- KEY1, KEY0 = 0b01 + write the pseudo error setting value (same as the previous value)
- KEY1, KEY0 = 0b10 + write the pseudo error setting value (same as the previous value)
- KEY1, KEY0 = 0b11 + write the pseudo error setting value (same as the previous value)
- The pseudo error setting value is enabled when the value is written for the 4th time.

The value written to this register is invalid if you do not follow this setting procedure (if a value is written or read to/from another register during the writing process, if the value written is incorrect, or if a value is read from this register during the writing process).

To clear a pseudo error setting, follow the same procedure for making a pseudo error setting.

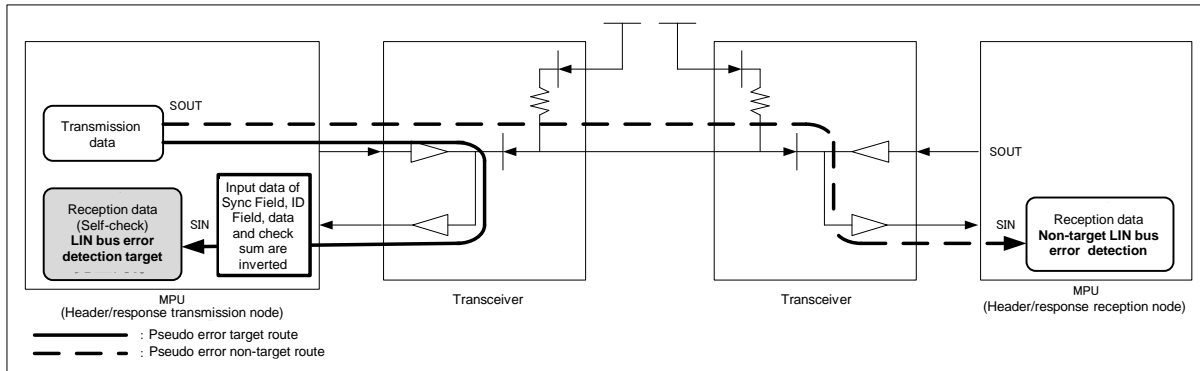

Notes:

- LIN communication stops when any of the following pseudo errors occurs in assist mode.
 - LIN bus error
 - LIN ID parity error
 - Framing error
- In manual mode (LAMCR:LAMEN = 0), do not set pseudo error test mode.

Overview of pseudo LIN bus error test mode

During a pseudo LIN bus error test, a node that transmits data receives the transmitted data by inverting it.

Figure 4-2 Overview of Pseudo LIN Bus Error Test Mode

To activate pseudo LIN bus error test mode, set the LIN bus error pseudo error setting bit (LAMERT:LBSERT = 1) according to the method used to activate pseudo error test mode.

Activating pseudo LIN bus error test mode causes the following operation to be performed.

■ Master

The Sync Field, ID Field, data, and checksum are transmitted.

Once the LIN bus error pseudo error setting is set (LAMERT:LBSERT = 1), the reception data is inverted at the stop bit timing. Then, a LIN bus error occurs during the self-check and the flag bit (LAMESR:LBSER) is set to "1".

■ Slave

Data and the checksum are transmitted.

Once the LIN bus error pseudo error setting is set (LAMERT:LBSERT = 1), the reception data is inverted at the stop bit timing. Then, a LIN bus error occurs during the self-check and the flag bit (LAMESR:LBSER) is set to "1".

Notes:

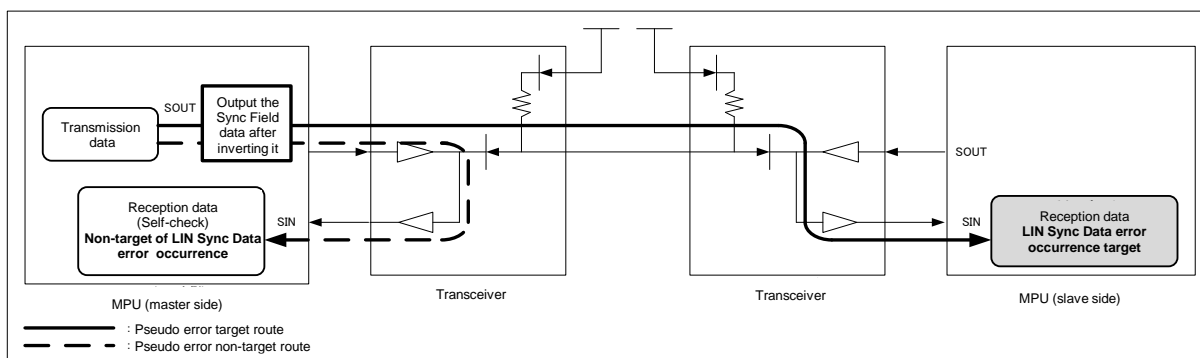

- When a LIN bus error is detected (LAMESR:LBSER = 1), the transmission/reception processing of the header and response sections in assist mode stops.
- Enable this test mode only when transmitting a header or response.

Overview of Pseudo LIN Sync Data Error Test Mode

In a pseudo LIN Sync Data error test, the Sync Field value (0x55) is transmitted after being inverted.

The master that transmits the Sync Field cannot detect a pseudo LIN Sync Data error.

Figure 4-3 Overview of Pseudo LIN Sync Data Error Test Mode

To activate pseudo LIN Sync Data error test mode, it is necessary to enable the LIN Sync Data error pseudo error setting bit (LAMERT:LSFERT = 1) according to the method used to activate pseudo error test mode.

When the pseudo LIN Sync Data error pseudo error setting (LAMERT:LSFERT = 1) is set in the master before the start bit of the Sync Field, the master outputs the value (0x55) after inverting it when transmitting the Sync Field.

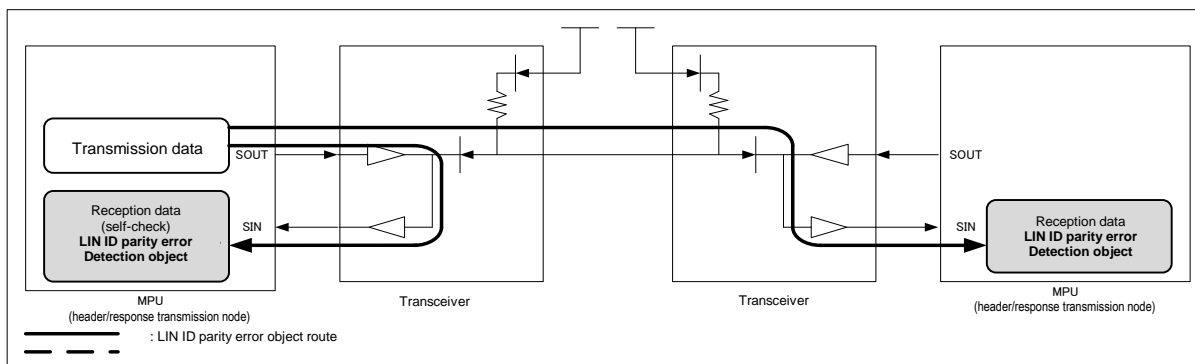

Notes:

- A LIN Sync Data error is detected in the slave (SCR:MS = 1) in assist mode (LAMCR:LAMEN = 1).
- When a LIN Sync Data error is detected (LAMESR:LSFER = 1), the reception processing of the header and transmission/reception processing for the response in assist mode stops.
- Both master and slave modes can be set; however, a pseudo LIN Sync Data error can be generated only in master mode.
- Set (SCR:LBR = 1) before LIN communication starts.
- Set the LIN bus error pseudo error setting bit (LAMERT:LBSERT = 1) at the same time as this bit (LAMERT:LSFERT = 1) is set.

Overview of Pseudo LIN ID Parity Error Test Mode

During the pseudo LIN ID parity error test, a parity bit is transmitted after being inverted.

Figure 4-4 Overview of Pseudo LIN ID Parity Error Test Mode

To activate pseudo LIN ID parity error test mode, it is necessary to enable the LIN ID parity error pseudo error setting bit (LAMERT:LPTERT = 1) according to the method used to activate the pseudo error test mode.

When the pseudo LIN ID parity error pseudo error setting (LAMERT:LPTERT = 1) is made on the master before the start bit of the ID Field, the master outputs the parity values (2 bits) to the ID Field after inverting them all when transmitting the ID Field.

When receiving the ID Field, a LIN ID parity error occurs and the flag bit (LAMESR:LPTER) is set to "1".

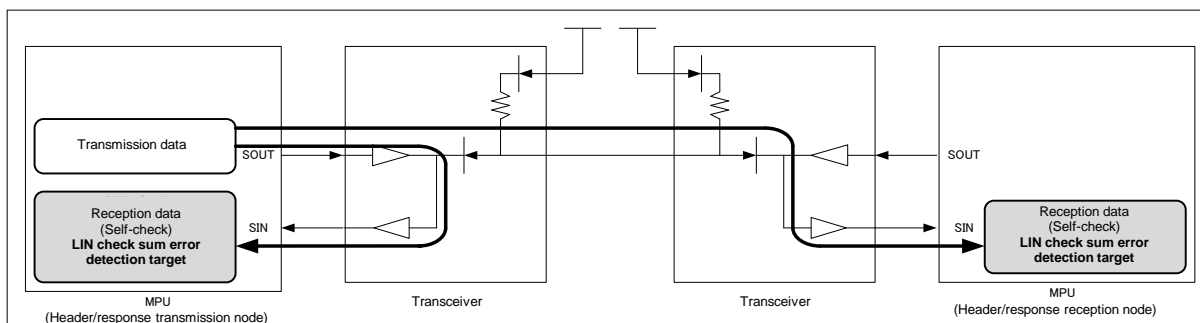

Notes:

- The transmission/reception processing for a response in assist mode stops once a LIN ID parity error is detected (LAMESR:LPTER = 1).
- Both master and slave mode can be set; however, a pseudo LIN parity error can be generated only in master mode.
- Set (SCR:LBR = 1) before the LIN communication starts.

Overview of Pseudo LIN Checksum Error Test Mode

During the pseudo LIN checksum error test, the checksum data is transmitted after being inverted.

Figure 4-5 Overview of Pseudo LIN Checksum Error Test Mode

To activate pseudo LIN checksum error test mode, it is necessary to enable the LIN checksum error pseudo error setting bit (LAMERT:LCSERT = 1) according to the method used to activate pseudo error test mode.

When transmitting the checksum, the checksum data is transmitted after being inverted. At this time, the flag bit is set to "1" (LAMESR:LCSEr) because the LIN bus is monitored.

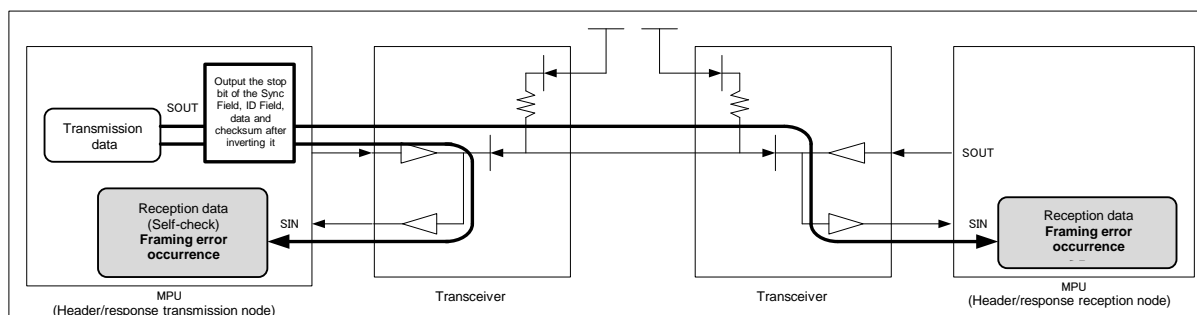

Notes:

- In master mode, set (SCR:LBR = 1) before LIN communication starts.
- In slave mode, make this setting before transmitting a response.

Overview of Pseudo Framing Error Test Mode

During the pseudo framing error test, the stop bit is transmitted after being inverted.

Figure 4-6 Overview of Pseudo Framing Error Test Mode

To activate pseudo framing error test mode, it is necessary to enable the framing error pseudo error setting bit (LAMERT:FRET = 1) according to the method used to activate pseudo error test mode.

Activating pseudo framing error test mode causes the following operation to be performed.

■ Master

When the framing error pseudo error setting is made (LAMERT:FRET = 1) before the stop bit of each Field, the stop bit value ("H" level) is output after being inverted when transmitting the Sync Field, ID Field, data, and checksum.

During reception, a framing error occurs and the flag bit (SSR:FRE) is set to "1".

■ Slave

When the framing error pseudo error setting is made (LAMERT:FRET = 1) before the stop bit of each Field, the stop bit value ("H" level) is output after being inverted when transmitting the data and checksum.

During reception, a framing error occurs and the flag bit (SSR:FRE) is set to "1".

Note:

- When a framing error is detected (SSR:FRE = 1), transmission/reception processing of the header and response sections in assist mode stops.

5. Dedicated Baud Rate Generator

The transmission and reception clock source for the LIN interface (v2.1) can be selected from the following.

- Dedicated baud rate generator (reload counter)
- Input of an external clock to the baud rate generator (reload counter)

LIN Interface (v2.1) Baud Rate

A baud rate can be selected from the following 2 types:

Baud Rate Obtained by Dividing the Internal Clock by the Dedicated Baud Rate Generator (Reload Counter)

There are 2 internal reload counters, each of which corresponds to the transmission or reception serial clock. A baud rate can be selected by setting a 15-bit reload value in the baud rate generator register 1 or 0 (BGR1, BGR0).

The reload counters divide the internal clock according to the set value.

Set the clock source by selecting an internal clock (BGR1:EXT = 0).

Note:

- When auto baud rate adjustment is enabled (SACSR:AUTE = 1), set in the internal clock (BGR1:EXT=0),

Baud Rate Obtained by Dividing an External Clock by the Dedicated Baud Rate Generator (Reload Counter)

An external clock is used as the clock source for the reload counter.

A baud rate can be selected by setting a 15-bit reload value in the baud rate generator register 1 or 0 (BGR1, BGR0).

The reload counters divide the external clock according to the set value.

Set a clock source by selecting the use of an external clock and the baud rate generator clock (BGR1:EXT = 1).

This mode is provided for dividing and using an oscillator with a special frequency.

Notes:

- Make the setting of the external clock (BGR1:EXT = 1) under the condition whereby the reload counter is stopped (BGR1/0 = 0x0000).
- When the external clock setting is specified (BGR1:EXT = 1), the "H" width and "L" width of the external clock must be 2 bus clocks or more.
- When the external clock setting is specified (BGR1:EXT = 1), auto baud rate adjustment is disabled (SACSR:AUTE = 0).

5.1. Setting Baud Rate

This section describes baud rate setting. This section also describes the result of calculating the serial clock frequency.

Calculation of Baud Rate

The 2 15-bit reload counters are set by baud rate generator registers 1, 0 (BGR1, BGR0).

The baud rate calculation formulas are shown below.

(1) Reload value:

$$V = \Phi / b - 1$$

V : reload value b : baud rate Φ : frequency of bus clock or that of external clock

(2) Calculation example

When bus clock is 16MHz, using internal clock, baud rate is 19200 bps, the reload value can be calculated as follows.

reload value :

$$V = (16 \times 1000000) / 19200 - 1 = 832$$

then baud rate will be

$$b = (16 \times 1000000) / (832 + 1) = 19208\text{bps}$$

(3) Baud rate error

The baud rate error is obtained by the following formula.

$$\text{error rate(\%)} = (\text{calculated value} - \text{target value}) / \text{target value} \times 100$$

(ex. When bus clock is 20MHz, target baud rate is 153600 bps,

the result will be as follows.

$$\text{reload value} = (20 \times 1000000) / 153600 - 1 = 129$$

$$\text{calculated baud rate} = 20 \times 1000000 / (129 + 1) = 153846 \text{ (bps)}$$

$$\text{error rate (\%)} = (153846 - 153600) / 153600 \times 100 = 0.16 \text{ (\%)}$$

Notes:

- Setting the reload value to "0" stops the reload counter.
- When the reload value is even, the "L" width of the serial clock is 1-bus-clock-cycle longer than the "H" width. When the reload value is odd, the "L" width and the "H" width of the serial clock are equal.
- Set the reload value to 3 or larger. However, data may not be received normally depending on the baud rate errors and the reload value setting.
- When considering the tolerable baud rate range, also consider the impact of any jitter in the clock input on the macro.

Example of Reload Values and Baud Rate Settings for Individual Bus Clock Frequencies

The following table shows example reload values and baud rate settings.

Table 5-1 Example Reload Values and Baud Rate Settings

Baud Rate (bps)	8 MHz		10 MHz		16 MHz		20 MHz		24 MHz		32 MHz	
	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR	Value	ERR

Reception Baud Rate Tolerance

Described here is the number of errors in the receiver baud rate that can be tolerated during reception.

Use the following formula to ensure that the baud rate errors during data reception fall within the tolerable range.

Figure 5-1 Reception Baud Rate Tolerance

After the detection of a start bit, the sampling timing for the reception data is determined by the counters set in registers BGR1/0 as shown in the figure. The data can be received normally if all the data up to the last data (stop bit) is included in this sampling timing.

Theoretically, this derives the following for 10-bit data reception.

When the sampling timing margin is 1 bus clock cycle (ϕ), the tolerable minimum transfer rate (FLmin) will be as follows:

$$FL_{min} = (10 \text{ bits} * (V + 1) - (V + 1) / 2 + 2) / \phi = (19V + 23) / 2 \phi \text{ (s)} \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

Therefore, the maximum transmitted baud rate (BGmax) that can be received will be as follows:

$$BG_{max} = 10 / FL_{min} = 20 \phi / (19V + 23) \text{ (bps)} \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

When receiving data at the tolerable maximum transfer rate (FLmax), sampling is done at the first point of the received 10th-bit.

Therefore, the tolerable maximum transfer rate (FLmax) will be as follows:

$$9 / 10 * FL_{max} = (10 \text{ bits} * (V + 1) - (V + 1) / 2) / \phi \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

$$FL_{max} = (19 / 18 * 10 * (V + 1)) / \phi$$

When the sampling timing margin (ϕ) is 2 clock cycles, the tolerable maximum transfer rate (FLmax) will be as follows:

$$9 / 10 * FL_{max} = (10 \text{ bits} * (V + 1) - (V + 1) / 2 - 2) / \phi \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

$$FL_{max} = (19 / 18 * 10 * (V + 1) - 40 / 18) / \phi = (190V + 150) / 20 \phi \text{ (s)} \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

Therefore, the minimum transmitted baud rate (BGmin) that can be received will be as follows:

$$BG_{min} = 10 / FL_{max} = 18 \phi / (19V + 15) \text{ (bps)} \quad V: \text{Reload value}, \phi: \text{Bus clock}$$

The baud rate tolerable errors for the LIN interface (v2.1) and the transmission destination will be as follows, when calculated using the above formulas for the minimum and maximum baud rate values.

Reload Value (V)	Maximum Baud Rate Error Tolerable	Minimum Baud Rate Error Tolerable
3	0%	0
10	+3.28%	-3.41%
50	+4.83%	-4.87%
100	+5.04%	-5.07%
200	+5.15%	-5.16%
32767	+5.26%	-5.26%

Note:

- The receiving accuracy depends on the number of bits in a frame, the bus clock, and the reload value. A higher accuracy is achieved through the use of a higher bus clock and a higher division ratio.

External Clock

Writing "1" to the EXT bit in the baud rate generator register (BGR1) causes the baud rate generator to divide the external clock.

Note:

- The external clock synchronizes with the internal clock of the LIN interface (v2.1). Therefore, an external clock that cannot be synchronized causes the operation to become unstable.

Reload Counter Function

The transmission reload counter and reception reload counter both function as dedicated baud rate generators. They each consist of 15-bit registers for the reload values. They generate a transmission clock and a reception clock from either an external clock or the internal clock.

Start of Counting

When a reload value is written to the baud rate generator registers (BGR1 and BGR0), the reload counters start counting.

Restarting

A reload counter restarts under the following conditions:

For both the Transmission and Reception Reload Counters

- Programmable reset (SCR:UPCL bit)

Reception Reload Counter

- Detection of a falling edge of the start bit in asynchronous mode

6. Block Transfer

This section describes the operation of block transfer.

Setting Block Transfer

Block transfer can be performed for reception by setting RXBLKEN in the extended control register (ECR) to 1 and for transmission by setting TXBLKEN to 1.

Block transfer can be performed in that mode in which it is operated with the READ/WRITE access standard (RW access mode).

The block size can be set with the transmission block size register and FBYTE register (for the reception side).

The threshold at which to output a block transfer request can be set with the FBYTE register for reception and with the FTICR register for transmission. When the amount of data in the reception FIFO exceeds the setting made for the FBYTE register, a reception block transfer request is output. When the amount of free space in the transmission FIFO exceeds the setting made for the FTICR register, a transmission block transfer request is output.

6.1. RW Access Mode

This section describes block transfer in RW access mode.

Reception Block Transfer

Reception block transfer is performed as described below.

If the amount of data in the reception FIFO is over the threshold (FBYTE), a reception block transfer request (RIRQ) is asserted. At this time, the value of the reception block size is reloaded from the FBYTE register to the Read counter. When the reception FIFO is not used, the value of the reception block size is "1".

After the reception block transfer request, if reading a reception data occurs, the reception block transfer request (RIRQ) is cleared. With reading a reception data, the Read counter is decremented.

When the Read counter becomes "0", if the amount of data in the reception FIFO is over the threshold (FBYTE), the reception block transfer request (RIRQ) is asserted again. With the assertion of the reception block transfer request (RIRQ), the Read counter is reloaded.

During application operation, if the next block transfer request occurs before the completion of the previous block transfer, this state might be reported to the system by a block transfer error. This state does not occur if you configure FBYTE=1. Completion of block transfer by DMA depends on occupation of bus transaction by application. You need to fully evaluate the application integrally, design the system, and choose the optimal number of block transfers.

Figure 6-1 Reception Block Transfer in RW Access Mode

Transmission Block Transfer

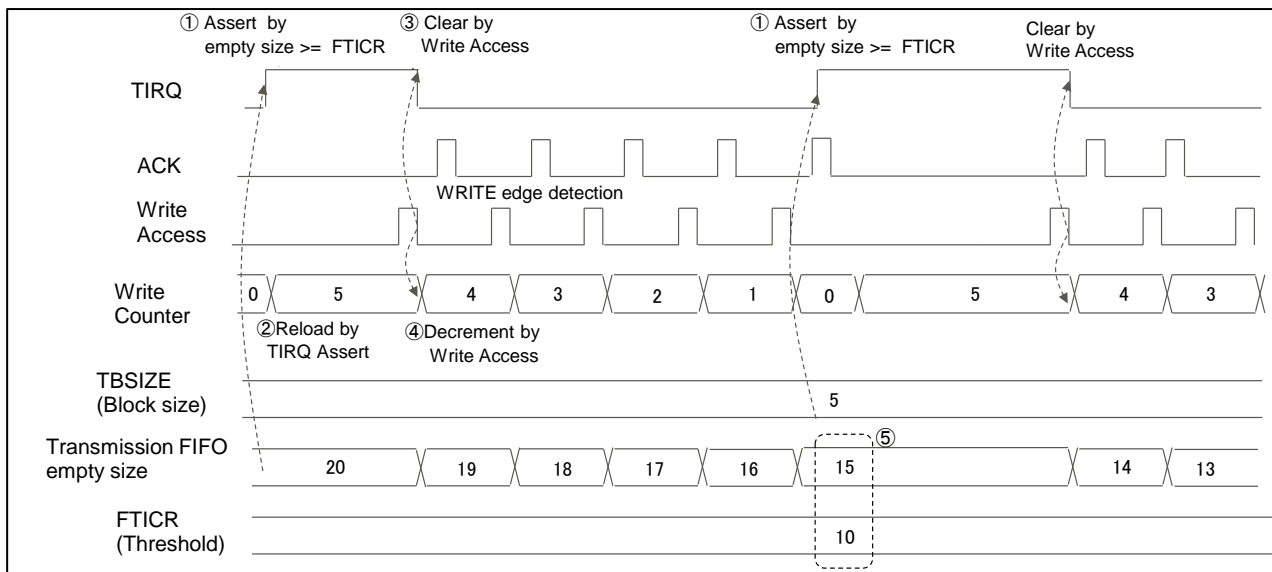

Transmission block transfer is performed as described below.

If the amount of free space in the transmission FIFO exceeds the threshold (FTICR), a transmission block transfer request (TIRQ) is asserted. At this time, the value of the transmission block size is reloaded from the TBSIZE register to the Write counter. When the transmission FIFO is not used, the value of the transmission block size is "1".

After the transmission block transfer request, if writing a transmission data occurs, the transmission block transfer request (TIRQ) is cleared. By writing a transmission data, the Write counter is decremented.

When the Write counter becomes "0", if the free space in the transmission FIFO exceeds the threshold (FTICR), the transmission block transfer request (TIRQ) is asserted again. With the assertion of the transmission block transfer request (TIRQ), the Write counter is reloaded.

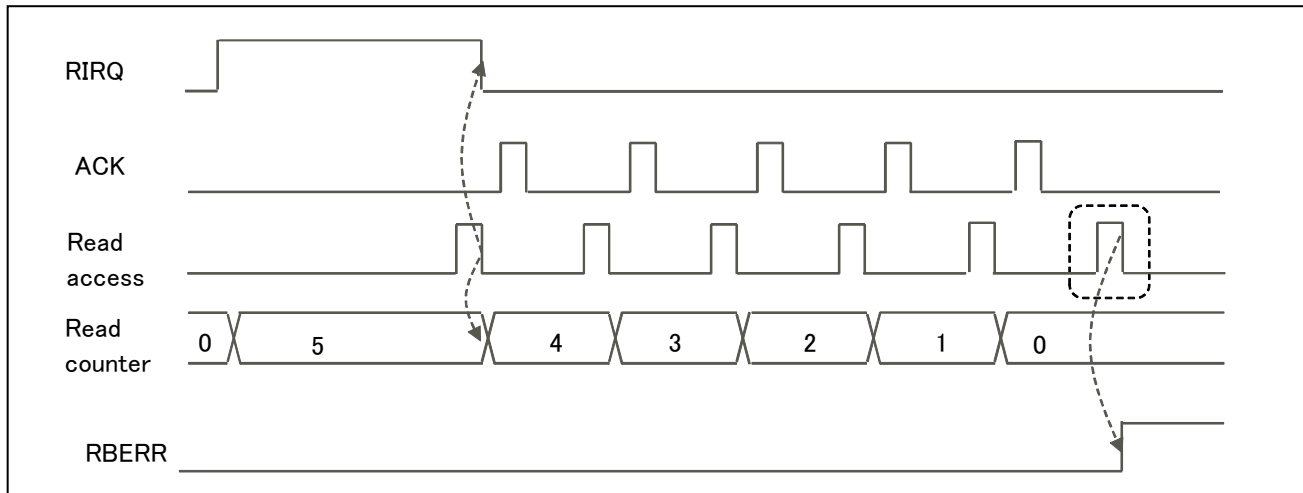

Figure 6-2 Transmission Block Transfer in RW Access Mode

Reception Block Transfer Error

If, while the Read counter is "0", a read access occurs before the next reception block transfer request (RIRQ) is asserted, a reception block transfer error occurs, and the ESR:RBERR bit is asserted.

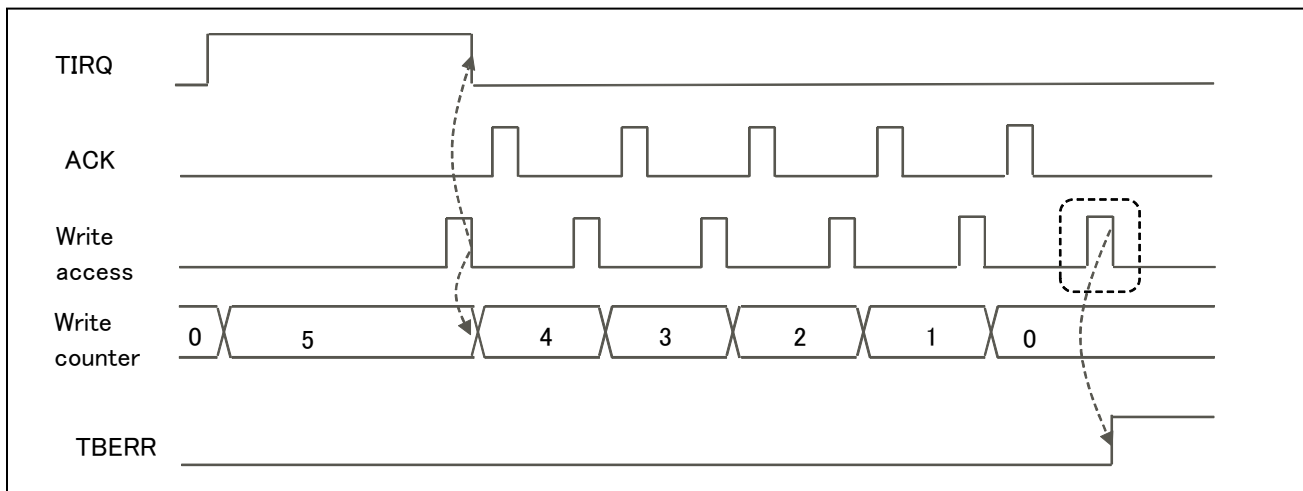

Figure 6-3 Reception Block Transfer Error in RW Access Mode

Transmission Block Transfer Error

If, while the Write counter is "0", a write access occurs before the next transmission block transfer request (TIRQ) is asserted, a transmission block transfer error occurs, and the ESR:TBERR bit is asserted.

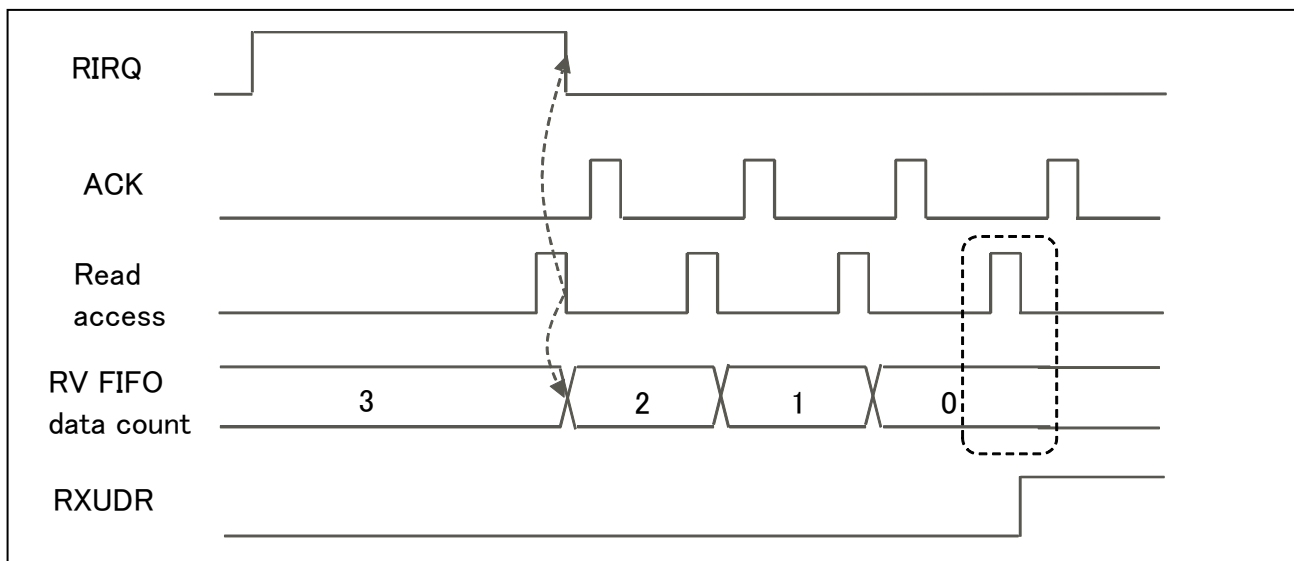

Figure 6-4 Transmission Block Transfer Error in RW Access Mode

Reception FIFO Underrun

If, while the amount of data in the reception FIFO is "0", reception data is read from the reception FIFO, a reception FIFO underrun occurs, and the ESR:RXUDR bit is asserted.

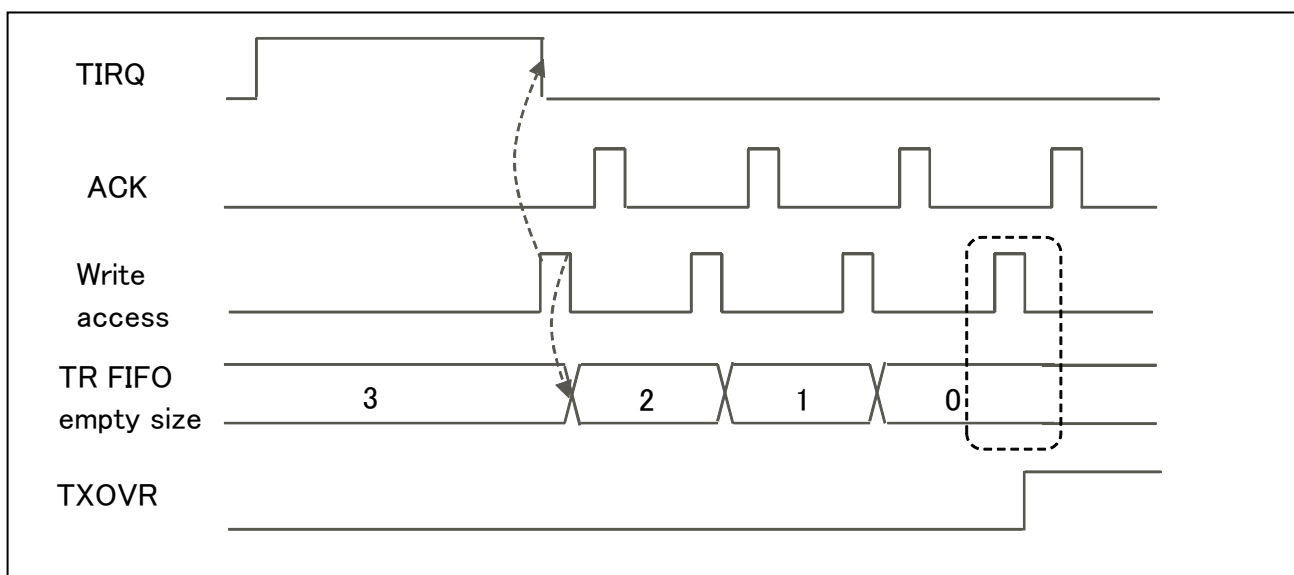

Figure 6-5 Reception FIFO Underrun in RW Access Mode

Transmission FIFO Overrun

If, while the amount of free space in the transmission FIFO is "0", transmission data is written to the transmission FIFO, a transmission FIFO overrun occurs, and the ESR:TXOVR bit is asserted.

Figure 6-6 Transmission FIFO Overrun in RW Access Mode

7. LIN Interface (V2.1) Operation

The LIN interface (v2.1) operates using master/slave bidirectional LIN communication.

7.1. Manual Mode

This section describes the operations in manual mode.

Master Operation

Selecting Master Operation

To enable operation as the master, set the SCR:MS bit to "0".

LIN Break Field Transmission to Sync Field Transmission

- The LIN Break Field length (ESCR:LBL1, LBL0) and LIN Break Field delimiter length (ESCR:DEL1, DEL0) can be selected.
- When transmission is enabled (SCR:TXE = 1) and the SCR:LBR bit (LIN Break Field setting bit) is set to "1", LIN Break Field is transmitted.
- Sync Field will be transmitted by writing 0x55 to the transmission data register (TDR).

Notes:

- After setting the SCR:LBR bit (LIN Break Field setting bit) to "1", set the transmission data register (TDR) to 0x55.
- Even when the SCR:RXE bit (reception operation enable bit) is set to "1", the LIN Break Field part does not perform reception.

Figure 7-1 LIN Break Field to Sync Field Transmission

Sync Field Transmission to ID Field Transmission

- When the 1st bit of Sync Field (0x55) is transmitted, the SSR:TDRE (transmission data empty) bit is set to "1".
At this time, a transmission interrupt occurs if transmission interrupt is enabled (SCR:TIE = 1).
- When a transmission interrupt occurs, the ID Field can be written in the transmission data register (TDR).
- When a reception interrupt occurs, the transmission data and reception data are compared to verify that there is no error.
- The data length of the ID Field is 8 bits, and the output is LSB first.

Figure 7-2 Sync Field to ID Field Transmission

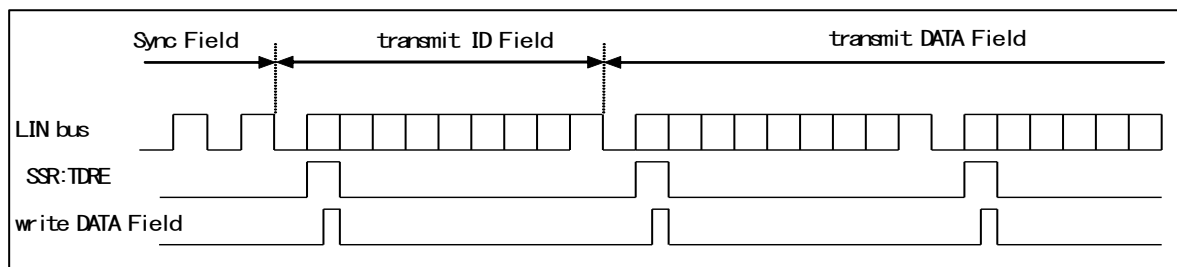

ID Field Transmission to DATA Field Transmission and Reception

This step selects whether the DATA Field is to be transmitted to or received by a slave device.

(When the DATA Field is transmitted)

When the 1st bit of the ID Field is transmitted, it is set as SSR:TDRE = 1. At this time, the DATA Field can be written.

Figure 7-3 ID Field Transmission to DATA Field Transmission

(When the DATA Field is received)

- When the 1st bit of the ID Field is transmitted, it is set as SSR:TDRE = 1. However, do not write any transmission data.
In addition, disable transmission interrupt (SCR:TIE = 0).
- When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if the reception interrupt is enabled (SCR:RIE = 1).

- A start bit is detected when both of the following are satisfied: 1. The noise-filtered result (the result of the rule of majority on the 3-time bus clock sampling of the serial data input) shows falling. 2. The filtered data shows "L" at the sampling point.

Figure 7-4 ID Field Transmission to DATA Field Reception

**Notes:**

- There is a built-in noise filter (the rule of majority being applied to 3-time bus clock sampling of the serial data input). However, we suggest that you design the board in such a way that noise does not pass through the filter. Alternatively, we suggest that you implement a communication method whereby noise passing through the filter does not cause a problem (by, for example, appending a checksum to the data at the end of transmission for retransmission in case of an error).
- During data reception, the following occurs if a falling edge of serial data is detected at the same time as, or 1 or 2 bus clocks earlier than, the sampling point: The edge becomes invalid and the frame that follows cannot be received normally. When frames are successively output, it is recommended that intervals be provided between the frames.

Master Operation Timing Chart (When a FIFO is Not Used)
Figure 7-5 LIN Bus Timing (When a DATA Field Is Transmitted: When a FIFO Is Not Used)

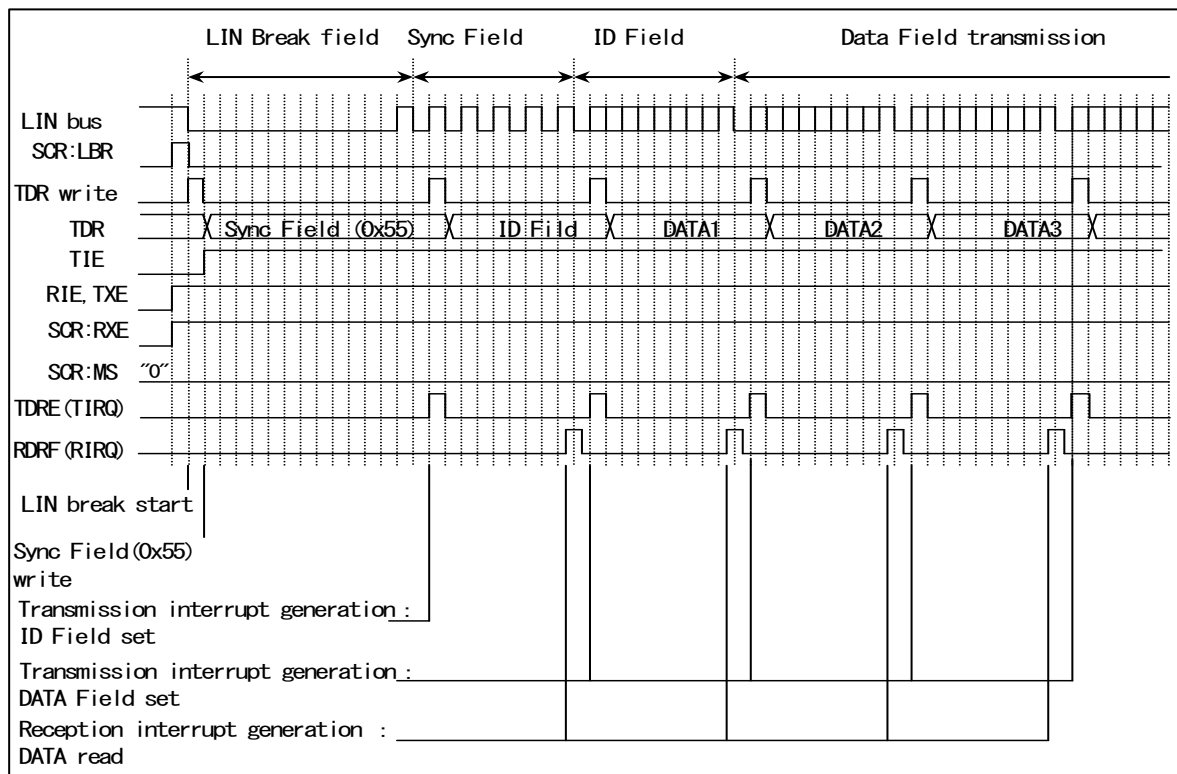

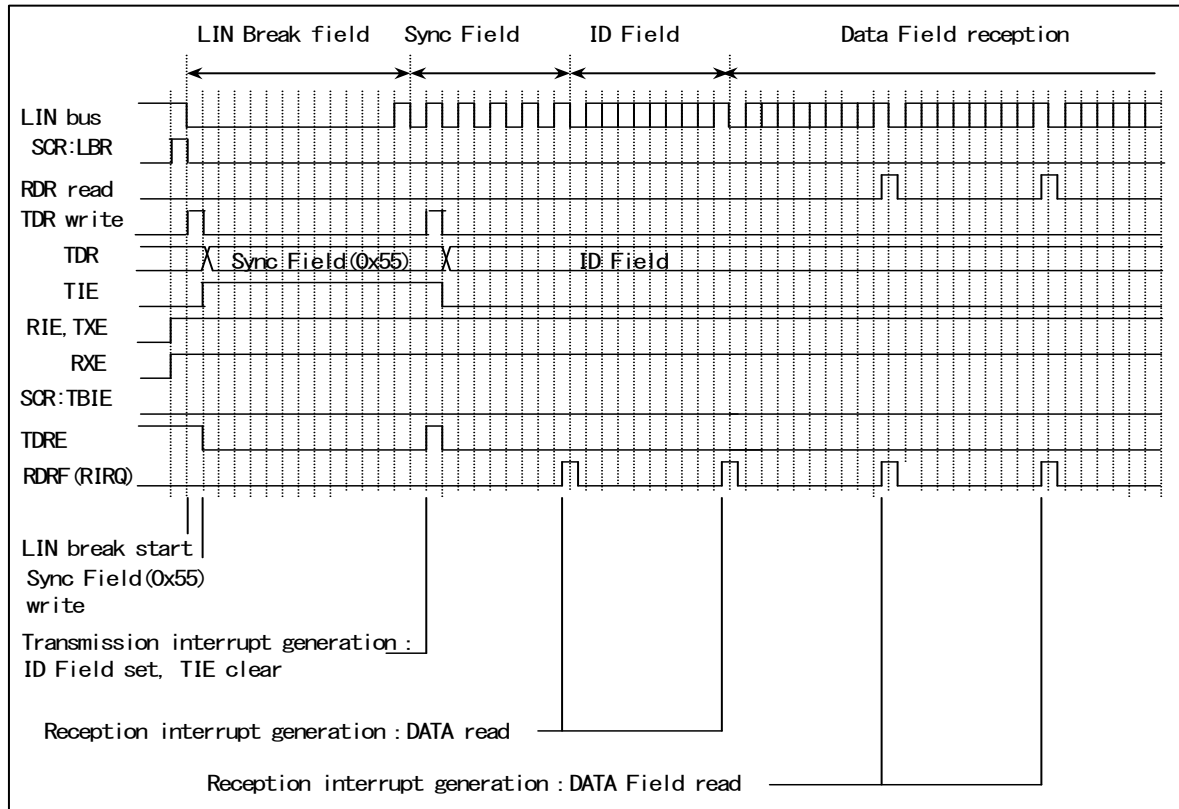

Figure 7-6 LIN Bus Timing (When a DATA Field Is Received: When a FIFO Is Not Used)

Master Operation Timing Chart (When a FIFO is Used)
Figure 7-7 LIN Bus Timing (When a DATA Field Is Transmitted: When a FIFO Is Used)

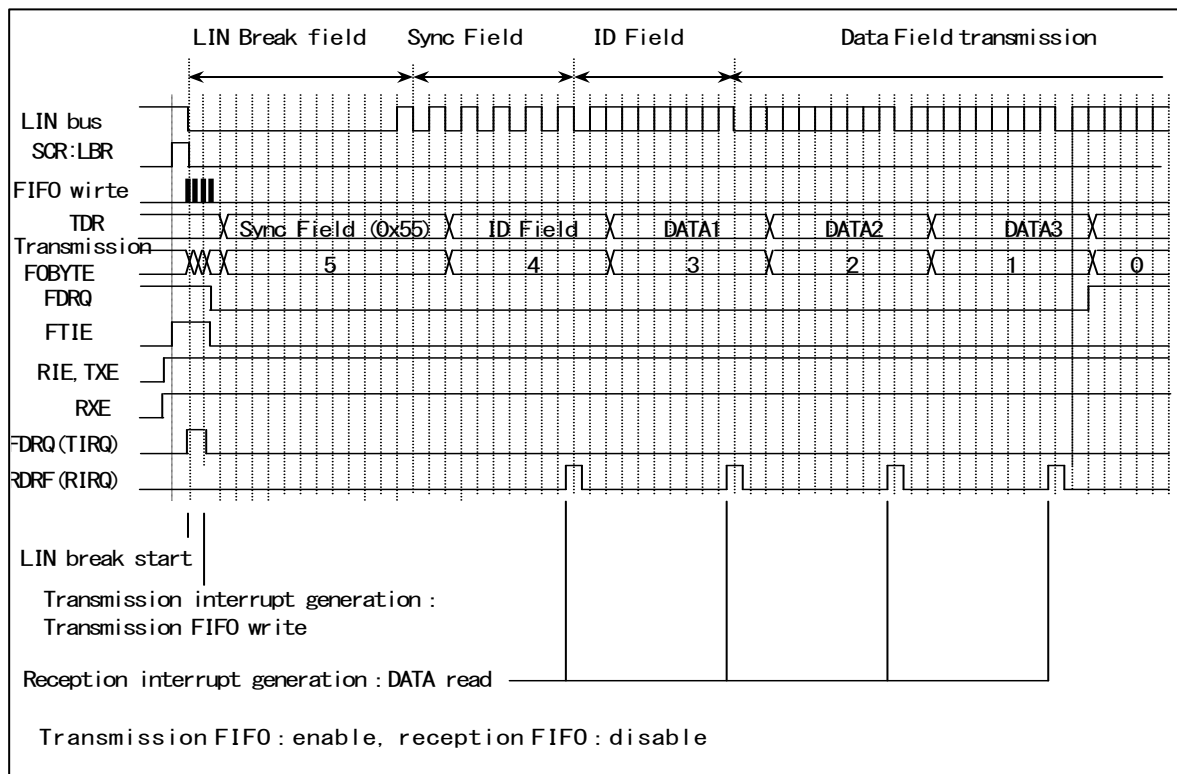

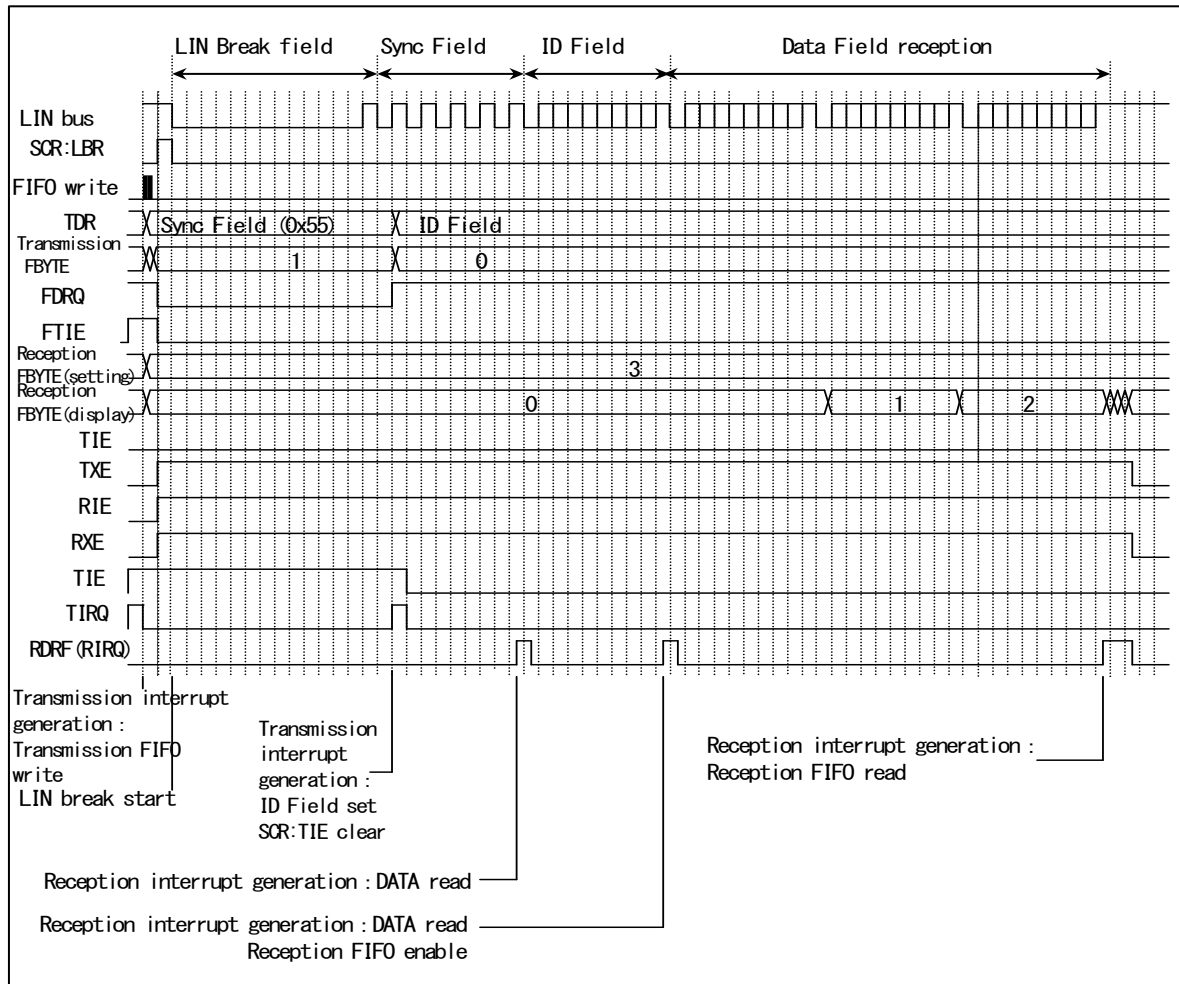

Figure 7-8 LIN Bus Timing (When a DATA Field Is Received: When a FIFO Is Used)

Slave Operation

Selecting Slave Operation

To enable operation as a slave, set SCR:MS bit to "1".

LIN Break Field Reception to Sync Field Reception

There are 2 methods to verify whether auto baud rate adjustment was applied between LIN Break Field reception and Sync Field reception, as follows:

■ Method for comparing BGR and STMR

■ Method for confirming the SACSr:BST bit

The process using each method is as follows:

1. Method for comparing BGR and STMR

(1) Enable auto baud rate adjustment (SACSr:AUTE = 1)

(2) When the LIN Break Field is entered, the LIN Break Field is detected (SSR:LBD = 1) at the 11th bit.

At this time, a status interrupt occurs if the ESCR:LBIE bit is set to "1". After the LIN Break Field is detected (SSR:LBD = 1), the serial timer is disabled (SACSr:TMRE = 0).

(3) When the LIN Interface (v2.1) detects the 1st falling edge of the Sync Field, it initializes the serial timer register (STMR) to 0.

(4) When the 5th falling edge of the Sync Field is detected, the Sync Field detection flag (SACSr:SFD) is set to "1".

(5) When the 5th falling edge of the Sync Field is detected, the Sync Field detection flag (SACSr:SFD) is set to "1". Then, the following is verified to check whether auto baud rate adjustment was performed.

- When auto baud rate adjustment was performed, the data read from the serial timer register (STMR) and baud rate generator register (BGR) are the same upon the detection of the Sync Field (SACSr:SFD = 1).
- When auto baud rate adjustment was not performed, the data read from the serial timer register (STMR) and baud rate generator register (BGR) differs upon the detection of the Sync Field (SACSr:SFD = 1).

Note:

- When auto baud rate adjustment is enabled (SACSr:AUTE = 1), set in the internal clock(BGR1:EXT=0),

2. Method of using the SACSr:BST bit

(1) Enable auto baud rate adjustment (SACSr:AUTE = 1)

(2) When the LIN Break Field is entered, the LIN Break Field will be detected (SSR:LBD = 1) at the 11th bit.

At this time, a status interrupt occurs if ESCR:LBIE bit is set to "1".

(3) When LIN Interface (v2.1) detects the 1st falling edge of the Sync Field, it initializes serial timer register (STMR) to 0.

(4) When the 5th falling edge of the Sync Field is detected, the Sync Field detection flag (SACSr:SFD) is set to "1".

(5) When the falling edge of the 5th Sync Field is detected, the following operation is performed depending on the value of the serial timer register (STMR).

- When the value of serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR1, BGR0), and the baud rate setting flag (SACSR:BST) is set to "1".
- When the value of serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR1, BGR0) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0".

Figure 7-9 LIN Break Field Reception to Sync Field Reception (When STMR Is between SFUR and SFLR)

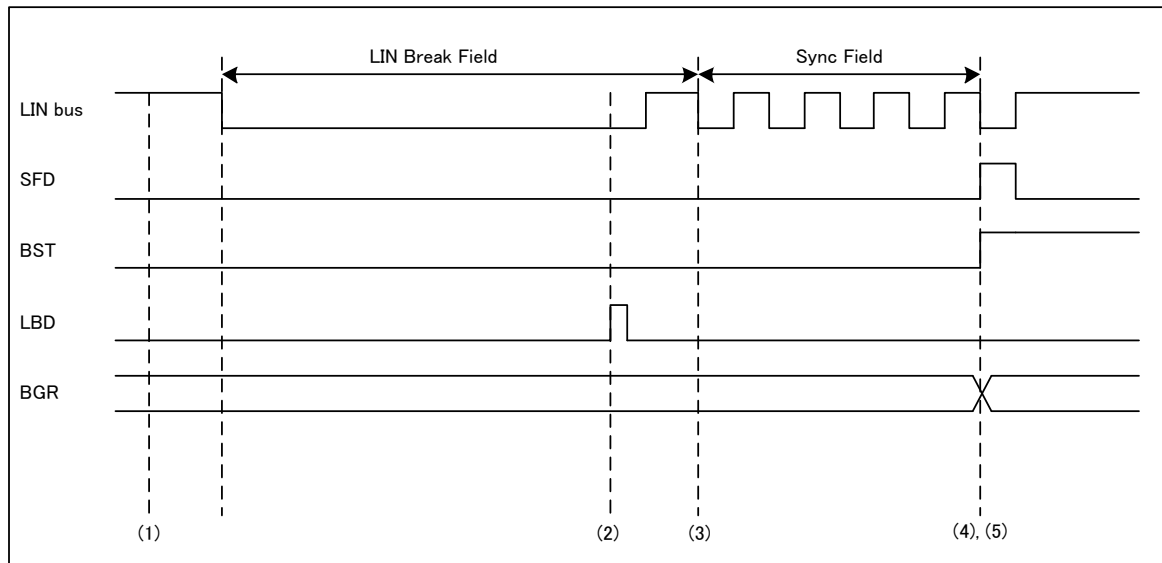

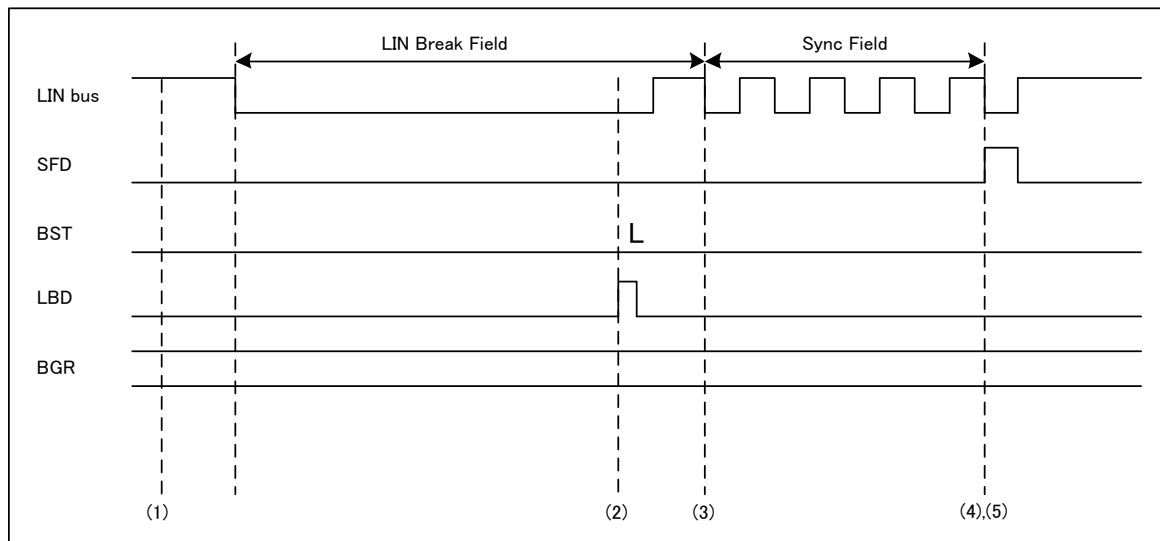

Figure 7-10 LIN Break Field Reception to Sync Field Reception (When STMR Is Not between SFUR and SFLR)

Notes:

- Disable reception ($SCR:RXE = 0$) for the LIN Break Field and Sync Field.
- When auto baud rate adjustment is enabled ($SACSR:AUTE = 1$), set in the internal clock ($BGR1:EXT=0$),

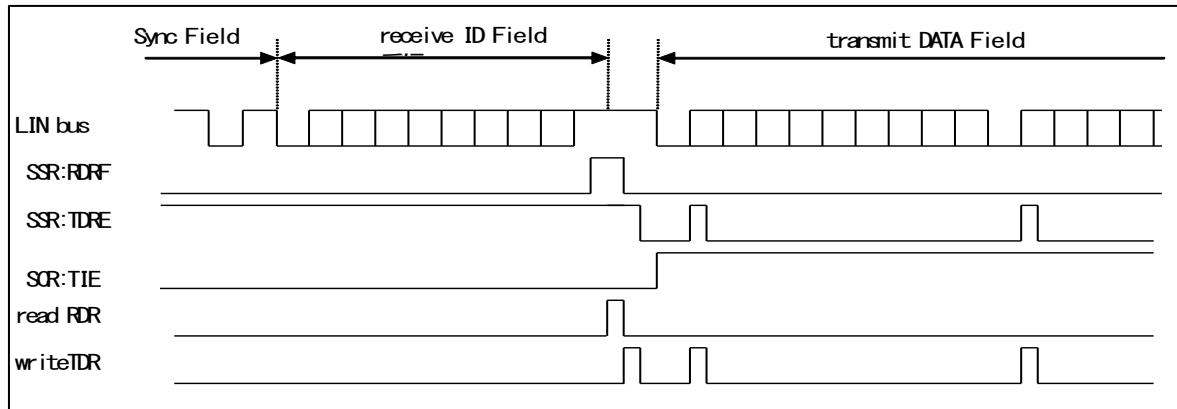

ID Field Reception to DATA Field Transmission and Reception

After the reception of the ID Field, it is possible to select whether the DATA Field is to be transmitted to or received by the master device.

(When the DATA Field is transmitted)

After receiving the ID Field, write the data into the transmission data register (TDR). In this case, enable the transmission interrupt (SCR:TIE = 1).

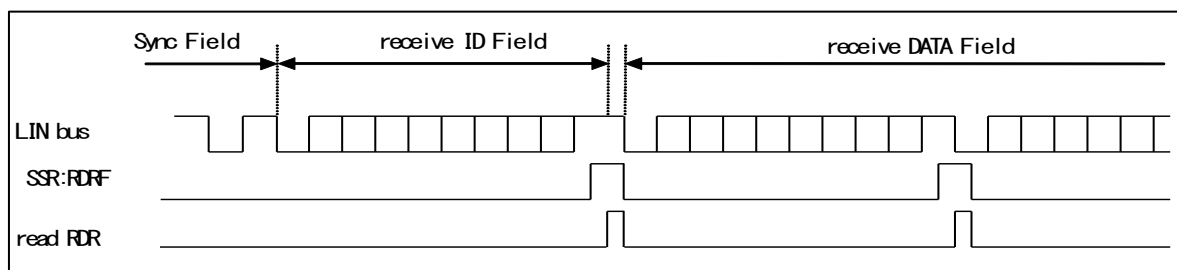

Figure 7-11 ID Field Reception to DATA Field Transmission

(When the DATA Field is received)

- Every time the DATA Field is received, SSR:RDRF is set to "1". At this time, a reception interrupt occurs if reception interrupt has been enabled (SCR:RIE = 1).
- A start bit is detected when both of the following are satisfied: 1. The noise-filtered result (the result of the rule of majority on the 3-time bus clock sampling of the serial data input) shows falling. 2. The filtered data shows "L" at the sampling point.

Figure 7-12 ID Field Reception to DATA Field Reception

Notes:

- There is a built-in noise filter (the rule of majority being applied to 3-time bus clock sampling of the serial data input). However, we suggest that you design the board in such a way that noise does not pass through the filter. Alternatively, we suggest that you implement a communication method whereby noise passing through the filter does not cause a problem (by, for example, appending a checksum to the data at the end of transmission for retransmission in case of an error).
- During data reception, the following occurs if a falling edge of serial data is detected at the same time as, or 1 or 2 bus clocks earlier than, the sampling point: The edge becomes invalid

and the frame that follows cannot be received normally. When frames are successively output, it is recommended that intervals be provided between the frames.

7.2. Assist Mode

Assist mode processes the auto transmission/reception of the LIN header and the following generation and detection.

- Generation and detection of parity for ID Field
- Generation and detection of checksum
- Detection of LIN bus error

Master Operation

Auto Header Transmission Setting

To process auto header transmission using assist mode, after initial setting, set the SCR:LBR bit (LIN Break Field setting bit) to "1". Setting to "1" initiates the auto transmission of the LIN Break Field, Sync Field and ID Field. How to set transmission is described below:

- To enable operation as the master, set the SCR:MS bit (master/slave function selection bit) to "0".
- Set the LAMCR:LAMEN bit (LIN assist mode processing enable bit) to "1".
- Select and set the LIN Break Field length (ESCR:LBL2, LBL1, LBL0) and LIN Break Field delimiter length (ESCR:DEL1, DEL0).
- Select and set the stop bit length (SMR:SBL and ESCR:ESBL).
- When the assist mode transmission ID register (LAMTID) is used for ID transmission, set the LAMCR:LIDEN bit (LIN ID register enable bit) to "1".
When the data transmission register (TDR) is used for ID transmission, set the LAMCR:LIDEN bit (LIN ID register use enable bit) to "0".
- Set the ID value in the register selected for ID transmission.
- Set the LIN data length (LAMCR:LDL3 to LDL0) which corresponds to the ID.
- Select and set the checksum to either standard or extended. (LAMCR:LCSTYP).
- Disable the LIN Break Field interrupt enable bit (ESCR:LBIE = 0). When LIN Break Field interrupt enable bit is enabled (ESCR:LBIE = 1), since LIN Break Field is also detected at the master, a status interrupt (SSR:LBD bit (LIN Break Field detection flag)) occurs.
- Disable Sync Field detection interrupt enable bit (SACSR:SFDE = 0). When the Sync Field detection interrupt enable bit is enabled (SACSR:SFDE = 1), since the Sync Field is also detected at the master, a status interrupt (SACSR:SFD bit (Sync Field detection flag)) occurs.
- Set the reception operation enable bit (SCR:RXE) to "0" (reception disabled).

LIN Break Field to ID Field Transmission

- Set the transmission operation enable bit (SCR:TXE) to "1" (transmission enabled).
- Set the LIN Break Field setting bit (SCR:LBR) to "1" (LIN Break Field generation). The LIN Break Field set at ESCR:LBL2 to LBL0 is transmitted.
- The master receives the LIN Break Field transmitted by the master, and checks for bus errors.
- After the transmission of the LIN Break Field, the LIN Break Field delimiter set at ESCR:DEL1, DEL0 will be transmitted.
- After the transmission of the LIN Break Field delimiter, the Sync Field (0x55 fixed value) is transmitted.
- The master receives the Sync Field transmitted by the master, and checks for bus error/framing errors.
- After the transmission of the Sync Field, the set ID Field value is transmitted. When the LAMCR:LIDEN bit (LIN ID register use enable bit) is set to "0", the ID Field value is transmitted as set in the transmission data register (TDR). When the LAMCR:LIDEN bit (LIN ID register use enable bit)

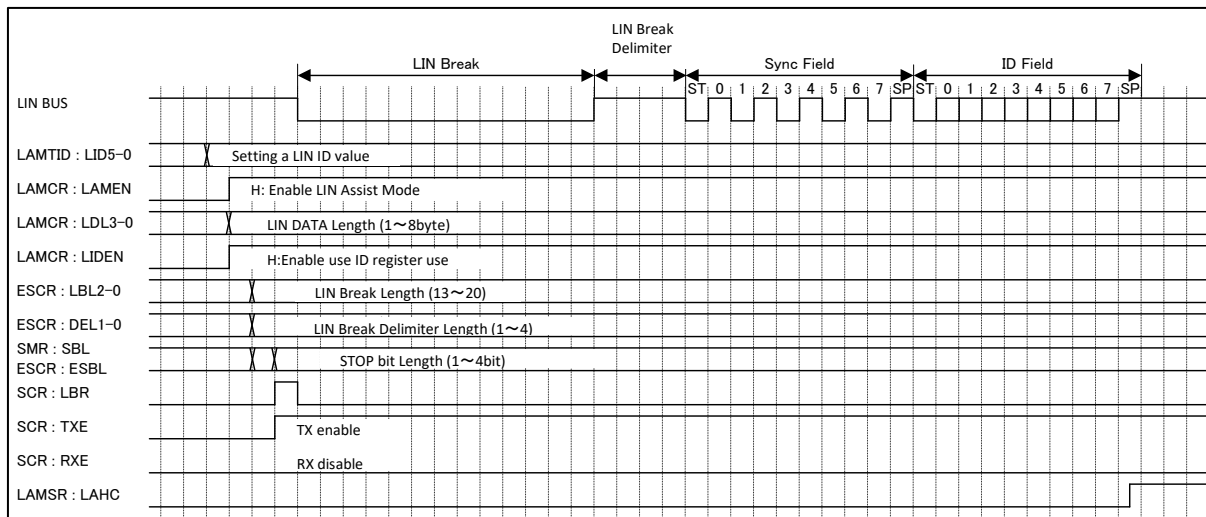

is set to "1", the ID field value is transmitted as set in the LIN assist mode transmission ID register (LAMTID).

- When the transmission data register (TDR) is used for ID Field transmission (LAMCR:LIDEN = 0), and the 1st bit of the ID Field is transmitted, the SSR:TDRE (transmission data empty) bit is set to "1". At this time, a transmission interrupt occurs if the transmission interrupt is enabled (SCR:TIE = 1). When a transmission interrupt (TDRE) occurs, the transmission data can be written in the transmission data register (TDR).
- The data length of the ID Field is 8 bits, and the output is LSB first. The LIN parity in the ID Field is calculated automatically.
- The master receives the ID Field transmitted by the master, and checks for a bus error/framing error.
- When the ID Field transmission is completed, the LIN auto header completion flag is set (LAMSR:LAHC = 1). In this case, when the LIN auto header transmission completion interrupt enable bit is enabled (LAMIER:LAHCIE=1), a status interrupt occurs.
- When the following errors occur, transmission is halted.
 - LIN bus error
 - LIN ID parity error
 - Framing error

Notes:

- In the header transmission setting (from LBR activation (SCR:LBR = 1) to LIN auto header completion (LAMSR:LAHC = 1)), the auto header transmission setting shall not be changed.
- Disable reception (SCR:RXE = 0) while the master header is being transmitted in assist mode.
- While the master is operating in assist mode, the transmission data values of the Sync Field and ID Field are not stored to the RDR register.
- When response data is received without using the LIN assist mode transmission ID register (LAMTID), and the 1st bit of the ID Field is transmitted, it is set as SSR:TDRE = 1. However, do not write data. In addition, disable the transmission interrupt (SCR:TIE = 0).
- When the response data is received using the LIN assist mode transmission ID register (LAMTID), the transmission data register (TDR) can be written after the LIN Break Field setting bit (SCR:LBR) is set to "1". However, do not write data.

Figure 7-17 LIN Break Field to ID Field Transmission

LIN Break Field Retransmission during Assist Mode Processing

The LIN Break Field (SCR:LBR = 1) shall be set at the following timing.

- After the completion of header transmission (LAMSR:LAHC = 1)
- After the completion of response transmission and reception (LAMSR:LCSC = 1)

Data Field Transmission and Reception

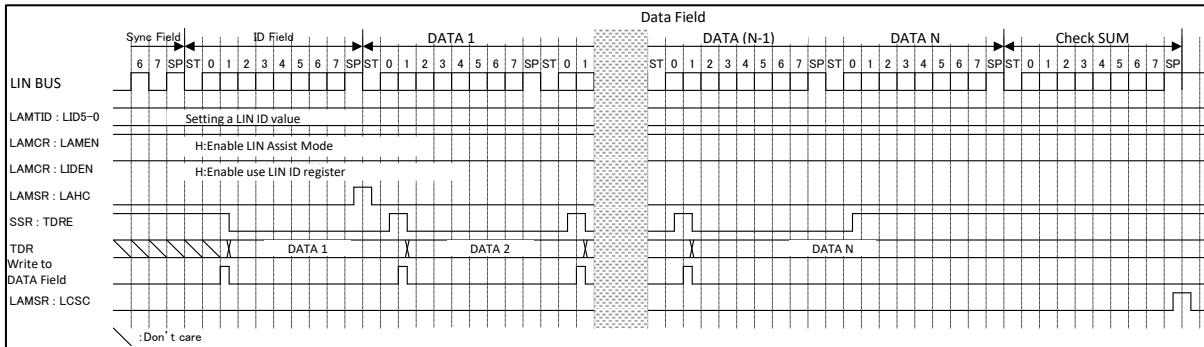

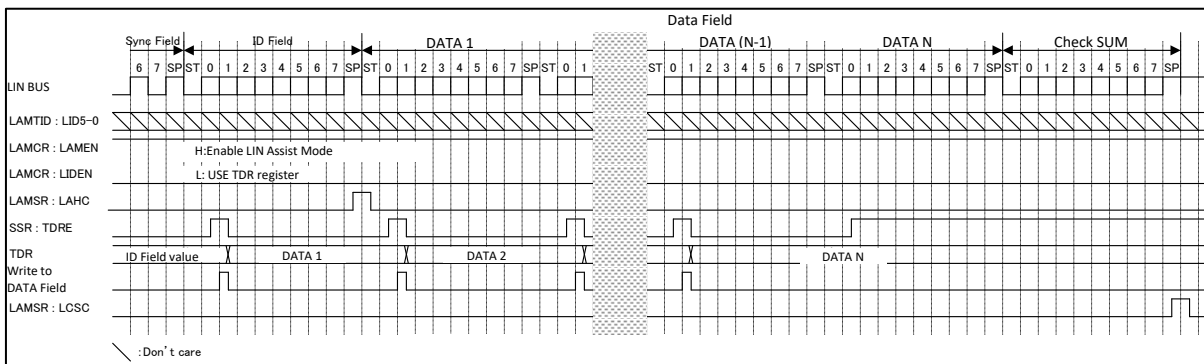

This step selects whether the DATA Field shall be transmitted to or received by a slave device.

(When the DATA Field is transmitted)

- When the LIN assist mode transmission ID register (LAMTID) is not used, after the 1st bit of the ID Field is transmitted, it is set as SSR:TDRE = 1. At this time, the DATA Field can be written.
- When the LIN assist mode transmission ID register (LAMTID) is used, and the LIN Break Field setting bit (SCR:LBR) is set to "1", the DATA Field becomes writable.
- After the LIN Break Field setting bit (SCR:LBR) is set to "1" but before the start of response transmission, enable transmission (SCR:TXE = 1).
- In LIN assist mode, the checksum calculation is performed automatically. For the checksum calculation, the calculation method can be selected with the LIN checksum type selection bit (LAMCR:LCSTYP).
- After the completion of the checksum calculation, the checksum calculation completion flag (LAMSR:LCSC) is set. In this case, when the checksum calculation completion interrupt enable bit is set (LAMIER:LCSCIE = 1), a status interrupt occurs.
- After the completion of response transmission (LAMSR:LCSC = 1), disable transmission (SCR:TXE = 0).

Notes:

- While a response is being transmitted during an assist mode operation, do not enable reception (SCR:RXE = 1).
- During assist mode operation, response transmission data (Data Field, checksum) cannot be stored into the RDR register.
- When a FIFO is being used, after setting the LIN Break Field setting bit (SCR:LBR) to "1" (LIN Break Field generation bit), write data to the FIFO.
- When the LIN data length is set to 0 bytes (LAMCR:LDL3 to LDL0 = 0000) for response transmission, write dummy data into the TDR register to automatically perform the checksum calculation and then transmit the data. (Any value can be written.) The TDR setting value does not affect the checksum calculation.
- When the LIN data length is set to "0" (LAMCR:LDL3 to LDL0 = 0000), the checksum values will be as follows:
 - With the standard checksum setting (LAMCR:LCSTYP = 0), the checksum value is 0xFF.
 - With the extended checksum setting (LAMCR:LCSTYP = 1), the checksum value is the inverse value of the ID Field.
- During the transmission of response data, do not change the transmission data length (LAMCR:LDL3 to LDL0).

Figure 7-18 ID Field Transmission to DATA Field Transmission (When ID Register Is Used and a FIFO Is Not Used)**Figure 7-19 ID Field Transmission to DATA Field Transmission (When ID Register Is Not Used and a FIFO Is Not Used)**

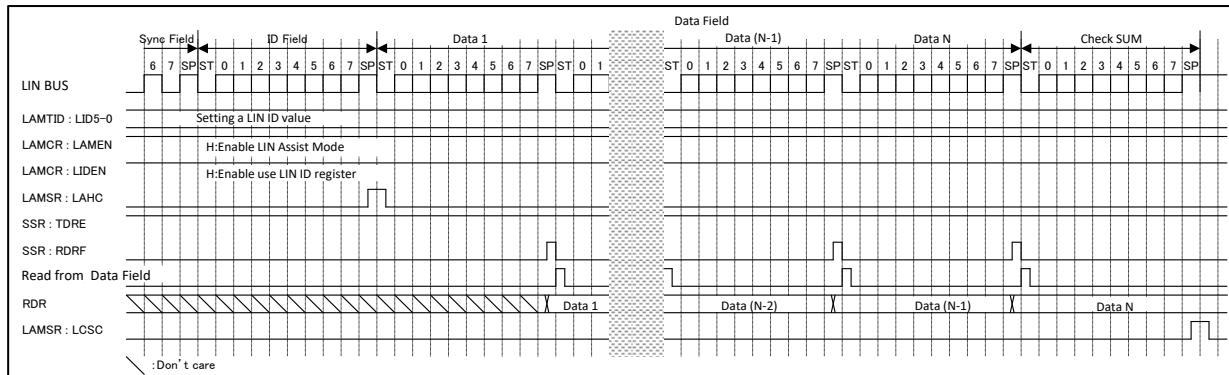

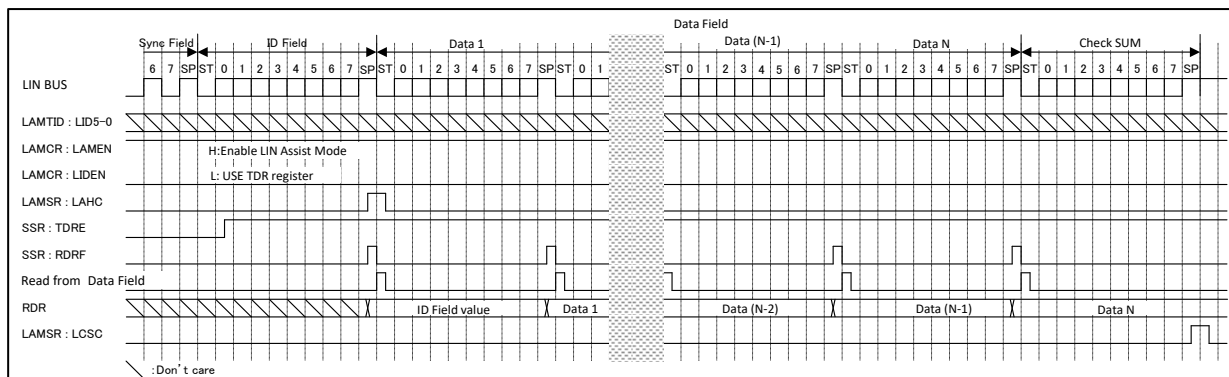

(When the DATA Field is received)

- Between LIN auto header completion (LAMSR:LAHC = 1) and the start of response reception, enable reception (SCR:RXE = 1) and disable transmission (SCR:TXE = 0).
- When the DATA Field is received, SSR:RDRF is set to 1. At this time, a reception interrupt occurs if a reception interrupt is enabled (SCR:RIE = 1).
- After the completion of checksum reception, the LIN checksum calculation completion flag is set (LAMSR:LCSC = 1). In this case, when the checksum calculation completion interrupt enable bit is set (LAMIER:LCSCIE = 1), a status interrupt occurs.
- After the completion of checksum reception (LAMSR:LCSC = 1), disable reception (SCR:RXE = 0).

Notes:

- During data reception, the following occurs if a falling edge of serial data is detected at the same time as, or 1 or 2 bus clocks earlier than, the sampling point: The edge becomes invalid and the frame that follows cannot be received normally. When frames are successively output, it is recommended that intervals be provided between the frames.
- The checksum value for response reception during assist mode operation is not stored into the RDR register.
- When the LIN data length is set to "0" (LAMCR:LDL3 to LDL0 = 0000), the checksum values will be as follows:

- With the standard checksum setting (LAMCR:LCSTYP = 0), the checksum value is 0xFF.
- With the extended checksum setting (LAMCR:LCSTYP = 1), the checksum value is the inverse value of the ID Field.
- During the reception of response data, do not change the reception data length (LAMCR:LDL3 to LDL0).

Figure 7-28 LIN Bus Timing (the ID Register Is Used, the DATA Field Is Received, and a FIFO Is Used)

Figure 7-29 LIN Bus Timing (the ID Register Is Not Used, the DATA Field Is Received, and a FIFO Is Used)**Slave Operation****Auto Header Reception Setting**

To process auto header reception using assist mode, set the following:

- To enable operation as a slave, set the SCR:MS bit (master/slave function selection bit) to "1".
- To enable operation using LIN assist mode, set the LAMCR:LAMEN bit (LIN assist mode processing enable bit) to "1".
- Select and set the stop bit length (SMR:SBL and ESCR:ESBL).
- When the assist mode reception ID register (LAMRID) is used for ID reception, set the LAMCR:LIDEN bit (LIN ID register enable bit) to "1".
When the data reception register (RDR) is used for ID reception, set the LAMCR:LIDEN bit (LIN ID register use enable bit) to "0".
- To enable auto baud rate adjustment, set the SACSRAUTE bit (auto baud rate adjustment bit) to "1" and set in the internal clock(BGR1:EXT = 0).
- Set the reception enable bit (SCR:RXE) to "0" (reception disabled).

LIN Break Field Reception to ID Field Reception

(1) When the LIN Break Field is entered, the LIN Break Field is detected (SSR:LBD = 1) at the 11th bit. At this time, a status interrupt occurs if the ESCR:LBIE bit is set to "1".

The following operations are performed as part of auto baud rate adjustment.

(2) When the LIN Interface (v2.1) detects the 1st falling edge of the Sync Field, it initializes the serial timer register (STMR) to 0.

(3) When the 5th falling edge of the Sync Field is detected, the Sync Field detection flag (SACSR:SFD) is set to "1". At this time, a status interrupt occurs if the SACSR:SFDE bit is set to "1".

(4) When the falling edge of the 5th Sync Field is detected, the following operation is performed depending on the value of the serial timer register (STMR).

- When the value of the serial timer register (STMR) is between that of the Sync Field lower limit register (SFLR) and Sync Field upper limit register (SFUR), the value of the serial timer register (STMR) is set in the baud rate generator register (BGR1, BGR0), and the baud rate setting flag (SACSR:BST) is set to "1".
- When the value of the serial timer register (STMR) is below that of the Sync Field lower limit register (SFLR) or exceeds that of the Sync Field upper limit register (SFUR), the baud rate generator register (BGR1, BGR0) will not be changed and the baud rate setting flag (SACSR:BST) is reset to "0".

Figure 7-30 LIN Break Field to ID Field Reception (When STMR Is Between SFUR and SFLR)

Figure 7-31 LIN Break Field to ID Field Reception (When STMR Is Not between SFUR and SFLR)

The following operations are performed when auto baud rate adjustment is not conducted.

(5) When auto baud rate adjustment is not conducted, set the SACSR:AUTE bit (auto baud rate adjustment bit) to "0". Treat the Sync Field value as data, and verify that the Sync Field value is 0x55. When it is 0x55, the Sync Field detection flag (SACSR:SFD) is set to "1". When it is other than 0x55, the Sync Data error flag bit (LAMESR:LSFER) is set to "1".

Figure 7-32 LIN Break Field to ID Field Reception (When Auto Baud Rate Adjustment Is Not Performed)

The following operations are common both to when auto baud rate adjustment is performed and when it is not performed.

(6) When auto header reception is completed in LIN assist mode, the LAMSR:LAHC bit (LIN auto header completion flag) is set to "1". If a LIN parity error (LAMESR:LPTER = 1) occurs in the ID Field, the LAMSR:LAHC bit (LIN auto header completion flag) is set to "1". So, if the LAMSR:LAHC bit is set to "1", verify that the error is not detected.

(7) When the ID Field is correctly received, set the checksum type (LAMCR:LCSTYP) and the LIN data length setting bit (LAMCR:LDL3 to LDL0).

Figure 7-33 LIN Break Field to ID Field Reception (When a Parity Error Occurs)**Figure 7-34 LIN Break Field to ID Field Reception (When the LIN Data Length Is Set)****Notes:**

- Disable reception (SCR:RXE = 0) while the slave header is being received in assist mode.

- *The setting of the transmission enable bit (SCR:TXE) is ignored while the slave header is received in assist mode.*
- *While the slave is operating in assist mode, the Sync Field value cannot be stored in the reception data register (RDR).*
- *During slave operation, suppose that the setting is such that the reception data register (RDR) is used for the reception of the ID Fields (LAMCR:LIDEN = 0). Then, when an ID Field is received, the received ID value is stored into the reception data register (RDR) and the reception data full flag bit is set (SSR:RDRF = 1). Check the ID value after the LIN auto header completion flag is set (LAMSR:LAHC = 1).*
- *Even when it is determined that there is no need for auto baud rate adjustment (SACSR:BST = 0), there are cases that the reception of the ID Field continues, and LIN auto header completion flag (LAMSR:LAHC = 1) and error flag may be set. Therefore, when the LIN auto header completion flag (LAMSR:LAHC) is set to "1", verify the baud rate setting flag.*

ID Field Reception to DATA Field Transmission and Reception

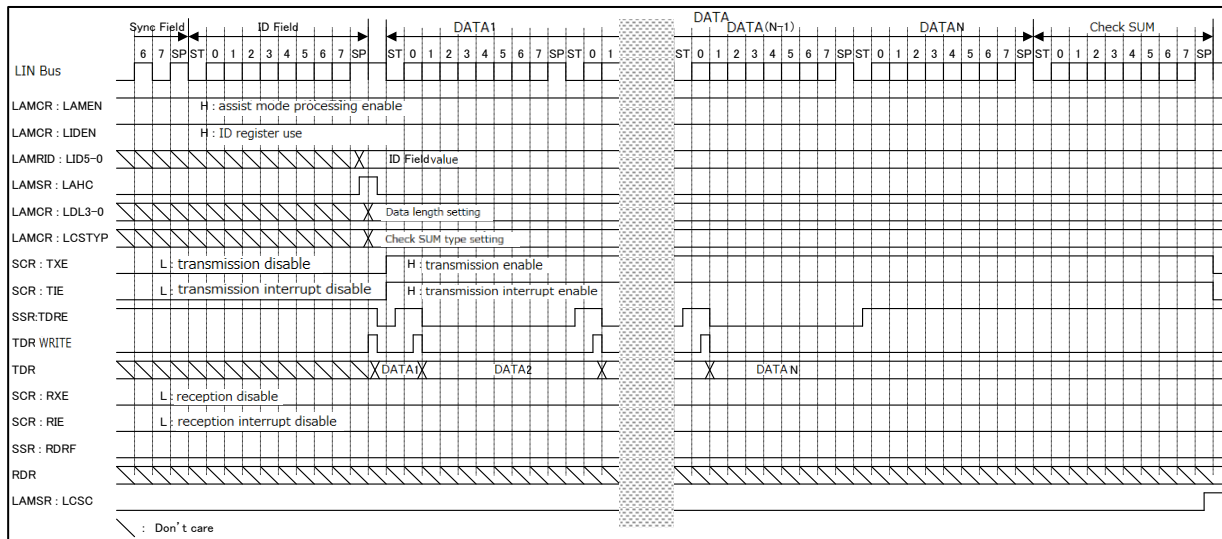

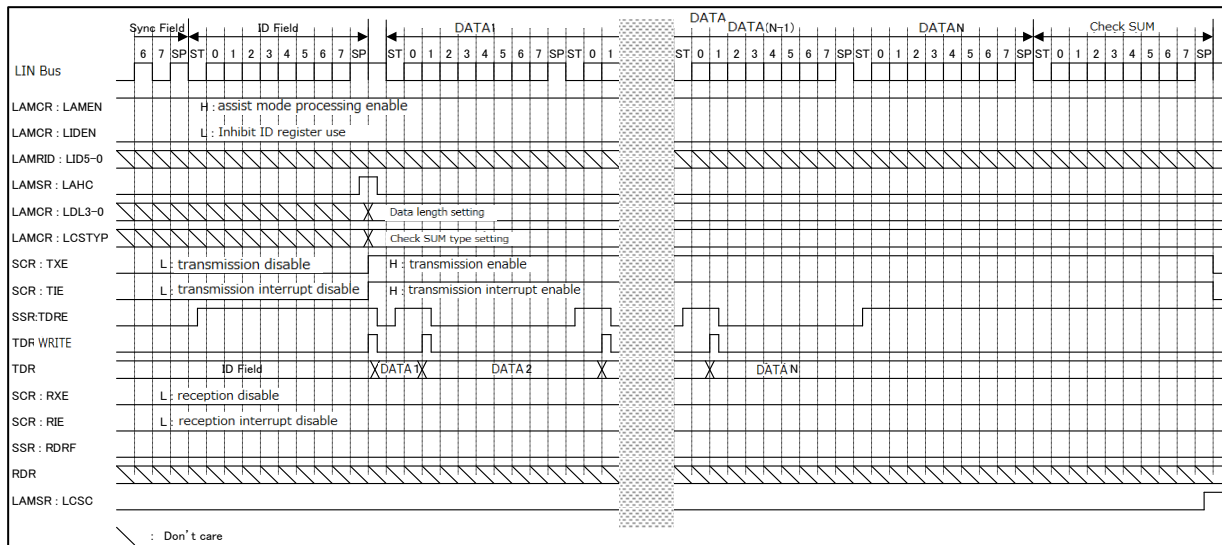

After the reception of the ID Field, it is possible to select whether the DATA Field is to be transmitted to or received by the master device.

(When the DATA Field is transmitted)

- Using the received ID Field value, set the checksum type (LAMCR:LCSTYP) and LIN data length setting bit (LAMCR:LDL3 to LDL0).
- After receiving the ID Field, write the data into the transmission data register (TDR). In this case, enable transmission (SCR:TXE = 1) and the transmission interrupt (SCR:TIE = 1).
- Perform the checksum calculation based on the LIN data length setting bit (LAMCR:LDL3 to LDL0), and automatically transmit the checksum after transmitting the final data.
- For the checksum calculation, the calculation method can be selected with the LIN checksum type selection bit (LAMCR:LCSTYP).
- After the reception of checksum data, set the checksum calculation completion flag (LAMSR:LCSC). In this case, when the checksum calculation completion interrupt enable bit is set (LAMIER:LCSCIE = 1), a status interrupt occurs.
- After the completion of the checksum calculation (LAMSR:LCSC = 1), disable transmission (SCR:TXE = 0).

Notes:

- While a response is being transmitted during an assist mode operation, disable reception (SCR:RXE = 0).
- During assist mode operations, response transmission data (data, checksum) cannot be stored in the reception data register (RDR).
- When the LIN data length is set to 0 bytes (LAMCR:LDL3 to LDL0 = 0000) for response transmission, write dummy data to the TDR register to automatically start the checksum calculation and transmit the data. (Any value can be written.) The TDR setting value does not affect the checksum calculation.
- When the LIN data length is set to "0" (LAMCR:LDL3 to LDL0 = 0000), the checksum values will be as follows:
 - With the standard checksum setting (LAMCR:LCSTYP = 0), the checksum value is 0xFF.
 - With the extended checksum setting (LAMCR:LCSTYP = 1), the checksum value is the inverse value of the ID Field.

Figure 7-35 ID Field Reception to DATA Field Transmission (When the ID Register Is Used)

Figure 7-36 ID Field Reception to DATA Field Transmission (When the ID Register Is Not Used)

(When the DATA Field is received)

- Using the received ID Field value, set the checksum type (LAMCR:LCSTYP) and LIN data length setting bit (LAMCR:LDLEN3 to LDLEN0).
- Enable reception (SCR:RXE = 1).
- The checksum calculation is performed automatically. For the checksum calculation, the calculation method can be selected with the LIN checksum type selection bit (LAMCR:LCSTYP).
- For each reception of DATA Field, SSR:RDRF is set to "1". A reception interrupt occurs if the reception interrupt is enabled (SCR:RIE = 1).
- When the checksum calculation completion flag is set (LCSC = 1), check for a checksum error. In this case, when the checksum calculation completion interrupt is enabled, a status interrupt occurs. When the checksum error interrupt is enabled, a reception interrupt occurs.
- After the completion of checksum reception (LAMSR:LCSC = 1), disable reception (SCR:RXE = 0).

Notes:

- During data reception, the following occurs if a falling edge of serial data is detected at the same time as, or 1 or 2 bus clocks earlier than, the sampling point: The edge becomes invalid and the frame that follows cannot be received normally. When frames are successively output, it is recommended that intervals be provided between the frames.
- The checksum value of response reception during assist mode operations is not stored in the reception data register (RDR).
- When the LIN data length is set to "0" (LAMCR:LDL3 to LDL0 = 0000), the checksum values will be as follows:
 - With the standard checksum setting (LAMCR:LCSTYP = 0), the checksum value is 0xFF.
 - With the extended checksum setting (LAMCR:LCSTYP = 1), the checksum value is the inverse value of the ID Field.
- For slave operation, when the LIN communication speed is 19.2 kbps, within about 25 μ s after the auto header completion flag is set (LAMSR:LAHC = 1), set the checksum type (LAMCR:LCSTYP) and the LIN data length (LAMCR:LDL3 to LDL0), and disable the transmission (SCR:TXE), the transmission interrupt (SCR:TIE), the reception (SCR:RXE) and the reception interrupt (SCR:RIE) . (Set to a value less than half of one cycle time for LIN communication.)

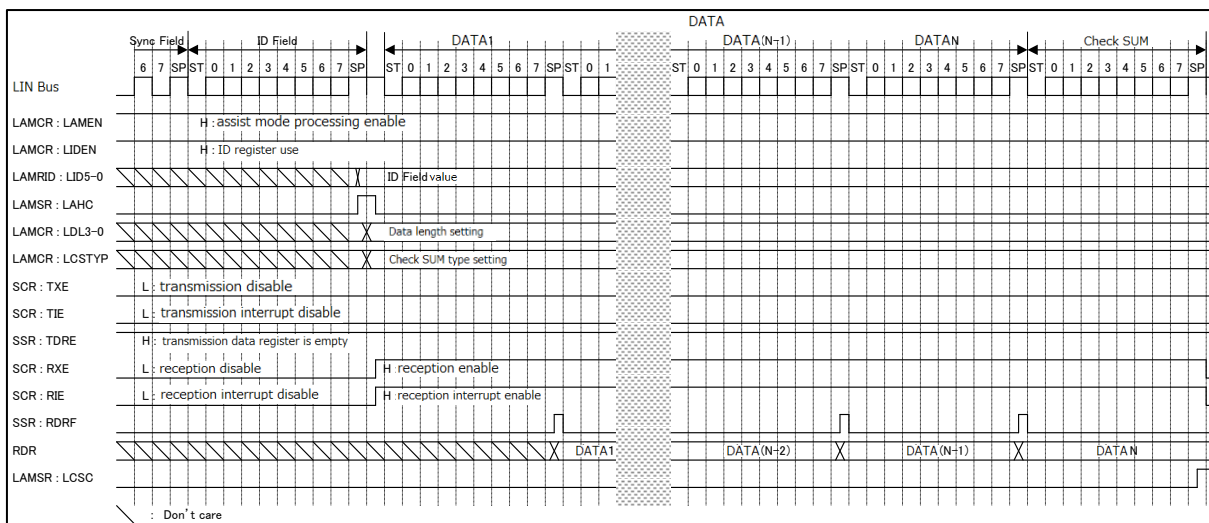

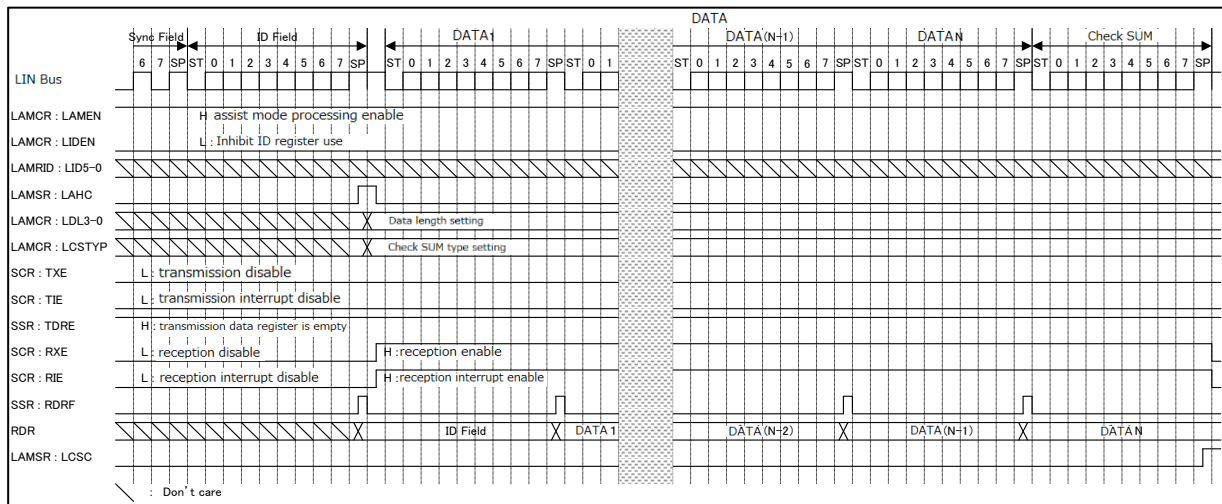

Figure 7-37 ID Field Reception to DATA Field Reception (When the ID Register Is Used)

Figure 7-38 ID Field Reception to DATA Field Reception (When the ID Register Is Not Used)

LIN Break Field Reception during Assist Mode Processing

When the LIN Break Field (SSR:LBD = 1) was detected from Sync Field to Checksum, the following procedure is required:

- Disable reception (SCR:RXE = 0) and transmission (SCR:TXE = 0).
- Clear the error flag.
- Abandon any data received before LIN Break Field was detected.
 - When a reception FIFO is used, after disabling the reception FIFO operation (FCR0:FE1 = 0 or FCR0:FE2 = 0), reset the reception FIFO (FCR0:FCL1 = 1 or FCR0:FCL2 = 1).
 - Then, to clear the reception data register, read the RDR register.
- Abandon any data transmitted before the LIN Break Field is detected.
 - When a transmission FIFO is used, after disabling the transmission FIFO operation (FCR0:FE1 = 0 or FCR0:FE2 = 0), reset the transmission FIFO (FCR0:FCL1 = 1 or FCR0:FCL2 = 1).
 - Then, execute transmission data register clear (LAMCR:LTDRCL = 1) to attain the transmission bus idle status.

Slave Operation Timing Chart

8. Setup Procedure and Program Flow for Operation Mode 3 (LIN Communication Mode)

Operation mode 3 (LIN communication mode) can be used for either the LIN master system or the LIN slave system.

Register Setting

Connection between MCUs

Figure 8-1 illustrates the communication system between a LIN master and a LIN slave. The LIN interface (v2.1) can operate as either the LIN master or the LIN slave.

Figure 8-1 Example of LIN Bus System Communication

8.1. Manual Mode

This section provides an example of a flow chart for the master or slave side in manual mode.

Flow Chart Example

Master Operation

Figure 8-2 Example of LIN Communication Master Mode (a FIFO Is Not Used)

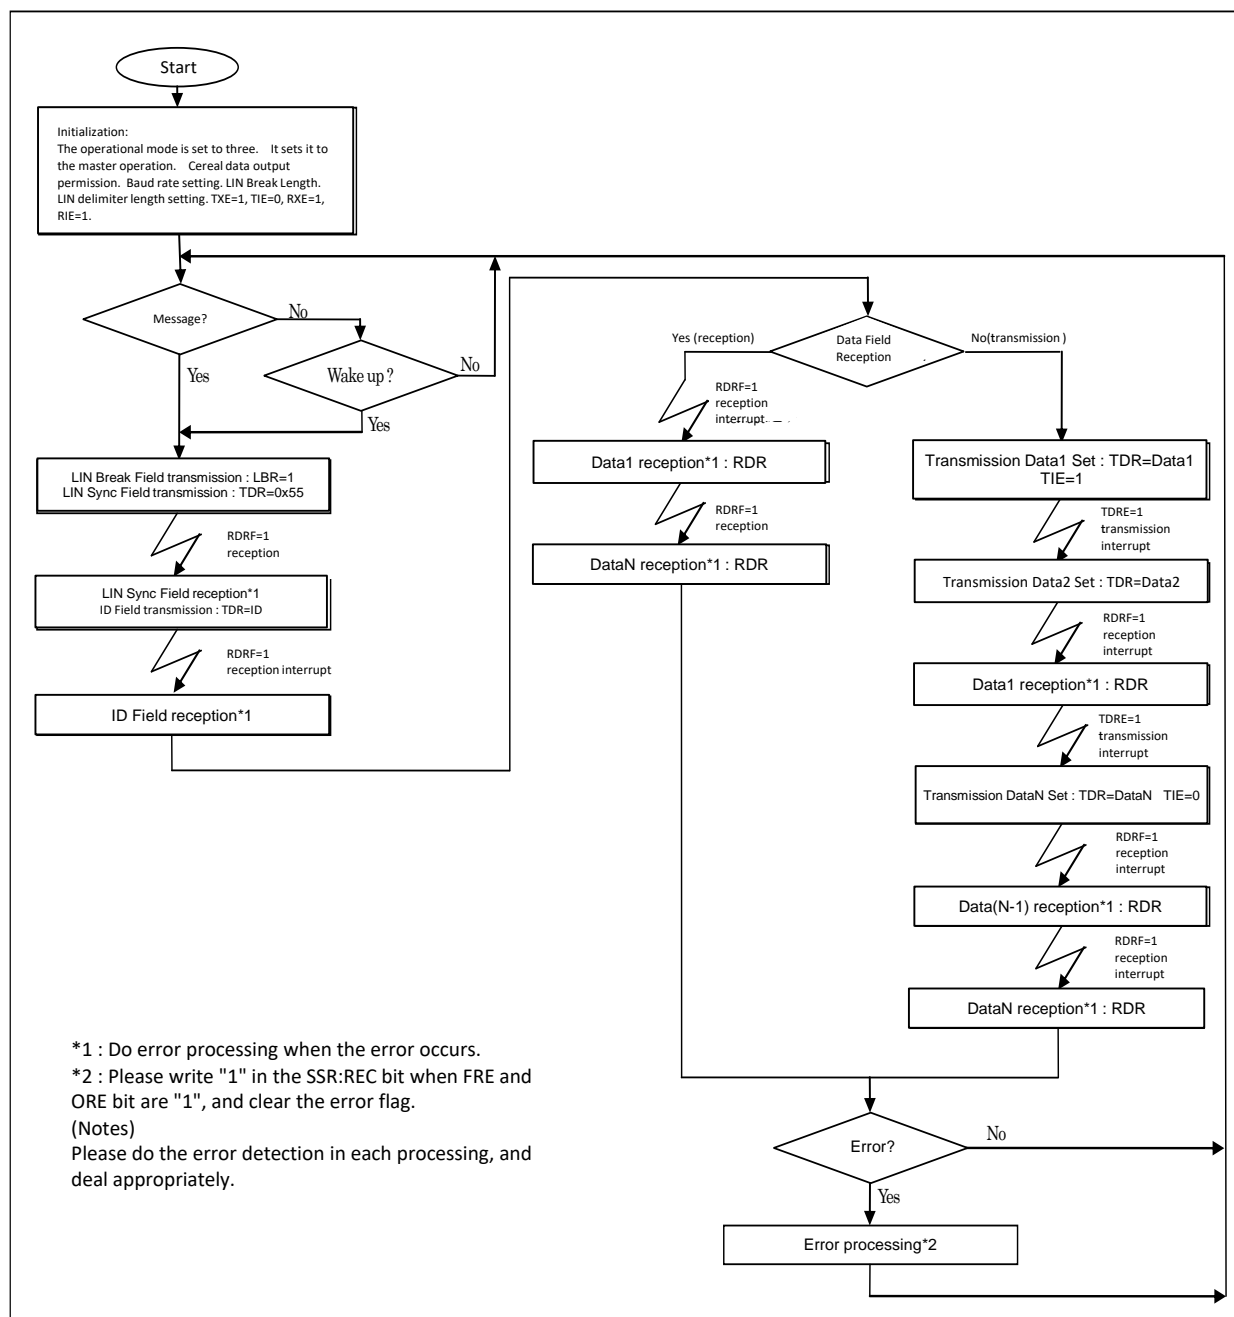

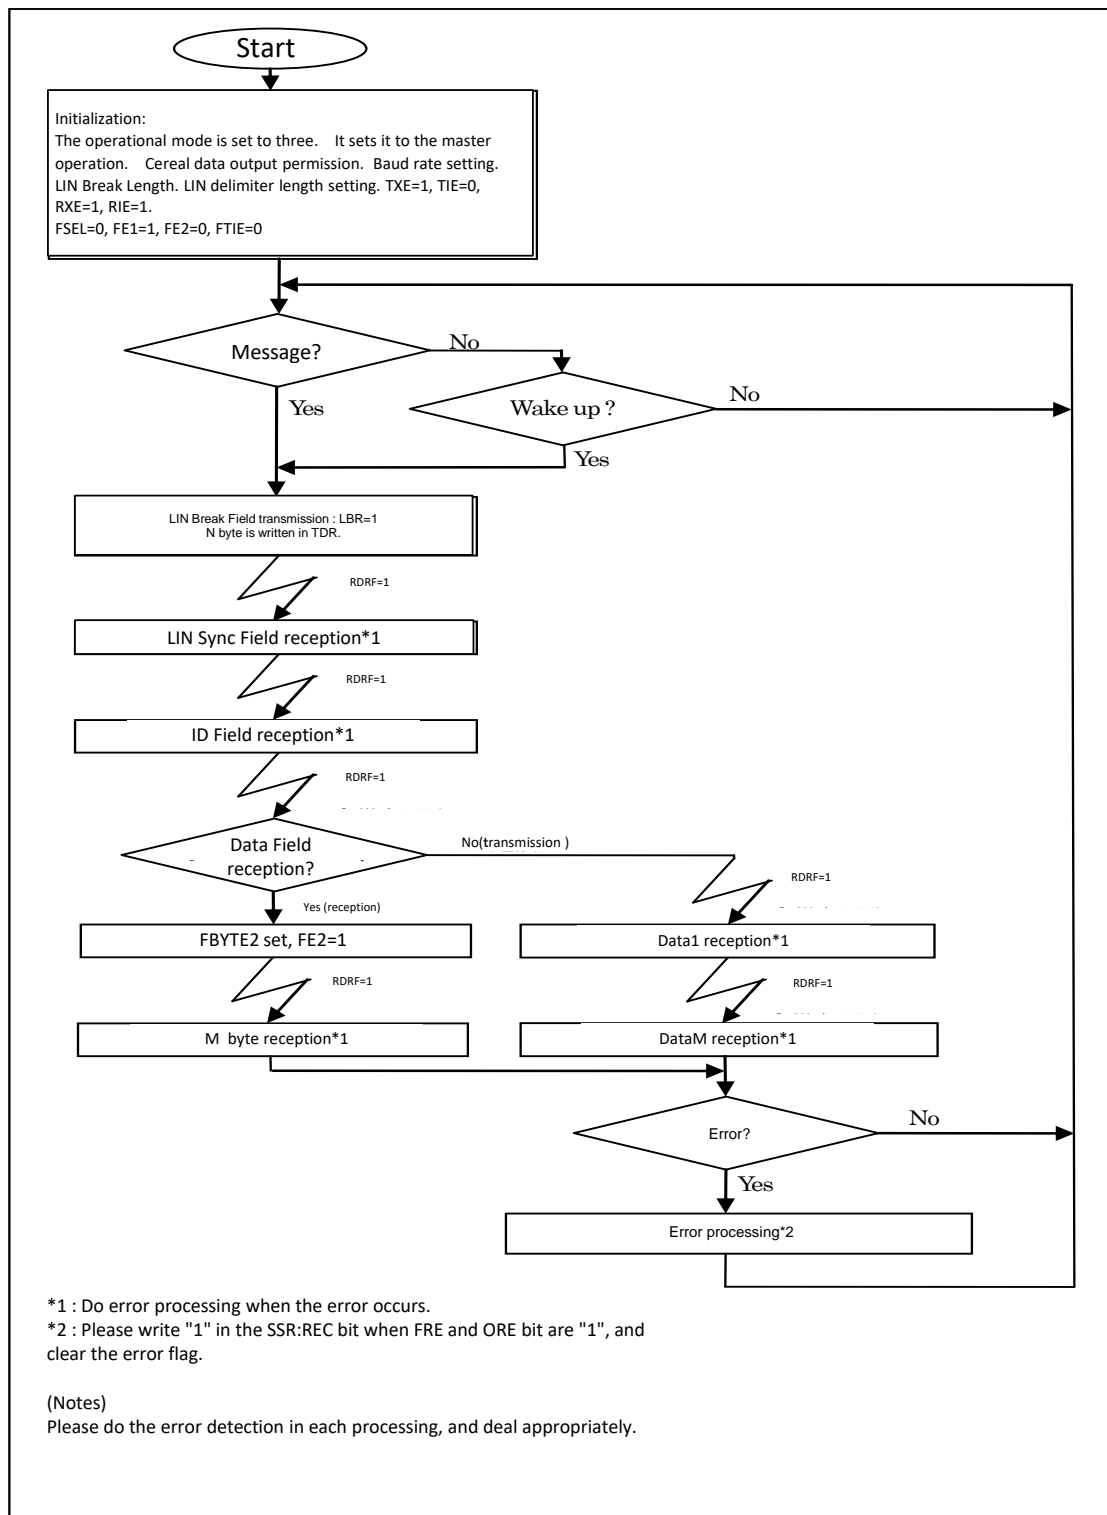

Figure 8-3 Example of LIN Communication Master Mode (a FIFO Is Used)

Slave Operation

*1: Access from the mirror address area

9.1. Serial Control Register (SCR)

The serial control register (SCR) is used to enable/disable transmission/reception interrupts, enable/disable transmission idle interrupts, and enable/disable transmission/reception operations. This register also includes the settings for LIN Break Field generation and LIN interface (v2.1) reset.

Serial Control Register (SCR)

Figure 9-1 shows the bit configuration of the serial control register (SCR).

Figure 9-1 Bit Configuration of Serial Control Register (SCR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	UPCL	MS	LBR	RIE	TIE	TBIE	RXE	TXE	(SMR)		
R/W Attribute	R0,W	R/W	R0,W	R/W	R/W	R/W	R/W	R/W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] UPCL: Programmable Clear Bit

This bit initializes the internal status of the LIN interface (v2.1).

- This bit is set when the SCRS:UPCLS bit in the set register is set to "1". [*]

When "1" is set:

- The LIN interface (v2.1) is directly reset (software reset). However, the register settings are retained. At this time, transmission and reception communications are immediately disconnected.
- The baud rate generator reloads the setting values of the BGR1/0 registers and then restarts.
- All transmission/reception and status interrupt factors (SSR:TDRE, TBI, RDRF, FRE, ORE, LBD, SACSR: TINT, SFD, LAMSR:LER, SER, RDRF, TDRE, TBI, LCSC, LAHC, LAMESR:LCSER, LPTER, LSFER, and LBSER) are initialized.
- The baud rate setting flag (SACSR:BST) is initialized.

When "0" is set:

There is no effect.

When it is read, "0" is always read.

Bit	Programmable Clear Bit	
	Write	Read
0	No effect	"0" is always read.
1	Programmable clear	

Notes:

- Execute programmable clear after setting interrupt prohibition.
- When a FIFO is used, prohibit the FIFO (FCR0:FE2, FE1 = 0) before executing programmable clear.
- Programmable clear does not clear the transmission/reception FIFOs.
- Executing programmable clear (SCR:UPCL = 1) does not clear the value of the serial timer register (STMR).

[bit14] MS: Master/Slave Function Select Bit

This bit selects either master or slave mode.

- This bit is reset when the SCRC:MSC bit in the clear register is set to "1". [*]

- This bit is set when the SCRS:MSS bit in the set register is set to "1". [*]

When set to "0": The system is placed in master mode.

When set to "1": The system is placed in slave mode.

Bit	Master/Slave Function Select Bit
0	Master mode
1	Slave mode

[bit13] LBR: LIN Break Field Setting Bit (Effective Only for Master Operation)

- In LIN manual mode operation (LAMCR:LAMEN = 0):
 - Setting this bit to "1" generates the LIN Break Field and LIN Break delimiter in the lengths specified by the ESCR:LBL1/0 and ESCR:DEL1/0 bits.
- In LIN assist mode operation (LAMCR:LAMEN = 1):
 - Setting this bit to "1" generates the LIN Break Field and LIN Break delimiter in the lengths specified by the ESCR:LBL2/1/0 and ESCR:DEL1/0 bits, and then transmits the Sync Field and the ID Field.
- This bit is set when the SCRS:LBRS bit in the set register is set to "1".

When writing:

- Writing "0": No effect
- Writing "1":
 - In LIN manual mode operation (LAMCR: LAMEN = 0),
 - a LIN Break Field is generated.
 - In LIN assist mode operation (LAMCR: LAMEN = 1),
 - a LIN Break Field is generated, and a Sync Field and an ID Field are transmitted.

When reading:

"0" is always read.

Bit	LIN Break Field Setting Bit	
	Write	Read
0	No effect	"0" always read
1	In LIN manual mode, a LIN Break Field is generated. In LIN assist mode, the LIN Break Field to ID Field are transmitted.	

Notes:

- This bit is effective only for master operation (MS = 0).
- This bit must not be set to "1" when a header is being transmitted or when a response is being transmitted or received.
- If an attempt is made to perform programmable clear (writing UPCL = 1) and LBR setting (writing LBR= 1) simultaneously, the programmable clear takes precedence.

[bit12] RIE: Reception Interrupt Enable Bit

- This bit enables/disables reception interrupt request output to the CPU.

- For ECR:EISEL = 0, a reception interrupt request is issued when the RIE bit and the reception data flag bit (SSR:RDRF) are "1" or when one of the error flag bits (SSR:FRE, ORE, ESR:RXUDR, RBERR) is "1".
- For ECR:EISEL = 1, a reception interrupt request is issued when the RIE bit and the reception data flag bit (SSR:RDRF) are "1".
- This bit is reset when the SCRC:RIEC bit in the clear register is set to "1".
- This bit is set when the SCRS:RIES bit in the set register is set to "1".

Bit	Reception Interrupt Enable Bit
0	Disable reception interrupts.
1	Enable reception interrupts.

[bit11] TIE: Transmission Interrupt Enable Bit

- This bit enables/disables transmission interrupt request output to the CPU.
- For ECR:EISEL = 0, a transmission interrupt request is issued when the TIE bit and the SSR:TDRE bit are set to "1" or when one of the error flag bits (ESR:TXOVR, TBERR) is set to "1".
- For ECR:EISEL = 1, a transmission interrupt request is issued when the TIE bit and the SSR:TDRE bit are "1".
- This bit is reset when the SCRC:TIEC bit in the clear register is set to "1".
- This bit is set when the SCRS:TIES bit in the set register is set to "1".

Bit	Transmission Interrupt Enable Bit
0	Disable transmission interrupts.
1	Enable transmission interrupts.

[bit10] TBIE: Transmission Bus Idle Interrupt Enable Bit

- This bit enables/disables transmission bus idle interrupt request output to the CPU.
- A transmission bus idle interrupt request is output when the TBIE bit and the SSR:TBI bit are "1".
- This bit is reset when the SCRC:TBIEC bit in the clear register is set to "1".
- This bit is set when the SCRS:TBIES bit in the set register is set to "1".

Bit	Transmission Bus Idle Interrupt Enable Bit
0	Disable transmission bus idle interrupts.
1	Enable transmission bus idle interrupts.

[bit9] RXE: Reception Operation Enable Bit

This bit controls enable/disable of the receiving operation of the LIN interface (v2.1).

- This bit is reset when the SCRC:RXEC bit in the clear register is set to "1".
- This bit is set when the SCRS:RXES bit in the set register is set to "1".

- When set to "0": Data frame reception operation is disabled.
- When set to "1": Data frame reception operation is enabled.

Bit	Reception Operation Enable Bit
0	Disable reception.
1	Enable reception.

Notes:

- Even if reception operation is enabled ($RXE = 1$), reception operation does not start unless a falling edge of a start bit is input.
- In master operation, even if reception operation is enabled ($RXE = 1$), data is not received while LIN Break Field is being transmitted.
- In manual mode ($LAMCR:LAMEN = 0$), disabling reception operation ($RXE = 0$) during reception immediately stops reception operation.
- In assist mode ($LAMCR:LAMEN = 1$), disable reception ($RXE = 0$) during transmission or reception of a header and during response transmission.
- In assist mode ($LAMCR:LAMEN = 1$), even if reception operation is disabled ($RXE = 0$) during header reception, header reception operation does not stop. To stop the reception, disable the reception ($RXE = 0$) and set manual mode ($LAMCR:LAMEN = 0$).
- In assist mode ($LAMCR:LAMEN = 1$), disabling reception operation ($RXE = 0$) during reception of a response immediately stops reception operation.
- Framing error detection ($SSR:FRE = 1$) is enabled when a LIN Break Field is received and reception is enabled ($RXE = 1$).

[bit8] TXE: Transmission Operation Enable Bit

This bit enables/disables transmission by the LIN interface (v2.1).

- This bit is reset when the SCRC:TXEC bit in the clear register is set to "1".
- This bit is set when the SCRS:TXES bit in the set register is set to "1".
- When set to "0": Data frame transmission operation is disabled.
- When set to "1": Data frame transmission operation is enabled.

Bit	Transmission Operation Enable Bit
0	Disable transmission.
1	Enable transmission.

Notes:

- In manual mode ($LAMCR:LAMEN = 0$), disabling transmission operation ($TXE = 0$) during transmission immediately stops transmission operation.
- In assist mode ($LAMCR:LAMEN = 1$), even if transmission operation is disabled ($TXE = 0$) during header transmission, header transmission operation does not stop. To stop the transmission, disable the transmission ($TXE = 0$) and set manual mode ($LAMCR:LAMEN = 0$).
- In assist mode ($LAMCR:LAMEN = 1$), disabling transmission operation ($TXE = 0$) during transmission of a response immediately stops transmission operation.

9.2. Serial Mode Register (SMR)

The serial mode register (SMR) is responsible for the following: 1. Operation mode setting, 2. Selection of the transfer direction, the data length, and the stop bit length, and 3. Setting of enabling/disabling of output on the serial data and clock pins.

Serial Mode Register (SMR)

Figure 9-2 shows the bit configuration of the serial mode register (SMR).

Figure 9-2 Bit Configuration of Serial Mode Register (SMR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SCR)			MD2	MD1	MD0	WUCR	SBL	Reserved	Reserved	SOE
R/W Attribute				R/W	R/W	R/W	R/W	R/W	R0,W0	R0,W0	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] MD[2:0]: Operation Mode Setting Bits

These bits set the operation mode.

Bits			Operation Mode Setting Bit
0	0	0	Operation mode 0 (asynchronous normal mode)
0	0	1	Operation mode 1 (asynchronous multi-processor mode)
0	1	0	Operation mode 2 (clock synchronous mode)
0	1	1	Operation mode 3 (LIN communication mode)
1	0	0	Operation mode 4 (I2C mode)

* This section describes the register and its operations in operation mode 3.

Notes:

- Settings other than those described above are prohibited.
- To switch the operation mode, execute programmable clear (SCR:UPCL = 1) and then switch the operation mode.
- Set the registers only after setting an operation mode.

[bit4] WUCR: WAKE UP Control Bit

WUCR is not supported

This bit selects a pin used for external interrupts.

- This bit is reset when the SMRC:WUCRC bit in the clear register is set to "1".
- This bit is set when the SMRS:WUCRS bit in the set register is set to "1".

"0": Set the INT pin for external interrupts.

"1": Set the SIN pin for external interrupts.

Bit	WAKE UP Control Bit
0	Disable the WAKE UP function.
1	Enable the WAKE UP function.

Note:

- The WAKE UP function is not supported.

[bit3] SBL: Stop Bit Length Selection Bit

This bit sets the length of the stop bits (frame end mark of the transmission data).

- This bit is reset when the SMRC:SBLC bit in the clear register is set to "1".
- This bit is set when the SMRS:SBLS bit in the set register is set to "1".

Settings where SBL is "0" and ESCR:ESBL is "0": The stop bit is set to 1 bit.

Settings where SBL is "1" and ESCR:ESBL is "0": The stop bit is set to 2 bits.

Settings where SBL is "0" and ESCR:ESBL is "1": The stop bit is set to 3 bits.

Settings where SBL is "1" and ESCR:ESBL is "1": The stop bit is set to 4 bits.

Bit	Stop Bit Length Selection Bit	
0	ESCR.ESBL = 0	1 bit
	ESCR.ESBL = 1	3 bits
1	ESCR.ESBL = 0	2 bits
	ESCR.ESBL = 1	4 bits

Notes:

- Reception always detects only the first stop bit.
- Set this bit when transmission is disabled (SCR:TXE = 0).

[bit2:1] Reserved: Reserved Bits**[bit0] SOE: Serial Data Output Enable Bit**

This bit enables/disables the output of serial data.

- This bit is reset when the SMRC:SOEC bit in the clear register is set to "1".
- This bit is set when the SMRS:SOES bit in the set register is set to "1".

Bit	Serial Data Output Enable Bit
0	Serial data output disable
1	Serial data output enable

9.3. Serial Status Register (SSR)

The serial status register (SSR) checks the transmission and reception status, checks the reception error flag, detects the LIN Break Field, or clears the reception error flag.

Serial Status Register (SSR)

Figure 9-3 shows the bit configuration of the serial status register (SSR).

Figure 9-3 Bit Configuration of Serial Status Register (SSR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	REC	Reserved	LBD	FRE	ORE	RDRF	TDRE	TBI	(ESCR)		
R/W Attribute	R0,W	R0,W0	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	1	1			

[bit15] REC: Reception Error Flag Clear Bit

This bit clears the FRE and ORE bits in the serial status register (SSR) and the SER flag in the LIN assist mode status register (LAMSR).

- This bit is set when the SSRS:RECS bit in the set register is set to "1".
- Writing "1" clears the error flag.
- Writing "0" does not have any effect.

If it is read, "0" is always read.

Bit	Reception Error Flag Clear Bit	
	Write	Read
0	No effect	"0" is always read.
1	Clear the reception error flags (FRE, ORE, and LAMSR:SER).	

[bit14] Reserved: Reserved Bit

[bit13] LBD: LIN Break Field Detection Flag Bit

This bit indicates LIN Break Field detection.

The LBD bit is set to "1" when the serial input (SIN) has "L" input for an interval of 11 bits or more. At this time, a status interrupt occurs if the LIN Break Field interrupt enable bit (LBIE) is set to "1".

- This bit is reset when the SSRC:LBDC bit in the clear register is set to "1".

(When reading)

"1": Detect a LIN Break Field.

"0": Do not detect a LIN Break Field.

(When writing)

Writing to this bit has no effect.

Bit	LIN Break Field Flag Bit	
	Write	Read
0	No effect	No LIN Break Field detected
1	No effect	LIN Break Field detected

Note:

- This bit is set "0" when Software reset (SCR:UPCL=1) is done.

[bit12] FRE: Framing Error Flag Bit

- This bit is set to "1" when a framing error occurs during reception. This bit is cleared by writing "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is issued when the FRE bit and the RIE bit are "1".
- For details on interrupt request output, see Table 2-3.
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when a reception FIFO is used, the reception FIFO enable bits are cleared, and no reception data is stored to the reception FIFO.

Bit	Framing Error Flag Bit
0	No framing error
1	Framing error found

Notes:

- During reception of a LIN Break Field, a framing error is detected before detection of a LIN Break Field if the reception enable setting (SCR:RXE = 1) is made. However, header reception is performed normally without being stopped.
- In assist mode (LAMCR:LAMEN), suppose that a LIN Break Field is detected and a new LIN Break is then transmitted from the master before the completion of ID Field reception. Then, a framing error is detected by the "L" level at the 10th bit in the new LIN Break Field regardless of the reception disable setting (SCR:RXE = 0). However, header reception is performed normally without being stopped.
- This bit is set "0" when Software reset (SCR:UPCL=1) is done.

[bit11] ORE: Overrun Error Flag Bit

- This bit is set to "1" if an overrun occurs during reception. This bit is cleared by writing "1" to the REC bit in the serial status register (SSR).
- A reception interrupt request is issued when the ORE bit and the RIE bit are "1".
- For details on the interrupt request output, see Table 2-3.
- If this flag is set, the reception data register (RDR) data will be invalid.
- If this flag is set when a reception FIFO is used, the reception FIFO enable bits are cleared, and no reception data is stored to the reception FIFO.

Bit	Overrun Error Flag Bit
0	No overrun error
1	Overrun error found

Note:

- This bit is set "0" when Software reset (SCR:UPCL=1) is done.

[bit10] RDRF: Reception Data Full Flag Bit

- This flag indicates the status of the reception data register (RDR).
- This bit is set to "1" when reception data is loaded into RDR. Reading the reception data register (RDR) causes this bit to be cleared to "0".
- A reception interrupt request is issued when the RDRF bit and the RIE bit are "1".
- When the reception FIFO is used, if the reception FIFO receives a prescribed number of data items, RDRF is set to "1".
- When reception FIFO available, SSR:RDRF is set "1" when conditions under below and the condition that the reception idle state continues for at least 8 clock pulses of the baud rate clock are satisfied.
 - The reception FIFO idle detection enable bit (FCR1:FRIDE) is set to "1".
 - The reception FIFO has not received the prescribed number of data items, and data remains in the reception FIFO.

During an 8-clock count, the counter is reset to 0 when RDR is read, and starts to count the 8clocks again.

- For ECR:RXBLKEN = 0, when the reception FIFO is used, this bit is cleared to "0" when the reception FIFO becomes empty as a result of data being read from it.
- For ECR:RXBLKEN = 1, when the reception FIFO is used, this bit is cleared to "0" when the number of data items in the reception FIFO is equal to or less than the value set in the FBYTE register.

Bit	Reception Data Full Flag Bit
0	The reception data register (RDR) is empty.
1	The reception data register (RDR) contains data.

Notes:

- When the reception FIFO is used and RDRF has become "1", resetting the reception FIFO (FCR0:FCL2, FCL1 = 1) does not cause RDRF to be set to "0". Therefore, in order to set RDRF to "0" after resetting the reception FIFO, perform a dummy reading of the reception data register in reception disable status (SCR:RXE = 0).
- During slave operation (SCR:MS = 1) in assist mode (LAMCR:LAMEN = 1), suppose that the setting is such that the reception data register (RDR) is used for the reception of ID Fields (LAMCR:LIDEN = 0). Then, the loading of an ID Field into the reception data register (RDR) sets the reception data full flag bit (RDRF = 1). The LIN auto header completion flag is also set (LAMSR:LAHC = 1) at this time.
- During slave operation (SCR:MS = 1) in assist mode (LAMCR:LAMEN = 1), suppose that the setting is such that the LIN assist mode reception ID register is used for the reception of ID Fields (LAMCR:LIDEN = 1). Then, when an ID Field is received, the received ID value is not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
- The Sync Field and the checksum are not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
- The transmitted fields are not stored in the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
- This bit is set "0" when Software reset (SCR:UPCL = 1) is done.

[bit9] TDRE: Transmission Data Empty Flag Bit

- This bit indicates the status of the transmission data register (TDR).
- Writing transmission data to TDR sets this bit to "0", indicating that TDR contains valid data. Loading data into the transmission shift register to start transmission sets this bit to "1", indicating that TDR does not contain valid data.
- A transmission interrupt request is issued when the TDRE bit and the TIE bit are "1".
- The TDRE bit is set to "1" when programmable clear (SCR:UPCL=1) is done.
- During master operation (SCR:MS = 0) in assist mode (LAMCR:LAMEN = 1), suppose that the setting is such that the transmission data register (TDR) is used for the transmission of ID Fields (LAMCR:LIDEN = 0). Then, transmission of the first bit in the ID Field sets the transmission data empty flag (TDRE = 1).
- For details on the setting and clearing timing of the TDRE bit when the transmission FIFO is used, see "Occurrence of Interrupts and Flag Set Timing When Using Transmission FIFO."

Bit	Transmission Data Empty Flag Bit
0	The transmission data register (TDR) holds data.
1	The transmission data register is empty.

[bit8] TBI: Transmission Bus Idle Flag Bit

- This bit indicates that the LIN interface (v2.1) is not performing transmission.
- This bit is set to "0" when transmission data is written to the transmission data register (TDR).
- This bit is set to "1" during those periods in which the transmission data register (TDR) is empty (TDRE = 1) and transmission is not performed.
- In manual mode (LAMCR:LAMEN = 0):
 - Setting the LIN Break Field (SMR:LBR = 1) sets this bit to "0".
 - Once transmission of the LIN Break Field is complete and the transmission data register is empty, this bit is set to "1".
- In assist mode (LAMCR:LAMEN = 1):
 - This bit is set to "0" during transmission of a header in the master operation (SCR:MS = 0).
 - Once the header transmission (ID Field transmission) is complete and the transmission data register is empty, this bit is set to "1".
 - This bit is set to "0" during the transmission of a response.
 - Once response transmission (checksum transmission) is complete and the transmission data register is empty, this bit is set to "1".
- A transmission interrupt request is issued if this bit is set to "1" and transmission bus idle interrupt is enabled (SCR:TBIE = 1).

Bit	Transmission Bus Idle Flag Bit
0	Transmission in progress
1	No transmission

9.4. Extended Communication Control Register (ESCR)

The extended communication control register (ESCR) enables/disables LIN Break Field interrupts, detects LIN Break Fields, and selects lengths for the LIN Break Field, the LIN Break delimiter, and the stop bit.

Extended Communication Control Register (ESCR)

Figure 9-4 shows the bit configuration of the extended communication control register (ESCR).

Figure 9-4 Bit Configuration of Extended Communication Control Register (ESCR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SSR)			Reserved	ESBL	LBL2	LBIE	LBL1	LBL0	DEL1	DEL0
R/W Attribute				R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

[bit6] ESBL: Extended Stop Bit Length Selection Bit

This bit selects the length of the stop bits (frame end mark of the transmission data).

- This bit is reset when the ESCRC:ESBLC bit in the clear register is set to "1".
- This bit is set when the ESCRS:ESBLS bit in the set register is set to "1".

Settings where SBL is "0" and ESCR:ESBL is "0": The stop bit is set to 1 bit.

Settings where SBL is "1" and ESCR:ESBL is "0": The stop bit is set to 2 bits.

Settings where SBL is "0" and ESCR:ESBL is "1": The stop bit is set to 3 bits.

Settings where SBL is "1" and ESCR:ESBL is "1": The stop bit is set to 4 bits.

Bit	Extended Stop Bit Length Selection Bit	
0	SMR.SBL = 0	1 bit
	SMR.SBL = 1	2 bits
1	SMR.SBL = 0	3 bits
	SMR.SBL = 1	4 bits

Notes:

- Reception always detects only the first stop bit.
- Set this bit when transmission is disabled (SCR:TXE = 0).
- In assist mode (LAMCR:LAMEN = 1), set this bit before setting the LIN Break Field (SCR:LBR = 1).

[bit4] LBIE: LIN Break Field Detection Interrupt Enable Bit

This bit enables/disables LIN Break Field detection interrupts.

When the LIN Break Field detection flag (LBD) is "1", enabling interrupts (LBIE = 1) generates a status interrupt.

- This bit is reset when the ESCRC:LBIEC bit in the clear register is set to "1".
- This bit is set when the ESCRS:LBIES bit in the set register is set to "1".

Bit	LIN Break Field Detection Interrupt Enable Bit
0	Disable LIN Break Field detection interrupts.
1	Enable LIN Break Field detection interrupts.

[bit5, bit3:2] LBL[2:0]: LIN Break Field Length Selection Bits (Effective Only for Master Operation)

- These bits set the LIN Break Field duration as a number of bits.
- Set these bits before setting the LIN Break Field setting bit (SCR:LBR) to "1".
- During slave operation, a LIN Break Field is detected at the 11th bit regardless of the setting of these bits.

Bits			LIN Break Field Length Selection Bit
0	0	0	13-bit length
0	0	1	14-bit length
0	1	0	15-bit length
0	1	1	16-bit length
1	0	0	17-bit length
1	0	1	18-bit length
1	1	0	19-bit length
1	1	1	20-bit length

Notes:

- This function is effective only during master operation (SCR:MS = 0).
- Set these bits before setting the LIN Break Field (SCR:LBR = 1).
- In manual mode (LAMCR:LAMEN = 0), only 13-bit to 16-bit lengths are effective. Therefore, always set LBL2 to "0".

[bit1:0] DEL[1:0]: LIN Break Delimiter Length Selection Bits (Effective Only for Master Operation)

- These bits set the length of the LIN Break delimiter as a number of bits.
- Set these bits before setting the LIN Break Field setting bit(SCR:LBR) to "1".

Bits		LIN Break Delimiter Length Selection Bit
0	0	1-bit length
0	1	2-bit length
1	0	3-bit length
1	1	4-bit length

Notes:

- This function is effective only during master operation (SCR:MS = 0).
- In assist mode (LAMCR:LAMEN = 1), set this bit before setting the LIN Break Field (SCR:LBR = 1).

9.5. Reception Data Register/Transmission Data Register (RDR/TDR)

The reception data register and the transmission data register are placed at the same address. If read, the register functions as a reception data register, and if written to, it functions as a transmission register.

Reception Data Register (RDR)

Figure 9-5 shows the bit configuration of the serial reception register (RDR).

Figure 9-5 Bit Configuration of Reception Data Register (RDR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field				D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute				R	R	R	R	R	R	R	R
ProtectionAttribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

The reception data register (RDR) is the data buffer register used for the reception of serial data.

- Serial data signals transmitted to the serial input pin (SIN pin) are converted by the shift register, and are then stored into the reception data register (RDR).
- The reception data full flag bit (SSR:RDRF) is set to "1" when reception data is stored into the reception data register (RDR). If reception interrupts are enabled (SCR:RIE = 1), a reception interrupt request is generated.
- Read the reception data register (RDR) when the reception data full flag bit (SSR:RDRF) is "1". The reception data full flag bit (SSR:RDRF) is automatically cleared to "0" when reading data from the serial reception data register (RDR).
- If a reception error occurs (when SSR:ORE or FRE becomes "1"), the data in the reception data register (RDR) will be invalid.

Notes:

- If a reception error occurs, the data in the reception data register (RDR) will be invalid.
- The operation in assist mode (LAMCR:LAMEN = 1) is as follows:
 - During slave operation, suppose that the setting is such that the LIN assist mode reception ID register is used for the reception of ID Fields (LAMCR:LIDEN = 1). Then, when an ID Field is received, the received ID value is not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
 - During slave operation, suppose that the setting is such that the reception data register (RDR) is used for the reception of ID Fields (LAMCR:LIDEN = 0). Then, when an ID Field is received, the received ID value is stored into the reception data register (RDR) and the reception data full flag bit is set (SSR:RDRF = 1). Check the ID value after the LIN auto header completion flag is set (LAMSR:LAHC = 1).
 - The Sync Field and the checksum are not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
 - The transmitted fields are not stored into the reception data register (RDR) and the reception data full flag bit (SSR:RDRF) is not set.
 - Transmission and reception processing for assist mode stops when a reception error occurs (SSR:FRE, ORE, LAMESR:LCSE, LSFER, LBSE, or LPTER). At this time, the response reception processing stops the storing of the reception data in the reception data register, regardless of the reception enable setting (SCR:RXE = 1).

- The operation when the reception FIFO is used is as follows:
 - When the reception FIFO receives a predefined data count, the RDRF to "1".
 - When the reception FIFO becomes empty, RDRF is cleared to "0".
 - If a reception error occurs (when SSR:ORE, FRE becomes "1"), the enable bit in the reception FIFO is cleared and the reception data is not stored into the reception FIFO.

Transmission Data Register (TDR)

Figure 9-6 shows the bit configuration of the transmission data register.

Figure 9-6 Bit Configuration of Transmission Data Register (TDR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field				D7	D6	D5	D4	D3	D2	D1	D0
R/W Attribute				W	W	W	W	W	W	W	W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				1	1	1	1	1	1	1	1

The transmission data register (TDR) is the data buffer register used for the transmission of serial data.

- If transmission operation is enabled (SCR:TXE = 1), and the data to transmit is written to the transmission data register (TDR), the transmission data is transferred to the transmission shift register, is converted into serial data, and is then sent out from the serial data output pin (SOUT pin).
- The transmission data empty flag (SSR:TDRE) is cleared to "0" when the transmission data is written to the serial transmission data register (TDR).
- If the transmission FIFO is disabled or empty, the transmission data empty flag (SSR:TDRE) is set to "1" when transmission data is transferred to the transmission shift register to start transmission.
- If the transmission data empty flag (SSR:TDRE) is "1", the next data for transmission can be written. If transmission interrupts are enabled, a transmission interrupt is generated. Write the next transmission data after a transmission interrupt is generated or when the transmission data empty flag (SSR:TDRE) is "1".
- When the transmission data empty flag (SSR:TDRE) is "0" and the transmission FIFO is disabled or full, transmission data cannot be written to the transmission data register (TDR).

Notes:

- The transmission data register is a write-only register, and the reception data register is a read-only register. The two registers are placed at the same address, so the written value differs from the read value.
- For details on the set timing of the transmission data empty flag (SSR:TDRE) when the transmission FIFO is used, see "Occurrence of Interrupts and Flag Set Timing When Using Transmission FIFO."
- The upper 2 bits of data are ignored when all of the following conditions are satisfied.
 - LIN hardware assist mode (LAMCR:LAMEN = 1)
 - ID DATA register not used (LAMCR:LIDEN = 0)
 - ID DATA being transmitted

9.6. Serial Auxiliary Control Status Register (SACSR)

The serial auxiliary control status register (SACSR) controls the serial test operation, enables/disables auto baud rate adjustment, enables/disables Sync Field interrupts, selects a serial timer activation method, enables/disables timer interrupts, sets the division value of the serial timer operation clock, and enables/disables the serial timer.

Bit Configuration of Serial Auxiliary Control Status Register (SACSR)

Figure 9-7 shows the bit configuration of the serial auxiliary control status register (SACSR).

Figure 9-7 Bit Configuration of Serial Auxiliary Control Status Register (SACSR)

Bit	15	14	13	12	11	10	9	8
Field	STST	BST	SFD	SFDE	AUTE	TRG1	TRG0	TINT
R/W Attribute	R/W	R, WX	R, WX	R/W	R/W	R/W	R/W	R, WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TINTE	Reserved	TRGE	TDIV3	TDIV2	TDIV1	TDIV0	TMRE
R/W Attribute	R/W	R0, W0	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] STST: Serial Test Bit

This bit enables or disables serial test mode.

When serial test mode is enabled, SOUT and SIN are connected together inside the multi-function serial interface, so that the data transmitted from SOUT can be directly received from SIN.

When serial test mode is enabled, the SOUT pin is fixed to "H", and any data input to the SIN pin is ignored.

- This bit is reset when the SACSRC:STSTC bit in the clear register is set to "1".
- This bit is set when the SACSRS:STSTS bit in the set register is set to "1".

Bit	Serial Test Bit
0	Disable serial test mode.
1	Enable serial test mode.

Note:

- This bit can be changed only when transmission/reception are disabled (SCR:TXE = 0, SCR:RXE = 0).

[bit14] BST: Baud Rate Setting Flag

This bit indicates that auto baud rate adjustment has been performed upon the reception of a Sync Field.

This bit is updated upon the detection of a 5th falling edge of the LIN bus in the Sync Field.

Bit	Baud Rate Setting Flag	
	Write	Read
0	No effect	Without auto baud rate adjustment
1		With auto baud rate adjustment

Notes:

- This bit is fixed to "0" when auto baud rate adjustment is disabled (AUTE = 0).
- A software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is effective only when the Sync Field detection flag (SACSR:SFD) is "1".
- Writing to this bit is invalid.

[bit13] SFD: Sync Field Detection Flag

This bit indicates that a Sync Field has been detected.

This bit is set to "1" upon the detection of a 5th falling edge of the LIN bus in the Sync Field.

When this bit is "1" and the Sync Field detection interrupt enable bit (SFDE) is "1", a status interrupt request is issued.

This bit is reset when the SACSRC:SFDC bit in the clear register is set to "1".

Bit	Sync Field Detection Flag	
	Write	Read
0	No effect	Sync Field not detected
1	No effect	Sync Field detected

Notes:

- A software reset (SCR:UPCL = 1) resets this bit to "0".
- Writing to this bit is invalid.
- This bit is effective both in master mode (SCR:MS = 0) and in slave mode (SCR:MS = 1).

[bit12] SFDE: Sync Field Detection Interrupt Enable Bit

This bit enables/disables Sync Field interrupts to the CPU.

When this bit is "1" and the Sync Field detection flag (SFD) is "1", a status interrupt request is issued.

- This bit is reset when the SACSRC:SFDEC bit in the clear register is set to "1".

This bit is set when the SACSRS:SFDES bit in the set register is set to "1".

Bit	Sync Field Detection Interrupt Enable Bit
0	Disable interrupts of Sync Field detection.
1	Enable interrupts of Sync Field detection.

[bit11] AUTE: Auto Baud Rate Adjustment Bit

This bit enables/disables auto baud rate adjustment.

- This bit is reset when the SACSRC:AUTEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:AUTES bit in the set register is set to "1".

Bit	Auto Baud Rate Adjustment Bit
0	Disable auto baud rate adjustment.
1	Enable auto baud rate adjustment.

Notes:

- This bit is internally fixed to "0" in master mode (SCR:MS = 0).
- Setting this bit to "1" sets the timer operation clock division bits (TDIV[3:0]) to 0b0011 (division by 8).
- These bits can be changed from "0" to "1" only when the serial timer enable bit (TMRE) is "0".
- When auto baud rate adjustment is enabled (AUTE = 1), set in the internal clock(BGR1:EXT=0),

[bit10:9] TRG[1:0]: Trigger Selection Bits

These bits select the detection method for the external trigger edges that are used to activate the serial timer.

Bits		Edge Detection Method for External Trigger
0	0	Rising edge detection
0	1	Falling edge detection
1	0	Both edge detection
1	1	Setting prohibited

Notes:

- These bits are invalid if the external trigger enable bit (TRGE) is "0".
- These bits can be changed only when the serial timer enable bit (TMRE) is "0".

[bit8] TINT: Timer Interrupt Flag

If the serial timer register (STMR) and the serial timer comparison register (STMCR) match, the serial timer register (STMR) is set to "0", and this bit is set to "1".

When this bit is "1" and the timer interrupt enable bit (TINTE) is "1", a status interrupt request is issued.

Writing to this bit is invalid.

- This bit is reset when the SACSRC:TINTC bit in the clear register is set to "1".

Bit	Description	
	Write	Read
0	No effect	No timer interrupt request
1	No effect	Timer interrupt request issued

Note:

- A software reset (SCR:UPCL = 1) resets this bit to "0".

[bit7] TINTE: Timer Interrupt Enable Bit

This bit enables/disables timer interrupts to the CPU.

When this bit is "1" and the timer interrupt flag (TINT) is "1", a status interrupt request is issued.

- This bit is reset when the SACSRC:TINTEC bit in the clear register is set to "1".
- This bit is set when the bit SACSRS:TINTES in the set register is set to "1".

Bit	Description
0	Disable interrupts triggered by the serial timer.
1	Enable interrupts triggered by the serial timer.

[bit6] Reserved: Reserved Bit**[bit5] TRGE: External Trigger Enable Bit**

This bit selects the method used to activate the serial timer.

- This bit is reset when the SACSRC:TRGEC bit in the clear register is set to "1".
- This bit is set when the SACSRS:TRGES bit in the set register is set to "1".

Bit	Description
0	The serial timer starts when value of the serial timer enable bit (TMRE) is changed from "0" to "1".
1	If the serial timer enable bit (TMRE) is set to "1", the detection of an external trigger edge specified by the trigger selection bit (TRG1, TRG0) starts the serial timer.

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is "0".
- If the serial timer enable bit (TMRE) is set to "0", the detection of an external trigger edge specified by the trigger selection bit (TRG1, TRG0) does not start the serial timer.

[bit4:1] TDIV[3:0]: Timer Operation Clock Division Bits

These bits set the division ratio of the serial timer.

Bits				Timer Operation Clock						
				Division Ratio	Φ = 8 MHz	Φ = 10 MHz	Φ = 16 MHz	Φ = 20 MHz	Φ = 24 MHz	Φ = 32 MHz
0	0	0	0	Φ	125 ns	100 ns	62.5 ns	50 ns	41.67 ns	31.25 ns
0	0	0	1	$\Phi/2$	250 ns	200 ns	125 ns	100 ns	83.33 ns	62.5 ns
0	0	1	0	$\Phi/4$	500 ns	400 ns	250 ns	200 ns	166.67 ns	125 ns
0	0	1	1	$\Phi/8$	1 μ s	800 ns	500 ns	400 ns	333.33 ns	250 ns
0	1	0	0	$\Phi/16$	2 μ s	1.6 μ s	1 μ s	800 ns	666.67 ns	500 ns
0	1	0	1	$\Phi/32$	4 μ s	3.2 μ s	2 μ s	1.6 μ s	1.33 μ s	1 μ s
0	1	1	0	$\Phi/64$	8 μ s	6.4 μ s	4 μ s	3.2 μ s	2.67 μ s	2 μ s
0	1	1	1	$\Phi/128$	16 μ s	12.8 μ s	8 μ s	6.4 μ s	5.33 μ s	4 μ s
1	0	0	0	$\Phi/256$	32 μ s	25.6 μ s	16 μ s	12.8 μ s	10.67 μ s	8 μ s

Φ : Bus clock

Notes:

- These bits can be changed only when the serial timer enable bit (TMRE) is "0".
- Settings other than the above are prohibited.

[bit0] TMRE: Serial Timer Enable Bit

This bit enables or disables the serial timer operation.

- This bit is reset when the SACSRC:TMREC bit in the clear register is set to "1".

This bit is set when the SACSRS:TMRES bit in the set register is set to "1".

Bit	Serial Timer Enable Bit
0	Stop serial timer operation. When stopped, the value of the serial timer register (STMR) is retained.
1	Changing this bit from "0" to "1" initializes the serial timer register (STMR) to "0" and starts serial timer operation.

Note:

- If the external trigger is enabled ($TRGE = 1$), setting this bit to "1" does not start the serial timer until detection of an external trigger edge specified by the trigger selection bits (SACSR:TRG1, TRG0).

9.7. Serial Timer Register (STMR)

The serial timer register (STMR) represents the timer value of the serial timer.

Bit Configuration of Serial Timer Register (STMR)

Figure 9-8 shows the bit configuration of the serial timer register (STMR).

Figure 9-8 Bit Configuration of Serial Timer Register (STMR)

Bit	15	14	13	12	11	10	9	8
Field	TM15	TM14	TM13	TM12	TM11	TM10	TM9	TM8
R/W Attribute	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TM7	TM6	TM5	TM4	TM3	TM2	TM1	TM0
R/W Attribute	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TM15-0: Timer Data Bits

These bits indicate the timer value of the serial timer.

During timer operation, the timer value of the serial timer is incremented by 1 for each timer operation clock (specified by SACS:TDIV3 to TDIV0).

Note:

- These bits are initialized to "0" when the timer operation starts.

9.8. Serial Timer Comparison Register (STMCR)

The serial timer comparison register (STMCR) sets the timer comparison value of the serial timer.

Bit Configuration of Serial Timer Comparison Register (STMCR)

Figure 9-9 shows the bit configuration of the serial timer comparison register (STMCR).

Figure 9-9 Bit Configuration of Serial Timer Comparison Register (STMCR)

Bit	15	14	13	12	11	10	9	8
Field	TC15	TC14	TC13	TC12	TC11	TC10	TC9	TC8
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TC7	TC6	TC5	TC4	TC3	TC2	TC1	TC0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15:0] TC15-0: Compare Bits

These bits set a comparison value for the serial timer.

These bits are compared with the serial timer register (STMR). If the serial timer register (STMR) coincides with these bits when updated, the serial timer register is set to "0". At this time, the timer interrupt flag (SACSR:TINT) is set to "1".

The period below is (STMCR:TC+1) X The timer clock (set by SACSR:TDIV3-0)

- SACSR:TINT is set "1"

Notes:

- The timer interrupt flag (SACSR:TINT) is fixed to "1" when all of the following conditions are satisfied.
 - Synchronous transmission is disabled (SACSR:TSYNE = 0).
 - 0x0000 is set in this register.
 - The timer is operating.
 - 0b0000 is set as the timer operating clock division value (SACSR:TDIV3-0).
- This register can be changed only when the serial timer is disabled (SACSR:TMRE = 0).
- The serial timer register (STMR) may be reset to 0x0000 before baud rate adjustment when all of the following conditions are satisfied. For this reason, set these bits to a value larger than that set for the Sync Field upper limit bits (SFUR) when the auto baud rate adjustment bit (SACSR:AUTE) is "1".
 - The auto baud rate adjustment bit (SACSR:AUTE) is "1".
 - The value of these bits is equal to or less than the value set for the Sync Field upper limit bits (SFUR).

9.9. Sync Field Upper Limit Register (SFUR)

The Sync Field upper limit register (SFUR) sets the upper limit on the values that can be set in the baud rate generator register for auto baud rate adjustment.

Bit Configuration of Sync Field Upper Limit Register (SFUR)

Figure 9-10 shows the bit configuration of the Sync Field upper limit register (SFUR).

Figure 9-10 Bit Configuration of Sync Field Upper Limit Register (SFUR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved	TU14	TU13	TU12	TU11	TU10	TU9	TU8
R/W Attribute	R0, W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] Reserved: Reserved Bit

[bit14:0] TU14-0: Upper Limit Bits

These bits set the upper limit on the values that can be set in the baud rate generator register (BGR1, BGR0) for auto baud rate adjustment.

Suppose that the auto baud rate adjustment bit (SACSR:AUTE) is "1" and that operation is being performed in slave mode (SCR:MS = 1). Also suppose that the value of the serial timer register (STMR) after receiving Sync Field does not exceed the value of these bits and is not less than the value of the Sync Field lower limit register (SFLR). Then, the baud rate generator register (BGR1, BGR0) is set to the value of the serial timer register (STMR).

Note:

- These bits can be changed when the auto baud rate adjustment bit (SACSR:AUTE) is "0".

9.10. Sync Field Lower Limit Register (SFLR)

The Sync Field lower limit register (SFLR) sets the lower limit for the values that can be set in the baud rate generator register for auto baud rate adjustment.

Bit Configuration of Sync Field Lower Limit Register (SFLR)

Figure 9-11 shows the bit configuration of the Sync Field lower limit register (SFLR).

Figure 9-11 Bit Configuration of Sync Field Lower Limit Register (SFLR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved	TL14	TL13	TL12	TL11	TL10	TL9	TL8
R/W Attribute	R0, W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TL7	TL6	TL5	TL4	TL3	TL2	TL1	TL0
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] Reserved: Reserved Bit

[bit14:0] TL14-0: Lower Limit Bits

These bits set the lower limit on the values that can be set in the baud rate generator register (BGR1, BGR0) for auto baud rate adjustment.

Suppose that the auto baud rate adjustment bit (SACSR:AUTE) is "1" and that operation is being performed in slave mode (SCR:MS = 1). Also suppose that the value of the serial timer register (STMR) after receiving Sync Field does not exceed the value of the Sync Field upper limit register (SFUR) and is not less than the value of these bits. Then, the baud rate generator register (BGR1, BGR0) is set to the value of the serial timer register (STMR).

Note:

- These bits can be changed when the auto baud rate adjustment bit (SACSR:AUTE) is "0".

9.11. Baud Rate Generator Register 1, 0 (BGR1, BGR0)

Baud rate generator register 1, 0 (BGR1, BGR0) sets the division ratio of the serial clock. An external clock can also be selected as the clock source of the reload counter.

Bit Configuration of Baud Rate Generator Register 1, 0 (BGR0/1)

Figure 9-12 shows the bit configuration of baud rate generator register 1, 0 (BGR1, BGR0).

Figure 9-12 Bit Configuration of Baud Rate Generator Register 1, 0 (BGR1, BGR0)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	EXT	BGR1							BGR0							
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

- The baud rate generator registers set the division ratio of the serial clock.
- BGR1 represents the higher bits while BGR0 represents the lower bits. The reload value for counting can be written to these registers, and the set reload values can be read from these registers.
- The reload counter starts counting when a reload value is written in baud rate generator register 1, 0 (BGR1, BGR0).
- The EXT bit, bit15, selects the internal clock or an external clock as the clock source of the reload counter. EXT = 0 selects the internal clock. EXT = 1 selects an external clock.

[bit15] EXT: External Clock Selection Bit

Bit	External Clock Selection Bit
0	Use the internal clock.
1	Use an external clock.

[bit14:8] BGR1: Baud Rate Generator Register 1

BGR1	Baud Rate Generator Register 1
Write	Write to reload counter bits 8 to 14.
Read	Read the setting value of BGR1.

[bit7:0] BGR0: Baud Rate Generator Register 0

BGR0	Baud Rate Generator Register 0
Write	Write to reload counter bits 0 to 7.
Read	Read the setting value of BGR0.

Notes:

- Use 16-bit access for writing a value to the baud rate generator register (BGR1, BGR0).
- If the values set in the baud rate generator registers (BGR1, BGR0) are changed, the new values are reloaded when the counter value becomes "00000"hex. Therefore, to enable the new value immediately, execute programmable clear (UPCL) after changing the values of BGR1/0.

- *When the reload value is even, the "L" width of the serial clock is 1-bus-clock-cycle longer than the "H" width. When the reload value is odd, the "L" width and the "H" width of the serial clock are equal.*
- *Set the reload value to 3 or larger. However, data may not be received normally depending on baud rate errors and the reload value setting.*
- *To change the clock setting to that of the external clock (EXT = 1) when the baud rate generator is operating, perform the following: 1. Write "0" to baud rate generators 1, 0 (BGR1, BGR0). 2. Execute programmable clear (UPCL). 3. Set external clock mode (EXT = 1).*
- *When auto baud rate adjustment is enabled (SACSR:AUTE = 1), set in the internal clock(BGR1:EXT=0),*

9.12. LIN Assist Mode Status Register (LAMSR)

The LIN assist mode status register (LAMSR) checks the auto header transmission/reception status and the reception error flag.

LIN Assist Mode Status Register (LAMSR)

Figure 9-13 shows the bit configuration of the LIN assist mode status register (LAMSR).

Figure 9-13 LIN Assist Mode Status Register (LAMSR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	LER	SER	RDRF	TDRE	TBI	LCSC	Reserved	LAHC	(LAMCR)		
R/W Attribute	R, WX	R, WX	R, WX	R, WX	R, WX	R, WX	R0, W0	R, WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	1	1	0	0	0			

[bit15] LER: LIN Representative Error Flag Bit

- This bit is set to "1" when any of the following errors occurs. For details on the setting and clearing conditions for the error flag bit, see the explanations of the individual bits of the LIN assist mode error status register (LAMESR).
 - LIN bus error flag bit (LBSEr)
 - LIN Sync Data error flag bit (LSFER)
 - LIN ID parity error flag bit (LPTer)
 - LIN checksum error flag bit (LCSEr)

Bit	LIN Representative Error Flag Bit
0	There is no error.
1	An error has occurred.

Notes:

- This bit is effective in assist mode (LAMCR:LAMEN = 1).
- In manual mode (LAMCR:LAMEN = 0), this bit is always read as "0".

[bit14] SER: Serial Interface Representative Error Flag Bit

- This bit is set to "1" when any of the following errors occurs. For details on the setting and clearing conditions for the error flag bit, see the explanations of the individual bits of the serial status register (SSR).
 - Framing error flag bit (FRE)
 - Overrun error flag bit (ORE)

Bit	Serial Interface Representative Error Flag Bit
0	There is no error.
1	An error has occurred.

[bit13] RDRF: Reception Data Full Flag Bit

- This bit is the same as the reception data full flag bit (RDRF) in the serial status register (SSR). For an explanation of this bit, see the description of the serial status register (SSR).

[bit12] TDRE: Transmission Data Empty Flag Bit

- This bit is the same as the transmission data empty flag bit (TDRE) in the serial status register (SSR). For an explanation of this bit, see the description of the serial status register (SSR).

[bit11] TBI: Transmission Bus Idle Flag Bit

- This bit is the same as the transmission bus idle flag bit (TBI) in the serial status register (SSR). For an explanation of this bit, see the description of the serial status register (SSR).

[bit10] LCSC: LIN Checksum Calculation Completion Flag Bit

- This bit indicates the completion of checksum calculation.
- This bit is set to "1" upon the completion of checksum calculation, which happens when data of the configured length (LAMCR:LDL3 to LDL0) and a checksum are received during assist mode (LAMCR:LAMEN = 1) reception operation.
- A status interrupt request is issued when the LIN checksum calculation completion flag bit (LCSC) and the checksum calculation completion interrupt enable bit (LCSCIE) are "1".

(When reading)

"1": Checksum calculation completion has been detected.

"0": Checksum calculation completion has not been detected.

(When writing)

No effect.

Bit	Checksum Calculation Completion Flag Bit	
	Write	Read
0	No effect	Checksum calculation is in progress. Or Checksum calculation start is being awaited.
1	No effect	Checksum calculation has been completed.

Notes:

This bit is reset when the LAMSRC:LCSCC bit in the clear register is set to "1".

- This bit is effective in assist mode (LAMCR:LAMEN = 1).
- This bit is set "0" when Software reset is done (SCR:UPCL=1).

[bit9] Reserved: Reserved Bit

[bit8] LAHC: LIN Auto Header Completion Flag Bit

- This bit indicates the LIN auto header status.
- This bit is set to "1" when a LIN header is received in assist mode (LAMCR:LAMEN = 1).

- A status interrupt request is issued when the LIN auto header completion flag bit (LAHC) and the LIN auto header completion interrupt enable bit (LAHCIE) are "1".
- After this bit is set to "1", reading the LIN auto header reception ID register (LAMRID) sets this bit to "0".

(When reading)

"1": LIN auto header completion has been detected.

"0": LIN auto header completion has not been detected.

(When writing)

"No effect.

Bit	LIN Auto Header Completion Flag Bit	
	Write	Read
0	No effect	LIN auto header is being received. Or, its reception is being awaited.
1	No effect	LIN auto header has been received.

Notes:

This bit is reset when the LAMSRC:LAHCC bit in the clear register is set to "1".

- *This bit is effective in assist mode (LAMCR:LAMEN = 1).*
- *This bit is set "0" when Software reset is done (SCR:UPCL=1).*

9.13. LIN Assist Mode Control Register (LAMCR)

The LIN assist mode control register (LAMCR) enables LIN auto header processing, enables the use of the LIN ID register, selects a LIN checksum type, clears TDR, and sets the LIN data length in LIN assist mode.

LIN Assist Mode Control Register (LAMCR)

Figure 9-14 shows the bit configuration of the LIN assist mode control register (LAMCR).

Figure 9-14 Bit Configuration of LIN Assist Mode Control Register (LAMCR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(LAMSR)			LDL3	LDL2	LDL1	LDL0	LTDRCL	LCSTYP	LIDEN	LAMEN
R/W Attribute				R/W	R/W	R/W	R/W	R0, W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:4] LDL[3:0]: LIN Data Length Setting Bit

- These bits set the length of the LIN response data within a range of 0 to 8 bytes.
- The setting value should represent the data length.
- Data of the length specified by these bits is sent in the transmission operation.
- Data of the length specified by these bits is received in the reception operation.

Bits				LIN Data Length Setting Bits
0	0	0	0	0 byte
0	0	0	1	1 byte
0	0	1	0	2 bytes
0	0	1	1	3 bytes
0	1	0	0	4 bytes
0	1	0	1	5 bytes
0	1	1	0	6 bytes
0	1	1	1	7 bytes
1	0	0	0	8 bytes
Other than the above				Setting prohibited

Notes:

- This function is effective only in LIN assist mode (LAMEN = 1).
- During master mode operation, set these bits before the generation of LIN Break Fields (SCR:LBR = 1).
- During slave mode operation, set these bits before the start of response transmission/reception.

[bit3] LTDRCL: LIN Transmission Data Register Clear Bit

- This bit clears the transmission data register (TDR).
- When set to "1": The transmission data empty flag bit (SSR:TDRE) and the transmission bus idle flag bit (SSR:TBI) are set to "1".
- When set to "0": No effect on the operation.

- When it is read, "0" is always read.
- This bit is set when the LAMCRS:LTDRCLS bit in the set register is set to "1".

Bit	LIN Transmission Data Register Clear Bit	
	Write	Read
0	No effect	"0" is always read.
1	Set the transmission data empty flag bit (SSR:TDRE) and the transmission bus idle flag bit (SSR:TBI) to "1".	

Notes:

- Clearing the transmission data register does not reset the transmission FIFO.
- When the transmission FIFO is used, clear the transmission FIFO (FCR0:FCL1 or FCR0:FCL2) and then clear the transmission data register.
- Do not set this bit to "1" during transmission.

[bit2] LCSTYP: LIN Checksum Type Selection Bit

This bit selects the LIN checksum type.

- This bit is reset when the LAMCRC:LCSTYPC bit in the clear register is set to "1".
- This bit is set when the LAMCRS:LCSTYPS bit in the set register is set to "1".

"0": The standard checksum is selected.

"1": The extended checksum is selected.

Bit	LIN Checksum Type Selection Bit
0	Standard checksum
1	Extended checksum

Notes:

- This function is effective only in LIN assist mode (LAMEN = 1).
- During master mode operation, set these bits before the generation of LIN Break Fields (SCR:LBR = 1).
- During slave mode operation, set these bits before the start of response transmission/reception.

[bit1] LIDEN: LIN ID Register Use Enable Bit

This bit sets whether to use the LIN assist mode transmission/reception ID register (LAMTID/LAMRID).

- This bit is reset when the LAMCRC:LIDENC bit in the clear register is set to "1".
- This bit is set when the LAMCRS:LIDENS bit in the set register is set to "1".

(In master mode (SCR:MS = 0))

When set to "0": Data written to the transmission data register (TDR) as the transmission data of LIN ID Field is used.

When set to "1": Data written to the LIN assist mode transmission ID register (LAMTID) as the transmission data of LIN ID Field is used.

(In slave mode (SCR:MS = 1))

When set to "0": The received data of LIN ID Field is stored into the reception data register (RDR).

When set to "1": The received data of LIN ID Field is stored into the LIN assist mode reception ID register (LAMRID).

Bit	LIN ID Register Use Enable Bit	
	Master	Slave
0	Use the transmission data register (TDR).	Use the reception data register (RDR).
1	Use the LIN assist mode transmission ID register (LAMTID).	Use the LIN assist mode reception ID register (LAMRID).

Note:

- This function is effective only in LIN assist mode (LAMEN = 1).

[bit0] LAMEN: LIN Assist Mode Processing Enable Bit

This bit sets whether LIN assist mode is used.

- This bit is reset when the LAMCRC:LAMENC bit in the clear register is set to "1".
- This bit is set when the LAMCRS:LAMENS bit in the set register is set to "1".

When set to "0": LIN manual mode is selected.

When set to "1": LIN assist mode is selected.

Bit	LIN Assist Mode Enable Bit
0	Manual mode
1	Assist mode

Notes:

- In manual mode, change this bit when LIN transmission/reception is disabled (SCR:RXE = 0, SCR:TXE = 0).
- In assist mode, do not change this bit when LIN is operating.
- When changing this bit, execute programmable clear (SCR:UPCL = 1) immediately after changing the bit.

9.14. LIN Assist Mode Interrupt Enable Register (LAMIER)

The LIN assist mode interrupt enable register (LAMIER) enables/disables LIN auto header completion interrupts, LIN checksum calculation completion interrupts, LIN bus error interrupts, LIN ID parity error interrupts, LIN Sync Data error interrupts, and LIN checksum error interrupts.

LIN Assist Mode Interrupt Enable Register (LAMIER)

Figure 9-15 shows the bit configuration of the LIN assist mode interrupt enable register (LAMIER).

Figure 9-15 Bit Configuration of LIN Assist Mode Interrupt Enable Register (LAMIER)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	LCSERIE	LPTERIE	LSFERIE	LBSERIE	LCSCIE	Reserved	LAHCIE	(LAMTID/LAMRID)		
R/W Attribute	R0, W0	R/W	R/W	R/W	R/W	R/W	R0, W0	R/W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

Note:

- Please use 8bit access to access this register.

[bit15] Reserved: Reserved Bit

[bit14] LCSERIE: LIN Checksum Error Interrupt Enable Bit

- This bit enables/disables LIN checksum error interrupt request output to the CPU.
- A reception interrupt request is issued when the LCSERIE bit and the LAMESR:LCSEIR bit are "1".
- This bit is reset when the LAMIERC:LCSEIRIEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LCSEIRIES bit in the set register is set to "1".

Bit	LIN Checksum Error Interrupt Enable Bit
0	Disable LIN checksum error interrupts.
1	Enable LIN checksum error interrupts.

[bit13] LPTERIE: LIN ID Parity Error Interrupt Enable Bit

- This bit enables/disables LIN ID parity error interrupt request output to the CPU.
- A reception interrupt request is issued when the LPTERIE bit and the LAMESR:LPTER bit are "1".
- This bit is reset when the LAMIERC:LPTERIEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LPTERIES bit in the set register is set to "1".

Bit	LIN ID Parity Error Interrupt Enable Bit
0	Disable LIN ID parity error interrupts.
1	Enable LIN ID parity error interrupts.

[bit12] LSFERIE: LIN Sync Data error interrupt enable bit

- This bit enables/disables LIN Sync Data error interrupt request output to the CPU.

- A reception interrupt request is issued when the LSFERIE bit and the LAMESR:LSFER bit are "1".
- This bit is reset when the LAMIERC:LSFERIEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LSFERIES bit in the set register is set to "1".

Bit	LIN Sync Data Error Interrupt Enable Bit
0	Disable LIN Sync Data error interrupts.
1	Enable LIN Sync Data error interrupts.

[bit11] LBSERIE: LIN Bus Error Interrupt Enable Bit

- This bit enables/disables LIN bus error interrupt request output to the CPU.
- A reception interrupt request is issued when the LBSERIE bit and the LAMESR:LBSEB bit are "1".
- This bit is reset when the LAMIERC:LBSEBEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LBSEBES bit in the set register is set to "1".

Bit	LIN Bus Error Interrupt Enable Bit
0	Disable LIN bus error interrupts.
1	Enable LIN bus error interrupts.

[bit10] LCSCIE: LIN Checksum Calculation Completion Interrupt Enable Bit

- This bit enables/disables LIN checksum calculation completion interrupt request output to the CPU.
- A status interrupt request is issued when the LCSCIE bit and the LAMSR:LCSC bit are "1".
- This bit is reset when the LAMIERC:LCSCIEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LCSCIES bit in the set register is set to "1".

Bit	LIN Checksum Calculation Completion Interrupt Enable Bit
0	Disable LIN checksum calculation completion interrupts.
1	Enable LIN checksum calculation completion interrupts.

[bit9] Reserved: Reserved Bit

[bit8] LAHCIE: LIN Auto Header Completion Interrupt Enable Bit

- This bit enables/disables LIN auto header completion interrupt request output to the CPU.
- A status interrupt request is issued when the LAHCIE bit and the LAMSR:LAHC bit are "1".
- This bit is reset when the LAMIERC:LAHCIEC bit in the clear register is set to "1".
- This bit is set when the LAMIERC:LAHCIES bit in the set register is set to "1".

Bit	LIN Auto Header Completion Interrupt Enable Bit
0	Disable LIN auto header completion interrupts.
1	Enable LIN auto header completion interrupts.

9.15. LIN Assist Mode Transmission/Reception ID Register (LAMTID/LAMRID)

The LIN assist mode transmission/reception ID register (LAMTID/LAMRID) displays the reception LIN ID parity, sets the transmission LIN ID, and displays the reception ID.

LIN Assist Mode Transmission ID Register (LAMTID)

Figure 9-16 shows the bit configuration of the LIN assist mode transmission ID register (LAMTID).

Figure 9-16 Bit Configuration of LIN Assist Mode Transmission ID Register (LAMTID)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(LAMIER)			Reserved	Reserved	LID5	LID4	LID3	LID2	LID1	LID0
R/W Attribute				W0	W0	W	W	W	W	W	W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:6] Reserved: Reserved Bits

[bit5:0] LID5-0: LIN ID Setting Bits

(When writing)

When assist mode is set to master and the LIN ID register use enable bit (LIDEN) is set to enabled, these bits set LIN ID Field data.

Note:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).

LIN Assist Mode Reception ID Register (LAMRID)

Figure 9-17 shows the bit configuration of the LIN assist mode reception ID register (LAMRID).

Figure 9-17 Bit Configuration of LIN Assist Mode Reception ID Register (LAMRID)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(LAMIER)			P1	P0	LID5	LID4	LID3	LID2	LID1	LID0
R/W Attribute	-			R	R	R	R	R	R	R	R
Protection Attribute	-			-	-	-	-	-	-	-	-
Initial Value	-			0	0	0	0	0	0	0	0

[bit7:6] P1, P0: LIN ID Parity Display Bits

(When reading)

When assist mode is set to slave and the LIN ID register use enable bit (LIDEN) is set to enabled, these bits indicate the parity value of the received LIN ID Field.

[bit5:0] LID5-0: LIN ID Display Bits

(When reading)

When assist mode is set to slave and the LIN ID register use enable bit (LIDEN) is set to enabled, these bits indicate the data of the received LIN ID Field.

Notes:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).
- These bits indicate the data of the ID Field received in this register even if a LIN ID parity error occurs.

9.16. LIN Assist Mode Error Status Register (LAMESR)

The LIN assist mode error status register (LAMESR) checks the flag of a LIN checksum error, LIN Sync Data error, LIN ID parity error, and LIN bus error.

LIN Assist Mode Error Status Register (LAMESR)

Figure 9-18 shows the bit configuration of the LIN assist mode error status register (LAMESR).

Figure 9-18 Bit Configuration of LIN Assist Mode Error Status Register (LAMESR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	LCSER	LPTEr	LSFER	LBSEr	Reserved	Reserved	Reserved	(LAMERT)		
R/W Attribute	R0,W0	R,WX	R,WX	R,WX	R,WX	R0,W0	R0,W0	R0,W0			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

Note:

- This register just can be accessed with 8bit access or 16bit access.

[bit15] Reserved: Reserved Bit

[bit14] LCSER: LIN Checksum Error Flag Bit

- This bit is set to "1" when a LIN checksum error occurs.
- A reception interrupt request is issued when the LCSER bit and the LCSErIE bit are "1".
- For details on interrupt request output, see Table 2-6
- This bit is reset when the LAMESRC:LCSErC bit in the clear register is set to "1".

Bit	LIN Checksum Error Flag Bit	
	Write	Read
0	No effect	There is no error.
1	No effect	An error has occurred.

Notes:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).
- This bit is set "0" when Software reset is done (SCR:UPCL=1).

[bit13] LPTEr: LIN ID Parity Error Flag Bit

- This bit is set to "1" if a LIN ID parity error occurs.
- A reception interrupt request is issued when the LPTEr bit and the LPTErIE bit are "1".
- For details on interrupt request output, see Table 2-6
- When this flag is set, the received ID Field data is displayed in the LIN reception ID register (LAMRID) or the reception data register (RDR).
- This bit is reset when the LAMESRC:LPTErC bit in the clear register is set to "1".

Bit	LIN ID Parity Error Flag Bit	
	Write	Read
0	No effect	There is no error.
1	No effect	An error has occurred.

Notes:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).
- This bit is set "0" when Software reset is done (SCR:UPCL=1).

[bit12] LSFER: LIN Sync Data Error Flag Bit

- This bit detects whether the Sync Field value is 0x55 when auto baud rate adjustment is disabled (SACSR:AUTE = 0) in slave mode (SCR:MS = 1).
- A LIN Sync Data error is set to "1" when auto baud rate adjustment is disabled (SACSR:AUTE = 0) in slave mode (SCR:MS = 1).
- A reception interrupt request is issued when the LSFER bit and the LSFERIE bit are "1".
- For details on interrupt request output, see Table 2-6
- This bit is reset when the LAMESRC:LSFERC bit in the clear register is set to "1".

Bit	LIN Sync Data Error Flag Bit	
	Write	Read
0	No effect	There is no error.
1	No effect	An error has occurred.

Notes:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).
- This bit is set "0" when Software reset is done (SCR:UPCL=1).

[bit11] LBSER: LIN Bus Error Flag Bit

- This bit is set to "1" when a LIN bus error occurs.
- A reception interrupt request is issued when the LBSER bit and the LBSER IE bit are "1".
- For details on interrupt request output, see Table 2-6
- Reception data with an error is stored in the reception data register (RDR), when this flag is set in the ID Field and data field.
- This bit is reset when the LAMESRC:LBSERC bit in the clear register is set to "1".

Bit	LIN Bus Error Flag Bit	
	Write	Read
0	No effect	There is no error.
1	No effect	An error has occurred.

Notes:

- This function is effective only in LIN assist mode (LAMCR:LAMEN = 1).
- This bit is set "0" when Software reset is done (SCR:UPCL=1).

[bit10:8] Reserved: Reserved Bits

9.17. LIN Assist Mode Error Test Register (LAMERT)

The LIN assist mode error test register (LAMERT) sets the pseudo error setting for a framing error, LIN bus error, LIN Sync Data error, LIN ID parity error, and LIN checksum error based on the settings of the key code control bit and pseudo error setting bit.

LIN Assist Mode Error Test Register (LAMERT)

Figure 9-19 shows the bit configuration of the LIN assist mode error test register (LAMERT).

Figure 9-19 Bit Configuration of LIN Assist Mode Error Test Register (LAMERT)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(LAMESR)			KEY1	KEY0	Reserved	LCSERT	LPTERT	LSFERT	LBSERT	FRET
R/W Attribute				R0,W	R0,W	R0,W0	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

Notes:

- In manual mode (LAMCR:LAMEN = 0), the setting of pseudo error test mode is prohibited.
- This register just can be accessed with 8bit access or 16bit access.

[bit7:6] KEY1, KEY0: Key Code Control Bits

- This bit is a key code register that enables the following pseudo error settings.
 - Framing error pseudo error setting bit (FRET)
 - LIN bus error pseudo error setting bit (LBSERT)
 - LIN Sync Data error pseudo error setting bit (LSFERT)
 - LIN ID parity error pseudo error setting bit (LPTERT)
 - LIN checksum error pseudo error setting bit (LCSERT)
- To set the pseudo error setting, write a value according to the following procedure.
 - KEY1, KEY0 = 0b00 + write a pseudo error setting value
 - KEY1, KEY0 = 0b01 + write the pseudo error setting value (same as the previous value)
 - KEY1, KEY0 = 0b10 + write the pseudo error setting value (same as the previous value)
 - KEY1, KEY0 = 0b11 + write the pseudo error setting value (same as the previous value)
 - The pseudo error setting value is enabled when the value is written for the 4th time.
- The value written to this register is invalid if you do not follow this setting procedure (if a value is written or read to/from another register during the writing process, if the value written is incorrect, or if a value is read from this register during the writing process).
- To clear a pseudo error setting, follow the same procedure as that for making a pseudo error setting.
- The read value is "0".

Notes:

- Assist mode is stopped when any of the following errors occurs.
 - LIN bus error
 - LIN framing error
 - LIN Sync Data error
 - LIN ID parity error
 - LIN checksum error

[bit5] Reserved: Reserved Bit

[bit4] LCSERT: LIN Checksum Error Pseudo Error Setting Bit

- This bit controls the occurrence of a LIN checksum error.
- In assist mode, set this bit to "1" (an error has occurred) before sending response data. When sending a checksum, it is output after being inverted. When an inverted checksum is received, a LIN checksum error occurs and the flag bit (LAMESR:LCSER) is set to "1".
- The pseudo error function is enabled and the error continues to occur until the setting of this bit is disabled (= 0).

Bit	LIN Checksum Error Pseudo Error Setting Bit
0	No error
1	An error has occurred.

[bit3] LPTERT: LIN ID Parity Error Pseudo Error Setting Bit

- This bit controls the occurrence of a LIN ID parity error.
- Set this bit to "1" (an error has occurred) before setting the Lin Break Field (SCR:LBR = 0) when assist mode is set to master (SCR:MS = 0). When sending the ID Field, the ID parity bit (2-bit) is output after being inverted. When the ID Field of an inverted ID parity is received, a LIN ID parity error occurs and the flag bit (LAMESR:LPTER) is set to "1".
- The pseudo error function is enabled and the error continues to occur until the setting of this bit is disabled (= 0).

Bit	LIN ID Parity Error Pseudo Error Setting Bit
0	No error
1	An error has occurred.

[bit2] LSFERT: LIN Sync Data Error Pseudo Error Setting Bit

- This bit controls the occurrence of a LIN Sync Data error.
- Set this bit to "1" (an error has occurred) before setting the Lin Break Field (SCR:LBR = 0) when assist mode is set to master (SCR:MS = 0). All bits in the LIN Sync Field are output after being inverted.
- The pseudo error function is enabled and this bit continues to output the inverted Sync Field data until this bit set is disabled (= 0).

Bit	LIN Sync Data Error Pseudo Error Setting Bit
0	No error
1	An error has occurred.

Note:

- Set the LIN bus error pseudo error setting bit (LBSERT = 1) at the same time as this bit (LSFERT = 1) is set.

[bit1] LBSER: LIN Bus Error Pseudo Error Setting Bit

- This bit controls the occurrence of a LIN bus error.
- When assist mode is set to master and when this bit is set to "1" (an error has occurred) in each field (Sync Field, ID Field, data, and checksum) to which data has been sent, a LIN bus error occurs and the flag bit (LAMESR:LBSER) is set to "1".
- When assist mode is set to slave and when this bit is set to "1" (an error has occurred) in each field (data and checksum) to which a response has been sent, a LIN bus error occurs and the flag bit (LAMESR:LBSER) is set to "1".
- The pseudo error function is enabled and the error continues to occur until the setting of this bit is disabled (= 0).

Bit	LIN Bus Error Pseudo Error Setting Bit
0	No error
1	An error has occurred.

Note:

- The LIN bus error pseudo error setting cannot be set for the LIN Break Field.

[bit0] FRET: Framing Error Pseudo Error Setting Bit

- This bit controls the occurrence of a LIN framing error.
- In assist mode, when this bit is set to "1" (an error has occurred) in each field (Sync Field, ID Field, data, and checksum), the stop bit is output after being inverted. If an inverted stop bit is received, a framing error occurs and the flag bit (SSR:FRE) is set to "1".
- The pseudo error function is enabled and the error continues to occur until the setting of this bit is disabled (= 0).

Bit	Framing Error Pseudo Error Setting Bit
0	No error
1	An error has occurred.

9.18. FIFO Control Register 1 (FCR1)

The FIFO control register 1 (FCR1) sets the FIFO test, selects transmission and reception FIFOs, enables transmission FIFO interrupts, and controls the interrupt flag.

Bit Configuration of FIFO Control Register 1 (FCR1)

Figure 9-20 shows the bit configuration of FIFO control register 1 (FCR1).

Figure 9-20 Bit Configuration of FIFO Control Register 1 (FCR1)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	FLSTE	FRIIE	FDRQ	FTIE	FSEL	(FCR0)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R/W	R/W	R,WX	R/W	R/W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	1	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTE: Retransmission Data Lost Detection Enable Bit

This bit enables the detection of FIFO retransmission Data Lost Flag Bit (FCR0:FLST).

- This bit is reset when the FCR1C:FLSTEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FLSTES bit in the set register is set to "1".

"0": Disable FLST bit detection.

"1": Enable FLST bit detection.

Bit	Retransmission Data Lost Detection Enable Bit
0	Disable data lost detection.
1	Enable data lost detection.

Note:

- To set this bit to "1", first set the FSET bit to "1" and then set this bit to "1".

[bit11] FRIIE: Reception FIFO Idle Detection Enable Bit

When the reception FIFO contains valid data, this bit enables or disables the detection of continuation of reception idle status for an 8-bit time or longer. If the reception interrupt is enabled (SCR:RIE = 1), the detection of reception idle status triggers a reception interrupt.

- This bit is reset when the FCR1C:FRIIEC bit in the clear register is set to "1".
- This bit is set when the bit FCR1S:FRIIES in the set register is set to "1".

"0": Disable detection of reception idle status.

"1": Enable detection of reception idle status.

Bit	Reception FIFO Idle Detection Enable Bit
0	Disable detection of reception FIFO idle.
1	Enable detection of reception FIFO idle.

Note:

- To use the reception FIFO, set this bit to "1".

[bit10] FDRQ: Transmission FIFO Data Request Bit

This bit requests transmission FIFO data.

Value "1" of this bit indicates that transmission data is requested. At this time, a transmission interrupt request is issued if transmission interrupt is enabled (FTIE = 1).

FDRQ set conditions

- When transmission FIFO interrupt control is not used
 - FBYTE (for transmission) = 0 (Transmission FIFO is empty.)
 - Reset of the transmission FIFO
- When transmission FIFO interrupt control is used
 - When ECR:TXBLKEN=0
 - FTICR setting value \geq FTICR read value (The amount of data in the transmission FIFO is equal to the interrupt trigger level or lower.)
 - When ECR:TXBLKEN=1
 - FTICR setting value \leq the number of transmission FIFO empty data
 - Reset of the transmission FIFO

FDRQ clearing conditions

- "1" is written to FCR1C:FDRQC.
- For ECR:TXBLKEN = 0:
 - The transmission FIFO is full.
- For ECR:TXBLKEN = 1:
- FTICR setting value \geq number of vacant data items in the transmission FIFO

Bit	Transmission FIFO Data Request Bit
0	No transmission FIFO data request
1	Transmission FIFO data request issued

Notes:

- The FSEL bit cannot be changed when this bit is "0".
 - Writing to this bit is invalid.
 - Writing "0" to this bit is prohibited when the set value is equal to or less than a setting value.
- When you write required data to the transmission FIFO after a transmission interrupt occurs, write "1" to the FIFO transmission data request clear bit (FCR1C:FDRQC) to clear the interrupt request.

[bit9] FTIE: Transmission FIFO Interrupt Enable Bit

This bit enables a transmission FIFO interrupt. If this bit is set to "1", a transmission interrupt occurs when the FDRQ bit is "1".

- This bit is reset when the FCR1C:FTIEC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FTIES bit in the set register is set to "1".

Bit	Transmission FIFO Interrupt Enable Bit
0	Disable transmission FIFO interrupts.
1	Enable transmission FIFO interrupts.

Note:

- During block transfer , set FTIE to "1" when transmission FIFO is not being used.

[bit8] FSEL: FIFO Selection Bit

This bit selects the transmission and reception FIFO.

- This bit is reset when the FCR1C:FSELC bit in the clear register is set to "1".
- This bit is set when the FCR1S:FSELS bit in the set register is set to "1".

"0": Allocate as transmission FIFO: FIFO1 and as reception FIFO: FIFO2.

"1": Allocate as transmission FIFO: FIFO2 and as reception FIFO: FIFO1.

Bit	FIFO Selection Bit
0	Transmission FIFO: FIFO1, reception FIFO: FIFO2
1	Transmission FIFO: FIFO2, reception FIFO: FIFO1

Notes:

- This bit is not cleared by a FIFO reset (FCL2, FCL1 = 1).
- To change the value of this bit, disable the FIFO operation (FE2, FE1 = 0) first.
- This bit cannot be changed when FDRQ = 0.
- Set the FIFO selection bit (FSEL) before setting the FIFO byte register (FBYTE) and the transmission FIFO interrupt control register (FTICR).
- Access cannot be performed at the same time as the FIFO byte register (FBYTE).

9.19. FIFO Control Register 0 (FCR0)

FIFO control register 0 (FCR0) enables/disables FIFO operation, resets a FIFO, saves the read pointer, and makes the retransmission setting.

Bit Configuration of FIFO Control Register 0 (FCR0)

Figure 9-21 shows the bit configuration of FIFO control register 0 (FCR0).

Figure 9-21 Bit Configuration of FIFO Control Register 0 (FCR0)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(FCR1)			Reserved	FLST	FLD	FSET	FCL2	FCL1	FE2	FE1
R/W Attribute				R0,W0	R,WX	R,W	R0,W	R0,W	R0,W	R/W	R/W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

When read, always it can be read "0".

When written, always it is set "0".

[bit6] FLST: FIFO Retransmission Data Lost Flag Bit

This bit indicates that the retransmission data for the transmission FIFO has been lost.

FLST set condition

- Data is written to the FIFO when the FLSTE bit in the FIFO control register 1 (FCR1) is "1" and the write pointer of the transmission FIFO and the read pointer saved by the FSET bit coincide.

FLST clearing conditions

- transmission FIFO reset
 - When FCR1:FSEL=0, set "1" to the FCR0:FCL1
 - When FCR1:FSEL=1, set "1" to the FCR0:FCL2
- Writing "1" to the FSET bit

If "1" is set in this bit, the data pointed to by the read pointer saved with the FSET bit is overwritten. For this reason, re-transmission with the FLD bit cannot be set even if an error occurs. When performing retransmission with this bit set to "1", reset the FIFO and then write the data to the FIFO again.

Bit	FIFO Retransmission Data Lost Flag Bit
0	Data has not been lost.
1	Data has been lost.

[bit5] FLD: FIFO Pointer Reload Bit

This bit reloads, to the read pointer, the data saved to the transmission FIFO by the FSET bit. This bit is used for retransmission in cases such as communication errors.

This bit is set to "0" when retransmission setting has been completed.

- This bit is set when the FCR0S:FLDS bit in the set register is set to "1".

Bit	FIFO Pointer Reload Bit
0	Do not execute reload.
1	Execute reload.

Notes:

- While this bit is set to "1", reloading to the read pointer is in progress, so writing is prohibited except in the case of a FIFO reset.
- Setting this bit to "1" is prohibited when FIFO is enabled or transmission is in progress.
- To set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then enable the transmission FIFO and set the TIE and TBIE bits to "1".

[bit4] FSET: FIFO Pointer Saving Bit

This bit stores the read pointer of the transmission FIFO.

If the read pointer is saved before transmission starts and then a communication error occurs, retransmission is possible if the FLST bit is "0".

- This bit is set when the FCR0S:FSETS bit in the set register is set to "1".

"1": Save the current read pointer value.

"0": No effect.

Bit	FIFO Pointer Saving Bit	
	Write	Read
0	Do not save.	Always read "0"
1	Save the read pointer value.	

Note:

- Set this bit to "1" when the transmission byte count (FBYTE) is 0.

[bit3] FCL2: FIFO2 Reset Bit

This bit resets FIFO2.

If this bit is set to "1", the internal status of FIFO2 is initialized.

Only the FCR0:FLST bit is initialized. The values of the other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL2S bit in the set register is set to "1".

Bit	FIFO2 Reset Bit	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO2.	

Notes:

- Disable transmission/reception first and then execute a FIFO2 reset.
- Execute the reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count for the FBYTE2 register is set to 0.
- The TDR register and RDR register are not initialized.

[bit2] FCL1: FIFO1 Reset Bit

This bit resets FIFO1.

If this bit is set to "1", the internal status of FIFO1 is initialized.

Only the FCR0:FLST bit is initialized. The values of the other bits in the FCR1/0 registers are retained.

- This bit is set when the FCR0S:FCL1S bit in the set register is set to "1".

Bit	FIFO1 Reset Bit	
	Write	Read
0	No effect	"0" is always read.
1	Reset FIFO1.	

Notes:

- Disable transmission/reception first and then execute a FIFO1 reset.
- Execute the reset after setting the transmission FIFO interrupt enable bit to "0".
- The valid data count of the FBYTE1 register is set to 0.
- The TDR register and RDR register are not initialized.

[bit1] FE2: FIFO2 Operation Enable Bit

This bit enables or disables the operation of FIFO2.

- Set this bit to "1" when using FIFO2.
- When FIFO2 is specified as the transmission FIFO (FCR1:FSEL=1) and "1" is written to this bit, transmission starts immediately if FIFO2 contains data and LIN interface (v2.1) transmission is enabled (SCR:TXE = 1). At this time, to set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the TIE and TBIE bits to "1".
- A reception error caused this bit to be cleared to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. After that, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO2 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO2 as the reception FIFO, first disable reception (SCR:RXE = 0) and then set this bit to "0" when the reception buffer is empty (SSR:RDRF = 0) and the reception FIFO does not contain valid data (FBYTE2 = 0).

- To use FIFO2 as the reception FIFO, first disable reception (SCR:RXE = 0) and then set this bit to "1" when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO2 does not change the state of FIFO2.
- This bit is reset when the FCR0C:FE2C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE2S bit in the set register is set to "1".

Bit	FIFO2 Operation Enable Bit
0	Disable FIFO2 operation.
1	Enable FIFO2 operation.

[bit0] FE1: FIFO1 Operation Enable Bit

This bit enables or disables the operation of FIFO1.

- Set this bit to "1" when using FIFO1.
- When FIFO1 is specified as the transmission FIFO and "1" is written to this bit, transmission starts immediately if FIFO1 contains data and LIN interface (v2.1) transmission is enabled (SCR:TXE = 1). At this time, to set the TIE and TBIE bits to "1", first set them to "0" and write "1" to this bit, and then set the TIE and TBIE bits to "1".
- A reception error causes this bit to be cleared to "0" if the FIFO is selected as the reception FIFO by the FSEL bit. After that, this bit cannot be set to "1" unless the reception error is cleared.
- To use FIFO1 as the transmission or reception FIFO, set this bit to "1" or "0" when the transmission or reception buffer is empty ((SSR:TDRE = 1) or (SSR:RDRF = 0)), respectively.
- To use FIFO1 as the reception FIFO, first disable reception (SCR:RXE = 0) and then set this bit to "0" when the reception buffer is empty (SSR:RDRF = 0) and the reception FIFO does not contain valid data (FBYTE1 = 0).
- To use FIFO1 as the reception FIFO, first disable reception (SCR:RXE = 0) and then set this bit to "1" when the reception buffer is empty (SSR:RDRF = 0).
- Disabling FIFO1 does not change the state of FIFO1.
- This bit is reset when the FCR0C:FE1C bit in the clear register is set to "1".
- This bit is set when the FCR0S:FE1S bit in the set register is set to "1".

Bit	FIFO1 Operation Enable Bit
0	Disable FIFO1 operation.
1	Enable FIFO1 operation.

9.20. FIFO Byte Register (FBYTE)

The FIFO byte register (FBYTE) indicates the valid data count for the FIFO. This register also specifies whether a reception interrupt is generated when the predefined amount of data is received by the reception FIFO.

Bit Configuration of FIFO Byte Register (FBYTE)

Figure 9-22 shows the bit configuration of the FIFO byte register (FBYTE).

Figure 9-22 Bit Configuration of FIFO Byte Register (FBYTE)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FBYTE2								FBYTE1							
R/W	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,	R,
Attribute	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W	W
Protection	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The FBYTE register indicates the valid data count for the FIFO. The table below shows the setting conditions for different FCR1:FSEL bit values.

Table 9-2 Data Count Indication

FSEL	FIFO Selection	Data Count Indication
0	FIFO2: Reception FIFO, FIFO1: Transmission FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1
1	FIFO2: Transmission FIFO, FIFO1: Reception FIFO	FIFO2:FBYTE2, FIFO1:FBYTE1

- The initial transfer count value for the FBYTE register is 0x08.
- Set the data count, on which the generation of the reception interrupt flag is based, as the transfer count of the FBYTE for the reception FIFO. When the transferred data count and the data count indication in the FBYTE register coincide, the interrupt flag (RDRF) is set to "1".
- When both of the following conditions are satisfied, the continuation of the reception idle status for 8 baud rate clocks or longer sets the interrupt flag (RDRF) to "1".
 - Reception FIFO idle detection enable bit (FRIIE) is "1".
 - The number of data items in the reception FIFO does not reach the transfer count.

During an 8-clock count, the counter is reset to 0 when RDR is read, and the system starts counting the 8 clocks again. The counter is reset to 0 when the reception FIFO is disabled. If the reception FIFO is enabled when data remains in the reception FIFO, counting restarts.

- The value of FBYTE of transmission FIFO is incremented by 1 when a transmission data is written to TDR 1 time.
- The value of FBYTE of reception FIFO is decremented by 1 when a reception data is read from RDR 1 time.
- During block transfer, the value of this register indicates the number of transfer blocks.

[bit15:8] FBYTE2: FIFO2 Data Count Indication Bit

[bit7:0] FBYTE1: FIFO1 Data Count Indication Bit

FBYTE2, FBYTE1	Description
Write	Set the transfer count.
Read	Read valid data count.

Read (valid data count)

Transmission: Data count that was written but not sent to the transmission FIFO

Reception: Data count that has been received but not read by the reception FIFO

Write (transfer count)

Transmission: Set 0x00.

Reception: Set the data count that triggers reception interrupts.

Table 9-3 Data Count Stored in FIFO

FIFO Capacity	Max FBYTE Count	Data Count That Can Be Stored
16 bytes	16	16
32 bytes	32	32
64 bytes	64	64

Notes:

- Set 0x00 to FBYTE for the transmission FIFO.
- When the reception FIFO is not used, the reception block size during block transfer will be "1".
- Change the value after disabling the reception operation.
- Any setting that would exceed the FIFO capacity is prohibited.
- Set the FIFO byte register (FBYTE) after setting the FIFO selection bit (FCR1:FSEL).
- The FIFO selection bit (FCR1:FSEL) and the FIFO byte register (FBYTE) cannot be set at the same time.
- As the FIFO data count for transmission, the transmission data count that has been written, minus 1, is displayed as the valid data count. This is because an attempt to write transmission data to the TDR register stores the data in the transmission FIFO if the TDR register contains data that has yet to be transmitted. When the data in the TDR register is transmitted, the data in the transmission FIFO that is yet to be transmitted is transferred to the TDR register.
- The FIFO data count for reception represents the data count received by the reception FIFO but which has not yet been read. The data count does not include the data being received by the RDR register.

9.21. Transmission FIFO Interrupt Control Register (FTICR)

The transmission FIFO interrupt control register (FTICR) sets the condition for interrupts triggered by the valid data count of the FIFO transmission.

Transmission FIFO Interrupt Control Register (FTICR)

Figure 9-23 shows the bit configuration of the transmission FIFO interrupt control register (FTICR).

Figure 9-23 Bit Configuration of Transmission FIFO Interrupt Control Register (FTICR)

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	FTICR2								FTICR1							
R/W Attribute	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W	R, W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The function of these bits varies depending on the setting of the ECR:TXBLKEN bit. The details are as follows:

- ECR:TXBLKEN = 0
 - The FTICR is set the trigger level to interrupt for transmission FIFO's transmission valid data number (remained data number).
- ECR:TXBLKEN = 1
 - The FTICR register sets the trigger level for interrupts according to the vacant data count of the transmission FIFO.
 - The table below shows setting values of the FCR1:FSEL bit.

Table 9-4 Transmission FIFO Setting by FCR1:FSEL

FSEL	Selection of Transmission FIFO	Transmission FIFO Interrupt Control Register
0	FIFO1	FTICR1
1	FIFO2	FTICR2

- The initial value of the valid data count for triggering interrupts of the FTICR register is 0x00.
- Set the number of data items that generate a transmission interrupt to the FTICR of the transmission FIFO.
 - For ECR:TXBLKEN = 0, if the data count that was set becomes equal to or smaller than, the indication of the valid data count in the transmission FIFO (FTICR or FBYTE), the interrupt flag (FDRQ) is set to "1".
 - For ECR:TXBLKEN = 1, the interrupt flag (FDRQ) is set to "1" when the data count that was set becomes equal to or smaller than the vacant data count of the transmission FIFO. If the data count set to these bits becomes greater than the vacant data count of the transmission FIFO, the interrupt flag (FDRQ) is set to "0".
- Set FTICR so that it satisfies "FTICR ≤ FIFO capacity - 2".
- The read value indicates the valid data count of the FIFO.
- Transmission FIFO: The data count written in the transmission FIFO that has not yet been transmitted.
- Reception FIFO: The data count received by the reception FIFO that has not yet been read.

[bit15:8]FTICR2: FIFO2 Data Count Indication Bit

[bit7:0]FTICR1: FIFO1 Data Count Indication Bit

FTICR2, FTICR1	Description
Write	Set the number of valid data items that generates an interrupt.
Read	Read valid data count.

Notes:

- Any setting that would exceed the FIFO capacity is prohibited.
- The setting value cannot be read.
- As the FIFO data count for transmission, the transmission data count that has been written, minus 1, is displayed as the valid data count. This is because an attempt to write transmission data to the TDR register stores the data in the transmission FIFO if the TDR register contains data that has yet to be transmitted. When the data in the TDR register is transmitted, the data in the transmission FIFO that is yet to be transmitted is transferred to the TDR register.
- The FIFO data count for reception represents the data count received by the reception FIFO but which has not yet been read. The data count does not include the data being received by the RDR register.
- For ECR:TXBLKEN = 0, if block transfer is performed during DMA transfer, only 1 can be set as the block size.
- To perform block transfer with ECR:TXBLKEN = 1, set the value of the block size to this register.

9.22. Extended Control Register (ECR)

The extended control register (ECR) can set block transfer.

Bit Configuration of Extended Control Register (ECR)

Figure 9-24 shows the bit configuration of the extended control register (ECR).

Figure 9-24 Bit Configuration of Extended Control Register (ECR)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(ESR)			Reserved	Reserved	Reserved	EISEL	REIE	TEIE	RXBLKEN	TXBLKEN
R/W Attribute				R0,W0	R0,W0	R0,W0	R/W	R/W	R/W	R/W	R/W
Protection Attribute				-	-	-	-	-			
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved: Reserved Bits

[bit4] EISEL: Error Interrupt Request Output Selection Bit

This bit selects whether an error interrupt is output from the interrupt request pin or from the error interrupt request pin. For details on interrupt output selection, see Table 2-2, Table 2-3, Table 2-5, and Table 2-6.

Bit	Error Interrupt Request Output Selection Bit
0	Output the reception error interrupt request from the reception interrupt request pin. Output the transmission error interrupt request from the transmission interrupt request pin.
1	Output the reception error interrupt request from the reception error interrupt request pin. Output the transmission error interrupt request from the transmission error interrupt request pin.

[bit3] REIE: Reception Error Interrupt Enable Bit

This bit enables/disables reception error interrupt request output. For details on the target interrupt factors, see Table 2-3 and Table 2-6.

Bit	Reception Error Interrupt Enable Bit
0	Disable reception error interrupts.
1	Enable reception error interrupts.

[bit2] TEIE: Transmission Error Interrupt Enable Bit

This bit enables/disables transmission error interrupt request output. For details on the target interrupt factors, see Table 2-2 and Table 2-5.

Bit	Transmission Error Interrupt Enable Bit
0	Disable transmission error interrupts.
1	Enable transmission error interrupts.

[bit1] RXBLKEN: Reception Block Transfer Setting Bit

This bit sets the DMA transfer mode for reception.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Reception Block Transfer Setting Bit
0	Demand transfer mode
1	Block transfer mode

[bit0] TXBLKEN: Transmission Block Transfer Setting Bit

This bit sets the DMA transfer mode for transmission.

- "0": Perform DMA transfer in demand transfer mode.
- "1": Perform DMA transfer in block transfer mode.

Bit	Transmission Block Transfer Setting Bit
0	Demand transfer mode
1	Block transfer mode

9.23. Extended Status Register (ESR)

The extended status register (ESR) checks the reception block transfer error flag and the transmission block transfer error flag.

Extended Status Register (ESR)

Figure 9-25 shows the bit configuration of the extended status register (ESR).

Figure 9-25 Bit Configuration of Extended Status Register (ESR)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	Reserved	RXUDR	TXOVR	RBERR	TBERR	(ECR)		
R/W Attribute	R0,W0	R0,W0	R0,W0	R0,W0	R,WX	R,WX	R,WX	R,WX			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDR: Reception FIFO Underrun Flag Bit

This bit is set to "1" if the reception FIFO becomes empty due to block transfer, and then a read occurs.

- This bit is reset when the ESRC:RXUDRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-3 for manual mode, Table 2-6 for assist mode.

Bit	Reception FIFO Underrun Flag Bit
0	Indicate that no reception FIFO underrun has occurred.
1	Indicate that reception FIFO underrun has occurred.

Notes:

- A software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" when the reception block transfer enable bit (ECR:RXBLKEN) is "0".
- This bit is set only when the reception FIFO is used.
- This bit is "0" when reception FIFO is not available.

[bit10] TXOVR: Transmission FIFO Overrun Flag Bit

This bit is set to "1" if the transmission FIFO becomes full due to block transfer, and then a write occurs.

- This bit is reset when the ESRC:TXOVRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-2 for manual mode, Table 2-5 for assist mode.

Bit	Transmission FIFO Overrun Flag Bit
0	Indicate that no transmission FIFO overrun has occurred.
1	Indicate that transmission FIFO overrun has occurred.

Notes:

- A software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" when the transmission block transfer enable bit (ECR:TXBLKEN) is "0".
- This bit is set only when the transmission FIFO is used.

- This bit is "0" when transmission FIFO is not available.

[bit9] RBERR: Reception Block Transfer Error Bit

This bit indicates that a block transfer error has occurred during reception.

Suppose that block transfer is performed with a value larger than the threshold specified in the FBYTE register, this bit is set to "1" to indicate a block transfer error. A reception interrupt occurs if reception interrupt is enabled (SCR:RIE = 1).

- This bit is reset when the ESRC:RBERRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-3 for manual mode, Table 2-6 for assist mode.

Bit	Reception Block Transfer Error Bit
0	Indicate that no reception block transfer error has occurred.
1	Indicate that a reception block transfer error has occurred.

Notes:

- A software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" when the reception block transfer enable bit (ECR:RXBLKEN) is "0" or when the reception interrupt enable bit (SCR:RIE) is "0".

[bit8] TBERR: Transmission Block Transfer Error Bit

This bit indicates that a block transfer error has occurred during transmission.

Suppose that block transfer is performed with a value larger than the threshold specified in the FTICR register, this bit is set to "1" to indicate a block transfer error to stop DMA transfer for transmission. At this time, a transmission interrupt occurs if transmission interrupts are enabled (SSR:TIE = 1).

- This bit is reset when the ESRC:TBERRC bit in the clear register is set to "1".
- For details on interrupt request output, see Table 2-2 for manual mode, Table 2-5 for assist mode.

Bit	Transmission Block Transfer Error Bit
0	Indicate that no transmission block transfer error has occurred.
1	Indicate that a transmission block transfer error has occurred.

Notes:

- A software reset (SCR:UPCL = 1) resets this bit to "0".
- This bit is "0" while the transmission block transfer enable bit (ECR:TXBLKEN) is "0".
- When the transmission FIFO is OFF, and block transfer is performed under any one of the following conditions, this bit is set to "1" to indicate a block transfer error.
 - A transmission interrupt is enabled (SCR:TIE = 1) and the transmission data register contains data (SSR:TDRE = 0).
 - A transmission interrupt is disabled (SCR:TIE = 0), a transmission bus idle interrupt is enabled (SCR:TBIE = 1), and transmission is in progress (SSR:TBI = 0).
If a transmission interrupt is enabled (SCR:TIE = 1) and a transmission bus idle interrupt is enabled (SCR:TBIE = 1), the condition for enabling transmission interrupt (SCR:TIE = 1) is given priority.

9.24. Transmission Block Size Register (TBSIZE)

The transmission block size register sets the block size for transmission block transfer.

Bit Configuration of Transmission Block Size Register (TBSIZE)

Figure 9-26 shows the bit configuration of the transmission block size register (TBSIZE).

Figure 9-26 Bit Configuration of Transmission Block Size Register (TBSIZE)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	-										
R/W Attribute	TBSIZE										
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0

The TBSIZE register sets the block size for transmission block transfer.

[bit7:0]TBSIZE

TBSIZE	Description
Write	Set the transmission block count.
Read	Read a setting value.

Notes:

- Any setting that would exceed the FIFO capacity is prohibited.
- Setting this bit to "0" is prohibited.
- Any setting that would exceed the setting value of the transmission FIFO interrupt control register (FTICR) is prohibited.
- In this register, set the same value as that set for the transmission block size in the DMA controller.
- When the transmission FIFO is not used, the transmission block size during block transfer will be "1", regardless of the setting of this register.

9.25. Serial Control Clear Register (SCRC)

The serial control clear register (SCRC) can clear a bit in the serial control register (SCR).

Note:

- For details on the operations performed on this register, also see the description of the target register SCR.

Bit Configuration of Serial Control Clear Register (SCRC)

Figure 9-27 shows the bit configuration of the serial control clear register (SCRC).

Figure 9-27 Bit Configuration of Serial Control Clear Register (SCRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	MSC	Reserved	RIEC	TIEC	TBIEC	RXEC	TXEC	(SMRC)		
R/W Attribute	R0, W0	R0,W	R0, W0	R0,W	R0,W	R0,W	R0,W	R0,W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] Reserved: Reserved Bit

[bit14] MSC: Clearing the Master/Slave Function Selection Bit.

Writing "1" to this bit resets the SCR:MS to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] Reserved: Reserved Bit

[bit12] RIEC: Clearing the Reception Interrupt Enable Bit.

Writing "1" to this bit resets the SCR:RIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] TIEC: Clearing the Transmission Interrupt Enable Bit

Writing "1" to this bit resets the SCR:TIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TBIEC: Clearing the Transmission Bus Idle Interrupt Enable Bit

Writing "1" to this bit resets the SCR:TBIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RXEC: Clearing the Reception Operation Enable Bit

Writing "1" to this bit resets the SCR:RXE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TXEC: Clearing the Transmission Operation Enable Bit

Writing "1" to this bit resets the SCR:TXE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.26. Serial Mode Clear Register (SMRC)

The serial mode clear register (SMRC) can clear a bit in the serial mode register (SMR).

Note:

- For details on the operations performed on this register, also see the description of the target register SMR.

Bit Configuration of Serial Mode Clear Register (SMRC)

Figure 9-28 shows the bit configuration of the serial mode clear register (SMRC).

Figure 9-28 Bit Configuration of Serial Mode Clear Register (SMRC)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SCRC)			Reserve d	Reserve d	Reserve d	WUCRC	SBLC	Reserve d	Reserve d	SOEC
R/W Attribute				R0, W0	R0, W0	R0, W0	R0,W	R0,W	R0, W0	R0, W0	R0,W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved: Reserved Bits

[bit4] WUCRC: Clearing the WAKE UP Control Bit

Writing "1" to this bit resets SMR:WUCR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] SBLC: Clearing the Stop Bit Length Selection Bit

Writing "1" to this bit resets the SMR:SBL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2:1] Reserved: Reserved Bits

[bit0] SOEC: Clearing the Serial Data Output Enable Bit

Writing "1" to this bit resets the SMR:SOE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.27. Serial Status Clear Register (SSRC)

The serial status clear register (SSRC) can clear a bit in the serial status register (SSR).

Note:

- For details on the operations performed on this register, also see the description of the target register SSR.

Bit Configuration of Serial Status Clear Register (SSRC)

Figure 9-29 shows the bit configuration of the serial status clear register (SSRC).

Figure 9-29 Bit Configuration of Serial Status Clear Register (SSRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserve d	Reserve d	LBDC	Reserve d	Reserve d	Reserve d	Reserve d	Reserve d	(ESCRC)		
R/W Attribute	R0, W0	R0, W0	R0, W	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:14] Reserved: Reserved Bits

[bit13] LBDC: Clearing the LIN Break Field Detection Flag Bit

Writing "1" to this bit resets the SSR:LBD to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12:8] Reserved: Reserved Bits

9.28. Extended Communication Control Clear Register (ESCRC)

The extended communication control clear register (ESCRC) can be used to clear a bit in the extended communication control register (ESCR).

Note:

- For details on the operations performed on this register, also see the description of the target register ESCR.

Bit Configuration of Extended Communication Control Clear Register (ESCRC)

Figure 9-30 shows the bit configuration of the extended communication control clear register (ESCRC).

Figure 9-30 Bit Configuration of Extended Communication Control Clear Register (ESCRC)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SSRC)			Reserve d	ESBLC	Reserve d	LBIEC	Reserve d	Reserve d	Reserve d	Reserve d
R/W Attribute				R0, W0	R0,W	R0, W0	R0,W	R0, W0	R0, W0	R0, W0	R0, W0
ProtectionAttribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

[bit6] ESBLC: Clearing the Extended Stop Bit Length Selection Bit

Writing "1" to this bit resets the ESCR:ESBL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] Reserved: Reserved Bit

[bit4] LBIEC: Clearing the LIN Break Field Detection Interrupt Enable Bit

Writing "1" to this bit resets the ESCR:LBIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3:0] Reserved: Reserved Bits

9.29. Serial Auxiliary Control Status Clear Register (SACSRC)

The serial auxiliary control status clear register (SACSRC) can clear the bits in the serial auxiliary control status register (SACSR).

Note:

- For details on the operations performed on this register, also see the description of the target register SACSR.

Bit Configuration of Serial Auxiliary Control Status Clear Register (SACSRC)

Figure 9-31 shows the bit configuration of the serial auxiliary control status clear register (SACSRC).

Figure 9-31 Bit Configuration of Serial Auxiliary Control Status Clear Register (SACSRC)

Bit	15	14	13	12	11	10	9	8

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] STSTC: Clearing the Serial Test Bit

Writing "1" to this bit resets SACSR:STST to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] Reserved: Reserved Bit

[bit13] SFDC: Clearing the Sync Field Detection Flag

Writing "1" to this bit resets SACSR:SFD to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] SFDEC: Clearing the Sync Field Detection Interrupt Enable Bit

Writing "1" to this bit resets SACSR:SFDE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] AUTEC: Clearing the Auto Baud Rate Adjustment Bit

Writing "1" to this bit resets SACSR:AUTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10:9] Reserved: Reserved Bits

[bit8] TINTC: Clearing the Timer Interrupt Flag

Writing "1" to this bit resets SACSR:TINT to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7] TINTEC: Clearing the Timer Interrupt Enable Bit

Writing "1" to this bit resets SACSR:TINTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] Reserved: Reserved Bit

[bit5] TRGEC: Clearing the External Trigger Enable Bit

Writing "1" to this bit resets the SACSR:TRGE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved: Reserved Bits

[bit0] TMREC: Clearing the Serial Timer Enable Bit

Writing "1" to this bit resets SACSR:TMRE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.30. LIN Assist Mode Status Clear Register (LAMSRC)

The LIN assist mode status clear register (LAMSRC) can be used to clear a bit in the LIN assist mode status register (LAMSR).

Note:

- For details on the operations performed on this register, also see the description of target register LAMSR.

Bit Configuration of LIN Assist Mode Status Clear Register (LAMSRC)

Figure 9-32 shows the bit configuration of the LIN assist mode status clear register (LAMSRC).

Figure 9-32 Bit Configuration of LIN Assist Mode Status Clear Register (LAMSRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	Reserved	Reserved	LCSCC	Reserved	LAHCC	(LAMCRC)		
R/W Attribute	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0, W	R0, W0	R0, W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:11] Reserved: Reserved Bits

[bit10] LCSCC: Clearing the LIN Checksum Calculation Completion Flag

Writing "1" to this bit resets LAMSR:LCSC to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] Reserved: Reserved Bit

[bit8] LAHCC: Clearing the LIN Auto Header Completion Flag

Writing "1" to this bit resets the LAMSR:LAHC to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.31. LIN Assist Mode Control Clear Register (LAMCRC)

The LIN assist mode control clear register (LAMCRC) can be used to clear a bit in the LIN assist mode control register (LAMCR).

Note:

- For details on the operations performed on this register, also see the description of target register LAMCR.

Bit Configuration of LIN Assist Mode Control Clear Register (LAMCRC)

Figure 9-33 shows the bit configuration of the LIN assist mode control clear register (LAMCRC).

Figure 9-33 Bit Configuration of LIN Assist Mode Control Clear Register (LAMCRC)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(LAMSRC)			Reserved	Reserved	Reserved	Reserved	Reserved	LCSTYPC	LIDENC	LAMENC
R/W Attribute				R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0, W	R0, W	R0, W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:3] Reserved: Reserved Bits

[bit2] LCSTYPC: Clearing the LIN Checksum Type Selection Bit

Writing "1" to this bit resets the LAMCR:LCSTYP to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] LIDENC: Clearing the LIN ID Register Use Enable Bit

Writing "1" to this bit resets LAMCR:LIDEN to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] LAMENC: Clearing the LIN Assist Mode Processing Enable Bit

Writing "1" to this bit resets the LAMCR:LAMEN to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.32. LIN Assist Mode Interrupt Enable Clear Register (LAMIERC)

The LIN assist mode interrupt enable clear register (LAMIERC) can be used to clear a bit in the LIN assist mode interrupt enable register (LAMIER).

Note:

- For details on the operations performed on this register, also see the description of target register LAMIER.

Bit Configuration of LIN Assist Mode Interrupt Enable Clear Register (LAMIERC)

Figure 9-34 shows the bit configuration of the LIN assist mode interrupt enable clear register (LAMIERC).

Figure 9-34 Bit Configuration of LIN Assist Mode Interrupt Enable Clear Register (LAMIERC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	LCSERIEC	LPTERIEC	LSFERIEC	LBSEIEC	LCSCIEC	Reserved	LAHCIEC	Reserved		
R/W Attribute	R0, W0	R0,W	R0,W	R0,W	R0,W	R0,W	R0, W0	R0,W			R0,W0
Protection Attribute	-	-	-	-	-	-	-	-			-
Initial Value	0	0	0	0	0	0	0	0			00000000

[bit15] Reserved: Reserved Bit

[bit14] LCSERIEC: Clearing the LIN Checksum Error Interrupt Enable Bit

Writing "1" to this bit resets LAMIER:LCSERIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] LPTERIEC: Clearing the LIN ID Parity Error Interrupt Enable Bit

Writing "1" to this bit resets the LAMIER:LPTERIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] LSFERIEC: Clearing the LIN Sync Data Error Interrupt Enable Bit

Writing "1" to this bit resets the LAMIER:LSFERIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] LBSEIEC: Clearing the LIN Bus Error Interrupt Enable Bit

Writing "1" to this bit resets LAMIER:LBSEIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] LCSCIEC: Clearing the LIN Checksum Calculation Completion Interrupt Enable Bit

Writing "1" to this bit resets LAMIER:LCSCIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] Reserved: Reserved Bit

[bit8] LAHCIEC: Clearing the LIN Auto Header Completion Interrupt Enable Bit

Writing "1" to this bit resets LAMIER:LAHCIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7:0] Reserved: Reserved Bits

All "0" are always read from these bits.

9.33. LIN Assist Mode Error Status Clear Register (LAMESRC)

The LIN assist mode error status clear register (LAMESRC) can be used to clear a bit in the LIN assist mode error status register (LAMESR).

Note:

- For details on the operations performed on this register, also see the description of target register LAMESR.

Bit Configuration of LIN Assist Mode Error Status Clear Register (LAMESRC)

Figure 9-35 shows the bit configuration of the LIN assist mode error status clear register (LAMESRC).

Figure 9-35 Bit Configuration of LIN Assist Mode Error Status Clear Register (LAMESRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	LCSERC	LPTERC	LSFERC	LBSERC	Reserved	Reserved	Reserved	Reserved		Reserved
R/W Attribute	R0, W0	R0, W	R0, W	R0, W	R0, W	R0, W0	R0, W0	R0, W0	R0, W0		R0, W0
Protection Attribute	-	-	-	-	-	-	-	-	-		-
Initial Value	0	0	0	0	0	0	0	0	0		00000000

[bit15] Reserved: Reserved Bit

[bit14] LCSERC: Clearing the LIN Checksum Error Flag

Writing "1" to this bit resets LAMESR:LCSER to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] LPTERC: Clearing the LIN ID Parity Error Flag

Writing "1" to this bit resets LAMESR:LPTER to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] LSFERC: Clearing the LIN Sync Data Error Flag

Writing "1" to this bit resets LAMESR:LSFER to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] LBSERC: Clearing the LIN Bus Error Flag

Writing "1" to this bit resets LAMESR:LBSER to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10:0] Reserved Bits

All "0" are always read from these bits.

All "0" are always written to these bits.

9.34. FIFO Control Clear Register 1 (FCR1C)

FIFO control clear register 1 (FCR1C) can clear a bit in FIFO control register 1 (FCR1).

Note:

- For details on the operations performed on this register, also see the description of target register FCR1.

Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Figure 9-36 shows the bit configuration of FIFO control clear register 1 (FCR1C).

Figure 9-36 Bit Configuration of FIFO Control Clear Register 1 (FCR1C)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	FLSTEC	FRIIEC	FDRQC	FTIEC	FSELC	(FCR0C)		
R/W Attribute	R0, W0	R0, W0	R0, W0	R0, W	R0, W	R0, W	R0, W	R0, W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTEC: Clearing the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit resets FCR1:FLSTE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIEC: Clearing the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit resets FCR1:FRIIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] FDRQC: Clearing the Transmission FIFO Data Request Bit

Writing "1" to this bit resets FCR1:FDRQ to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] FTIEC: Clearing the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit resets FCR1:FTIE to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELC: Clearing the FIFO Selection Bit

Writing "1" to this bit resets FCR1:FSEL to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.35. FIFO Control Clear Register 0 (FCR0C)

FIFO control clear register 0 (FCR0C) can clear a bit in FIFO control register 0 (FCR0).

Note:

- For details on the operations performed on this register, also see the description of the target register FCR0.

Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Figure 9-37 shows the bit configuration of FIFO control clear register 0 (FCR0C).

Figure 9-37 Bit Configuration of FIFO Control Clear Register 0 (FCR0C)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(FCR1C)			Reserve d	Reserve d	Reserve d	Reserve d	Reserve d	Reserve d	FE2C	FE1C
R/W Attribute				R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0,W	R0,W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:2] Reserved: Reserved Bits

[bit1] FE2C: Clearing the FIFO2 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE2 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1C: Clearing the FIFO1 Operation Enable Bit

Writing "1" to this bit resets FCR0:FE1 to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.36. Extended Status Clear Register (ESRC)

The extended status clear register (ESRC) can clear a bit in the extended status register (ESR).

Extended Status Clear Register (ESRC)

Figure 9-38 shows the bit configuration of the extended status clear register (ESRC).

Figure 9-38 Bit Configuration of Extended Status Clear Register (ESRC)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	Reserved	Reserved	Reserved	Reserved	RXUDRC	TXOVR	RBERRC	TBERRC	-		
R/W Attribute	R0, W0	R0, W0	R0, W0	R0, W0	R0, W	R0, W	R0, W	R0, W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:12] Reserved: Reserved Bits

[bit11] RXUDRC: Reception FIFO Underrun Flag Clear Bit

Writing "1" to this bit resets ESR:RXUDR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TXOVR: Transmission FIFO Overrun Flag Clear Bit

Writing "1" to this bit resets ESR:TXOVR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RBERRC: Reception Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:RBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TBERRC: Transmission Block Transfer Error Clear Bit

Writing "1" to this bit resets ESR:TBERR to "0".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.37. Serial Control Set Register (SCRS)

The serial control set register (SCRS) can set a bit in the serial control register (SCR).

Note:

- For details on the operations performed on this register, also see the description of target register SCR.

Bit Configuration of Serial Control Set Register (SCRS)

Figure 9-39 shows the bit configuration of the serial control set register (SCRS).

Figure 9-39 Bit Configuration of Serial Control Set Register (SCRS)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	UPCLS	MSS	LBRS	RIES	TIES	TBIES	RXES	TXES	(SMRS)		
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] UPCLS: Setting the Programmable Clear Bit

Writing "1" to this bit sets SCR:UPCL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14] MSS: Setting the Master/Slave Function Selection Bit

Writing "1" to this bit sets SCR:MS to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] LBRS: Setting the LIN Break Field Setting Bit (Effective Only for the Master Operation)

Writing "1" to this bit sets SCR:LBR to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] RIES: Setting the Reception Interrupt Enable Bit

Writing "1" to this bit sets SCR:RIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] TIES: Setting the Transmission Interrupt Enable Bit

Writing "1" to this bit sets SCR:TIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] TBIES: Setting the Transmission Bus Idle Interrupt Enable Bit

Writing "1" to this bit sets SCR:TBIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] RXES: Setting the Reception Operation Enable Bit

Writing "1" to this bit sets the SCR:RXE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] TXES: Setting the Transmission Operation Enable Bit

Writing "1" to this bit sets SCR:TXE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.38. Serial Mode Set Register (SMRS)

The serial mode set register (SMRS) can set a bit in the serial mode register (SMR).

Note:

- For details on the operations performed on this register, also see the description of target register SMR.

Bit Configuration of Serial Mode Set Register (SMRS)

Figure 9-40 shows the bit configuration of the serial mode set register (SMRS).

Figure 9-40 Bit Configuration of Serial Mode Set Register (SMRS)

Bit	15	...	8	7	6	5	4	3	2	1	0
Field	(SCRS)			Reserve d	Reserve d	Reserve d	WUCRS	SBLS	Reserve d	Reserve d	SOES
R/W Attribute				R0, W0	R0, W0	R0, W0	R0,W	R0,W	R0, W0	R0, W0	R0,W
Protection				-	-	-	-	-	-	-	-
Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:5] Reserved: Reserved Bits

[bit4] WUCRS: Setting the WAKE UP Control Bit

Writing "1" to this bit sets SMR:WUCR to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] SBLS: Setting the Stop Bit Length Selection Bit

Writing "1" to this bit sets the SMR:SBL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2:1] Reserved: Reserved Bits

[bit0] SOES: Setting the Serial Data Output Enable Bit

Writing "1" to this bit sets SMR:SOE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.39. Serial Status Set Register (SSRS)

The serial status set register (SSRS) can set a bit in the serial status register (SSR).

Note:

- For details on the operations performed on this register, also see the description of target register SSR.

Bit Configuration of Serial Status Set Register (SSRS)

Figure 9-41 shows the bit configuration of the serial status set register (SSRS).

Figure 9-41 Bit Configuration of Serial Status Set Register (SSRS)

Bit	15	14	13	12	11	10	9	8	7	...	0
Field	RECS	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	(ESCRS)		
R/W Attribute	R0,W	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0	R0, W0			
Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15] RECS: Setting the Reception Error Flag Clear Bit

Writing "1" to this bit sets SSR:REC to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14:8] Reserved: Reserved Bits

9.40. Extended Communication Control Set Register (ESCRS)

The extended communication control set register (ESCRS) can be used to set a bit in the extended communication control register (ESCR).

Note:

- For details on the operations performed on this register, also see the description of the target register *ESCR*.

Bit Configuration of Extended Communication Control Set Register (ESCRS)

Figure 9-42 shows the bit configuration of the extended communication control set register (ESCRS).

Figure 9-42 Bit Configuration of Extended Communication Control Set Register (ESCRS)

Initial Value				0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

[bit6] ESBLS: Setting the Extended Stop Bit Length Selection Bit

Writing "1" to this bit sets the ESCR:ESBL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit5] Reserved: Reserved Bit

[bit4] LBIES: Setting the LIN Break Field Detection Interrupt Enable Bit

Writing "1" to this bit sets the ESCR:LBIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3:0] Reserved: Reserved Bits

9.41. Serial Auxiliary Control Status Set Register (SACSRS)

The serial auxiliary control status set register (SACSRS) can set the bits in the serial auxiliary control status register (SACSR).

Note:

- For details on the operations performed on this register, also see the description of target register SACSR.

Bit Configuration of Serial Auxiliary Control Status Set Register (SACSRS)

Figure 9-43 shows the bit configuration of the serial auxiliary control status set register (SACSRS).

Figure 9-43 Bit Configuration of Serial Auxiliary Control Status Set Register (SACSRS)

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] STSTS: Setting the Serial Test Bit

Writing "1" to this bit sets SACSR:STST to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit14:13] Reserved: Reserved Bits

[bit12] SFDES: Setting the Sync Field Detection Interrupt Enable Bit

Writing "1" to this bit sets the SACSR:SFDE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] AUTES: Setting the Auto Baud Rate Adjustment Bit

Writing "1" to this bit sets SACSR:AUTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10:8] Reserved: Reserved Bits

[bit7] TINTES: Setting the Timer Interrupt Enable Bit

Writing "1" to this bit sets SACSР:ТINTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit6] Reserved: Reserved Bit

[bit5] TRGES: Setting the External Trigger Enable Bit

Writing "1" to this bit sets SACSР:TRGE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4:1] Reserved Bits

[bit0] TMRES: Setting the Serial Timer Enable Bit

Writing "1" to this bit sets SACSР:TMRE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.42. LIN Assist Mode Control Set Register (LAMCRS)

The LIN assist mode control set register (LAMCRS) can be used to set a bit in the LIN assist mode control register (LAMCR).

Note:

- For details on the operations performed on this register, also see the description of target register LAMCR.

Bit Configuration of LIN Assist Mode Control Set Register (LAMCRS)

Figure 9-44 shows the bit configuration of the LIN assist mode control set register (LAMCRS).

Figure 9-44 Bit Configuration of LIN Assist Mode Control Set Register (LAMCRS)

Initial Value	00000000		0		0	0	0	0	0	0	0

[bit15:4] Reserved Bits

[bit3] LTDRCLS: Setting the LIN Transmission Data Register Clear Bit

Writing "1" to this bit sets LAMCR:LTDRCL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] LCSTYPS: Setting the LIN Checksum Type Selection Bit

Writing "1" to this bit sets LAMCR:LCSTYP to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] LIDENS: Setting the LIN ID Register Use Enable Bit

Writing "1" to this bit sets LAMCR:LIDEN to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] LAMENS: Setting the LIN Assist Mode Processing Enable Bit

Writing "1" to this bit sets LAMCR:LAMEN to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.43. LIN Assist Mode Interrupt Enable Set Register (LAMIERS)

The LIN assist mode interrupt enable set register (LAMIERS) can be used to set a bit in the LIN assist mode interrupt enable register (LAMIER).

Note:

- For details on the operations performed on this register, also see the description of target register LAMIER.

Bit Configuration of LIN Assist Mode Interrupt Enable Set Register (LAMIERS)

Figure 9-45 shows the bit configuration of the LIN assist mode interrupt enable set register (LAMIERS).

Figure 9-45 Bit Configuration of LIN Assist Mode Interrupt Enable Set Register (LAMIERS)

Protection Attribute	-	-	-	-	-	-	-	-	-		
Initial Value	0	0	0	0	0	0	0	0	00000000		

[bit15] Reserved: Reserved Bit

[bit14] LCSERIES: Setting the LIN Checksum Error Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LCSERIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit13] LPTERIES: Setting the LIN ID Parity Error Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LPTERIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit12] LSFERIES: Setting the LIN Sync Data Error Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LSFERIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] LB SERIES: Setting the LIN Bus Error Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LB SERIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] LCSCIES: Setting the LIN Checksum Calculation Completion Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LCSCIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit9] Reserved: Reserved Bit

[bit8] LAHCIES: Setting the LIN Auto Header Completion Interrupt Enable Bit

Writing "1" to this bit sets LAMIER:LAHCIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit7:bit0] Reserved Bits

9.44. FIFO Control Set Register 1 (FCR1S)

FIFO control set register 1 (FCR1S) can set a bit in FIFO control register 1 (FCR1).

Note:

- For details on the operations performed on this register, also see the description of target register FCR1.

Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Figure 9-46 shows the bit configuration of FIFO control set register 1 (FCR1S).

Figure 9-46 Bit Configuration of FIFO Control Set Register 1 (FCR1S)

Bit	15	14	13	12	11	10	9	8	7	...	0

Protection Attribute	-	-	-	-	-	-	-	-			
Initial Value	0	0	0	0	0	0	0	0			

[bit15:13] Reserved: Reserved Bits

[bit12] FLSTES: Setting the Retransmission Data Lost Detection Enable Bit

Writing "1" to this bit sets FCR1:FLSTE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit11] FRIIES: Setting the Reception FIFO Idle Detection Enable Bit

Writing "1" to this bit sets FCR1:FRIIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit10] Reserved: Reserved Bit

[bit9] FTIES: Setting the Transmission FIFO Interrupt Enable Bit

Writing "1" to this bit sets FCR1:FTIE to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit8] FSELS: Setting the FIFO Selection Bit

Writing "1" to this bit sets FCR1:FSEL to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

9.45. FIFO Control Set Register 0 (FCR0S)

FIFO control set register 0 (FCR0S) can set a bit in FIFO control register 0 (FCR0).

Note:

- For details on the operations performed on this register, also see the description of target register FCR0.

Bit Configuration of FIFO Control Set Register 0 (FCR0S)

Figure 9-47 shows the bit configuration of FIFO control set register 0 (FCR0S).

Figure 9-47 Bit Configuration of FIFO Control Set Register 0 (FCR0S)

R/W Attribute				R0, W0	R0, W0	R0, W	R0, W	R0, W	R0, W	R0, W	R0, W
Protection Attribute				-	-	-	-	-	-	-	-
Initial Value				0	0	0	0	0	0	0	0

[bit7:6] Reserved: Reserved Bits

[bit5] FLDS: Setting the FIFO Pointer Reload Bit

Writing "1" to this bit sets FCR0:FLD to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit4] FSETS: Setting the FIFO Pointer Saving Bit

Writing "1" to this bit sets FCR0:FSET to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit3] FCL2S: Setting the FIFO2 Reset Bit

Writing "1" to this bit sets FCR0:FCL2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit2] FCL1S: Setting the FIFO1 Reset Bit

Writing "1" to this bit sets FCR0:FCL1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit1] FE2S: Setting the FIFO2 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE2 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

[bit0] FE1S: Setting the FIFO1 Operation Enable Bit

Writing "1" to this bit sets FCR0:FE1 to "1".

Writing "0" to this bit is invalid.

"0" is always read from this bit.

CHAPTER 40: Base Timer

This chapter explains the functions and operations of the base timer.

1. Overview of the Base Timer
2. Block Diagrams of the Base Timer
3. Operations of the Base Timer
4. 32-Bit Mode Operation
5. Interrupts from the Base Timer
6. Start of DMA Controller (DMAC)
7. Registers of the Base Timer
8. Notes on Using the Base Timer
9. Base Timer Description by Function Mode

BT-TXXPT03P01R01L08-E1-XX

1. Overview of the Base Timer

Only one of the following timer functions can be selected for the base timer in the FMD2 to FMD0 bit settings in the timer control register (TMCR): reset mode, 16-bit PWM timer, 16-bit PPG timer, 16-/32-bit reload timer, and 16-/32-bit PWC timer. This section provides an overview of the various selectable timers.

Relationship between Mode Settings and Various Timer Functions

FMD2 to FMD0 Bit Settings in the Timer Control Register (TMCR)	Function
000	Reset mode
001	16-bit PWM timer
010	16-bit PPG timer
011	16/32-bit reload timer
100	16/32-bit PWC timer

Reset Mode

Reset mode is the state in which the base timer macros have been reset (to the initial values in each register). To use another timer function or switch the T32 bit setting, first enter this mode and then set the other timer function or the T32 bit. However, after a macro reset, it is possible to set a timer function and the T32 bit without entering this mode.

16-Bit PWM Timer

The 16-bit PWM timer operates with the cycle of 16-bit.

This timer consists of a 17-bit down counter that takes into account the start delay period, a 16-bit data register with a cycle setting buffer, a 16-bit compare register with a duty setting buffer, a start delay value setting register, an ADC trigger value setting register, and a pin controller.

The 16-bit PWM timer is described to be 16-bit down counter where irrelevant to the start delay control.

The registers with buffers store the cycle and duty data, enabling rewriting while the timer is operating.

The counter clock of the 17-bit down counter can be selected from 12 types of internal clocks (internal clock divided by 1/2/4/8/16/32/64/128/256/512/1024/2048) and 3 types of external clocks (rising-edge, falling-edge, and both-edges detection).

One-shot mode and continuous mode can be selected. In one-shot mode, counting stops when an underflow occurs. In continuous mode, counting is repeated following a reload.

The start of the 16-bit PWM timer can be selected from a software trigger and three types of external events (rising-edge, falling-edge, and both-edges detection).

The start delay function can delay the PWM control start time after trigger input.

An ADC trigger signal is output when the ADC trigger value setting register matches the count value of the 16-bit down counter.

16-Bit PPG Timer

This timer consists of a 16-bit down counter, a 16-bit data register for the H width setting, a 16-bit data register for the L width setting, and a pin controller.

The count clock of the 16-bit down counter can be selected from 12 types of internal clocks (internal clock divided by 1/2/4/8/16/32/64/128/256/512/1024/2048) and 3 types of external clocks (rising-edge, falling-edge, and both-edges detection).

One-shot mode and continuous mode can be selected. In one-shot mode, counting stops when an underflow occurs. In continuous mode, counting is repeated following a reload.

The start of the 16-bit PPG timer can be selected from a software trigger and three types of external events (rising-edge, falling-edge, and both-edges detection).

16-/32-Bit Reload Timer

This timer consists of a 16-bit down counter, a 16-bit reload register, and a pin controller.

The count clock of the 16-bit down counter can be selected from 12 types of internal clocks (internal clock divided by 1/2/4/8/16/32/64/128/256/512/1024/2048) and 3 types of external clocks (rising-edge, falling-edge, and both-edges detection).

One-shot mode and continuous mode can be selected. In one-shot mode, counting stops when an underflow occurs. In continuous mode, counting is repeated following a reload.

An external factor pin can be selected as a trigger input function or a gate function when the 16/32-bit reload timer is operating.

If the trigger input function is selected, the start of the 16/32-bit reload timer can be selected from a software trigger and three types of external events (rising-edge, falling-edge, and both-edges detection).

If the gate function is selected, the 16/32-bit reload timer counts only while a valid level is being input to the external factor pin.

16-/32-Bit PWC Timer

This timer consists of a 16-bit up counter, measurement input pins, and a control register.

With the input of external pulses, the timer measures the time between events.

The reference count clock can be selected from 12 types of internal clocks (divided by 1/2/4/8/16/32/64/128/256/512/1024/2048).

Each measurement mode: H pulse width (rising to falling) / L pulse width (falling to rising)

Rising cycle (rising to rising) / falling cycle (falling to falling)

Edge-to-edge measurement (rising or falling to falling or rising)

An interrupt request can be generated at the measurement end time.

The measurement is 1-time only or continuous. Either can be selected.

Interrupt request and DMA request

Interrupt request of this module can be used for purposes below:

1. Interrupt request to CPU (via Interrupt Controller)
2. DMA request to DMA Controller

To use the interrupt as interrupt request to CPU, following configuration is necessary:

- Enable the interrupt request in this module
- Enable the interrupt channel of the interrupt in Interrupt Controller

To use the interrupt as DMA request to DMA Controller, following configuration is necessary:

- Enable the interrupt request in this module
- Select the DMA channel from this module as DMA client in DMA Controller

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Block Diagrams of the Base Timer

Figure 2-1 to Figure 2-4 are block diagrams of the base timer in each mode.

Figure 2-1 Block Diagram of the 16-Bit PWM Timer

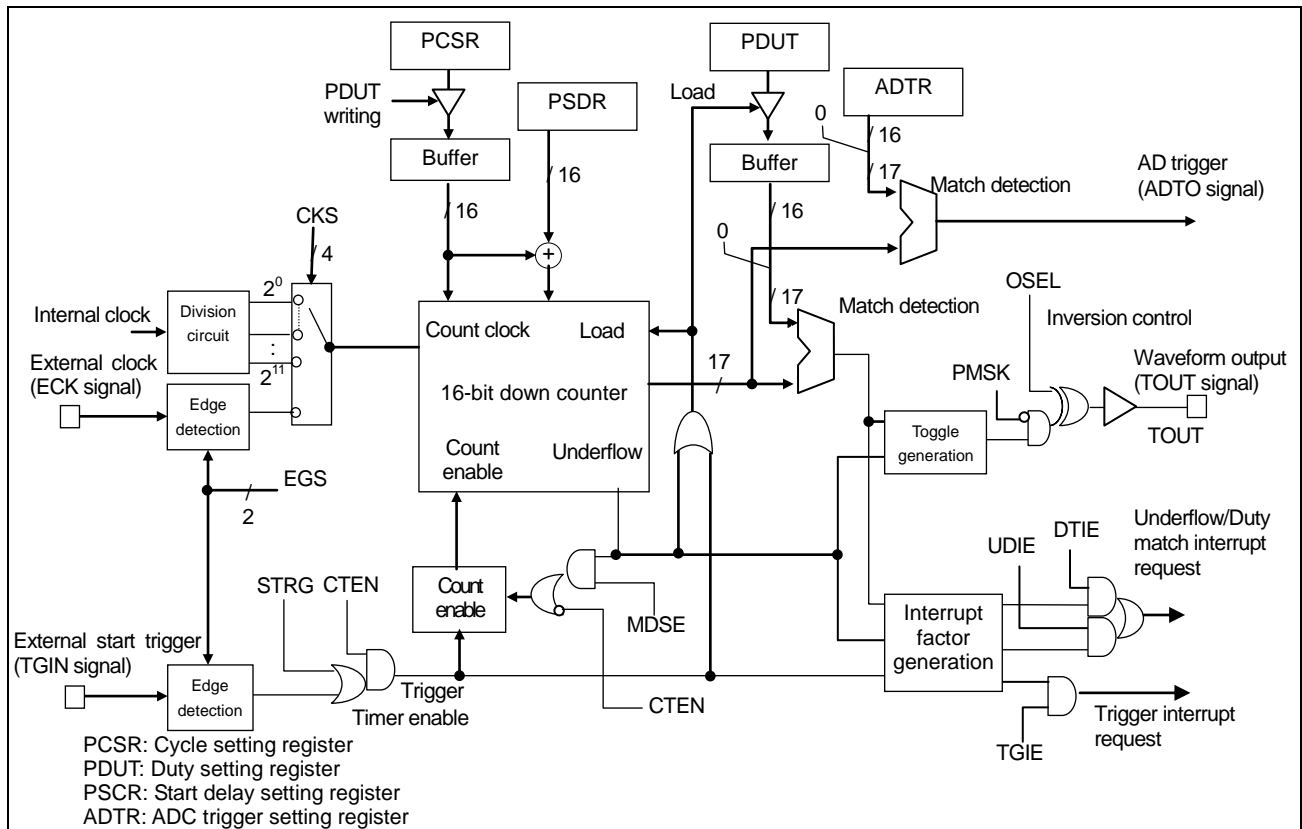

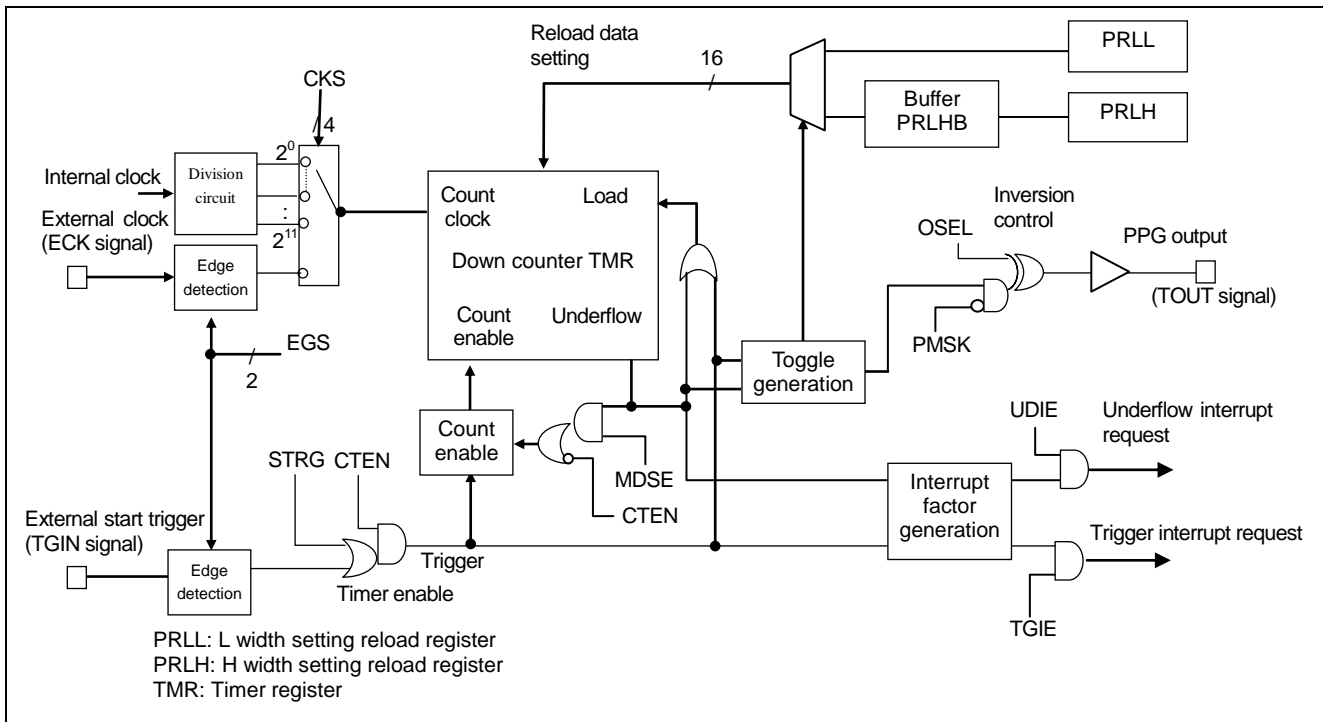

Figure 2-2 Block Diagram of the 16-Bit PPG Timer

Figure 2-3 Block Diagram of the 16-/32-Bit Reload Timer (ch.1, ch.0)

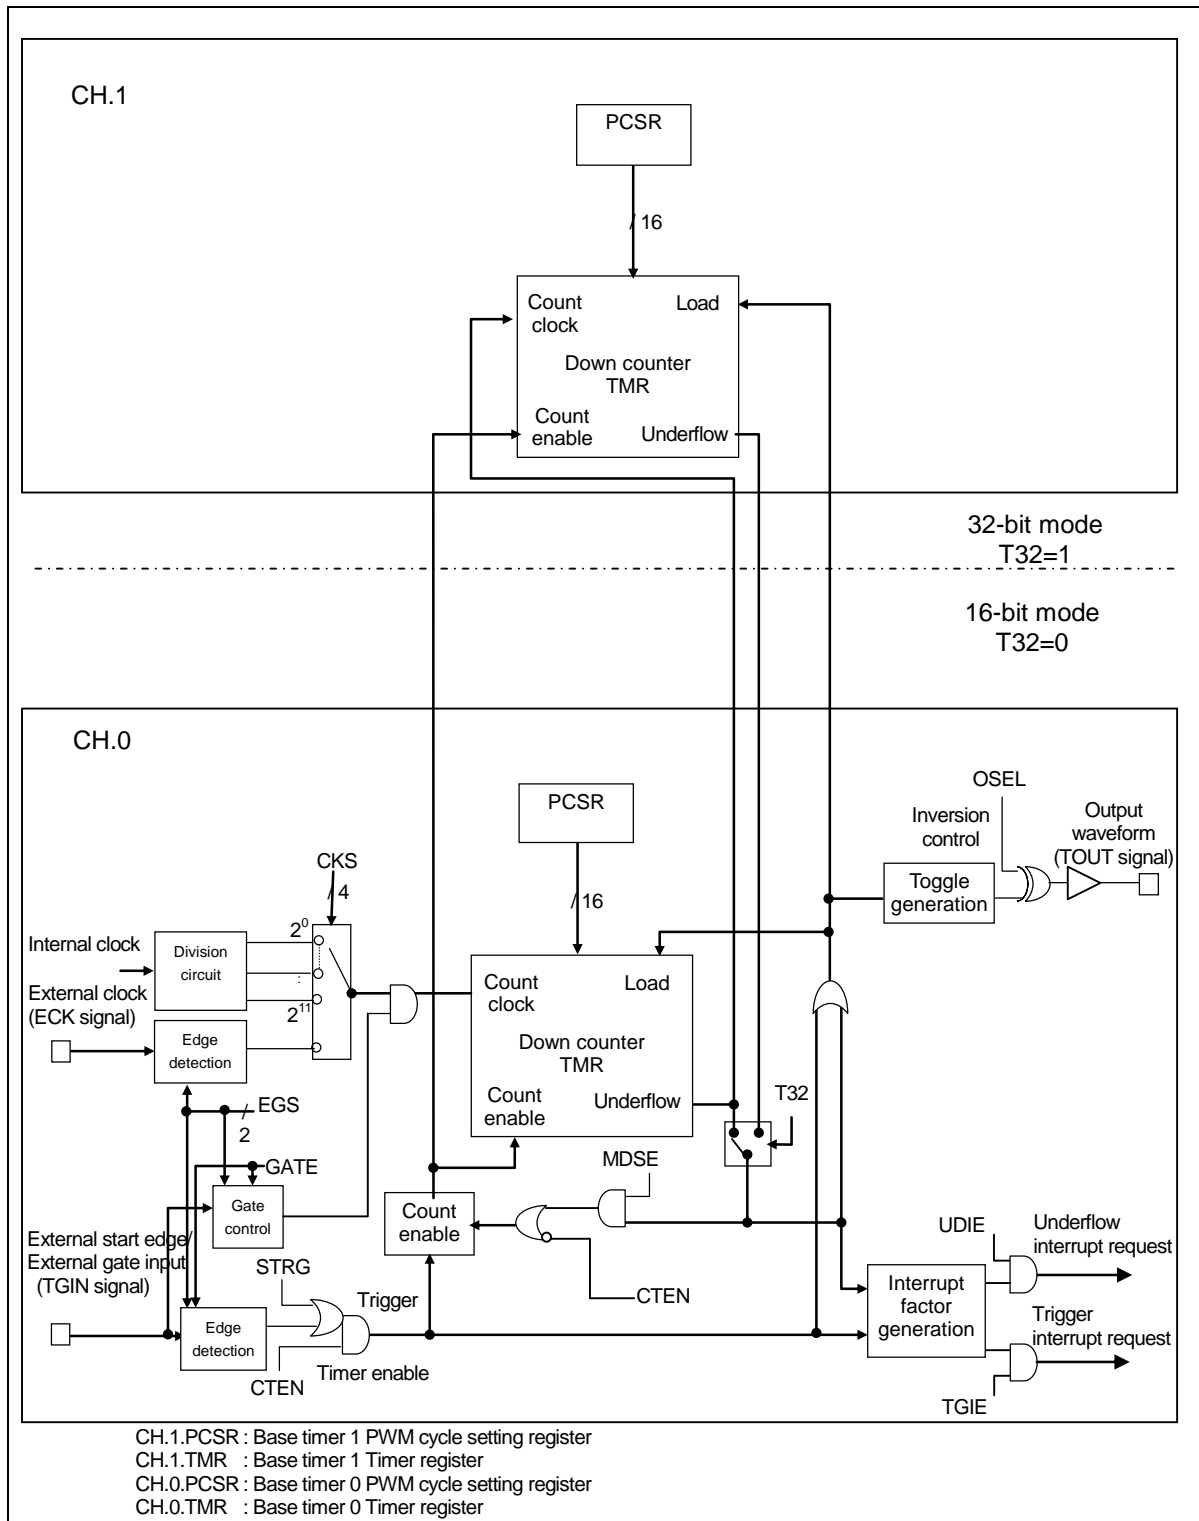

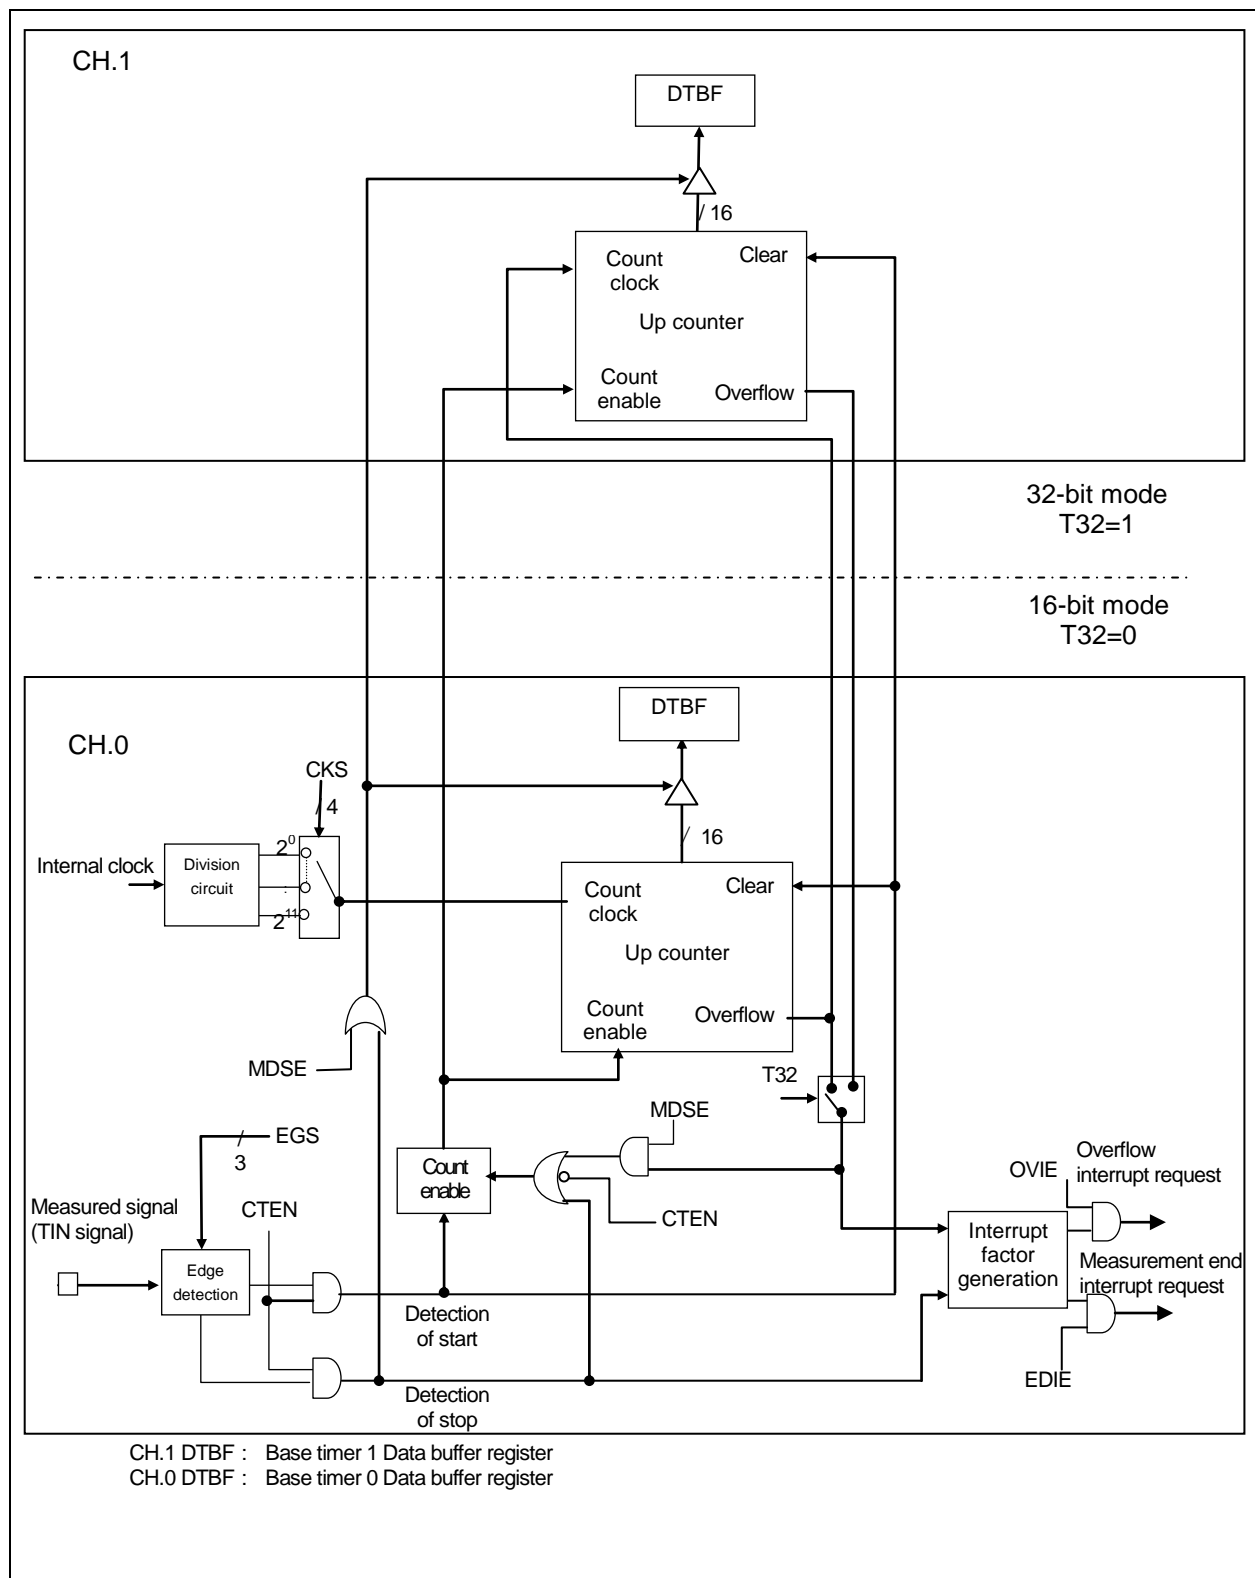

Figure 2-4 Block Diagram of the 16/32-Bit PWC Timer (ch.1, ch.0)

3. Operations of the Base Timer

This section explains the operations of the base timer.

Operations of Base Timer

Reset Mode

Reset mode is the state in which the base timer macros have been reset (to the initial values in each register). To use another timer function or switch the T32 bit setting, first enter this mode and then set the other timer function or the T32 bit. However, after a macro reset, it is possible to set a timer function and the T32 bit without entering this mode. If this mode is set for the even-numbered channel when 32-bit mode is set, the odd-numbered channel is reset at the same time, so reset mode need not be set for the odd-numbered channel.

16-Bit PWM Timer

The 16-bit PWM timer starts counting down from the set cycle value upon trigger activation. The first output at that time is the L level. If the 16-bit down counter matches the set value in the duty setting register, the output is inverted to the H level. Then, the output is inverted to the L level again when the counter underflows. Thus, this timer can generate a waveform with an arbitrary cycle and duty.

16-Bit PPG Timer

The 16-bit PPG timer starts counting down from the set value in the L width setting reload register upon trigger activation. The first output at that time is the L level. The output is inverted to the H level when the counter underflows. Subsequently, the counter starts counting down from the set value in the H width setting reload register. The output is inverted to the L level when the counter underflows. Thus, this timer can generate a waveform with an arbitrary L width and H width.

16-Bit Reload Timer

The 16-bit reload timer starts counting down from the set cycle value upon trigger activation. An interrupt flag is set to "1" when the 16-bit down counter underflows. The output level is either toggle output or pulse output. Toggle output is the output inverted for each underflow by the MDSE bit setting. Pulse output is the output of "H" due to the start of counting or "L" due to an underflow.

32-Bit Reload Timer

With the same basic operation as the 16-bit reload timer, this timer uses two channels, an even-numbered channel and an odd-numbered channel, to operate as a 32-bit reload timer. The even-numbered channel performs the lower 16-bit timer operations, and the odd-numbered channel performs the upper 16-bit timer operations. The interrupt controller and output waveform control conform to the settings of only the even-numbered channel. To set a cycle, write it first to the upper register (odd-numbered channel) and then to the lower register (even-numbered channel).

To read the timer value, read it first from the lower register (even-numbered channel) and then from the upper register (odd-numbered channel).

16-Bit PWC Timer

The PWC timer starts the 16-bit up counter upon input of the set measurement start edge. The timer stops the counter upon the detection of a measurement end edge. The count value at this time is stored as a pulse width in the data buffer register.

32-Bit PWC Timer

With the same basic operation as the 16-bit PWC timer, this timer uses two channels, an even-numbered channel and an odd-numbered channel, to operate as a 32-bit PWC timer. The even-numbered channel performs the lower 16-bit count operations, and the odd-numbered channel performs the upper 16-bit count operations. The interrupt controller conforms to the settings of only the even-numbered channel. To read a measurement value or count value, read it first from the lower register (even-numbered channel) and then from the upper register (odd-numbered channel).

4. 32-Bit Mode Operation

The reload timer and PWC are capable of 32-bit mode operation using two channels. This section shows the basic functions/operations of the 32-bit mode function.

32-Bit Mode Function

This function realizes the operation of the 32-bit data reload timer or 32-bit data PWC timer by using two base timer channels. The value of the timer or counter in operation can also be read when the lower 16-bit timer or counter value of the even-numbered channel is read. This is because the upper 16-bit timer or counter value of the odd-numbered channel is also fetched at the time.

32-Bit Mode Settings

First, reset the state by setting the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to 0b000 for reset mode. Then, in the same way as in 16-bit mode, make reload timer or PWC timer selection and operation settings. To set 32-bit operation mode at this time, write "1" to the T32 bit in the TMCR register. Keep the T32 bit of the odd-numbered channel at "0". There is no need to set reset mode. For the reload timer, set the upper 16-bit reload value of the 32 bits in the cycle setting register of the odd-numbered channel. Then, set the lower 16-bit reload value in the cycle setting register of the even-numbered channel.

After the writing of the T32 bit, the change to 32-bit operation mode is reflected immediately, so change the settings for both channels in the count stopped state.

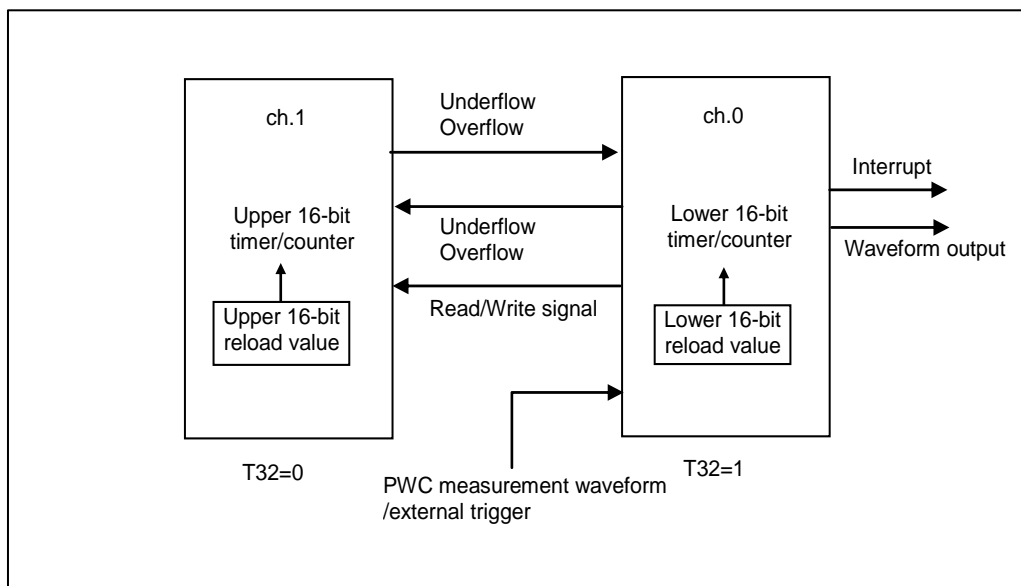

To change from 32-bit mode to 16-bit mode, set the FMD2 to FMD0 bits in the TMCR register of the even-numbered channel to 0b000 for reset mode. This resets the states of both the even-numbered and odd-numbered channels. As a result, the settings for 16-bit mode can be made for each of the channels.

32-Bit Mode Operation

After 32-bit mode is set, if the reload timer or PWC timer is started with even-numbered channel control, the even-numbered channel timer/counter performs the lower 16-bit operations. The odd-numbered channel timer/counter performs the upper 16-bit operations.

Operation in 32-bit mode conforms to the settings made for the even-numbered channel. Thus, the settings made for the odd-numbered channel (excluding those in the cycle setting register at the reload timer time) are ignored. Timer start, waveform output, and interrupt signals for the even-numbered channel are valid. (The odd-numbered channel is fixed at "L" and masked.)

Figure 4-1 shows the configuration of ch.0 and ch.1.

Figure 4-1 Configuration of 32-Bit Mode Operation (for ch.0 and ch.1)

5. Interrupts from the Base Timer

This section shows a list summarizing the interrupt request flags, interrupt enable bits, and interrupt factors in each function of the base timer.

Interrupt Controller Bits and Interrupt Factors of Each Function

Table 5-1 shows the interrupt controller bits and interrupt factors of each function.

Table 5-1 Interrupt Controller Bits and Interrupt Factors in Each Mode

	Status Control Register (STC)			
	Interrupt Request Flag Bit	Interrupt Request Enable Bit	Interrupt Factor	Interrupt Factor Output Signal
PWM Timer Function	UDIR : bit0	UDIE : bit4	Detection of underflow	IRQ0
	DTIR : bit1	DTIE : bit5	Detection of duty match	
	TGIR : bit2	TGIE : bit6	Detection of timer activation trigger	IRQ1
PPG Timer Function	UDIR : bit0	UDIE : bit4	Detection of underflow	IRQ0
	TGIR : bit2	TGIE : bit6	Detection of timer activation trigger	IRQ1
Reload Timer Function	UDIR : bit0	UDIE : bit4	Detection of underflow	IRQ0
	TGIR : bit2	TGIE : bit6	Detection of timer activation trigger	IRQ1
PWC Timer Function	OVIR : bit0	OVIE : bit4	Detection of overflow	IRQ0
	EDIR : bit2	EDIE : bit6	Detection of measurement end	IRQ1

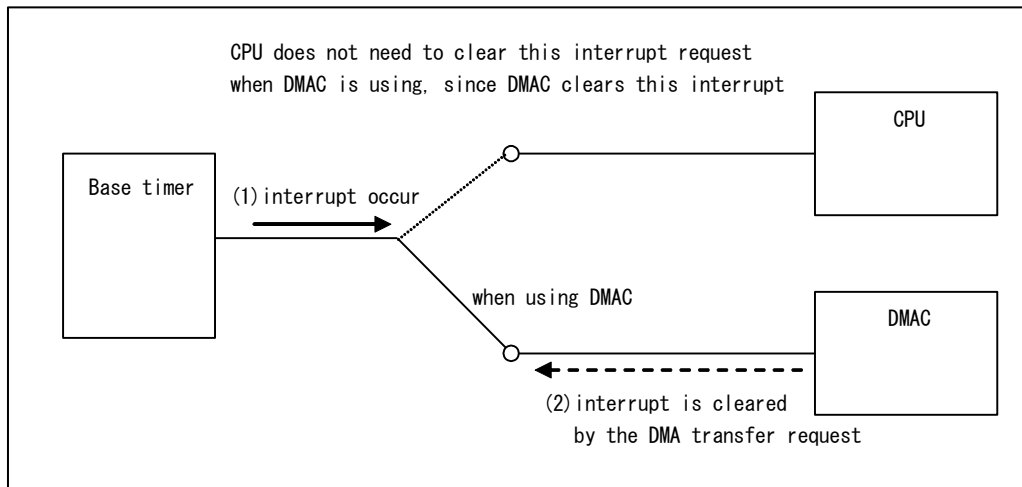

6. Start of DMA Controller (DMAC)

The generation of a base timer interrupt request can be used to start the DMAC.

DMA Transfer Operation Using Base Timer Interrupt Factor

The generation of a base timer interrupt factor can be used to start the DMAC. Figure 6-1 shows an overview of DMAC start with the base timer.

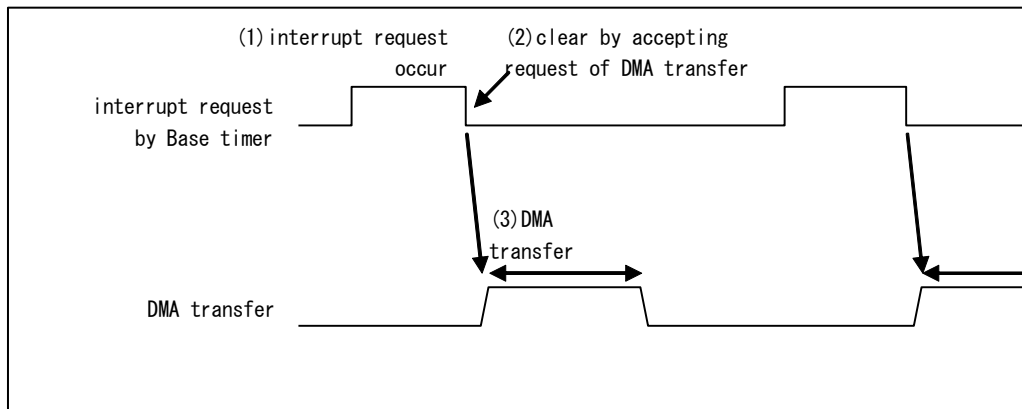

Figure 6-1 Overview of DMAC Start with the Base Timer

Configure the DMAC before starting it with the base timer. For details on DMAC settings, see the following chapter: "DMA Controller".

Figure 6-2 shows an example of a DMA transfer operation with a base timer interrupt request.

Figure 6-2 DMA Transfer Operation Example

7. Registers of the Base Timer

This section lists the registers of each mode of the base timer.

List of Registers When 16-Bit PWM Timer is Selected

Table 7-1 List of Registers When the 16-Bit PWM Timer is Selected

Abbreviated Register Name	Register Name	Reference
TMCR	Timer control register	9.1.8
TMCR2	Timer control register 2	9.1.8
STC	Status control register	9.1.8
STCC	Status Control Clear Register	9.1.8
STCS	Status Control Set Register	9.1.8
PCSR	PWM cycle setting register	9.1.9
PDUT	PWM duty setting register	9.1.10
TMR	Timer register	9.1.11
PSDR	Start delay value setting register	9.1.12
ADTR	ADC trigger value setting register	9.1.13

List of Registers When 16-Bit PPG Timer is Selected

Table 7-2 List of Registers When the 16-Bit PPG Timer is Selected

Abbreviated Register Name	Register Name	Reference
TMCR	Timer control register	9.2.6
TMCR2	Timer control register 2	9.2.6
STC	Status control register	9.2.6
STCC	Status Control Clear Register	9.2.6
STCS	Status Control Set Register	9.2.6
PRLL	L width setting reload register	9.2.7
PRLH	H width setting reload register	9.2.8
TMR	Timer register	9.2.9

List of Registers When Reload Timer is Selected

Table 7-3 List of Registers When the Reload Timer is Selected

Abbreviated Register Name	Register Name	Reference
TMCR	Timer control register	9.3.3
TMCR2	Timer control register 2	9.3.3
STC	Status control register	9.3.3
STCC	Status Control Clear Register	9.3.3
STCS	Status Control Set Register	9.3.3
PCSR	Cycle setting register	9.3.4
TMR	Timer register	9.3.5

List of Registers When PWC Timer is Selected

Table 7-4 List of Registers When the PWC Timer is Selected

Abbreviated Register Name	Register Name	Reference
TMCR	Timer control register	9.4.2
TMCR2	Timer control register 2	9.4.2
STC	Status control register	9.4.2
STCC	Status Control Clear Register	9.4.2
STCS	Status Control Set Register	9.4.2
DTBF	Data buffer register	9.4.3

Table 7-5 Offset Addresses

CH No.	Offset_Address (Common PERI #2)	CH No.	Offset_Address (Common PERI #1)	CH No.	Offset_Address (Common PERI #0)

* The initial value is XXXXXXXX_XXXXXXX only during reload timer operation.

8. Notes on Using the Base Timer

This section explains precautions on use of the base timer.

Notes to Observe When Accessing Register

Status Control Register (STC) Access

- This register supports writing from the bit-band alias area. For details on the bit-band alias area, see "CHAPTER: BIT-BAND UNIT."
- To clear a specific bit in this register, write "1" to the corresponding bit in the status control clear register (STCC).
- To set a specific bit in this register, write "1" to the corresponding bit in the status control set register (STCS).
- Direct writing to this register is possible only during writing to all bits.

Notes to Observe on Configuration Using Program, Common to Use of Timers

- Rewriting of the following bits in the TMCR2 register and TMCR register during operation is prohibited. Be sure that such rewriting is done either before the timer starts or after it stops.

[TMCR2 bit8], [TMCR bit14,13,12]	CKS3 to CKS0: Clock selection bits
[bit10,9,8]	EGS2, EGS1, EGS0: Measurement edge selection bits
[bit7]	T32: 32-bit timer selection bit (when the reload timer and PWC function are selected)
[bit6,5,4]	FMD2 to FMD0: Timer function selection bits
[bit2]	MDSE: Measurement mode (single/continuous) selection
bit	

- All the registers of the base timer are initialized when the FMD2 to FMD0 bits in the TMCR register are set to 0b000 for reset mode. For this reason, all the registers must be reconfigured.
- The settings for bits other than the FMD2 to FMD0 bits in the TMCR register are ignored and initialized when the FMD2 to FMD0 bits in the TMCR register are set to 0b000 for reset mode.

Notes on Using the 16-Bit PWM/PPG/Reload Timer

- If the interrupt request flag set timing and clear timing overlap, the flag set has priority, and the clear operation is disabled.
- If the load timing and count timing overlap, the load operation has priority for the down counter.
- After configuring the timer function with the FMD2 to FMD0 bits in the TMCR register, set the cycle, duty, H width, and L width.
- If a restart is detected at the count end time in one-shot mode, the count value is reloaded. Then, the restart begins.

Notes on Using the PWC Timer

- If "1" is written to the count start enable bit (CTEN), the counter is cleared. Thus, any data in the counter before the start is enabled is invalid.
- If the PWC mode setting (FMD2 to FMD0 = 0b100) and the measurement start setting (CTEN= 1) are made from a system reset and reset mode at the same time, the resulting operation may depend on the state of the immediately preceding measurement signal.
- If a measurement start edge is detected at the same time that a restart is set in continuous measurement mode, the timer starts counting immediately from 0x0001.
- If a restart is performed after a count operation begins, operations such as the following may occur, depending on the timing.
 - For a restart at the same time as a measurement end edge in pulse-width single measurement mode

The restart is performed and the measurement start edge wait state begins, but the measurement end flag (EDIR) is set to "1".

- For a restart at the same time as a measurement end edge in pulse-width continuous measurement mode

The restart is performed and the measurement start edge wait state begins, but the measurement end flag (EDIR) is set to "1" and the measurement results at that point are transferred to DTBF.

Note the operation of the flag when using the interrupt controller, etc. at the restart time during operation as described above.

9. Base Timer Description by Function Mode

This section explains each function of the base timer.

Functions of the Base Timer

1. PWM Timer Function
2. PPG Timer Function
3. Reload Timer Function
4. PWC Timer Function

9.1. PWM Timer Function

Only one of the following timer functions can be selected for the base timer in the FMD2 to FMD0 bit settings in the timer control register (TMCR): 16-bit PWM timer, 16-bit PPG timer, 16/32-bit reload timer, and 16/32-bit PWC timer. This section explains the timer function with the PWM setting.

1. 16-Bit PWM Timer Operation
2. One-Shot Operation
3. Start Delay Function
4. ADC Trigger Output Timing
5. Interrupt Factors and Timing Chart
6. Output Waveform
7. Timer Control Registers (TMCR,TMCR2), Status Control Register (STC) , Status Control Clear Register (STCC), and Status Control Set Register (STCS)
8. PWM Cycle Setting Register (PCSR)
9. PWM Duty Setting Register (PDUT)
10. Timer Register (TMR)
11. Start Delay Value Setting Register (PSDR)
12. ADC Trigger Value Setting Register (ADTR)

9.1.1. 16-Bit PWM Timer Operation

In PWM operation, waveforms of the set cycle can be output either singly or continuously upon the detection of a trigger. The cycle of the output pulse can be controlled through PCSR value changes. The duty ratio can be controlled through PDUT value changes. After writing data to PCSR, be sure to write to PDUT.

Continuous Operation

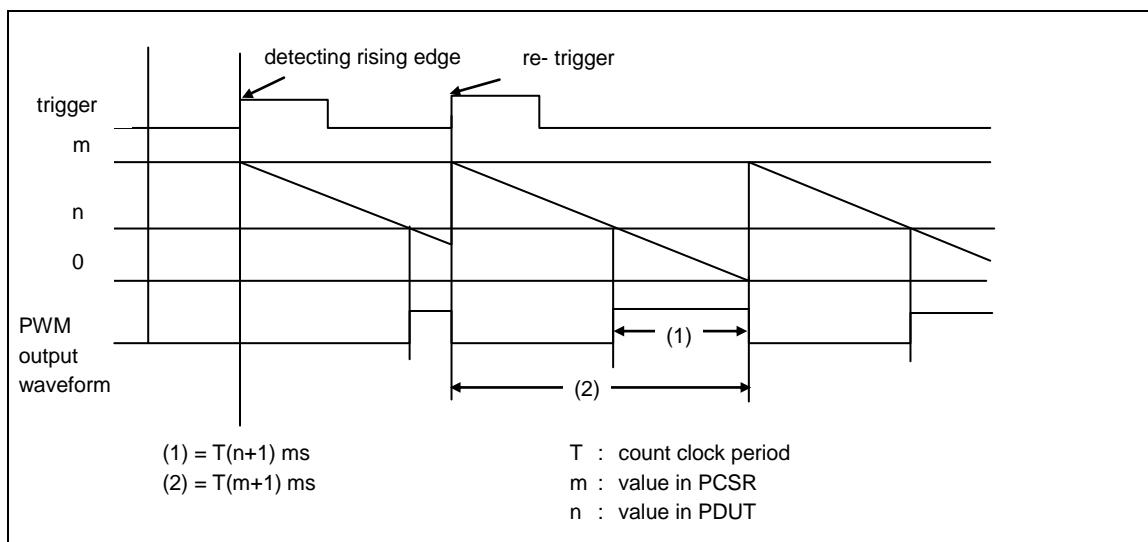

When Restart is Disabled (RTGEN=0)

Figure 9-1 PWM Operation Timing Chart (When Restart is Disabled)

When Restart is Enabled (RTGEN=1)

Figure 9-2 PWM Operation Timing Chart (When Restart is Enabled)

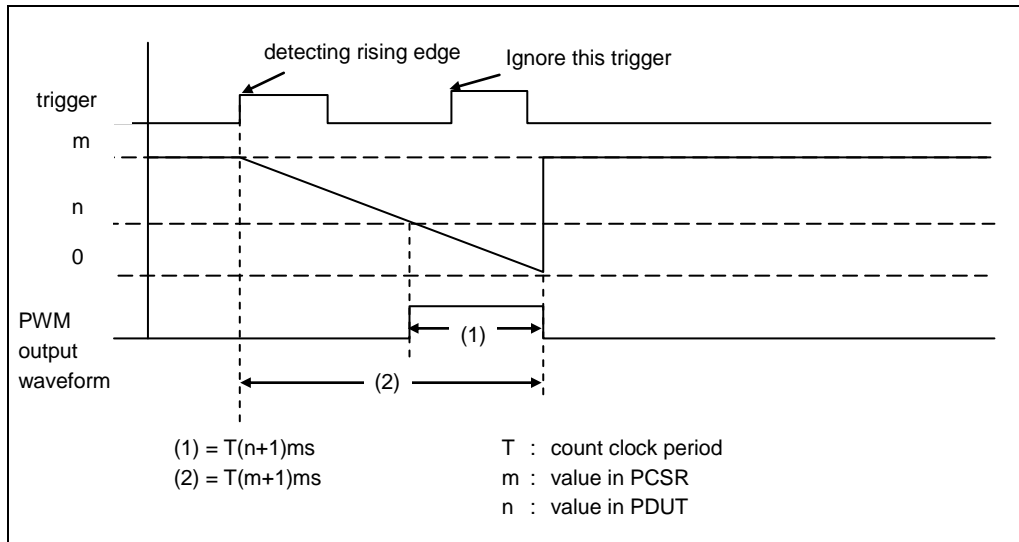

9.1.2. One-Shot Operation

In one-shot operation, a trigger can cause the output of a single pulse of any width. If restart is enabled, the counter is reloaded when an edge is detected during operation.

One-Shot Operation

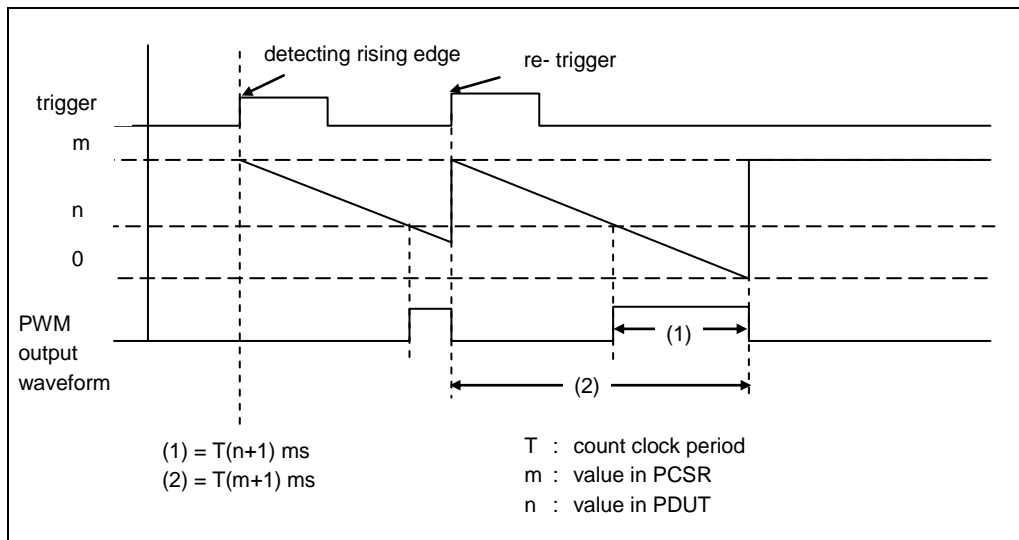

When Restart is Disabled (RTGEN=0)

Figure 9-3 One-Shot Operation Timing Chart (Trigger Restart Disabled)

When Restart is Enabled (RTGEN=1)

Figure 9-4 One-Shot Operation Timing Chart (Trigger Restart Enabled)

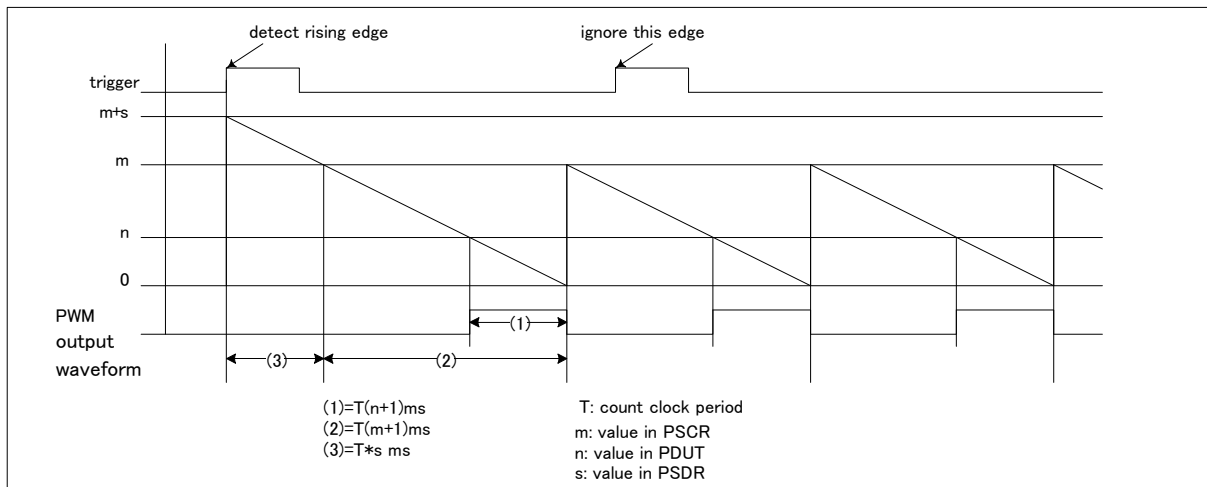

9.1.3. Start Delay Function

The start delay function can delay the time when PWM control starts after a trigger input.

Start Delay Operation in Continuous Operation

When Restart is Disabled (RTGEN=0)

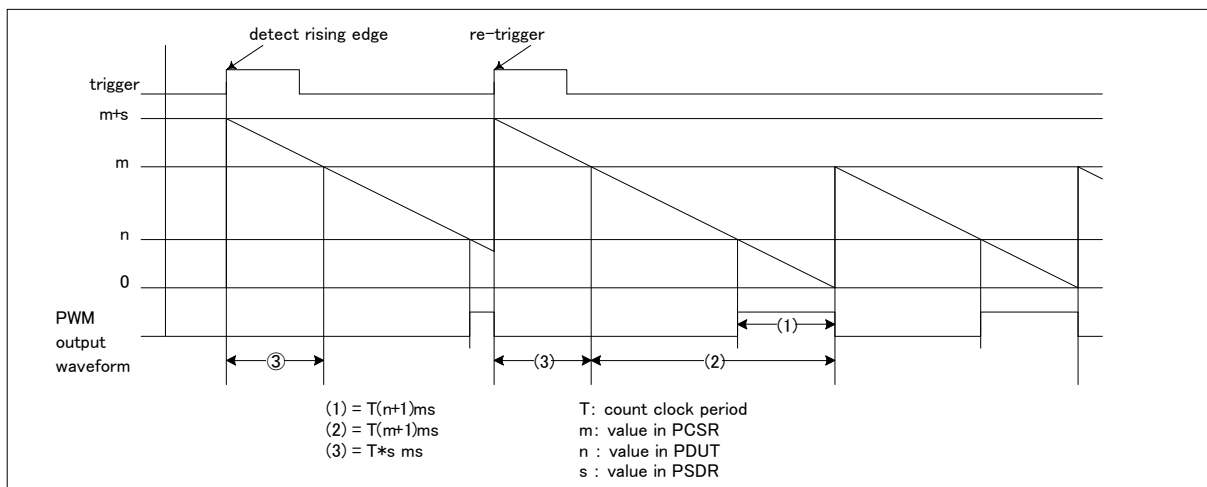

Figure 9-5 Start Delay Operation in Continuous Operation (Trigger Restart Disabled)

No PWM waveform is output during the start delay period ((3) above).

When Restart is Enabled (RTGEN=1)

Figure 9-6 Start Delay Operation in Continuous Operation (Trigger Restart Enabled)

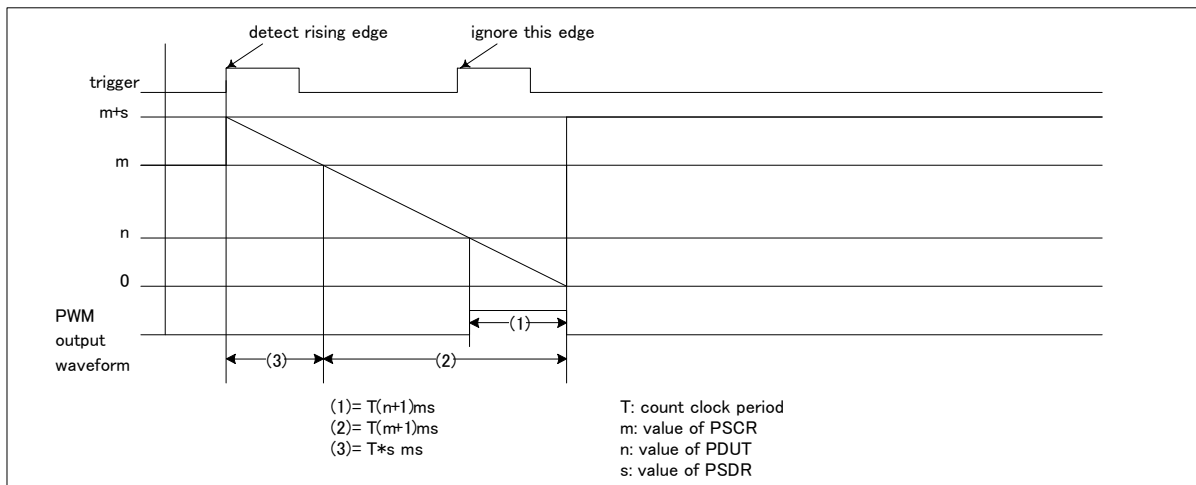

No PWM waveform is output during the start delay period ((3) above).

Start Delay Operation in One-Shot Operation

When Restart is Disabled (RTGEN=0)

Figure 9-7 Start Delay Operation in One-Shot Operation (Trigger Restart Disabled)

No PWM waveform is output during the start delay period ((3) above).

When Restart is Enabled (RTGEN=1)

Figure 9-8 Start Delay Operation in One-Shot Operation (Trigger Restart Enabled)

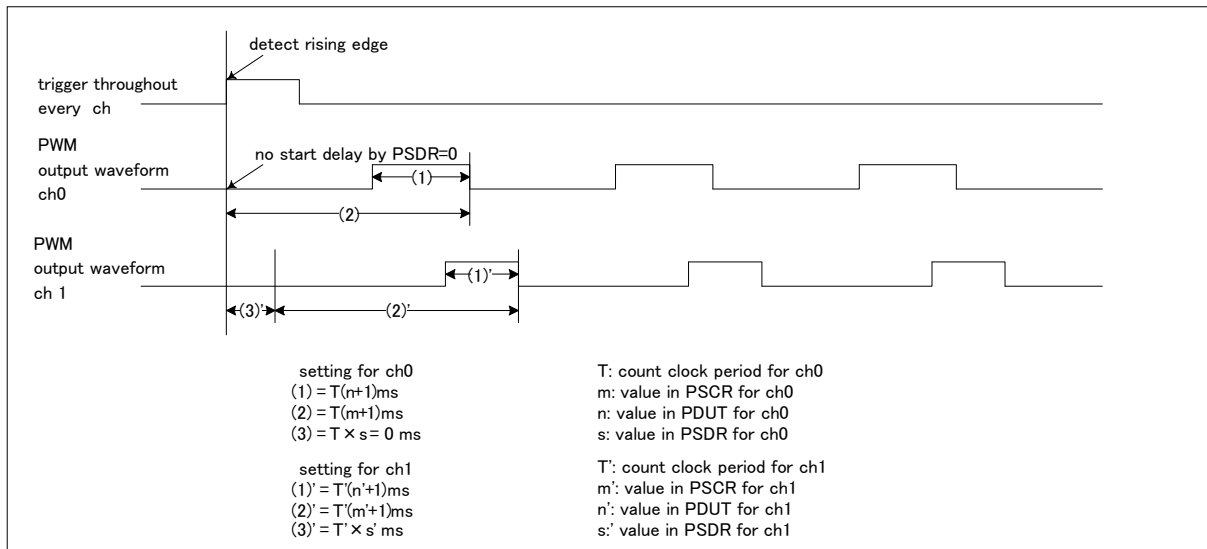

No PWM waveform is output during the start delay period ((3) above).

Start Delay Operation with Multiple Channels Interlocked

Operation with multiple channels interlocked in a certain phase relationship is enabled through control of a trigger as common to the channels.

When Restart is Disabled (RTGEN=0)

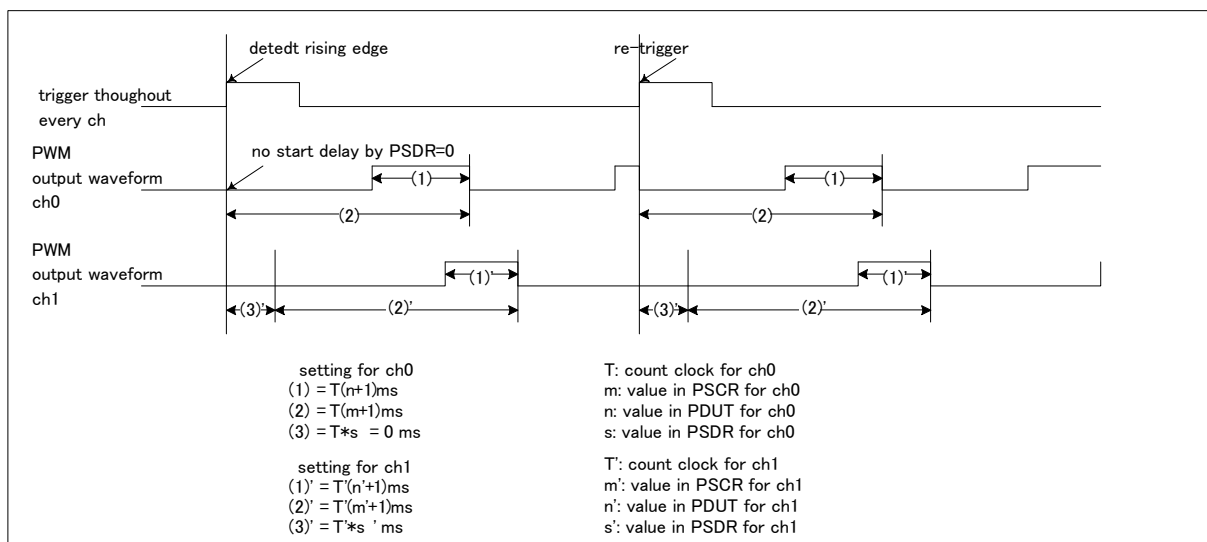

Figure 9-9 Start Delay Operation in Continuous Operation with Multiple Channels Interlocked (Trigger Restart Disabled)

No PWM waveform is output during the start delay period ((3) above).

When Restart is Enabled (RTGEN=1)

Figure 9-10 Start Delay Operation in Continuous Operation with Multiple Channels Interlocked (Trigger Restart Enabled)

No PWM waveform is output during the start delay period ((3) above).

9.1.4. ADC Trigger Output Timing

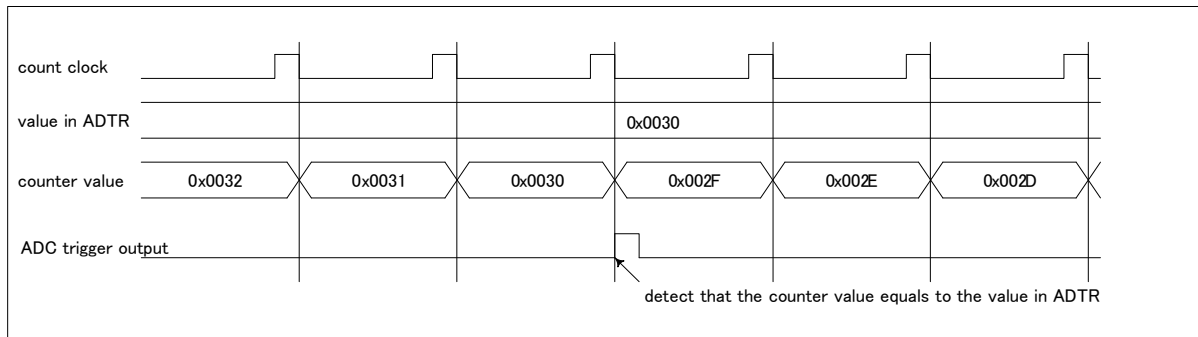

This section explains the ADC trigger output timing.

ADC Trigger Output Timing

ADC trigger is output when the 16-bit down counter is compared with the ADTR register and they match.

Figure 9-11 shows a timing chart of ADC trigger output when ADTR is 0x0030.

Figure 9-11 Timing Chart of ADC Trigger Output

9.1.5. Interrupt Factors and Timing Chart

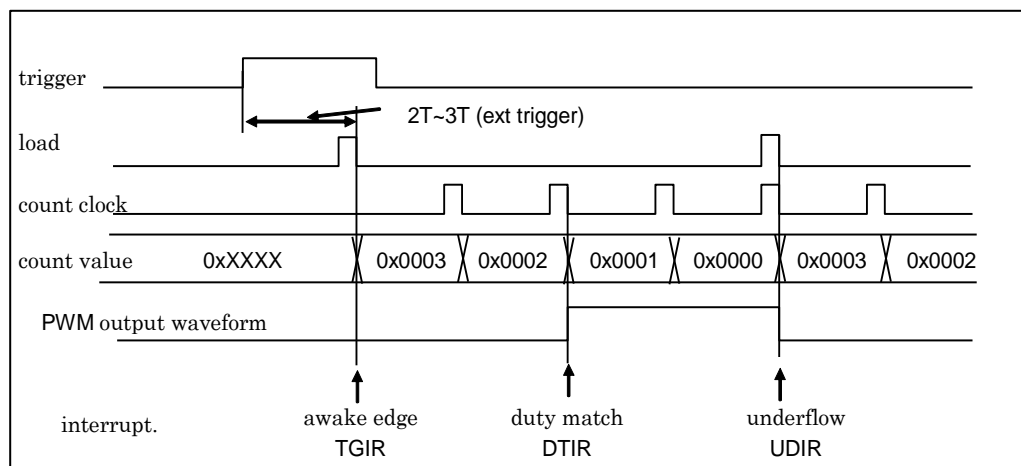

This section shows interrupt factors and a timing chart.

Interrupt Factors and Timing Chart (PWM Output: Normal Polarity)

As the time from the input of a trigger until the loading of a counter value, the required software trigger time is T , and the required external trigger time is $2T$ to $3T$ (T : internal clock cycle).

Figure 9-12 shows the interrupt factors and a timing chart where the cycle setting value is 3 and the duty value is 1.

Figure 9-12 PWM Timer Interrupt Factors and Timing Chart

9.1.6. Output Waveform

This section shows PWM output.

Output Methods for All "L" or All "H" in PWM Output

Figure 9-13 shows an output method where the PWM output is all "L". Figure 9-14 shows an output method where it is all "H".

Figure 9-13 Example Where PWM Output is All "L" Level

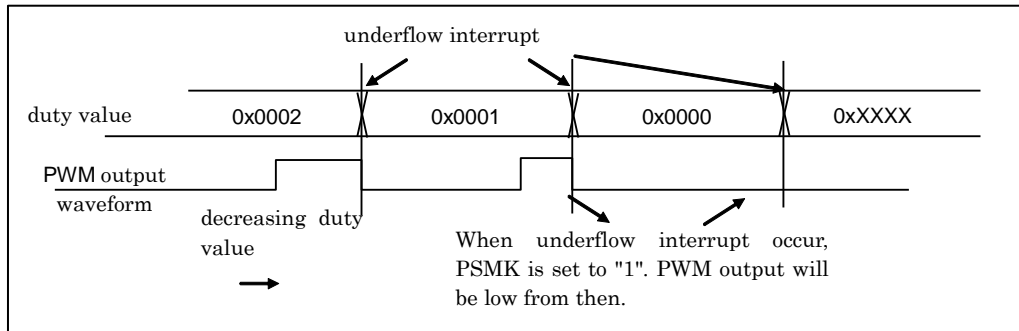

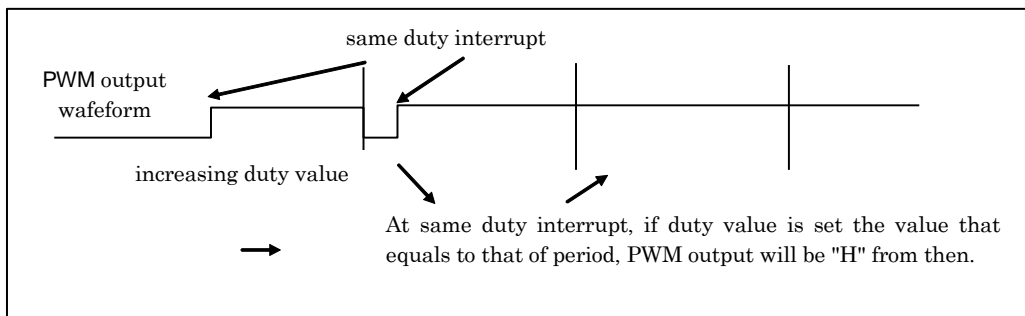

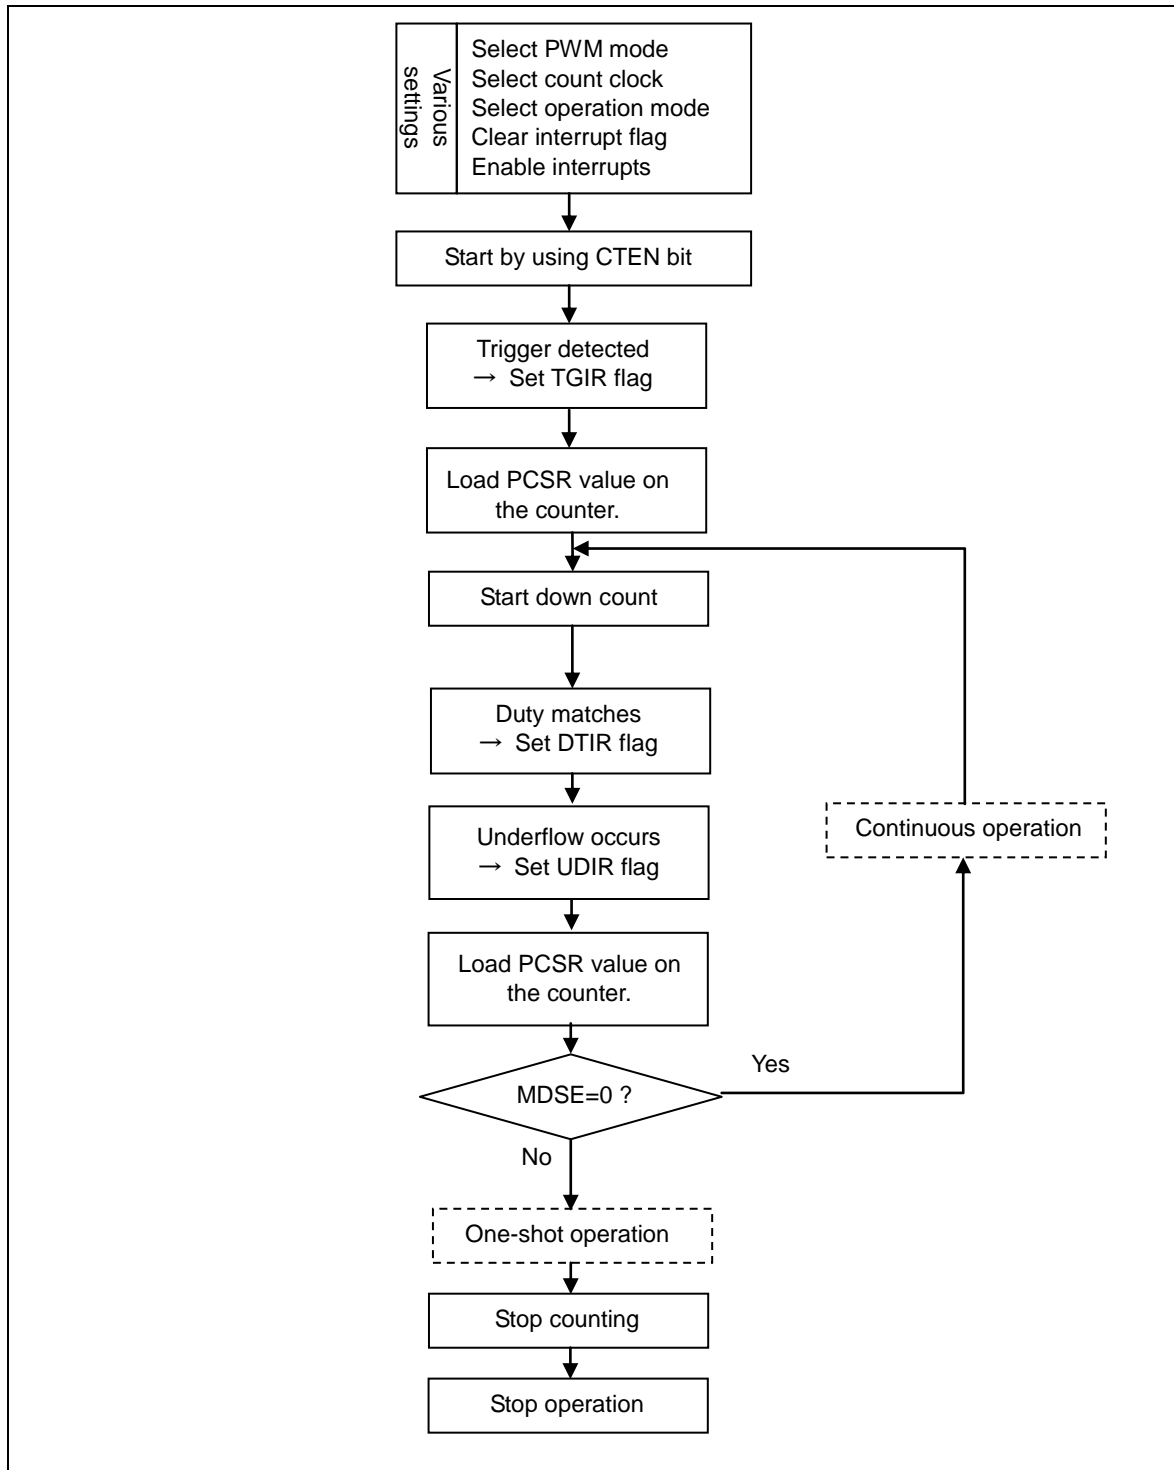

Figure 9-14 Example Where PWM Output is All "H" Level

9.1.7. PWM Timer Operation Flow

This section shows the PWM timer operation flow.

PWM Timer Operation Flow

9.1.8. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS)

The timer control register (TMCR) controls the PWM timer. Note that there are bits that cannot be rewritten during PWM timer operation.

For details on writing to the status control register (STC), see "CHAPTER 40:8. Notes on Using the Base Timer."

Timer Control Register (Upper Byte of TMCR)

bit	15	14	13	12	11	10	9	8
Field	Reserved	CKS2	CKS1	CKS0	RTGEN	PMSK	EGS1	EGS0
R/W Attribute	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[TMCR2:bit8,bit14:12] CKS[3:0]: Count Clock Selection Bits

- These bits select a count clock for the 17-bit down counter.
- Any modification to the count clock is reflected immediately after the setting is changed. Therefore, modify CKS3 to CKS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the count operation enable bit (CTEN).

Bits				Description
0	0	0	0	Internal clock
0	0	0	1	Internal clock divided by 4
0	0	1	0	Internal clock divided by 16
0	0	1	1	Internal clock divided by 128
0	1	0	0	Internal clock divided by 256
0	1	0	1	External clock (rising-edge event)
0	1	1	0	External clock (falling-edge event)
0	1	1	1	External clock (both-edges event)
1	0	0	0	Internal clock divided by 512
1	0	0	1	Internal clock divided by 1024
1	0	1	0	Internal clock divided by 2048
1	0	1	1	Internal clock divided by 2
1	1	0	0	Internal clock divided by 8
1	1	0	1	Internal clock divided by 32
1	1	1	0	Internal clock divided by 64
1	1	1	1	Setting prohibited

[bit11] RTGEN: Restart Enable Bit

This bit enables restart by a software trigger or trigger input.

Bit	Description
0	Disable restart.
1	Enable restart.

[bit10] PMSK: Pulse Output Mask Bit

- This bit controls the output waveform level of the PWM output waveform.
- When the bit is "0", the PWM waveform is output as is.
- When the bit is "1", PWM output is masked to L output regardless of the cycle or duty setting value.

Note:

- If the output polarity specification bit (OSEL) in the timer control register (lower byte of TMCR) is set for inverted output, setting the PMSK bit to "1" results in masking to H output.

Bit	Description
0	Normal output
1	Fixed at L output

[bit9:8] EGS[1:0]: Trigger Input Edge Selection Bits

- These bits select the valid edge for an input waveform as an external start factor, and they set trigger conditions.
- For the initial value or the 0b00 setting, no valid edge is selected for an input waveform, so no external waveform causes a start.

Note:

- If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.

- Modify EGS1 and EGS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits		Description
0	0	Trigger input invalid
0	1	Rising edge
1	0	Falling edge
1	1	Both edges

Timer Control Register (Lower Byte of TMCR)

bit	7	6	5	4	3	2	1	0
Field	Reserved	FMD2	FMD1	FMD0	OSEL	MDSE	CTEN	STRG
R/W Attribute	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6:4] FMD[2:0]: Timer Function Selection Bits

- These bits select the timer function.
- If 0b001 is set in the FMD2 to FMD0 bits, the PWM function is selected.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits			Description
0	0	0	Reset mode
0	0	1	16-bit PWM timer
0	1	0	16-bit PPG timer
0	1	1	16/32-bit reload timer
1	0	0	16/32-bit PWC timer
1	0	1	Setting prohibited
1	1	0	
1	1	1	

[bit3] OSEL: Output Polarity Specification Bit

- This bit sets the PWM output polarity.

Polarity	After Reset	Duty Match	Underflow
Normal	"L" output		
Inverse	"H" output		

Bit	Description
0	Normal polarity
1	Inverse polarity

[bit2] MDSE: Mode Selection Bit

- This bit selects either operation for continuous pulse output or one-shot operation for single-pulse output.
- Modify the bit while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bit	Description
0	Continuous operation
1	One-shot operation

[bit1] CTEN: Count Operation Enable Bit

- This bit enables operation of the down counter.
- If "0" is written to this bit when counter operation is enabled (CTEN bit is "1"), the counter stops.

Bit	Description	
	Read	Write
0	Stop operation.	Set this bit to "0".
1	Enable operation.	Set this bit to "1".

[bit0] STRG: Software Trigger Bit

- If "1" is written to the STRG bit when the CTEN bit is "1", a software trigger is applied.
- The read value of the STRG bit is always "0".

Notes:

- Even if "1" is written to the CTEN and STRG bits at the same time, a software trigger is applied.
- If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.

Bit	Description
0	Invalid
1	Startup by software

Timer Control Register 2 (TMCR2)

bit	15	14	13	12	11	10	9	8
Field	Reserved							CKS3
R/W Attribute	R0,W0							R/W
Protection Attribute	-							-
Initial Value	0000000							0

Note: This register is located in the upper byte of the STC register.

[bit15:9] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit8] CKS3: Count Clock Selection Bit

See "Count clock selection bits" in See "Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS)."

Status Control Register (STC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIE	DTIE	UDIE	Reserved	TGIR	DTIR	UDIR
R/W Attribute	R0,W0	R/W	R/W	R/W	R0,W0	R,WX	R,WX	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: The TMCR2 register is located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIE: Trigger Interrupt Request Enable Bit

- This bit controls interrupt requests of the trigger interrupt request bit (bit2 TGIR).
- If the TGIE bit is enabled and the TGIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:TGIEC bit clears this bit.
- Writing "1" to the STCS:TGIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit5] DTIE: Duty Match Interrupt Request Enable Bit

- This bit controls interrupt requests of the duty match interrupt request bit (bit1 DTIR).
- If the DTIE bit is enabled and the DTIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:DTIEC bit clears this bit.
- Writing "1" to the STCS:DTIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit4] UDIE: Underflow Interrupt Request Enable Bit

- This bit controls interrupt requests of the underflow interrupt request bit (bit0 UDIR).
- If the UDIE bit is enabled and the UDIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:UDIEC bit clears this bit.
- Writing "1" to the STCS:UDIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIR: Trigger Interrupt Request Bit

- The TGIR bit is set to "1" when a software trigger or trigger input is detected.
- Writing "1" to the STCC:TGIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

[bit1] DTIR: Duty Match Interrupt Request Bit

- The DTIR bit is set to "1" when the count value matches the duty setting value.
- Writing "1" to the STCC:DTIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

[bit0] UDIR: Underflow Interrupt Request Bit

- The UDIR bit is set to "1" when the count value underflows from 0x0000 to 0xFFFF.
- Writing "1" to the STCC:UDIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

Status Control Clear Register (STCC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIEC	DTIEC	UDIEC	Reserved	TGIRC	DTIRC	UDIRC
R/W Attribute	R0,W0	R0,W	R0,W	R0,W	R0,W0	R0,W	R0,W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIEC: Trigger Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:TGIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIE bit.

[bit5] DTIEC: Duty Match Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:DTIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the DTIE bit.

[bit4] UDIEC: Underflow Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:UDIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIE bit.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIRC: Trigger Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:TGIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIR bit.

[bit1] DTIRC: Duty Match Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:DTIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the DTIR bit.

[bit0] UDIRC: Underflow Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:UDIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIR bit.

Status Control Set Register (STCS)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIES	DTIES	UDIES	Reserved			
R/W Attribute	R0,W0	R0,W	R0,W	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-			
Initial Value	0	0	0	0	0000			

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIES: Trigger Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:TGIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the TGIE bit.

[bit5] DTIES: Duty Match Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:DTIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the DTIE bit.

[bit4] UDIES: Underflow Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:UDIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the UDIE bit.

[bit3-0] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

9.1.9. PWM Cycle Setting Register (PCSR)

The PWM cycle setting register (PCSR) is a register with a buffer for setting a cycle. There is a transfer to the timer register at the start time and at the underflow time.

bit	15	0
Field	PCSR[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXXXX	

These bits compose the register with a buffer for setting a cycle. There is a transfer to the timer register at the start time and at the underflow time.

When initializing and rewriting the cycle setting register, be sure to write to the duty setting register after writing to the cycle setting register.

- Use 16- or 32-bit data access for the PCSR register.
- After configuring the PWM function with the FMD2 to FMD0 bits in the TMCR register, set a cycle in the PCSR register.

9.1.10. PWM Duty Setting Register (PDUT)

The PWM duty setting register (PDUT) is a register with a buffer for setting a duty. An underflow causes a buffer transfer.

bit	15	0
Field	PDUT[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXX	

These bits compose the register with a buffer for setting a duty. An underflow causes a transfer from the buffer.

If the set values of the cycle setting register and duty setting register are the same value, the output for normal polarity is all "H", and the output for inverse polarity is all "L".

If PCSR < PDUT in the set values, the output for normal polarity is all "L", and the output for inverse polarity is all "H".

- Use 16- or 32-bit data access for the PDUT register.
- After configuring the PWM function with the FMD2 to FMD0 bits in the TMCR register, set a duty in the PDUT register.

9.1.11. Timer Register (TMR)

The timer register (TMR) can read the value of the 17-bit down counter.

bit	31	17	16
Field	Reserved		TMR[16]
R/W Attribute	R0,W0		R,WX
Protection Attribute	-		-
Initial Value	0x0000		0

bit	15	0
Field	TMR[15:0]	
R/W Attribute	R,WX	
Protection Attribute	-	
Initial Value	0x0000	

[bit31:17] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit16:0] TMR16 to TMR0: Timer Value Data Bits

The timer register can read the value of the 17-bit down counter that takes into account the start delay period.

- During trigger input, a value of "start delay period (PSDR) + PWM cycle (PCSR)" is reloaded into the TMR register.
- A value of "PWM cycle (PCSR)" is reloaded into the TMR register when an underflow occurs.
- Use 32-bit data access for the TMR register.

9.1.12. Start Delay Value Setting Register (PSDR)

The start delay value setting register (PSDR) sets a start delay value for the start delay function.

bit	15	0
Field	PSDR[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	0x0000	

The PSDR[15:0] bits set a start delay value to delay the start of the PWM timer after trigger input.

- To not use the start delay function, set the PSDR[15:0] bits to 0x0000.
- No PWM waveform is output during start delay control period after trigger input.
- After configuring the PWM function with the FMD2 to FMD0 bits in the TMCR register, set a cycle in the PSDR register.
- Use 16- or 32-bit data access for the PSDR register.
- Any modification to the PSDR[15:0] bits is reflected immediately after the setting is changed. Set the PSDR[15:0] bits while counting is stopped (TMCR:CTEN= 0).

9.1.13. ADC Trigger Value Setting Register (ADTR)

The ADC trigger value setting register (ADTR) sets the time for ADC trigger output.

bit	15	0
Field	ADTR[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	0x0000	

The ADC trigger is output when the 16-bit down counter is compared with the ADTR[15:0] bits and they match.

- For the ADTR register, set a value equal to or less than the PCSR[15:0] bits in the PCSR register.
- Use 16- or 32-bit data access for the ADTR register.
- After configuring the PWM function with the FMD2 to FMD0 bits in the TMCR register, set a cycle in the ADTR register.

9.2. PPG Timer Function

Only one of the following timer functions can be selected for the base timer in the FMD2 to FMD0 bit settings in the timer control register (TMCR): 16-bit PWM timer, 16-bit PPG timer, 16/32-bit reload timer, and 16/32-bit PWC timer. This section explains the timer function with the PPG setting.

1. 16-Bit PPG Timer Operation
2. Continuous Operation
3. One-Shot Operation
4. Interrupt Factors and Timing Chart
5. PPG Timer Operation Flow
6. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PPG Timer is Selected
7. L Width Setting Reload Register (PRLl)
8. H Width Setting Reload Register (PRLH)
9. Timer Register (TMR)

9.2.1. 16-Bit PPG Timer Operation

PPG timer operation can control output pulses by using the L width and H width settings for the output pulses in the respective reload registers.

Overview of Operation

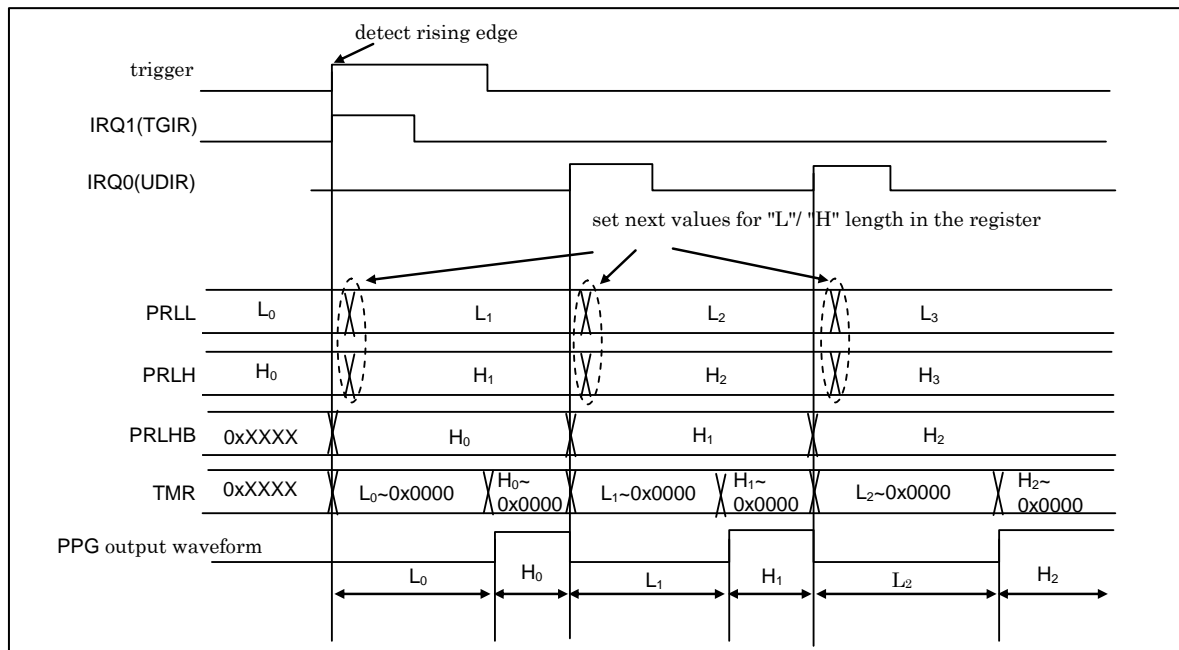

There are two 16-bit reload registers for the L width and H width settings and one buffer for the H width setting (PRLl, PRLH, and PRLHB).

An activation trigger first causes loading of the set value of PRLl into the 16-bit down counter. At the same time, the set value of PRLH is transferred to PRLHB. The PPG output level changes to L, and each count clock counts down. The detection of an underflow causes reloading of the PRLHB value into the counter and inversion of the PPG output waveform. Meanwhile, each count clock counts down. The detection of another underflow causes inversion of the PPG output waveform, reloading of the set value of PRLl into the counter, and transfer of the set value of PRLH to PRLHB.

The pulse output by the output waveform from this operation has an L width and H width corresponding to each reload register value.

Timing of Writing to Reload Registers

Data is written to the reload registers PRLl and PRLH when an activation trigger is detected during the period after the underflow interrupt factor (UDIR) is set to "1" and before the change to the next cycle. The data that is set at this time is the settings for the next cycle. The set data in PRLl and PRLH is automatically transferred to TMR and PRLHB, respectively, when an activation trigger is detected or when an underflow occurs at the H width count end time. The data transferred to PRLHB is automatically reloaded into TMR when an underflow occurs at the L width count end time.

9.2.2. Continuous Operation

In continuous operation, pulses can be output continuously through updating of the L width and H width at the set timing for each interrupt factor. If restart is enabled, the counter is reloaded when an edge is detected during operation.

Continuous Operation

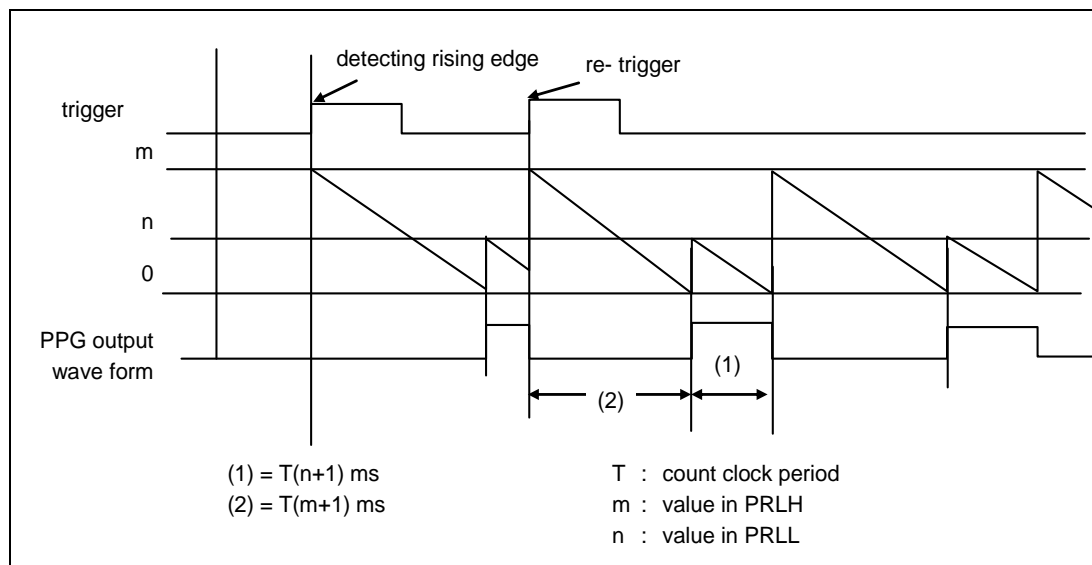

When Restart is Disabled (RTGEN=0)

Figure 9-15 PPG Operation Timing Chart (When Restart is Disabled)

When Restart is Enabled (RTGEN=1)

Figure 9-16 PPG Operation Timing Chart (When Restart is Enabled)

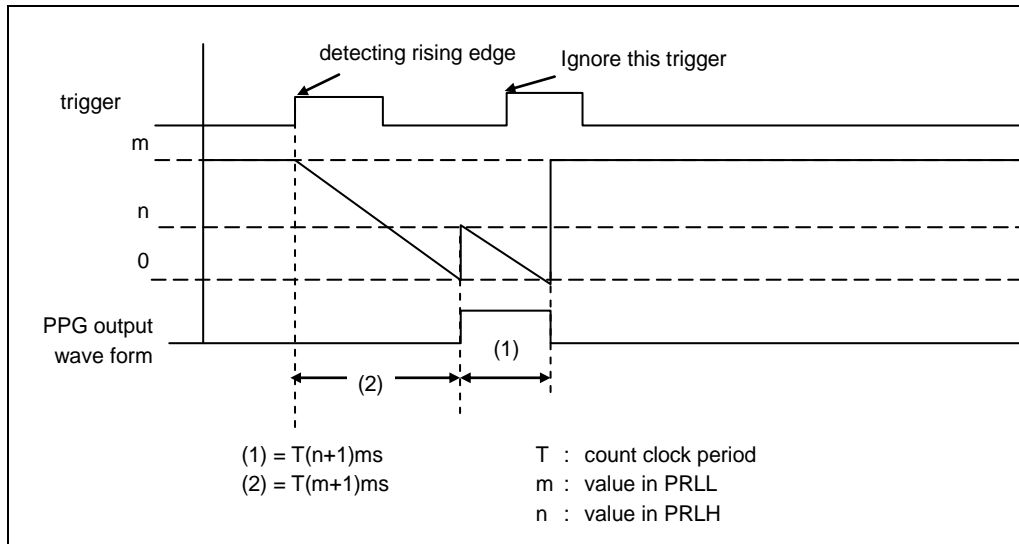

9.2.3. One-Shot Operation

In one-shot operation, a trigger can cause the output of a single pulse of any width. If restart is enabled, the counter is reloaded when an edge is detected during operation.

One-Shot Operation

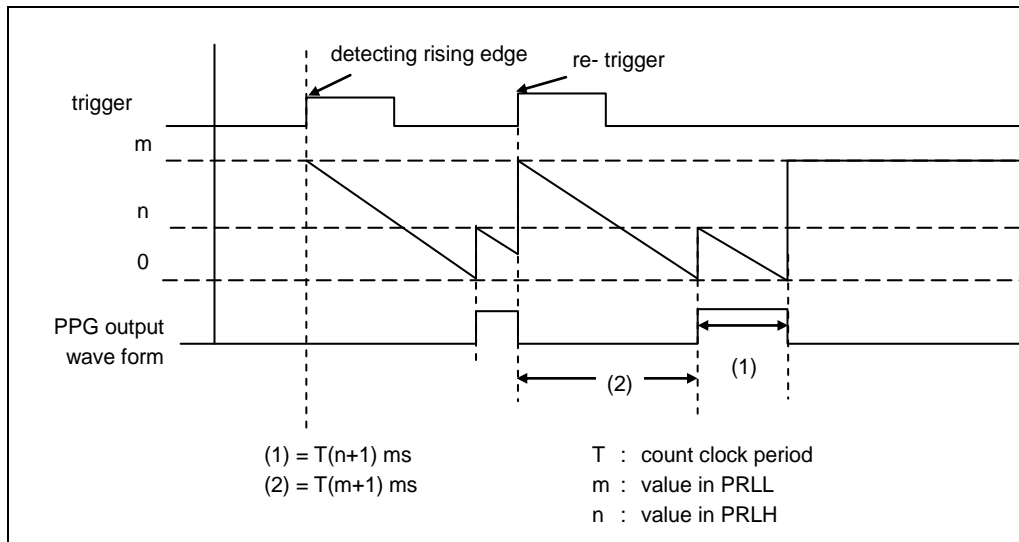

When Restart is Disabled (RTGEN=0)

Figure 9-17 One-Shot Operation Timing Chart (Trigger Restart Disabled)

When Restart is Enabled (RTGEN=1)

Figure 9-18 One-Shot Operation Timing Chart (Trigger Restart Enabled)

Relationship between Reload Value and Pulse Width

The output pulse width is the following value: 1 is added to the value written to the 16-bit reload register, and the sum is multiplied by the cycles of the count clock. Therefore, the pulse width of 1 cycle of the count clock is the value when the reload register value is 0x0000. The pulse width of 65536 cycles of the count clock is the value when the reload register value is 0xFFFF. The pulse width calculation formula is as follows.

$$\begin{aligned} PL &= T \times (L + 1) & PL: L \text{ pulse width} \\ PH &= T \times (H + 1) & PH: H \text{ pulse width} \end{aligned}$$

T: Count clock cycle
L: PRLl value
H: PRLH value

9.2.4. Interrupt Factors and Timing Chart

This section shows interrupt factors and a timing chart.

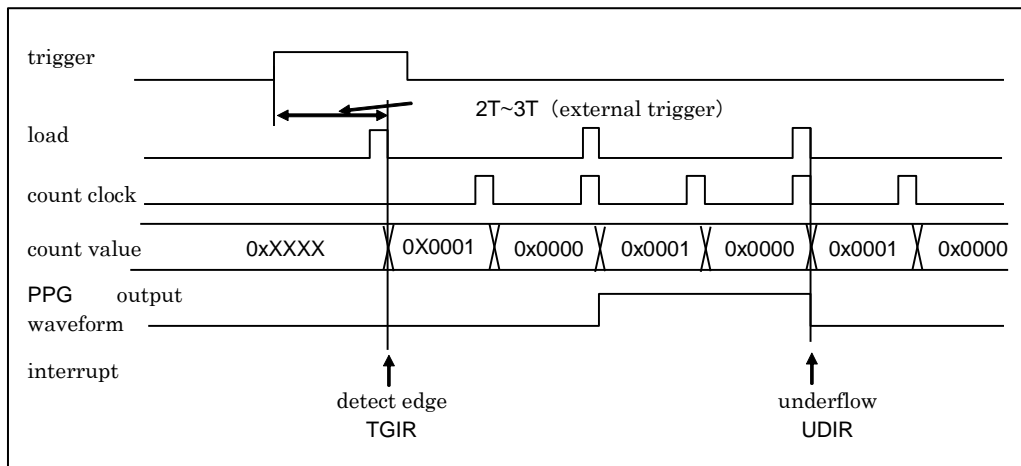

Interrupt Factors and Timing Chart (PPG Output: Normal Polarity)

For the period from trigger application until the loading of a counter value, the required software trigger time is T , and the required external trigger time is $2T$ to $3T$ (T : Internal clock cycle).

An interrupt factor is generated when a PPG activation trigger is detected or when an underflow is detected at the H level output time.

Figure 9-19 shows the interrupt factors and a timing chart where the L width setting value is 1 and the H width setting value is 1.

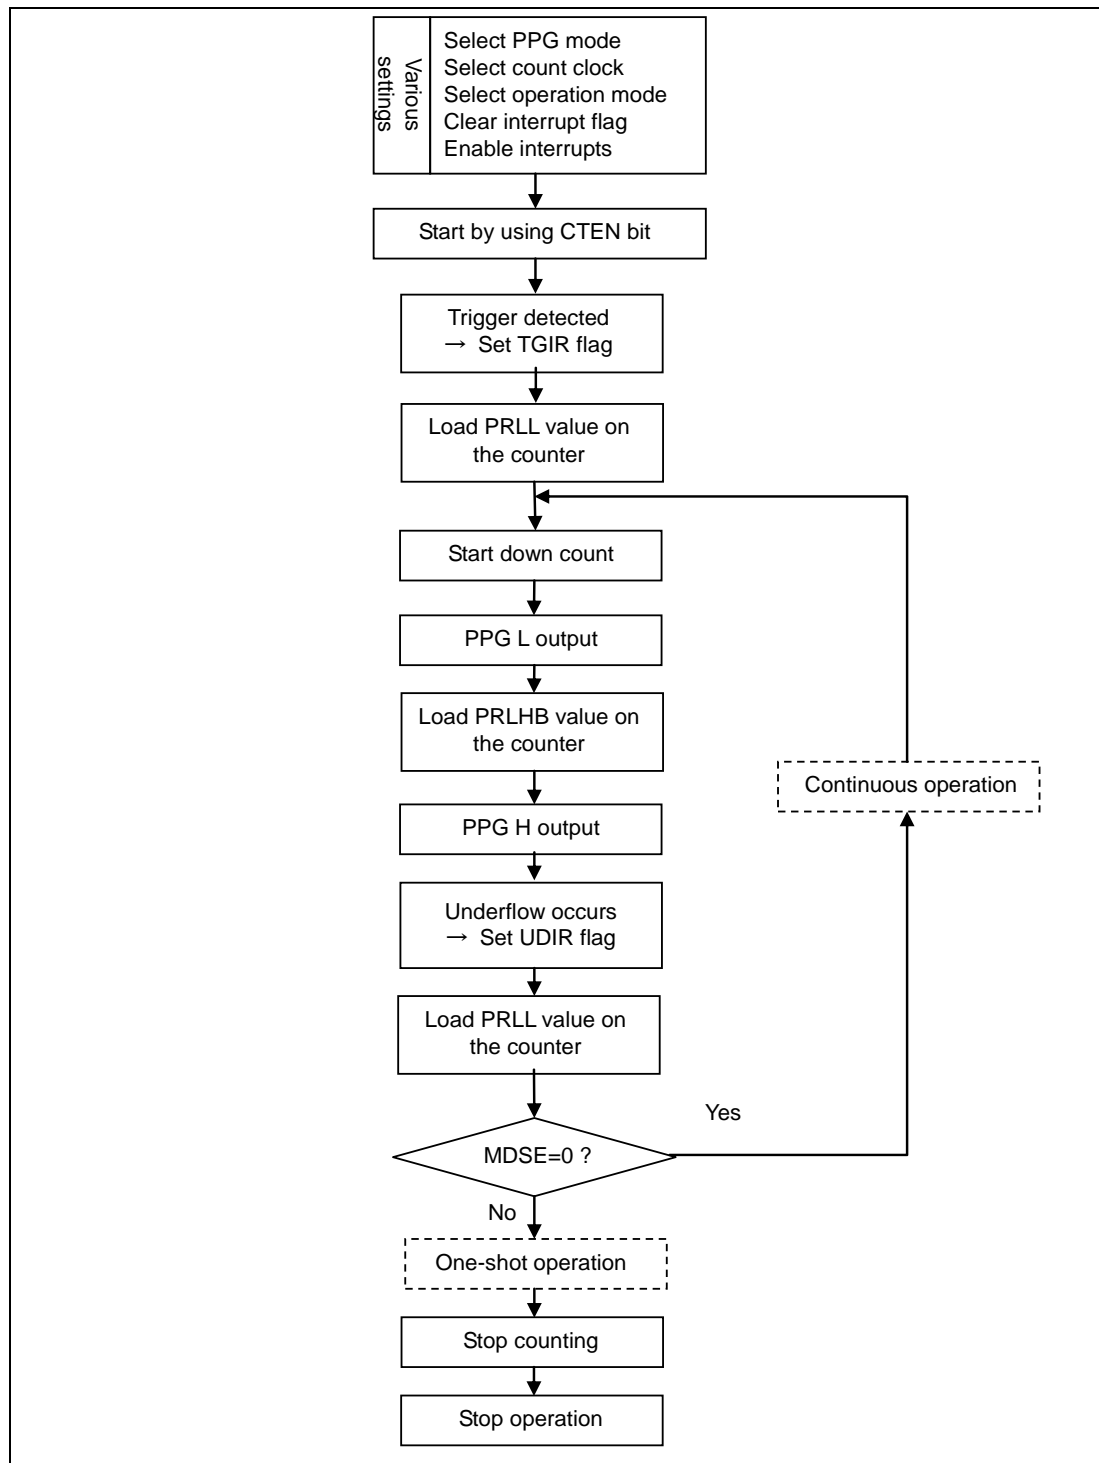

Figure 9-19 PPG Timer Interrupt Factors and Timing Chart

9.2.5. PPG Timer Operation Flow

This section shows the PPG timer operation flow.

PPG Timer Operation Flow

9.2.6. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PPG Timer is Selected

For details on writing to the status control register (STC), see "CHAPTER 40:8. Notes on Using the Base Timer."

Timer Control Register (Upper Byte of TMCR)

bit	15	14	13	12	11	10	9	8
Field	Reserved	CKS2	CKS1	CKS0	RTGEN	PMSK	EGS1	EGS0
R/W Attribute	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[TMCR2:bit8,bit14:12] CKS[3:0]: Count Clock Selection Bits

- These bits select a count clock for the 16-bit down counter.
- Any modification to the count clock is reflected immediately after the setting is changed. Therefore, modify CKS3 to CKS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Use of PWM Start Delay Mode and ADC Trigger Mode

Bits				Description
0	0	0	0	Internal clock
0	0	0	1	Internal clock divided by 4
0	0	1	0	Internal clock divided by 16
0	0	1	1	Internal clock divided by 128
0	1	0	0	Internal clock divided by 256
0	1	0	1	External clock (rising-edge event)
0	1	1	0	External clock (falling-edge event)
0	1	1	1	External clock (both-edges event)
1	0	0	0	Internal clock divided by 512
1	0	0	1	Internal clock divided by 1024
1	0	1	0	Internal clock divided by 2048
1	0	1	1	Internal clock divided by 2
1	1	0	0	Internal clock divided by 8
1	1	0	1	Internal clock divided by 32
1	1	1	0	Internal clock divided by 64
1	1	1	1	Setting prohibited

[bit11] RTGEN: Restart Enable Bit

This bit enables restart by a software trigger or trigger input.

Bit	Description
0	Disable restart.
1	Enable restart.

[bit10] PMSK: Pulse Output Mask Bit

- This bit controls the output waveform level of the PPG output waveform.
- When the bit is "0", the PPG waveform is output as is.
- When the bit is "1", PPG output is masked to L output regardless of the cycle or duty setting value.

Note:

- If the output polarity specification bit (OSEL) in the timer control register (lower byte of TMCR) is set for inverted output, setting the PMSK bit to "1" results in masking to H output.

Bit	Description
0	Normal output
1	Fixed at L output

[bit9:8] EGS[1:0]: Trigger Input Edge Selection Bits

- These bits select the valid edge for an input waveform as an external start factor, and they set trigger conditions.
- For the initial value or the 0b00 setting, no valid edge is selected for an input waveform, so no external waveform causes a start.

Note:

- If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.

- Modify EGS1 and EGS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits		Description
0	0	Trigger input invalid
0	1	Rising edge
1	0	Falling edge
1	1	Both edges

Timer Control Register (Lower Byte of TMCR)

bit	7	6	5	4	3	2	1	0

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6:4] FMD[2:0]: Timer Function Selection Bits

- These bits select the timer function.
- If 0b010 is set in the FMD2 to FMD0 bits, the PPG function is selected.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits			Description
0	0	0	Reset mode
0	0	1	16-bit PWM timer
0	1	0	16-bit PPG timer
0	1	1	16/32-bit reload timer
1	0	0	16/32-bit PWC timer
1	0	1	Setting prohibited
1	1	0	
1	1	1	

[bit3] OSEL: Output Polarity Specification Bit

- This bit sets the PPG output polarity.

Polarity	After Reset	L Width Count End	H Width Count End
Normal	"L" output		
Inverse	"H" output		

Bit	Description
0	Normal polarity
1	Inverse polarity

[bit2] MDSE: Mode Selection Bit

- This bit selects either operation for continuous pulse output or one-shot operation for single-pulse output.
- Modify the bit while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bit	Description
0	Continuous operation
1	One-shot operation

[bit1] CTEN: Count Operation Enable Bit

- This bit enables operation of the down counter.
- If "0" is written to this bit when counter operation is enabled (CTEN bit is "1"), the counter stops.

Bit	Description	
	Read	Write
0	Stop operation.	Set this bit to "0".
1	Enable operation.	Set this bit to "1".

[bit0] STRG: Software Trigger Bit

- If "1" is written to the STRG bit when the CTEN bit is "1", a software trigger is applied.
- The read value of the STRG bit is always "0".

Notes:

- Even if "1" is written to the CTEN and STRG bits at the same time, a software trigger is applied.
- If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.

Bit	Description
0	Invalid
1	Startup by software

Timer Control Register 2 (TMCR2)

bit	15	14	13	12	11	10	9	8
Field	Reserved							CKS3
R/W Attribute	R0,W0							R/W
Protection Attribute	-							-
Initial Value	0000000							0

Note: This register is located in the upper byte of the STC register.

[bit15:9] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit8] CKS3: Count Clock Selection Bit

See "Count clock selection bits" in "9.2.6Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PPG Timer is Selected."

Status Control Register (STC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIE	Reserved	UDIE	Reserved	TGIR	Reserved	UDIR
R/W Attribute	R0,W0	R/W	R0,W0	R/W	R0,W0	R,WX	R0,W0	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: The TMCR2 register is located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIE: Trigger Interrupt Request Enable Bit

- This bit controls interrupt requests of the trigger interrupt request bit (bit2 TGIR).
- If the TGIE bit is enabled and the TGIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:TGIEC bit clears this bit.
- Writing "1" to the STCS:TGIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIE: Underflow Interrupt Request Enable Bit

- This bit controls interrupt requests of the underflow interrupt request bit (bit0 UDIR).
- If the UDIE bit is enabled and the UDIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:UDIEC bit clears this bit.
- Writing "1" to the STCS:UDIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIR: Trigger Interrupt Request Bit

- The TGIR bit is set to "1" when a software trigger or trigger input is detected.
- Writing "1" to the STCC:TGIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

[bit1] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit0] UDIR: Underflow Interrupt Request Bit

- During counting from the set H width value, the UDIR bit is set to "1" when the count value underflows and changes from 0x0000 to 0xFFFF.
- Writing "1" to the STCC:UDIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

Status Control Clear Register (STCC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIEC	Reserved	UDIEC	Reserved	TGIRC	Reserved	UDIRC
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0	R0,W	R0,W0	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIEC: Trigger Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:TGIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIEC: Underflow Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:UDIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIE bit.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIRC: Trigger Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:TGIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIR bit.

[bit1] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit0] UDIRC: Underflow Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:UDIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIR bit.

Status Control Set Register (STCS)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIES	Reserved	UDIES	Reserved			
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-			
Initial Value	0	0	0	0	0000			

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIES: Trigger Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:TGIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the TGIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIES: Underflow Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:UDIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the UDIE bit.

[bit3:0] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

9.2.7. L Width Setting Reload Register (PRL)

The L width setting reload register (PRL) is the register used to set the L width of the PPG output waveform. An underflow at the activation trigger detection time or after the end of H width counting causes a transfer to the timer register.

bit	15	0
Field	PRL[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXX	

These bits compose the register used to set the L width of the PPG output waveform. An underflow at the activation trigger detection time or H width count end time causes a transfer to the timer register.

- Use 16- or 32-bit data access for the PRL register.
- After configuring the PPG function with the FMD2 to FMD0 bits in the TMCR register, set the L width in the PRL register.

9.2.8. H Width Setting Reload Register (PRLH)

The H width setting reload register (PRLH) is the register with a buffer used to set the H width of the PPG output waveform. An underflow when an activation trigger is detected or after H width counting ends causes a transfer from PRLH to the buffer register. An underflow at the L width count end time causes a transfer from the buffer register to the timer register.

bit	15	0
Field	PRLH[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXX	

These bits compose the register used to set the H width of the PPG output waveform. An underflow at the activation trigger detection time or H width count end time causes a transfer from PRLH to the buffer register. An underflow at the L width count end time causes a transfer from the buffer register to the timer register.

- Use 16- or 32-bit data access for the PRLH register.
- After configuring the PPG function with the FMD2 to FMD0 bits in the TMCR register, set the H width in the PRLH register.

9.2.9. Timer Register (TMR)

The timer register (TMR) can read the value of the 16-bit down counter.

bit	15	0
Field	TMR[15:0]	
R/W Attribute	R,WX	
Protection Attribute	-	
Initial Value	0x0000	

The timer register can read the value of the 16-bit down counter.

- Use 16- or 32-bit data access for the TMR register.

9.3. Reload Timer Function

Only one of the following timer functions can be selected for the base timer in the FMD2 to FMD0 bit settings in the timer control register (TMCR): 16-bit PWM timer, 16-bit PPG timer, 16/32-bit reload timer, and 16/32-bit PWC timer. This section explains the timer function with the reload timer setting.

1. Operations of 16-Bit Reload Timer
2. Reload Timer Operation Flow
3. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the Reload Timer is Selected
4. Cycle Setting Register (PCSR)
5. Timer Register (TMR)

9.3.1. Operations of 16-Bit Reload Timer

The reload timer operates by performing a countdown from the set value in the cycle setting register, in synchronization with the count clock. When the count value becomes 0, the counting ends, or the timer automatically loads the cycle setting to continue operating until the countdown is stopped.

Count Operation When Internal Clock is Selected

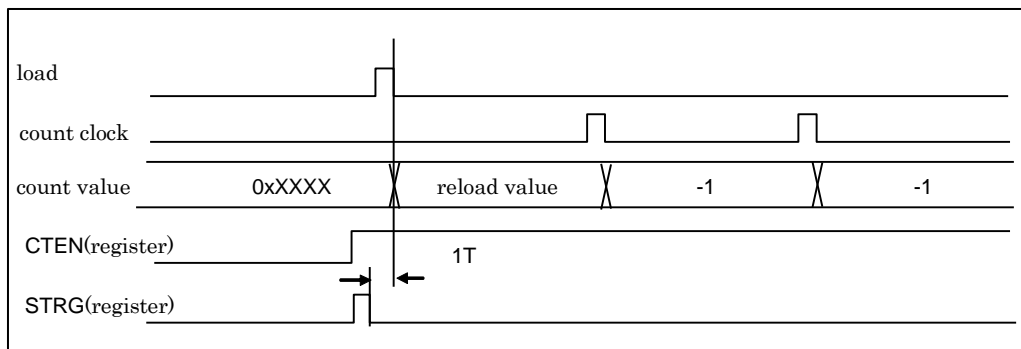

To start a count operation at the same time as counting is enabled, write "1" to both the CTEN bit and STRG bit in the timer control register. In a state where the timer has started (CTEN= 1), trigger input with the STRG bit is always enabled regardless of the operation mode.

With count operations enabled, the start of the timer by a software trigger or external trigger results in the cycle setting register value being loaded into the counter and a countdown being started.

The time required from the generation of a counter start trigger until the loading of cycle setting register data into the counter is 1T (T: Internal clock cycle).

Figure 9-20 shows the start and operation of the counter using a software trigger.

Figure 9-20 Count Operation When the Internal Clock is Selected

Underflow Operation

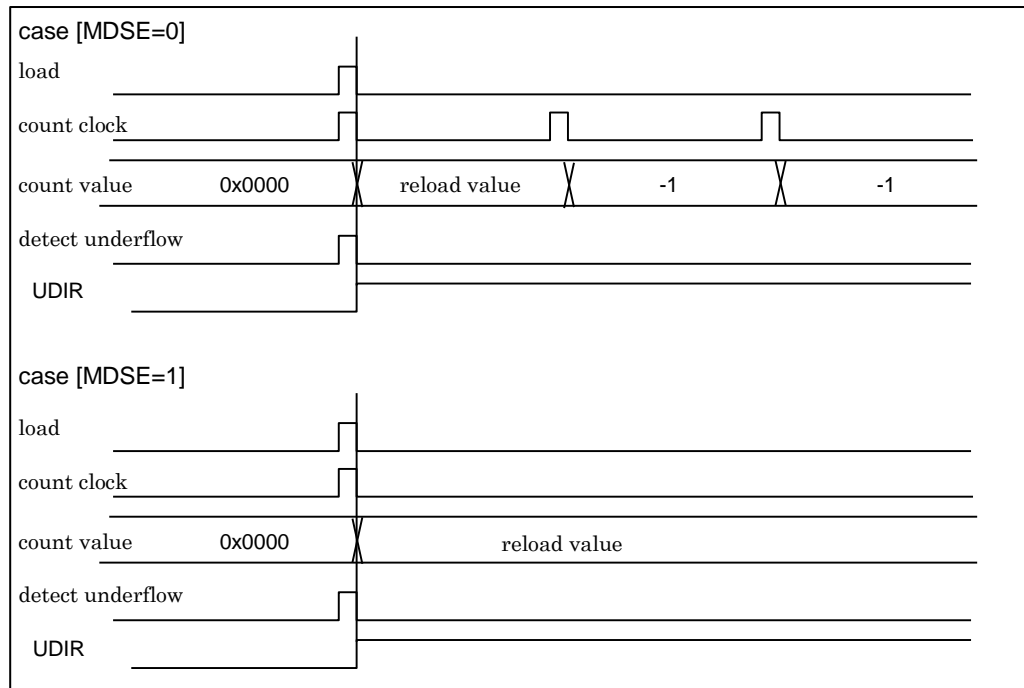

If the counter value changes from 0x0000 to 0xFFFF, an underflow has occurred. Therefore, an underflow occurs at the count of [set value of cycle setting register + 1].

The cycle setting register (PCSR) contents are loaded into the counter when an underflow occurs. If the MDSE bit in the timer control register (TMCR) is "0", the count operation continues. If the MDSE bit is "1", the count operation stops with the loaded counter value unchanged.

The UDIR bit in the status control register (STC) is set to "1" by an underflow. If the UDIE bit is "1" at this time, an interrupt request is generated.

Figure 9-21 shows an underflow operation timing chart.

Figure 9-21 Underflow Operation Timing Chart

Operation of Input Pin Function

If the trigger input function (TMCR2:GATE= 0) is selected, the TGIN pin can be used as trigger input. When a valid edge is input to the TGIN pin, the cycle setting register contents are loaded into the counter, and a count operation begins. For the period from trigger application until the loading of a counter value, the required time is $2T$ to $3T$ (T : internal clock cycle).

Figure 9-22 shows trigger input operation where the valid edge specification is a rising edge.

Figure 9-22 Trigger Input Operation (TMCR2:GATE= 0)

If the gate function (TMCR2:GATE= 1) is selected, the TGIN pin can be used as the gate function.

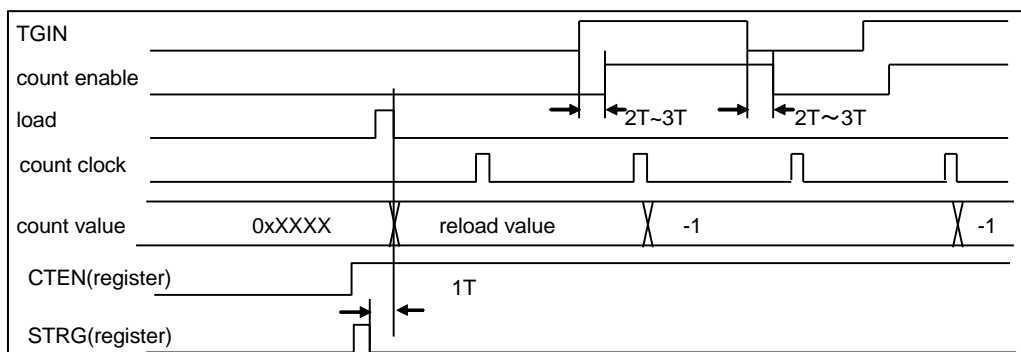

With count operations enabled (TMCR:CTEN= 1), the start of the timer by a software trigger (TMCR:STRG= 1) results in the cycle setting register (PCSR) value being loaded into the counter. The count clock counts down only for a period when a valid level is being input to the TGIN pin.

For synchronization of a signal input from the TGIN pin, the time required from the input of a valid level until count enable becomes effective is $2T$ to $3T$ for each of the start and end (T : internal clock cycle).

The gate function and trigger input function are controlled exclusively. Therefore, activation by an external event cannot be used when the gate function is in use.

Figure 9-23 shows gate function operation where the valid level is "H".

Figure 9-23 Gate Function Operation(TMCR2:GATE= 1)

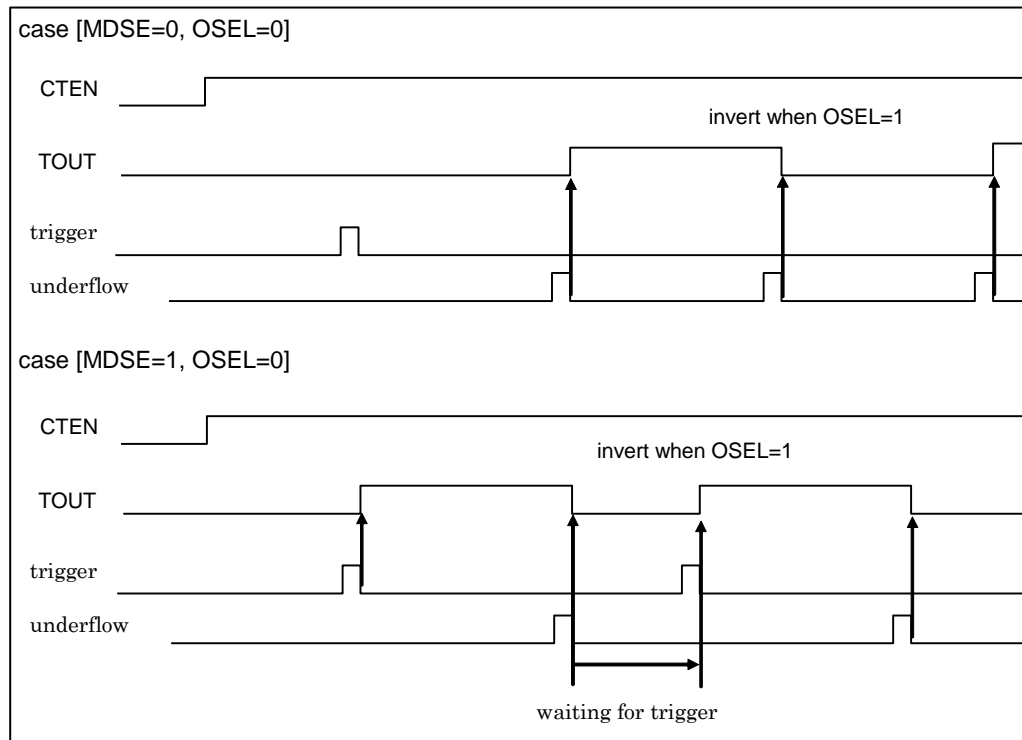

Operation of Output Pin Function

The TOUT output pin functions as toggle output in reload mode and as pulse output in one-shot mode. The toggle output is inverted by an underflow. The pulse output indicates that counting is in progress. The OSEL bit in the timer control register (TMCR) can set the output polarity. If OSEL is "0", the initial value is "0" for toggle output, and "1" is output during counting for one-shot pulse output. If OSEL is "1", the output waveform is inverted.

Figure 9-24 shows an output pin function operation timing chart.

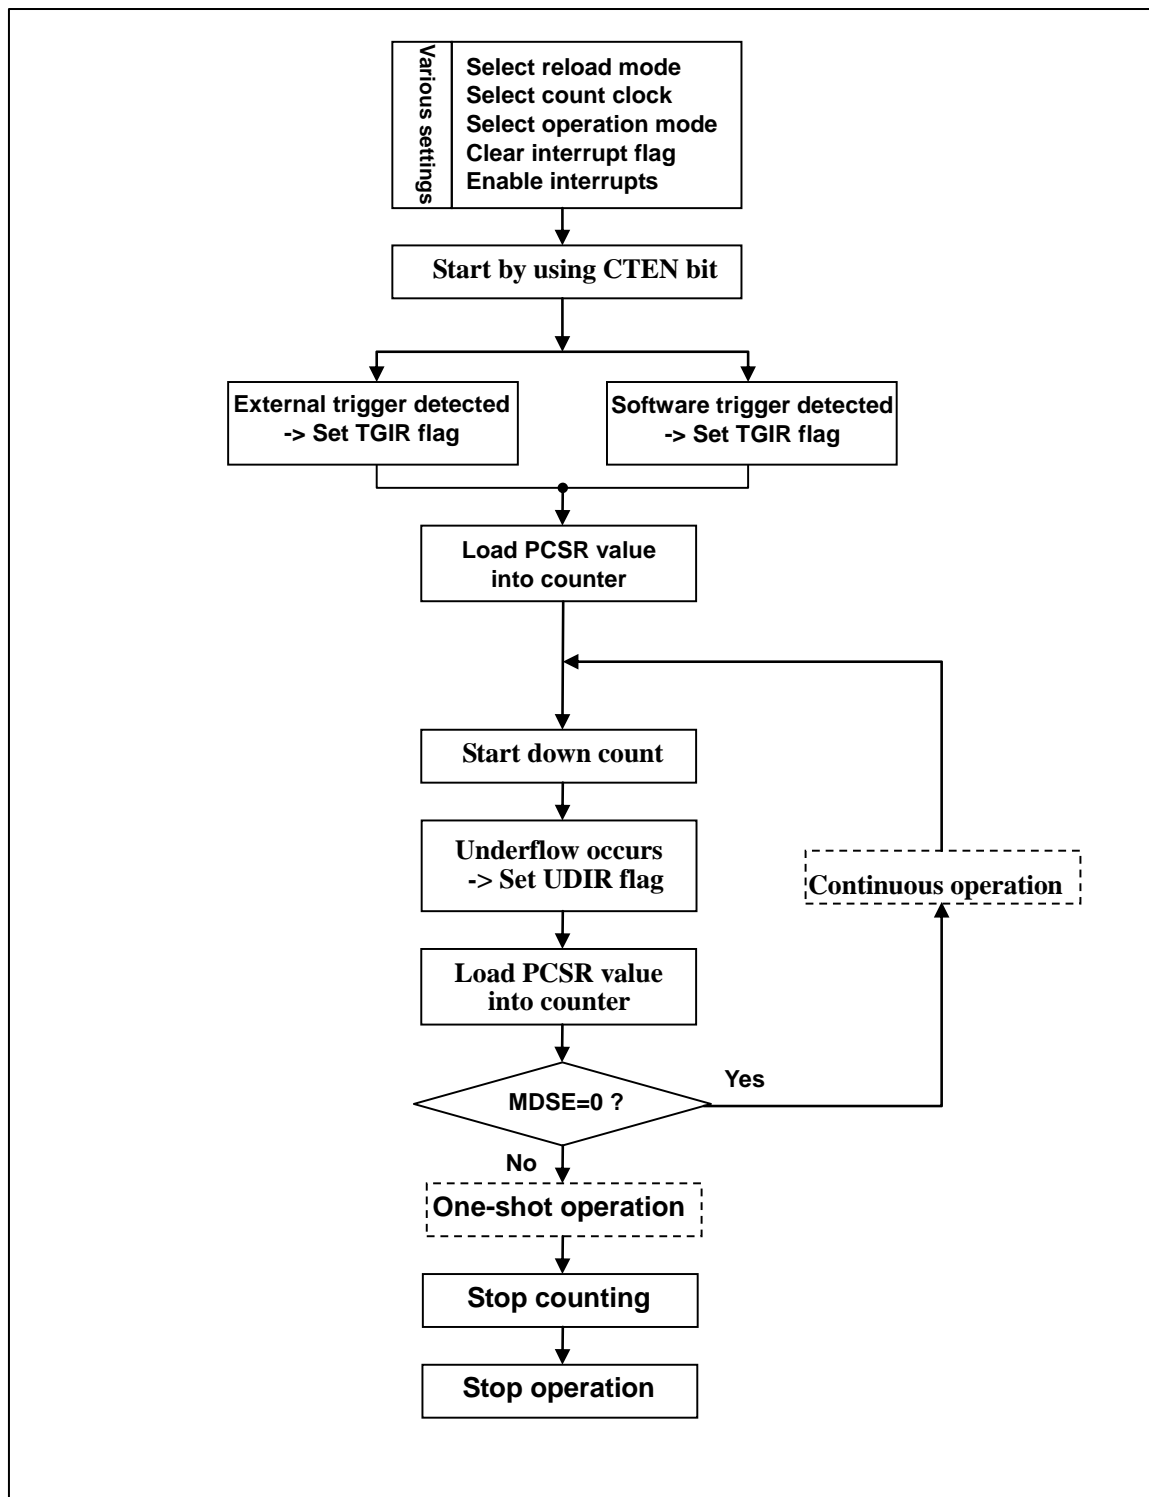

Figure 9-24 Output Pin Function Operation Timing Chart

9.3.2. Reload Timer Operation Flow

This section shows the reload timer operation flow.

Reload Timer Operation Flow

9.3.3. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the Reload Timer is Selected

The timer control register (TMCR) controls timer operation.

For details on writing to the status control register (STC), see "CHAPTER 40:8. Notes on Using the Base Timer."

Timer Control Register (Upper Byte of TMCR)

bit	15	14	13	12	11	10	9	8
Field	Reserved	CKS2	CKS1	CKS0	Reserved		EGS1	EGS0
R/W Attribute	R0,W0	R/W	R/W	R/W	R0,W0		R/W	R/W
Protection Attribute	-	-	-	-	-		-	-
Initial Value	0	0	0	0	00		0	0

[bit15] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[TMCR2:bit8,bit14:12] CKS[3:0]: Count Clock Selection Bits

- These bits select a count clock for the 16-bit down counter.
- Any modification to the count clock is reflected immediately after the setting is changed. Therefore, modify CKS3 to CKS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits				Description
0	0	0	0	Internal clock
0	0	0	1	Internal clock divided by 4
0	0	1	0	Internal clock divided by 16
0	0	1	1	Internal clock divided by 128
0	1	0	0	Internal clock divided by 256
0	1	0	1	External clock (rising-edge event)
0	1	1	0	External clock (falling-edge event)
0	1	1	1	External clock (both-edges event)
1	0	0	0	Internal clock divided by 512
1	0	0	1	Internal clock divided by 1024
1	0	1	0	Internal clock divided by 2048
1	0	1	1	Internal clock divided by 2
1	1	0	0	Internal clock divided by 8
1	1	0	1	Internal clock divided by 32
1	1	1	0	Internal clock divided by 64
1	1	1	1	Setting prohibited

[bit11:10] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit9:8] EGS[1:0]: Trigger Input Edge and Gate Function Level Selection Bits

- Trigger input selected (TMCR2:GATE= 0)
 - These bits select the valid edge for an input waveform as an external start factor, and they set trigger conditions.
 - For the initial value or the 0b00 setting, no valid edge is selected for an input waveform, so no external waveform causes a start.
- Gate function selected (TMCR2:GATE= 1)
 - These bits select a valid level corresponding to an input waveform as an external count factor, and the down counter counts down only while the selected level is valid.

Note:

- *If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.*
- Modify EGS1 and EGS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits		Description	
		Trigger Input Selected (TMCR2:GATE= 0)	Gate Function Selected (TMCR2:GATE= 1)
0	0	Trigger input invalid	"L" level
0	1	External trigger(rising edge)	"H" level
1	0	External trigger(falling edge)	"L" level
1	1	External trigger(both edges)	"H" level

Timer Control Register (Lower Byte of TMCR)

bit	7	6	5	4	3	2	1	0
Field	T32	FMD2	FMD1	FMD0	OSEL	MDSE	CTEN	STRG
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] T32: 32-Bit Timer Selection Bit

- This bit selects the 32-bit timer function.
- If the reload timer function is selected with 0b011 set in the FMD2 to FMD0 bits, setting the T32 bit to "1" results in operation in 32-bit timer mode.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bit can be modified at the same time as "1" is written to the CTEN bit. (See 32-Bit Mode Operation.)

Bit	Description
0	16-bit timer mode
1	32-bit timer mode

[bit6:4] FMD[2:0]: Timer Function Selection Bits

- These bits select the timer function.
- If 0b011 is set in the FMD2 to FMD0 bits, the reload timer function is selected.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits			Description
0	0	0	Reset mode
0	0	1	16-bit PWM timer
0	1	0	16-bit PPG timer
0	1	1	16/32-bit reload timer
1	0	0	16/32-bit PWC timer
Other than above			Setting prohibited

[bit3] OSEL: Output Polarity Specification Bit

- This bit selects either normal or inverse output as the timer output level.
- When combined with the mode selection bit (bit2 MDSE), this bit generates an output waveform as follows.

MDSE	OSEL	Output Waveform
0	0	Toggle output of "L" at the count start time
0	1	Toggle output of "H" at the count start time
1	0	Rectangular output of "H" during counting
1	1	Rectangular output of "L" during counting

Bit	Description
0	Normal polarity
1	Inverse polarity

[bit2] MDSE: Mode Selection Bit

- If the MDSE bit is set to "0", reload mode is selected. The cycle setting register (PCSR) value is loaded into the counter at the same time that the count value underflows from 0x0000 to 0xFFFF, and the count operation continues.
- If the MDSE bit is set to "1", one-shot mode is selected. When the count value underflows from 0x0000 to 0xFFFF, operation stops.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bit	Description
0	Reload mode
1	One-shot mode

[bit1] CTEN: Timer Enable Bit

- This bit enables operation of the down counter.
- If "0" is written to this bit when counter operation is enabled (CTEN bit is "1"), the counter stops.

Bit	Description	
	Read	Write
0	Stop operation.	Set this bit to "0".
1	Enable operation.	Set this bit to "1".

[bit0] STRG: Software Trigger Bit

- If "1" is written to the STRG bit when the CTEN bit is "1", a software trigger is applied.
- The read value of the STRG bit is always "0".

Notes:

- Even if "1" is written to the CTEN and STRG bits at the same time, a software trigger is applied.
- If "1" is written to the STRG bit, the software trigger becomes valid regardless of the EGS1 and EGS0 settings.

Bit	Description
0	Invalid
1	Startup by software

Timer Control Register 2 (TMCR2)

bit	15	14	13	12	11	10	9	8
Field	GATE	Reserved						CKS3
R/W Attribute	R/W	R0,W0						R/W
Protection Attribute	-	-						-
Initial Value	0	000000						0

Note: This register is located in the upper byte of the STC register.

[bit15] GATE: Gate Input Enable Bit

This bit selects whether to use the external factor pin for the trigger input function or gate function during reload timer operation.

- Trigger input function: A countdown begins when a valid edge is input to the external factor pin.
- Gate function: A countdown is performed only while a valid level is being input to the external factor pin.

After configuring the reload timer function with the FMD2 to FMD0 bits in the TMCR register, set the GATE bit.

Bit	Description
0	Trigger input function
1	Gate function

[bit14:9] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit8] CKS3: Count Clock Selection Bit

See "Count clock selection bits" in "9.3.Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the Reload Timer is Selected."

Status Control Register (STC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIE	Reserved	UDIE	Reserved	TGIR	Reserved	UDIR
R/W Attribute	R0,W0	R/W	R0,W0	R/W	R0,W0	R,WX	R0,W0	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: The TMCR2 register is located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIE: Trigger Interrupt Request Enable Bit

- This bit controls interrupt requests of the trigger interrupt request bit (bit2 TGIR).
- If the TGIE bit is enabled and the TGIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:TGIEC bit clears this bit.
- Writing "1" to the STCS:TGIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIE: Underflow Interrupt Request Enable Bit

- This bit controls interrupt requests of the underflow interrupt request bit (bit0 UDIR).
- If the UDIE bit is enabled and the UDIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:UDIEC bit clears this bit.
- Writing "1" to the STCS:UDIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIR: Trigger Interrupt Request Bit

- The TGIR bit is set to "1" when a software trigger or trigger input is detected.
- Writing "1" to the STCC:TGIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

[bit1] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit0] UDIR: Underflow Interrupt Request Bit

- The UDIR bit is set to "1" when the count value underflows and changes from 0x0000 to 0xFFFF.
- Writing "1" to the STCC:UDIRC bit clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

Status Control Clear Register (STCC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIEC	Reserved	UDIEC	Reserved	TGIRC	Reserved	UDIRC
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0	R0,W	R0,W0	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIEC: Trigger Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:TGIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIEC: Underflow Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:UDIE bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIE bit.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] TGIRC: Trigger Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:TGIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the TGIR bit.

[bit1] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit0] UDIRC: Underflow Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:UDIR bit is cleared to "0".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the UDIR bit.

Status Control Set Register (STCS)

bit	7	6	5	4	3	2	1	0
Field	Reserved	TGIES	Reserved	UDIES	Reserved			
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] TGIES: Trigger Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:TGIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the TGIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] UDIES: Underflow Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:UDIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the UDIE bit.

[bit3:0] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

9.3.4. Cycle Setting Register (PCSR)

The cycle setting register (PCSR) is a register that retains the initial count value. In 32-bit mode, this value for the even-numbered channel is the initial value of the lower 16-bit count. This value for the odd-numbered channel is the initial value of the upper 16-bit count. The initial value at the reset time is undefined. Be sure to access this register with 16- or 32-bit data transfer instructions.

bit	15	0
Field	PCSR[15:0]	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXXXX	

These bits compose the register used to set a cycle. An underflow causes a transfer to the timer register.

- Use 16- or 32-bit data access for the PCSR register.
- After configuring the reload timer function with the FMD2 to FMD0 bits in the TMCR register, set a cycle in the PCSR register.
- To write data to the PCSR register in 32-bit mode, access first the upper 16-bit data (data for the odd-numbered channel) and then the lower 16-bit data (data for the even-numbered channel).

9.3.5. Timer Register (TMR)

The timer register (TMR) is a register that can read the count value of a timer. In 32-bit mode, this value for the even-numbered channel is the value of the lower 16-bit count. This value for the odd-numbered channel is the value of the upper 16-bit count. The initial value is undefined.

Be sure to read this register with 16- or 32-bit data transfer instructions.

bit	15	0
Field	TMR[15:0]	
R/W Attribute	R,WX	
Protection Attribute	-	
Initial Value	XXXXXXXXXXXXXXXXXX	

The timer register can read the value of the 16-bit down counter.

- Use 16- or 32-bit data access for the TMR register.
- To read the TMR register in 32-bit mode, access first the lower 16-bit data (data for the even-numbered channel) and then the upper 16-bit data (data for the odd-numbered channel).

9.4. PWC Timer Function

Only one of the following timer functions can be selected for the base timer in the FMD2 to FMD0 bit settings in the timer control register (TMCR): 16-bit PWM timer, 16-bit PPG timer, 16/32-bit reload timer, and 16/32-bit PWC timer. This section explains the timer function with the PWC setting.

1. Operations of PWC Timer
2. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PWC Timer is Selected
3. Data Buffer Register (DTBF)

9.4.1. Operations of PWC Timer

The PWC timer has a pulse width measurement function. The timer can select twelve types of count clocks, and it can measure the time and cycle between any input pulse events by using a counter. This section shows the basic functions/operations of the pulse width measurement function.

Pulse Width Measurement Function

After the start, the function does not perform a count operation until the counter is cleared to 0x0000 and the set measurement start edge is input. The function starts counting up from 0x0001 when the measurement start edge is detected. It stops counting when the measurement end edge is detected. The count value at this time is stored as a pulse width in the register.

An interrupt request can be generated at the measurement end time and at the overflow occurrence time.

After measurement ends, the function operates according to the measurement mode as follows.

- In single measurement mode: It stops operating.
- In continuous measurement mode: It first transfers the counter value to the buffer register and then stops counting until the measurement start edge is input again.

Figure 9-25 Pulse Width Measurement Operation (Single Measurement Mode/"H" Width Measurement)

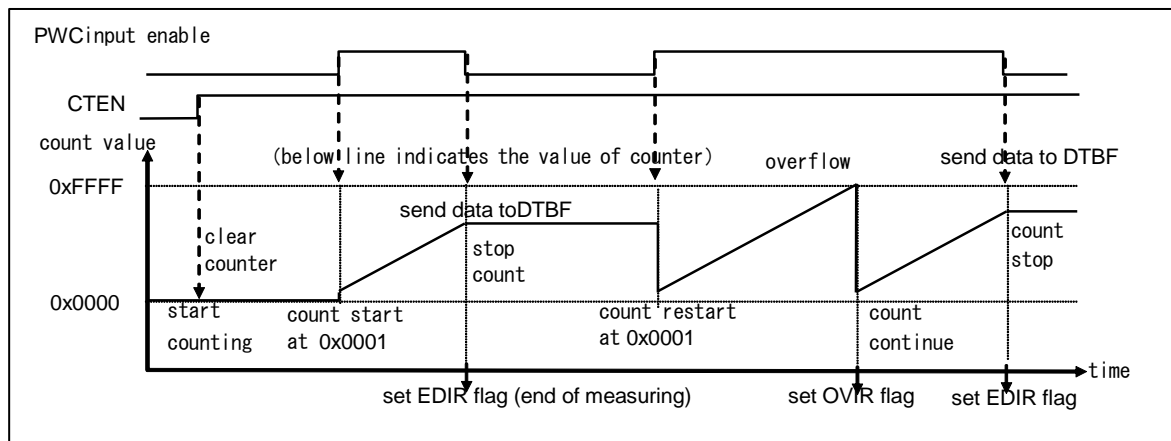

Figure 9-26 Pulse Width Measurement Operation (Continuous Measurement Mode/"H" Width Measurement)

Selection of Count Clock

Twelve types of count clocks can be selected for the counter through the setting of TMCr2 register bit8 (CKS3) and TMCr register bit14 to 12 (CKS2, CKS1, and CKS0).

The following count clocks can be selected.

TMCr2 and TMCr Registers	Internal Count Clock Selected
CKS3, CKS2, CKS1, and CKS0 Bits	
0000	Internal clock [initial value]
0001	Internal clock divided by 4
0010	Internal clock divided by 16
0011	Internal clock divided by 128
0100	Internal clock divided by 256
0101	Setting prohibited
0110	
0111	
1000	
1001	Internal clock divided by 512
1010	Internal clock divided by 1024
1011	Internal clock divided by 2048
1100	Internal clock divided by 2
1101	Internal clock divided by 8
1110	Internal clock divided by 32
1111	Internal clock divided by 64
	Setting prohibited

The initial value selected after a reset is the internal clock.

Be sure to select a count clock before starting the counter.

Selection of Operation Mode

To select each operation mode/measurement mode, set TMCR.

Operation mode setting ... TMCR bit10 to 8: EGS2, EGS1, EGS0 (Select a measurement edge.)

Measurement mode setting ... TMCR bit2: MDSE (Select single measurement/continuous measurement.)

The following table lists a selection of operation modes.

Operation Mode		MDSE	EGS2	EGS1	EGS0
Rising to falling H pulse width measurement	Continuous measurement mode: Buffer enabled	0	0	0	0
	Single measurement mode: Buffer disabled	1	0	0	0
Rising to rising Cycle measurement between rising edges	Continuous measurement mode: Buffer enabled	0	0	0	1
	Single measurement mode: Buffer disabled	1	0	0	1
Falling to falling Cycle measurement between falling edges	Continuous measurement mode: Buffer enabled	0	0	1	0
	Single measurement mode: Buffer disabled	1	0	1	0
Measurement between rising or falling and falling or rising	Continuous measurement mode: Buffer enabled	0	0	1	1
	Single measurement mode: Buffer disabled	1	0	1	1
Falling to rising L pulse width measurement	Continuous measurement mode: Buffer enabled	0	1	0	0
	Single measurement mode: Buffer disabled	1	1	0	0
Setting prohibited		0	1	0	1
		1	1	0	1
		0	1	1	0
		1	1	1	0
		0	1	1	1
		1	1	1	1

The initial values selected after a reset are H pulse width measurement and continuous measurement mode.

Be sure to select an operation mode before starting the counter.

Starting and Stopping Pulse Width Measurement

To start/restart/forcibly stop each operation, set bit1 (CTEN bit) in TMCR.

Pulse width measurement is started/restarted by the writing of "1" to the CTEN bit and forcibly stopped by the writing of "0" to the CTEN bit.

CTEN	Function
1	Start/Restart pulse width measurement.
0	Stop pulse width measurement.

Post-Start Operation

The operations after the start of pulse width measurement mode do not include counting until the measurement start edge is input. After the detection of the measurement start edge, the 16-bit up counter starts counting from 0x0001.

Restart

After the start, a repeated start performed during operation (writing "1" again in a state where the CTEN bit is "1") is called a "restart." The operation in any such restart is described below.

- In the measurement start edge wait state:
There is no effect on operation.
- During measurement:
The count is cleared to 0x0000. Then, the measurement start edge wait state begins again. If the measurement end edge is detected at the same time as a restart, the measurement end flag (EDIR) is set to "1". Then, if the mode is continuous measurement mode, the measurement results are transferred to DTBF.

About Stopping

In single measurement mode, the count operation is automatically stopped by a counter overflow or the end of measurement, so stopping it does not need to be a concern. In continuous measurement mode, to stop counting before counting is automatically stopped, you need to forcibly stop it.

Counter Clearing and Initial Value

The 16-bit up counter is cleared to 0x0000 in the following cases.

- Upon a reset
- When "1" is written to bit1 (CTEN bit) in TMCR (even including restart times)

The 16-bit up counter is initialized to 0x0001 in the following case.

- When the measurement start edge is detected

Pulse Width Measurement Operation Details

Single Measurement and Continuous Measurement

The modes for pulse width measurement are a mode where measurement is 1-time only and a mode where measurement is continuous. Each mode is selected with the MDSE bit in TMCR. (See "Selection of Operation .") The modes differ as described below.

Single measurement mode:

The first input of the measurement end edge stops the counting by the counter and sets the measurement end flag (EDIR) in STC to "1". No subsequent measurements are made. However, if a restart is performed at the same time, the mode enters the measurement start wait state.

Continuous measurement mode:

The input of the measurement end edge stops the counting by the counter and sets the measurement end flag (EDIR) in STC to "1". The counting remains stopped until the measurement start edge is input again. The counter is initialized to 0x0001 and measurement begins when the measurement start edge is input again. The measurement results of the counter are transferred to DTBF at the measurement end time.

Be sure to select/change the measurement mode while the counter is stopped.

Measurement Result Data

The handling of measurement results and counter values and the function of DTBF differ between single measurement mode and continuous measurement mode. The measurement results from each mode differ as described below.

Single measurement mode:

If DTBF is read during operation, the count value being measured is obtained.

If DTBF is read after measurement ends, the measurement result data is obtained.

Continuous measurement mode:

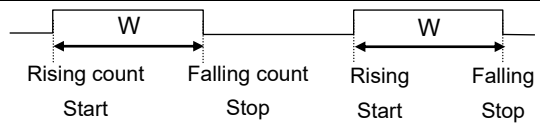

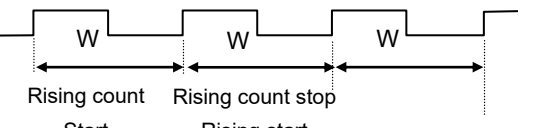

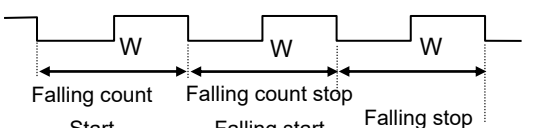

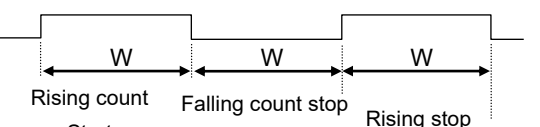

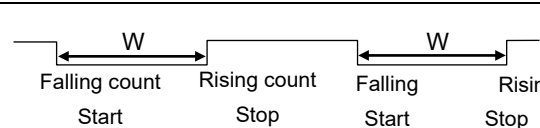

The measurement results of the counter are transferred to DTBF at the measurement end time. The immediately preceding measurement results are obtained when DTBF is read, and the last measurement results are retained even during a measurement operation. The count value being measured cannot be read.

In continuous measurement mode, if the next measurement ends before the measurement results are read, the last measurement results are overwritten by the new measurement results.

In such cases, the error flag (ERR) is set to "1" in STC. The error flag (ERR) is automatically cleared when DTBF is read.

Measurement Modes and Count Operations

The measurement mode can be selected from the following five types, depending on where the input pulse is measured. The following table explains them.

Measurement Mode	EGS2, 1, 0	Measurement Description (W: Pulse Width Measured)
H pulse width measurement	000	 <p>The width of the "H" period is measured. Count (measurement)start: Upon detection of a rising edge Count (measurement)end: Upon detection of a falling edge</p>
Cycle measurement between rising edges	001	 <p>The cycle between rising edges is measured. Count (measurement)start: Upon detection of a rising edge Count (measurement) end: Upon detection of a rising edge</p>
Cycle measurement between falling edges	010	 <p>The cycle between falling edges is measured. Count (measurement) start: Upon detection of a falling edge Count (measurement)end: Upon detection of a falling edge</p>
Pulse width measurement between all edges	011	 <p>The width between continuously input edges is measured. Count (measurement) start: Upon detection of an edge Count (measurement) end: Upon detection of an edge</p>
L pulse width measurement	100	 <p>The width of the "L" period is measured. Count (measurement) start: Upon detection of a falling edge Count (measurement) end: Upon detection of a rising edge</p>

In either measurement mode, after the counter is cleared to 0x0000 by the start of measurement, the counter does not do any counting until the measurement start edge is input. From the input of the measurement start edge, the counter continues counting up for each count clock until the measurement end edge is input.

For measurements such as pulse width measurement and cycle measurement between all edges in continuous measurement mode, the end edge is the next measurement start edge.

Pulse Width/Cycle Calculation Method

The method of calculating the pulse width/cycle from the obtained measurement result data in DTBF after measurement ends is shown below.

$$TW = n \times t$$

TW: Measured pulse width/cycle

n: Measurement result data in DTBF

t: Count clock cycle

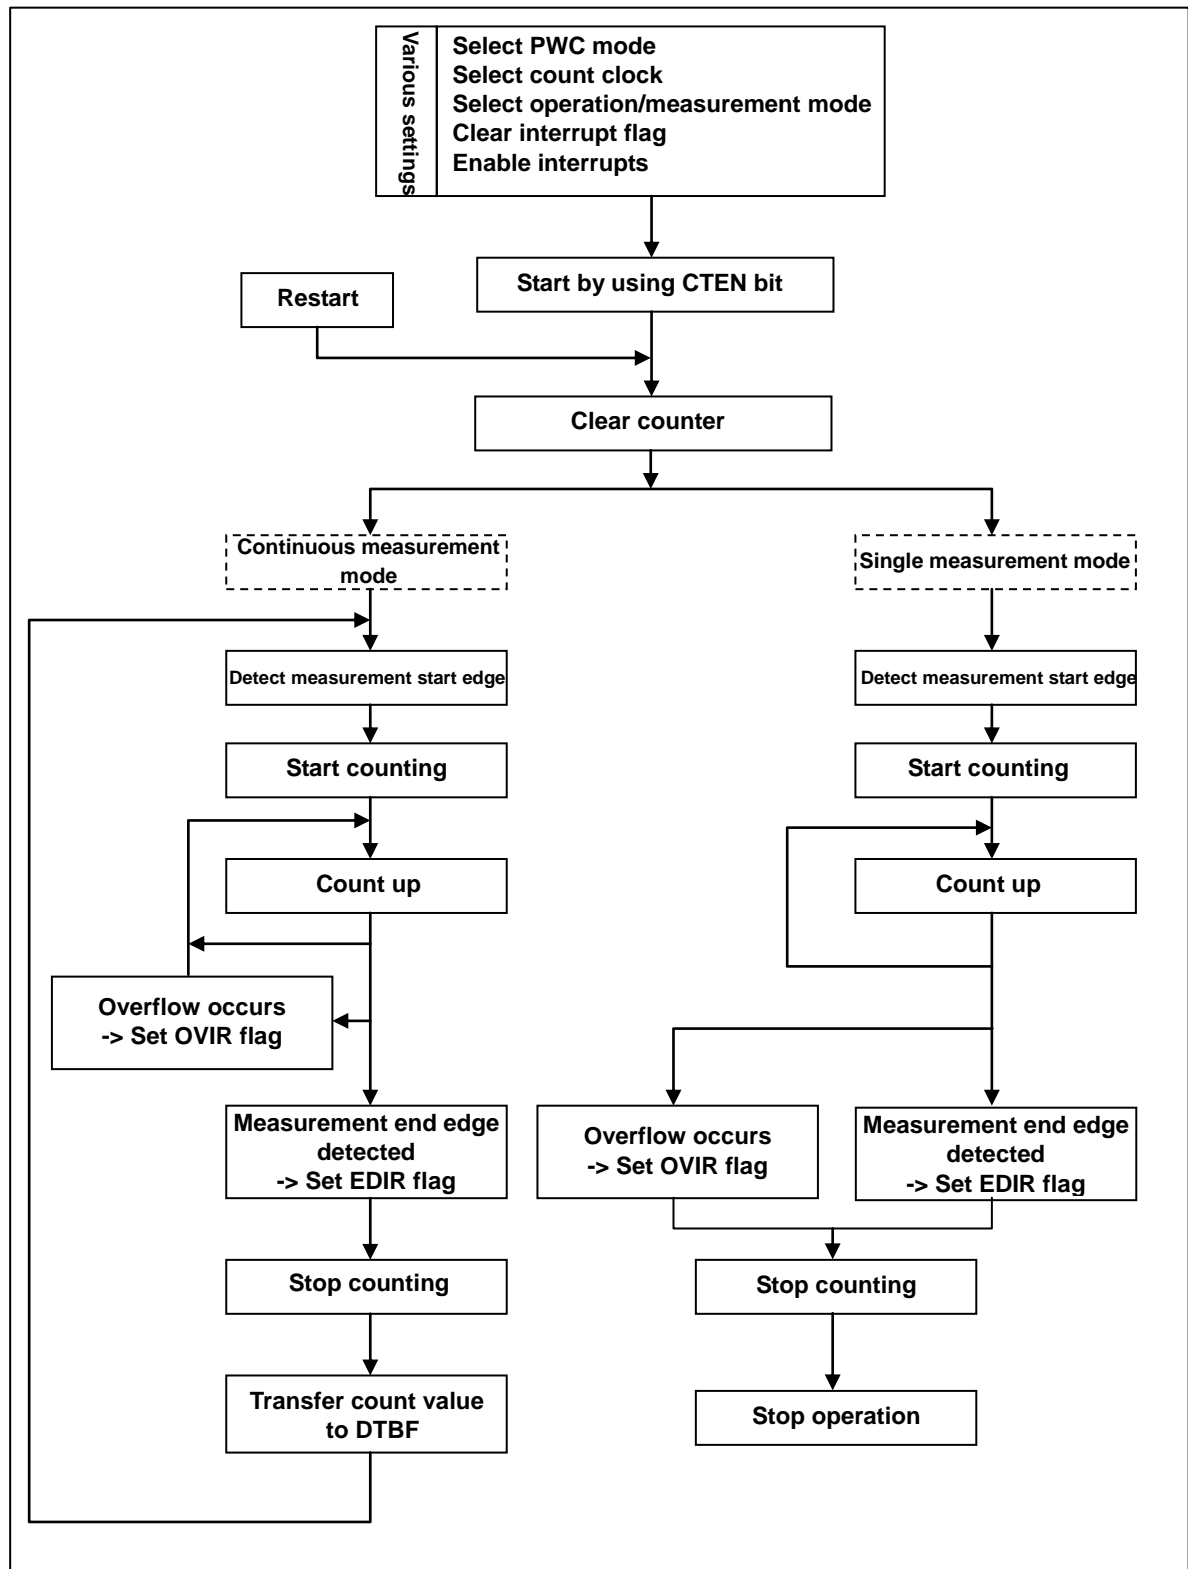

Interrupt Request Generation

The following two interrupt requests can be generated.

- Interrupt request due to a counter overflow
If counting up during measurement causes an overflow, the overflow flag (OVIR) is set to "1". Furthermore, if overflow interrupt requests are enabled, an interrupt request is generated.
- Interrupt request due to measurement end
If the measurement end edge is detected, the measurement end flag (EDIR) in STC is set to "1". Furthermore, if measurement end interrupt requests are enabled, an interrupt request is generated.
The measurement end flag (EDIR) is automatically cleared by the reading of the measurement results, DTBF.

Pulse Width Measurement Operation Flow

Figure 9-27 Pulse Width Measurement Operation Flow

9.4.2. Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PWC Timer is Selected

The timer control register (TMCR) controls timer operation.

For details on writing to the status control register (STC), see "CHAPTER 40:8. Notes on Using the Base Timer."

Timer Control Register (Upper Byte of TMCR)

Bit	15	14	13	12	11	10	9	8
Field	Reserved	CKS2	CKS1	CKS0	Reserved	EGS2	EGS1	EGS0
R/W Attribute	R0,W0	R/W	R/W	R/W	R0,W0	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit15] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[TMCR2:bit8,bit14:12] CKS[3:0]: Count Clock Selection Bits

- These bits select a count clock for the 16-bit down counter.
- Any modification to the count clock is reflected immediately after the setting is changed. Therefore, modify CKS3 to CKS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits				Description
0	0	0	0	Internal clock
0	0	0	1	Internal clock divided by 4
0	0	1	0	Internal clock divided by 16
0	0	1	1	Internal clock divided by 128
0	1	0	0	Internal clock divided by 256
0	1	0	1	Setting prohibited
0	1	1	0	
0	1	1	1	
1	0	0	0	Internal clock divided by 512
1	0	0	1	Internal clock divided by 1024
1	0	1	0	Internal clock divided by 2048
1	0	1	1	Internal clock divided by 2
1	1	0	0	Internal clock divided by 8
1	1	0	1	Internal clock divided by 32
1	1	1	0	Internal clock divided by 64
1	1	1	1	Setting prohibited

[bit11] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit10:8] EGS[2:0]: Measurement Edge Selection Bits

- These bits set a measurement edge condition.
- Modify EGS2 to EGS0 while counting is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits			Description
0	0	0	"H" pulse width measurement (rising to falling)
0	0	1	Cycle measurement between rising edges (rising to rising)
0	1	0	Cycle measurement between falling edges (falling to falling)
0	1	1	Pulse width measurement between all edges (rising or falling to falling or rising)
1	0	0	"L" pulse width measurement (falling to rising)
1	0	1	Setting prohibited
1	1	0	
1	1	1	

Timer Control Register (Lower Byte of TMCR)

bit	7	6	5	4	3	2	1	0
Field	T32	FMD2	FMD1	FMD0	Reserved	MDSE	CTEN	Reserved
R/W Attribute	R/W	R/W	R/W	R/W	R0,W0	R/W	R,W	R0,W0
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] T32: 32-Bit Timer Selection Bit

- This bit selects the 32-bit timer function.
- If the PWC function is selected with 0b100 set in the FMD2 to FMD0 bits, setting the T32 bit to "1" results in operation in 32-bit PWC mode.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bit can be modified at the same time as "1" is written to the CTEN bit. (See 32-Bit Mode Operation.)

Bit	Description
0	16-bit timer mode
1	32-bit timer mode

[bit6:4] FMD[2:0]: Timer Function Selection Bits

- These bits select the timer function.
- If 0b100 is set in the FMD2 to FMD0 bits, the PWC timer function is selected.
- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bits			Description
0	0	0	Reset mode
0	0	1	16-bit PWM timer
0	1	0	16-bit PPG timer
0	1	1	16/32-bit reload timer
1	0	0	16/32-bit PWC timer
1	0	1	Setting prohibited
1	1	0	
1	1	1	

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] MDSE: Mode Selection Bit

- Modify these bits while the timer is stopped (CTEN= 0). However, note that the bits can be modified at the same time as "1" is written to the CTEN bit.

Bit	Description
0	Continuous measurement mode (buffer register enabled)
1	Single measurement mode (stop after 1 measurement)

[bit1] CTEN: Timer Enable Bit

- This bit enables the starting or restarting of the up counter.
- If "1" is written with the counter in the operation enabled state (CTEN bit is "1"), a restart is assumed, the counter is cleared, and operation enters the measurement start edge wait state.
- If "0" is written to this bit when counter operation is enabled (CTEN bit is "1"), the counter stops.
- After measurement ends in single measurement mode, CTEN is cleared.

Bit	Description	
	Read	Write
0	Stop operation.	Set this bit to "0".
1	Enable operation.	Set this bit to "1".

[bit0] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

Timer Control Register 2 (TMCR2)

bit	15	14	13	12	11	10	9	8
Field	Reserved							CKS3
R/W Attribute	R0,W0							R/W
Protection Attribute	-							-
Initial Value	0000000							0

Note: This register is located in the upper byte of the STC register.

[bit15:9] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit8] CKS3: Count Clock Selection Bit

See "Count clock selection bits" in "9.4.2 Timer Control Registers (TMCR, TMCR2), Status Control Register (STC), Status Control Clear Register (STCC), and Status Control Set Register (STCS) When the PWC Timer is Selected."

Status Control Register (STC)

bit	7	6	5	4	3	2	1	0
Field	ERR	EDIE	Reserved	OVIE	Reserved	EDIR	Reserved	OVIR
R/W Attribute	R,WX	R/W	R0,W0	R/W	R0,W0	R,WX	R0,W0	R,WX
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

Note: The TMCR2 register is located in the upper byte of this register.

[bit7] ERR: Error Flag Bit

- This bit is a flag indicating that, in continuous measurement mode, the next measurement has ended before the measurement results in the DTBF register have been read. In this case, the DTBF register values are updated with the new measurement results, so the immediately preceding measurement results are lost.
- Measurement continues regardless of the ERR bit value.
- The ERR bit is read-only. Writing to the bit has no effect on the bit value.
- Reading the measurement results (DTBF) clears the ERR bit.

Bit	Description
0	Normal state
1	Overwrite any unread measurement results with the next measurement results.

[bit6] EDIE: Measurement End Interrupt Request Enable Bit

- This bit controls interrupt requests of the measurement end interrupt request bit (bit2 EDIR).
- If the EDIE bit is enabled and the EDIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:EDIEC bit clears this bit.
- Writing "1" to the STCS:EDIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] OVIE: Overflow Interrupt Request Enable Bit

- This bit controls interrupt requests of the overflow interrupt request bit (bit0 OVIR).
- If the OVIE bit is enabled and the OVIR bit is set to "1", an interrupt request is issued to the CPU.
- Writing "1" to the STCC:OVIEC bit clears this bit.
- Writing "1" to the STCS:OVIES bit sets this bit.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit3] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit2] EDIR: Measurement End Interrupt Request Bit

- This bit indicates that measurement has ended by setting the flag to "1" at the end time.
- Reading the measurement results (DTBF) clears the EDIR bit. The EDIR bit is read-only. Writing to the bit has no effect on the bit value.

Bit	Description
0	Read measurement results (DTBF).
1	Detect the interrupt factor.

[bit1] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit0] OVIR: Overflow Interrupt Request Bit

- The flag is set to "1" when the count value overflows from 0xFFFF to 0x0000.
- Writing "1" to the STCC:OVIRC clears this bit.
- This bit is read-only. Writing data to this bit has no effect on operation.

Bit	Description
0	The interrupt factor is cleared.
1	Detect the interrupt factor.

Status Control Clear Register (STCC)

bit	7	6	5	4	3	2	1	0
Field	Reserved	EDIEC	Reserved	OVIEC	Reserved			OVIRC
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0			R0,W
Protection Attribute	-	-	-	-	-			-
Initial Value	0	0	0	0	000			0

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] EDIEC: Measurement End Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:EDIE bit is cleared to "0".

- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the EDIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] OVIEC: Overflow Interrupt Request Enable Clear Bit

- If "1" is written to this bit, the STC:OVIE bit is cleared to "0".

- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the OVIE bit.

[bit3:1] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

[bit0] OVIRC: Overflow Interrupt Request Clear Bit

- If "1" is written to this bit, the STC:OVIR bit is cleared to "0".

- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Clear the OVIR bit.

Status Control Set Register (STCS)

bit	7	6	5	4	3	2	1	0
Field	Reserved	EDIES	Reserved	OVIIES	Reserved			
R/W Attribute	R0,W0	R0,W	R0,W0	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-			
Initial Value	0	0	0	0	0000			

Note: Reserved bits are located in the upper byte of this register.

[bit7] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit6] EDIES: Measurement End Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:EDIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the EDIE bit.

[bit5] Reserved: Reserved Bit

The read value is "0".

If writing to this bit, write "0".

[bit4] OVIIES: Overflow Interrupt Request Enable Set Bit

- If "1" is written to this bit, the STC:OVIE bit is set to "1".
- The read value of this bit is always "0".

Bit	Description
0	Invalid
1	Set the OVIE bit.

[bit3:0] Reserved: Reserved Bits

The read value is "0".

If writing to this bit, write "0".

9.4.3. Data Buffer Register (DTBF)

The data buffer register (DTBF) is a register that can read the measurement value or count value of the PWC timer. In 32-bit mode, the value of the lower 16 bits is read for the even-numbered channel, and the value of the upper 16 bits for the odd-numbered channel.

Be sure to read this register with 16- or 32-bit data transfer instructions.

bit	15	0
Field	DTBF[15:0]	
R/W Attribute	R,WX	
Protection Attribute	-	
Initial Value	0x0000	

- These bits compose the DTBF register as a read-only register in either continuous measurement mode or single measurement mode. Writing does not change the register value.
- In continuous measurement mode (TMCR bit2 MDSE = 0), the register is used as a buffer register to store the last measurement results.
- In single measurement mode (TMCR bit2 MDSE = 1), the up counter is directly accessed with the DTBF register. Reading is allowed even during counting so that the count value can be read. After measurement ends, the measurement results are stored as is.
- Use 16- or 32-bit data access for the DTBF register.

CHAPTER 41: Base Timer I/O Selection Function

This chapter explains the base timer I/O selection function.

1. Overview
2. Configuration
3. Explanation of Operation
4. Registers

BTSEL-TXXPT03P01R01L05-E1-XX

1. Overview

This section provides an overview of the base timer I/O selection function.

The base timer I/O selection function is a function for selecting a signal I/O method for the base timer by setting an I/O mode.

By switching the timer function, the base timer mounted in a channel can be used as any of the timers described below for each channel. The I/O method for the respective functions can be selected.

Timer outputs can be simultaneously read using TOUT Read Register (BT_BTTRR0, BT_BTTRR12, BT_BTTRR24).

The following 7 patterns can be selected for I/O pin connections.

- 16-bit timer standard mode
- 32-bit timer full-function mode
- PPG trigger 2-channel sharing mode
- Timer start/stop mode
- Simultaneous soft start mode
- Timer start/stop and simultaneous soft start mode
- Timer start mode

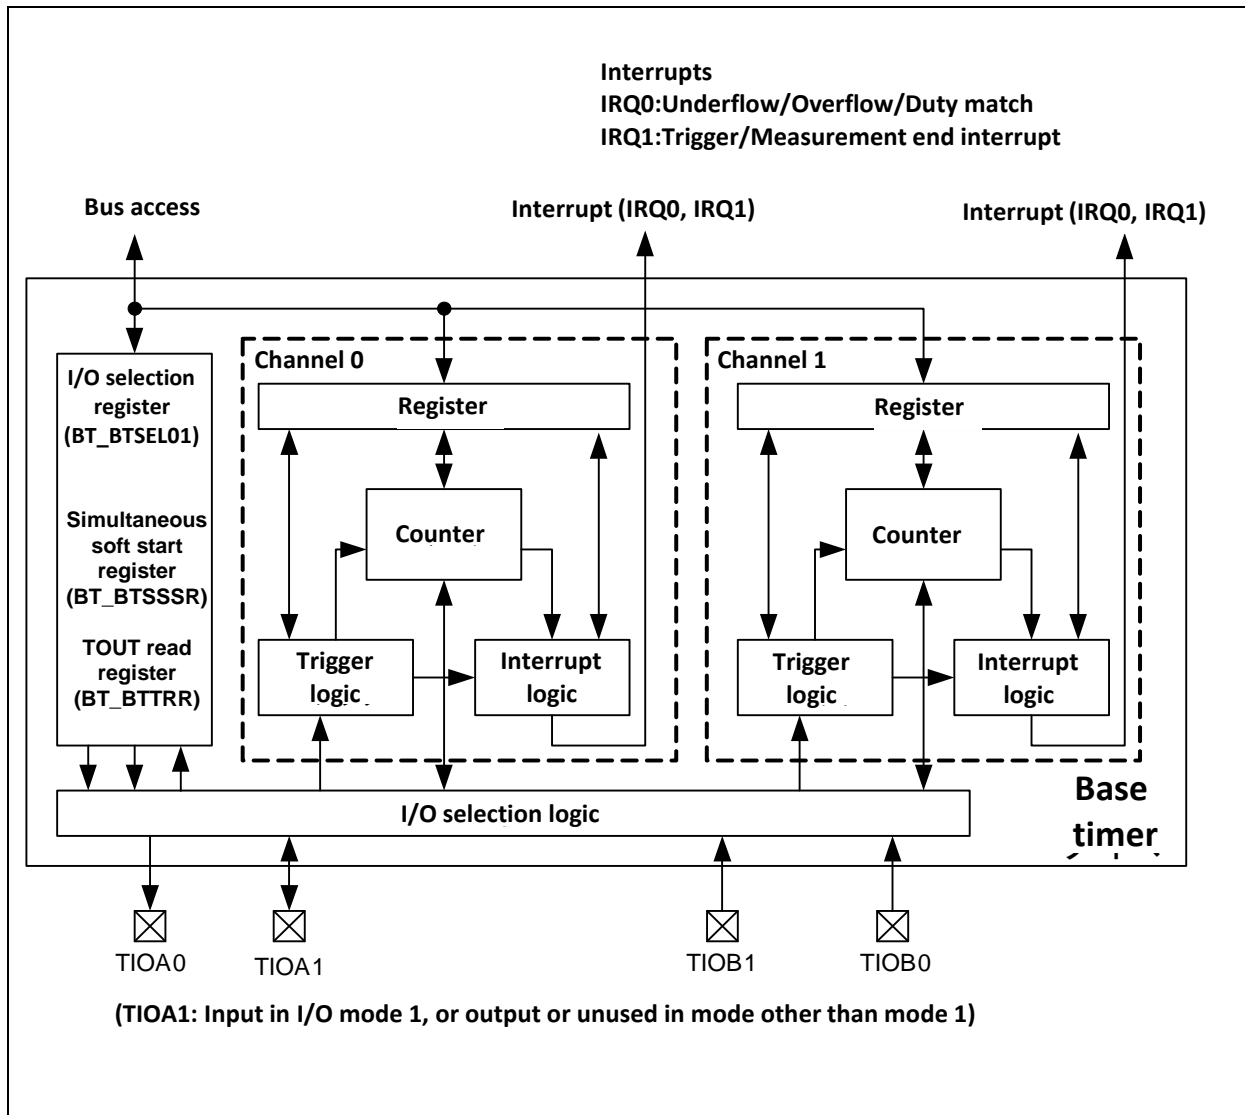

The 32-bit reload timer and 32-bit PWC timer can be implemented by using 2 channels of the mounted base timer. These 2 channels are channel m (m is an even number) and channel n ($n = m + 1$).

2. Configuration

The 32-bit reload timer and 32-bit PWC timer can be implemented by using 2 channels of the mounted base timer. These 2 channels are channel m (m is an even number) and channel n (n = m + 1).

This section explains the configuration of the base timer and I/O selection function.

Figure 2-1 Block Diagram

Configuration for channel 0 and channel 1

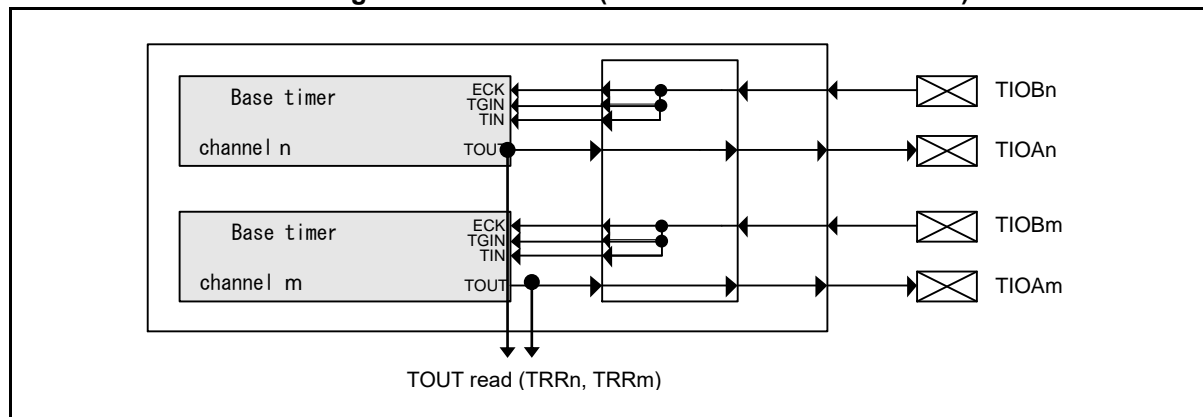

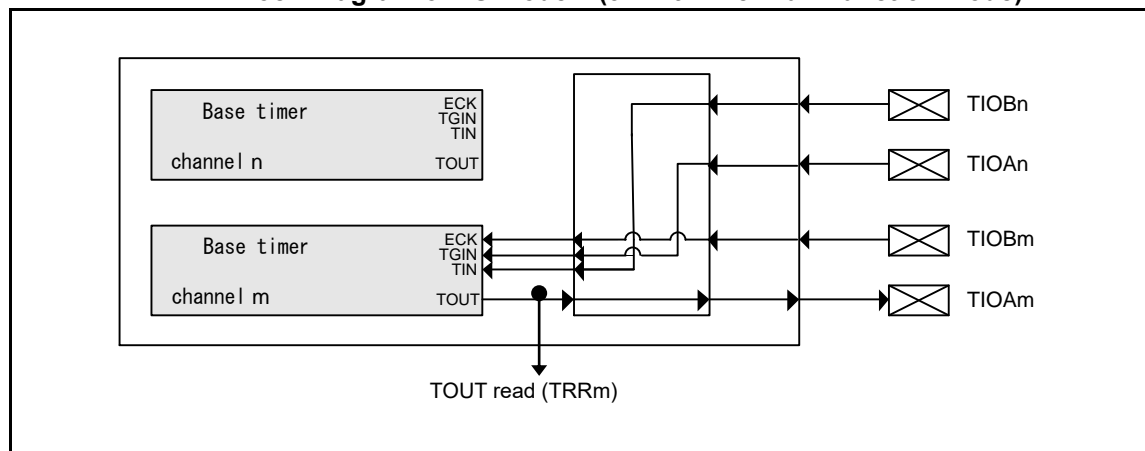

3. Explanation of Operation

This section explains base timer I/O assignment.

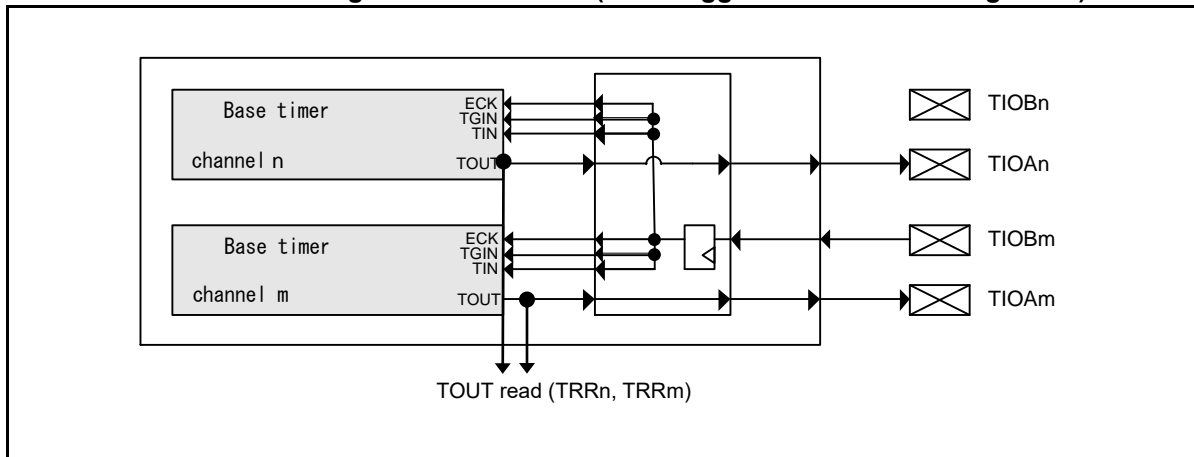

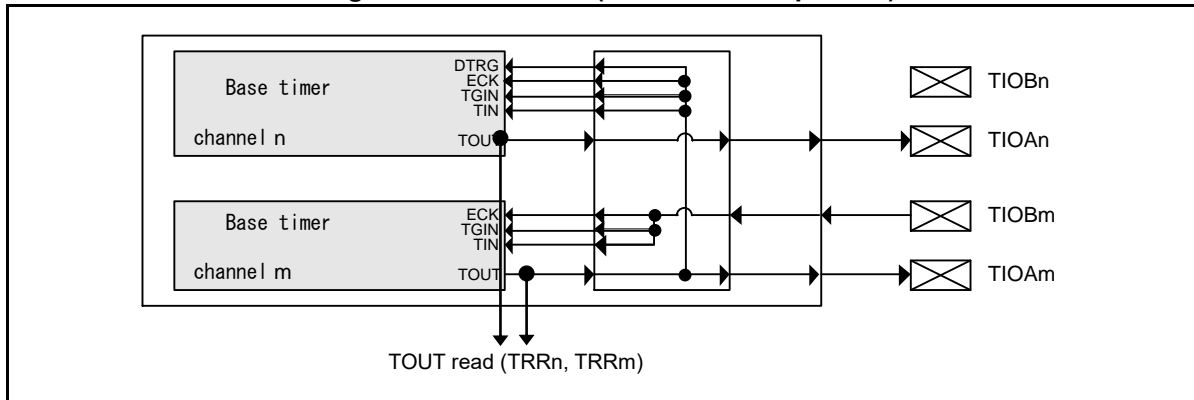

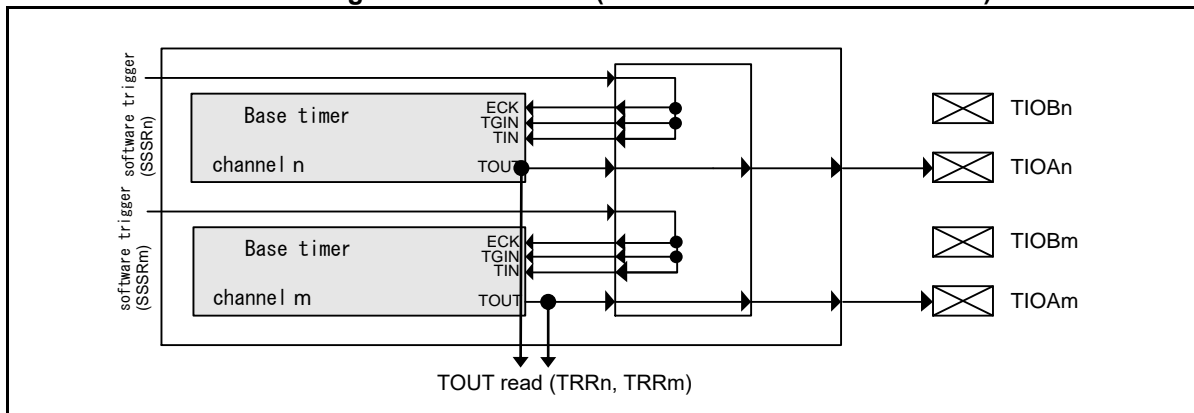

Before using a timer, make an I/O setting for the base timer by using the I/O mode selection bit (BTSEL01). You can select one of the following 7 modes.

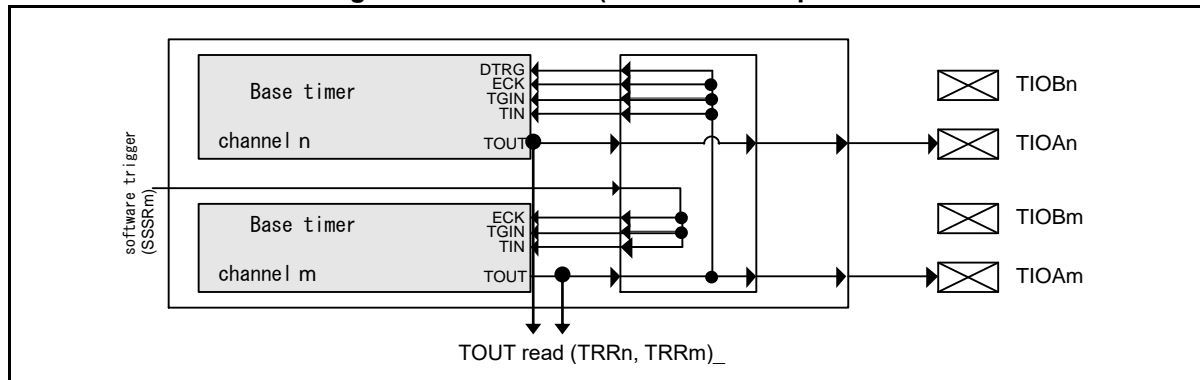

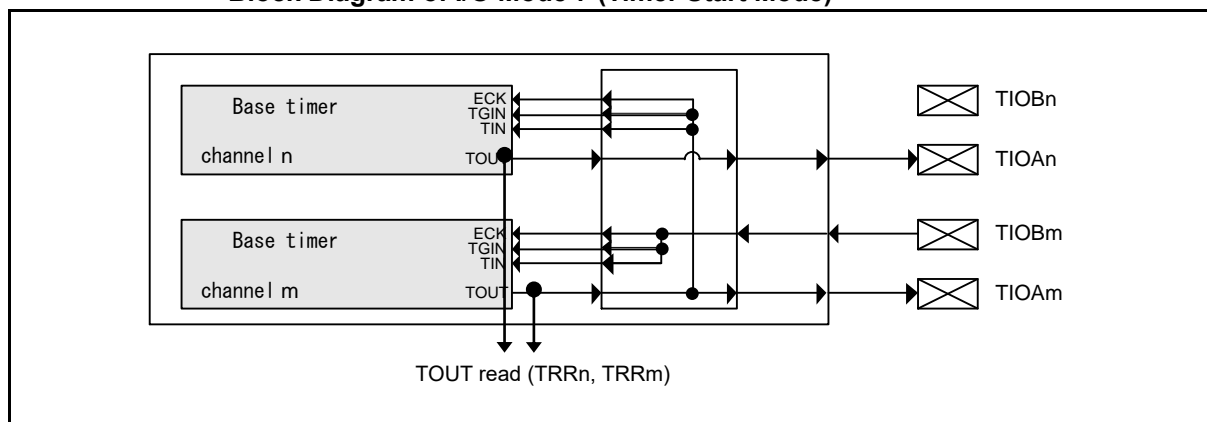

- I/O mode 0: 16-bit timer standard mode
In this mode, the base timer in 1 channel operates individually and separately from the others.
- I/O mode 1: 32-bit timer full-function mode
The signals of the even-numbered channels of the base timer are individually assigned to external pins in operation in this mode.
- I/O mode 2: PPG trigger 2-channel sharing mode
This mode enables simultaneous input of external start triggers to the base timers of 2 channels. The base timers of the 2 channels can be started simultaneously.
- I/O mode 4: Timer start/stop mode
In this mode, an even-numbered channel controls the start/stop of an odd-numbered channel. The odd-numbered channel is started by the rising edge* of an output signal from the even-numbered channel, and stopped by the falling edge*.
- I/O mode 5: Simultaneous soft start mode
In this mode, software starts multiple channels simultaneously.
- I/O mode 6: Soft start timer start/stop mode
In this mode, an even-numbered channel controls the start/stop of an odd-numbered channel. Software starts the even-numbered channel. The odd-numbered channel is started by the rising edge* of an output signal from the even-numbered channel, and stopped by the falling edge*.
- I/O mode 7: Timer start mode
In this mode, an even-numbered channel controls the start of an odd-numbered channel. The odd-numbered channel is started by the rising edge* of an output signal from the even-numbered channel.

*: Use the trigger input selection bit (BTxx_TMCR:EGS) for the setting.

Note:

- If I/O mode 1 is set, set TIOAn of the corresponding odd-numbered channel to port input mode by using the GPIO setting.

4. Registers

This section explains the base timer I/O selection function registers.

Table 4-1 List of Base Timer I/O Selection Registers

Abbreviated Register Name	Register Name	Reference
BT_BTSEL01	I/O selection register (channel 0, 1)	4.1
BT_BTSEL23	I/O selection register (channel 2, 3)	4.1
BT_BTSEL45	I/O selection register (channel 4, 5)	4.1
BT_BTSEL67	I/O selection register (channel 6, 7)	4.1
BT_BTSEL89	I/O selection register (channel 8, 9)	4.1
BT_BTSEL1011	I/O selection register (channel 10, 11)	4.1
BT_BTSEL1213	I/O selection register (channel 12, 13)	4.1
BT_BTSEL1415	I/O selection register (channel 14, 15)	4.1
BT_BTSEL1617	I/O selection register (channel 16, 17)	4.1
BT_BTSEL1819	I/O selection register (channel 18, 19)	4.1
BT_BTSEL2021	I/O selection register (channel 20, 21)	4.1
BT_BTSEL2223	I/O selection register (channel 22, 23)	4.1
BT_BTSEL2425	I/O selection register (channel 24, 25)	4.1
BT_BTSEL2627	I/O selection register (channel 26, 27)	4.1
BT_BTSEL2829	I/O selection register (channel 28, 29)	4.1
BT_BTSEL3031	I/O selection register (channel 30, 31)	4.1
BT_BTSEL3233	I/O selection register (channel 32, 33)	4.1
BT_BTSEL3435	I/O selection register (channel 34, 35)	4.1
BT_BTSSSR0	Simultaneous soft start register (channel 0)	4.2
BT_BTSSSR12	Simultaneous soft start register (channel 12)	4.2
BT_BTSSSR24	Simultaneous soft start register (channel 24)	4.2
BT_BTTRR0	TOUT read register (channel 0)	4.3
BT_BTTRR12	TOUT read register (channel 12)	4.3
BT_BTTRR24	TOUT read register (channel 24)	4.3

Tables 4.2, 4.3, and 4.4 show the register map of each mode.

The "****/****/****/****" expression in each table corresponds to the reload/PWM/PPG/PWC timer, respectively.

4.1. I/O Selection Registers (BT_BTSELmn)

This section shows the bit configuration of the I/O selection registers.

These bits set the I/O modes of the 2 channels of base timer channel m (m is 0 or an even number) and channel n (n = m + 1: odd number) for the following connection.

Bit	31											8
Field	Reserved											
R/W Attribute	R1,WX											
Protection Attribute	-											
Initial Value	11111111_11111111_11111111											

Bit	7	6	5	4	3	2	1	0
Field	Reserved				BTSELmn			
R/W Attribute	R1,WX				R/W0	R/W		
Protection Attribute	-							
Initial Value	1111				0000			

[bit31:4] Reserved: Reserved Bits

[bit3:0] BTSELmn: I/O Mode Selection Bits

These bits set the I/O modes of the 2 channels of base timer channel m and channel n for the following connection.

Bits				Description
0	0	0	0	I/O mode 0: 16-bit timer standard mode
0	0	0	1	I/O mode 1: 32-bit timer full-function mode
0	0	1	0	I/O mode 2: PPG trigger 2-channel sharing mode
0	0	1	1	Setting prohibited
0	1	0	0	I/O mode 4: Timer start/stop mode
0	1	0	1	I/O mode 5: Simultaneous soft start mode
0	1	1	0	I/O mode 6: Timer start/stop and simultaneous soft start mode
0	1	1	1	I/O mode 7: Timer start mode
1	x	x	x	Setting prohibited

Note:

- Do not change this register by setting reset mode (TMCR:FMD2 to 0="0b000"). After setting reset mode, rewrite this register.

4.2. Simultaneous Soft Start Register (BT_BTSSSR0, BT_BTSSSR12, BT_BTSSSR24)

This section shows the bit configuration of the simultaneous soft start register.

These bits represent input signals in I/O modes 5 and 6. This register can be used to generate triggers for all channels simultaneously.

Bit	31	16
Field	Reserved	
R/W Attribute	R1,WX	
Protection	-	
Attribute		
Initial Value	11111111_11111111

[bit31:12] Reserved: Reserved Bits

[bit11:0] SSSR[11:0]: Simultaneous Soft Start Bits

These bits represent input signals in I/O modes 5 and 6. For details on connections, see the block diagram of each I/O mode in "3. Explanation of Operation."

Writing "1" starts the corresponding channel, and writing "0" has no effect. Up to 12 channels with channel numbers 0 to 11 can be started simultaneously.

Correspondence of the channel number is below.

BT_BTSSSR0 : SSSR0-11 = ch0-11 (cperi0)

BT_BTSSSR12 : SSSR0-11 = ch12-23 (cperi1)

BT_BTSSSR24 : SSSR0-11 = ch24-35 (cperi2)

SSSR [X]	Description
0	No operation
1	Assigns the "1" pulse to input and starts the corresponding channel.

[X] represents the channel number of the base timer. It is a value from 0 to 11.

4.3. TOUT Read Register (BT_BTTRR0, BT_BTTRR12, BT_BTTRR24)

This section shows the bit configuration of the TOUT read register.

By using these bits, software can read TOUT status from the Base Timer channels.

Bit	31	16
Field	Reserved	
R/W Attribute	R1,WX	
Protection Attribute	-	
Initial Value	11111111_11111111	

Bit	15	14	13	12	11	10	9	8
Field	Reserved				TRR11	TRR10	TRR9	TRR8
R/W Attribute	R1, WX				R,WX	R,WX	R,WX	R,WX
Protection Attribute	-							
Initial Value	1111				0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	TRR7	TRR6	TRR5	TRR4	TRR3	TRR2	TRR1	TRR0
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit31:12] Reserved: Reserved Bits

[bit11:0] TRR[11:0]: Simultaneous TOUT Read Bits

These bits represent TOUT status of the Base Timer channels. For details on connections, see the block diagram of each I/O mode in 3. Explanation of Operation.

TRR[X]	Description
0	TOUT status is '0'
1	TOUT status is '1'

[X] represents the channel number of the base timer. It is a value from 0 to 11.

CHAPTER 42: 32-bit Free-run Timer

This chapter describes the functions of the 32-bit free-run timer.

1. Overview of the 32-Bit Free-Run Timer
2. Configuration and Block Diagram
3. Explanation of the 32-Bit Free-Run Timer Operation
4. Registers of the 32-Bit Free-Run Timer
5. Precautions for Using This Device

FRT-TXXPT03P01R01L06-E1-XX

1. Overview of the 32-Bit Free-Run Timer

The 32-bit free-run timer supports the 32-bit up count mode or up/down count mode. This timer can be used with the 32-bit input capture and the 32-bit output compare. This timer can measure the input pulse width and external clock cycle.

Functions of the 32-Bit Free-Run Timer

- The 32-bit free-run timer is composed of the 32-bit up/down counter, control register, 32-bit compare clear register, 32-bit compare clear buffer register, and prescaler.
- The 9 types of counter operation clocks (ϕ , $\phi/2$, $\phi/4$, $\phi/8$, $\phi/16$, $\phi/32$, $\phi/64$, $\phi/128$, and $\phi/256$) (ϕ : peripheral clock) can be selected.
- A compare clear interrupt is generated when the values of the compare clear register and the 32-bit counter are compared and their values match. A 0 detection interrupt is generated when the 32-bit counter detects the count value 0x00000000.
- The compare clear register has a buffer register (the data written to this buffer register is transferred to the compare clear register). When the 32-bit counter is stopped, the data is transferred as soon as data is written to the buffer. When the 32-bit counter is operating, data is transferred from the buffer upon detecting the count value 0x00000000.
- The count value is reset to 0x00000000 when a hardware reset occurs, software clears the timer, or the value of the compare clear register and the count value match in up count mode.
- The output value of the 32-bit counter can be used as a clock count of the output compare and the input capture.

Interrupt request and DMA request

- Interrupt request of this module can be used for purposes below:
 1. Interrupt request to CPU (via Interrupt Controller)
 2. DMA request to DMA Controller
- To use the interrupt as interrupt request to CPU, following configuration is necessary:
 - Enable the interrupt request in this module
 - Enable the interrupt channel of the interrupt in Interrupt Controller
- To use the interrupt as DMA request to DMA Controller, following configuration is necessary:
 - Enable the interrupt request in this module
 - Select the DMA channel from this module as DMA client in DMA Controller

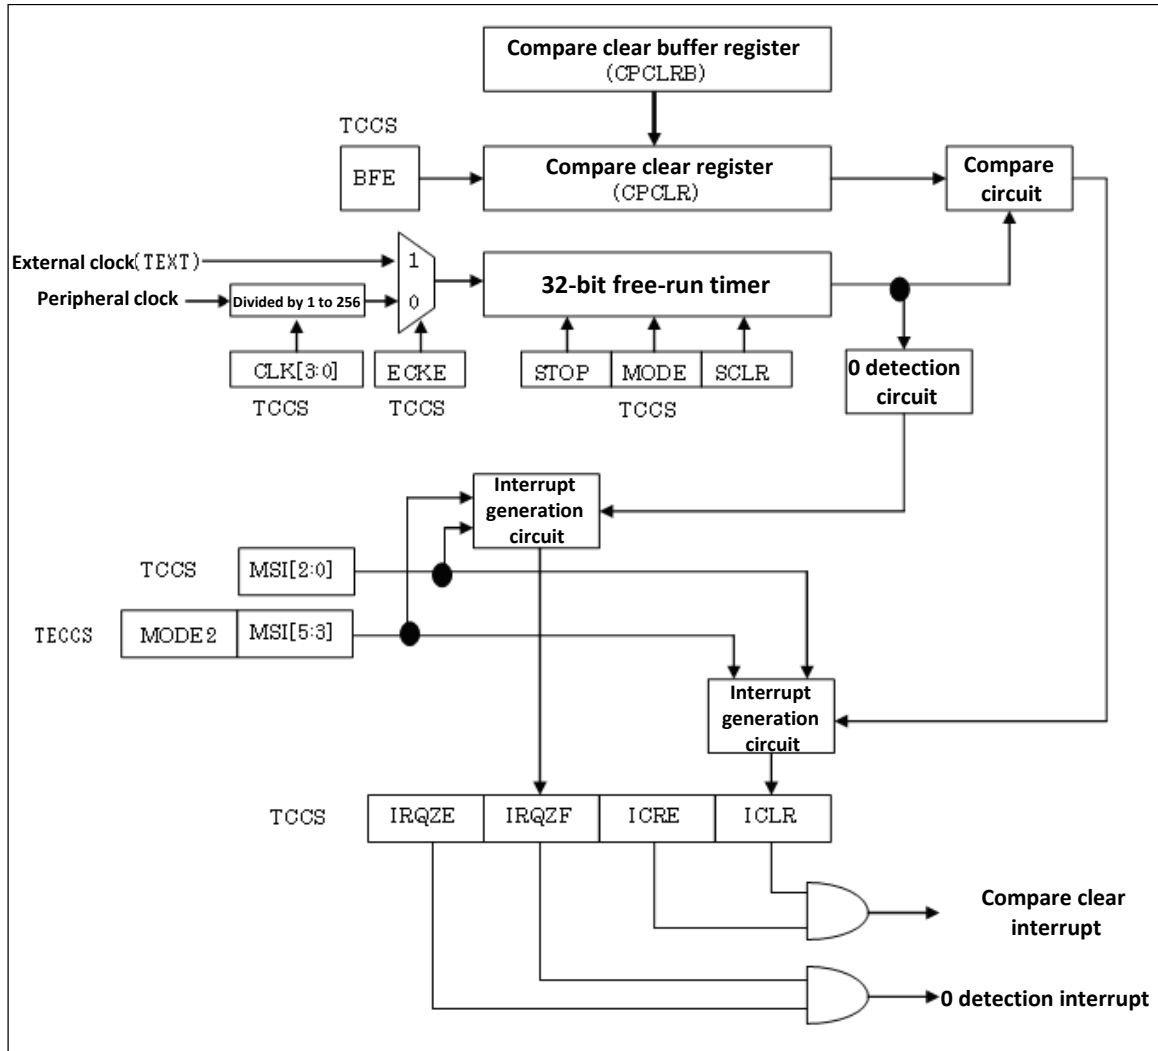

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Configuration and Block Diagram

Figure 2-1 is a configuration diagram of the 32-bit free-run timer.

Figure 2-1 Configuration Diagram of 32-Bit Free-Run Timer

3. Explanation of the 32-Bit Free-Run Timer Operation

This section provides a summary of the operation of the 32-bit free-run timer.

Operation of the 32-Bit Free-Run Timer

The 32-bit free-run timer starts counting from the value set in the timer data register (TCDT) after the timer is set to enabled (TCCS:STOP). When the 32-bit output compare and the 32-bit input capture are connected to the free-run timer, then the timer count value is used as base time of the 32-bit output compare and the 32-bit input capture.

Counter Clear

The count value of the free-run timer is cleared to 0 when any of the following conditions is met.

- When the count value matches the value of the compare clear register (CPCLR) in the up count mode (MODE: bit5=0 of the timer state control register (TCCS))
- When "1" is written to the timer clear bit (SCLR: bit4) of the timer state control register (TCCS) while the free-run timer is operating (STOP: bit6=0 of the timer state control register (TCCS))
- When 0x00000000 is written to the timer data register (TCDT) while the free-run timer is stopped (STOP: bit6=1 of the timer state control register (TCCS))
- When the hardware is reset. Upon reset, the counter is cleared immediately.

When "1" is written to the timer clear bit (SCLR: bit4) of the timer state control register (TCCS) or when the count value matches the value of the compare clear register, the counter is cleared synchronously with the count timing.

Figure 3-1 Clear Timing of 32-Bit Free-Run Timer

Note:

- The count value of the free-run timer is not cleared if "1" is written to the timer clear bit (SCLR: bit4) of the timer state control register (TCCS) while the timer is stopped.

Timer Mode

Either of the following modes can be selected for the free-run timer.

- Up count mode (MODE: bit5=0 of the timer state control register (TCCS))
- Up/down count mode (MODE: bit5=1 of the timer state control register (TCCS))

In the up count mode, the counter starts counting from the timer data register (TCDT) that is set in advance. The counter continues to count up until the count value matches the value of the compare clear register (CPCLR). Then, the counter is cleared to 0x00000000 and starts counting up again.

In the up/down count mode, the counter starts counting from the timer data register (TCDT) that is set in advance. The counter continues to count up until the count value matches the value of the compare clear register (CPCLR). Then, the counter changes the counting direction from up count to down count. It continues to count down until the counter value reaches 0x00000000 and starts counting up again.

A value can be written to the timer count mode bit (MODE: bit5) of the timer state control register (TCCS) at any time, even when the timer is operating or stopped. The value written to this bit during the timer operation is stored in a buffer. The count mode changes when the count value becomes 0x00000000.

Figure 3-2 Change of Timer Mode (While Timer Is Operating)

Compare Clear Buffer

The compare clear register (CPCLR) has a buffer function that can be enabled or disabled. When the buffer function is enabled (BFE: bit7=1 of the timer state control register (TCCS)), the data written to the compare clear buffer register (CPCLRB) is transferred to the CPCLR register upon detecting the count value 0. When the buffer function is disabled (BFE: bit7=0 of the timer state control register (TCCS)), the data can be directly written to the compare clear register (CPCLR).

Figure 3-3 Up Count Mode Operation When Compare Clear Buffer Is Disabled (BFE: bit7=0 of Timer State Control Register (TCCS))

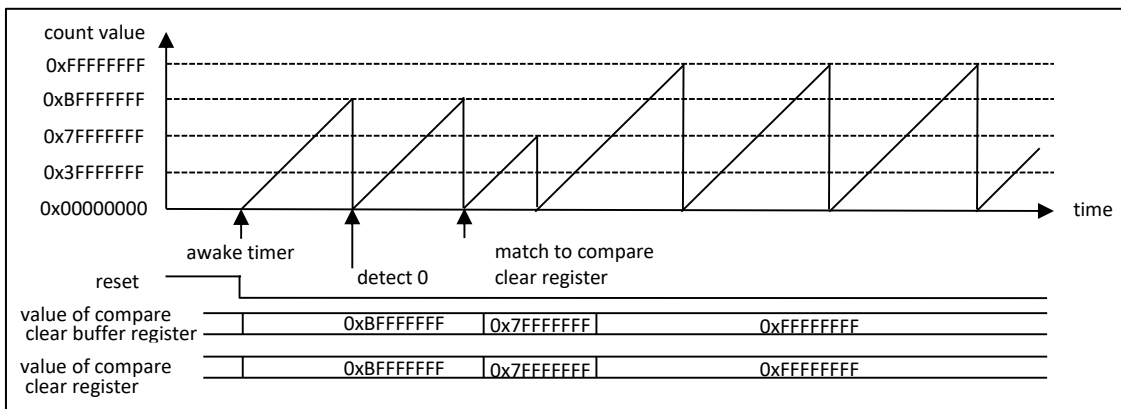

Figure 3-4 Up Count Mode Operation When Compare Clear Buffer Is Enabled (BFE: bit7=1 of Timer State Control Register (TCCS))

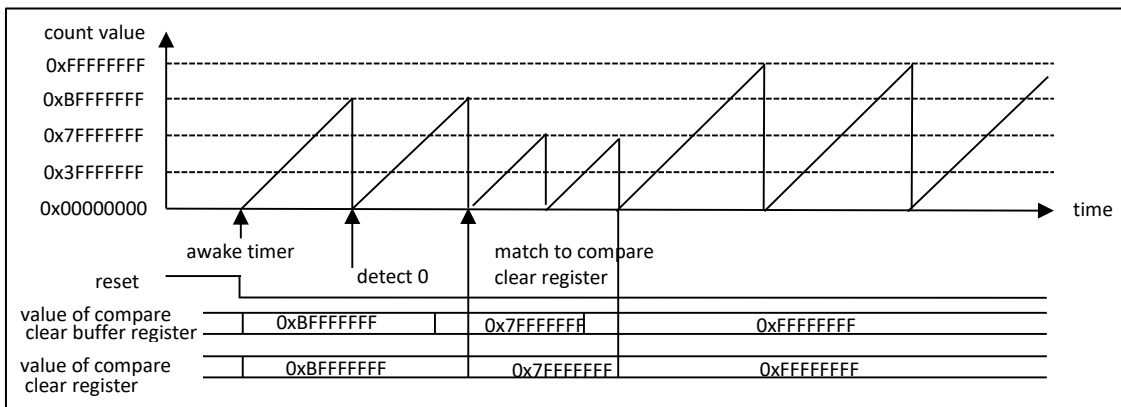

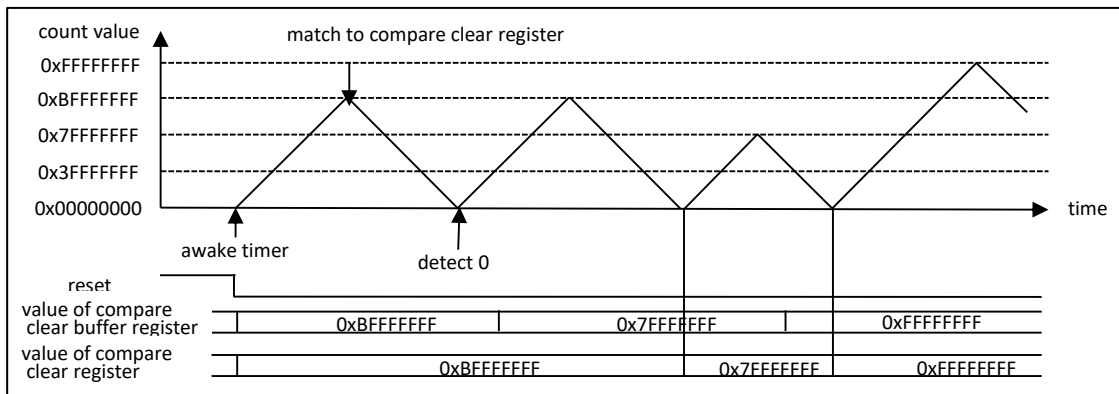

Figure 3-5 Up/Down Count Mode Operation When Compare Clear Buffer Is Enabled (BFE: bit7=1 of Timer State Control Register (TCCS))

Timer Interrupt

The 32-bit free-run timer can generate the following 2 interrupts.

- Compare clear interrupt
- 0 detection interrupt

The compare clear interrupt is generated when the count value matches the value of the compare clear register. The 0 detection interrupt is generated when the count value reaches 0x00000000H.

Note:

- The 0 detection interrupt is not generated when the timer is cleared (SCLR: bit4=1 of the timer state control register (TCCS)).

Figure 3-6 Interrupt Generated in Up Count Mode (MODE: bit5=0 of the Timer State Control Register (TCCS))

Figure 3-7 Interrupt Generated in Up/Down Count Mode (MODE: bit5=1 of the Timer State Control Register (TCCS))

Interrupt Mask Function

Either the 0 detection interrupt or the compare clear interrupt, or both interrupts can be masked.

The following describes the case when either interrupt is masked.

- An interrupt request flag can be masked by setting the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) of the timer state control register (TCCS). The interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) are the 3-bit reload down register that reloads the value when the mask count value reaches 0x000.
The mask count value can also be loaded by directly writing data to the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). The number of mask counts is the value set in the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10). An interrupt request flag is not masked when the mask count value (MSI2 to MSI0: bit12 to bit10) becomes 0x000.
- The mask control of an interrupt request varies depending on the count mode (MODE: bit5 of the timer state control register (TCCS)). In the up count mode (MODE: bit5=0), only the compare clear interrupt request flag can be masked and the 0 detection interrupt is generated every time a timer counter value of 0 is detected. In the up/down count mode (MODE: bit5=1), only the 0 detection interrupt request flag can be masked.

The following describes the case when both interrupt requests are masked.

- Both interrupts can be masked only when the free-run timer is in the up/down count mode (MODE: bit5=1) and when the timer extended state control register (TECCS) is set to MODE2: bit11=1 and the timer state control register (TCCS) is set to MODE: bit5=1.
- MSI2 to MSI0 bits of the timer state control register (TCCS) are used to mask the 0 detection interrupt. MSI5 to MSI3 bits of the timer extended state control register (TECCS) are used to mask the compare clear interrupt.

Notes:

- The 0 detection interrupt is not generated when the timer is cleared (SCLR: bit4=1 of the timer state control register (TCCS)).
- If Interrupt mask function "by setting TCCS.MSI[2:0] Register" is used, please write TCCS[15:8], TCCSC[15:8] and TCCSS[15:8] after 32bit free-run timer stopped.

Figure 3-8 Compare Clear Interrupts to Be Masked in Up Count Mode

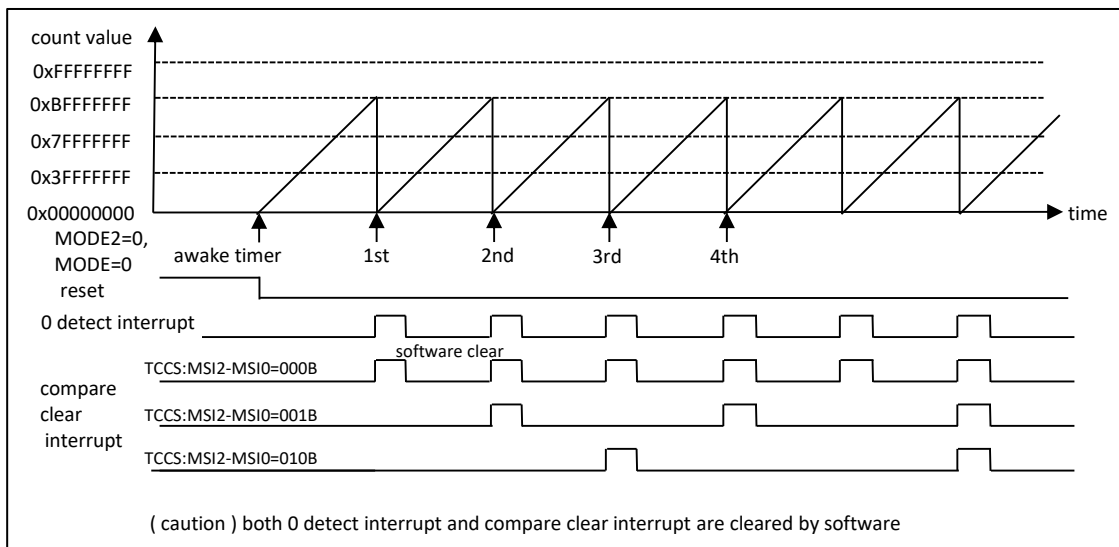

Figure 3-9 0 Detection Interrupts to Be Masked in Up/Down Count Mode

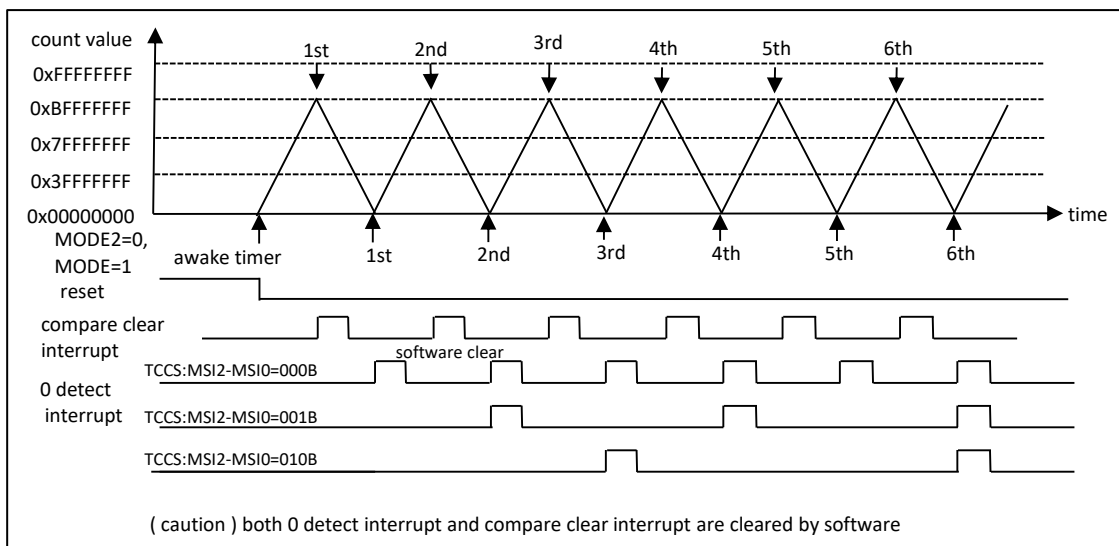

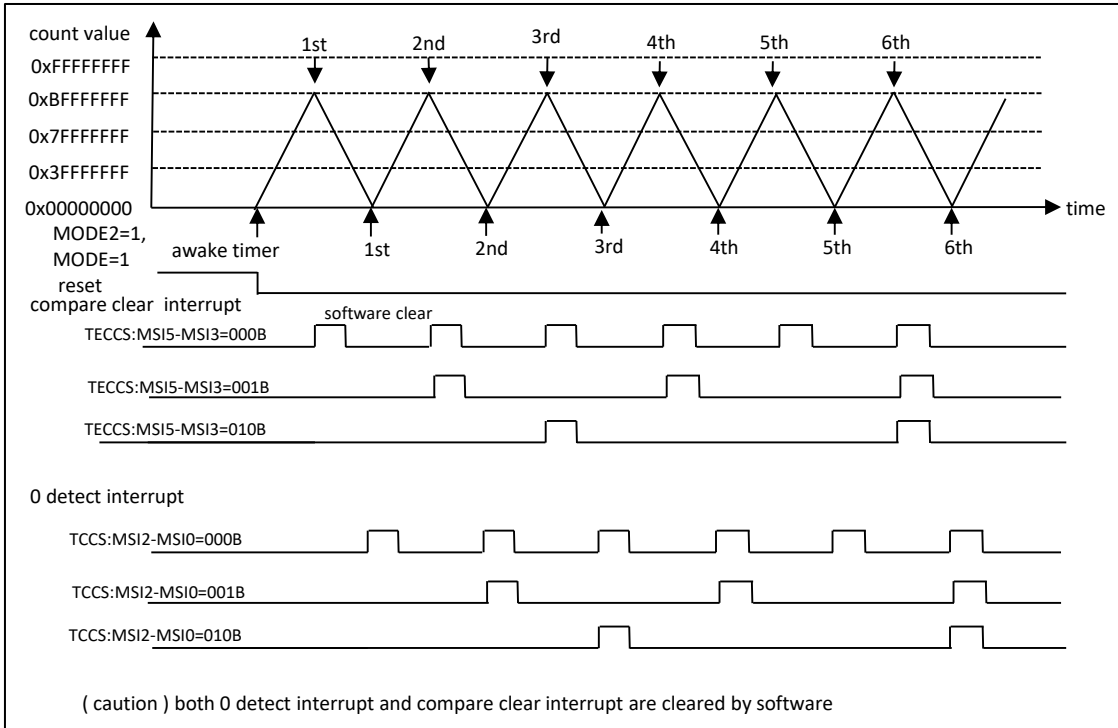

Figure 3-10 0 Detection Interrupts and Compare Clear Interrupts to Be Masked in Up/Down Count Mode

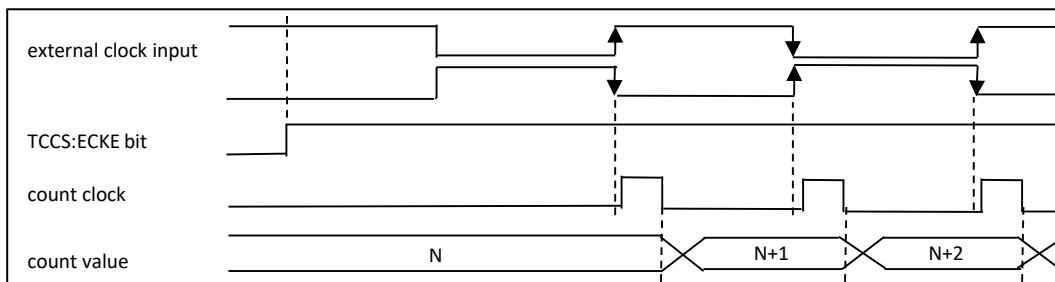

Selected External Count Clock

The free-run timer counts based on an input clock (peripheral clock or external clock).

If the external clock mode (ECKE: bit 15=1 of the timer state control register (TCCS)) is selected, the free-run timer starts counting at a rising edge of the external input when the initial value of the external clock input (TEXT) is "H". After that, the free-run timer counts at both edges. When the initial value of the external input is "L", the free-run timer starts counting at a falling edge of the external input. After that, the free-run timer counts up at both edges.

Figure 3-11 Count Timing of Free-Run Timer (in Up Count Mode)

Note:

- When the external clock input is used, the timer counts at both edges of the external clock.

3.1. Interrupts of the 32-Bit Free-Run Timer

There are the 2 types of interrupts as the interrupts of the 32-bit free-run timer: compare interrupt and 0 detection interrupt.

Free-Run Timer Interrupt

Table 2-1 shows the interrupt control bits and the interrupt factor of the free-run timer.

Table 3-1 Interrupt Control Bits and Interrupt Factor of Free-Run Timer

	Free-run Timer	
	Compare Clear	0 Detection
Interrupt request flag bit	Compare clear interrupt flag bit (ICLR:bit9) of the timer state control register (TCCS)	0 detection interrupt flag bit (IRQZF:bit14) of the timer state control register (TCCS)
Interrupt request enable bit	Compare clear interrupt request enable bit (ICRE:bit8) of the timer state control register (TCCS)	0 detection interrupt request enable bit (IRQZE:bit13) of the timer state control register (TCCS)
Interrupt Factor	The value of the free-run timer matches the value of the compare clear register (CPCLR).	The free-run timer value becomes "0".

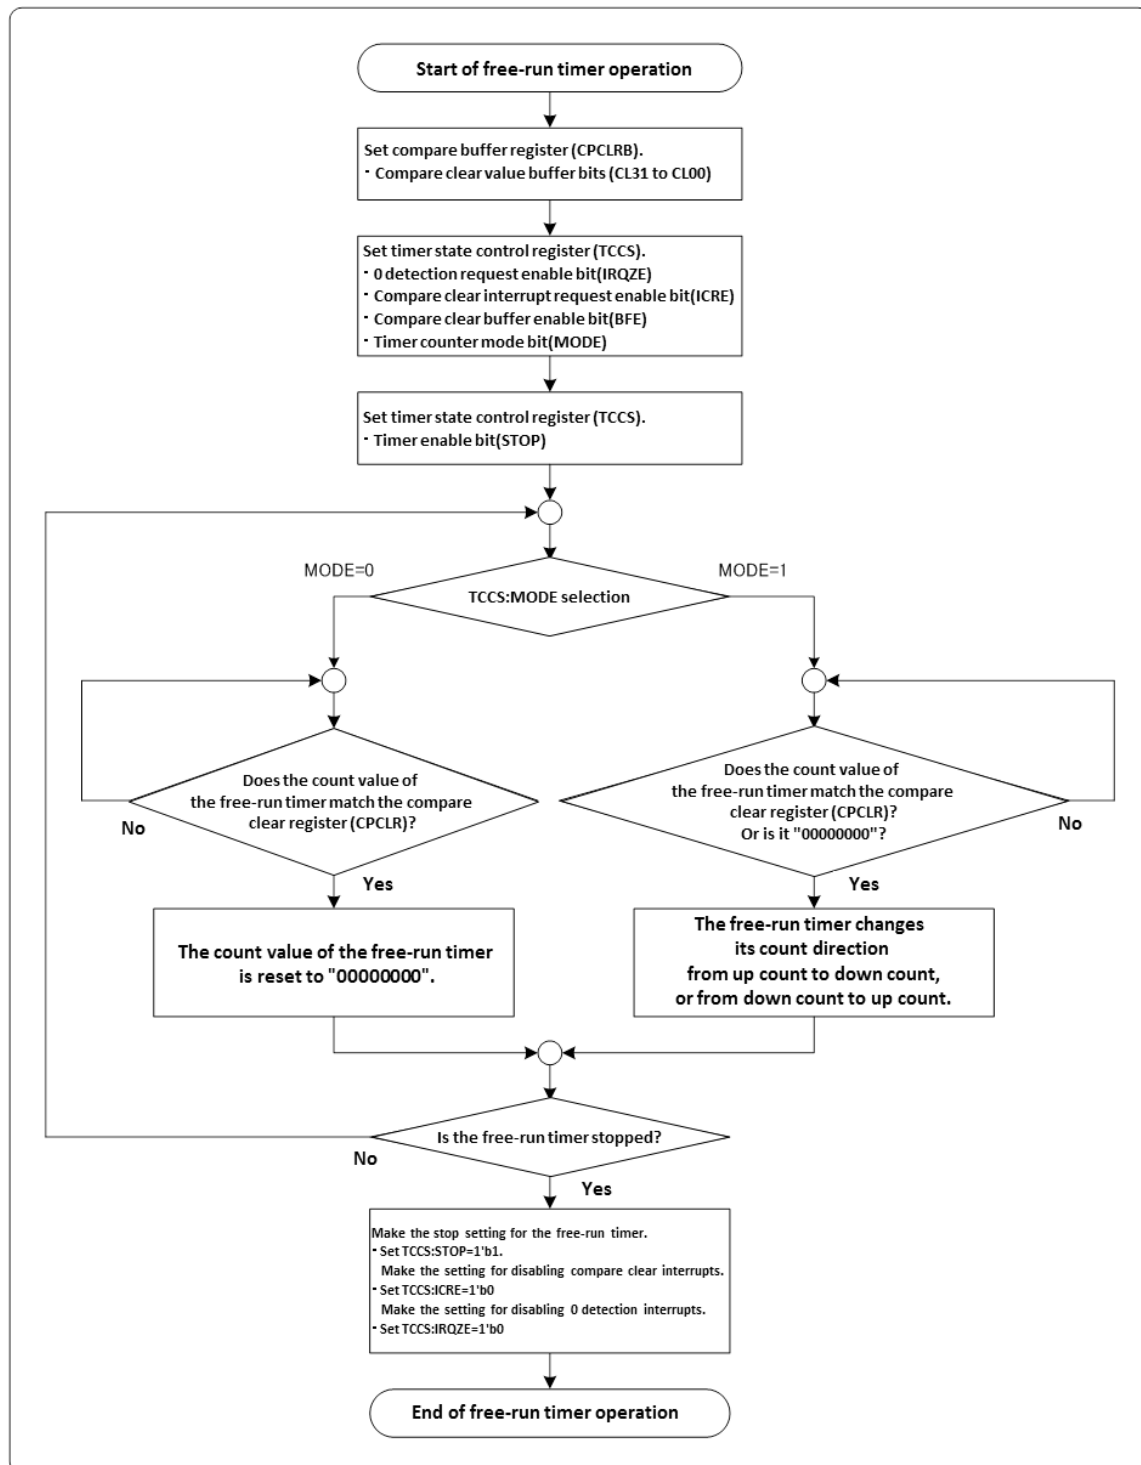

"1" is set to the compare clear interrupt flag (ICLR: bit9) of the timer state control register (TCCS) when the value of the free-run timer matches the value of the compare clear register (CPCLR). When the interrupt request is set to enabled (ICRE: bit8=1 of the timer state control register (TCCS)) in this state, then the interrupt request signal (MIRQ) becomes "H".

"1" is set to the 0 detection interrupt flag (IRQZF: bit14) of the timer state control register (TCCS) when the value of the free-run timer becomes 0x00000000. When the interrupt request is set to enabled (IRQZE: bit13=1 of the timer state control register (TCCS)) in this state, then the interrupt request signal (ZIRQ) becomes "H".

3.2. Setting Procedure Example of the 32-Bit Free-Run Timer

This section provides a setting procedure example of the free-run timer.

Figure 3-12 Setting Procedure Example of Free-Run Timer Operation

4. Registers of the 32-Bit Free-Run Timer

This section provides the register list of the 32-bit Free-run Timer.

Table 4-1 Register Map

Common Peripheral #0 Group (Channel No.:0, 1, 2, 3, 4, 5, 6, and 7)

Offset	Address Offset Value / Register Name				Block Name

4.1. Compare Clear Buffer Register (CPCLRB)/ Compare Clear Register (CPCLR)

The compare clear buffer register (CPCLRB) is the buffer register of the compare clear register (CPCLR). Both registers are located in the same address.

Compare Clear Buffer Register (CPCLRB)

bit	31	30	29	28	27	26	25	24
Field	CL31	CL30	CL29	CL28	CL27	CL26	CL25	CL24
R/W Attribute	W	W	W	W	W	W	W	W

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1

[bit31:0] CL31 to CL00: Compare Clear Value Buffer Bits

The compare clear buffer register (CPCLRB) is a buffer register that is located in the same address as the compare clear register (CPCLR).

The value of the compare clear buffer register (CPCLRB) is immediately transferred to the compare clear register (CPCLR) when the buffer function is set to disabled (BFE: bit7=0 of the timer state control register (TCCS)) or the free-run timer is stopped.

The value of the compare clear buffer register (CPCLRB) is transferred to the compare clear register (CPCLR) when the buffer function is set to enabled (BFE: bit7=1 of the timer state control register (TCCS)) and 0 is detected as the count value of the free-run timer.

Notes:

- Do not set 0x00000000 in the compare clear buffer register (CPCLRB).
- For access to this register, use word access instructions.

Compare Clear Register (CPCLR)

bit	31	30	29	28	27	26	25	24
Field	CL31	CL30	CL29	CL28	CL27	CL26	CL25	CL24
R/W Attribute	R	R	R	R	R	R	R	R

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1

[bit31:0] CL31 to CL00: Compare Clear Value Bits

The compare clear register (CPCLR) is used to compare the count value of the free-run timer.

In the up count mode (MODE: bit5=0 of the timer state control register (TCCS)), the count value of the free-run timer is reset to 0x00000000 when the value of this register matches the count value of the free-run timer.

In the up/down count mode (MODE: bit5=1 of the timer state control register (TCCS)), the free-run timer changes the counting direction from up count to down count when the value of the compare clear register (CPCLR) matches the count value of the free-run timer. The counting direction is changed from down count to up count when 0 is detected.

Note:

- For access to this register, use word access instructions.

4.2. Timer Data Register (TCDT)

The timer data register (TCDT) reads the count value of the free-run timer. This register can also be used to set the count value of the free-run timer.

bit	31	30	29	28	27	26	25	24
Field	T31	T30	T29	T28	T27	T26	T25	T24
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W

R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] T31 to T00: Timer Data Value Bits

The timer data register (TCDT) is used to read the count value of the free-run timer.

The count value can be set by writing a value to this register. However, a value needs to be written while the free-run timer is stopped (STOP: bit 6=1 of the timer state control register (TCCS)).

The counter is cleared to the count value 0x00000000 as soon as any of the following factors occurs.

- Hardware reset
- The timer clear bit (SCLR: bit4) of the timer state control register (TCCS) is "1" while the free-run timer is operating (STOP: bit6=0 of the timer state control register (TCCS)).
- The value of the compare clear register (CPCLR) matches the timer count value in the up count mode (MODE: bit5=0 of the timer state control register (TCCS)).

Notes:

- The free-run timer is not cleared to 0x00000000 even if the timer clear bit (SCLR: bit4) of the timer state control register (TCCS) is set to "1" while the free-run timer is stopped (STOP: bit6=1 of the timer state control register (TCCS)).
- For access to this register, use word access instructions.

4.3. Timer State Control Register (TCCS)

The timer state control register (TCCS) is a register that is used to control the operation of the free-run timer.

For details on writing to this register, see "5.Precautions for Using This Device."

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R1,WX							
Protection Attribute	-							
Initial Value	11111111							

bit	23	22	21	20	19	18	17	16

R/W Attribute	R/W	R/W	R/W	R0,W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	1	0	0	0	0	0	0

[bit31:16] Reserved Bits

"1" is always read from this bit.

Writing data to these bits has no effect on the operation.

[bit15] ECKE: Clock Selection Bit

This bit is used to select a peripheral clock or an external clock as the count clock of the free-run timer. When this bit is set to "0", a peripheral clock is selected.

To select the count clock frequency, the clock frequency selection bits (CLK3 to CLK0: bit3 to bit0) must also be selected.

When this bit is set to "1", an external clock is selected and the clock is input from the "TEXT" pin.

This bit is cleared to "0" by writing "1" to the ECKEC bit of the TCCSC register.

This bit is set to "1" by writing "1" to the ECKES bit of the TCCSS register.

Bit	Description
0	Peripheral clock
1	External clock

Note:

- The count clock is changed immediately when this bit is changed. Therefore, change this bit when the output compare and the input capture are stopped if the free-run timer is connected to them.

[bit14] IRQZF: 0 Detection Interrupt Flag Bit

This bit is set to "1" when the count value of the free-run timer is 0.

This bit is a read-only bit. Writing data to these bits has no effect on the operation.

This bit is cleared by writing "1" to the IRQZFC bit of the TCCSC register.

Bit	Description
0	0 is not detected.
1	0 is detected.

Notes:

- This bit is not set to "1" when the timer is cleared ("1" is written to the SCLR: bit4) while the free-run timer is operating (STOP: bit6=0 of the timer enable bit).
- In the up/down count mode (MODE: bit5=1), this bit is set to "1" when an interrupt that is set by the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) occurs. This bit is not set to "1" when no interrupt occurs.
- In the up count mode (MODE: bit5=0), this bit is set to "1" every time 0 is detected regardless of the value of the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10).

[bit13] IRQZE: 0 Detection Request Enable Bit

When this bit is set to "1" and the 0 detection interrupt flag bit (IRQZF: bit14) is set to "1", an interrupt request to the CPU is generated.

This bit is cleared to "0" by writing "1" to the IRQZEC bit of the TCCSC register. This bit is set to "1" by writing "1" to the IRQZES bit of the TCCSS register.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit12:10] MSI[2:0]: Interrupt Mask Selection Bits

For MODE2: bit11=0 of the timer extended state control register (TECCS)

- In the up count mode (MODE: bit5=0), these bits are used to set the number of times to mask the compare clear interrupt flag. In the up/down count mode bit (MODE: bit5=1), these bits are used to set the number of times to mask the 0 detection interrupt flag.

- When these bits are set to 0b000, the interrupt flags are not masked.

For MODE2: bit11=1 of the timer extended state control register (TECCS)

- In the up/down count mode (MODE: bit5=1), these bits are used to set the number of times to mask the 0 detection interrupt flag.

- In the up count mode (MODE: bit5=0), it is prohibited to use these bits to make this setting.

Bits			Description
0	0	0	Generate an interrupt flag at the first match occurrence.
0	0	1	Generate an interrupt flag at the second match occurrence.
0	1	0	Generate an interrupt flag at the third match occurrence.
0	1	1	Generate an interrupt flag at the fourth match occurrence.
1	0	0	Generate an interrupt flag at the fifth match occurrence.
1	0	1	Generate an interrupt flag at the sixth match occurrence.
1	1	0	Generate an interrupt flag at the seventh match occurrence.
1	1	1	Generate an interrupt flag at the eighth match occurrence.

Notes:

The value read is a mask counter value. The mask counter is a decrement counter.

- The written data is written to the mask register.
- If Interrupt mask function "by setting TCCS.MSI[2:0] Register" is used, please write TCCS[15:8], TCCSC[15:8] and TCCSS[15:8] after 32bit free-run timer stopped.
-

[bit9] ICLR: Compare Clear Interrupt Flag Bit

This bit is set to "1" when the value of the compare clear register (CPCLR) and the value of the free-run timer match.

This bit is a read-only bit. Writing data to these bits has no effect on the operation.

This bit is cleared by writing "1" to the ICLRC bit of the TCCSC register.

Bit	Description
0	No compare clear match.
1	Compare clear match.

Notes:

- In the up count mode (MODE: bit5=0), this bit is set to "1" when the interrupt flag set by the interrupt mask selection bits (MSI2 to MSI0) occurs. This bit is not set to "1" when no interrupt occurs.
- In the up/down count mode (MODE: bit5=1), regardless of the value of the interrupt mask selection bits (MSI2 to MSI0), this bit is set to "1" every time the compare clear occurs.

[bit8] ICRE: Compare Clear Interrupt Request Enable Bit

When this bit is set to "1" and the compare clear interrupt flag bit (ICLR: bit9) is set to "1", an interrupt request to the CPU is generated.

This bit is cleared to "0" by writing "1" to the ICREC bit of the TCCSC register.

This bit is set to "1" by writing "1" to the ICRES bit of the TCCSS register.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit7] BFE: Compare Clear Buffer Enable Bit

This bit is used to enable the compare clear buffer register (CPCLRB).

When this bit is set to "0":

The compare clear buffer register (CPCLRB) becomes invalid. Thus, data can be written directly to the compare clear register (CPCLR).

When this bit is set to "1":

The compare clear buffer register (CPCLRB) becomes valid. The data written and stored in the compare clear buffer register (CPCLRB) is transferred to the compare clear register (CPCLR) when "0" is detected as the count value of the free-run timer.

This bit is cleared to "0" by writing "1" to the BFEC bit of the TCCSC register.

This bit is set to "1" by writing "1" to the BFES bit of the TCCSS register.

Bit	Description
0	Disable the compare clear buffer.
1	Enable the compare clear buffer.

[bit6] STOP: Timer Enable Bit

This bit is used to stop/start counting of the free-run timer.

When this bit is set to "0":

The free-run timer starts counting.

When this bit is set to "1":

The free-run timer stops counting.

This bit is cleared to "0" by writing "1" to the STOPC bit of the TCCSC register.

This bit is set to "1" by writing "1" to the STOPS bit of the TCCSS register.

Bit	Description
0	Enable counting (start counting).
1	Disable counting (stop counting).

[bit5] MODE: Timer Count Mode Bit

This bit is used to select a count mode of the free-run timer.

When this bit is set to "0":

The up count mode is selected. The timer continues to count up until the count value matches the value of the compare clear register (CPCLR) and is reset to 0. After that, it starts counting up again.

When this bit is set to "1":

The up/down count mode is selected. The timer continues to count up until the count value matches the value of the compare clear register (CPCLR). After that, the count direction changes to down count.

When the count value reaches 0, the count direction changes to up count again.

A value can be written to this bit regardless of whether the timer is operating (STOP: bit6=0 of the timer enable bit) or stopped (STOP: bit6=1). When the timer is operating, the value written to this bit is stored in a buffer. After that, when the timer value becomes 0, the count mode is set based on the value stored in the buffer.

This bit is cleared to "0" by writing "1" to the MODEC bit of the TCCSC register.

This bit is set to "1" by writing "1" to the MODES bit of the TCCSS register.

Bit	Description
0	Up count mode
1	Up/down count mode

[bit4] SCLR: Timer Clear Bit

This bit is used to initialize the free-run timer.

Initializing the value of the free-run timer:

The free-run timer is initialized to 0 at the next count clock when "1" is written to this bit while the free-run timer is operating (STOP: bit6=0 of the timer enable bit).

The free-run timer is not initialized if "1" is written to this bit when the free-run timer is stopped (STOP: bit 6=1 of the timer enable bit).

Initializing the count direction of the free-run timer:

The free-run timer always starts the operation from up count when its operation is started again (STOP: bit6=0 of the timer enable bit) after "1" is written to this bit.

The free-run timer starts the operation from up count even if it stops the operation when counting down (STOP: bit6=1 of the timer enable bit), and then starts operating again (STOP: bit6=0 of the timer enable bit) after "1" is written to this bit.

This bit is set to "1" by writing "1" to the SCLRS bit of the TCCSS register.

The read value is always "0".

Bit	Description	
	During Read Operation	During Write Operation
0	"0" always read	Do not initialize the counter.
1		Initialize the counter to 0x00000000.

Notes:

- The 0 detection interrupt is not generated even if this bit is set to "1".
The timer is not cleared when "0" is written to this bit before the next count clock after "1" is written to this bit.
- In the up/down count mode, when "0" is written to the SCLR bit before updating the timer count after "1" is written to the SCLR bit while the timer is counting down, the count value is not updated and the count direction is changed to up count.

[bit3:0] CLK[3:0]: Clock Frequency Selection Bits

These bits are used to select the count clock frequency of the free-run timer.

The clock frequency is changed immediately upon setting these bits.

Bits				Description					
				Count Clock	$\phi = 40$ MHz	$\phi = 20$ MHz	$\phi = 10$ MHz	$\phi = 5$ MHz	$\phi = 2.5$ MHz
0	0	0	0	Φ	25 ns	50 ns	100 ns	200 ns	400 ns
0	0	0	1	$\Phi/2$	50 ns	100 ns	200 ns	400 ns	800 ns

ϕ : Peripheral clock.

4.4. Timer Extended State Control Register (TECCS)

The timer extended state control register (TECCS) is an extended control register that controls the operation of the free-run timer.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R1,WX							
Protection Attribute	-							
Initial Value	11111111							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R1,WX							
Protection Attribute	-							
Initial Value	11111111							

bit	15	14	13	12	11	10	9	8
Field	Reserved				MODE2	MSI5	MSI4	MSI3
R/W Attribute	R0,WX				R/W	R,W	R,W	R,W
Protection Attribute	-				-	-	-	-
Initial Value	0000				0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	Reserved							
R/W Attribute	R1,WX							
Protection Attribute	-							
Initial Value	11111111							

[bit31:16] Reserved: Reserved Bits

"1" is always read from this bit.

Writing data to these bits has no effect on the operation.

[bit15:12] Reserved: Reserved Bits

"0" is always read from this bit.

Writing data to these bits has no effect on the operation.

[bit11] MODE2: Interrupt Mask Mode Bit 2

This bit is used to independently mask the 0 detection interrupt and the compare clear interrupt when the free-run timer is in the up/down count mode (MODE: bit5=1 of the timer state control register (TCCS)).

If "1" is written to this bit when the free-run timer is in the up/down count mode (MODE: bit5=1 of the timer state control register (TCCS)), the value set to the compare clear interrupt mask selection bits (MSI5 to MSI3: bit10 to bit8) of this register is enabled and the compare clear interrupt flag is masked the specified number of times. The value set to the interrupt mask selection bits (MSI2 to MSI0: bit12 to bit10) of the timer state control register (TCCS) becomes valid as the number of times to mask the 0 detection interrupt flag.

Bits		Description
MODE2	MODE*	
0	0	The setting values of MSI5 to MSI3 are invalid.
0	1	The setting values of MSI5 to MSI3 are invalid.
1	0	The setting is prohibited (the operation is not guaranteed).
1	1	The setting values of MSI5 to MSI3 are valid.

*: bit5 of the timer state control register (TCCS)

Note:

- The operation when "1" is written to this bit is not guaranteed when the free-run timer is in the up count mode.

[bit10:8] MSI[5:3]: Compare Clear Interrupt Mask Selection Bits

- These bits are valid only when the interrupt mask mode bit 2 is "1" (MODE2: bit11=1) and the free-run timer is in the up/down count mode (MODE: bit5=1 of the timer state control register (TCCS)). These bits are used to set the number of times to mask the compare clear interrupt flag.

The number of times to mask the 0 detection interrupt flag is set by MSI2 to MSI0: bit12 to bit10 of the timer state control register (TCCS).

- The compare clear interrupt flag is not masked when these bits are set to 0b000.

Bits			Description
0	0	0	Generate an interrupt flag at the first match occurrence.
0	0	1	Generate an interrupt flag at the second match occurrence.
0	1	0	Generate an interrupt flag at the third match occurrence.
0	1	1	Generate an interrupt flag at the fourth match occurrence.
1	0	0	Generate an interrupt flag at the fifth match occurrence.
1	0	1	Generate an interrupt flag at the sixth match occurrence.
1	1	0	Generate an interrupt flag at the seventh match occurrence.
1	1	1	Generate an interrupt flag at the eighth match occurrence.

Notes:

- The value read is a mask counter value. The mask counter is a decrement counter.
- The written data is written to the mask register.

- *While the free-run timer is operating (the timer enable bit STOP: bit6=0 of the timer state control register (TCCS)), the value written to the mask register is reloaded to the counter only when the mask counter becomes 0.*
- *When the free-run timer is stopped (the timer enable bit STOP: bit6=1 of the timer state control register (TCCS)), the value written to the mask register is immediately reloaded to the mask counter.*

[bit7:0] Reserved: Reserved Bits

"1" is always read from this bit.

Writing data to these bits has no effect on the operation.

4.5. Timer State Control Clear Register (TCCSC)

The timer state control clear register (TCCSC) is a register that is used to clear bits of the timer state control register (TCCS).

For details on writing to this register, see "5. Precautions for Using This Device "

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	ECKEC	IRQZFC	IRQZEC	Reserved			ICLRC	ICREC
R/W Attribute	R0,W	R0,W	R0,W	R0,W0			R0,W	R0,W
Protection Attribute	-	-	-	-			-	-
Initial Value	0	0	0	000			0	0

bit	7	6	5	4	3	2	1	0
Field	BFEC	STOPC	MODEC	Reserved				
R/W Attribute	R0,W	R0,W	R0,W	R0,W0				
Protection Attribute	-	-	-	-				
Initial Value	0	0	0	00000				

[bit31:16] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

[bit15] ECKEC: ECKE Clear Bit

When "1" is written to this bit, the clock selection bit (ECKE) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the clock selection bit (ECKE) of the timer state control register (TCCS).
1	Clear the clock selection bit (ECKE) of the timer state control register (TCCS).

[bit14] IRQZFC: IRQZF Clear Bit

When "1" is written to this bit, the 0 detection interrupt flag bit (IRQZF) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the 0 detection interrupt flag bit (IRQZF) of the timer state control register (TCCS).
1	Clear the 0 detection interrupt flag bit (IRQZF) of the timer state control register (TCCS).

[bit13] IRQZEC: IRQZE Clear Bit

When "1" is written to this bit, the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS).
1	Clear the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS).

[bit12:10] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

[bit9] ICLRC: ICLR Clear Bit

When "1" is written to this bit, the compare clear interrupt flag bit (ICLR) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the compare clear interrupt flag bit (ICLR) of the timer state control register (TCCS).
1	Clear the compare clear interrupt flag bit (ICLR) of the timer state control register (TCCS).

[bit8] ICREC: ICRE Clear Bit

When "1" is written to this bit, the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS).
1	Clear the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS).

[bit7] BFEC: BFE Clear Bit

When "1" is written to this bit, the compare clear buffer enable bit (BFE) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the compare clear buffer enable bit (BFE) of the timer state control register (TCCS).
1	Clear the compare clear buffer enable bit (BFE) of the timer state control register (TCCS).

[bit6] STOPC: STOP Clear Bit

When "1" is written to this bit, the timer enable bit (STOP) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the timer enable bit (STOP) of the timer state control register (TCCS).
1	Clear the timer enable bit (STOP) of the timer state control register (TCCS).

[bit5] MODEC: MODE Clear Bit

When "1" is written to this bit, the timer count mode bit (MODE) of the timer state control register (TCCS) is cleared. "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the timer count mode bit (MODE) of the timer state control register (TCCS).
1	Clear the timer count mode bit (MODE) of the timer state control register (TCCS).

[bit4:0] Reserved: Reserved Bits

"0" is always read from this bit. Always write "0" to this bit.

4.6. Timer State Control Set Register (TCCSS)

The timer state control set register (TCCSC) is a register that is used to set bits of the timer state control register (TCCS).

For details on writing to this register, see "5. Precautions for Using This Device "

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	ECKES	Reserved	IRQZES	Reserved				ICRES
R/W Attribute	R0,W	R0,W0	R0,W	R0,W0				R0,W
Protection Attribute	-	-	-	-				-
Initial Value	0	0	0	0000				0

bit	7	6	5	4	3	2	1	0
Field	BFES	STOPS	MODES	SCLRS	Reserved			
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-			
Initial Value	0	0	0	0	0000			

[bit31:16] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

[bit15] ECKES: ECKE Set Bit

When "1" is written to this bit, the clock selection bit (ECKE) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the clock selection bit (ECKE) of the timer state control register (TCCS).
1	Set the clock selection bit (ECKE) of the timer state control register (TCCS).

[bit14] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

[bit13] IRQZES: IRQZE Set Bit

When "1" is written to this bit, the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS).
1	Set the 0 detection request enable bit (IRQZE) of the timer state control register (TCCS).

[bit12:9] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

[bit8] ICRES: ICRE Set Bit

When "1" is written to this bit, the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS).
1	Set the compare clear interrupt request enable bit (ICRE) of the timer state control register (TCCS).

[bit7] BFES: BFE Set Bit

When "1" is written to this bit, the compare clear buffer enable bit (BFE) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the compare clear buffer enable bit (BFE) of the timer state control register (TCCS).
1	Set the compare clear buffer enable bit (BFE) of the timer state control register (TCCS).

[bit6] STOPS: STOP Set Bit

When "1" is written to this bit, the timer enable bit (STOP) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the timer enable bit (STOP) of the timer state control register (TCCS).
1	Set the timer enable bit (STOP) of the timer state control register (TCCS).

[bit5] MODES: MODE Set Bit

When "1" is written to this bit, the timer count mode bit (MODE) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the timer count mode bit (MODE) of the timer state control register (TCCS).
1	Set the timer count mode bit (MODE) of the timer state control register (TCCS).

[bit4] SCLRS: SCLR Set Bit

When "1" is written to this bit, the timer clear bit (SCLR) of the timer state control register (TCCS) is set to "1". "0" is always read from this bit.

Bit	Description
0	Affect neither this bit nor the timer clear bit (SCLR) of the timer state control register (TCCS).
1	Set the timer clear bit (SCLR) of the timer state control register (TCCS).

[bit3:0] Reserved: Reserved Bits

"0" is always read from this bit.

Always write "0" to this bit.

5. Precautions for Using This Device

The following shows the notes when using the 32-bit free-run timer.

Notes to Observe When Accessing a Register

When Accessing the Compare Clear Register (CPCLR) or the Compare Clear Buffer Register (CPCLRB)

Use word access instructions to the compare clear register (CPCLR) and the compare clear buffer register (CPCLRB).

When Accessing the Timer State Control Register (TCCS)

- This register doesn't support writing from the bit-band alias area. For the bit-band alias area, see "CHAPTER: BIT-BAND UNIT."
- To clear a specified bit of this register, clear the bit by writing "1" to the applicable bit of the timer state control clear register (TCCSC).
- To set a specified bit of this register, set the bit by writing "1" to the applicable bit of the timer state control set register (TCCSS).
- Data can be written directly to this register only when writing to all bits.
- In the normal reading mode, the interrupt mask counter value is read from Interrupt Mask Selection bits(MSI[2:0]) in the Timer State Control Register (TCCS).
- If Interrupt mask function "by setting TCCS.MSI[2:0] Register" is used, please write TCCS[15:8], TCCSC[15:8] and TCCSS[15:8] after 32bit free-run timer stopped.

When Accessing the Timer Extended State Control Register (TECCS)

- In the normal reading mode, the interrupt mask counter value is read from MSI5 to MSI3.

Notes When Operating the Free-Run Timer

When Setting Using a Program

- When the hardware is reset, the count value becomes 0x00000000, but the 0 detection interrupt flag is not set.
- Because the timer mode bit (MODE: bit5 of the timer state control register (TCCS)) has a buffer, a specified timer mode is enabled after 0 is detected.
- The timer clear bit (SCLR: bit4=1 of the timer state control register (TCCS)) initializes the timer. However, this bit does not generate the 0 detection interrupt.
- The compare clear flag is not set if the timer starts counting when the value of the compare clear register (CPCLR) matches the count value.
- Set any values other than 0 to the compare clear register (CPCLR). Note that the following operations occur if 0 is set.
 - When the timer mode bit (MODE: bit5 of the timer state control register (TCCS)) is in the up count mode (MODE: bit5=0), the count value is updated to 0 and fixed to 0. Then, the 0 detection interrupt flag and the compare clear flag are set at every count clock.
 - When the timer count mode bit (MODE: bit5 of the timer state control register (TCCS)) is in the up/down count mode (MODE: bit5=1), the count value is counted up from 0x00000000 to 0xFFFFFFFF, and this up count operation is repeated. The 0 detection interrupt flag and the compare clear flag are set to "1" when the count value becomes 0.

CHAPTER 43: 32-bit Input Capture

This chapter describes the functions of the 32-bit input capture.

1. Overview of the 32-Bit Input Capture
2. Configuration and Block Diagram
3. Explanation of 32-Bit Input Capture Operation
4. Registers of the 32-Bit Input Capture
5. Precautions for Using This Device

ICU-TXXPT03P01R01L04-E1-XX

1. Overview of the 32-Bit Input Capture

The 32-bit input capture can measure the input pulse width and external clock cycle based on the value of the 32-bit free-run timer.

Functions of the 32-Bit Input Capture

- The 32-bit input capture is composed of 2 input captures. Each channel can be operated individually.
- Each input capture is composed of 2 independent external input pins (IN0 and IN1), capture registers that correspond to the pins, and the capture control register. When an edge signal is detected on an external input pin, the value of the free-run timer can be stored in the capture register. At the same time, an interrupt is generated.
- 3 types of trigger edges (rising edge, falling edge, and both edges) of an external input signal can be selected. There is a register that indicates whether a trigger edge is a rising or falling edge.
- An interrupt is generated when a valid edge is detected from an external input signal.

Interrupt request and DMA request

- Interrupt request of this module can be used for purposes below:
 1. Interrupt request to CPU (via Interrupt Controller)
 2. DMA request to DMA Controller
- To use the interrupt as interrupt request to CPU, following configuration is necessary:
 - Enable the interrupt request in this module
 - Enable the interrupt channel of the interrupt in Interrupt Controller
- To use the interrupt as DMA request to DMA Controller, following configuration is necessary:
 - Enable the interrupt request in this module
 - Select the DMA channel from this module as DMA client in DMA Controller

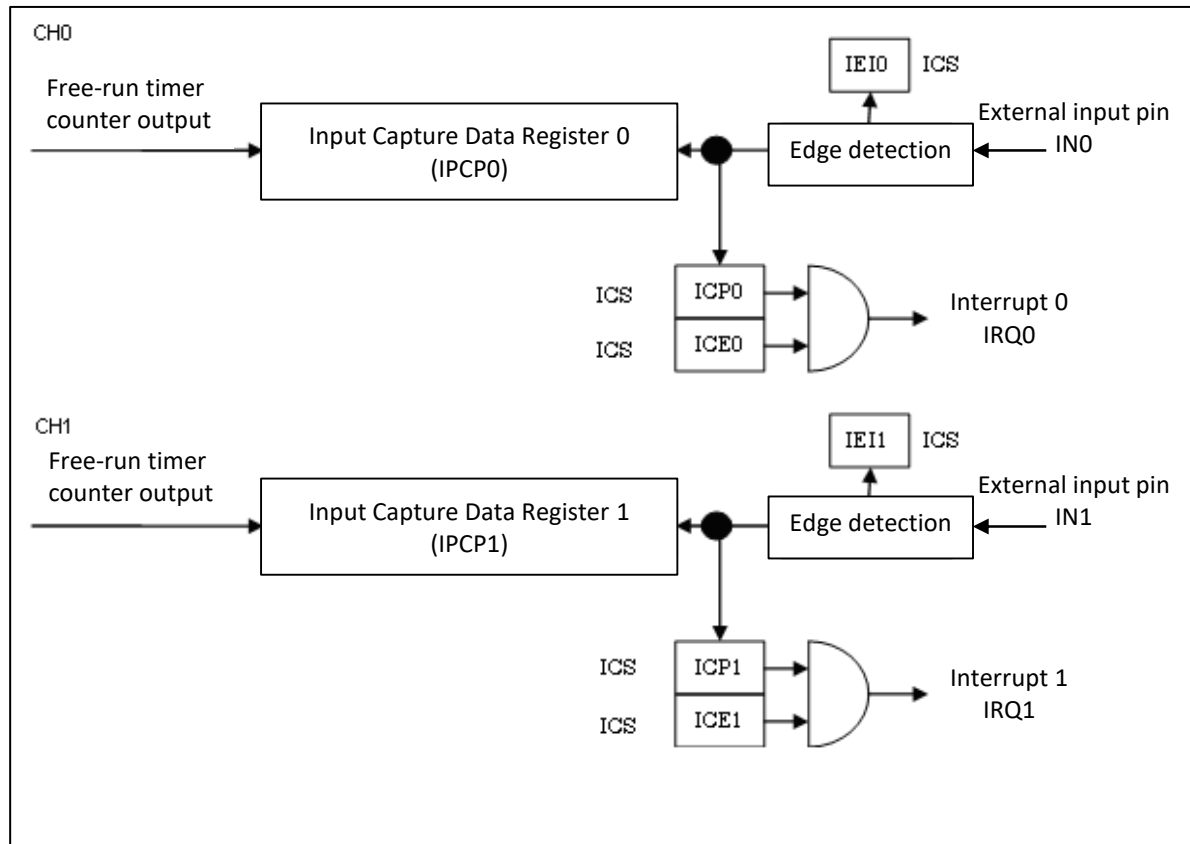

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Configuration and Block Diagram

Figure 2-1 is a configuration diagram of the 32-bit input capture.

Figure 2-1 Configuration Diagram of 32-Bit Input Capture

3. Explanation of 32-Bit Input Capture Operation

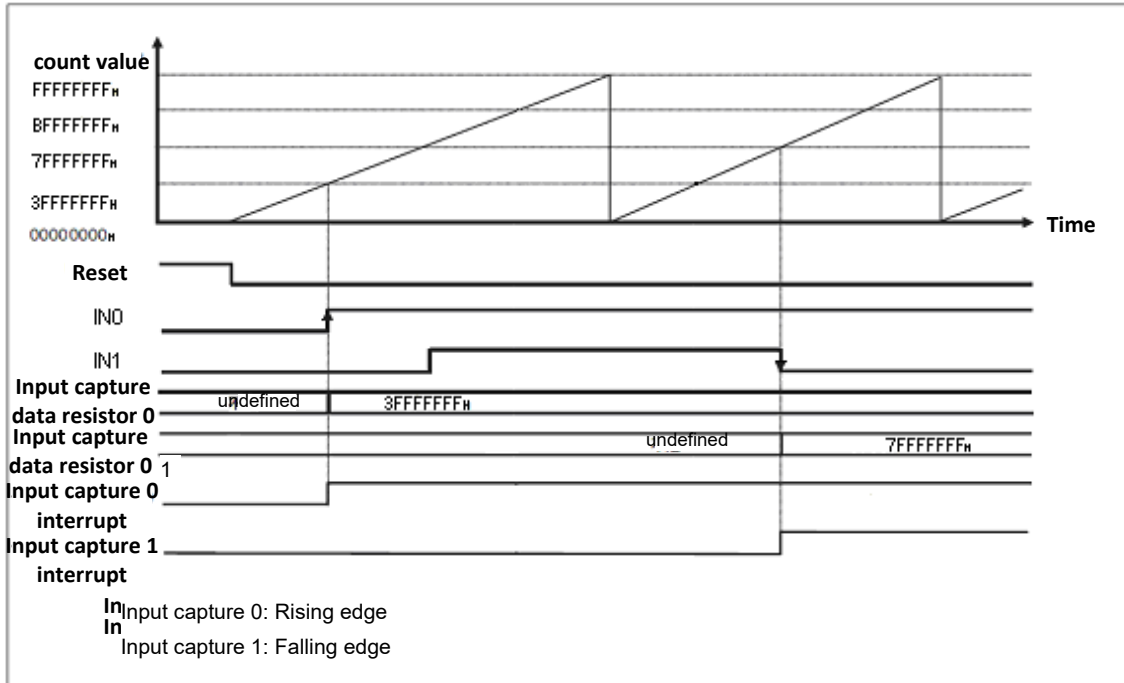

This section provides an overview of 32-bit input capture operation.

Operation of the 32-Bit Input Capture

The 32-bit input capture is used to detect a specified valid edge. When a valid edge is detected, an interrupt flag is set. Then the value of the 32-bit free-run timer is loaded to the input capture register.

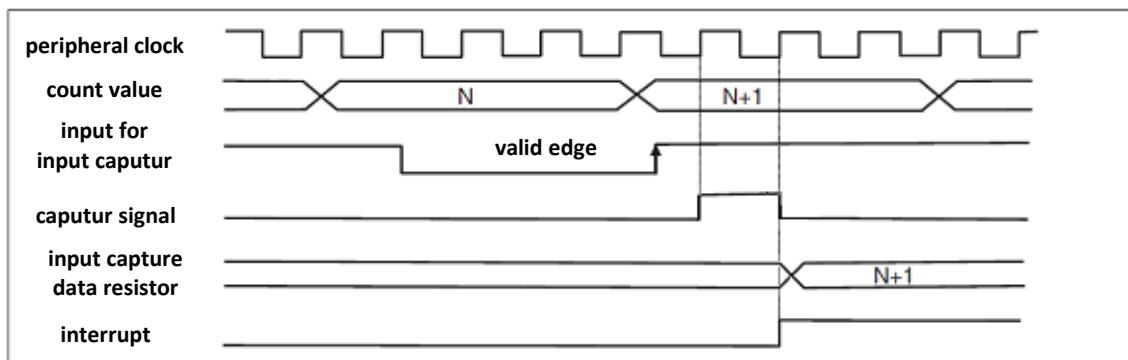

Input Capture Operation

Figure 3-1 Example of Input Capture Timing

Input Capture Input Timing

Figure 3-2 Example of Input Capture Timing for Input Signals

3.1. Interrupt of the 32-Bit Input Capture

As the interrupt of the 32-bit input capture, there is an input capture interrupt triggered by an external input signal.

Input Capture Interrupt

Table 2-1 shows the interrupt control bits and interrupt factor of the input capture.

Table 3-1 Interrupt Control Bits and Interrupt Factor of Input Capture 1, 0

	Input Capture 1, 0
Interrupt Request Flag Bit	The interrupt request flag bits ICP1, 0 (bit7, bit6) in the input capture state control register (ICS)
Interrupt Request Enable Bit	The interrupt request enable bits ICE1, 0 (bit5, bit4) in the input capture state control register (ICS)
Interrupt Factor	A valid edge is detected on the external input pin (IN1, IN0).

For the interrupt capture, when a valid edge is detected on the external input pin (IN1, IN0), the interrupt request flag (ICP1, ICP0: bit7, bit6) in the input capture state control register (ICS) is set to "1". When an interrupt request is set to enabled (ICE1, ICE0: bit5, bit4 = 0b11 in the input capture state control register (ICS)) in this state, then the interrupt request is output to the interrupt controller.

3.2. Setting Procedure Example

This section provides a setting procedure example of the input capture.

Figure 3-3 Procedure Example of Setting Input Capture Operation

4. Registers of the 32-Bit Input Capture

This section provides the register list of the 32-bit input capture.

Table 4-1 Register Map

Common Peripheral Group #0 (Channel No.:0, 1, 2, 3, 4, 5, 6, and 7)

4.1. Input Capture Data Registers 0, 1 (IPCP0, IPCP1)

Input capture data registers 0, 1 (IPCP0, IPCP1) are used to store the count value of the free-run timer when a valid edge of an external input signal is detected.

Input Capture Data Register (IPCP0)

bit	31	30	29	28	27	26	25	24

[bit31:0] CP[31:00]: Input Capture Data Value Bit

The input capture data register 0 (IPCP0) is used to store the value of the free-run timer when a valid edge of the external input pin IN0 signal is detected.

The free-run timer that is mentioned here indicates the operating state of the free-run timer that is connected to the input capture.

Note:

- For access to this register, use word access instructions.

[bit31:0] CP[31:00]: Input Capture Data Value Bit

Input capture data register 1 (IPCP1) is used to store the value of the free-run timer when a valid edge of the external input pin IN1 signal is detected.

The free-run timer that is mentioned here indicates the operating state of the free-run timer that is connected to the input capture.

Note:

- For access to this register, use word access instructions.

4.2. Input Capture State Control Register (ICS)

The input capture state control register (ICS) is used to select an edge, enable an interrupt request, and control an interrupt request flag. This register is also used to indicate a valid edge detected in the input captures 0, 1.

For details on writing to this register, see "5. Precautions for Using This Device."

Flag bits of the input capture state control registers are only read if the APB-IF is valid.

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R1,WX							
Protection Attribute	-							
Initial Value	11111111

R/W Attribute	R,WX	R,WX	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit31:10] Reserved: Reserved Bits

The read value is "1".

Writing data to these bits has no effect on the operation.

[bit9] IEI1: Valid Edge Indication Bit (Input Capture 1)

- This bit is a valid edge indication bit in input capture data register 1. This bit indicates that a rising or falling edge is detected.
- When a falling edge is detected, this bit is set to "0".
- When a rising edge is detected, this bit is set to "1".
- This bit is read-only.

Bit	Description
0	A falling edge is detected.
1	A rising edge is detected.

Notes:

- The value read is meaningless if the edge selection bit (EG11, EG10: bit3, bit2) is set to "00_B".
- If the edge selection bit (EG11, EG10: bit3, bit2) is set to any value other than "00_B", then the value is updated when the interrupt request flag (ICP1) is set.

[bit8] IEI0: Valid Edge Indication Bit (Input Capture 0)

- This bit is a valid edge indication bit in input capture data register 0. This bit indicates that a rising or falling edge is detected.
- When a falling edge is detected, this bit is set to "0".
- When a rising edge is detected, this bit is set to "1".
- This bit is a read-only bit.

Bit	Description
0	A falling edge is detected.
1	A rising edge is detected.

Notes:

- The value read is meaningless if the edge selection bit (EG01, EG00: bit1, bit0) is set to "00_B".
- If the edge selection bit (EG01, EG00: bit1, bit0) is set to any value other than "00_B", then the value is updated when the interrupt request flag (ICP0) is set.

[bit7] ICP1: Interrupt Request Flag Bit (Input Capture 1)

- This bit is used as an interrupt request flag of input capture 1.
- This bit is set to "1" immediately upon detecting a valid edge on the external input pin (IN1).
- An interrupt is generated as soon as this bit is set to "1" when the interrupt request enable bit (ICE1: bit5) is "1".
- This bit is a read-only bit. Writing data to these bits has no effect on the operation.
- This bit is cleared to "0" by writing "1" to the ICP1C bit in the ICSC register.

Bit	Description
0	No valid edge is detected.
1	A valid edge is detected.

[bit6] ICP0: Interrupt Request Flag Bit (Input Capture 0)

- This bit is used as an interrupt request flag of input capture 0.
- This bit is set to "1" immediately upon detecting a valid edge on the external input pin (IN0).
- An interrupt is generated as soon as this bit is set to "1" when the interrupt request enable bit (ICE0: bit4) is "1".
- This bit is a read-only bit. Writing data to these bits has no effect on the operation.
- This bit is cleared to "0" by writing "1" to the ICP0C bit in the ICSC register.

Bit	Description
0	No valid edge is detected.
1	A valid edge is detected.

[bit5] ICE1: Interrupt Request Enable Bit (Input Capture 1)

- This bit is used to enable an interrupt request of input capture1.
- An interrupt of input capture 1 is generated when the interrupt request flag bit (ICP1: bit7) is set while this bit is "1".
- This bit is cleared to "0" by writing "1" to the ICE1C bit in the ICSC register.
- This bit is set to "1" by writing "1" to the ICE1S bit in the ICSS register.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit4] ICE0: Interrupt Request Enable Bit (Input Capture 0)

- This bit is used to enable an interrupt request of input capture 0.
- An interrupt of input capture 0 is generated when the interrupt request flag bit (ICP0: bit6) is set while this bit is "1".
- This bit is cleared to "0" by writing "1" to the ICE0C bit in the ICSC register.
- This bit is set to "1" by writing "1" to the ICE0S bit in the ICSS register.

Bit	Description
0	Disable interrupt requests.
1	Enable interrupt requests.

[bit3:2] EG11, EG10: Edge Selection Bits (Input Capture 1)

- These bits are used to enable the operation of input capture 1. These bits specify a valid edge of the external input (IN1).

Bits		Description
EG11	EG10	
0	0	No edge is detected (stop).
0	1	A rising edge is detected.
1	0	A falling edge is detected.
1	1	Both edges are detected.

[bit1:0] EG01, EG00: Edge Selection Bits (Input Capture 0)

- These bits are used to enable the operation of input capture 0. These bits specify a valid edge of the external input (IN0).

Bits		Description
EG01	EG00	
0	0	No edge is detected (stop).
0	1	A rising edge is detected.
1	0	A falling edge is detected.
1	1	Both edges are detected.

4.3. Input Capture State Control Clear Register (ICSC)

The input capture state control clear register (ICSC) is a register to clear a bit in the input capture state control register (ICS).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	7	6	5	4	3	2	1	0
Field	ICP1C	ICP0C	ICE1C	ICE0C	Reserved			
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W0			
Protection Attribute	-	-	-	-	-			
Initial Value	0	0	0	0	0000			

[bit31:8] Reserved: Reserved Bits

The read value is "0".

Always write "0" to this bit.

[bit7] ICP1C: ICP1 Clear Bit

- Writing "1" to this bit clears the ICP1 bit in the ICS register.
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request flag bit (input capture1) (ICP1) in the input capture state control register (ICS).
1	Clear the interrupt request flag bit (input capture1) (ICP1) in the input capture state control register (ICS).

[bit6] ICP0C: ICP0 Clear Bit

- Writing "1" to this bit clears the ICP0 bit in the ICS register.
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request flag bit (input capture0) (ICP0) in the input capture state control register (ICS).
1	Clear the interrupt request flag bit (input capture0) (ICP0) in the input capture state control register (ICS).

[bit5] ICE1C: ICE1 Clear Bit

- Writing "1" to this bit clears the ICE1 bit in the ICS register.
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request enable bit (input capture 1) (ICE1) in the input capture state control register (ICS).
1	Clear the interrupt request enable bit (input capture 1) (ICE1) in the input capture state control register (ICS).

[bit4] ICE0C: ICE0 Clear Bit

- Writing "1" to this bit clears the ICE0 bit in the ICS register.
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request enable bit (input capture 0) (ICE0) in the input capture state control register (ICS).
1	Clear the interrupt request enable bit (input capture 0) (ICE0) in the input capture state control register (ICS).

[bit3:0] Reserved: Reserved Bits

The read value is "0".

Always write "0" to this bit.

4.4. Input Capture State Control Set Register (ICSS)

The input capture state control set register (ICSS) is a register that sets the bit in the input capture state control register (ICS).

bit	31	30	29	28	27	26	25	24
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	7	6	5	4	3	2	1	0
Field	Reserved	ICE1S	ICE0S	Reserved				
R/W Attribute	R0,W0	R0,W	R0,W	R0,W0				
Protection Attribute	-	-	-	-				
Initial Value	00	0	0	0000				

[bit31:6] Reserved: Reserved Bits

The read value is "0".

Always write "0" to this bit.

[bit5] ICE1S: ICE1 Set Bit

- Writing "1" to this bit sets the ICE1 bit in the ICS register to "1".
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request enable bit (input capture 1) (ICE1) in the input capture state control register (ICS).
1	Set the interrupt request enable bit (input capture 1) (ICE1) in the input capture state control register (ICS).

[bit4] ICE0S: ICE0 Set Bit

- Writing "1" to this bit sets the ICE0 bit in the ICS register to "1".
- "0" is always read from this bit.

Bit	Description
0	Do not affect this bit and the interrupt request enable bit (input capture 0) (ICE0) in the input capture state control register (ICS).
1	Set the interrupt request enable bit (input capture 0) (ICE0) in the input capture state control register (ICS).

[bit3:0] Reserved: Reserved Bit

The read value is "0".

Always write "0" to this bit.

5. Precautions for Using This Device

The following shows the notes when using the 32-bit input capture.

Notes to Observe when Accessing a Register

When Accessing the Input Capture Data Registers 0, 1 (IPCP0, 1)

Use word access instructions for the input capture data registers 0, 1 (IPCP0, 1).

When Accessing the Input Capture State Control Register (ICS)

- This register supports writing from the bit-band alias area. For the bit-band alias area, see "CHAPTER: BIT-BAND UNIT."
- To clear a specified bit in this register, clear the bit by writing "1" to the applicable bit in the input capture state control clear register (ICSC).
- To set a specified bit in this register, set the bit by writing "1" to the applicable bit in the input capture state control set register (ICSS).
- Data can be written directly to this register only when writing to all bits.

Notes on Interrupt Processing

- The valid edge indication bit (IEI1, IEI0: bit9, bit8) in the input capture state control register (ICS) indicates a detected latest edge when the level of the external input pin (IN0, IN1) switches while an interrupt routine is processing after the interrupt request flag (ICP1, ICP0) in the input capture state control register (ICS) is set to "1".

Notes on Input Capture Operation

About Capture Timing

- Capture resolution is 1 peripheral clock because the input capture operates according to the peripheral clock timing. The resolution is 1 timer count because the capture data is the timer counter value of the free-run timer.

CHAPTER 44: 32-bit Output Compare

This chapter describes the 32-bit output compare function.

1. Overview
2. Configuration
3. Explanation of Operation
4. Setting Procedure Example
5. Registers
6. Precautions for Using This Device

OCU-TXXPT03P01R01L05-E1-XX

1. Overview

The 32-bit output compare consists of the 32-bit compare register, compare output latch, and compare control register. It can output a waveform by using the timer value of the 32-bit free-run timer.

Functions of the 32-Bit Output Compare

- It consists of 2 output compares. You can set an initial value for each output pin (OUT0 and OUT1).
- The 32-bit output compare consists of the 32-bit compare register, compare output latch, and compare control register.
- You can use the 2 output compares in combination to control the output pins. The output pins are inverted by the use of the 2 compare registers.
- An interrupt is generated when the output compare register value matches the free-run timer value.

Interrupt request and DMA request

- Interrupt request of this module can be used for purposes below:
 1. Interrupt request to CPU (via Interrupt Controller)
 2. DMA request to DMA Controller
- To use the interrupt as interrupt request to CPU, following configuration is necessary:
 - Enable the interrupt request in this module
 - Enable the interrupt channel of the interrupt in Interrupt Controller
- To use the interrupt as DMA request to DMA Controller, following configuration is necessary:
 - Enable the interrupt request in this module
 - Select the DMA channel from this module as DMA client in DMA Controller

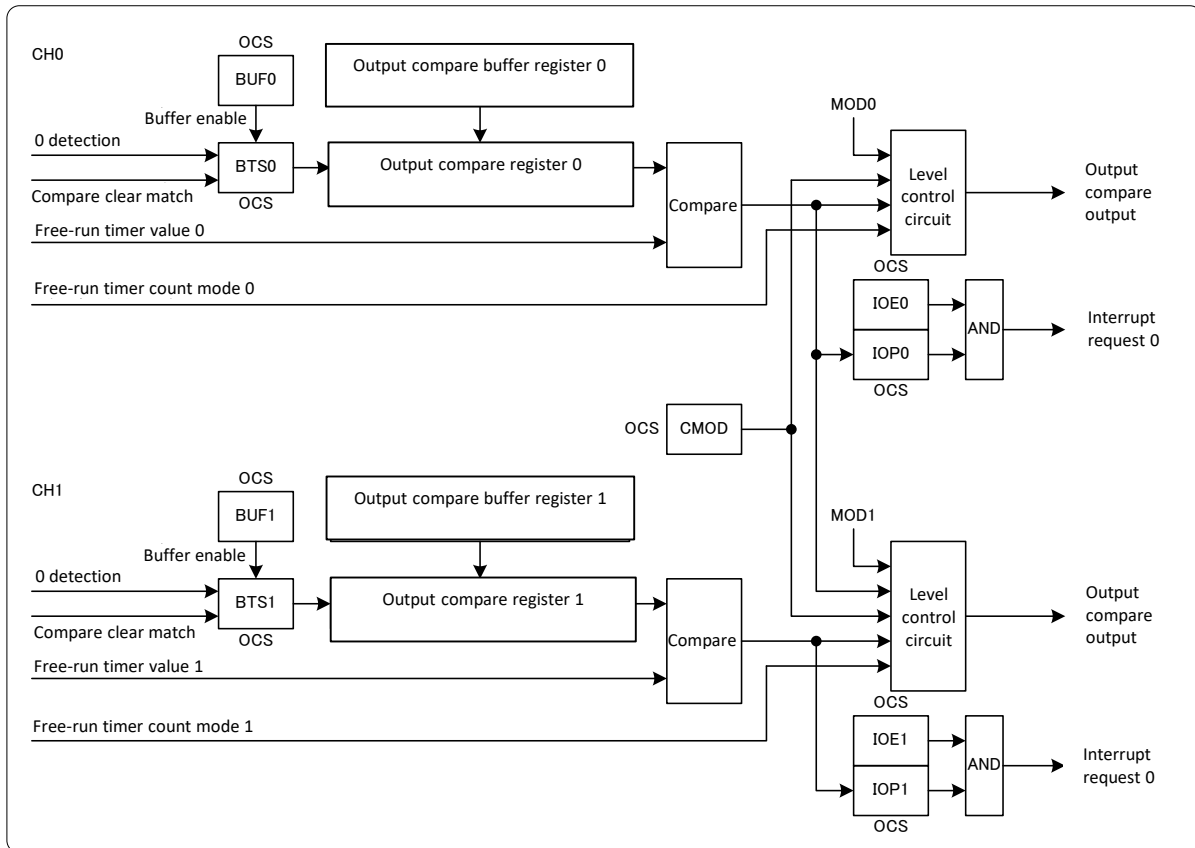

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Configuration

Figure 2-1 shows the configuration of the 32-bit output compare.

Figure 2-1 Configuration of the 32-Bit Output Compare

3. Explanation of Operation

3.1. Interrupt

There is the compare match interrupt as a 32-bit output compare interrupt.

Output Compare Interrupt

Table 3-1 Interrupt Control Bits and Interrupt Factors of Output Compares (CH.0, CH.1)

	Output Compare (CH.0)	Output Compare (CH.1)
Interrupt Request Flag Bit	Compare match interrupt flag bit in the compare control register (OCS) (IOP0: bit6)	Compare match interrupt flag bit in the compare control register (OCS) (IOP1: bit7)
Interrupt Request Enable Bit	Compare match interrupt enable bit in the compare control register (OCS) (IOE0: bit4)	Compare match interrupt enable bit in the compare control register (OCS) (IOE1: bit5)
Interrupt Factor	The free-run timer value matches the value in the output compare register (OCCP0).	The free-run timer value matches the value in the output compare register (OCCP1).

When the free-run timer value matches the value in the output compare register (OCCP0, 1), the compare match interrupt flag in the compare control register (OCS) (IOP1, IOP0) is set to "1". In this state, when the interrupt request is set to be enabled (OCS:IOE1 = 1, OCS:IOE0 = 1), the interrupt request signal (IRQ0, IRQ1) outputs "H".

3.2. 32-Bit Output Compare Operation

The 32-bit output compare is used to compare the "value set in the specified compare clear register" and "value in the 32-bit free-run timer." When a match is detected, the interrupt flag is set and a compare output level is set according to the control signal.

When the free-run timer is in up-down count mode and the count peak and compare register value match, the match signal is ignored.

Output Compare Operation (for MODn Pin = "L" (Invert Mode))

Each Channel can Perform the Compare Operation (CMOD:bit12 in the Compare Control Register (OCS) = 0).

- The output compare 0 output (OUT0) is immediately inverted when the free-run timer and compare register 0 (OCCP0) match.
- The output compare 1 output (OUT1) is immediately inverted when the free-run timer and compare register 1 (OCCP1) match.

Figure 3-1 Output Waveform Example for When Compare Registers 0 and 1 are Separately Used with Initial Output Value = 0 (Free-Run Timer is in Up Count Mode.)

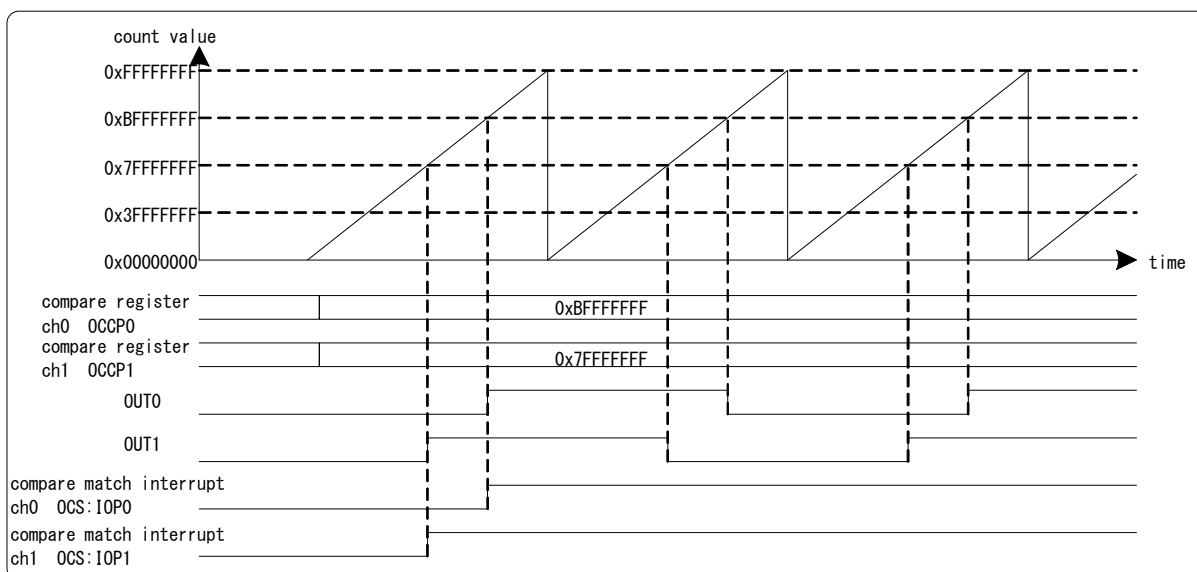

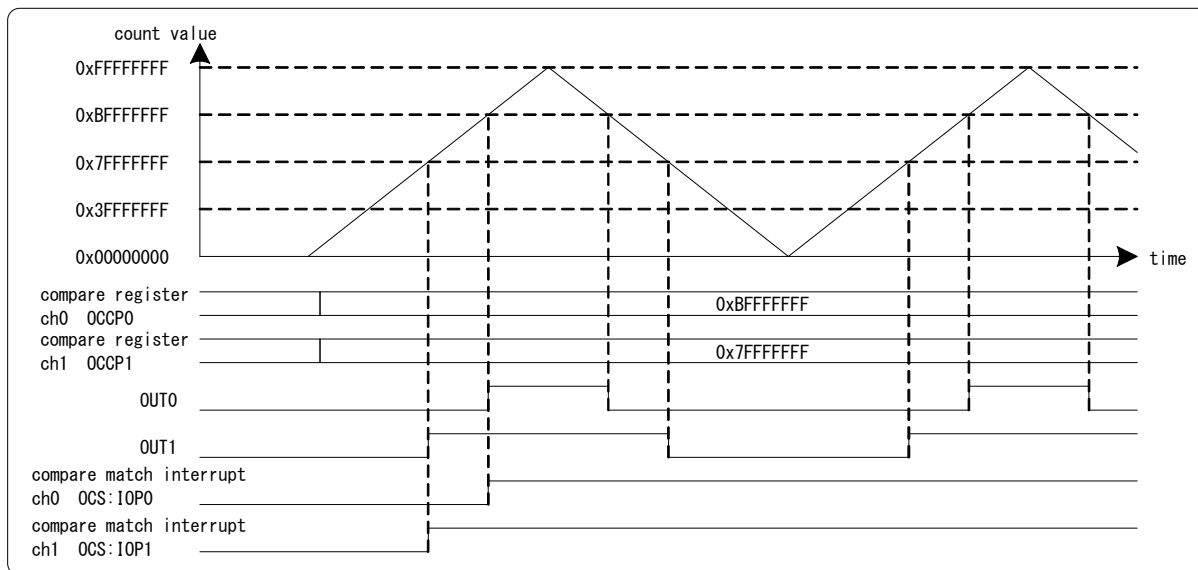

Figure 3-2 Output Waveform Example for When Compare Registers 0 and 1 are Separately Used with Initial Output Value = 0 (Free-Run Timer is in Up-Down Count Mode.)

The Channels can Perform the Compare Operation as a Pair of Channels (CMOD:bit12 in the Compare Control Register (OCS) = 1).

- The output compare 0 output (OUT0) is immediately inverted when the free-run timer and compare register 0 (OCCP0) match.
- The output compare 1 output (OUT1) is immediately inverted when the free-run timer and compare register 0 (OCCP0) or compare register 1 (OCCP1) match.

Figure 3-3 Output Waveform Example for When Compare Registers 0 and 1 are Used as a Pair with Initial Output Value = 0 (Free-Run Timer is in Up Count Mode.)

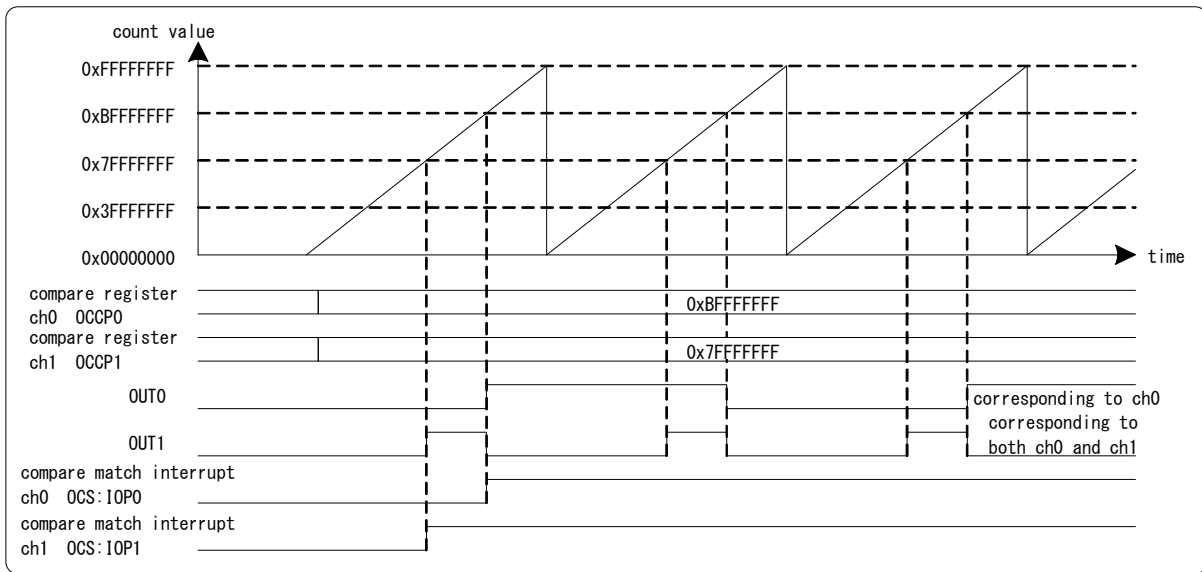

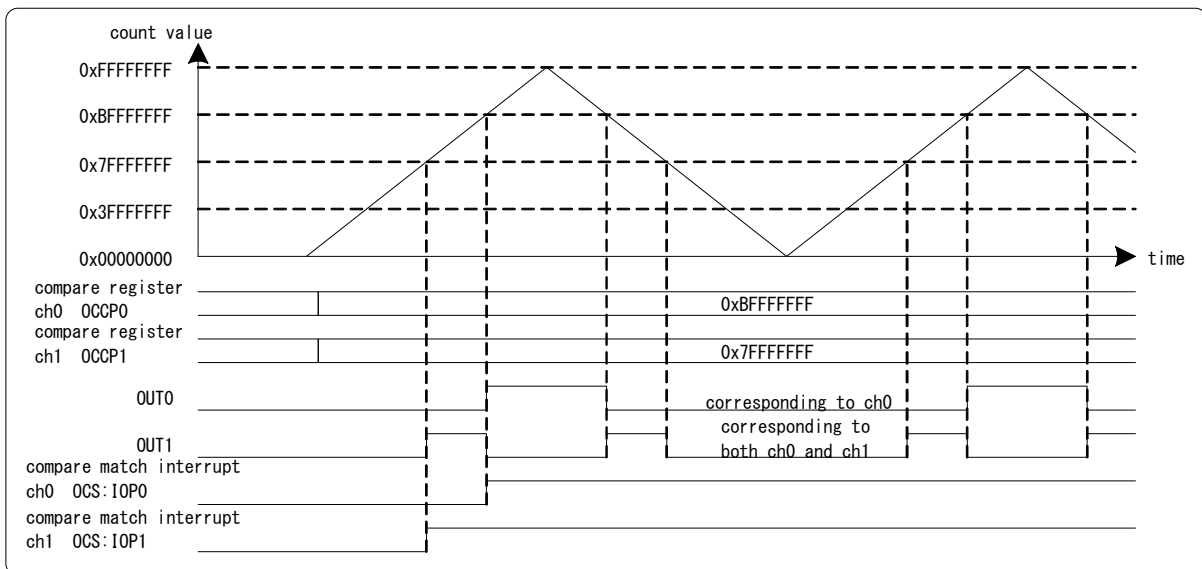

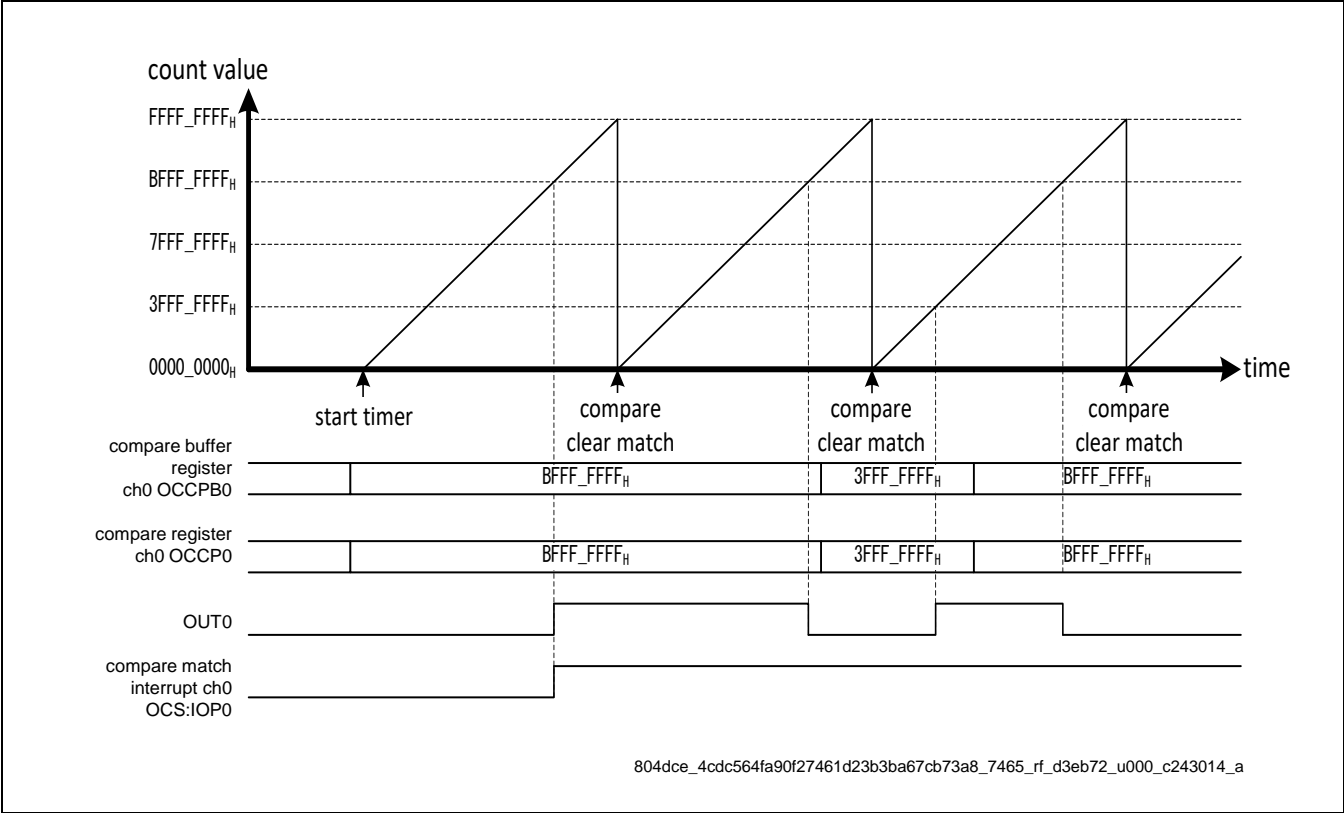

Figure 3-4 Output Waveform Example for When Compare Registers 0 and 1 are Used as a Pair with Initial Output Value = 0 (Free-Run Timer is in Up-Down Count Mode.)

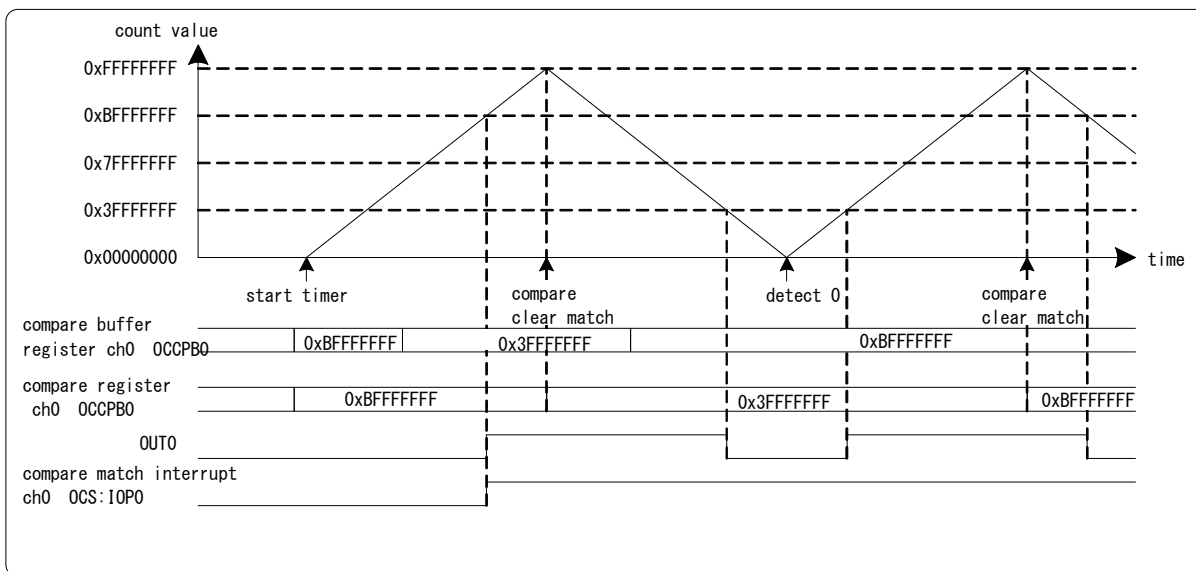

Output Waveform When the Compare Buffer is Disabled

Figure 3-5 Output Waveform Example for When the Compare Buffer is Disabled (Free-Run Timer is in Up Count Mode.)

Output Waveform When the Compare Buffer is Enabled

Figure 3-6 Output Waveform Example for When Compare Buffer Contents are Transferred at Occurrence of Compare Clear Match (Free-Run Timer is in Up-Down Count Mode.)

Output compare operation (for MODn Pin = "H" (Set/Reset Mode))

- When CMOD: bit12 in the compare control register (OCS) is "0"
 - Output compare outputs (OUT0, OUT1) are set to "H" when the count direction of the free-run timer is up count and the free-run timer matches the corresponding compare register (OCCP0, OCCP1).
 - Output compare outputs (OUT0, OUT1) are set to "L" when the count direction of the free-run timer is down count and the free-run timer matches the corresponding compare register (OCCP0, OCCP1).
- When CMOD: bit12 in the compare control register (OCS) is "1"
 - Output compare outputs (OUT0, OUT1) are set to "L" when the count direction of the free-run timer is up count and the free-run timer matches the corresponding compare register (OCCP0, OCCP1).
 - Output compare outputs (OUT0, OUT1) are set to "H" when the count direction of the free-run timer is down count and the free-run timer matches the the corresponding compare register (OCCP0, OCCP1).

Figure 3-7 Output Waveform for When the Output Pin is Set to "1" at Occurrence of Output Compare Match (Free-Run Timer is in Up Count Mode.)

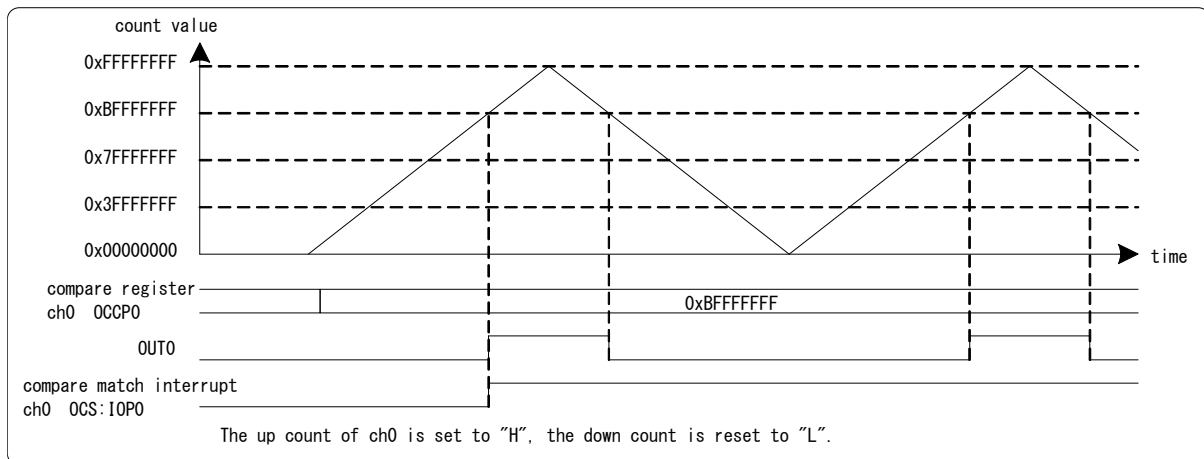

Figure 3-8 Output Waveform for When the Output Pin is Set/Reset at Occurrence of Output Compare Match (Free-Run Timer is in Up-Down Count Mode.)

Output Compare Timing

When the free-run timer value matches the output compare register value, the output compare generates the compare match signal, and controls the OUT pin output according to the mode to generate an interrupt flag.

When a compare match occurs, the OUT pin output is controlled in sync with the count timing of the free-run timer.

Figure 3-9 Timing of Output Compare Register Interrupt

Figure 3-10 Timing of Change in OUT Pin Output

When the compare operation is enabled (OCS.CSTn= 1) or disabled (OCS.CSTn= 0) after free-run timer is stopped or started, the output compare operations are as below.

Free-Run Timer Status	Compare Operation		Compare Match
Stop	Disable		Not occur
	Enable	When the free-run timer value matches the output compare register value	Occur continuously during stop. (only up-count mode)
		When the free-run timer value does not match the output compare register value	Not occur

Free-Run Timer Status	Compare Operation		Compare Match
Run	Disable		Not occur
	Enable	When the free-run timer value matches the output compare register value	Occur
		When the free-run timer value does not match the output compare register value	Not occur

When free-run timer is stopped or started after compare operation is enabled (OCS.CSTn= 1) or disabled (OCS.CSTn= 0), the output compare operations are as below.

Compare Operation Status	Free-Run Timer		Compare Match
Disable	Stop		Not occur
	Start		Not occur
Enable	Stop	When the free-run timer value matches the output compare register value	Occur continuously during stop. (only up-count mode)
		When the free-run timer value does not match the output compare register value	Not occur
	Start	When the free-run timer value matches the output compare register value	Occur (See Note)
		When the free-run timer value does not match the output compare register value	Not occur

Note:

- When in starting the free-run timer or at the compare match timing in Figure 3-9, the compare match signal occurs.

If the output compare is up count mode, stop the free-run timer after disabling compare operation.

Please enable compare operation after the free-run timer is cleared. The reason is that the compare match occurs continuously if the compare operation status is enabled under the condition that the free-run timer value matches the output compare register value.

Operation of the Output Compare and Free-Run Timer

Transfer Timing of the Output Compare Buffer Register (for When the Free-Run Timer is in Up Count Mode.)

Figure 3-11 For Transfer When a Compare Clear Match is Found

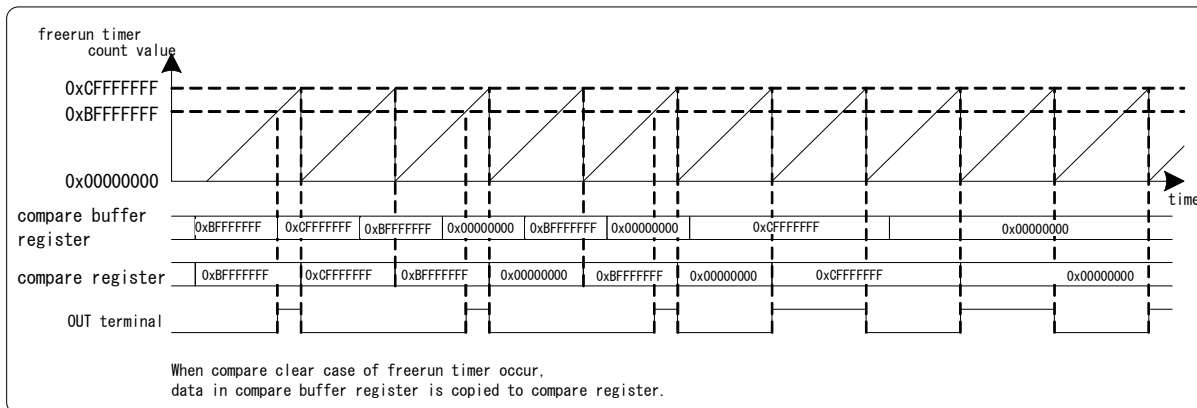

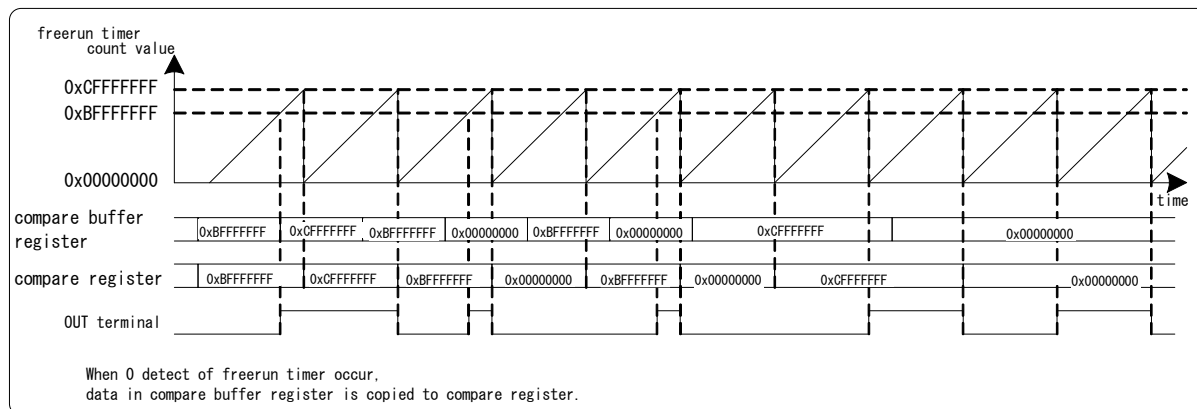

Figure 3-12 For Transfer When 0 is Detected

Output Compare Operation Example 1 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when a compare clear match is found for the free-run timer.
- In the case where the output is inverted when the output compare output matches (OCS:CMOD = 0, MOD pin = "L")

Figure 3-13 Output Compare Operation Example 1 (Free-Run Timer Up/Down Counting)

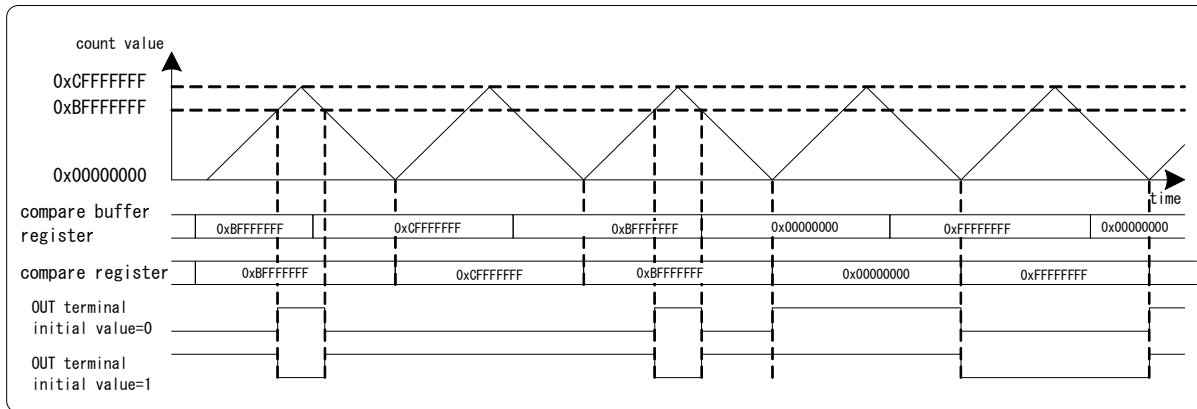

Notes:

- The OUT pin output is set to "H" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "1".)
- The OUT pin output is reset to "L" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "1".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

Output Compare Operation Example 2 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when 0 is detected in the free-run timer.
- In the case where the output is inverted when the output compare output matches (OCS:CMOD = 0, MOD pin = "L")

Figure 3-14 Output Compare Operation Example 2 (Free-Run Timer Up/Down Counting)

Notes:

- The OUT pin output is set to "H" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "1".)
- The OUT pin output is reset to "L" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "1".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

Output Compare Operation Example 3 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when a compare clear match is found for the free-run timer.
- In the case where the output compare output is set to "H" at a match in up-counting, and reset to "L" at a match in down-counting (OCS:CMOD = 0, MOD pin = "H")

Figure 3-15 Output Compare Operation Example 3 (Free-Run Timer Up/Down Counting)

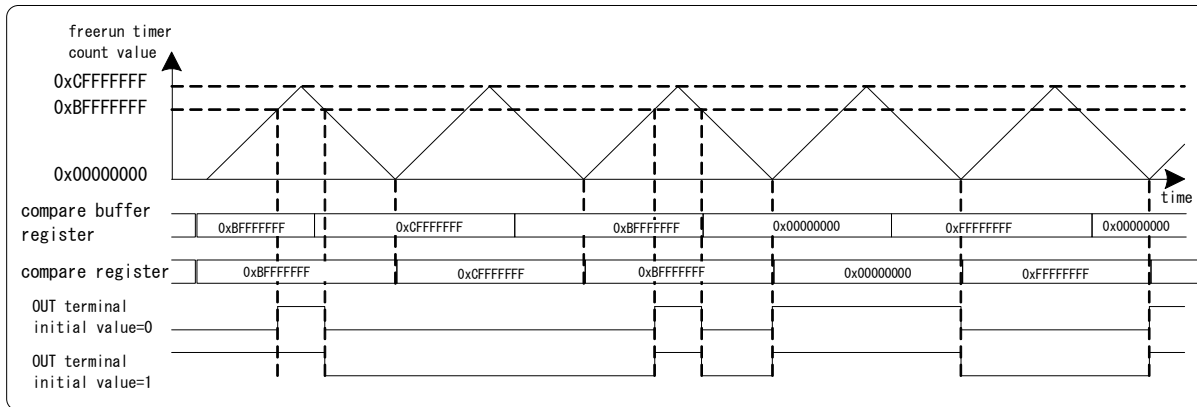

Notes:

- The OUT pin output is set to "H" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "1".)
- The OUT pin output is reset to "L" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "1".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

Output Compare Operation Example 4 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when 0 is detected in the free-run timer.
- In the case where the output compare output is set to "H" at a match in up-counting, and reset to "L" at a match in down-counting (OCS:CMOD = 0, MOD pin = "H")

Figure 3-16 Output Compare Operation Example 4 (Free-Run Timer Up/Down Counting)

Notes:

- The OUT pin output is set to "H" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "1".)
- The OUT pin output is reset to "L" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "1".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

Output Compare Operation Example 5 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when a compare clear match is found for the free-run timer.
- In the case where the output compare output is reset to "L" at a match in up-counting, and set to "H" at a match in down-counting (OCS:CMOD = 1, MOD pin = "H")

Figure 3-17 Output Compare Operation Example 5 (Free-Run Timer Up/Down Counting)

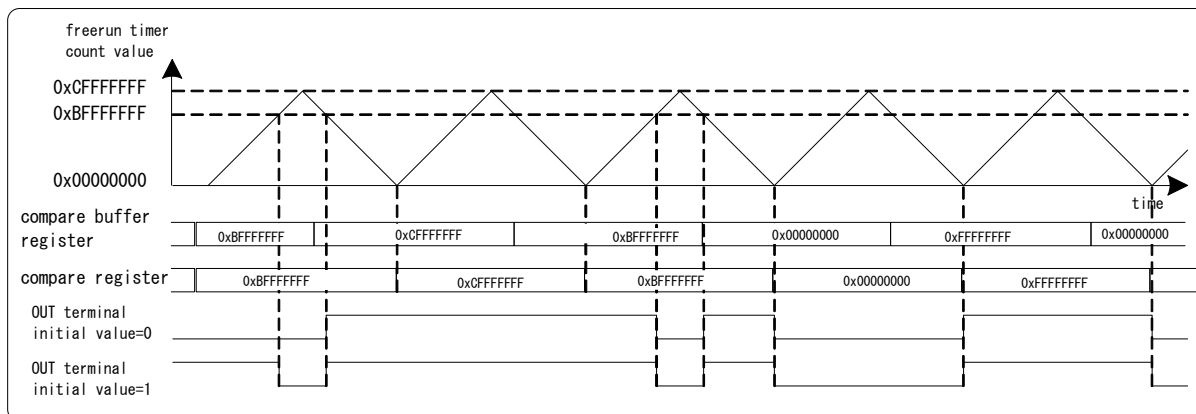

Notes:

- The OUT pin output is reset to "L" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "0".)
- The OUT pin output is set to "H" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "0".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

Output Compare Operation Example 6 (Free-Run Timer Up/Down Counting)

- The compare buffer data for output compare is transferred when 0 is detected in the compare timer of the free-run timer.
- In the case where the output compare output is reset to "L" at a match in up-counting, and set to "H" at a match in down-counting (OCS:CMOD = 1, MOD pin = "H")

Figure 3-18 Output Compare Operation Example 6 (Free-Run Timer Up/Down Counting)

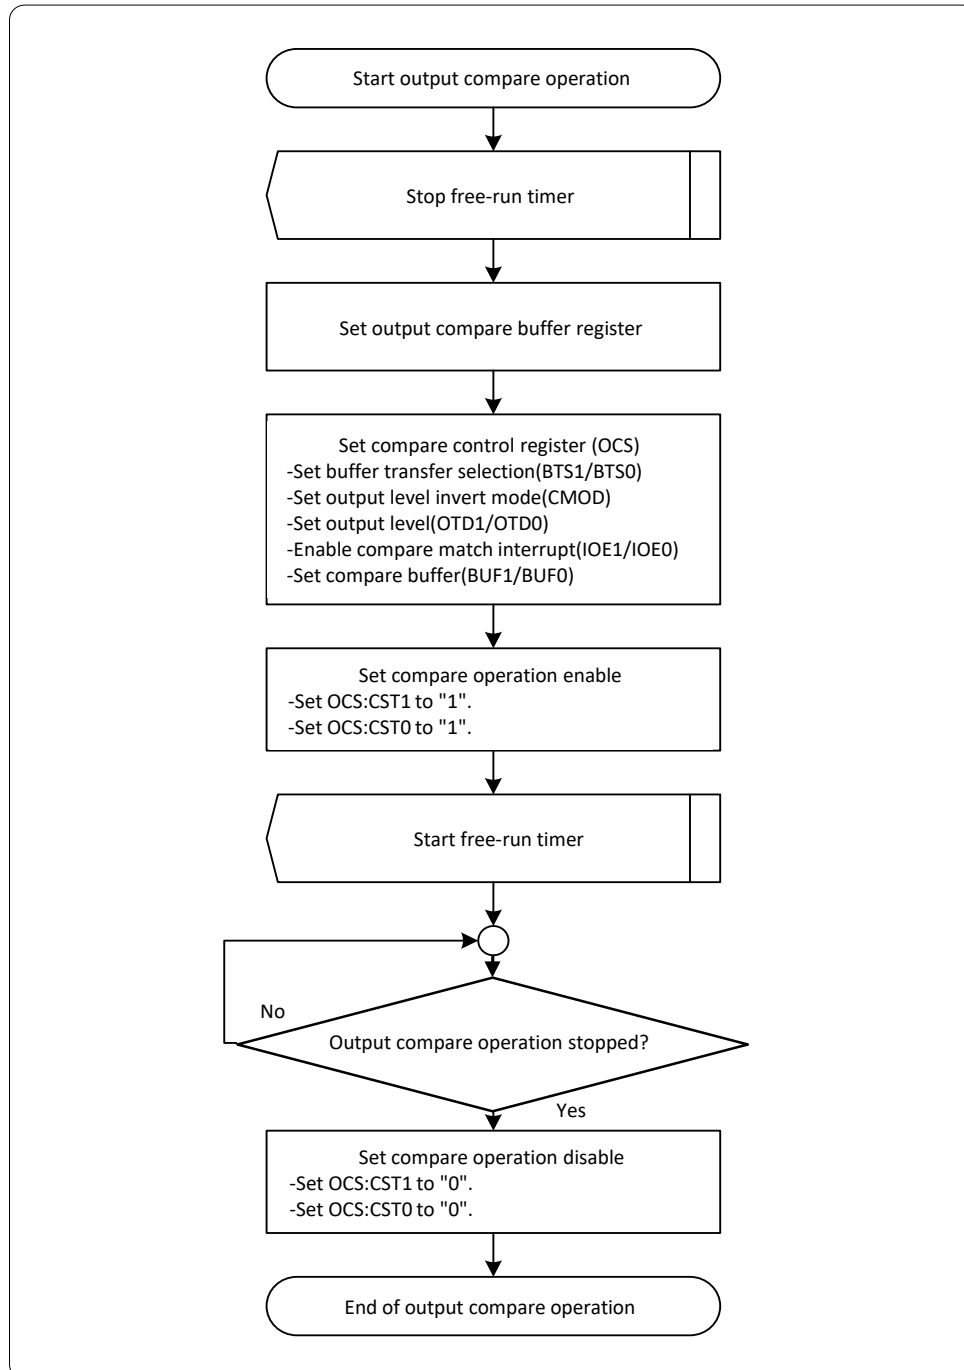

Notes:

- The OUT pin output is reset to "L" when the compare register value is set to 0x00000000, regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "0".)
- The OUT pin output is set to "H" when the compare register value is set to 0xFFFFFFFF, regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "0".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

4. Setting Procedure Example

Table 5-2 List of Register Mirror Area

Address of Register Mirror Area	Mirrored Peripheral	Mirror Area Behavior	PPU
0000_0020 to 0000_003F 0000_0040 to 0000_005F 0000_03E0 to 0000_03FF	OCU pair ch.0	Accessing this region results to the access to OCU pair ch.0 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #240 as well as the mirrored peripheral.
0000_0420 to 0000_043F 0000_0440 to 0000_045F 0000_07E0 to 0000_07FF	OCU pair ch.1	Accessing this region results to the access to OCU pair ch.1 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #241 as well as the mirrored peripheral.
0000_0820 to 0000_083F 0000_0840 to 0000_085F 0000_0BE0 to 0000_0BFF	OCU pair ch.2	Accessing this region results to the access to OCU pair ch.2 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #242 as well as the mirrored peripheral.
0000_0C20 to 0000_0C3F 0000_0C40 to 0000_0C5F 0000_0FE0 to 0000_0FFF	OCU pair ch.3	Accessing this region results to the access to OCU pair ch.3 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #243 as well as the mirrored peripheral.
0000_1020 to 0000_103F 0000_1040 to 0000_105F 0000_13E0 to 0000_13FF	OCU pair ch.4	Accessing this region results to the access to OCU pair ch.4 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #244 as well as the mirrored peripheral.
0000_1420 to 0000_143F 0000_1440 to 0000_145F 0000_17E0 to 0000_17FF	OCU pair ch.5	Accessing this region results to the access to OCU pair ch.5 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #245 as well as the mirrored peripheral.
0000_1820 to 0000_183F 0000_1840 to 0000_185F 0000_1BE0 to 0000_1BFF	OCU pair ch.6	Accessing this region results to the access to OCU pair ch.6 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #246 as well as the mirrored peripheral.
0000_1C20 to 0000_1C3F 0000_1C40 to 0000_1C5F 0000_1FE0 to 0000_1FFF	OCU pair ch.7	Accessing this region results to the access to OCU pair ch.7 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #247 as well as the mirrored peripheral.

Address of Register Mirror Area	Mirrored Peripheral	Mirror Area Behavior	PPU
0000_0020 to 0000_003F 0000_0040 to 0000_004F 0000_03E0 to 0000_03FF	OCU pair ch.8	Accessing this region results to the access to OCU pair ch.8 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #248 as well as the mirrored peripheral.
0000_0420 to 0000_043F 0000_0440 to 0000_043F 0000_07E0 to 0000_07FF	OCU pair ch.9	Accessing this region results to the access to OCU pair ch.9 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #249 as well as the mirrored peripheral.
0000_0820 to 0000_083F 0000_0840 to 0000_085F 0000_0BE0 to 0000_0BFF	OCU pair ch.10	Accessing this region results to the access to OCU pair ch.10 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #250 as well as the mirrored peripheral.
0000_0C20 to 0000_0C3F 0000_0C40 to 0000_0C5F 0000_0FE0 to 0000_0FFF	OCU pair ch.11	Accessing this region results to the access to OCU pair ch.11 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #251 as well as the mirrored peripheral.
0000_1020 to 0000_103F 0000_1040 to 0000_105F 0000_13E0 to 0000_13FF	OCU pair ch.12	Accessing this region results to the access to OCU pair ch.12 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #252 as well as the mirrored peripheral.
0000_1420 to 0000_143F 0000_1440 to 0000_145F 0000_17E0 to 0000_17FF	OCU pair ch.13	Accessing this region results to the access to OCU pair ch.13 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #253 as well as the mirrored peripheral.
0000_1820 to 0000_183F 0000_1840 to 0000_185F 0000_1BE0 to 0000_1BFF	OCU pair ch.14	Accessing this region results to the access to OCU pair ch.614 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #254 as well as the mirrored peripheral.
0000_1C20 to 0000_1C3F 0000_1C40 to 0000_1C5F 0000_1FE0 to 0000_1FFF	OCU pair ch.15	Accessing this region results to the access to OCU pair ch.15 register area with following offset. Offset: (addr & 0000_001F)	This area is covered by PPU #255 as well as the mirrored peripheral.

Register List of 32-Bit Output Compare
Table 5-1 Register List of 32-Bit Output Compare

5.1. Output Compare Buffer Register (OCCPB0, 1)/Output Compare Register (OCCP0, 1)

The output compare buffer register (OCCPB) is the buffer register for the output compare register (OCCP). The output compare buffer register (OCCPB) and the output compare register (OCCP) exist at the same address.

Output Compare Buffer Register (OCCPB0, OCCPB1)

bit	31	30	29	28	27	26	25	24
Field	OP31	OP30	OP29	OP28	OP27	OP26	OP25	OP24
Attribute	W	W	W	W	W	W	W	W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

bit	23	22	21	20	19	18	17	16

[bit31:0] OP31 to OP00: Output Compare Buffer Value Bits

- The output compare buffer register (OCCPB) is the buffer register for the output compare register (OCCP).
- The value in the output compare buffer register (OCCPB) is immediately transferred to the output compare register (OCCP) on the following condition: The buffer function is disabled (BUF1, BUF0: bit3, bit2 in the compare control register (OCS) = 0b11) or the free-run timer stops.
- When the buffer function is enabled (BUF1, BUF0: bit3, bit2 in the compare control register (OCS) = 0b00), the value in the output compare buffer register (OCCPB) is transferred to the output compare register (OCCP) on the following condition: a compare clear match or detection of 0 according to the transfer selection (BTS1, BTS0: bit14, bit13) in the compare control register (OCS).

Note:

- For access to the OCCPB0 and OCCPB1 registers, use word access instructions.

Output Compare Register (OCCP0, OCCP1)

Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] OP31 to OP00: Output Compare Value Bits

- The output compare register (OCCP) is used for comparison of its value with the count value of the free-run timer. Before enabling free-run timer operation, set a value in the output compare buffer register (OCCPB).
- When the value in output compare register (OCCP) matches the count value in the free-run timer, the compare signal is generated. Then, the output compare interrupt flag (IOP1, IOP0: bit7, bit6 in the compare control register (OCS)) is set to "1".

Notes:

- For access to the OCCP0 and OCCP1 registers, use word access instructions.
- If the free-run timer is operating in up-down count mode and OCS:CMOD is 0, when the compare register value is set to 0x00000000, the OUT pin output is set to "H" regardless of the free-run timer count value. (It is reset to "L" when OCS:CMOD is "1".) Also, when the compare register value is set to 0xFFFFFFFF and OCS:CMOD is 0, the OUT pin output is reset to "L" regardless of the free-run timer count value. (It is set to "H" when OCS:CMOD is "1".)
- If the compare clear register value of the free-run timer and the compare register value of output compare are the same, no comparison is performed. However, if the initial value of the free-run timer and the compare register value of output compare are the same, a comparison is performed first. At this time, if both the compare clear register value and the compare register

value are set to 0xFFFFFFFF, the OUT pin is reset to "L" regardless of the free-run timer count value.

*: In the explanation of the free-run timer, the operating state of the free-run timer connected to the output compare is described.

5.2. Compare Control Register (OCS)

The compare control register (OCS) controls the compare output (OUT pin) level, output enable, output level invert mode, compare operation enable, compare match interrupt enable, and compare match interrupt flag.

For details on writing to this register, see "6 Precautions for Using This Device."

Compare Control Register (OCS)

[bit31:16] Reserved: Reserved Bit

- When writing, always write "1".
- When reading, "1" is always read.

[bit15] Reserved: Reserved Bit

- When writing, always write "1".
- When reading, "1" is always read.

[bit14] BTS1: Buffer Transfer Selection Bit (CH.1)

Bit	Description
0	Start output compare (CH.1) transfer when 0 is detected.
1	Start output compare (CH.1) transfer when a compare clear match occurs.

- The BTS1 bit is used to select the timing of data transfer from output compare buffer register 1 (OCCPB1) to output compare register 1 (OCCP1).
- When the BTS1 bit is set to "0":
Data transfer starts when 0 is detected in the free-run timer.
- When the BTS1 bit is set to "1":
Data transfer starts when a compare clear match occurs in the free-run timer.
- The BTS1 bit is cleared to "0" by writing "1" to the BTS1C bit in the OCSC register.
- The BTS1 bit is set to "1" by writing "1" to the BTS1S bit in the OCSS register.

[bit13] BTS0: Buffer Transfer Selection Bit (CH.0)

Bit	Description
0	Start output compare (CH.0) transfer when 0 is detected.
1	Start output compare (CH.0) transfer when a compare clear match occurs.

- The BTS0 bit is used to select the timing of data transfer from output compare buffer register 0 (OCCPB0) to output compare register 0 (OCCP0).
- When the BTS0 bit is set to "0":
Data transfer starts when 0 is detected in the free-run timer.
- When the BTS0 bit is set to "1":
Data transfer starts when a compare clear match occurs in the free-run timer.
- The BTS0 bit is cleared to "0" by writing "1" to the BTS0C bit in the OCSC register.
- The BTS0 bit is set to "1" by writing "1" to the BTS0S bit in the OCSS register.

[bit12] CMOD: Output Level Invert Mode Bit

Bit	Description		
	MODn Pin* = "L" (Invert Mode)		MODn Pin* = "H" (Set/Reset Mode)
	OUT0	OUT1	OUT0, OUT1
0	The OUT0 level is immediately inverted when a match with compare register 0 occurs.	The OUT1 level is immediately inverted when a match with compare register 1 occurs.	Set to "H" for a match in up count mode. Set to "L" for a match in down count mode.
1	(Same as above)	The OUT1 level is immediately inverted when a match with compare register 0 or 1 occurs.	Set to "L" for a match in up count mode. Set to "H" for a match in down count mode.

*: The MODn (n = 0, 1) pin signal is an external input signal to control the OUTn output pin signal.

- The CMOD bit is used to switch the output level of the OUT pin when a match occurs.
- When "0" is set in the CMOD bit:
 - For MODn pin (n = 0, 1) = "L"

- The output level of the OUT0 pin is immediately inverted when the free-run timer and compare register 0 match.
- The output level of the OUT1 pin is immediately inverted when the free-run timer and compare register 1 match.
- For MODn pin* (n = 0, 1) = "H"
 - The output level of the OUTx pin is set to "H" when the free-run timer and compare register x match in up count mode. (x = 0, 1)
 - The output level of the OUTx pin is reset to "L" when the free-run timer and compare register x match in down count mode. (x = 0, 1)
- When "1" is set in the CMOD bit:
 - For MODn pin (n = 0, 1) = "L"
 - The output level of the OUT0 pin is immediately inverted when the free-run timer and compare register 0 match.
 - The output level of the OUT1 pin is immediately inverted when the free-run timer and compare register 0 or 1 match.
(If compare register 0 and 1 contain the same value, the behavior is the same as when 1 compare register is used.)
 - For MODn pin* (n = 0, 1) = "H"
 - The output level of the OUTx pin is reset to "L" when the free-run timer and compare register x match in up count mode. (x = 0, 1)
 - The output level of the OUTx pin is set to "H" when the free-run timer and compare register x match in down count mode. (x = 0, 1)
- The CMOD bit is cleared to "0" by writing "1" to the CMODC bit in the OCSC register.
- The CMOD bit is set to "1" by writing "1" to the CMODS bit in the OCSS register.

[bit11:10] Reserved: Reserved Bits

- When writing, always write "0".
- When reading, "0" is always read.

[bit9] OTD1: OUT1 Output Level Bit

Bit	Description	
	During Read Operation	During Write Operation
0	Output value of OUT1	Output "L" to OUT1.
1		Output "H" to OUT1.

- The OTD1 bit is used for setting an OUT1 pin output value of output compare 1.
- The initial value of OUT1 pin output is "L".
- When writing a value, be sure to stop the compare operation beforehand (compare operation enable bit CST1: bit1 = 0).
- The OTD1 bit is writable when the compare operation is stopped (compare operation enable bit CST1: bit1 = 0).
- The value read from the OTD1 bit indicates the OUT1 pin output value of output compare 1.
- The OTD1 bit is cleared to "0" by writing "1" to the OTD1C bit in the OCSC register when the compare operation is stopped (compare operation enable bit CST1: bit1 = 0).

- The OTD1 bit is set to "1" by writing "1" to the OTD1S bit in the OCSS register when the compare operation is stopped (compare operation enable bit CST1: bit1 = 1).

[bit8] OTD0: OUT0 Output Level Bit

Bit	Description	
	During Read Operation	During Write Operation
0	Output value of OUT0	Output "L" to OUT0.
1		Output "H" to OUT0.

- The OTD0 bit is used for setting an OUT0 pin output value of output compare 0.
- The initial value of OUT0 pin output is "L".
- When writing a value, be sure to stop the compare operation beforehand (compare operation enable bit CST0: bit0 = 0).
- The OTD0 bit is writable when the compare operation is stopped (compare operation enable bit CST0: bit0 = 0).
- The value read from the OTD0 bit indicates the OUT0 pin output value of output compare 0.
- The OTD0 bit is cleared to "0" by writing "1" to the OTD0C bit in the OCSC register when the compare operation is stopped (compare operation enable bit CST0: bit0 = 0).
- The OTD0 bit is set to "1" by writing "1" to the OTD0S bit in the OCSS register when the compare operation is stopped (compare operation enable bit CST0: bit0 = 0).

[bit7] IOP1: Compare Match Interrupt Flag Bit (CH.1)

Bit	Description
0	The compare match interrupt for compare register 1 does not occur.
1	The compare match interrupt for compare register 1 occurs.

- The IOP1 bit is an interrupt flag indicating that compare register 1 has matched the free-run timer value.
- The IOP1 bit is set to "1" when the compare register value matches the free-run timer value.
- When the IOP1 bit is set with the compare match interrupt enable bit (IOE1: bit5) set to "1", the output compare interrupt is generated.
- The IOP1 bit is cleared to "0" by writing "1" to the IOP1C bit in the OCSC register.

[bit6] IOP0: Compare Match Interrupt Flag Bit (CH.0)

Bit	Description
0	The compare match interrupt for compare register 0 does not occur.
1	The compare match interrupt for compare register 0 occurs.

- The IOP0 is an interrupt flag indicating that compare register 0 has matched the free-run timer value.
- The IOP0 bit is set to "1" when the compare register value matches the free-run timer value.
- When the IOP0 bit is set with the compare match interrupt enable bit (IOE0: bit4) set to "1", the output compare interrupt is generated.
- The IOP0 bit is cleared to "0" by writing "1" to the IOP0C bit in the OCSC register.

[bit5] IOE1: Compare Match Interrupt Enable Bit (CH.1)

Bit	Description
0	Disable the compare match interrupt for compare register 1.
1	Enable the compare match interrupt for compare register 1.

- The IOE1 bit is used to enable the output compare interrupt of compare register 1.
- When the compare match interrupt flag bit (IOP1: bit7) is set to "1" with the IOE1 bit set to "1", the output compare 1 interrupt is generated.
- The IOE1 bit is cleared to "0" by writing "1" to the IOE1C bit in the OCSC register.
- The IOE1 bit is set to "1" by writing "1" to the IOE1S bit in the OCSS register.

[bit4] IOE0: Compare Match Interrupt Enable Bit (CH.0)

Bit	Description
0	Disable the compare match interrupt for compare register 0.
1	Enable the compare match interrupt for compare register 0.

- The IOE0 bit is used to enable the output compare interrupt of compare register 0.
- When the compare match interrupt flag bit (IOP0: bit6) is set to "1" with the IOE0 bit set to "1", the output compare 0 interrupt is generated.
- The IOE0 bit is cleared to "0" by writing "1" to the IOE0C bit in the OCSC register.
- The IOE0 bit is set to "1" by writing "1" to the IOE0S bit in the OCSS register.

[bit3] BUF1: Compare Buffer Disable Bit (CH.1)

Bit	Description
0	Enable the compare buffer for compare register 1.
1	Disable the compare buffer for compare register 1.

- The BUF1 bit is used to disable the buffer function of output compare register 1.
- When the BUF1 bit is set to "0", the buffer function is enabled.
- When the BUF1 bit is set to "1", the buffer function is disabled.
- The BUF1 bit is cleared to "0" by writing "1" to the BUF1C bit in the OCSC register.
- The BUF1 bit is set to "1" by writing "1" to the BUF1S bit in the OCSS register.

[bit2] BUF0: Compare Buffer Disable Bit (CH.0)

Bit	Description
0	Enable the compare buffer for compare register 0.
1	Disable the compare buffer for compare register 0.

- The BUF0 bit is used to disable the buffer function of output compare register 0.
- When the BUF0 bit is set to "0", the buffer function is enabled.
- When the BUF0 bit is set to "1", the buffer function is disabled.
- The BUF0 bit is cleared to "0" by writing "1" to the BUF0C bit in the OCSC register.
- The BUF0 bit is set to "1" by writing "1" to the BUF0S bit in the OCSS register.

[bit1] CST1: Compare Operation Enable Bit (CH.1)

Bit	Description
0	Disable the compare operation for compare register 1.
1	Enable the compare operation for compare register 1.

- The CST1 bit is used to enable the compare operation between the free-run timer and compare register 1.
- When enabling the compare operation, be sure to write values in compare buffer register 1 (OCCPB1) and the timer data register of the free-run timer (TCDT) beforehand.
- The CST1 bit is cleared to "0" by writing "1" to the CST1C bit in the OCSC register.
- The CST1 bit is set to "1" by writing "1" to the CST1S bit in the OCSS register.

[bit0] CST0: Compare Operation Enable Bit (CH.0)

Bit	Description
0	Disable the compare operation for compare register 0.
1	Enable the compare operation for compare register 0.

- The CST0 bit is used to enable the compare operation between the free-run timer and compare register 0.
- When enabling the compare operation, be sure to write values in compare buffer register 0 (OCCPB0) and the timer data register of the free-run timer (TCDT) beforehand.
- The CST0 bit is cleared to "0" by writing "1" to the CST0C bit in the OCSC register.
- The CST0 bit is set to "1" by writing "1" to the CST0S bit in the OCSS register.

5.3. Compare Control Clear Register (OCSC)

The compare control clear register (OCSC) is a register to clear bits in the compare control register (OCS).

Compare Control Clear Register (OCSC)

bit	31	30	29	28	27	26	25	24
Field	Reserved							
Attribute	R0,W0							
Protection Attribute	-							
Initial value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	Reserved	BTS1C	BTS0C	CMODC	Reserved	Reserved	OTD1C	OTD0C
Attribute	R0,W0	R0,W	R0,W	R0,W	R0,W0	R0,W0	R0,W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	00	00	0	0

bit	7	6	5	4	3	2	1	0
Field	IOP1C	IOP0C	IOE1C	IOE0C	BUF1C	BUF0C	CST1C	CST0C
Attribute	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit31:16] Reserved: Reserved Bit

- When writing, always write "0".
- When reading, "0" is always read.

[bit15] Reserved: Reserved Bit

- When writing, always write "0".
- When reading, "0" is always read.

[bit14] BTS1C: BTS1 Clear Bit

Bit	Description
0	Do not affect the BTS1C bit and the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS).
1	Clear the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS).

- When "1" is written, the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the BTS1C bit.

[bit13] BTS0C: BTS0 Clear Bit

Bit	Description
0	Do not affect the BTS0C bit and the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS).
1	Clear the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS).

- When "1" is written, the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the BTS0C bit.

[bit12] CMODC: CMOD Clear Bit

Bit	Description
0	Do not affect the CMODC bit and the output level invert mode bit (CMOD) in the compare control register (OCS).
1	Clear the output level invert mode bit (CMOD) in the compare control register (OCS).

- When "1" is written, the output level invert mode bit (CMOD) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the CMODC bit.

[bit11:10] Reserved: Reserved bits

- When writing, always write "0".
- When reading, "0" is always read.

[bit9] OTD1C: OTD1 Clear Bit

Bit	Description
0	Do not affect the OTD1C bit and the OUT1 output level bit (OTD1) in the compare control register (OCS).
1	Clear the OUT1 output level bit (OTD1) in the compare control register (OCS).

- The OUT1 output level bit (OTD1) in the compare control register (OCS) can be cleared when the compare operation is stopped (the compare operation enable bit CST1: bit1 in the compare control register (OCS) = 0).
- When "1" is written, the OUT1 output level bit (OTD1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the OTD1C bit.

[bit8] OTD0C: OTD0 Clear Bit

Bit	Description
0	Do not affect the OTD0C bit and the OUT0 output level bit (OTD0) in the compare control register (OCS).
1	Clear the OUT0 output level bit (OTD0) in the compare control register (OCS).

- The OUT0 output level bit (OTD0) in the compare control register (OCS) can be cleared when the compare operation is stopped (compare operation enable bit CST0: bit0 in the compare control register (OCS) = 0).
- When "1" is written, the OUT0 output level bit (OTD0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the OTD0C bit.

[bit7] IOP1C: IOP1 Clear Bit

Bit	Description
0	Do not affect the IOP1C bit and the compare match interrupt flag bit (CH.1) (IOP1) in the compare control register (OCS).
1	Clear the compare match interrupt flag bit (CH.1) (IOP1) in the compare control register (OCS).

- When "1" is written, the compare match interrupt flag bit (CH.1) (IOP1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the IOP1C bit.

[bit6] IOP0C: IOP0 Clear Bit

Bit	Description
0	Do not affect the IOP0C bit and the compare match interrupt flag bit (CH.0) (IOP0) in the compare control register (OCS).
1	Clear the compare match interrupt flag bit (CH.0) (IOP0) in the compare control register (OCS).

- When "1" is written, the compare match interrupt flag bit (CH.0) (IOP0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the IOP0C bit.

[bit5] IOE1C: IOE1 Clear Bit

Bit	Description
0	Do not affect the IOE1C bit and the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS).
1	Clear the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS).

- When "1" is written, the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the IOE1C bit.

[bit4] IOE0C: IOE0 Clear Bit

Bit	Description
0	Do not affect the IOE0C bit and the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS).
1	Clear the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS).

- When "1" is written, the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the IOE0C bit.

[bit3] BUF1C: BUF1 Clear Bit

Bit	Description
0	Do not affect the BUF1C bit and the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS).
1	Clear the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS).

- When "1" is written, the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the BUF1C bit.

[bit2] BUF0C: BUF0 Clear Bit

Bit	Description
0	Do not affect the BUF0C bit and the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS).
1	Clear the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS).

- When "1" is written, the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the BUF0C bit.

[bit1] CST1C: CST1 Clear Bit

Bit	Description
0	Do not affect the CST1C bit and the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS).
1	Clear the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS).

- When "1" is written, the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the CST1C bit.

[bit0] CST0C: CST0 Clear Bit

Bit	Description
0	Do not affect the CST0C bit and the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS).
1	Clear the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS).

- When "1" is written, the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS) is cleared to "0".
- "0" is always read from the CST0C bit.

5.4. Compare Control Set Register (OCSS)

The compare control set register (OCSS) is a register to set bits in the compare control register (OCS).

Compare Control Register Set Register (OCSS)

bit	31	30	29	28	27	26	25	24
Field	Reserved							
Attribute	R0,W0							
Protection Attribute	-							
Initial value	00000000							

bit	23	22	21	20	19	18	17	16
Field	Reserved							
Attribute	R0,W0							
Protection Attribute	-							
Initial Value	00000000							

bit	15	14	13	12	11	10	9	8
Field	Reserved	BTS1S	BTS0S	CMODS	Reserved	Reserved	OTD1S	OTD0S
Attribute	R0,W0	R0,W	R0,W	R0,W	R0,W0	R0,W0	R0,W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	00	00	0	0

bit	7	6	5	4	3	2	1	0
Field	Reserved	IOE1S	IOE0S	BUF1S	BUF0S	CST1S	CST0S	
Attribute	R0,W0	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	00	0	0	0	0	0	0	0

[bit31:16] Reserved: Reserved Bit

- When writing, always write "0".
- When reading, "0" is always read.

[bit15] Reserved: Reserved Bit

- When writing, always write "0".
- When reading, "0" is always read.

[bit14] BTS1S: BTS1 Set Bit

Bit	Description
0	Do not affect the BTS1S bit and the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS).
1	Set the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS).

- When "1" is written, the buffer transfer selection bit (CH.1) (BTS1) in the compare control register (OCS) is set to "1".
- "0" is always read from the BTS1S bit.

[bit13] BTS0S: BTS0 Set Bit

Bit	Description
0	Do not affect the BTS0S bit and the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS).
1	Set the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS).

- When "1" is written, the buffer transfer selection bit (CH.0) (BTS0) in the compare control register (OCS) is set to "1".
- "0" is always read from the BTS0S bit.

[bit12] CMODS: CMOD Set Bit

Bit	Description
0	Do not affect the CMODS bit and the output level invert mode bit (CMOD) in the compare control register (OCS).
1	Set the output level invert mode bit (CMOD) in the compare control register (OCS).

- When "1" is written, the output level invert mode bit (CMOD) in the compare control register (OCS) is set to "1".
- "0" is always read from the CMODS bit.

[bit11:10] Reserved: Reserved Bits

- When writing, always write "0".
- When reading, "0" is always read.

[bit9] OTD1S: OTD1 Set Bit

Bit	Description
0	Do not affect the OTD1S bit and the OUT1 output level bit (OTD1) in the compare control register (OCS).
1	Set the OUT1 output level bit (OTD1) in the compare control register (OCS).

- The OUT1 output level bit (OTD1) in the compare control register (OCS) can be set when the compare operation is stopped (the compare operation enable bit CST1: bit1 in the compare control register (OCS) = 0).
- When "1" is written, the OUT1 output level bit (OTD1) in the compare control register (OCS) is set to "1".
- "0" is always read from the OTD1S bit.

[bit8] OTD0S: OTD0 Set Bit

Bit	Description
0	Do not affect the OTD0S bit and the OUT0 output level bit (OTD0) in the compare control register (OCS).
1	Set the OUT0 output level bit (OTD0) in the compare control register (OCS).

- The OUT0 output level bit (OTD0) in the compare control register (OCS) can be set when the compare operation is stopped (the compare operation enable bit CST0: bit0 in the compare control register (OCS) = 0).
- When "1" is written, the OUT0 output level bit (OTD0) in the compare control register (OCS) is set to "1".
- "0" is always read from the OTD0S bit.

[bit7:6] Reserved: Reserved Bits

- When writing, always write "0".
- When reading, "0" is always read.

[bit5] IOE1S: IOE1 Set Bit

Bit	Description
0	Do not affect the IOE1S bit and the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS).
1	Set the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS).

- When "1" is written, the compare match interrupt enable bit (CH.1) (IOE1) in the compare control register (OCS) is set to "1".
- "0" is always read from the IOE1S bit.

[bit4] IOE0S: IOE0 Set Bit

Bit	Description
0	Do not affect the IOE0S bit and the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS).
1	Set the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS).

- When "1" is written, the compare match interrupt enable bit (CH.0) (IOE0) in the compare control register (OCS) is set to "1".
- "0" is always read from the IOE0S bit.

[bit3] BUF1S: BUF1 Set Bit

Bit	Description
0	Do not affect the BUF1S bit and the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS).
1	Set the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS).

- When "1" is written, the compare buffer disable bit (CH.1) (BUF1) in the compare control register (OCS) is set to "1".
- "0" is always read from the BUF1S bit.

[bit2] BUF0S: BUF0 Set Bit

Bit	Description
0	Do not affect the BUF0S bit and the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS).
1	Set the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS).

- When "1" is written, the compare buffer disable bit (CH.0) (BUF0) in the compare control register (OCS) is set to "1".
- "0" is always read from the BUF0S bit.

[bit1] CST1S: CST1 Set Bit

Bit	Description
0	Do not affect the CST1S bit and the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS).
1	Set the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS).

- When "1" is written, the compare operation enable bit (CH.1) (CST1) in the compare control register (OCS) is set to "1".
- "0" is always read from the CST1S bit.

[bit0] CST0S: CST0 Set Bit

Bit	Description
0	Do not affect the CST0S bit and the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS).
1	Set the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS).

- When "1" is written, the compare operation enable bit (CH.0) (CST0) in the compare control register (OCS) is set to "1".
- "0" is always read from the CST0S bit.

6. Precautions for Using This Device

The following are precautions for using the 32-bit output compare.

Notes on Accessing the Output Compare Buffer Register (OCCPB) and Output Compare Register (OCCP)

- For access to the output compare buffer register (OCCPB) and output compare register (OCCP), use word access instructions.
- Also, do not use read-modify-write (RMW) instructions for access.

Notes on Accessing the Compare Control Register (OCS)

- This register supports writing from the bit-band alias area. For the bit-band alias area, see the chapter of "BIT-BAND UNIT."
- To clear a specified bit of this register, clear the bit by writing "1" to the applicable bit in the compare control clear register (OCSC).
- To set a specified bit of this register, set the bit by writing "1" to the applicable bit in the compare control set register (OCSS).
- Data can be written directly to this register only when writing to all bits.

Precautions for Using the Output Compare

Compare Output (OUT Pin) Level

- When the value in the output compare register (OCCP) matches the count value in the free-run timer, the compare signal is generated. Then, the output compare interrupt flag bit (IOP1, IOP0: bit7, bit6 in the compare control register OCS) is set to "1". However, if the peak value of the free-run timer matches the value in the output compare register (OCCP) when the free-run timer is in up-down count mode, the compare signal will not be generated.
- When the compare signal is generated, the output of the OUT pins (OUT0, OUT1) corresponding to output compare registers 0 and 1 is controlled by the output level invert mode bit (CMOD: bit12 in the compare control register OCS) and external input signal (MODn). Then, the output is set to the inverted level or "H/L" level, accordingly.

Compare Output (OUT Pin) When the Free-Run Timer is in Up-Down Count Mode

- When the output level invert mode bit (CMOD) of the compare control register (OCS) is 0
When 0xFFFFFFFF is set in the output compare register (OCCP), the OUT pin outputs "L" regardless of the free-run timer value or invert mode. If 0x00000000 is set, it outputs "H".
- When the output level invert mode bit (CMOD) of the compare control register (OCS) is 1
When 0xFFFFFFFF is set in the output compare register, the OUT pin outputs "H" regardless of the free-run timer value or invert mode. If 0x00000000 is set, it outputs "L".

CHAPTER 45: 32-bit Reload Timer

This chapter explains 32-bit Reload Timer

1. Overview
2. Configuration and Block Diagram
3. Operation of the 32-Bit Reload Timer
4. Registers

RLT-TXXPT03P01R01L02-E1-XX

1. Overview

This section gives a brief overview of the 32-bit Reload Timer.

Features of 32-Bit Reload Timer

The 32-bit Reload Timer consists of a 32-bit down counter, a 32-bit Reload register, one input(TIN), one output (TOT), and control registers. The 32-bit Reload Timer has the following features:

- External and internal clock/event source
- Trigger signal programmable as rising/falling edge or both
- Gated count function
- One-shot or reload counter mode
- Counter state can be made visible at external pin
- Prescaler with six different settings for the internal clock and two different settings for the external clock
- Several Reload Timers can be cascaded to form a longer Reload Timer
- Support for MCU debug mode

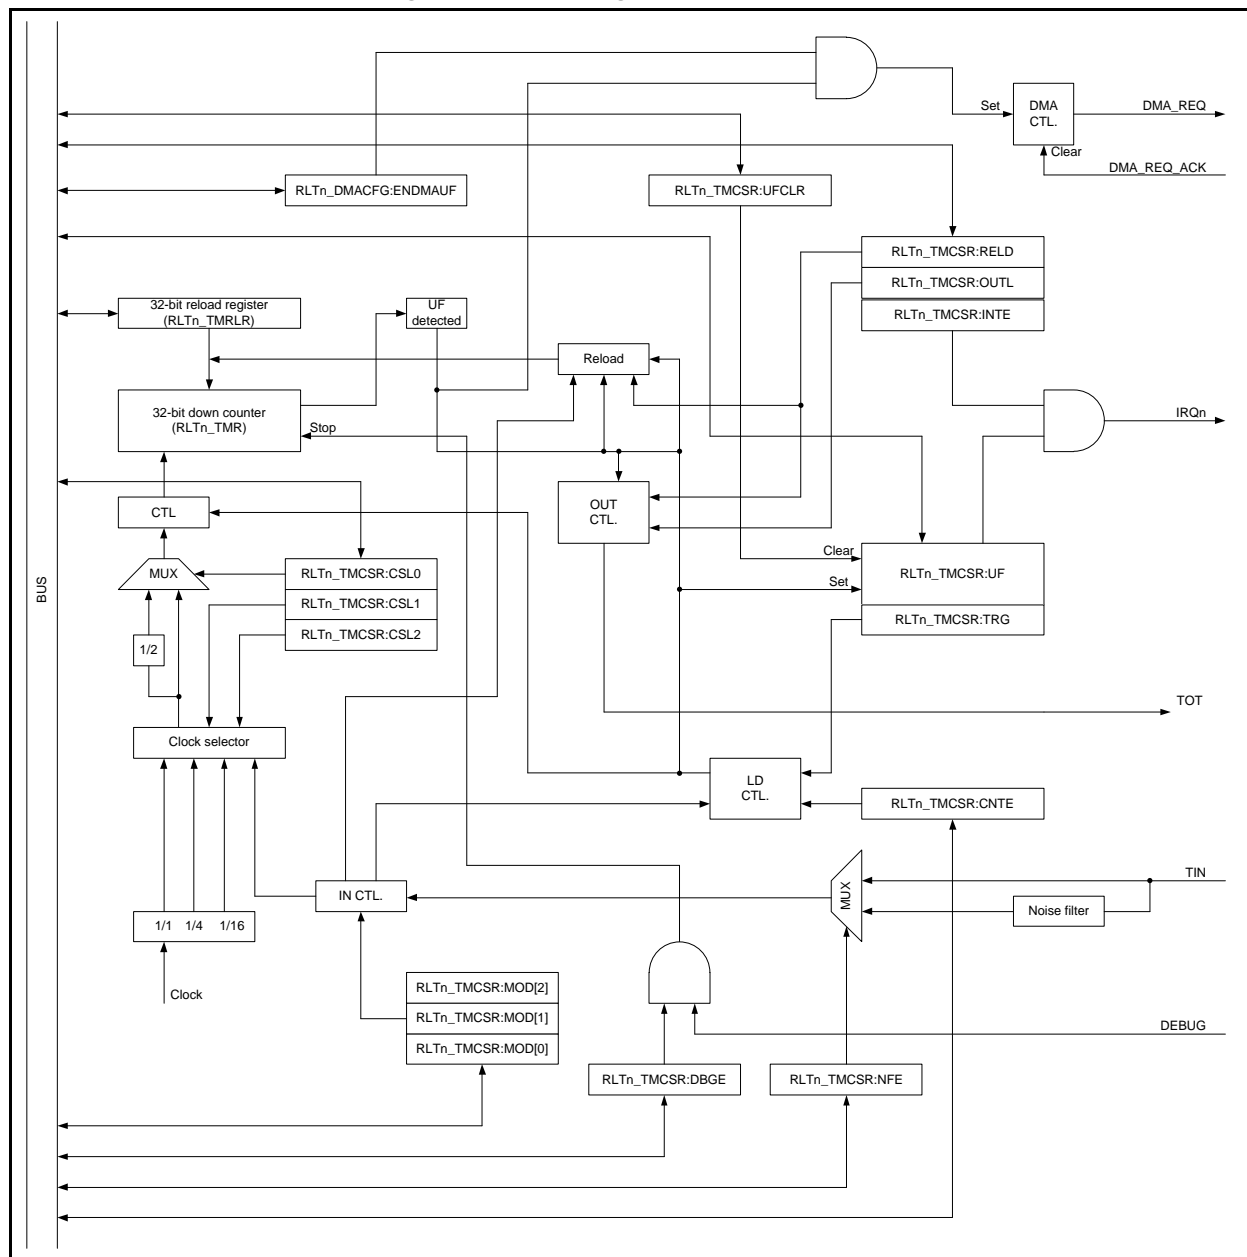

DMA and Interrupts

The 32-bit Reload Timer can generate DMA request which can be used to start DMA transfers.

The 32-bit Reload Timer can generate interrupt in case of underflow.

This section shows a block diagram of the 32-bit Reload Timer.

Figure 2-1 Block Diagram of 32-Bit Reload Timer

3. Operation of the 32-Bit Reload Timer

This section describes the operation of the 32-bit Reload Timer.

- 3.1 Internal Clock and External Event Counter Operations of 32-Bit Reload Timer
- 3.2 Underflow Operation of 32-Bit Reload Timer
- 3.3 Output Functions of 32-Bit Reload Timer
- 3.4 Counter Operation State
- 3.5 DMA Operation

3.1. Internal Clock and External Event Counter Operations of 32-Bit Reload Timer

In internal clock mode, the peripheral clock with different divider settings can be selected as the clock source for operating the Reload Timer. The external input TIN can be selected as either a trigger input, or as a gate input by a register setting.

In event counter mode, the TIN is used as an external event input. Each active edge on this input (rising, falling, or both) decrements the counter.

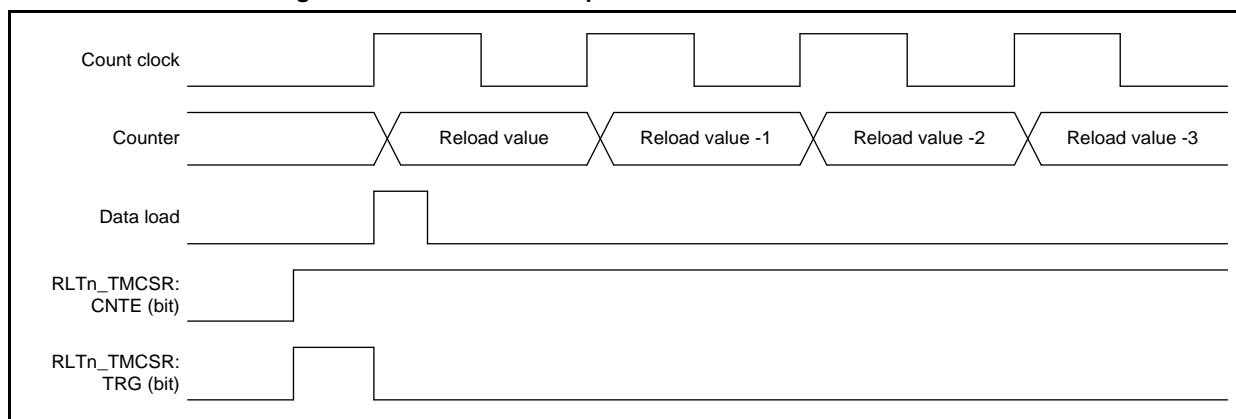

When $RLn_TMCSR:CSL0 = 1$, then each second event is counted.

Internal Clock Operation of 32-Bit Reload Timer

Writing "1" to both $RLn_TMCSR:CNTEN$ and $RLn_TMCSR:TRG$ bits enables and starts counting at the same time. Using the $RLn_TMCSR:TRG$ bit as a trigger input is always available when the timer is enabled ($RLn_TMCSR:CNTEN = 1$), regardless of the operation mode.

Figure 3-1 shows counter activation and counter operation.

Figure 3-1 Activation and Operation of 32-Bit Reload Timer Counter

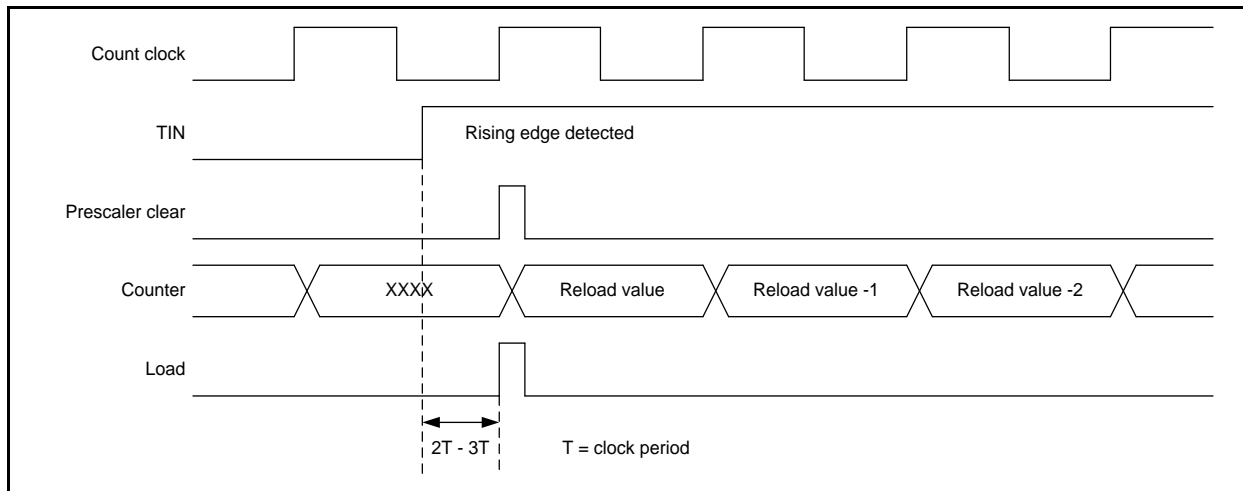

Input Functions of 32-Bit Reload Timer (In Internal Clock Mode)

The TIN input can be used as either a trigger input, or as a gate input, when an internal clock is selected as the clock source.

Trigger Input

When used as a trigger input, an active edge causes the timer to load the reload register contents and resets the internal prescaler. Then, count operation starts. For the minimum pulse width length of TIN refer to device specific datasheet.

Figure 3-2 Trigger Input Operation of 32-Bit Reload Timer

Gate Input

When used as a gate input, the counter only counts while the active level specified by the `RLTn_TMCSR:MOD[0]` bit is input to the TIN. In this case, the count clock continues to operate unless stopped. The software trigger can be used in gate mode, regardless of the gate level. For the minimum pulse width length of TIN refer to device specific datasheet.

Figure 3-3 Gate Input Operation of 32-Bit Reload Timer

External Event Counter

When external event count mode is selected, the TIN is used as an external event input. The counter counts on the active edge specified in the `RLTn_TMCSR`. For the minimum pulse width length of TIN refer to device specific datasheet.

3.2. Underflow Operation of 32-Bit Reload Timer

An underflow is defined for this timer as the time when the counter value changes from 0x00000000 to 0xFFFFFFFF or reload occurs (RLTn_TMCSR:RELD= 1). Therefore, an underflow occurs after (reload register setting + 1) counts.

Underflow Operation of 32-Bit Reload Timer

If the RLTn_TMCSR:RELD bit is "1" and an underflow occurs, the contents of the reload register is loaded into the counter and counting continues.

If the RLTn_TMCSR:RELD bit is "0", counting stops when counter reaches 0xFFFFFFFF.

The RLTn_TMCSR:UF bit is set when the underflow occurs. If the RLTn_TMCSR:INTE bit is "1" at this time, an interrupt request is generated.

Figure 3-4 shows the operation when an underflow occurs with various values of RLTn_TMCSR:RELD. Figure 3-5 shows the clearing operation of underflow flag.

Figure 3-4 Underflow Operation of 32-Bit Reload Timer

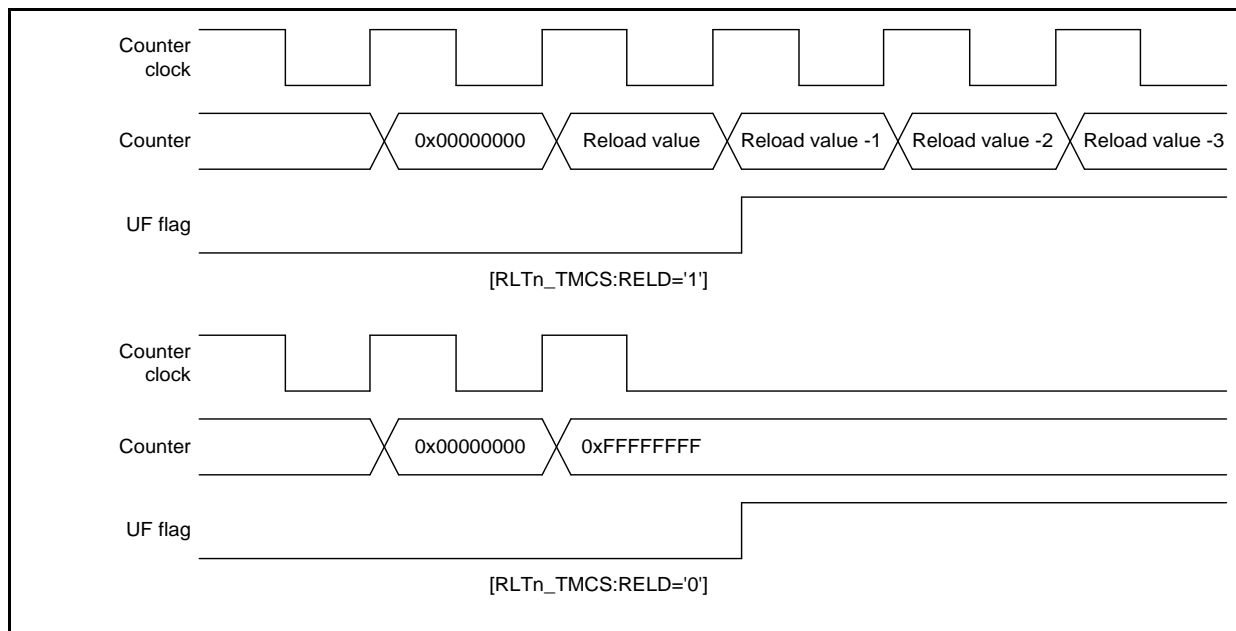

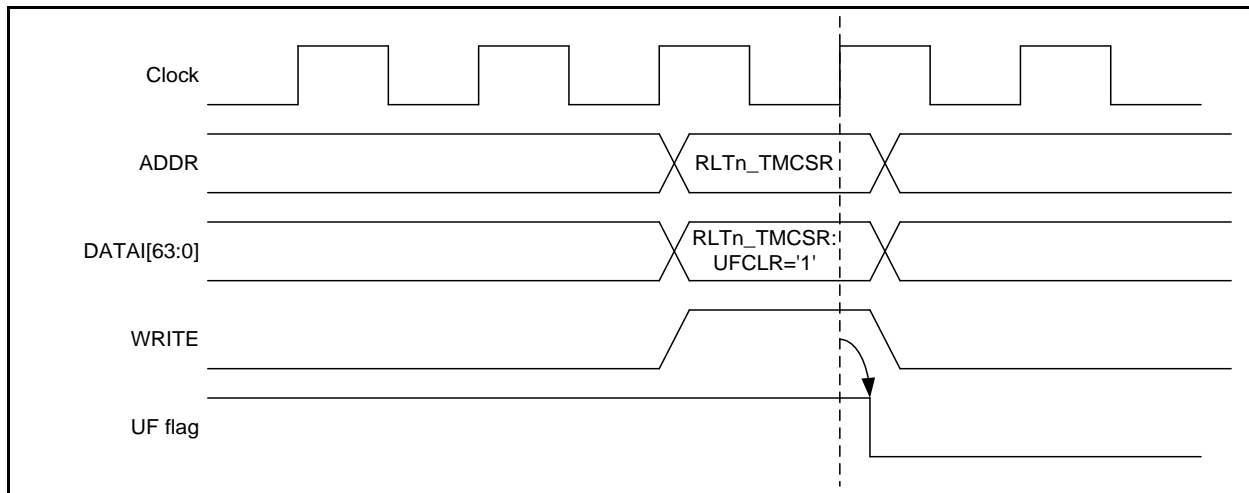

Figure 3-5 Clearing of Underflow Bit

3.3. Output Functions of 32-Bit Reload Timer

In reload mode, the TOT output performs toggle output (inverts at each underflow). In one-shot mode, the TOT output is used as a pulse output that shows the configured level while the counting is in progress.

Output Signal Functions of 32-Bit Reload Timer

The RL_{Tn}_TMCSR:OUTL bit sets the output polarity.

When RL_{Tn}_TMCSR:OUTL = 0, the initial value for toggle output is "L" and the one-shot pulse output is "H" while the count is in progress.

When RL_{Tn}_TMCSR:OUTL = 1, the output waveforms are opposite.

Figure 3-6 and Figure 3-7 show the output signal functions.

Figure 3-6 Output Signal Function of 32-Bit Reload Timer in Reload Mode

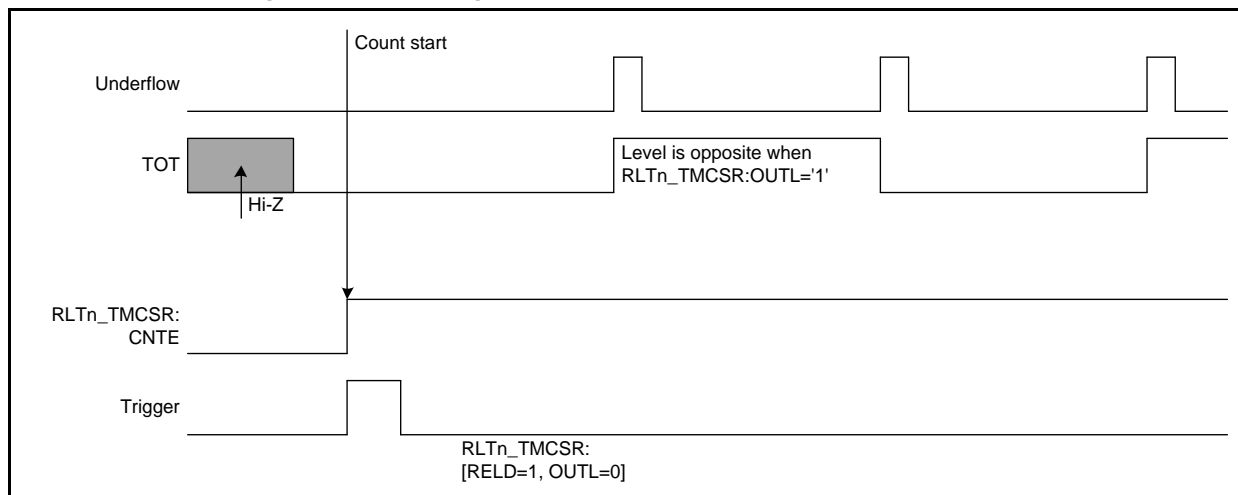

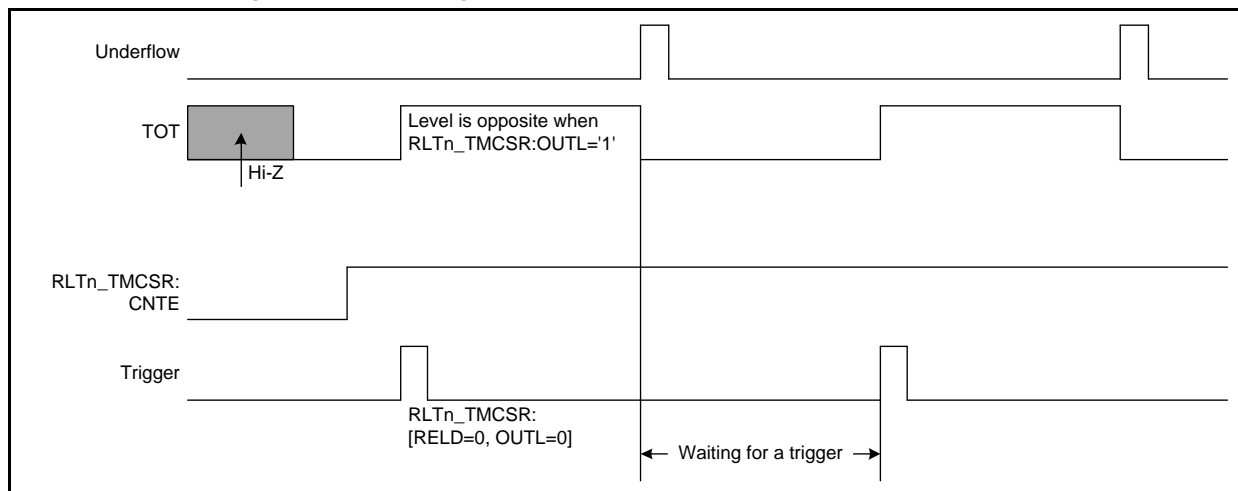

Figure 3-7 Output Signal Function of 32-Bit Reload Timer in One-Shot Mode

3.4. Counter Operation State

The counter state is determined by RL_n_TMCSR:CNTE bit in the Timer Control Status Register and the internal WAIT signal.

Available States for Reload Timer Are:

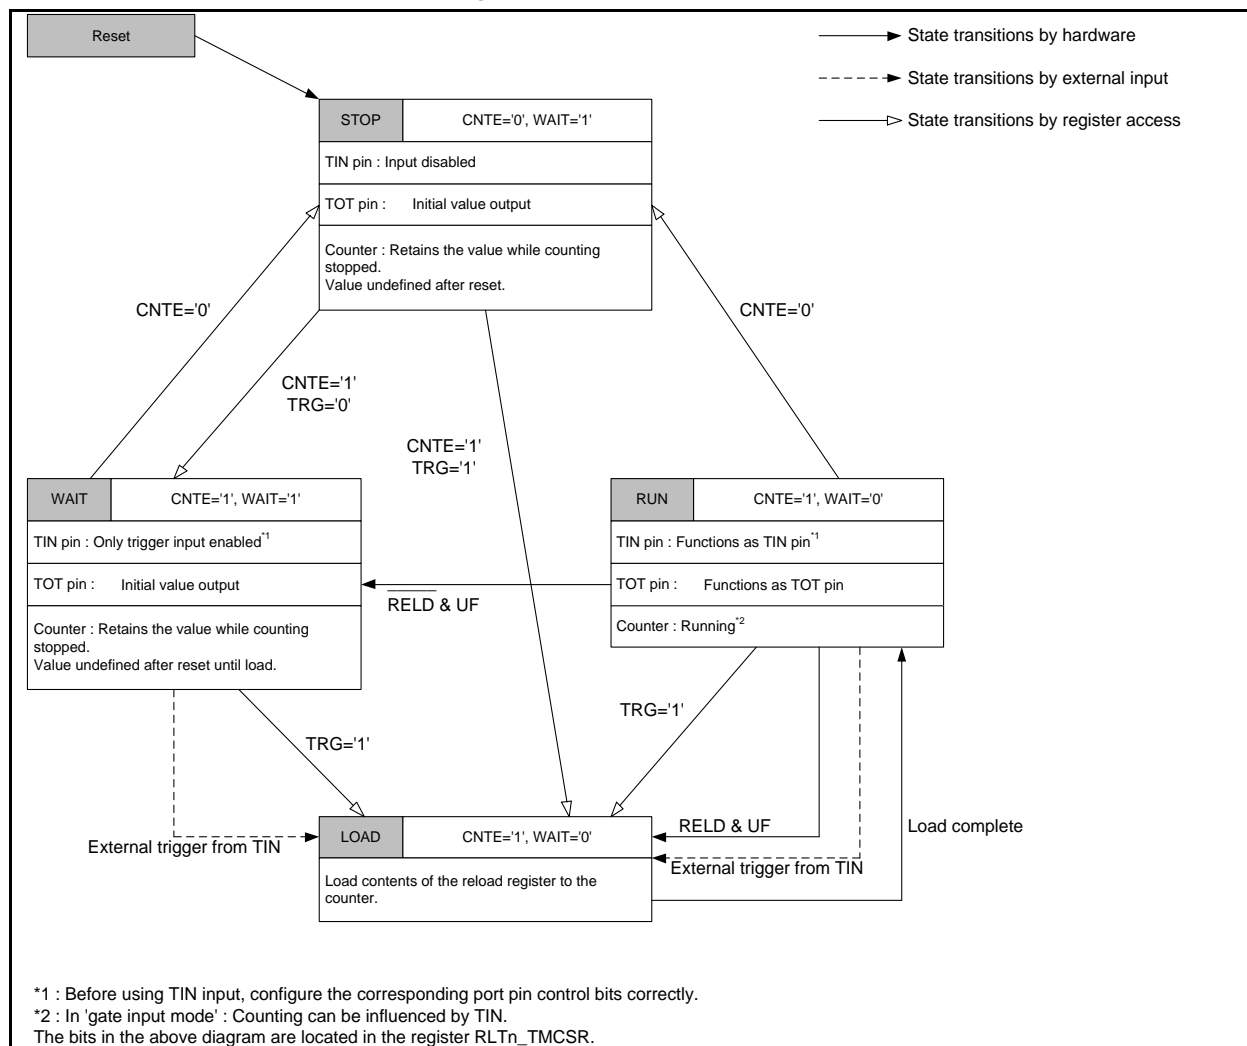

Stop state: RL_n_TMCSR:CNTE = 0 and WAIT = 1

Wait state: RL_n_TMCSR:CNTE = 1 and WAIT = 1

Run state: RL_n_TMCSR:CNTE = 1 and WAIT = 0

Counter Operation States

Figure 3-8 Counter Operation States

3.5. DMA Operation

The DMA support is determined by the RL_{Tn}_DMACFG:ENDMAUF bit. Setting this bit enables DMA request generation for DMA. Assertion of DMA_REQ_ACK signal acknowledges request and hence DMA_REQ signal gets de-asserted.

Enabling DMA Support

Writing "1" to RL_{Tn}_DMACFG:ENDMAUF enables DMA request generation for DMA when RL_{Tn}_TMCSR:UF bit sets. However, writing "0" to RL_{Tn}_DMACFG:ENDMAUF disables DMA request generation even if RL_{Tn}_TMCSR:UF bit sets.

When DMA_REQ_ACK is asserted the DMA_REQ signal gets de-asserted by acknowledging the DMA request.

Figure 3-9 shows behavior of DMA_REQ_ACK when asserted.

Figure 3-9 De-Asserting DMA_REQ Signal

4. Registers

This section describes the registers of 32-bit Reload Timer.

Table 4-1 Memory Layout of 32-Bit Reload Timer Registers

Offset	+3	+2	+1	+0
0x00000000	RLTn_DMACFG 00000000_00000000_00000000_00000000			
0x00000004	Reserved			
0x00000008	RLTn_TMCSR 00000000_00000000_00000000_00000000			
0x0000000C	Reserved			
0x00000010	RLTn_TMRLR XXXXXXXX_XXXXXXXX_XXXXXXXX_XXXXXXXX			
0x00000014	RLTn_TMR XXXXXXXX_XXXXXXXX_XXXXXXXX_XXXXXXXX			

Note:

- The initial register value after reset indicates as follows:
 - "1": Initial value "1"
 - "0": Initial value "0"
 - "X": Initial value undefined
 - "-": Reserved bit/Undefined bit
 - "*": Initial value "0" or "1" according to the setting

4.1. DMA Configuration Register (RLTn_DMACFG)

The DMA Configuration Register controls the DMA request generation for underflow condition.

[bit31:25] Reserved

[bit24] CNTE: Count enable

The Count Enable (CNTE) bit is a timer count enable bit.

Bit	Description
0	Stops count operation
1	Sets the timer to wait for a trigger

[bit23:19] Reserved

[bit18] TRG: Trigger

Software trigger bit.

Bit	Description
0	No effect
1	Applies a software trigger, causing the timer to load the reload register content to the counter and starts counting

Notes:

- Applying a trigger using this register is only valid when $RLTn_TMCSR:CNTEN = 1$. If $RLTn_TMCSR:CNTEN = 0$, writing "1" to TRG has no effect.
- Set this bit in 'gate input mode' and in 'event count mode' to load the reload register content before counting starts.

[bit17] UFCLR: Underflow interrupt clear

Bit	Description
0	No effect
1	Clears $RLTn_TMCSR:UF$ bit

[bit16] UF: Underflow

The Underflow (UF) is timer interrupt request flag.

Bit	Description
0	No underflow occurred
1	When an underflow occurred

Note:

- UF bit is cleared by writing "1" to $RLTn_TMCSR:UFCLR$ bit.

[bit15:13] MOD: Operation mode

The Operation Mode (MOD[2:0]) bits set the operation mode and input (TIN) functions.

Table 4-2 and Table 4-3 list the MOD[2:0] bit settings.

[bit12] CSL2: Clock select 2

The Clock Select 2 (CSL2) bit specifies the clock/event source and the clock division ratio.

Table 4-4 lists the selected clock sources for different CSL0/1/2 settings.

[bit11] CSL1: Clock select 1

The Clock Select 1 (CSL1) bit specifies the clock/event source and the clock division ratio.

Table 4-4 lists the selected clock sources for different CSL0/1/2 settings.

[bit10] CSL0: Clock select 0

The Clock Select 0 (CSL0) bit specifies the count clock division ratio.

Table 4-4 lists the selected clock sources for different CSL0/1/2 settings.

[bit9] Reserved**[bit8] NFE: Noise filter enable**

This bit is used to enable/disable the noise filter for the TIN input.

Bit	Description
0	Noise filter for TIN is disabled
1	Noise filter for TIN is enabled

[bit7] DBGE: Debug mode enable

This bit is used to enable/disable debug mode for RLT.

Bit	Description
0	Debug mode disabled
1	Debug mode enabled

Notes:

- When DBGE is set to "1" and the processor is in debug state, the timer counter operation is paused, and writing to the RL_{Tn}_TMRLR register directly updates the timer counter (RL_{Tn}_TMR register). When the processor leaves debug state or DBGE is set to "0", the timer counter operation is resumed.
- This bit is enable at
 - ✧ from ch. 0 to ch. 3 of CPERI#2
 - ✧ from ch.0 to ch. 1 of MCU_CONFIG_GROUP.

[bit6] Reserved
[bit5] OUTL: Output level

This Output Level (OUTL) bit sets the output level for the TOT.

Refer to Table 4-5.

[bit4] RELD: Reload

This Reload (RELD) bit enables reload operations.

Refer to Table 4-5.

Bit	Description
0	The timer operates in one-shot mode. In this mode, the count operation stops when an underflow occurs due to the counter value changing from 0x00000000 to 0xFFFFFFFF
1	The timer operates in reload mode. In this mode, the timer loads the reload register contents into the counter and continues counting whenever an underflow occurs

[bit3] INTE: Interrupt enable

Timer interrupt request enable bit.

Bit	Description
0	No interrupt request is generated even when the RL _{Tn} _TMCSR:UF bit changes to "1"
1	An interrupt request is generated when the RL _{Tn} _TMCSR:UF bit changes to "1"

[bit2:0] Reserved

Table 4-2 RL_{Tn}_TMCSR:MOD[2:0] Bit Settings for Internal Clock Mode (RL_{Tn}_TMCSR:CSL1 / RL_{Tn}_TMCSR:CSL2 = 0b00, 0b01, or 0b10)

MOD[2]	MOD[1]	MOD[0]	Input Function	Active Edge or Level
0	0	0	Trigger disabled	-

CSL2	CSL1	CSL0	Count Clock (Time for Peripheral Clock)
0	0	0	1/1
0	0	1	1/2
0	1	0	1/4
0	1	1	1/8
1	0	0	1/16
1	0	1	1/32
1	1	0	External event count mode, each event on TIN
1	1	1	External event count mode, each second event on TIN

Table 4-5 RL_{Tn}_TMCSR: RL_{Tn}_TMCSR:OUTL, and RL_{Tn}_TMCSR:RELD Settings

OUTL	RELD	Output Waveform
0	0	Output an "H" level pulse during counting.
1	0	Output an "L" level pulse during counting.
0	1	Toggle output. Starts with "L" level output. Changes level on timer reload.
1	1	Toggle output. Starts with "H" level output. Changes level on timer reload.

Note:

- Bits marked 'x' in the table can be set to any value.

4.3. 32-Bit Reload Register (RLTn_TMRLR)

The Timer Reload Register holds the reload value of the 32-bit Reload Timer.

BIT_OFFSET	31	30	29	28	27	26	25	24

PROT_TYPE	-							
INITIAL_VALUE	XXXXXXXX							

[bit31:0] TMRLR: Timer reload register

The Timer Reload Register (RLTn_TMRLR) is a 32-bit reload register holds the reload value. Initial value is undefined.

This register can be accessed only in 32-bit/64-bit mode.

When RLTn_TMCSR:DBGES is set to "1" and the processor is in debug state, writing to this register updates the timer counter immediately.

Note:

- This register is not initialized by Hard Reset (i.e. "X").

4.4. 32-Bit Timer Register (RLTn_TMR)

Reading this register returns the count value of the 32-bit Reload Timer. The initial value is undefined.

BIT_OFFSET	31	30	29	28	27	26	25	24
BIT_NAME	TMR[31:24]

BIT_NAME	TMR[7:0]							
ACCESS_TYPE	R,WX							
PROT_TYPE	-							
INITIAL_VALUE	XXXXXXXX							

[bit31:0] TMR: Timer register

Reading this Timer Register (RLTn_TMR) returns the count value of the 32-bit Reload Timer. Initial value is undefined.

This register can be accessed only in 32-bit/64-bit mode.

Note:

- This register is not initialized by Hard Reset (i.e. "X").

CHAPTER 46: Reload Timer Simultaneous Soft Start

This chapter describes the reload timer simultaneous soft start.

1. Overview
2. Configuration
3. Explanation of Operation
4. Registers

RLTSSSR-TXXPT03P01R01L05-E1-XX

1. Overview

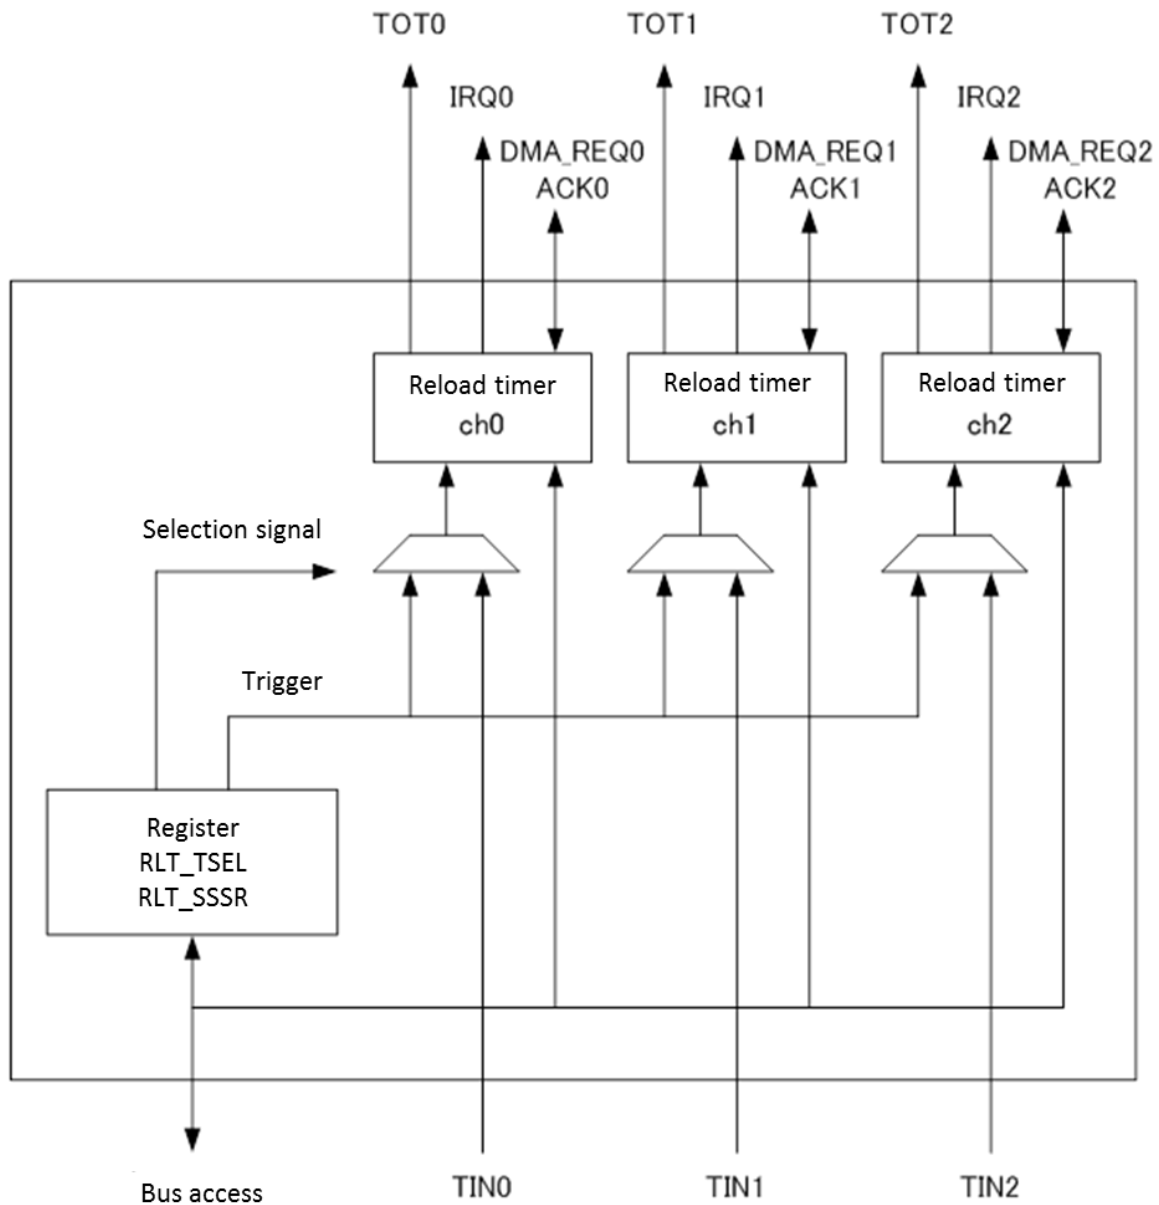

This section provides the overview of the reload timer simultaneous soft start.

The reload timer simultaneous soft start is a function to use a register write access as a trigger to start the reload timers of multiple channels simultaneously.

2. Configuration

This section describes the configuration of the reload timer simultaneous soft start.

Figure 2-1 Block Diagram

For Channel 0, Channel 1, and Channel 2

3. Explanation of Operation

This section describes the operation of the reload timer simultaneous soft start.

Trigger Selection Function

The RLTx_TSEL(x=0, 1, 2) register enables selections of the external trigger and software trigger for each channel.

Multiple Channel Simultaneous Start

A write access to the RLTx_SSSR(x=0, 1, 2) register can activate a software trigger to start multiple reload timers simultaneously. The software trigger is "0" in normal, and it changes from '0' to '1' to '0'.

Notes:

- *The reload timer simultaneous soft start activates a trigger that changes '0' to '1' to '0'. Set the register of the reload timer according to your needs.*
- *When the simultaneous soft start operates, set to disable the Noise Filter of Reload Timer.*

4. Registers

This section describes the registers of the reload timer simultaneous soft start.

Table 4-1 List of Register Area

Offset	Register name / Initial value				Block name
	+3	+2	+1	+0	
0000_0000	RLT0_TSEL 00000000 00000000 00000000 00000000				Common Peri #0

[bit31:16] Reserved: Reserved Bits

[bit15:0] TSEL15 to TSEL0: Trigger Selection Bits

These bits can select triggers for up to 16 channels.

TSEL15 to TSEL0 correspond to Channel 15 to Channel 0.

The channel that does not contain a reload timer can access registers, but it does not have a trigger selection function.

Bit	Description
0	Selects an external trigger (TIN).
1	Selects a software trigger.

4.2. Reload Timer Simultaneous Soft Start Register (RLT0_SSSR, RLT1_SSSR, RLT2_SSSR)

A write access can activate a software trigger to start multiple reload timers simultaneously.

[bit31:16] Reserved: Reserved Bits

[bit15:0] SSSR15 to SSSR0: Simultaneous Soft Start Bits

These bits activate software triggers for up to 16 channels simultaneously.

SSSR15 to SSSR0 correspond to Channel 15 to Channel 0.

The channel that does not contain a reload timer can access registers, but it does not have a software trigger function.

Bit	Description
0	Do not activate a software trigger.
1	Activate a software trigger.

CHAPTER 47: QPRC (Quadrature Position/Revolution Counter)

This chapter explains the functions and operations of the QPRC(Quadrature Position/Revolution Counter).

1. Overview
2. Configuration
3. Operations
4. Registers

QPRC-TXXPT03P01R02L02-E1-XX

1. Overview

The QPRC(Quadrature Position/Revolution Counter) is used to measure the position of Position Encoder. Also, it can be used as an up/down counter by its setting. The QPRC(Quadrature Position/Revolution Counter) contains a 16-bit position counter, a 16-bit revolution counter, two 16-bit compare registers, a control register, and its control circuit.

Features of QPRC(Quadrature Position/Revolution Counter)

The Position Counter can be Operated in One of the Following 3 Counting Modes

- PC_Mode1 : Up/down count mode
- PC_Mode2 : Phase difference count mode (supporting the 2-time and 4-time frequency multiplication)
- PC_Mode3 : Count mode with direction

The Revolution Counter can be Operated in One of the Following 3 Counting Modes

- RC_Mode1 : The revolution counter can count up or down at a ZIN active edge only.
- RC_Mode2 : The revolution counter can count up or down with an output value of position counter only.
- RC_Mode3 : The revolution counter can count up or down both with an output value of position counter and a signal at ZIN active edge.

A Signal Edge Detection can be Set for Detecting an Input Event from Three AIN, BIN and ZIN External Pins

- Detection of falling edge
- Detection of rising edge
- Detection of both rising and falling edges

The Following Two Functions can be Selected for Input in ZIN Pin

- Counter clear function
- Gate function

An Interrupt Request can be Generated If

- The position counter value matches the Position Compare Register,
- The position counter value matches the Position and Revolution Compare Register value, or the revolution counter value matches the Position and Revolution Compare Register value,
- The position counter underflows,
- The position counter overflows(that is, the position counter value matches the value of the QPRC Maximum Position Register),
- The position counter is reset at a ZIN active edge,
- The counting of position counter is inverted,
- The position counter matches the Position Compare Register value, and the revolution counter matches the Position and Revolution Compare Register value, or
- An outrange revolution counter value is detected.

The Following Useful Functions are Provided for Counting

- Swap function of AIN and BIN external pins
- Mask reset function of the position counter

- Count direction check function during position counter operation or during overflow/underflow occurrence

Interrupt request and DMA request

Interrupt request of this module can be used for purposes below:

1. Interrupt request to CPU (via Interrupt Controller)
2. DMA request to DMA Controller

To use the interrupt as interrupt request to CPU, following configuration is necessary:

- Enable the interrupt request in this module
- Enable the interrupt channel of the interrupt in Interrupt Controller

To use the interrupt as DMA request to DMA Controller, following configuration is necessary:

- Enable the interrupt request in this module
- Select the DMA channel from this module as DMA client in DMA Controller

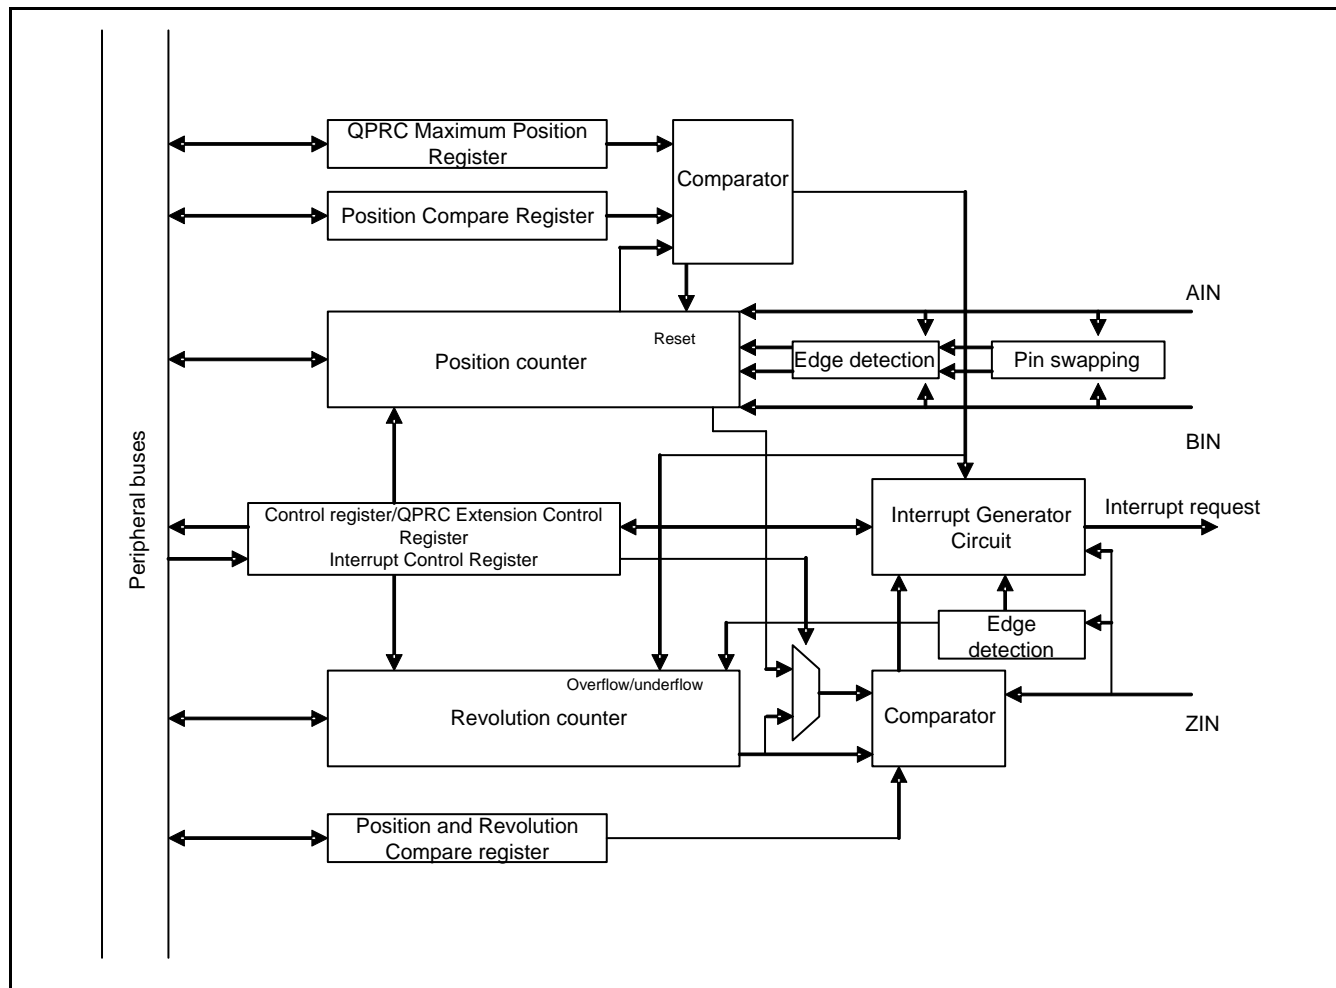

Note:

- *Interrupt request that supports for DMA request is product specification. Please refer to the product's HWM for detail.*

2. Configuration

The following shows the configuration of QPRC(Quadrature Position/Revolution Counter).

Figure 2-1 Block Diagram of QPRC(Quadrature Position/Revolution Counter)

3. Operations

This section explains the operation of QPRC(Quadrature Position/Revolution Counter).

3.1. Operation of Position Counter

The position counter receives an input signal from AIN or BIN external pin as an event of count clock, and increments or decrements the counter. As listed in Table 3-1, the position counter can select a counting mode by setting of the position counter mode bits(QCR.PCM[1:0]) of a control register. The counting conditions depend on the selected count mode.

The position counter is counted up or down in the following ZIN conditions only.

- If the ZIN function is set to the count clear function(QCR.CGSC= 0)
- If the ZIN function is set to the Gate function(QCR.CGSC= 1), the ZIN "L" level detection(QCR.CGE[1:0]= 0b01) is set, and the ZIN is "L"
- If the ZIN function is set to the Gate function(QCR.CGSC= 1), the ZIN "H" level detection(QCR.CGE[1:0]= 0b10) is set, and the ZIN is "H"

If the ZIN function is set to the Gate function(QCR.CGSC= 1) and if a level other than ZIN "H" or "L" level detection(QCR.CGE[1:0]= 0b00 or 0b11) is set, the position counter is not counted up or down.

Also, if the AIN and BIN configuration is swapped by SWAP bits of a control register, the AIN and BIN pins are swapped and the position counter is counted up or down.

For example, if PC_Mode1(QCR.PCM[1:0]= 0b01) and QCR.AES[1:0]= 0b10(rising edge) and QCR.BES[1:0]= 0b01(falling edge) are set, the following occurs.

- If QCR.SWAP= 0 and when a rising edge of AIN signal is detected, the position counter is counted up. When a falling edge of BIN signal is detected, the position counter is counted down.
- If QCR.SWAP= 1, the position counter is counted down at a falling edge of AIN signal but it is counted up at a rising edge of BIN signal.

Table 3-1 Counting Conditions of AIN and BIN Pin Position Counter

Position Count Mode(PC_Mode)	AIN Counting Conditions	BIN Counting Conditions
Count disable PC_Mode0:QCR.PCM[1:0]= 0b00	Position counter disable	Position counter disable
Up/down counting PC_Mode1:QCR.PCM[1:0]= 0b01	AIN Active edge	BIN Active edge
Phase difference count PC_Mode2:QCR.PCM[1:0]= 0b10	AIN Active edge or "H"/"L" level	"H"/"L" level or BIN active edge
Counting with direction PC_Mode3:QCR.PCM[1:0]= 0b11	"H"/"L" level	BIN Active edge

Note:

- *The active edge of AIN signal and the active edge of BIN signal mean a rising edge, a falling edge, or both of the respective signal if they are set by the AIN Detection Edge Select bits(QCR.AES[1:0]= 0b01 or 0b10 or 0b11) or by the BIN Detection Edge Select bits(QCR.BES[1:0]= 0b01 or 0b10 or 0b11).*

PC_Mode1: Up/Down Count Mode

An external signal entered from AIN or BIN external pin is received as the counting clock, and the position counter is counted up or down.

In this mode, the position counter is counted up when an active edge of AIN signal is detected. When an active edge of BIN signal is detected, the position counter is counted down.

Figure 3-1 Operations in Up/Down Count Mode
(QCR.AES[1:0]=0b10, QCR.BES[1:0]=0b10, QCR.SWAP= 0)

PC_Mode2: Phase Difference Count Mode(Supporting the 2-Time and 4-Time Frequency Multiplication)

- This mode is useful for counting the difference between phases A and B of "encoder output signal." If the phase-A and phase-B outputs are respectively connected to the AIN and BIN pins and if phase A is leading phase B, the counter is counted up. If delayed, the counter is counted down.
- In this mode, when an active edge of AIN signal is detected, the BIN signal level is checked and the position counter counts it. In the opposite case, the position counter also counts it.
- Counting in the 4-time or 2-time frequency multiplication can be made by setting the AES and BES bits of QPRC Control Register(QCR). The counting in these frequency multiplication modes allows more accurate position measurement as its counting resolution is very high.

Table 3-2 AES and BES Bit Settings in Frequency Multiplication Mode

Frequency Multiplication Mode	QCR.AES[1:0]	QCR.BES[1:0]
2-time frequency multiplication mode	11	00
	00	11
4-time frequency multiplication mode	11	11

**Table 3-3 Counting in 2-Time Frequency Multiplication Mode
(QCR.AES[1:0]=0b00, QCR.BES[1:0]=0b11, QCR.SWAP= 0)**

Edge Detection Pin	Detection Edge	Level Check Pin	Input Level	Counting Direction	Figure 3-2 Timing
BIN	Rising edge	AIN	"H"	Up	(1)
	Rising edge		"L"	Down	(2)
	Falling edge		"H"	Down	(3)
	Falling edge		"L"	Up	(4)

**Figure 3-2 Operation in 2-Time Frequency Multiplication Mode
(QCR.AES[1:0]=0b00, QCR.BES[1:0]=0b11, QCR.SWAP= 0)**

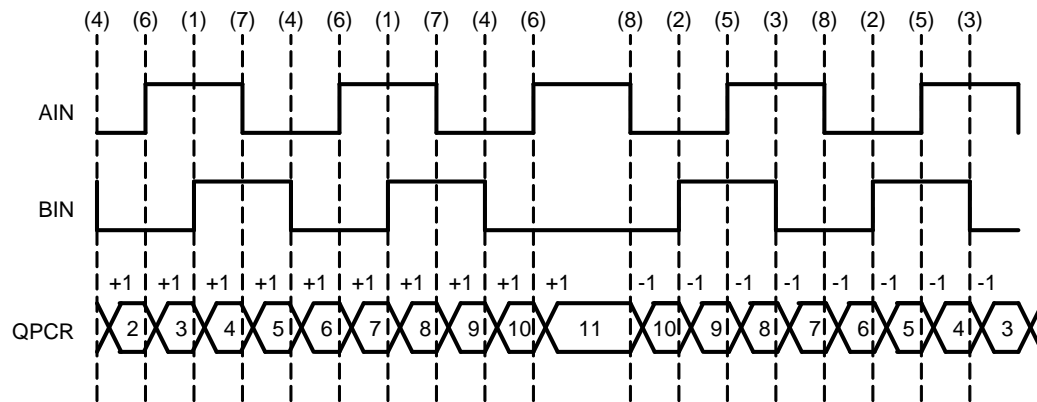

Table 3-4 Counting in 4-Time Frequency Multiplication Mode
(QCR.AES[1:0]=0b11, QCR.BES[1:0]=0b11)

BIN	Rising edge	AIN	"H"	Up	(1)
	Rising edge		"L"	Down	(2)
	Falling edge		"H"	Down	(3)
	Falling edge		"L"	Up	(4)
AIN	Rising edge	BIN	"H"	Down	(5)
	Rising edge		"L"	Up	(6)
	Falling edge		"H"	Up	(7)
	Falling edge		"L"	Down	(8)

Figure 3-3 Operation in 4-Time Frequency Multiplication Mode
(QCR.AES[1:0]=0b11, QCR.BES[1:0]=0b11, QCR.SWAP= 0)

PC_Mode3: Count Mode with Direction

- A signal entered from the BIN external pin is received as the counting clock, and an input level of the signal entered from the AIN external pin is used for count direction control for counter up/down counting.
- In this mode, when an active edge of BIN signal is detected, the AIN signal level is checked and the position counter counted up or down. A rising edge, a falling edge, or both can be set as the active edge.

Table 3-5 Counting in the Direction Control Counting Mode

Edge Detection Pin	Detection Edge	Level Check Pin	Input Level	Counting Direction	Figure 3-4 Timing
BIN	Active edge	AIN	"H"	Up	(1)
	Active edge		"L"	Down	(2)

Figure 3-4 Operation in the Direction Control Counting Mode
 (QCR.AES[1:0]=0b00, QCR.BES[1:0]=0b10, QCR.SWAP= 0)

3.2. Operation of Revolution Counter

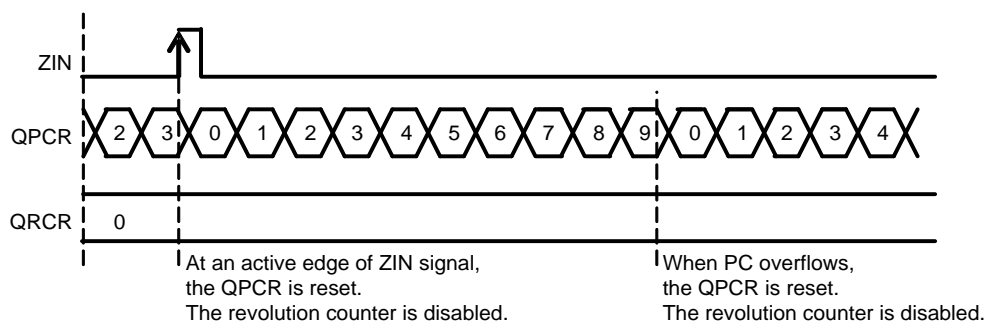

When the revolution counter receives an input from the ZIN pin(having the counter clear function) or an output of position counter(underflow or overflow), it is counted up or down. A rising edge, a falling edge, or both can be set as the active edge of ZIN signal.

The counting conditions of revolution counter depend on the selected mode as follows.

RC_Mode0(QCR.RCM[1:0]= 0b00)

- The revolution counter is disabled.
- If the ZIN signal is used for counter clear function(QCR.CGSC= 0), the position counter is reset at an active edge of the ZIN signal. Also, the position counter is reset when this counter overflows.

Figure 3-5 RC_Mode0 Operation(QPRC Maximum Position Register QMPR=9, QCR.CGSC= 0)

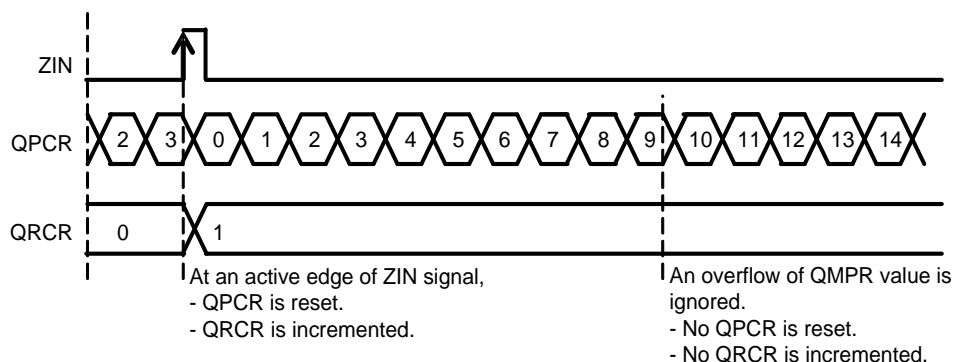

QPCR: QPRC Position Count Register

QRCR: QPRC Revolution Count Register

RC_Mode1(QCR.RCM[1:0]= 0b01)

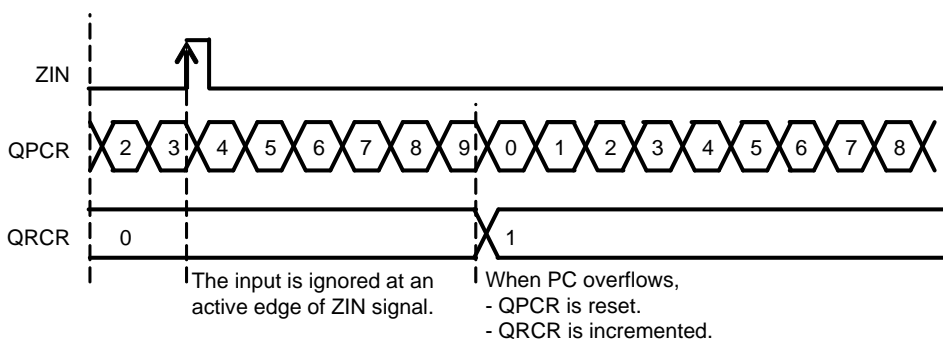

- When ZIN signal is used for the counter clear function(QCR.CGSC= 0), the revolution counter is operated only an active edge of ZIN signal(but an input from the position counter is ignored).
- When an active edge of ZIN signal is detected during incrementing of position counter(QICR.DIRPC= 0), the revolution counter is counted up. When an active edge of ZIN is detected during decrementing of position counter(QICR.DIRPC= 1), it is counted down.
- When the ZIN signal is used for counter clear function(QCR.CGSC= 0), the position counter is reset only at an active edge of ZIN signal.
- The position counter is not reset even when an overflow of position counter is detected. When an overflow of position counter is detected, the position counter is counted up and the overflow flag(QICR.OFDF) is set to "1".

Figure 3-6 RC_Mode1 Operation(QPRC Maximum Position Register QMPR=9, QCR.CGSC= 0)

Notes:

- When an active edge of ZIN signal and an active edge which counts down position counter are detected at the same time during incrementing of position counter(QICR.DIRPC= 0), the revolution counter is counted down.
- When an active edge of ZIN signal and an active edge which counts up position counter are detected at the same time during decrementing of position counter(QICR.DIRPC= 1), the revolution counter is counted up.
- When an active edge of ZIN signal, an active edge of AIN signal, and an active edge of BIN signal are detected at the same time, the revolution counter is counted up or down in accordance with the last position counter direction bit(QICR.DIRPC).

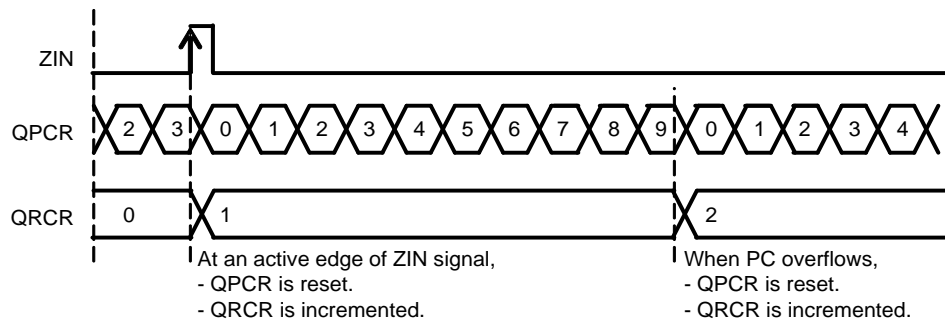

RC_Mode2(QCR.RCM[1:0]= 0b10)

- The revolution counter is counted up or down only by the output value of position counter.
- The position counter is reset only when an overflow of position counter is detected(but an event of ZIN signal is ignored).
- When an overflow of position counter is detected in any of 3 position counter modes(PC_Mode1, PC_Mode2 and PC_Mode3), the position counter is counted up. When an underflow of it is detected, the position counter is counted down.

Figure 3-7 RC_Mode2 Operation(QPRC Maximum Position Register QMPR=9)

RC_Mode3(QCR.RCM[1:0]= 0b11)

- In this mode, the revolution counter is operated with an output of position counter and when the ZIN signal is used for the counter clear function(QCR.CGSC= 0), the revolution counter is also counted up or down at an active edge of ZIN signal.
- When an active edge of ZIN signal is detected during incrementing of position counter(QICR.DIRPC= 0) or when an overflow of position counter is detected, the revolution counter is counted up.
- When an active edge of ZIN signal is detected during decrementing of position counter(QICR.DIRPC= 1) or when an underflow of position counter is detected, the revolution counter is counted down.
- When the ZIN signal is used for the counter clear function(QCR.CGSC= 0), the position counter is reset at an active edge of ZIN signal or at detection of position counter overflow.

Figure 3-8 RC_Mode3 Operation(QPRC Maximum Position Register QMPR=9, QCR.CGSC= 0)**Notes:**

- When an active edge of ZIN signal and an active edge which counts down position counter are detected at the same time during incrementing of position counter(QICR.DIRPC= 0), the revolution counter is counted down.
- When an active edge of ZIN signal and an active edge which counts up position counter are detected at the same time during decrementing of position counter(QICR.DIRPC= 1), the revolution counter is counted up.
- When an active edge of ZIN signal, an active edge of AIN signal, and an active edge of BIN signal are detected at the same time, the revolution counter is counted up or down in accordance with the last position counter direction bit(QICR.DIRPC).

3.3. Absolute Value of Positions

In RC_Mode2 and 3 mode(when the revolution counter operates with an output of position counter), each position has the following absolute value.

$$\text{QPRC Position Count Register(QPCR)} + \text{QPRC Revolution Count Register(QRCR)} \times (\text{QPRC Maximum Position Register(QMPR)} + 1)$$

Example: Time measurement

The revolution counter counts the "hours", and the position counter counts the "minutes".
 If QMPR=59, QPCR=20, and QRCR=5

$$\begin{aligned} \text{Time} &= 20 + 5 \times (59 + 1) \\ &= 320 \text{ minutes.} \end{aligned}$$

This is the absolute value in position counter units(minutes).

3.4. QPRC(Quadrature Position/Revolution Counter) Interrupts

The following table defines the conditions where an interrupt request of QPRC(Quadrature Position/Revolution Counter) can generate.

Table 3-6 Generation Conditions of QPRC(Quadrature Position/Revolution Counter) Interrupt Requests

Interrupt Request	Interrupt Request Flag	Interrupt Request is Enabled If	Interrupt Request is Cleared If
Count inversion interrupt request	QICR.CDCF= 1	QICR.CDCIE= 1	"0" is written to QICR.CDCF
Zero index interrupt request	QICR.ZIIF= 1	QICR.OUZIE= 1	"0" is written to QICR.ZIIF
Overflow interrupt request	QICR.OFDF= 1		"0" is written to QICR.OFDF
Underflow interrupt request	QICR.UFDF= 1		"0" is written to QICR.UFDF
PC and RC match interrupt request	QICR.QPRCMF= 1	QICR.QPRCMIE= 1	"0" is written to QICR.QPRCMF
PC match interrupt request	QICR.QPCMF= 1	QICR.QPCMIE= 1	"0" is written to QICR.QPCMF
PC match and RC match interrupt request	QICR.QPCNRCMF= 1	QICR.QPCNRCMIE= 1	"0" is written to QICR.QPCNRCMF
Outrange interrupt request	QECR.ORNGF= 1	QICR.ORNGIE= 1	"0" is written to QECR.ORNGF

QICR : QPRC Interrupt Control Register

QECR : QPRC Extension Control Register

3.5. Operation Example of QPRC Maximum Position Register(QMPR) Interrupt

The QPRC Maximum Position Register(QMPR) value is used as the reload data to the position counter when an overflow or underflow of position counter is detected.

When the position counter value matches the QPRC Maximum Position Register(QMPR) value, the operation of the revolution counter depends on the selected mode as follows:

- When the position counter is counted up in RC_Mode0(QCR.RCM[1:0]= 0b00), RC_Mode2(QCR.RCM[1:0]= 0b10) or RC_Mode3(QCR.RCM[1:0]= 0b11), the overflow flag(QICR.OFDF) is set to "1" and the position counter is reset.
- When the position counter is counted up in RC_Mode1(QCR.RCM[1:0]= 0b01), the overflow flag(QICR.OFDF) is set to "1". During this time, the position counter is not reset but is counted up.

The following gives an operation example where the QPRC Maximum Position Register(QMPR) is used in RC_Mode2(QCR.RCM[1:0]= 0b10).

During counting up:

When the position counter maximum value overflows to 0x0000, the revolution counter is counted up. During this time, the overflow flag(QICR.OFDF) is set to "1".

Example: If the QPRC Maximum Position Register(QMPR) is set to 18

Position counter	15	16	17	18	0	1	2
Revolution counter	1	1	1	1	2	2	2

During counting down:

When an underflow is detected with 0x0000 and when the value of Quad Counter Maximum Position Counter Register(QMPR) is reloaded to the position counter, the revolution counter is counted down. During this time, the underflow flag(QICR.UFDF) is set to "1".

Example: If the QPRC Maximum Position Register(QMPR) is set to 5

Position counter	4	3	2	1	0	5	4	3	2	1	0	5
Revolution counter	1	1	1	1	1	0	0	0	0	0	0	0xFFFF

Note:

- The counting direction of position counter depends on the AIN and BIN external input signals only.

3.6. Position Counter Reset Mask Function

The position counter reset mask function can be used only when RC_Mode0(QCR.RCM[1:0]= -b00) or RC_Mode3(QCR.RCM[1:0]= 0b11) is selected. This function operates regardless of setting of the position counter mode(PC_Mode1, PC_Mode2 or PC_Mode3).

The position counter reset mask function is executed in the following sequence.

1. When an active event of ZIN signal, an overflow of position counter, or an underflow of position counter are detected, a value being set by the position counter reset mask bits(QCR.PCRM[1:0]) is set to the mask counter*1.
2. When the position counter is counted up or down in the same counting direction, the mask counter*1 is counted down.
The position counter is reset only when the mask counter*1 is set to 0x0. Also, the revolution counter is not counted up or down.
When a count inversion of the position counter is detected, the mask counter*1 is set to 0x0.
3. If the mask counter*1 is set to 0x0, the position counter is set to 0x0000 when an active edge of ZIN signal or an overflow of position counter is detected.

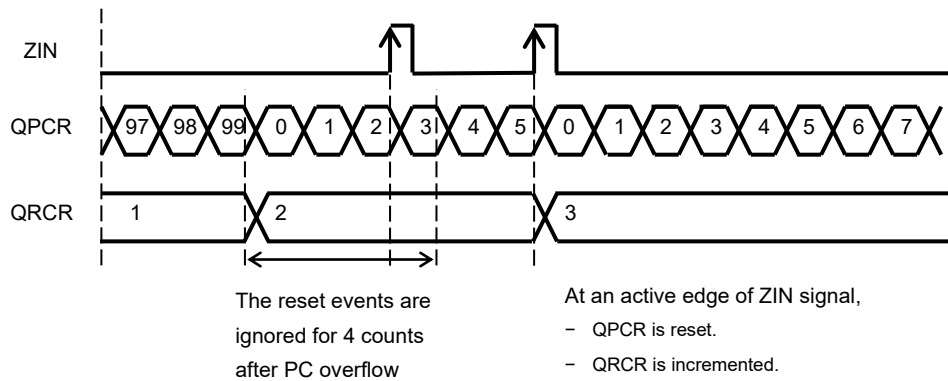

*1 : The number of times to mask both the reset of position counter and the counting up/down of revolution counter is counted. The masking continues until this counter value reaches 0x0.

The following gives an operation example where the position counter reset mask function is used in RC_Mode3(QCR.RCM[1:0]=0b11).

Example 1:

An active edge of ZIN signal is ignored for four(4) counts(QPRC=0 to 3) of position counter after occurrence of position counter overflow.

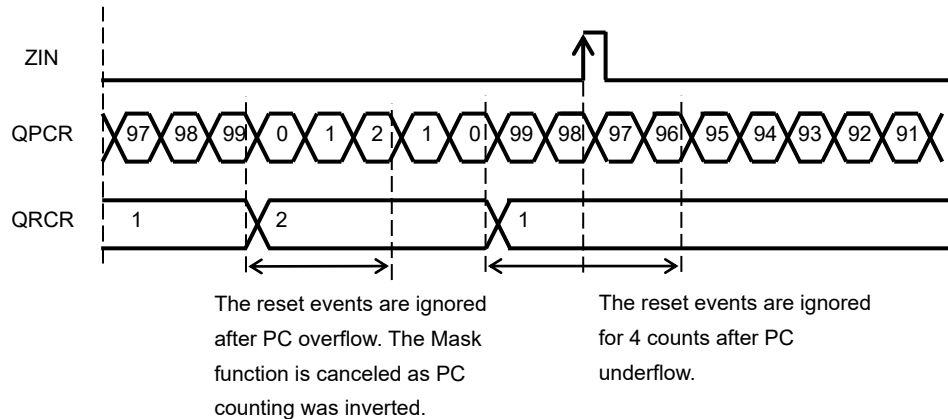

Figure 3-9 Position Counter Reset Mask Operation Example 1
 (QMPR=99, QCR.PCRM[1:0]= 0b10, QCR.CGSC= 0)

Example 2:

An active edge of ZIN signal is ignored for four(4) counts(QPCR=99 to 96) of position counter after occurrence of position counter underflow following count inversion of position counter.

Figure 3-10 Position Counter Reset Mask Operation Example 2
 (QMPR=99, QCR.PCRM[1:0]=0b10, QCR.CGSC= 0)

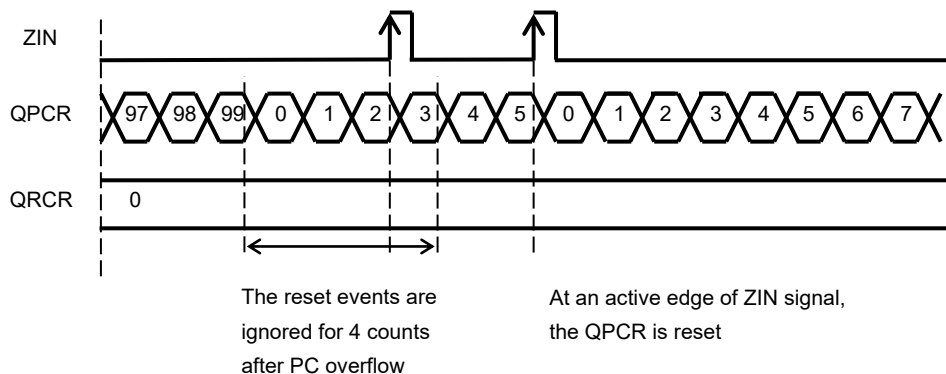

The following gives an operation example where the position counter reset mask function is used in RC_Mode0(QCR.RCM[1:0]= 0b00).

Example 3:

An active edge of ZIN signal is ignored for four(4) counts(QPRC=0 to 3) of position counter after occurrence of position counter overflow if the revolution counter is disabled.

Figure 3-11 Position Counter Reset Mask Operation Example 3

(QMPR=99, QCR.PCRM[1:0]= 0b10, QCR.CGSC= 0)

Notes:

- While the position counter reset mask function is operating, the mask function is released and the position counter can be reset in the following conditions.
 - The position counter mode bit(QCR.PCM[1:0]) is changed, or
 - The revolution counter mode bit(QCR.RCM[1:0]) is changed, or
 - The direction of the position counter is changed.
- Even if an overflow or underflow of the position counter occurs without inversion of the position counter while the position counter reset mask function is operating in RC_Mode0(QCR.RCM[1:0]= 0b00) or RC_Mode3(QCR.RCM[1:0]= 0b11), the revolution counter is not counted up or down. However, if an overflow occurs, the position counter becomes 0x0000. If an underflow occurs, the QMPR is reloaded to the position counter. The overflow interrupt request flag bit(QICR.OFDF) or the underflow interrupt request flag bit(QICR.UFDF) is set to "1".

4. Registers

This section explains the configuration and functions of the registers used for the QPRC(Quadrature Position/Revolution Counter).

Table 4-1 List of QPRC(Quadrature Position/Revolution Counter) Register

Abbreviation	Register Name	See
QPCR	QPRC Position Count Register	4.1
QRCR	QPRC Revolution Count Register	4.2
QPCCR	QPRC Position Counter Compare Register	4.3
QPRCR	QPRC Position and Revolution Counter Compare Register	4.4
QCR	QPRC Control Register	4.5
QECR	QPRC Extension Control Register	4.6

0x020 to 0x3FC	-			

4.1. Position Count Register(QPCR)

The QPRC Position Count Register(QPCR) indicates the position counter

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	QPCR[15:0]															
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[bit15:0] QPCR[15:0]:

Reading this register reads out the current value of the position counter. While the position counter stops counting(QCR.PSTP= 1), the count value can be written to this register.

This register is set to 0x0000 in the following one of conditions.

- Reset
- A ZIN active edge is detected in the following conditions.
 - The ZIN function is set to the counter clear function(QCR.CGSC= 0) in RC_Mode1(QCR.RCM[1:0]= 0b01).
 - After the position counter has been incremented or decremented by the mask set value when the count inversion of the position counter is not detected where the ZIN function is set to the counter clear function(QCR.CGSC= 0) and the reset mask function of the position counter is valid(QCR.PCRM[1:0]= 0b01 or 0b10 or 0b11) in RC_Mode0(QCR.RCM[1:0]= 0b00) or RC_Mode3(QCR.RCM[1:0]= 0b11)
 - The ZIN function is set to the counter clear function(QCR.CGSC= 0) and the reset mask function of the position counter is invalid(QCR.PCRM[1:0]= 0b00) in RC_Mode0(QCR.RCM[1:0]= 0b00) or RC_Mode3(QCR.RCM[1:0]= 0b11).
- A position counter overflow is detected in the following conditions.
 - RC_Mode2(QCR.RCM[1:0]= 0b10)
 - After the position counter has been incremented or decremented by the mask set value when the count inversion of the position counter is not detected where the ZIN function is set to the counter clear function(QCR.CGSC= 0) and the reset mask function of the position counter is valid(QCR.PCRM[1:0]= 0b01 or 0b10 or 0b11) in RC_Mode0(QCR.RCM[1:0]= 0b00) or RC_Mode3(QCR.RCM[1:0]= 0b11)
 - The ZIN function is set to the counter clear function(QCR.CGSC= 0) and the reset mask function of the position counter is invalid(QCR.PCRM[1:0]= 0b00) in RC_Mode0(QCR.RCM[1:0]= 0b00) or RC_Mode3(QCR.RCM[1:0]= 0b11).
- 0x0000 is written to this QPCR while the position counter is under suspension(QCR.PSTP= 1).

The value of the QPRC Maximum Position Register(QMPR) is set to this register in the following condition.

- A position counter underflow is detected.

Notes:

- *Do not access the QPRC Position Count Register(QPCR) with a byte access instruction.*
- *After the count value was written to the QPRC Position Count Register(QPCR) while the position counter was under suspension(QCR.PSTP= 1) in RC_Mode0(QCR.RCM[1:0]= 0b00), RC_Mode1(QCR.RCM[1:0]= 0b01), or RC_Mode3(QCR.RCM[1:0]= 0b11), if a ZIN active edge is detected with the count function(QCR.CGSC= 0), the QPRC Position Count Register(QPCR) will be set to 0x0000.*
To write the count value to the QPRC Position Count Register(QPCR), make the ZIN detection edge invalid(QCR.CGE[1:0]= 0b00) before writing it to the QPCR.

4.2. QPRC Revolution Count Register(QRCR)

The QPRC Revolution Count Register(QRCR) indicates the revolution counter.

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	QRCR[15:0]															
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[bit15:0] QRCR[15:0] :

Reading this register reads out the current value of the revolution counter. While the revolution counter stops counting(QCR.RCM[1:0]= 0b00), the count value can be written to this register.

This register is set to 0x0000 in the following one of conditions.

- Reset
- 0x0000 is written to this register while the revolution counter is under suspension(QCR.RCM[1:0]= 0b00).

Notes:

- Do not access the QPRC Revolution Count Register(QRCR) with a byte access instruction.
- As the direction of the position counter is not detected in PC_Mode0(QCR.PCM[1:0]= 0b00), the last position counter direction bit(QICR.DIRPC) becomes indefinite. Therefore, if the mode is changed from PC_Mode0(QCR.PCM[1:0]= 0b00) to another mode, when a ZIN active edge is detected before an AIN/BIN active edge is detected, the following operations apply.
 - The position counter is reset if the mode is RC_Mode0(QCR.RCM[1:0]= 0b00),RC_Mode1(QCR.RCM[1:0]= 0b01), or RC_Mode3(QCR.RCM[1:0]= 0b11)
 - The revolution counter is not counted up or down.

4.3. QPRC Position Counter Compare Register(QPCCR)

The QPRC Position Counter Compare Register(QPCCR) is used to compare with the count value of the position counter.

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	QPCCR[15:0]															
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[bit15:0] QPCCR[15:0] : QPRC Position Counter Compare

If the value of this register matches that of the position counter, the QPRC position counter comparison match flag(QICR.QPCMF) is set to "1". This Compare Register can be used only to compare with the count value of the position counter.

Note:

- Do not access the QPRC Position Counter Compare Register(QPCCR) with a byte access instruction.

4.4. QPRC Position and Revolution Counter Compare Register(QPRCR)

The QPRC Position and Revolution Counter Compare Register(QPRCR) is used to compare with the selected count value of the position or revolution counter.

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	QPRCR[15:0]															
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Protection	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[bit15:0] QPRCR[15:0] : QPRC Position and Revolution Counter Compare

Select whether to compare with the count value of the position or revolution counter using the RSEL bit of the QPRC Control Register(QCR). If the value of this register matches that of the position or revolution counter, the QPRC position and revolution counter comparison match flag(QICR.QPRCMF) is set to "1".

Note:

- Do not access the QPRC Position and Revolution Counter Compare Register(QPRCR) with a byte access instruction.

4.5. QPRC Control Register(QCR)

The QPRC Control Register(QCR) is used to specify the operation mode of the position counter or 16-bit revolution counter. It is also used to start or stop each counter.

Low-Order Bytes of QPRC Control Register(QCRL)

bit	7	6	5	4	3	2	1	0
Field	SWAP	RSEL	CGSC	PSTP	RCM[1:0]		PCM[1:0]	
R/W	R/W	R/W	R/W	R/W	R/W		R/W	
Attribute								
Protection	-	-	-	-	-		-	
Attribute								
Initial Value	0	0	0	0	00		00	

[bit7] SWAP : Swap Bit

This bit is used to swap the connections of the AIN input and BIN input to the position counter.

When this bit is set to "0", the AIN pin is used for the AIN input of the position counter, and the BIN pin is used for the BIN input of the position counter. When this bit is set to "1", the AIN pin is used for the BIN input of the position counter, and the BIN pin is used for the AIN input of the position counter.

Bit	Description
0	No swap
1	Swaps AIN and BIN inputs.

Note:

- Change the swap bit(SWAP) when the position counter is disabled(PCM[1:0]= 0b00).

[bit6] RSEL : Register Function Selection Bit

This bit is used to select whether to compare the value of the QPRC Position and Revolution Counter Compare Register(QPRCR) with that of the position or revolution counter.

Bit	Description
0	Compares the value of the QPRC Position and Revolution Counter Compare Register(QPRCR) with that of the position counter.
1	Compares the value of the QPRC Position and Revolution Counter Compare Register(QPRCR) with that of the revolution counter.

Note:

- When the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) and also the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR), the PC match and RC match interrupt request flag bit(QICR: QPCNRCMF) is set to "1" regardless of the setting of this bit.

[bit5] CGSC : Count Clear or Gate Selection Bit

This bit is used to select the function of the ZIN external pin.

When the counter clear function is enabled(QGSC= 0), the ZIN pin clears the position counter if the revolution count mode is set to RC_Mode0(RCM[1:0]= 0b00), RC_Mode1(RCM[1:0]= 0b01), or RC_Mode3(RCM[1:0]= 0b11). The CGE[1] and CGE[0] bits of the QCR register clear the position counter by selecting a valid edge of the ZIN pin and detecting the selected edge.

When the gate function is enabled(QGSC= 1), the ZIN pin controls the count operation of the position counter. The CGE[1] and CGE[0] bits of the QCR register count the position counter at the valid level of the ZIN pin.

Bit	Description
0	Counter clear function
1	Gate function

[bit4] PSTP : Position Counter Stop Bit

This bit is used to stop the position counter.

Bit	Description
0	Enables count operation.
1	Stops count operation.

[bit3:2] RCM[1:0] : Revolution Counter Mode Bits

These bits are used to select the count mode of the revolution counter and the reset mode of the position counter. For the effect on the position counter, see "3.2 Operation of Revolution Counter".

Bits	Description
00	Disables the revolution counter(RC_Mode0).
01	The revolution counter is counted up or down only with a ZIN active edge(RC_Mode1).
10	The revolution counter is counted up or down only when overflow or underflow is detected in the position counter that matches QMPR(RC_Mode2).
11	The revolution counter is counted up or down in two cases: a position counter overflow or underflow is detected and a ZIN active edge is detected(RC_Mode3).

[bit1:0] PCM[1:0] : Position Counter Mode Bits

These bits are used to select the count mode of the position counter.

Bits	Description
00	Disables the position counter(PC_Mode0) to stop it.
01	Up/down count mode(PC_Mode1) Increments the value with an AIN active edge and decrements it with a BIN active edge.
10	Phase difference count mode(PC_Mode2) Counts up if AIN is leading BIN and down if BIN is leading AIN.
11	Directional count mode(PC_Mode3) Counts up or down with the BIN active edge and AIN level.

Note:

- *As the direction of the position counter is not detected in PC_Mode0(PCM[1:0]= 0b00), the last position counter direction bit(QICR.DIRPC) becomes indefinite. Therefore, if the mode is changed from PC_Mode0(PCM[1:0]= 0b00) to another mode, when a ZIN active edge is detected before an AIN/BIN active edge is detected, the following operations apply.*
 - The position counter is reset if the mode is RC_Mode0(RCM[1:0]= 0b00), RC_Mode1(RCM[1:0]= 0b01), or RC_Mode3(RCM[1:0]= 0b11)
 - The revolution counter is not counted up or down

High-Order Bytes of QPRC Control Register(QCRH)

bit	15	14	13	12	11	10	9	8
Field	CGE[1:0]		BES[1:0]		AES[1:0]		PCRM[1:0]	
R/W Attribute	R/W		R/W		R/W		R/W	
Protection	-		-		-		-	
Attribute	-		-		-		-	
Initial Value	00		00		00		00	

[bit15:14] CGE[1:0] : Detection Edge Selection Bits

These bits are used to select the detection edge when the ZIN external pin is used for the counter clear function(CGSC= 0). They are also used to select the detection level when the ZIN external pin is used for the gate function(CGSC= 1).

Bits	ZIN Used for Counter Clear Function (CGSC= 0)	ZIN Used for Gate Function (CGSC="1")
00	Disables edge detection.	Disables level detection.
01	Detects a falling edge.	Detects level "L".
10	Detects a rising edge.	Detects level "H".
11	Detects both rising and falling edges.	Disables level detection.

[bit13:12] BES[1:0] : BIN Detection Edge Selection Bits

These bits are used to select the detection edge of the BIN external pin.

Bits	Description
00	Disables edge detection.
01	Detects a falling edge.
10	Detects a rising edge.
11	Detects both rising and falling edges.

[bit11:10] AES[1:0] : AIN Detection Edge Selection Bits

These bits are used to select the detection edge of the AIN external pin.

Bits	Description
00	Disables edge detection.
01	Detects a falling edge.
10	Detects a rising edge.
11	Detects both rising and falling edges.

[bit9:8] PCRM[1:0] : Position Counter Reset Mask Bits

These bits are used to specify the period(mask time) to ignore the events shown below after detecting a position counter overflow or underflow or detecting a ZIN active edge.

- Position counter resetting
- Revolution counter increment or decrement

This mask function is released when the count direction of the position counter is changed, and restarts when a position counter overflow or underflow is detected or a ZIN active edge is detected.

Bits	Description
00	No reset mask
01	The position counter reset or a revolution counter count-up or -down events are ignored until the position counter changes twice.
10	The position counter reset or a revolution counter count-up or -down events are ignored until the position counter changes four times.
11	The position counter reset or a revolution counter count-up or -down events are ignored until the position counter changes eight times.

Notes:

- The position counter reset mask function is available only in RC_Mode0(RCM[1:0]= 0b00) and RC_Mode3(RCM[1:0]= 0b11). This function operates regardless of the setting of the position counter mode(PC_Mode1, PC_Mode2, or PC_Mode3).
- While the position counter reset mask function is operating, the mask function is released and the position counter can be reset in the following conditions.
 - When the position counter mode bit(PCM[1:0]) is changed
 - When the revolution counter mode bit(RCM[1:0]) is changed
 - When the direction of the position counter is changed

4.6. QPRC Extension Control Register(QECCR)

The QPRC Extension Control Register(QECCR) is used to select that the revolution counter is inside the count range, indicate that the revolution counter is outside the count range, or control whether or not to generate an interrupt when the revolution counter gets out of the range.

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	Reserved													ORNGIE	ORNGF	ORNGMD
R/W	R	R	R	R	R	R	R	R	R	R	R	R	R	R/W	R,W	R/W
Attribute	0	0	0	0	0	0	0	0	0	0	0	0	0	-	-	-
Protection	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

[bit15:3] Reserved : Reserved Bits

These bits must always be written to "0".

The read value is "0".

[bit2] ORNGIE : Outrange Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the outrange interrupt request flag(ORNGF) is set to "1". When this bit is set to "1", an interrupt is generated if the value of the revolution counter gets out of the range(ORNGF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

[bit1] ORNGF : Outrange Interrupt Request Flag Bit

This flag indicates that the revolution counter is outside the count range.

If a positive number is selected as the outrange mode of the revolution counter(ORNGMD= 0), this flag is set to "1" when the revolution counter changes from 0x0001 to 0x0000 after counting down or when it changes from 0xFFFFE to 0xFFFF after counting up.

If the 8K value is selected as the outrange mode of the revolution counter(ORNGMD= 1), this flag is set to "1" when the revolution counter changes from 0x8001 to 0x8000 after counting down or when it changes from 0x7FFFE to 0x7FFF after counting up.

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Out of range is not detected.	Clears this bit.
1	Out of range is detected.	No effect.

[bit0] ORNGMD : Outrange Mode Selection Bit

This bit defines the outrange mode of the revolution counter.

Bit	Description
0	Selects a positive number(in the range from 0x0000 to 0xFFFF).
1	Selects the 8K value(in the range from 0x0000 to 0x7FFF).

4.7. Low-Order Bytes of QPRC Interrupt Control Register(QICRL)

The Low-Order Bytes of QPRC Interrupt Control Register(QICRL) are used to control a position counter overflow or underflow interrupt, zero index interrupt, QPRC position counter comparison match interrupt, or QPRC position and revolution counter comparison match interrupt.

bit	7	6	5	4	3	2	1	0
Field	ZIIF	OFDF	UFDf	OUZIE	QPRCMF	QPRCMIE	QPCMF	QPCMIIE
R/W Attribute	R,W	R,W	R,W	R,W	R,W	R,W	R,W	R,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] ZIIF : Zero Index Interrupt Request Flag Bit

This flag is set to "1" when the position counter is reset by the ZIN input.

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no zero index.	Clears this bit.
1	Detects zero index.	No effect.

Note:

- The zero index interrupt request flag bit(ZIIF) is not set to "1" even if ZIN is used as the gate function(QCR.CGSC= 1) or the position counter is reset in RC_Mode2(QCR.RCM[1:0]= 0b10).

[bit6] OFDF : Overflow Interrupt Request Flag Bit

This flag indicates that a position counter overflow occurs. When the set value of the QPRC Maximum Position Register(QMPR) matches the value of the position counter and the position counter is counted up, this bit is set to "1".

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no overflow.	Clears this bit.
1	Detects overflow.	No effect.

[bit5] UFDF : Underflow Interrupt Request Flag Bit

This flag indicates that a position counter underflow occurs. When the position counter is 0x0000 and the position counter is counted down, this bit is set to "1".

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no underflow.	Clears this bit.
1	Detects underflow.	No effect.

[bit4] OUZIE : Overflow, Underflow, or Zero Index Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the overflow interrupt request flag bit(OFDF), underflow interrupt request flag bit(UFDF), or zero index interrupt request flag bit(ZIIF) is set to "1". When this bit is set to "1", an interrupt is generated if overflow is detected(OFDF= 1), underflow is detected(UFDF= 1), or zero index is detected(ZIIF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

[bit3] QPRCMF : PC and RC Match Interrupt Request Flag Bit

This flag indicates whether the value of the position counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) or the value of the revolution counter(QRCR) matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).

When the comparison between the position counter and QPRC Position and Revolution Counter Compare Register(QPRCR) is selected(QCR.RSEL= 0), this flag is set to "1" if the value of the position counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).

When the comparison between the revolution counter and QPRC Position and Revolution Counter Compare Register(QPRCR) is selected(QCR.RSEL= 1), this flag is set to "1" if the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no comparison match with the QPRCR value.	Clears this bit.
1	Detects a comparison match with the QPRCR value.	No effect.

Notes:

- *If the register function selection bit(QCR.RSEL) is set to "0", the PC and RC match interrupt request flag bit(QPRCMF) is set to "1" immediately when the following one of conditions is satisfied.*
 - The mode is changed to PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11) when the position counter is disabled(QCR.PCM[1:0]= 0b00) and the value of the position counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).
 - The value of the position counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) when data is written to the QPRC Position Count Register(QPCR) or QPRC Position and Revolution Counter Compare Register(QPRCR) in PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11)
- *If the register function selection bit(QCR.RSEL) is set to "1", the PC and RC match interrupt request flag bit(QPRCMF) is set to "1" immediately when the following condition is satisfied.*
 - The value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) by writing data to the QPRC Position and Revolution Counter Compare Register(QPRCR) when the mode is RC_Mode1(QCR.RCM[1:0]= 0b01), RC_Mode2(QCR.RCM[1:0]= 0b10), or RC_Mode3(QCR.RCM[1:0]= 0b11).
 - The value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) by changing the mode from RC_Mode0(QCR.RCM[1:0]= 0b00) to another mode.
- *When the register function selection bit(QCR.RSEL) is changed, the PC and RC match interrupt request flag bit(QPRCMF) is set to "1" immediately if the following one of conditions is satisfied.*
 - The value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) when the register function selection bit(QCR.RSEL) is changed from "0" to "1" in the mode other than RC_Mode0(QCR.RCM[1:0]= 0b00).
 - The value of the position counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) when the register function selection bit(QCR.RSEL) is changed from "1" to "0" in the mode other than RC_Mode0(QCR.RCM[1:0]= "00")

[bit2] QPRCMIE : PC and RC Match Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the PC and RC match interrupt request flag(QPRCMF) is set to "1". When this bit is set to "1", an interrupt is generated if the value of the position or revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR)(QPRCMF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

[bit1] QPCMF : PC Match Interrupt Request Flag Bit

This flag indicates whether or not the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR).

This flag is set to "1" if the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR).

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no comparison match with the QPCCR value.	Clears this bit.
1	Detects a comparison match with the QPCCR value.	No effect.

Note:

- The PC match interrupt request flag bit(QPCMF) is set to "1" immediately when the following one of conditions is satisfied.
 - The mode is changed to PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11) when the position counter is disabled(QCR.PCM[1:0]= 0b00) and the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR).
 - The value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) by writing to the QPRC Position Count Register(QPCR) when the position counter stop bit(QCR.PSTP) is "1" and when the mode is PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11).
 - The value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) by writing to the QPRC Position Counter Compare Register(QPCCR) when the mode is PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11).

[bit0] QPCMIE : PC Match Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the PC match interrupt request flag(QPCMF) is set to "1".

When this bit is set to "1", an interrupt is generated if the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR)(QPCMF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

4.8. High-Order Bytes of QPRC Interrupt Control Register(QICRH)

The High-Order Bytes of QPRC Interrupt Control Register(QICRH) are used to control a match between the position counter and QPCCR, a match between the revolution counter and QPRCR, and a count inversion interrupt. They are also used to indicate the direction of the position counter when the last underflow or overflow interrupt was detected or the last value of the position counter was changed.

bit	15	14	13	12	11	10	9	8
Field	Reserved		QPCNRCMF	QPCNRCMIE	DIROU	DIRPC	CDCF	CDCIE
R/W	R0,W0		R,W	R/W	R,WX	R,WX	R,W	R/W
Attribute								
Protection	-		-	-	-	-	-	-
Attribute								
Initial Value	00		0	0	0	0	0	0

[bit15:14] Reserved : Reserved Bits

These bits must always be written to "0".

The read value is "0".

[bit13] QPCNRCMF : PC Match and RC Match Interrupt Request Flag Bit

This flag indicates whether or not the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) and the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).

This flag is set to "1" when the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR)(QPCMF= 1) and the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Detects no match.	Clears this bit.
1	Detects a match.	No effect.

Note:

- The PC match and RC match interrupt request flag bit(QPCNRCMF) is set to "1" immediately when the following one of conditions is satisfied.
 - The mode is changed to PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11) when the position counter is disabled(QCR.PCM[1:0]= 0b00) and the revolution counter is in the mode other than RC_Mode0(QCR.RCM[1:0]= 0b00) while the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) and the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR).
 - The value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) when data is written to the QPRC Position Count Register(QPCR) or QPRC Position Counter Compare Register(QPCCR) where the value of the revolution counter matches that of the QPRC Position & Revolution Counter Compare Register(QPRCR) when the mode is PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11) and the revolution counter is in the mode other than RC_Mode0(QCR.RCM[1:0]= 0b00).
 - The value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) when the data is written to the QPRC Position and Revolution Counter Compare Register(QPRCR) in the mode other than RC_Mode0(QCR.RCM[1:0]= 0b00) where the specified value matches that of the QPRC Position Count Register(QPCR) or QPRC Position Counter Compare Register(QPCCR) in PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11).
 - The value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) when the mode is changed from RC_Mode0(QCR.RCM[1:0]= 0b00) to another mode where the specified value matches that of the QPRC Position Count Register(QPCR) or QPRC Position Counter Compare Register(QPCCR) in PC_Mode1(QCR.PCM[1:0]= 0b01), PC_Mode2(QCR.PCM[1:0]= 0b10), or PC_Mode3(QCR.PCM[1:0]= 0b11).
 - This bit is set to "1" when the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) and the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR) regardless of the setting of the register function selection bit(QCR.RSEL).

[bit12] QPCNRCMIE : PC Match and RC Match Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the PC match and RC match interrupt request flag(QPCNRCMF) is set to "1".

When this bit is set to "1", an interrupt is generated if the value of the position counter matches that of the QPRC Position Counter Compare Register(QPCCR) and the value of the revolution counter matches that of the QPRC Position and Revolution Counter Compare Register(QPRCR)(QPCNRCMF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

[bit11] DIROU : Last Position Counter Flow Direction Bit

This bit indicates the direction of the position counter when the last position counter overflow or underflow was detected.

Bit	Description
0	The position counter was incremented.
1	The position counter was decremented.

[bit10] DIRPC : Last Position Counter Direction Bit

This bit indicates the count direction when the position counter was last changed.

Bit	Description
0	The position counter was incremented.
1	The position counter was decremented.

Note:

- As the direction of the position counter is not detected in PC_Mode0(QCR.PCM[1:0]= 0b00), the last position counter direction bit(QICR.DIRPC) becomes indefinite. Therefore, if the mode is changed from PC_Mode0(QCR.PCM[1:0]= 0b00) to another mode, when a ZIN active edge is detected before an AIN/BIN active edge is detected, the following operations apply.
 - The position counter is reset if the mode is RC_Mode0(QCR.RCM[1:0]= 0b00), RC_Mode1(QCR.RCM[1:0]= 0b01), or RC_Mode3(QCR.RCM[1:0]= 0b11)
 - The revolution counter is not counted up or down

[bit9] CDCF : Count Inversion Interrupt Request Flag Bit

This bit indicates whether or not the position counter inverted the count direction.

This bit is set to "1" when the position counter inverts the count direction. Inverting the count direction means that the counter counts down at the next counting after counting up, or the counter counts up at the next counting after counting down.

This flag can be only cleared to "0" in write mode. Setting "1" has no effect.

"1" is read by the read-modify-write access operation.

Bit	Description	
	Read	Write
0	Does not invert the count direction of the position counter.	Clears this bit.
1	Inverts the count direction of the position counter at least once.	No effect.

Note:

- As the direction of the position counter is not detected in PC_Mode0(QCR.PCM[1:0]= 0b00), the last position counter direction bit(QICR.DIRPC) becomes indefinite. Therefore, after the mode is changed from PC_Mode0(QCR.PCM[1:0]= 0b00) to another mode, even if an AIN/BIN active edge is detected and the direction of the position counter is inverted, the count inversion interrupt request flag bit(QICR.CDCF) is not set to "1".

[bit8] CDCIE : Count Inversion Interrupt Enable Bit

This bit is used to control whether or not to issue an interrupt notification to the MCU when the count inversion interrupt request flag(CDCF) is set to "1".

When this bit is set to "1", an interrupt is generated if the count direction of the position counter is inverted(CDCF= 1).

Bit	Description
0	Interrupt disabled
1	Interrupt enabled

4.9. QPRC Maximum Position Register(QMPR)

The QPRC Maximum Position Register(QMPR) is used to specify the maximum value of the position counter.

bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Field	QMPR[15:0]															
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-
Initial Value	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

[bit15:0] QMPR[15:0] :

When the set value of the QPRC Maximum Position Register(QMPR) matches the value of the position counter and the position counter is counted up, a position counter overflow is detected(QICR.OFDF= 1). The set value of the QPRC Maximum Position Register(QMPR) is reloaded to the position counter if a position counter underflow is detected(QICR.UFDF= 1).

Note:

- Do not access the QPRC Maximum Position Register(QMPR) with a byte access instruction.

CHAPTER 48: External Interrupt Capture

This chapter describes functions and operations of the EICU module.

1. Overview
2. Configuration
3. Explanation of Operation
4. Setting Procedure Examples
5. Registers

EICU-TXXPT03P01R01L06-E1-XX

1. Overview

This section describes the features and the block diagram of EICU module.

Features of External Interrupt Capture Unit (EICU)

The EICU module samples the interrupt pin level in isochronous steps after being triggered by an External Interrupt event on that pin. It can be used to record the bit stream that causes the External Interrupt event like CAN wakeup. Features of the EICU are:

- It supports the capture of events among 32 External Interrupt Pins (Pin INTk)
- The capture on any interrupt pin is maskable
- It has a 6-bit linearly programmable prescaler to provide a sample frequency range of 500 Hz to 16 MHz
- Software can read the sample registers and enable for the next observation
- Software can also read the channel number being observed
- It supports the Peripheral Protection Unit (PPU)

DMA and Interrupts

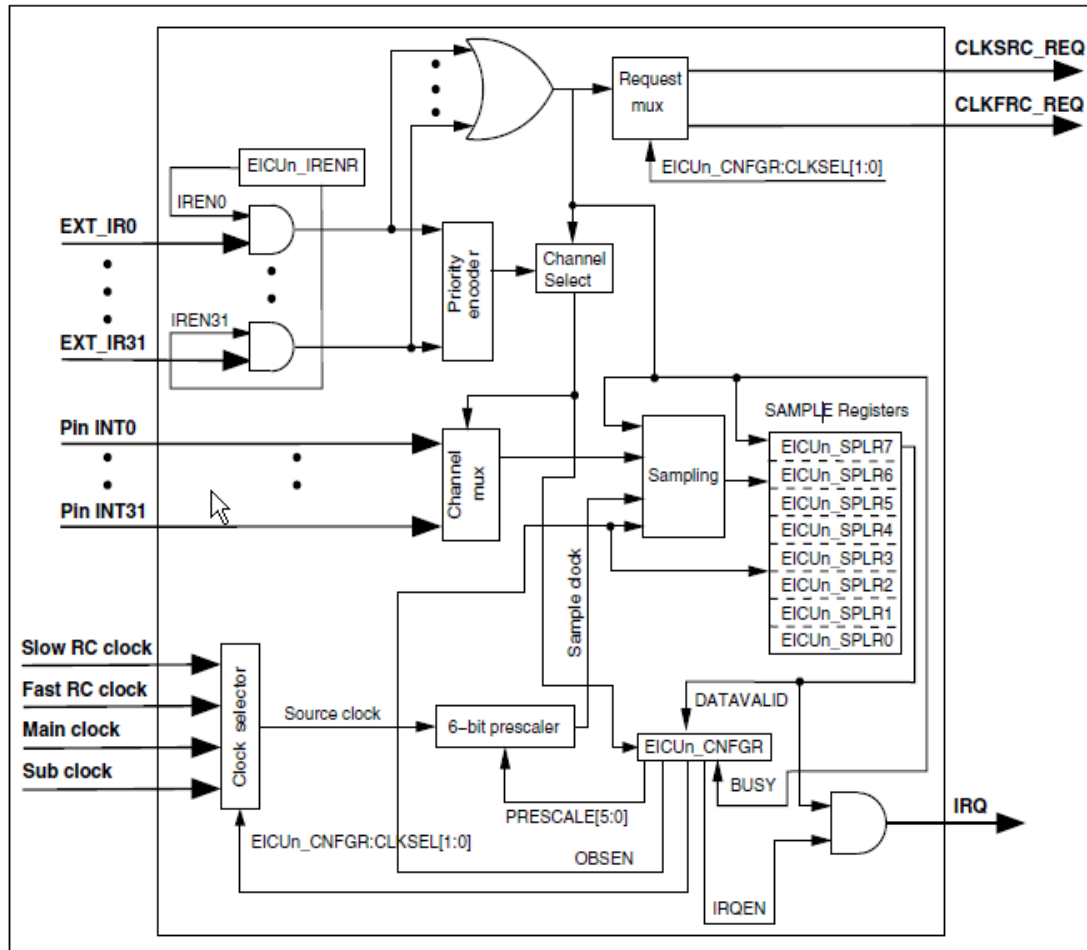

This module does not generate any DMA requests.

An interrupt is generated when valid data is available in the sample registers.

2. Configuration

Shown below is a block diagram of the EICU module.

Figure 2-1 Block Diagram

3. Explanation of Operation

This section describes operation of EICU.

The following section explains the top level block diagram of EICU and its operation. The block diagram of the EICU is shown in Figure 2-1.

Priority Encoder and Channel Select

EXT_IRk inputs come from the External Interrupts module and are the latch output of the first event in the corresponding Pin INTk. The channel select stores the channel (pin) number of the enabled channel (specified by EICUn_IRENr register) which had the first event. It is stored in EICUn_CNFR:OBSCH[4:0]. In the event of a simultaneous event, the channel number is stored based on priority. Channel 0 has the highest priority and channel 31 has the lowest.

Clock Request

With the first event on any of the enabled interrupt pins, Pin INTk (EXT_IRk = 1), a clock request is sent to the clock controller block only if EICUn_CNFR:CLKSEL[1:0] is programmed for Slow or Fast CR clock. If the EICUn_CNFR:CLKSEL[1:0] is programmed for Main or Sub clock, it is assumed that the clocks are already available.

Note:

- *During power saving modes (which disables the Main and/or Sub clock), only the CR clock shall be used with the EICU. Between the first event in any of the channels and the arrival of the selected clock (EICUn_CNFR:CLKSEL[1:0] = Slow CR clock/Fast CR clock), there can be a possible loss of levels on the interrupt pins (Pin INTk). The first activated interrupt pin (enabled pin) will be selected and sampled. For proper sampling, four times oversampling is suggested. This means, after recognizing an External Interrupt event, the fast CR clock must be started.*

Clock Settings

This block selects between the following four source clocks based on EICUn_CNFR:CLKSEL[1:0] programming:

- Slow CR clock
- Fast CR clock
- Main clock and
- Sub clock

Prescaler bits scale the selected source clock based on EICUn_CNFR:PRESCALE[5:0] programming and generate a sample clock.

Signal Sampling and Storing

This module captures 256 samples of the selected channel (Pin INTk) based on the channel select. The sampling is done with respect to the sample clock and the data is stored in eight 32-bit Sample Registers (SPLR). During the sampling period, the EICUn_CNFR:BUSY bit is set and it is reset with EICUn_CNFR:DATAVALID = 1. The EICUn_CNFR:DATAVALID bit is set when 256 samples are collected in the SPLR. When EICUn_CNFR:DATAVALID = 1, the interrupt (IRQ) is also sent to the host in case EICUn_CNFR:IRQEN is set.

Enabling/Disabling of the Capture Function

Using the EICUn_CNFR:OBSEN bit, the sampling function of the External Interrupt Pins can be enabled or disabled. If EICUn_CNFR:OBSEN = 1, sampling starts with an event on any one of the

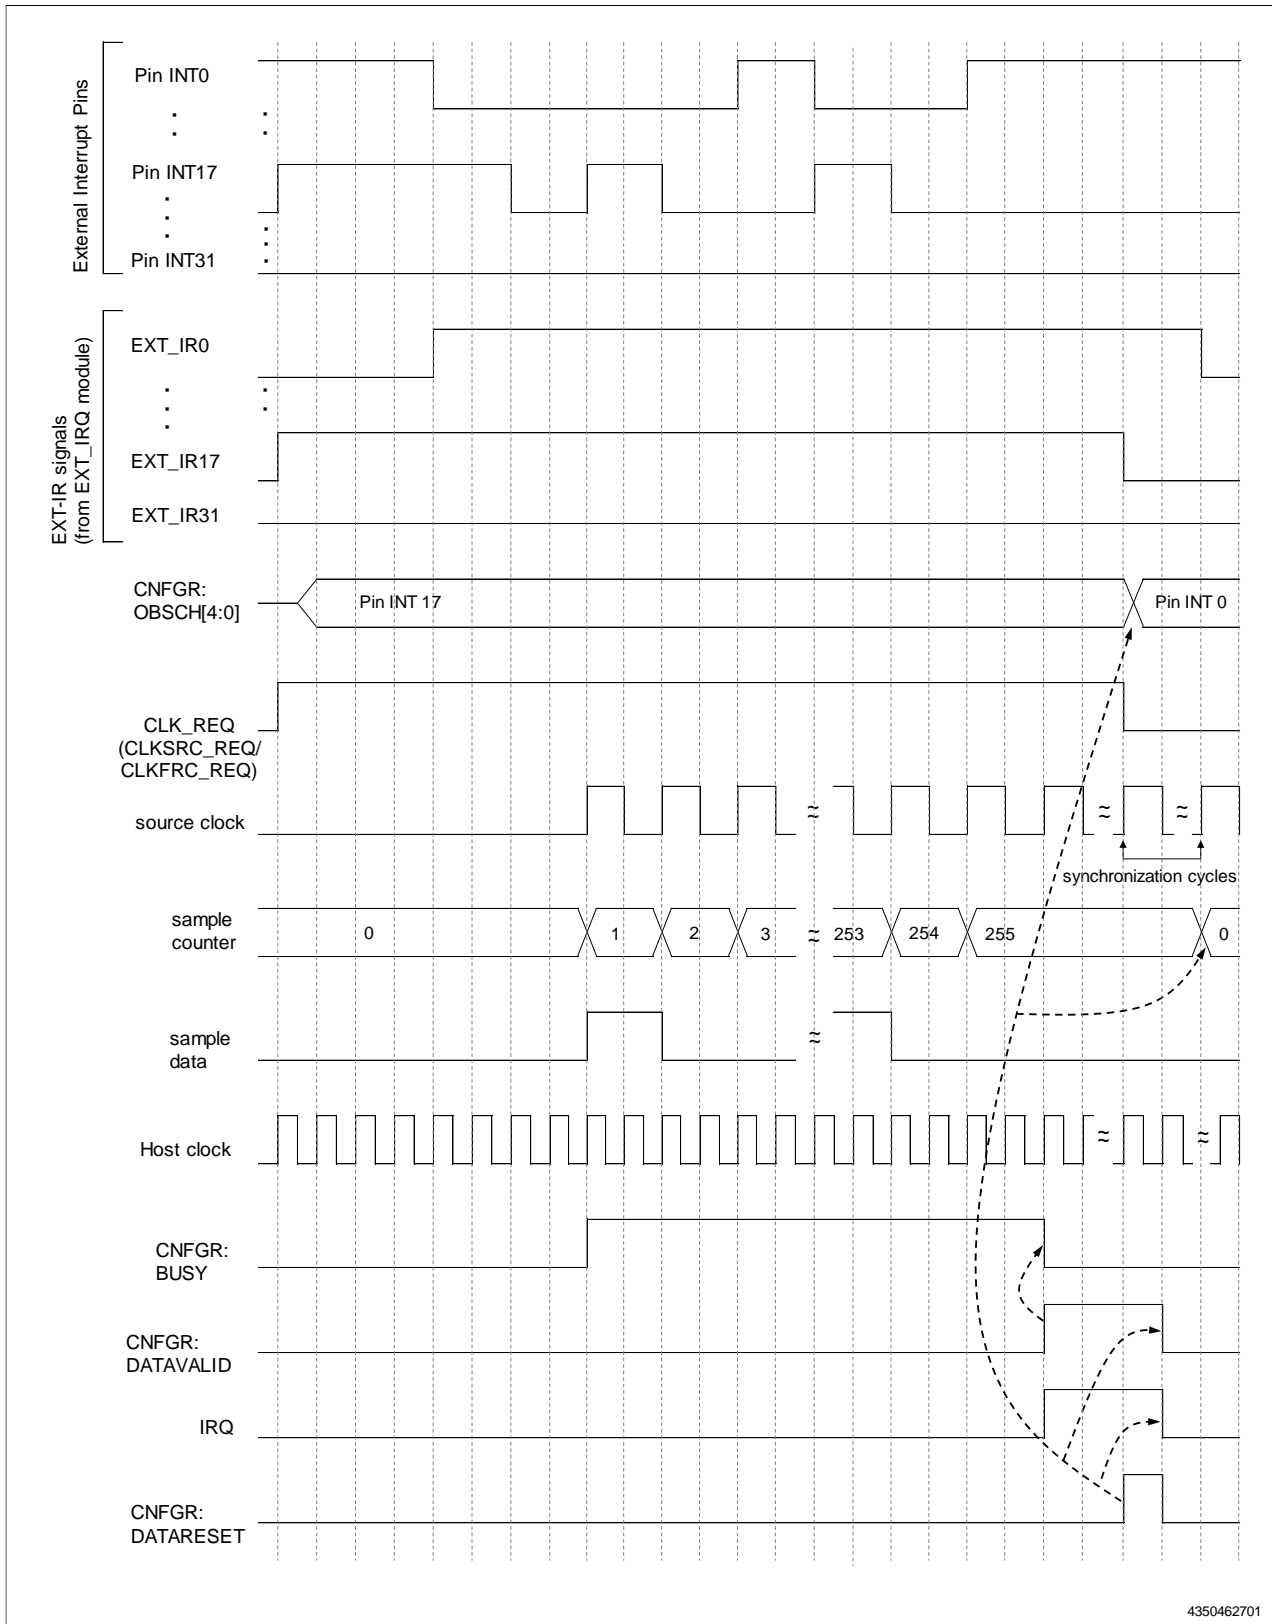

enabled External Interrupt channels. If EICUn_CNFR:OBSEN = 0, the SPLR are flushed, and the EICUn_CNFR:DATAVALID and EICUn_CNFR:BUSY bits are reset.

Example Operation of EICU

The timing diagram in Figure 3-1 typically shows the operation of the EICU. Here the assumption is that all the External Interrupt Pins are enabled for event monitoring and EICUn_CNFR:OBSEN is set for the entire period. Pin INT17 has the first event followed by Pin INT0. All other interrupt pins are inactive. With the event on Pin INT17, a clock request is generated (EICUn_CNFR:CLKSEL[1:0] = Slow CR/Fast CR clock) and channel select is updated to Pin INT17. Even in the event of another event on Pin INT0, channel select is not updated with Pin INT0. EICUn_CNFR:BUSY is set when sampling starts and is reset once EICUn_CNFR:DATAVALID is set. EICUn_CNFR:DATAVALID is set after 256 samples have been collected and stored in the Sample Registers. An interrupt is sent to the host once EICUn_CNFR:DATAVALID is set (assuming EICUn_CNFR:IRQEN = 1) and it is de-asserted with EICUn_CNFR:DATAVALID = 0. With EICUn_CNFR:DATARESET = 1, EICUn_CNFR:DATAVALID is de-asserted.

Note:

- External Interrupt generation and clear logic is independent of the EICU.

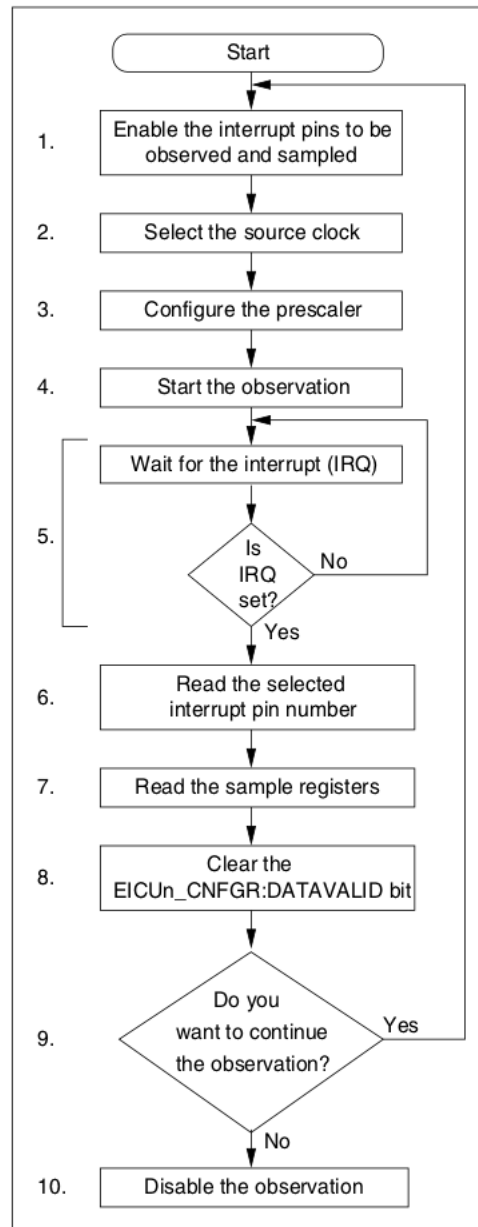

Figure 3-1 Timing Chart

4. Setting Procedure Examples

This section describes how to use the EICU.

Shown below are setting procedure examples of EICU:

Figure 4-1 Procedure Example Flow

General steps a programmer shall follow while using the EICU:

- After the system reset, set the corresponding bits in EICUn_IRENr register for the interrupt pins to be observed and sampled. By default all the interrupt pins are disabled for observation. To sample any interrupt pin, the corresponding enable for that interrupt should also be enabled in the External Interrupt block. Event detection (signal detection) on the interrupt pin depends on the External Interrupt block settings (falling/rising edge, high/low level). For more details, refer to External Interrupt chapter.
- Program the EICUn_CNFR:CLKSEL[1:0] bits to select the desired source clock from Slow CR clock, Fast CR clock, Main clock, and Sub clock. Note that at reset the Slow CR clock is selected, but by default Slow RC Osc is disabled. Also requirement of glitch free clock switching is that both (old and new) clock sources to be enabled at the time of EICUn_CNFR:CLKSEL[1:0] change. So, before switching from Slow RC Osc clock to Main clock, the user needs to ensure that both oscillators are enabled. Once switching is done, the old clock (Slow RC Osc) can be disabled. However, the Main Osc still needs to be enabled during Power Saving State (PSS) so that it can sample the data at wakeup.
- Set the EICUn_CNFR:PRESCALE[5:0] bits to select the appropriate scaling factor for the source clock.
 - Sampling frequency = $\text{source frequency} / (\text{EICUn_CNFR:PRESCALE}[5:0] + 1)$
 - Sampling frequency should be preferably four times faster than the fastest baud rate available amongst the enabled External Interrupt Pins. Source clock and prescaler values should be programmed accordingly.
- Set the EICUn_CNFR:OBSEN to start the observation.
- With the first event in any of the enabled interrupt pins ($\text{EXT_IRk} = 1$), the clock is requested (CLKSRC_REQ/CLKFRC_REQ), if the EICUn_CNFR:CLKSEL[1:0] is programmed for Slow CR clock or Fast CR clock. After the arrival of the source clock (refer to the datasheet for the time required for the Slow RC and Fast CR clock), the sampling frequency is calculated based on the prescaler setting. The External Interrupt Pin number with the first event is stored in EICUn_CNFR:OBSC[4:0] (channel select). The Pin INTk corresponding to the selected channel is sampled for 256 samples at the sampling frequency and the samples are stored in the SPLR. After capturing 256 samples, EICUn_CNFR:DATAVALID bit is set. Simultaneously the interrupt (IRQ) is also set if EICUn_CNFR:IRQEN = 1. The user should wait for EICUn_CNFR:DATAVALID = 1 to read the SPLR. The clock request is de-asserted after the EICUn_CNFR:DATAVALID bit is set.
- The selected channel number can be read from EICUn_CNFR:OBSC[4:0]. In the event of simultaneous events in more than one enabled External Interrupt Pin, priority is always given to the lower channel number. On other words Pin INT0 has the highest priority and Pin INT31 has the lowest priority.
- After the arrival of the interrupt, the user can read the data from the 32-bit EICUn_SPLR0 to 7 registers.

- The user should set EICUn_CNFR:DATARESET to clear EICUn_CNFR:DATAVALID and subsequently the interrupt (IRQ) after reading the EICUn_SPLR0 to 7 registers. To start a new observation, EICUn_CNFR:DATAVALID should be always cleared. EICUn_CNFR:DATAVALID is cleared only when the user sets the EICUn_CNFR:DATARESET bit or EICUn_CNFR:OBSN is cleared
- To continue the observation with the same set of enabled Pin INTk channels, the source clock and prescaler settings, go directly to step 5.
- If you want to change any programmed values or want to discontinue observation, disable the EICUn_CNFR:OBSN bit. The observation and sampling process is inactive when the EICUn_CNFR:OBSN bit is "0" or EICUn_CNFR:DATAVALID is "1"

Example Usage of EICU for CAN

In the event that wake-up via CAN is required and the wake-up message needs to be detected, the EICU can be used. Based on the assumption that the MCU is in low-power mode, the steps below are needed to configure the EICU for wake-up using CAN and must be carried out before the MCU goes to low-power mode:

- Enable the CAN Rx interrupt in the External Interrupt block for interrupt generation according to the CAN bus dominant bit setting.
- Enable observation of the interrupt pin (EICUn_IENR) connected to the CAN RX pin.
- Select the appropriate capture frequency depending on CAN bit rate.: For example, if CAN is working at 1 Mbps, the sampling frequency should be configured for 4 MHz.
- Enable observation by setting the EICUn_CNFR:OBSN bit.

Operation of the EICU

- The device enters low-power state.
- In the event that a wake-up message is received, the External Interrupt block will detect an event on the CAN RX interrupt pin.
- This triggers a wake up sequence of the MCU and EICU.
- After the CR clock is operable (refer to the datasheet for time required for Slow RC and Fast CR clock), capturing the CAN bit stream starts.
- The interrupt pin is sampled and the 256 samples are stored in the SPLR (EICUn_SPLR0 to 7).
- After the 256 samples have been collected, the EICUn_CNFR:DATAVALID bit will be set and an interrupt is generated if enabled.
- After the device and application has finished the wake-up procedure, the application can check the capture values and recalculate the received message.

5. Registers

A list of registers for EICU is shown:

The EICU module has various registers that enable the channels for observation, configure the prescaler and source clock, and store the sample data. It also has a status register to update the data validity status and the channel number under observation. All registers in the EICU module are explained in this section.

The suffix 'n' in the register name indicates that the register is in instance 'n' of the module.

The following registers are available for each instance of EICU:

- Configuration Register (EICUn_CNFRGR)
- External Interrupt Pin Enable Register (EICUn_IENR)
- Sample Registers 0 to 7 (EICUn_SPLR0 to 7)

Table 5-1 EXTERNAL INTERRUPT Capture Unit Registers

Abbreviated Register Name	Register Name	Reference
EICUn_CNFRGR	Configuration Register	5.1
EICUn_IENR	External Interrupt Pin Enable Register	5.2
EICUn_SPLR0 to 7	Sample Registers 0 to 7	5.3

Table 5-2 Register Map

Offset	Register Name/Initial Value
0x0000_0000	EICUn_CNFRGR 00000000_00000000_00000000_00000000
0x0000_0004	EICUn_IENR 00000000_00000000_00000000_00000000
0x0000_0008	EICUn_SPLR0 00000000_00000000_00000000_00000000
0x0000_000C	EICUn_SPLR1 00000000_00000000_00000000_00000000
0x0000_0010	EICUn_SPLR2 00000000_00000000_00000000_00000000
0x0000_0014	EICUn_SPLR3 00000000_00000000_00000000_00000000
0x0000_0018	EICUn_SPLR4 00000000_00000000_00000000_00000000
0x0000_001C	EICUn_SPLR5 00000000_00000000_00000000_00000000
0x0000_0020	EICUn_SPLR6 00000000_00000000_00000000_00000000
0x0000_0024	EICUn_SPLR7 00000000_00000000_00000000_00000000

5.1. Configuration Register (EICUn_CNFR)

This register is used to configure the module for its prescaler value and source clock. It also gives information concerning the sampling status, data validity in the Sampling Registers (SPLR) and the current interrupt pin being sampled. An interrupt (IRQ) can also be set along with the EICUn_CNFR: DATAVALID bit once 256 samples are stored in the SPLR registers. EICUn_CNFR: OBSCH[4:0] shows the current interrupt pin being sampled. Writing "1" to EICUn_CNFR: DATARESET clears the EICUn_CNFR: DATAVALID.

bit	31	30	29	28	27	26	25	24
Field	Reserved					IRQEN	OBSCH	DATARESET
R/W Attribute	R0, WX					R/W	R/W	R0, W
Protection Attribute	-							
Initial Value	00000					0	0	0

bit	23	22	21	20	19	18	17	16
Field	DATAVALID	BUSY	Reserved	OBSCH[4:0]				
R/W Attribute	R,WX	R,WX	R0,WX	R,WX				
Protection Attribute	-							
Initial Value	0	0	0	00000				

bit	15	14	13	12	11	10	9	8
Field	Reserved							
R/W Attribute	R0, WX							
Protection Attribute	-							
Initial Value	00000000							

bit	7	6	5	4	3	2	1	0
Field	PRESCALE[5:0]						CLKSEL[1:0]	
R/W Attribute	R/W						R/W	
Protection Attribute	-							
Initial Value	000000						00	

[bit31:27] Reserved: Reserved Bits

[bit26] IRQEN: Interrupt Enable

This bit enables the interrupt from the module.

The interrupt is set when both the EICUn_CNFR: DATAVALID and IRQEN bits are high.

"0": Interrupt is disabled

"1": Interrupt is enabled

[bit25] OBSEN: Observation Enable

This bit is used to enable the observation and sampling of the available 32 External Interrupt Pins. When the OBSEN bit is low, ongoing sampling is stopped immediately. With this bit going high, new sampling is started from 0 to 255.

"0": Observation and sampling is disabled

"1": Observation and sampling is enabled

[bit24] DATARESET: Data Reset

This bit is used to reset the EICUn_CNFG:DATAVALID bit.

"0": No effect

"1": EICUn_CNFG:DATAVALID bit is reset

Reading this bit always returns "0".

[bit23] DATAVALID: Data Valid

This bit is set when the data in the EICUn_SPLR is valid (256 samples are collected).

"0": Data is not valid

"1": Data is valid,

As long as DATAVALID is "1", sampling of External Interrupt Pin (Pin INTk) is disabled (no further sample request is processed).

[bit22] BUSY: Sampling Status

This bit shows the sampling status of EICUn_CNFG:OBSC (Pin INTk). It is reset with EICUn_CNFG:DATAVALID bit = 1 or EICUn_CNFG:OBSEN bit = 0.

"0": Sampling of the observed channel is not ongoing

"1": Sampling of observed channel is ongoing,

[bit21] Reserved: Reserved Bits**[bit20:16] OBSC: Observed Channel**

These bits specify the External Interrupt Pin (Pin INTk) number being observed and sampled (out of the 32 available interrupt pins). Observed channel should be read only when

EICUn_CNFG:DATAVALID bit is "1".

[bit15:8] Reserved: Reserved Bits**[bit7:2] PRESCALE: Prescale**

These bits decide the prescaler value for deriving sample clock from source clock. It can be programmed from 0 to 63. The sample clock calculation is shown in the Section ' Setting Procedure Examples '.

prescaler value = PRESCALE + 1

sample clock = source clock / (prescaler value)

[bit1:0] CLKSEL: Clock Select

These bits select the source clock for sampling.

"00": Slow RC oscillator clock

"01": Fast RC oscillator clock

"10": Main oscillator clock

"11": Sub oscillator clock

5.2. External Interrupt Pin Enable Register (EICUn_IRENr)

The External Interrupt Pin Enable Register bits enable/disable the respective External Interrupt pins (Pin INTk) to be observed. In the event of simultaneous events in more than one enabled interrupt pin, priority is always given to the lower pin number, i.e. Pin INT0 has the highest priority and Pin INT31 has the lowest priority. All 256 samples are taken from one single interrupt pin. By default all the interrupt pins are disabled for observation.

bit	31							0
Field	IREN[31:0]							
R/W Attribute	R/W							
Protection Attribute	-							
Initial Value	00000000_00000000_00000000_00000000							

[bit31:0] IREN: External Interrupt Pin Observe Enable

These bits enable/disable the observation of the corresponding External Interrupt Pin.

"0": Corresponding Pin INTk is disabled for observation and sampling

"1": Corresponding Pin INTk is enabled for observation and sampling

5.3. Sample Registers 0 to 7 (EICUn_SPLR0 to 7)

These registers contain the sampled data of the interrupt pin (Pin INTk) captured. There are eight such 32-bit registers, storing a total of 256 samples. These registers act as a 256 bit shift register and the data in these registers are valid only when EICUn_CNFR:DATAVALID bit is set (after collection of the 256 samples). Only EICUn_SPLR0 is described here. Other registers (i.e. EICUn_SPLR1, EICUn_SPLR2, EICUn_SPLR3, EICUn_SPLR4, EICUn_SPLR5, EICUn_SPLR6, and EICUn_SPLR7) have similar bit fields.

bit	31							0
Field	SPL[31:0]							
R/W Attribute	R,WX							
Protection Attribute	-							
Initial Value	00000000_00000000_00000000_00000000							

[bit31:0] SPL: Sample 0 Register

These bits store the level of the interrupt pin being sampled at isochronous steps.

Note:

- *Sample 0 to Sample 7 registers store 256 samples of the levels of the enabled interrupt channel in isochronous steps. The first sample will be stored in EICUn_SPLR0[0] and the last sample will be stored in EICUn_SPLR7[31].*

CHAPTER 49: CRC (Cyclic Redundancy Check)

This chapter explains the functions and operations of the CRC.

1. Overview
2. Configuration and Diagram
3. Operations
4. Registers

CRC-TXXPT03P01R01L05-E1-XX

1. Overview

The CRC (Cyclic Redundancy Check) is an error detection system. The CRC code is a remainder after an input data string is divided by the pre-defined generator polynomial, assuming the input data string is a high order polynomial. Ordinarily, a data string is suffixed by a CRC code when being sent, and the received data is divided by a generator polynomial as described above. If the received data is dividable, it is judged to be correct.

CRC Functions

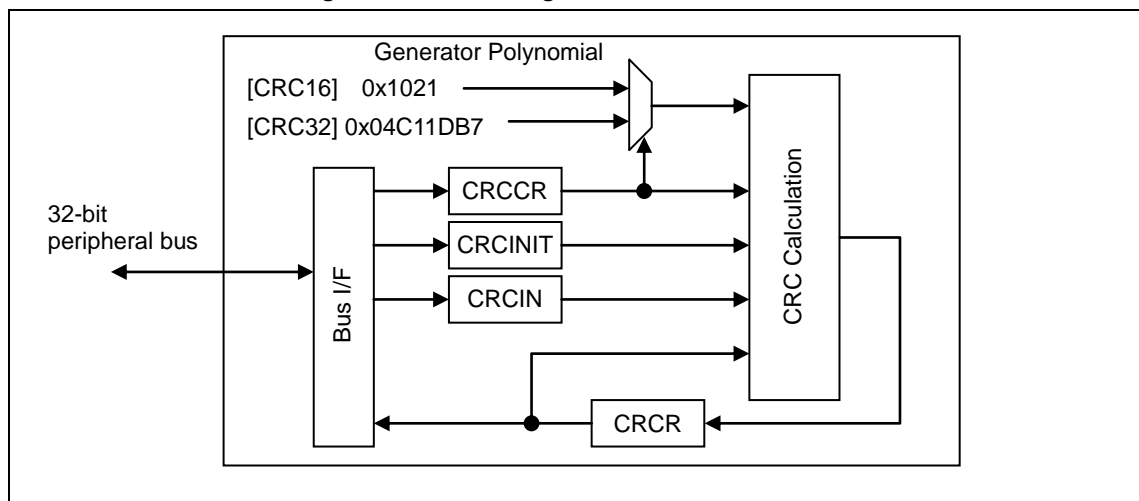

This module enables the calculation in both CCITT CRC16 and IEEE-802.3 CRC32. In this module, the generator polynomial is fixed to the numeric values for those two modes; therefore, the CRC value based on other generator polynomials cannot be calculated.

- CCITT CRC16 generator polynomial: 0x1021
- IEEE-802.3 CRC32 generator polynomial: 0x04C11DB7

2. Configuration and Diagram

Figure 2-1 shows the CRC configuration.

Figure 2-1 CRC Configuration

- CRCCR (CRC Control Register)
Used to control CRC calculation.
- CRCINIT (Initial Value Register)
Used to specify the initial values for CRC calculation.
- CRCIN (Input Data Register)
Used to set input data for CRC calculation.
- CRCR (CRC Register)
Used to output the CRC calculation result.
- CRC Calculation
A circuit to perform CRC calculation.

3. Operations

This section provides an overview of CRC operations.

CRC Definition

[CCITT CRC16 Standard]

Generator polynomial	0x1021	(CRCCR.CRC32= 0)
Initial value	0xFFFF	
Final XOR value	0x0000	(CRCCR.FXOR= 0)
Bit order	MSB First	(CRCCR.LSBFST= 0)
Output bit order	MSB First	(CRCCR.CRCLSF= 0)
(The input-output byte order can be specified arbitrarily.)		

[IEEE-802.3 CRC32 Ethernet Standard]

Generator polynomial	0x04C11DB7	(CRCCR.CRC32= 1)
Initial value	0xFFFFFFFF	
Final XOR value	0xFFFFFFFF	(CRCCR.FXOR= 1)
Bit order	LSB First	(CRCCR.LSBFST= 1)
Output bit order	LSB First	(CRCCR.CRCLSF= 1)
(The input-output byte order can be specified arbitrarily.)		

Reset Operations

When resetting, the Initial Value Register (CRCINIT) and CRC Register (CRCCR) are set to 0xFFFFFFFF. Other registers are cleared to "0".

Initialization

Initializing with the initialization bit (CRCCR.INIT) loads the value of the Initial Value Register to the CRC Register (CRCCR).

Processing Byte and Bit Orders

The following shows how to process byte and bit orders, using examples.

Input the following one word to the CRC computing unit.

133.82.171.1 = "10000101" "01010010" "10101011" "00000001"

If the byte order is set to big endian (CRCCR.LTLEND= 0), the sending sequence in bytes is configured as shown below.

"10000101"	"01010010"	"10101011"	"00000001"
(1st)	(2nd)	(3rd)	(4th)

If the bit order is set to LSB First (CRCCR.LSBFST= 1), the sending sequence in bits is configured as shown below.

"10100001"	"01001010"	"11010101"	"10000000"
(Head)			(End)

Note:

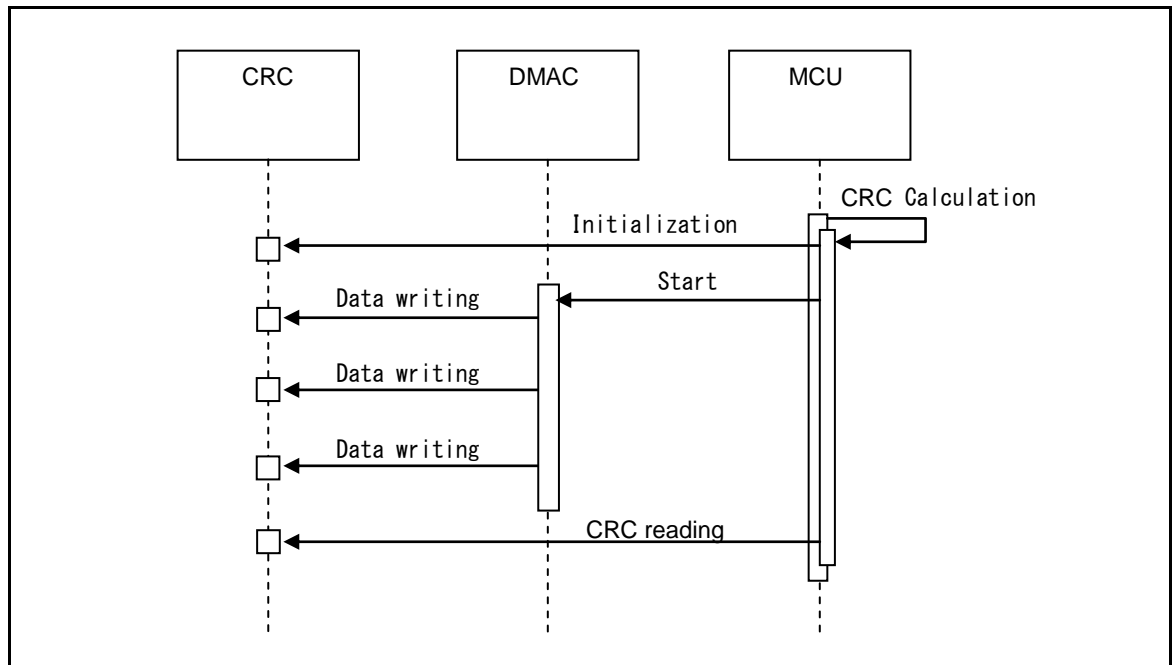

- At CRCCR.CRCLTE= 1, the CRC result is rearranged in bytes with the 32-bit width in both CRC16 and CRC32.
In particular, in CRC16 mode, note that data is output to the D[31:16] of CRC Register (CRCCR).

3.1. Calculation Sequence

Figure 3-1 shows the CRC calculation sequence. In this section, it is assumed that the Initial Value Register (CRCINIT) setting, CRC16 or CRC32 mode selection (CRCCR.CRC32), and byte- or bit- order setting (CRCCR.LTLEND, CRCCR.LSBFST) have already been configured.

If the initial value can be set to 0xFFFFFFFF, the Initial Value Register (CRCINIT) setting can be omitted.

Figure 3-1 CRC Calculation Sequence

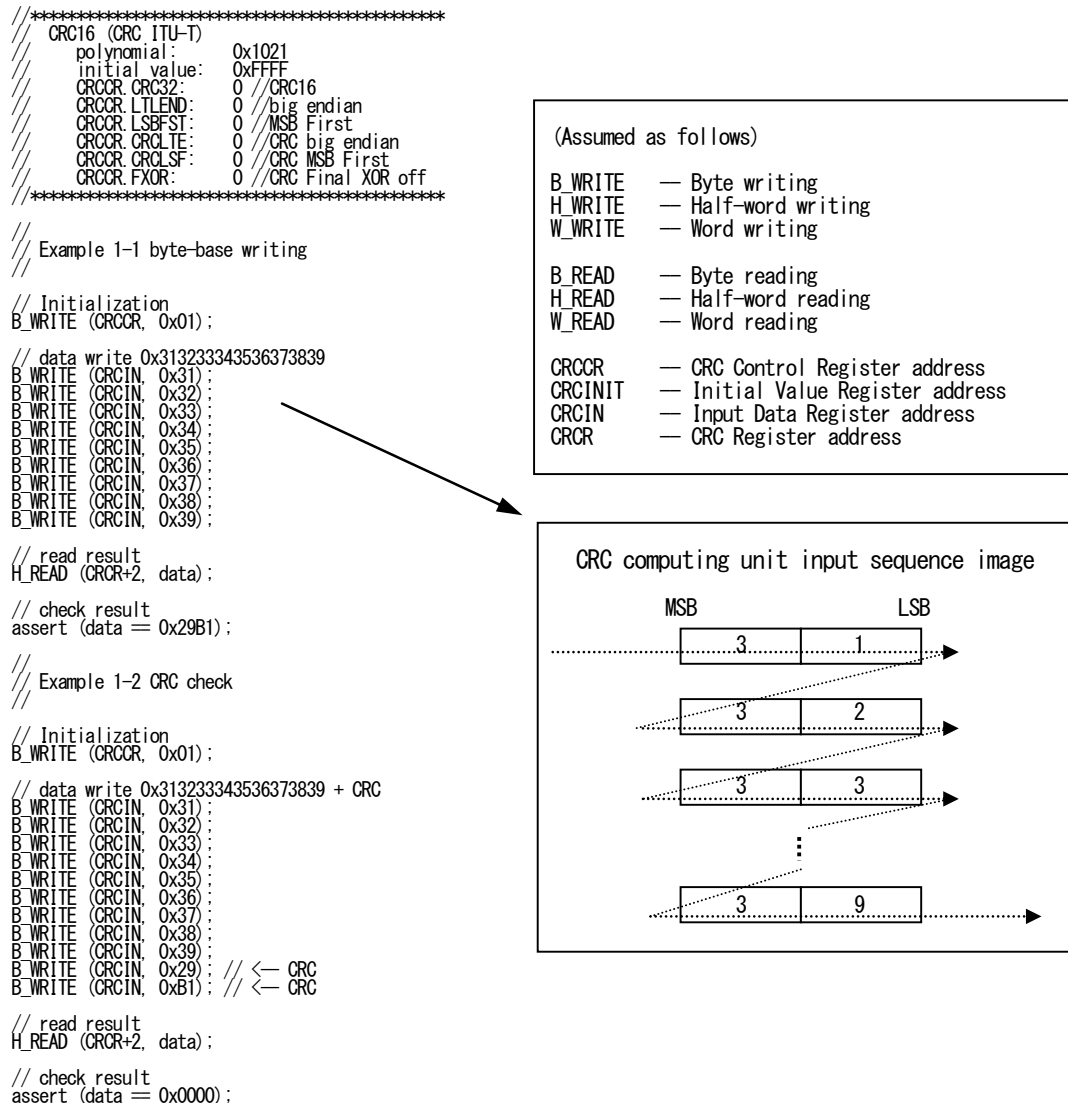

- To perform initialization, write "1" to the initialization bit (CRCCR.INIT). The value of the Initial Value Register (CRCINIT) is loaded to the CRC Register (CRCCR).
- To write input data, write to the Input Data Register (CRCIN). This then starts CRC calculation. If necessary, input data can be written continuously. Furthermore, different bit widths can be used in a sequence to write input data.
- To obtain a CRC code, read the CRC Register (CRCCR).

3.2. Use Examples

Figure 2-2 to Figure 2-5 show CRC use examples.

Use Example 1 CRC16, Byte Input Fixed

Figure 3-2 Use Example 1 (CRC16, Byte Input Fixed, Core Byte Order: Big Endian)

The byte and half-word writing positions are arbitrary. In this example, data is written continuously at position +0.

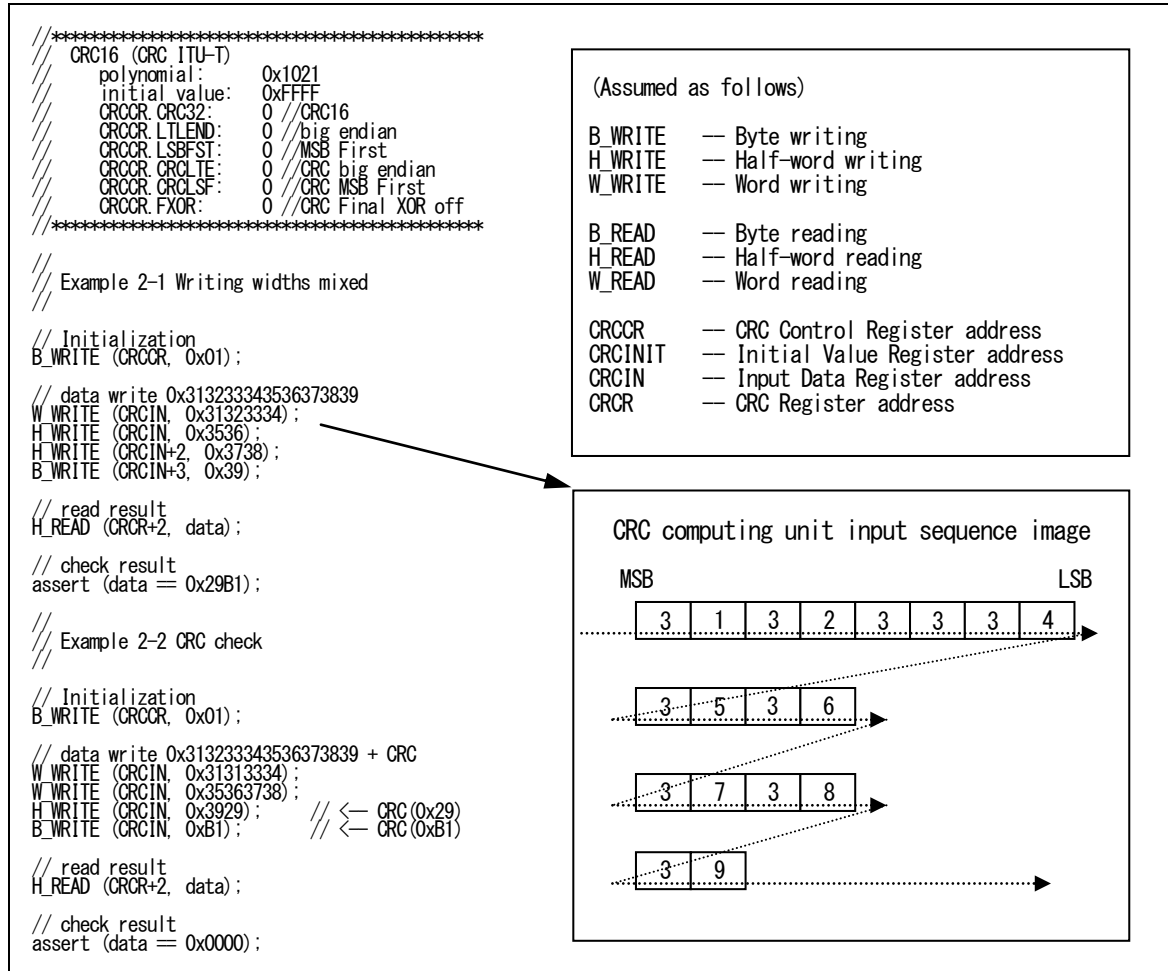

Table 3-1 shows the CRC result byte order, CRCCR (CRC Register) output position, and read address in CRC16 mode.

Table 3-1 CRC Result Byte Order, and CRCR Read Address

Core Byte Order	CRC Result Byte Order	Output Position to CRCR	CRCR H_READ Address
Big endian	Big endian	D[15:0]	CRCR +2
Big endian	Little endian	D[31:16]	CRCR +0
Little endian	Big endian	D[15:0]	CRCR +0
Little endian	Little endian	D[31:16]	CRCR +2

Use Example 2 CRC16, Different Input Bit Widths Mixed

Figure 3-3 Use Example 2 (CRC16, Different Input Bit Widths Mixed, Core Byte Order: Big Endian)

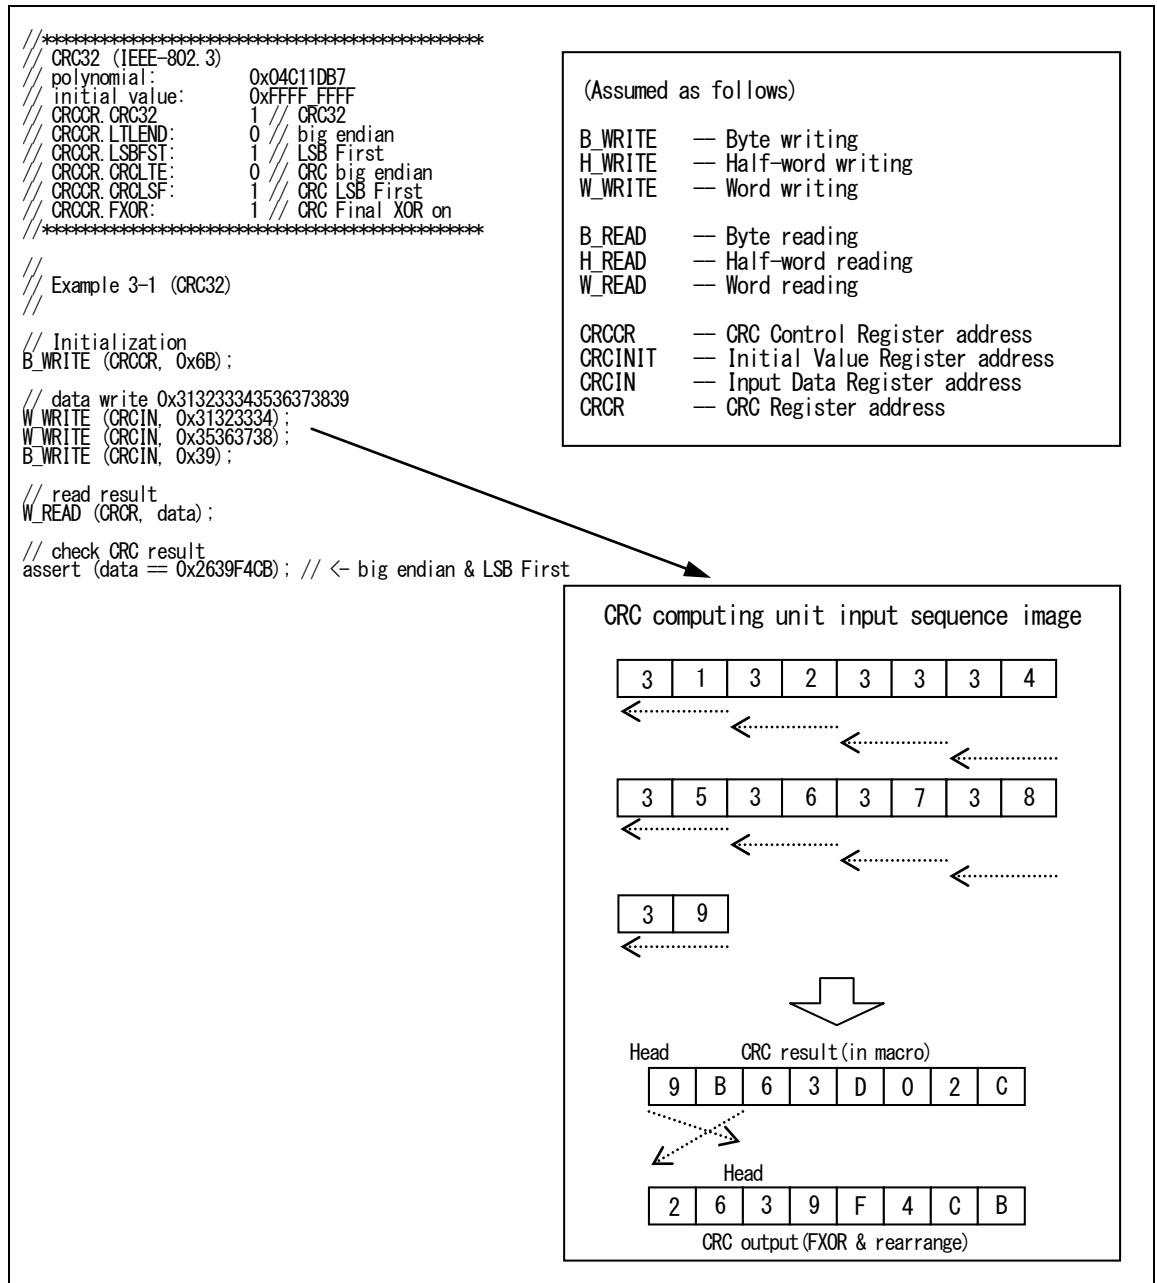

If the byte or bit order setting is correct and the bit input sequence to the CRC computing unit is the same, the writing width can be specified arbitrarily.

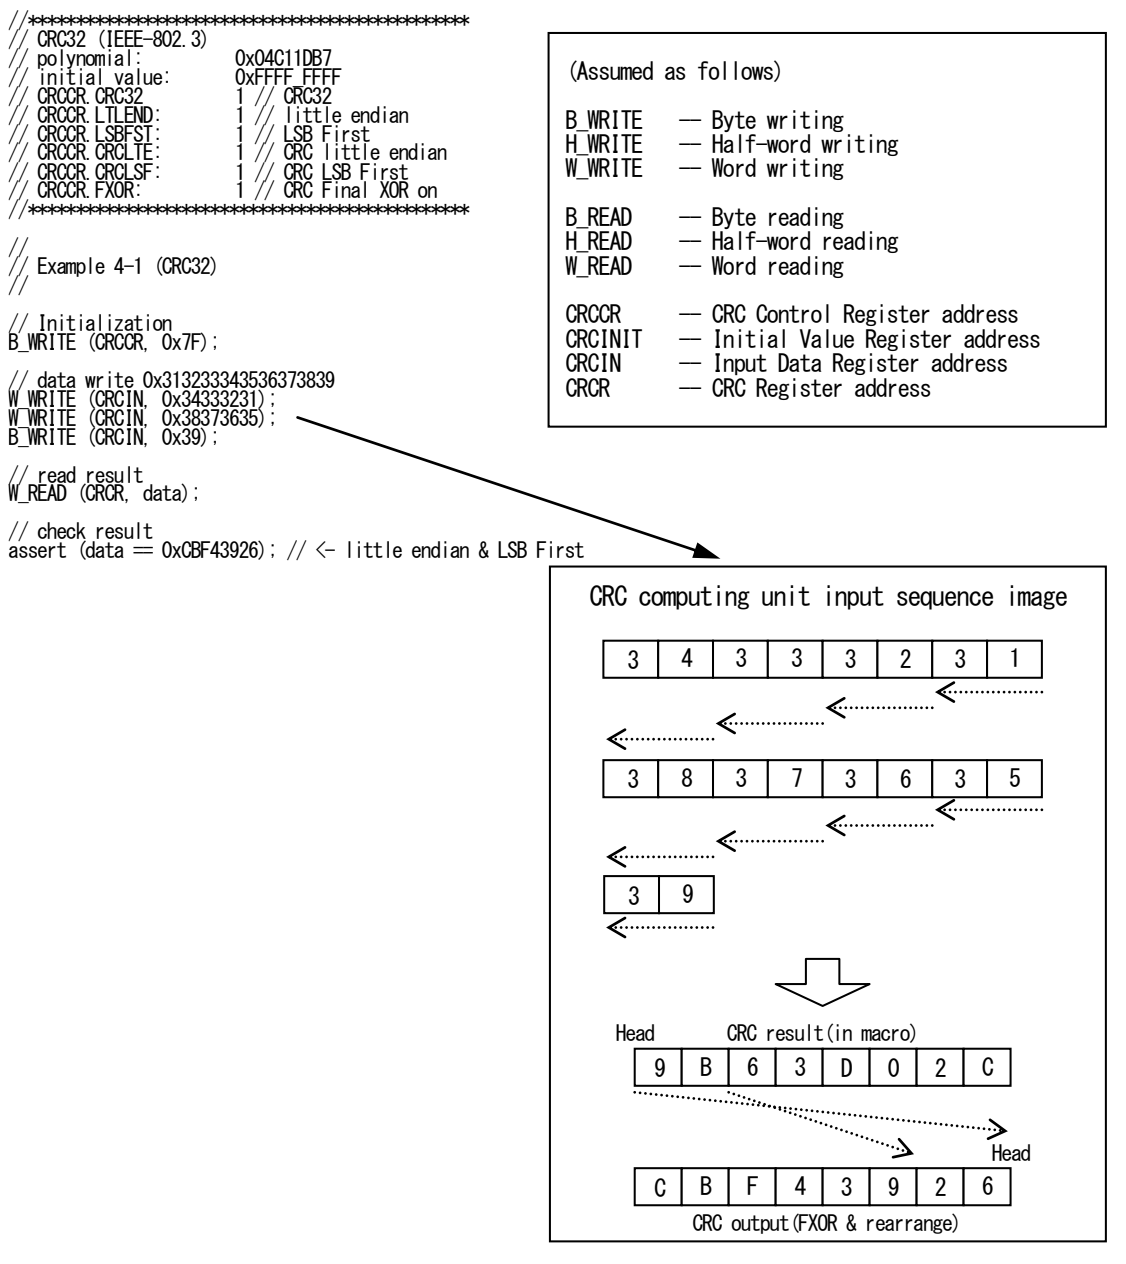

For example, if a 1-, 2-, or 3-byte fraction is obtained in the word-base writing mode, both byte and half-word writings may be enabled.

Use Example 3 CRC32, Byte Order: Big Endian

Figure 3-4 Use Example 3 (CRC32, Byte Order: Big Endian)

In CRC32 (IEEE-802.3) mode, the bit order is set to LSB First. This CRC computing unit supports both the big endian and little endian as the byte order. The figure above shows an example for big endian.

Use Example 4 CRC32, Byte Order: Little Endian**Figure 3-5 Use Example 4 (CRC32, Byte Order: Little Endian)**

In CRC32 (IEEE-802.3) mode, the bit order is set to LSB First. This CRC computing unit supports both the big endian and little endian as the byte order. The figure above shows an example for little endian.

If bit inversion is not required for the CRC result, perform either one of the following processes to release the bit inversion for the current result.

- Initialize with 0x3F before calculation.
- After data was input, set the CRCCR.FXOR bit to "0" (for example, CRCCR=0x3E).

4. Registers

This section provides a list of CRC registers.

The prefix "CRCxx_" is added to every register name (abbreviation).
xx is the channel number (00 to 03).

Table 4-1 List of CRC Register List

Abbreviation	Register Name	Reference
CRCCR	CRC Control Register	4.1
CRCINIT	Initial Value Register	4.2
CRCIN	Input Data Register	4.3
CRCR	CRC Register	4.4

Table 4-2 shows the register map.

Table 4-2 Register Map

Offset	Register Name			
	+3	+2	+1	+0
0x0000_0000	Reserved			CRCxx_CRCCR 00000000
0x0000_0004	CRCxx_CRCINIT 11111111_11111111_11111111_11111111			
0x0000_0008	CRCxx_CRCIN 00000000_00000000_00000000_00000000			
0x0000_000C	CRCxx_CRCR 11111111_11111111_11111111_11111111			

4.1. CRC Control Register (CRC00_CRCCR, CRC01_CRCCR, CRC02_CRCCR, CRC03_CRCCR)

The CRC Control Register (CRCCR) is used to control CRC calculation.

Bit	7	6	5	4	3	2	1	0
Field	Reserved	FXOR	CRCLSF	CRCLTE	LSBFST	LTLEND	CRC32	INIT
R/W Attribute	R0,W0	R/W	R/W	R/W	R/W	R/W	R/W	R0,W
Protection Attribute	-	-	-	-	-	-	-	-
Initial Value	0	0	0	0	0	0	0	0

[bit7] Reserved: Reserved Bit

This bit must always be written to "0".

The read value is "0".

[bit6] FXOR: Final XOR Control Bit

This bit is used to output the CRC result as the XOR value or XOR.

The XOR value is set to 0xFFFFFFFF. The CRC result value is inverted at FXOR="1".

This processing is performed in the latter part of the CRC Register (CRCCR) processing. The CRC result is therefore reflected on the read value immediately after this bit was set.

Bit	Description
0	None
1	Yes

[bit5] CRCLSF: CRC Result Bit-Order Setting Bit

This is a bit-order setting bit for CRC result.

This bit is used to rearrange bits within each byte. Set "0" to specify MSB First and set "1" to specify LSB First.

This processing is performed in the latter part of the CRC Register (CRCCR) processing. The CRC result is therefore reflected on the read value immediately after this bit was set.

Bit	Description
0	MSB First
1	LSB First

[bit4] CRCLTE: CRC Result Byte-Order Setting Bit

This is a byte-order setting bit for CRC result.

This bit is used to rearrange the byte order in each word. Set "0" to specify big endian and set "1" to specify little endian.

This processing is performed in the latter part of the CRC Register (CRCCR) processing. The CRC result is therefore reflected on the read value immediately after this bit was set.

If this bit is set to "1" in CRC16 mode, data is output to the D[31:16] of CRC Register (CRCCR).

Bit	Description
0	Big endian
1	Little endian

[bit3] LSBFST: Bit-Order Setting Bit

This is a bit-order setting bit

This bit is used to specify the head bit of a byte (8 bits). Set "0" to specify MSB First and set "1" to specify LSB First.

Four types of processing orders can be specified when this bit is combined with the LTLEND setting.

Bit	Description
0	MSB First
1	LSB First

[bit2] LTLEND: Byte-Order Setting Bit

This is a byte-order setting bit.

This bit is used to specify the byte order with the write width. Set "0" to specify big endian and set "1" to specify little endian.

Bit	Description
0	Big endian
1	Little endian

[bit1] CRC32: CRC Mode Selection Bit

This bit is used to select the CRC16 or CRC32 mode.

Bit	Description
0	CRC16
1	CRC32

[bit0] INIT: Initialization Bit

This is an initialization bit. Writing "1" initializes data. This bit does not have a value, and always returns "0" at reading.

At initialization, the value of the Initial Value Register (CRCINIT) is loaded to the CRC Register (CRCR). Initialization must be performed once at the start of CRC calculation.

Bit	Description	
	Write	Read
0	Invalid	Always reads "0".
1	Initialization	

4.2. Initial Value Register (CRC00_CRCINIT, CRC01_CRCINIT, CRC02_CRCINIT, CRC03_CRCINIT)

The initial value Register (CRCINIT) is used to save the initial values for CRC calculation.

Bit	31	0
Field	D	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	11111111_11111111_11111111_11111111	

[bit31:0] D[31:0]: Initial Value Bit

These bits are used to save the initial values for CRC calculation.

Write the initial values for CRC calculation to this register.

In CRC16 mode, D[15:0] are used while D[31:16] are ignored.

4.3. Input Data Register (CRC00_CRCIN, CRC01_CRCIN, CRC02_CRCIN, CRC03_CRCIN)

The Input Data Register (CRCIN) is used to set input data for CRC calculation.

Bit	31	0
Field	D	
R/W Attribute	R/W	
Protection Attribute	-	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] D[31:0]: Input Data bit

These bits are used to set input data for CRC calculation.

Write input data for CRC calculation to this register. There are three types of bit widths: 8, 16, and 32, which can be specified together.

The byte and half-word writing positions are arbitrary. The available address positions are as follows.

- Byte writing : +0, +1, +2, +3
- Half word writing: +0, +2

4.4. CRC Register (CRC00_CRCCR, CRC01_CRCCR, CRC02_CRCCR, CRC03_CRCCR)

The CRC Register (CRCCR) is used to output the CRC calculation result. This register must be initialized before start calculating.

Bit	31	0
Field	D	
R/W Attribute	R, WX	
Protection	-	
Attribute		
Initial Value	11111111_11111111_11111111_11111111	

[bit31:0] D[31:0]: CRC bit

These bits are used to read the CRC calculation result. If "1" is written to the initialization bit (CRCCR.INIT), the value of the Initial Value Register (CRCINIT) is loaded to this register.

If input data for CRC calculation is written to the Input Data Register (CRCIN), the CRC calculation result is set to this register after one peripheral clock cycle has elapsed. When all input data writing has been completed, this register holds the final CRC code.

In CRC16 mode, when the byte order is set to big endian (CRCCR.CRCLTE= 0), the result is output to D[15:0]. When the byte order is set to little endian (CRCCR.CRCLTE= 1), the result is output to D[31:16].

CHAPTER 50: I/O Port

This chapter describes I/O port.

1. Overview
2. Configuration and Block Diagrams
3. Setting Procedure Examples
4. Register List
5. Precautions for Using This Device

GPIO-TXXPT03P01R01L11-E1-XX

1. Overview

This section provides an overview of I/O port.

I/O port has a general-purpose I/O module. The external pins can be used as I/O ports. Assignment of an external pin and input to an internal resource can be set.

General-Purpose I/O Port Module (GPIO)

General-purpose I/O module enables using external pins as I/O ports. The general-purpose I/O module is composed of (product specification) GPIO ports. Each GPIO port has 32 channels, which correspond to external pins. For example, the external pin P216 corresponds to the channel 16 setting of the GPIO port 2.

Key code settings are required for writing to registers.

Port Configuration Module (PPC)

- The port configuration module sets I/O from/to an external pin. This setting can be set per external pin.
 - Output enable display
 - I/O status display
 - Pull-up/Pull-down setting
 - Input level setting
 - Output drive capacity setting
 - Input disable setting
- Output (GPIO, resource) function selection
- Key code settings are required for writing to registers.

Resource Input Configuration Module (RIC)

The resource input configuration module selects input from an external pin or output from another internal resource as resource input.

2. Configuration and Block Diagrams

This section describes the block diagram of I/O port.

Figure 2-1 and Figure 2-2 show the I/O port configuration diagrams.

Figure 2-1 Configuration Diagram of GPIO and PPC

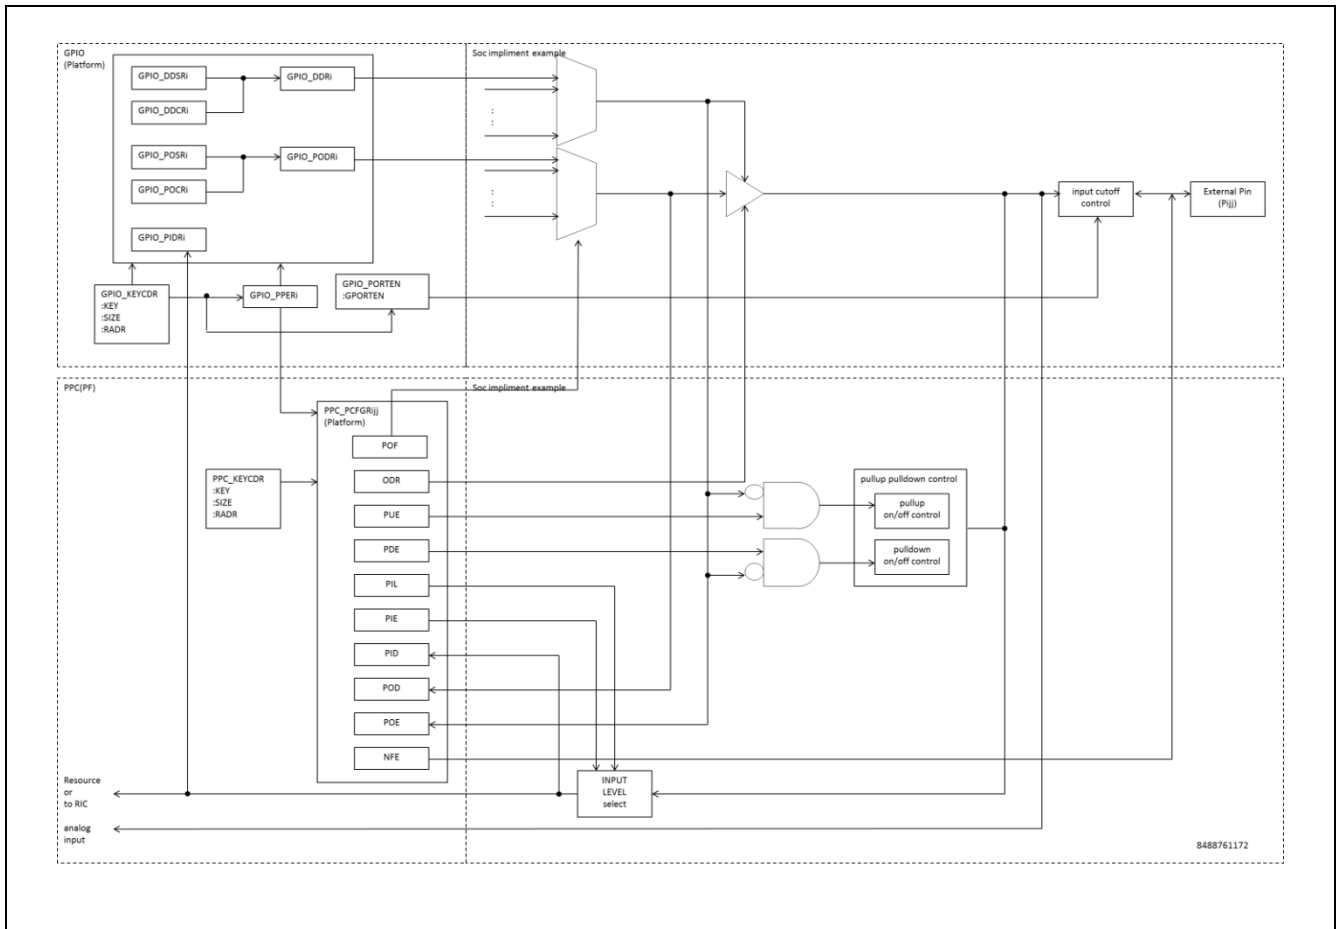

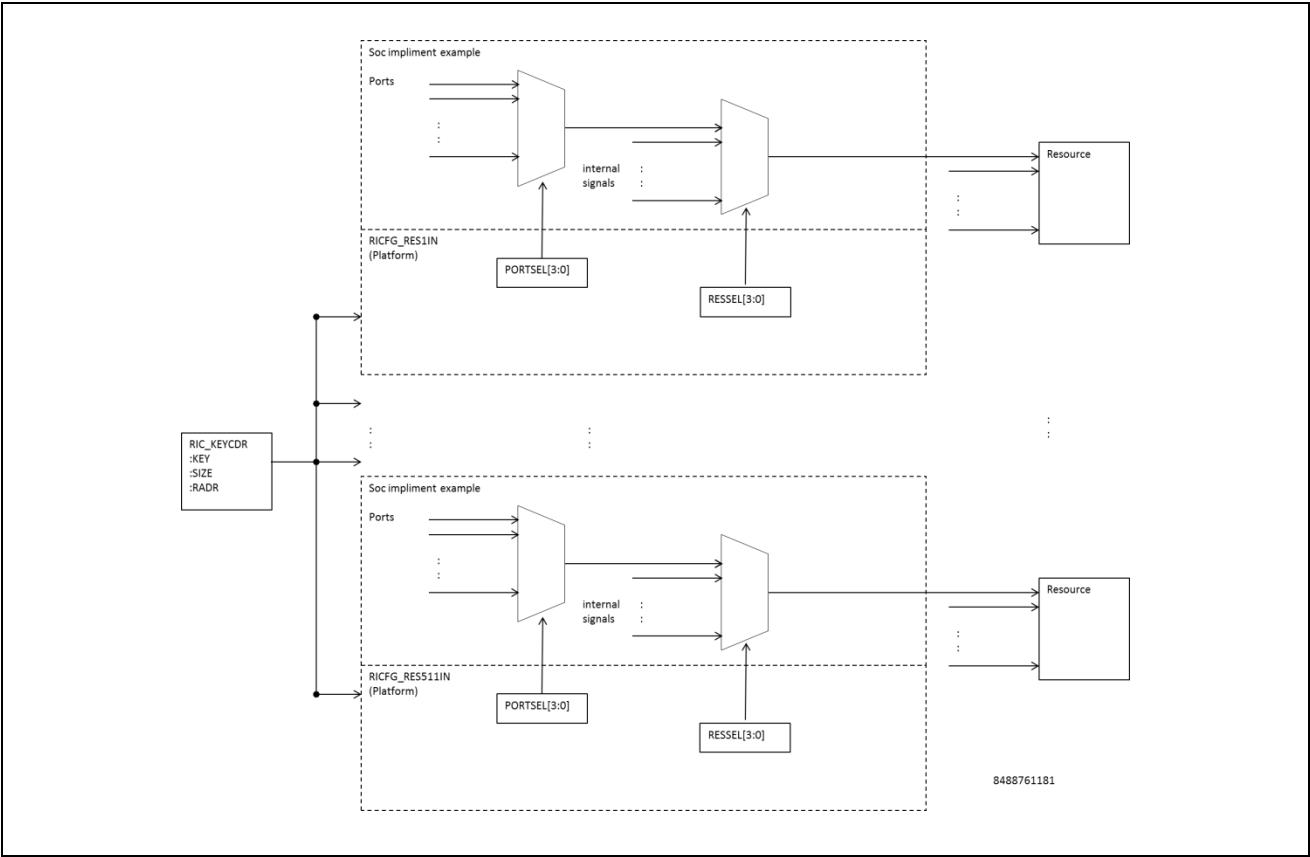

Figure 2-2 Configuration Diagram of RIC

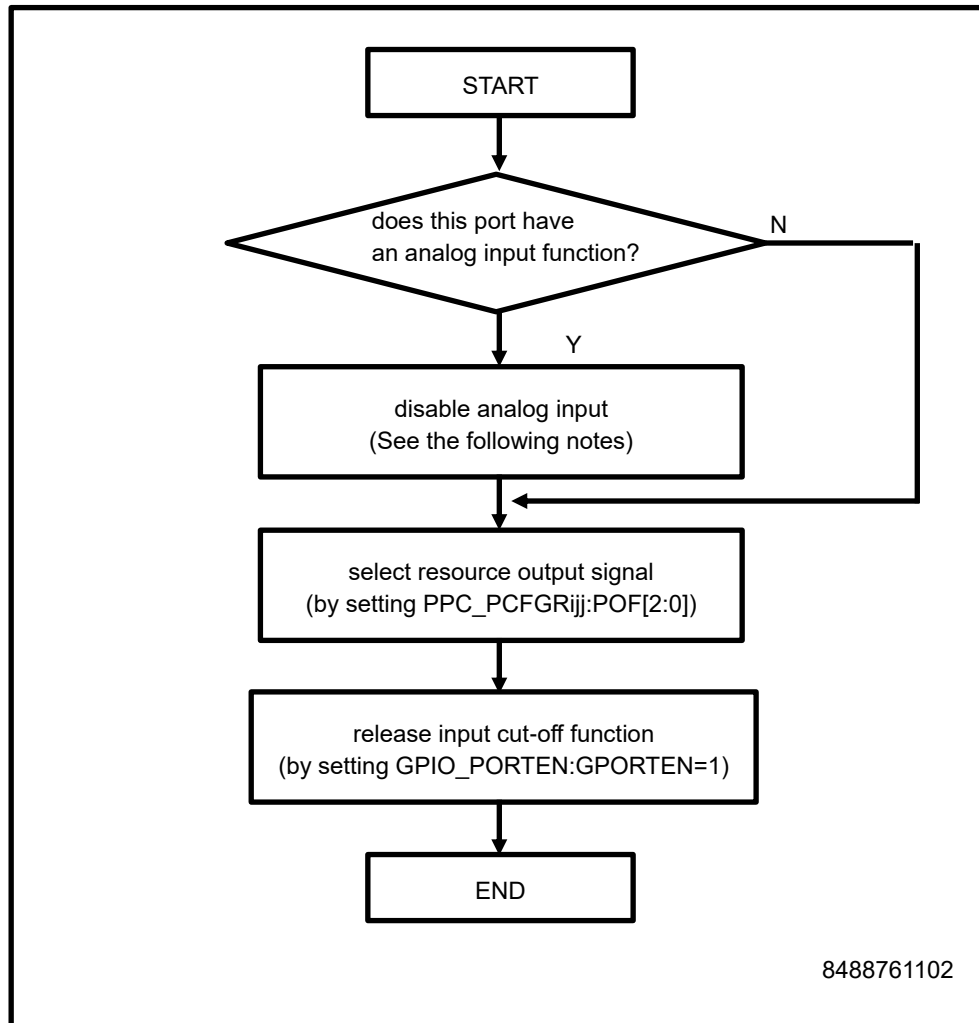

3. Setting Procedure Examples

This section describes the setting procedure examples of I/O port.

Assignment of resource I/O Pin (both Directions)

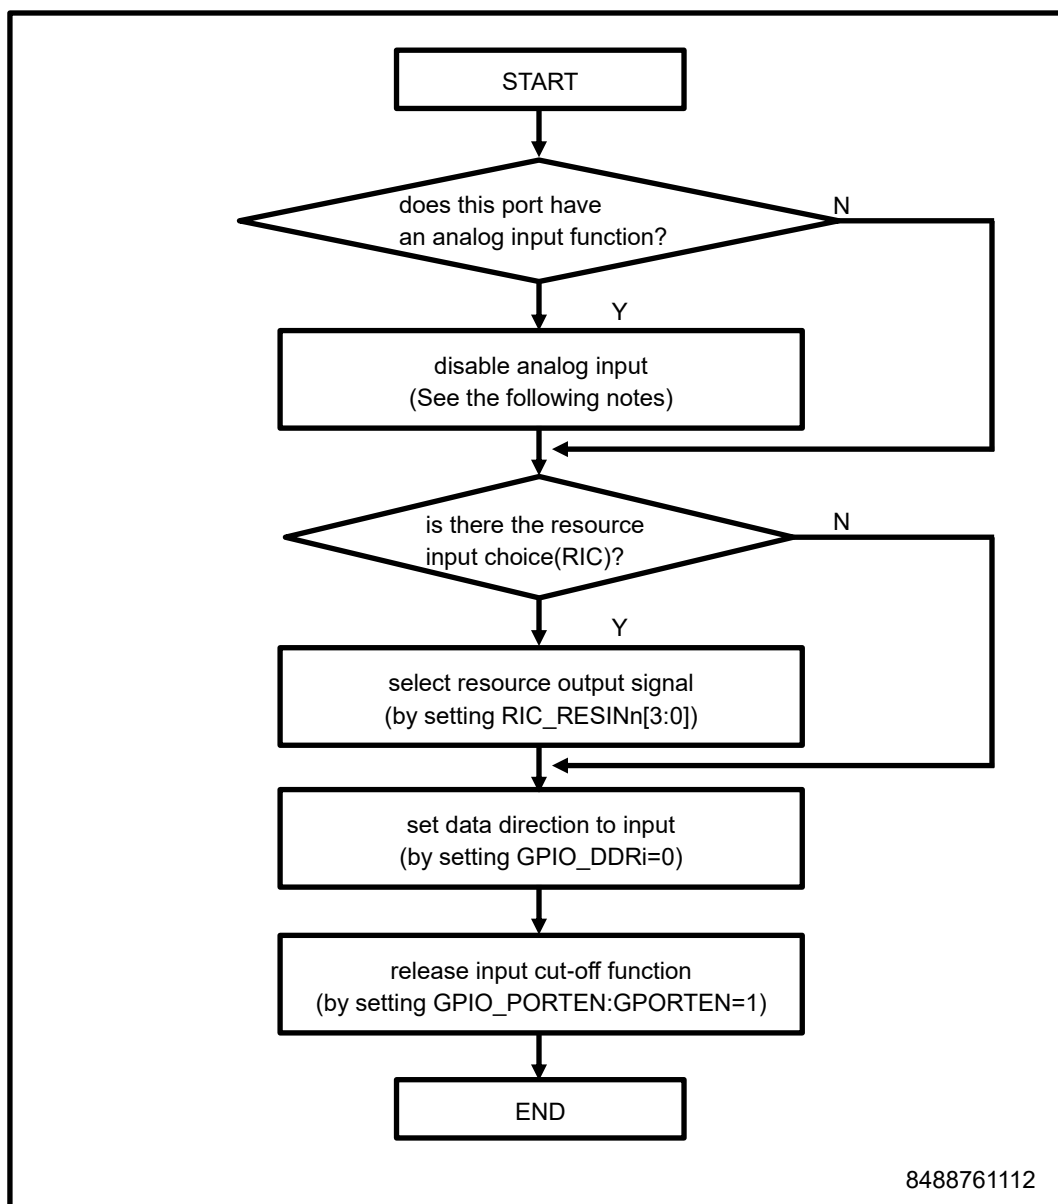

Figure 3-1 Setting Procedure

Note:

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Port enable register (GPIO_PORTEN)

Assignment of Resource Input Pin (Selecting the Resource Input of an External Pin)
Figure 3-2 Setting Procedure

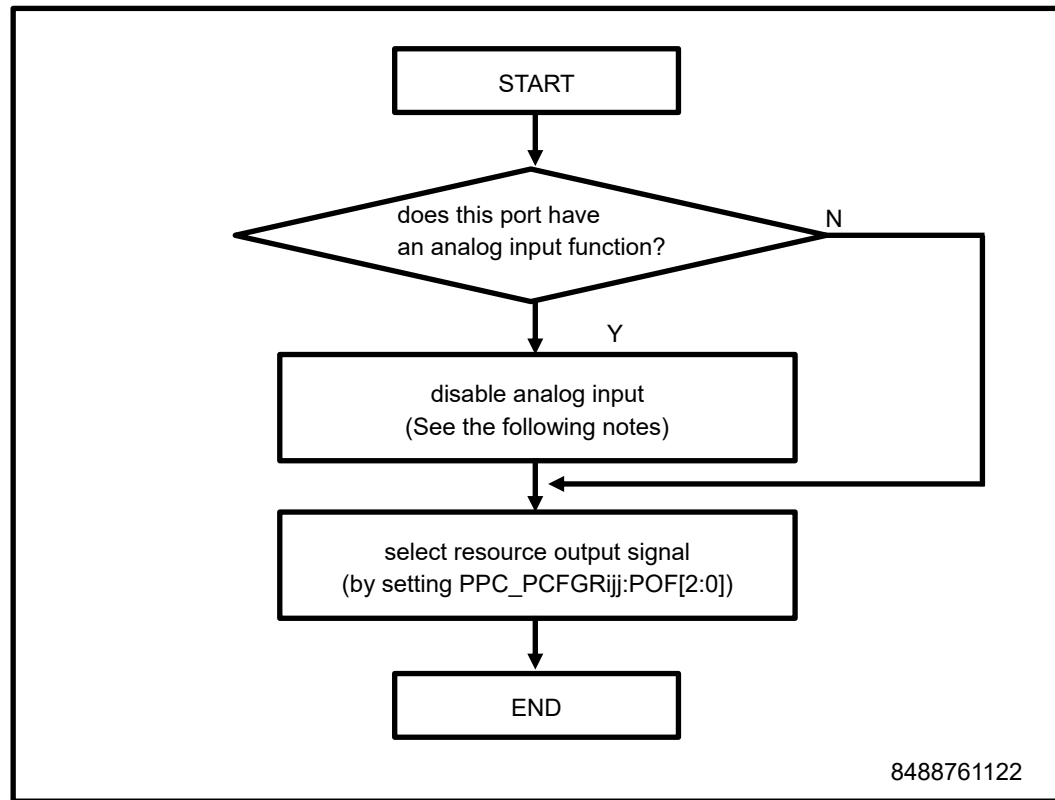

Note:

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Data direction register (GPIO_DDRI)
 - Port enable register (GPIO_PORTEN)

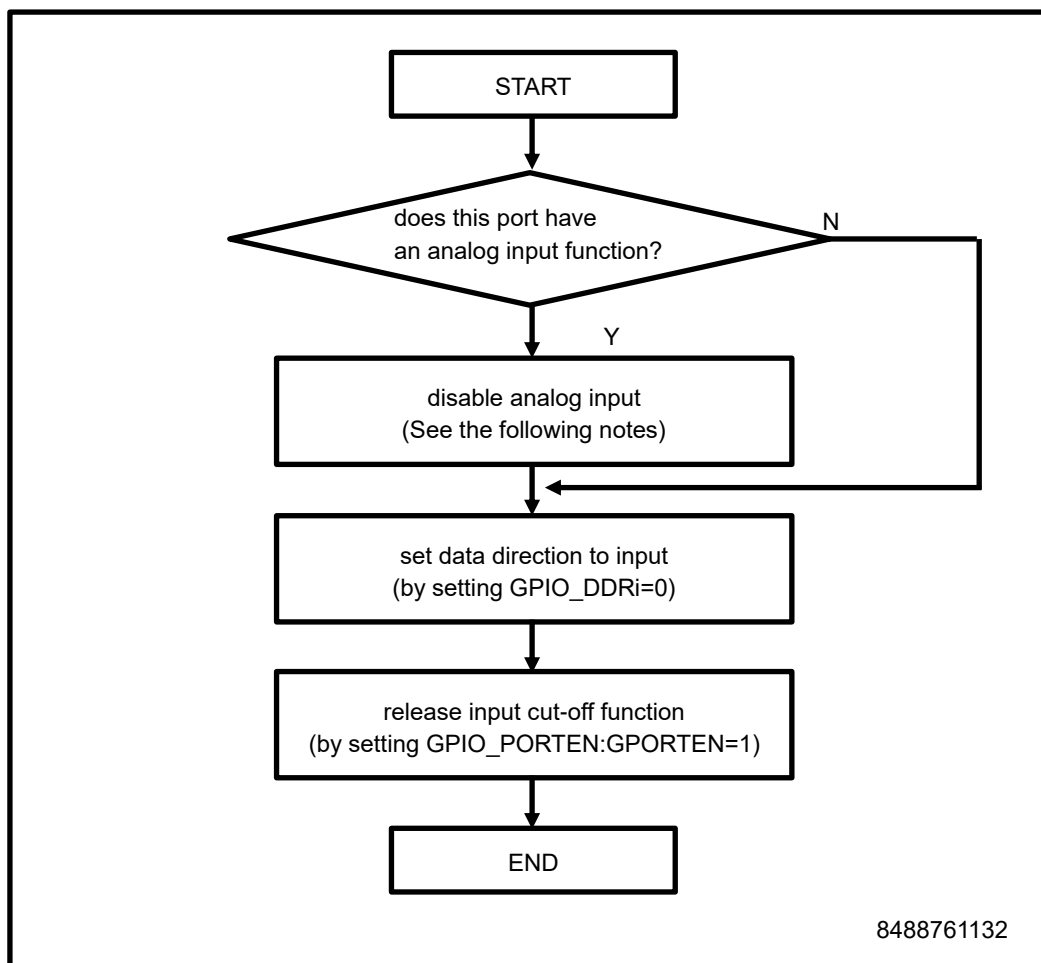

Assignment of Resource Output Pin

Figure 3-3 Setting Procedure

Note:

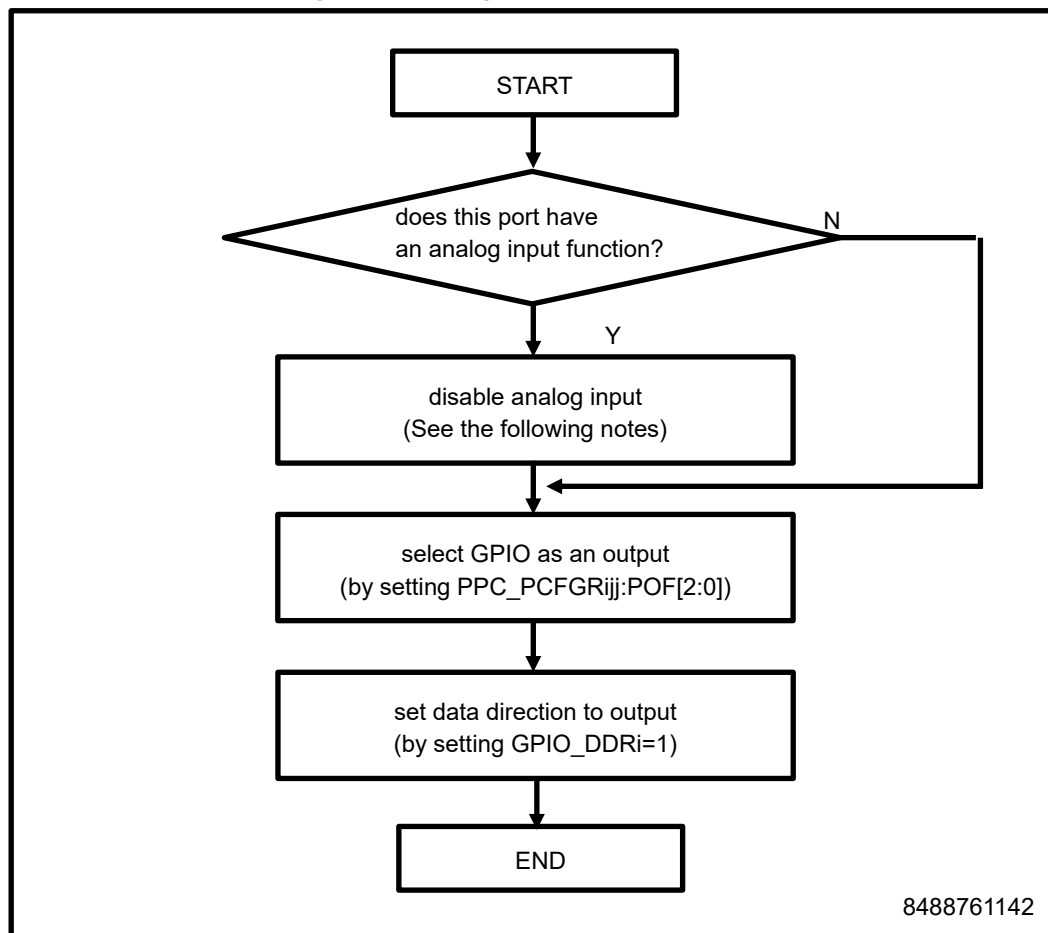

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Port setting register (PPC_PCFGRijj)

Assignment of Port Function (Input)**Figure 3-4 Setting Procedure****Note:**

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Data direction register (GPIO_DDRI)
 - Port enable register (GPIO_PORTEN)

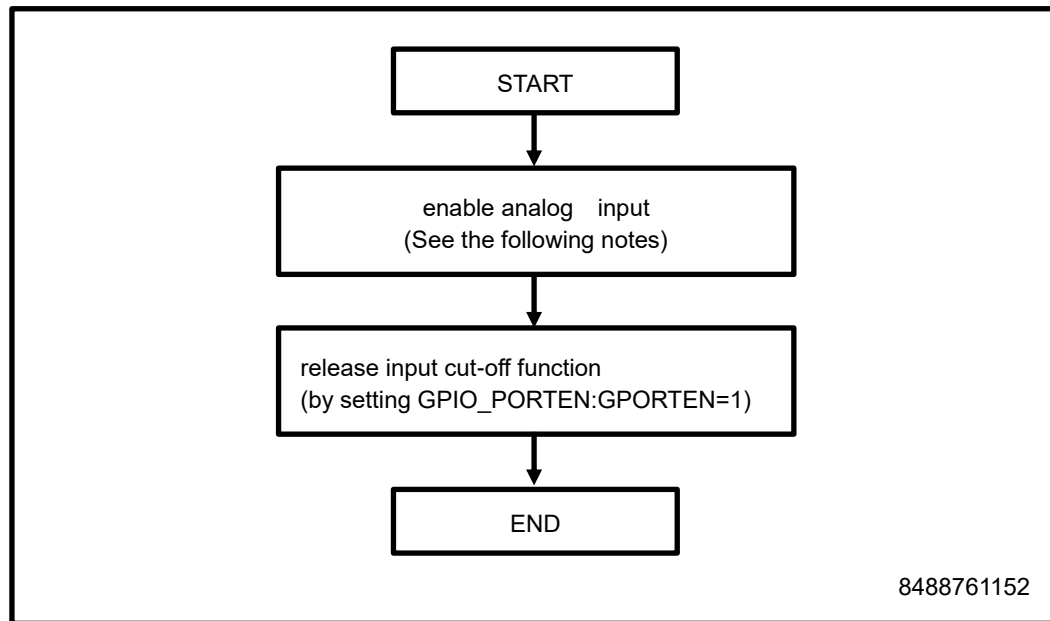

Assignment of Port Function (Output)

Figure 3-5 Setting Procedure

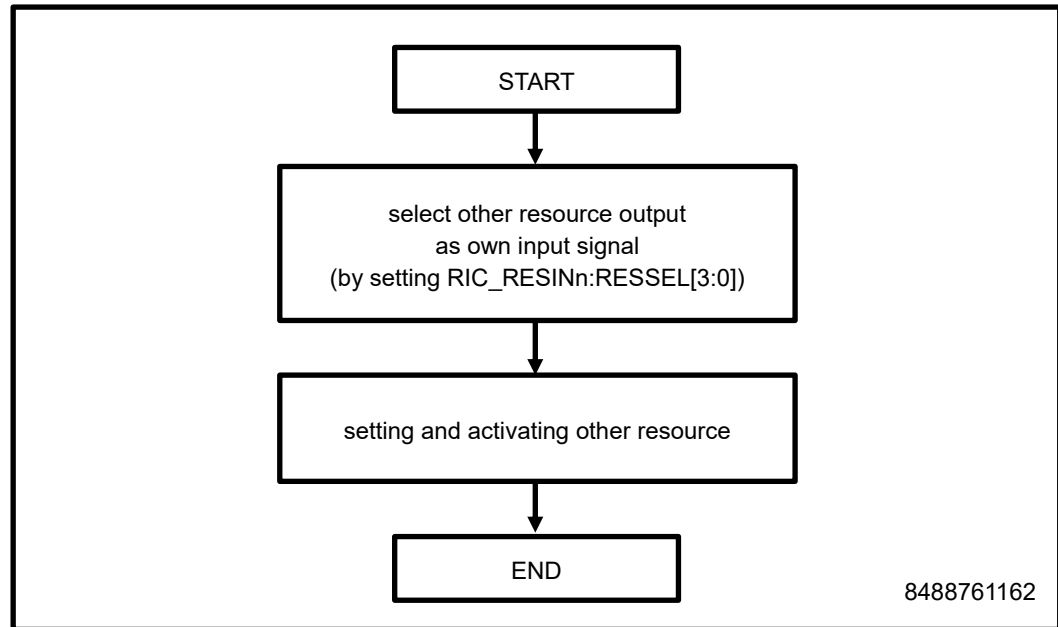

Note:

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Port setting register (PPC_PCFGRIj)

Assignment of AD Converter Input**Figure 3-6 Setting Procedure****Note:**

- The description of the analog input by A/D converter function should be referred in the product hardware manual.
- The following registers are the applicable key code registers.
 - Port enable register (GPIO_PORTEN)

Resource Input Selection (Selecting Other Resource Output)
Figure 3-7 Setting Procedure

Note:

- For details on resource input selection, see product specification.

4. Register List

This section describes the register list of the I/O port.

Table 4-1 I/O Port Register List

Abbreviated Register Name	Register Name	Reference
GPIO_DDRI	Data direction register	4.1
GPIO_DDSDRI	Data direction set register	4.2
GPIO_DDCRI	Data direction clear register	4.3
GPIO_PODRI	Port output data register	4.4
GPIO_POSRI	Port output set register	4.5
GPIO_POCRI	Port output clear register	4.6
GPIO_PORTEN	Port input enable register	4.7
GPIO_PIDRI	Port input data register	4.8
GPIO_KEYCDR	GPIO key code register	4.9
PPC_PCFGRijj	Port setting register	4.10
PPC_KEYCDR	PPC key code register	4.11
RIC_RESINn	Resource input setting register	4.12
RIC_KEYCDR	RIC key code register	4.13

i: GPIO port number (i = 0 to (product specification))

jj: GPIO channel number (jj = 00 to 31)

n: Number of selectable resource inputs (n = 0 to (product specification))

4.1. Data Direction Register (GPIO_DDRI) (i = 0 to (product specification))

This register sets the I/O direction of a pin. The direction is set when a GPIO is selected by the port output function selection bit (POF[2:0]) of the port setting register (PPC_PCFGRijj). This register can be directly written or can be set/cleared using the data direction set register (GPIO_DDSRi) and the data direction clear register (GPIO_DDCRi).

Bit	31	0
Field	DD	
R/W Attribute	R/W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] DD[n]: Data Direction Selection Bit (n = 0 to 31)

DD[n] n=0 to 31	Description
0	Set data direction to input.
1	Set data direction to output.

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response, and it can't write the data correctly.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.2. Data Direction Set Register (GPIO_DDSRi) (i = 0 to (product specification))

This register is used to set the data direction selection bit (GPIO_DDRi: DD31 to DD0).

Bit	31	0
Field	DDS	
R/W Attribute	R0,W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] DDS[n]: Data Direction Set Bit (n = 0 to 31)

DDS[n] n=0 to 31	Description
0	No effect
1	Set the data direction selection bit (GPIO_DDRi: DD31 to DD0) to "1".

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.3. Data Direction Clear Register (GPIO_DDCRi) (i = 0 to (product specification))

The data direction clear (DDC) register is used to clear the corresponding GPIO_DDRI bit.

Bit	31	0
Field	DDC	
R/W Attribute	R0,W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] DDC[n]: Data Direction Clear Register (DDC[n]) (n=0 to 31)

DDC[n] n=0 to 31	Description
0	No effect
1	Clear the data direction selection bit (GPIO_DDRI: DD31 to DD0) to "0".

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.4. Port Output Data Register (GPIO_PODR_i) (i = 0 to (product specification))

This register is used to set a port output value. The setting value is enabled when a port output is selected (GPIO_DDR_i: DD31 to DD0 = 1). This register can be directly written or can be set/cleared using the port output set register (GPIO_POSR_i) and the port output clear register (GPIO_POCR_i).

Bit	31	0
Field	POD	
R/W Attribute	R/W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] POD[n]: Port Output Data Bit (n = 0 to 31)

POD[n] n=0 to 31	Description
0	Output "L".
1	Output "H".

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.5. Port Output Set Register (GPIO_POSRi) (i = 0 to (product specification))

This register is used to set the port output data bit (GPIO_PODRi: POD31 to POD0).

Bit	31	0
Field	POS	
R/W Attribute	R0,W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] POS[n]: Port Output Set Bit (n = 0 to 31)

POS[n] n=0 to 31	Description
0	No effect
1	Set the port output data bit (GPIO_PODRi: POD31 to POD0) to "1".

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.6. Port Output Clear Register (GPIO_POCRI) (i = 0 to (product specification))

This register is used to clear the port output data bit (GPIO_PODRi: POD31 to POD0).

Bit	31	0
Field	POC	
R/W Attribute	R0,W	
Protection Attribute	WS	
Initial Value	00000000_00000000_00000000_00000000	

[bit31:0] POC[n]: Port Output Clear Bit (n = 0 to 31)

POC[n] n=0 to 31	Description
0	No effect
1	Clear the port output data bit (GPIO_PODRi: POD31 to POD0) to "0".

Notes:

- This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

This register sets the input rejection of a port.

- *This is the applicable key code register. To write to this register, the GPIO key code register (GPIO_KEYCDR) must be set.*
- *If this register is written before the key code is released, a bus error response is returned.*
- *After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.*
- *Please be sure to read and check a preset value after writing to a GPIO register.*

4.8. Port Input Data Register (GPIO_PIDR*i*) (*i* = 0 to (product specification))

This register indicates an input data value. This register indicates input data according to the setting of the input level selection bit (PPC_PCFGRIj*j*:PIL[1:0]) when the global input enable bit (GPIO_PORTEN:GPORTEN) is "1". An indefinite value is read from the port input data register when the global input enable bit (GPIO_PORTEN:GPORTEN) is "0".

Bit	31	0
Field	PID	
R/W Attribute	R,WX	
Protection Attribute	-	
Initial Value	XXXXXXXX_XXXXXXXX_XXXXXXXX_XXXXXXXX	

[bit31:0] PID[n]: Port Input Data Register (*n* = 0 to 31)

PID[n] <i>n</i> =0 to 31	Description
0	"L" is input.
1	"H" is input.

Note:

- This register is not initialized by Hard Reset (i.e. "X")

4.9. GPIO Key Code Register (GPIO_KEYCDR)

This register sets register writing with a function for protection against erroneous writing. If writing to this register is not done using the prescribed method, writing to the relevant register is invalid. A lock target register can write only once in after unlocking. When writing continuously, please unlock once again.

Bit	31	30	29	28	27	26	25	24
Field	KEY		SIZE		Reserved			
R/W Attribute	R0,W		R0,W		R0,WX			
Protection Attribute	-							
Initial Value	00		00		0000			

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,WX							
Protection Attribute	-							
Initial Value	00000000							

Bit	15	14	13	12	11	10	9	8
Field	Reserved	RADR[14:8]						
R/W Attribute	R0,WX	R0,W						
Protection Attribute	-							
Initial Value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	RADR[7:0]							
R/W Attribute	R0,W							
Protection Attribute	-							
Initial Value	00000000							

[bit31:30] KEY: Key Code Bits

These are key code setting bits. Write 0b00, 0b01, 0b10, and 0b11 continuously to these bits in this order. The key code setting becomes invalid immediately upon any writing to these bits in a different order. In such cases, set the key code again from the beginning.

Bits		Description
0	0	1st key code
0	1	2nd key code
1	0	3rd key code
1	1	4th key code

[bit29:28] SIZE: Access Size Bits

These bits set the access size for writing to the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

Bits		Description
0	0	Set byte access.
0	1	Set half-word access.
1	0	Set word access.
1	1	Reserved

[bit27:15] Reserved: Reserved Bits**[bit14:0] RADR: Port Address Bits**

These bits set the lower 15 bits of the address of the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

RADR	Description
-	Set the lower 15 bits of the address of the applicable key code register.

Notes:

- The key code setting becomes invalid upon any writing to the KEY[1:0] in any order than 0b00, 0b01, 0b10, and 0b11. In such case, set the key code again from the beginning.
- When different data is written to the SIZE[1:0] or the RADR[14:0] while writing the key code 0b00, 0b01, 0b10, and 0b11, the key code setting will become invalid. In such case, set it again from the beginning.
- The applicable key code registers are the following registers.
 - Data direction register (GPIO_DDRI)
 - Data direction set register (GPIO_DDRI)
 - Data direction clear register (GPIO_DDCRI)
 - Port Output Data Register (GPIO_PODRI)
 - Port Output Set Register (GPIO_POSRI)
 - Port Output Clear Register (GPIO_POCRI)
 - Port input enable register (GPIO_PORTEN)
- This register is valid only for word access.
- There is no effect on the key code protection release process even if registers other than this register and the applicable key code register that is in the release processing (the register set by the RADR) are accessed while writing the key code 0b00, 0b01, 0b10, and 0b11.

4.10. Port Setting Register (PPC_PCFGRIjj) (i = 0 to (product specification), jj = 00 to 31)

This register sets and displays I/O from/to an external pin.

Bit	15	14	13	12	11	10	9	8
Field	POE	POD	PID	PIE	PIL		PUE	PDE
R/W Attribute	R,WX	R,WX	R,WX	R/W	R/W		R/W	R/W
Protection Attribute	WS							
Initial Value	0	0	X	0	00		0	0

Bit	7	6	5	4	3	2	1	0
Field	ODR		NFE	Reserved		POF		
R/W Attribute	R/W		R/W	R0,WX		R/W		
Protection Attribute	WS							
Initial Value	00		0	00		000		

[bit15] POE: Port Output Enable Bit

This bit indicates whether pin output is enabled.

Bit	Description
0	Pin output is high-impedance.
1	Pin output is enabled.

[bit14] POD: Port Output Data Bit

This bit indicates the value outputted to a pin.

Bit	Description
0	Output "L".
1	Output "H".

[bit13] PID: Port Input Data Bit

This bit indicates the value inputted to the pin selected by the input level bit (PIL[1:0]).

This bit is indefinite when the global input enable bit (GPORTEN) is "0".

Bit	Description
0	The pin input is "L".
1	The pin input is "H".

[bit12] PIE: Port Input Enable Bit

This bit selects a pin input.

Bit	Description
0	Pin input is disabled or analog input.
1	Pin input is enabled.

[bit11:10] PIL: Input Level Bit

This bit selects a pin input level.

Bits		Description
0	0	Type A
0	1	Type B
1	0	Type C
1	1	Type D

For details, see product specification.

[bit9] PUE: Pull Up Enable Bit

This bit set to enable pull-up resistor, when the port is configured as input.

Bit	Description
0	No pull up.
1	Pull up.

[bit8] PDE: Pull Down Enable Bit

This bit set to enable pull-down resistor, when the port is configured as input.

Pull up (PUE) has priority over pull down, if pull down and pull up (PUE) are competing.

Bit	Description
0	No pull down.
1	Pull down.

[bit7:6] ODR: Port Output Drive Selection Bit

This bit selects an output drive capacity of a port.

Bits		Description
0	0	Type A
0	1	Type B
1	0	Type C
1	1	Type D

For details, see product specification.

[bit5] NFE: Port Noise Filter Enable/Disable Select Bit

This bit selects whether to enable or disable the noise filter for the port.

Bit	Description
0	Disable the noise filter.
1	Enable the noise filter.

[bit4:3] Reserved: Reserved Bits

[bit2:0] POF: Port Output Function Selection Bit

This bit selects a function to output to a port.

Bits			Description
0	0	0	Resource A output
0	0	1	Resource B output
0	1	0	Resource C output
0	1	1	Resource D output
1	0	0	Resource E output
1	0	1	Resource F output
1	1	0	Resource G output
1	1	1	Resource H output

For details, see product specification.

Notes:

- This is the applicable key code register. To write to this register, the PPC key code register (PPC_KEYCDR) must be set.
- If this register is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.
- This register is not initialized by Hard Reset (i.e. “X”).

4.11. PPC Key Code Register (PPC_KEYCDR)

This register sets register writing with a function for protection against erroneous writing. If writing to this register is not done using the prescribed method, writing to the relevant register is invalid.

Bit	31	30	29	28	27	26	25	24
Field	KEY		SIZE		Reserved			
R/W Attribute	R0,W		R0,W		R0,WX			
Protection Attribute	-							
Initial Value	00		00		0000			

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,WX							
Protection Attribute	-							
Initial Value	00000000							

Bit	15	14	13	12	11	10	9	8
Field	Reserved	RADR[14:8]						
R/W Attribute	R0,WX	R0,W						
Protection Attribute	-							
Initial Value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	RADR[7:0]							
R/W Attribute	R0,W							
Protection Attribute	-							
Initial Value	00000000							

[bit31:30] KEY: Key Code Bits

These are key code setting bits. Write 0b00, 0b01, 0b10, and 0b11 continuously to these bits in this order. The key code setting becomes invalid immediately upon any writing to these bits in a different order. In such cases, set the key code again from the beginning.

Bits		Description
0	0	1st key code
0	1	2nd key code
1	0	3rd key code
1	1	4th key code

[bit29:28] SIZE: Access Size Bits

These bits set the access size for writing to the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

Bits		Description
0	0	Set byte access.
0	1	Set half-word access.
1	0	Set word access.
1	1	Reserved

[bit27:15] Reserved: Reserved Bits

[bit14:0] RADR: Port Address Bits

These bits set the lower 15 bits of the address of the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

RADR	Description
-	Set the lower 15 bits of the address of the applicable key code register.

Notes:

- The key code setting becomes invalid upon any writing to the KEY[1:0] in any order than 0b00, 0b01, 0b10, and 0b11. In such case, set the key code again from the beginning.
- When different data is written to the SIZE[1:0] or the RADR[14:0] while writing the key code 0b00, 0b01, 0b10, and 0b11, the key code setting will become invalid. In such case, set it again from the beginning.
- The applicable key code register is the port setting register (PPC_PCFGR_{ijj}).
- This register is valid only for word access.
- There is no effect on the key code protection release process even if registers other than this register and the applicable key code register that is in the release processing (the register set by the RADR) are accessed while writing the key code 0b00, 0b01, 0b10, and 0b11.

4.12. Resource Input Setting Register (RIC_RESINn) (n = 0 to (product specification))

This register selects an external pin input or an output from another internal resource as resource input.

Bit	15	14	13	12	11	10	9	8
Field	Reserved					PORTSEL		
R/W Attribute	R0,WX					R/W		
Protection Attribute	WS							
Initial Value	0000					0000		

Bit	7	6	5	4	3	2	1	0
Field	Reserved				RESSEL			
R/W Attribute	R0,WX				R/W			
Protection Attribute	WS							
Initial Value	0000				0000			

[bit15:12] Reserved: Reserved Bits

[bit11:8] PORTSEL: Resource Selection Bit

This bit selects an input to a corresponding resource.

Bits				Description
0	0	0	0	Source A
0	0	0	1	Source B
0	0	1	0	Source C
0	0	1	1	Source D
0	1	0	0	Source E
0	1	0	1	Source F
0	1	1	0	Source G
0	1	1	1	Source H
1	0	0	0	Source I
1	0	0	1	Source J
1	0	1	0	Source K
1	0	1	1	Source L
1	1	0	0	Source M
1	1	0	1	Source N
1	1	1	0	Source O
1	1	1	1	Source P

For details, see product specification.

[bit7:4] Reserved: Reserved Bits

[bit3:0] RESSEL: Resource Selection Bit

This bit selects an input to a resource.

Bits				Description
0	0	0	0	Source A
0	0	0	1	Source B
0	0	1	0	Source C
0	0	1	1	Source D
0	1	0	0	Source E
0	1	0	1	Source F
0	1	1	0	Source G
0	1	1	1	Source H
1	0	0	0	Source I
1	0	0	1	Source J
1	0	1	0	Source K
1	0	1	1	Source L
1	1	0	0	Source M
1	1	0	1	Source N
1	1	1	0	Source O
1	1	1	1	Source P

For assignment of source, see product specification.

Notes:

- The PORTSEL is the applicable key code bit. To write to this bit, the RIC key code register (RIC_KEYCDR) must be set.
- If this bit is written before the key code is released, a bus error response is returned.
- The RESSEL is the applicable key code bit. To write to this bit, the RIC key code register (RIC_KEYCDR) must be set.
- If this bit is written before the key code is released, a bus error response is returned.
- After key code release, writing to a different address or using a different access size than specified in the key code sequence will not generate an error response.
- Please be sure to read and check a preset value after writing to a GPIO register.

4.13. RIC Key Code Register (RIC_KEYCDR)

This register sets register writing with a function for protection against erroneous writing. If writing to this register is not done using the prescribed method, writing to the relevant register is invalid.

Bit	31	30	29	28	27	26	25	24
Field	KEY		SIZE		Reserved			
R/W Attribute	R0,W		R0,W		R0,WX			
Protection Attribute	-							
Initial Value	00		00		0000			

Bit	23	22	21	20	19	18	17	16
Field	Reserved							
R/W Attribute	R0,WX							
Protection Attribute	-							
Initial Value	00000000							

Bit	15	14	13	12	11	10	9	8
Field	Reserved	RADR[14:8]						
R/W Attribute	R0,WX	R0,W						
Protection Attribute	-							
Initial Value	0	0000000						

Bit	7	6	5	4	3	2	1	0
Field	RADR[7:0]							
R/W Attribute	R0,W							
Protection Attribute	-							
Initial Value	00000000							

[bit31:30] KEY: Key Code Bits

These are key code setting bits. Write 0b00, 0b01, 0b10, and 0b11 continuously to these bits in this order. The key code setting becomes invalid immediately upon any writing to these bits in a different order. In such cases, set the key code again from the beginning.

Bits		Description
0	0	1st key code
0	1	2nd key code
1	0	3rd key code
1	1	4th key code

[bit29:28] SIZE: Access Size Bits

These bits set the access size for writing to the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

Bits		Description
0	0	Set byte access.
0	1	Set half-word access.
1	0	Set word access.
1	1	Reserved

[bit27:15] Reserved: Reserved Bits

[bit14:0] RADR: Port Address Bits

These bits set the lower 15 bits of the address of the applicable key code register. Write the same data to these bits when writing key codes 0b00, 0b01, 0b10, and 0b11 in this order.

RADR	Description
-	Set the lower 15 bits of the address of the applicable key code register.

Notes:

- The key code setting becomes invalid upon any writing to the KEY[1:0] in any order than 0b00, 0b01, 0b10, and 0b11. In such case, set the key code again from the beginning.
- When different data is written to the SIZE[1:0] or the RADR[14:0] while writing the key code 0b00, 0b01, 0b10, and 0b11, the key code setting will become invalid. In such case, set it again from the beginning.
- The applicable key code register is the resource input setting register (RIC_RESINn).
- This register is valid only for word access.
- There is no effect on the key code protection release process even if registers other than this register and the applicable key code register that is in the release processing (the register set by the RADR) are accessed while writing the key code 0b00, 0b01, 0b10, and 0b11. When key code protection is released, register of protection target can be written once. If several registers are to be written, it is necessary to release the protection for each register writing.

5. Precautions for Using This Device

Notes on switching the I/O port function are shown below.

A glitch may occur for a brief second (2 or 3 ns) when a general-purpose I/O port is switched (from input to output or from output to input or from port function to resource or from resource to port function).

If this glitch may cause a problem for the system, please write a value to port output data register (GPIO_PODRi) in advance at a level that will not cause a problem.

When a resource input is valid and its assignment is moved to another pin, a trigger which causes resource operation may occur if the pin levels before switching and after switching are different.

Therefore, please switch input pins when the resource input function is stopped.

CHAPTER 51: Peripheral Protection Unit

This chapter explains Peripheral Protection Unit (PPU).

1. Overview
2. Configuration and Block Diagram
3. Operation of the PPU
4. Registers
5. Setup Steps of PPU Register

PPU-TXXPT03P01R01L06-E1-XX

1. Overview

This section gives a brief overview of Peripheral Protection Unit.

The Peripheral Protection Unit (PPU) controls and monitors unauthorized access from the master to the peripherals against PPU configurations.

- Used to protect peripherals from unauthorized access.
- Provide read and write access attribute for peripherals.
- The attributes can be set independently in user mode and privileged mode.
- Support two types of attribute
 - Read/Access mode: Write access permission always includes read access permission.
 - Read/Write mode: Read access permission can be given independently to the write access permission.
- Return bus error response for the violated accesses.
- Have status registers to give information for the violations.
- The PPU supports privilege mode forced change function and it changes to privilege mode a privilege level of a peripheral side interface.

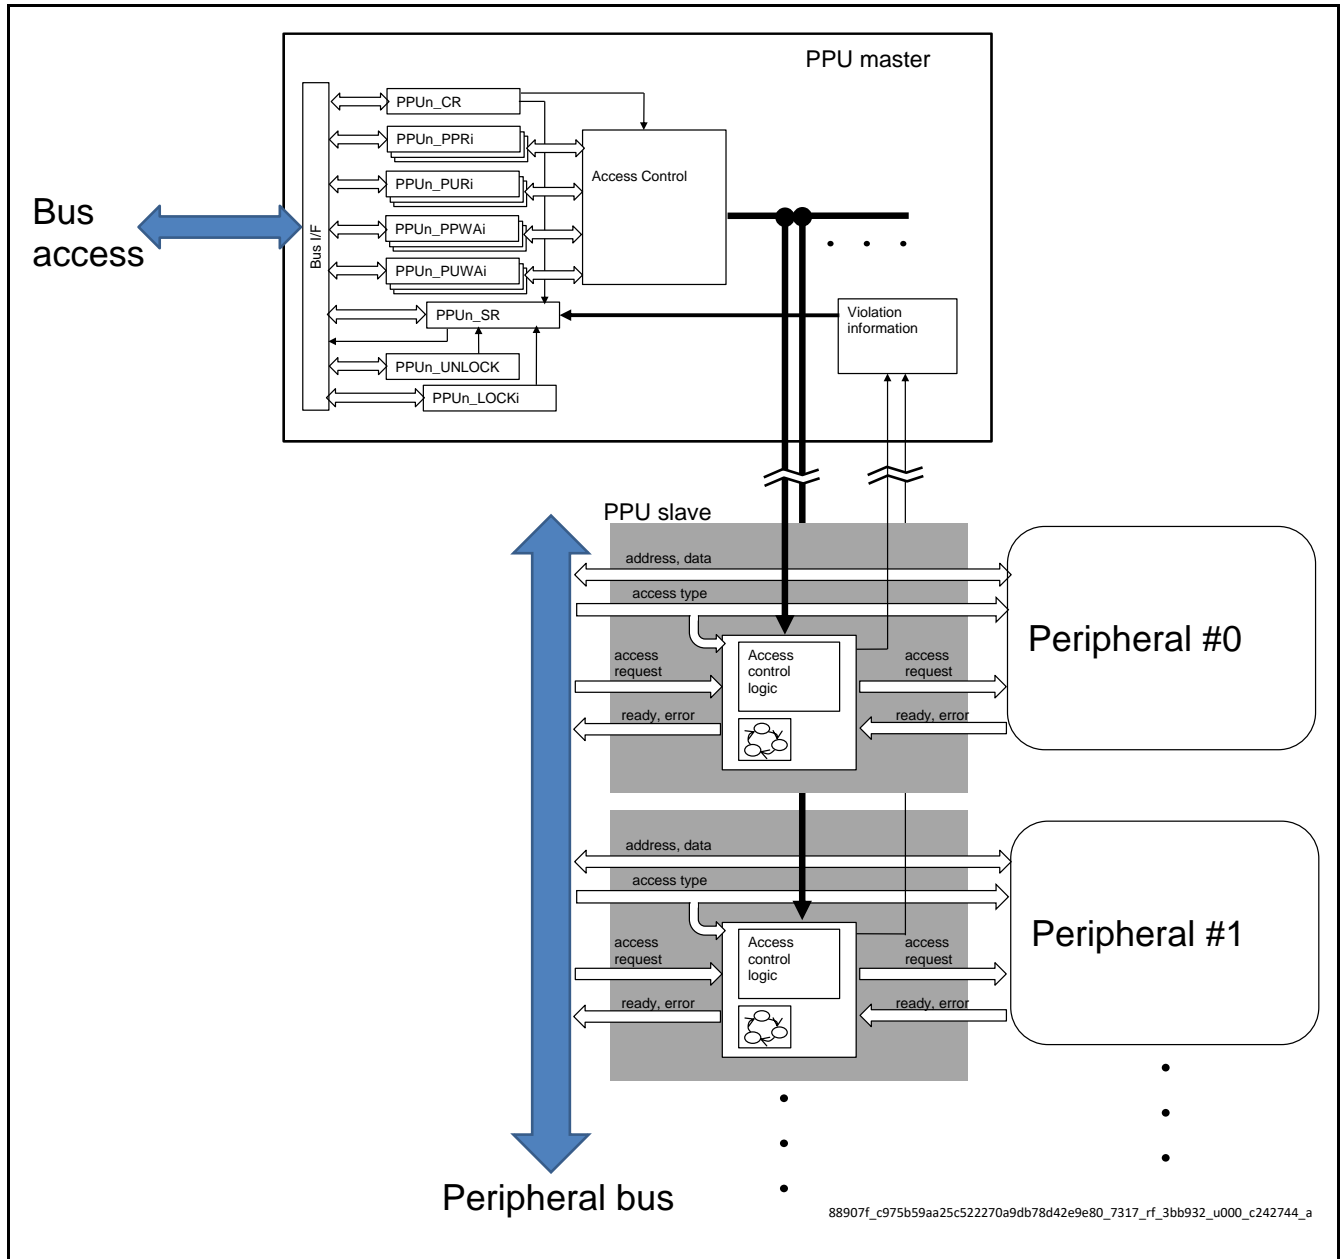

Only CPU is the bus master which is attached by PPU.

Refer PLATFORM OVERVIEW chapter to confirm which peripherals are covered by the PPU.

2. Configuration and Block Diagram

This section shows a block diagram of PPU.

Figure 2-1 Block Diagram

3. Operation of the PPU

This section describes the operation of PPU.

3.1. Access Type and PPU Operation

In this section, PPU protection behavior in each access type is tabulated.

The PPU can identify access type (read or write) and privilege level (privilege mode or user mode). The PPU permits or forbids access to the peripheral according to the PPU configuration.

The permission is configured according to PPU operation mode which is configured by PPU0_CR:MODE bit and PPU0_PPRi/PURi/PPWAI/PUWAI registers. Following table describes the access permissions in each configuration.

Table 3-1 Access Permission at Read/Write Mode in Privilege Mode Access

Read Attribute (PPU0_PPRi)	Write Attribute (PPU0_PPWAI)	Read Access in Privilege Mode	Write Access in Privilege Mode
0	0	Forbidden	Forbidden
0	1	Forbidden	Permitted
1	0	Permitted	Forbidden
1	1	Permitted	Permitted

Table 3-2 Access Permission at Read/Access Mode in Privilege Mode Access

Read Attribute (PPU0_PPRi)	Access Attribute (PPU0_PPWAI)	Read Access in Privilege Mode	Write Access in Privilege Mode
0	0	Forbidden	Forbidden
1	0	Permitted	Forbidden
0 or 1	1	Permitted	Permitted

Table 3-3 Access Permission at Read/Write Mode in User Mode Access

Read Attribute (PPU0_PURi)	Write Attribute (PPU0_PUWAI)	Read Access in User Mode	Write Access in User Mode
0	0	Forbidden	Forbidden
0	1	Forbidden	Permitted
1	0	Permitted	Forbidden
1	1	Permitted	Permitted

Table 3-4 Access Permission at Read/Access Mode in User Mode Access

Read Attribute (PPU0_PURi)	Access Attribute (PPU0_PUWAI)	Read Access in User Mode	Write Access in User Mode
0	0	Forbidden	Forbidden
1	0	Permitted	Forbidden
0 or 1	1	Permitted	Permitted

Accessing to peripheral in forbidden type, the violation will be occurred. For the access violation, refer 3.3 Access Violation for more details.

3.2. Access Protection to PPU Register

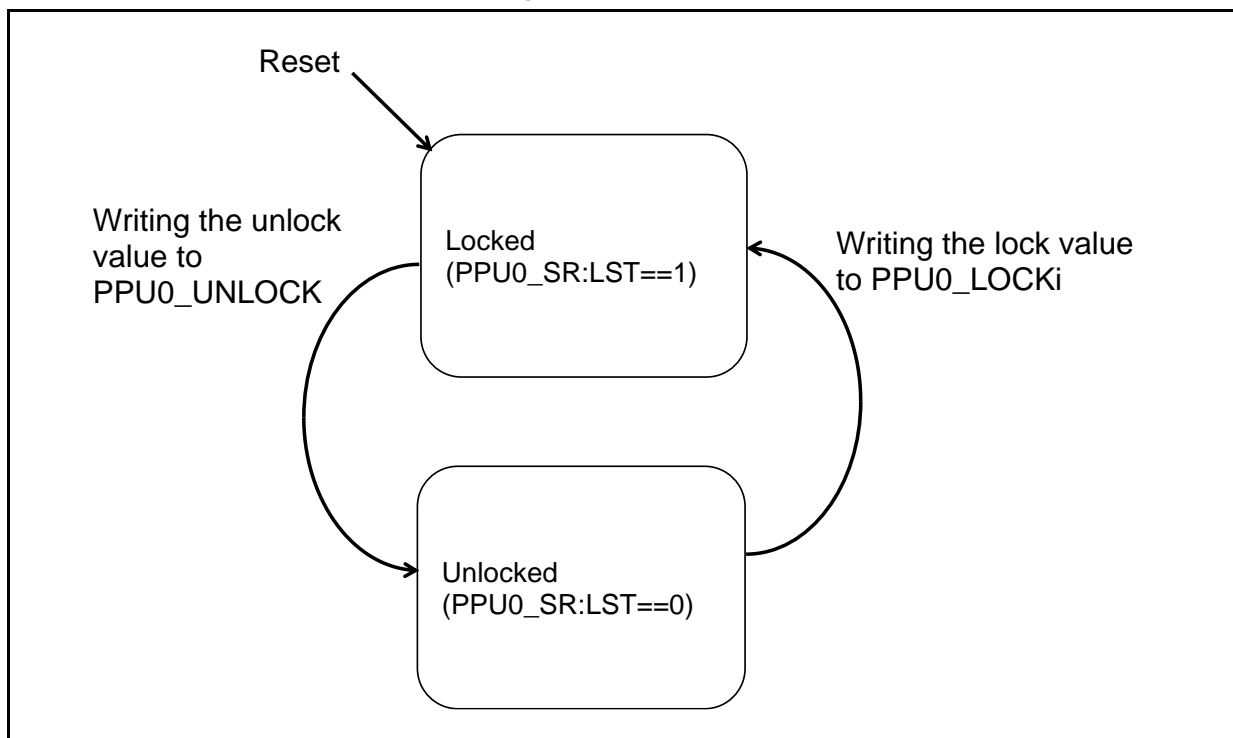

In this section explains access protection scheme to PPU registers.

The PPU has lock/unlock mechanism to writing its registers. To write the registers, it is needed to unlock the PPU by writing unlock value. PPU can be locked using PPU0_LOCKi register. To reconfigure PPU again, you need to unlock the PPU by writing PPU0_UNLOCK register again.

The lock status is always shown in PPU0_CR:LST bit.

There are several lock registers in PPU(Substance is one.). PPU can be locked by writing the lock value in either of the lock registers. They are prepared for a convenience for locking PPU by a programming by DMA transfer(Please refer from Table 3-5 to Table 3-8.).

Figure 3-1 Lock and Unlock

The writing procedure to the PPU0_PPRi register by the DMA forwarding is shown(Please refer to Table 3-5.).

Table 3-5 Write to PPU0_PPRI by DMA Transfer

No.	Offset	Register Name	Value
1	0x008	PPU0_UNLOCK	Unlock value (0x35AB16CC)
2	0x00C	PPU0_WPQCLR	Setting which does not trigger Quick Clear (WPQCLR = 0)
3	0x010	PPU0_WUQCLR	Setting which does not trigger Quick Clear (WUQCLR = 0)
4	0x014	PPU0_RPQCLR	Setting which does not trigger Quick Clear (RPQCLR = 0)
5	0x018	PPU0_RUQCLR	Setting which does not trigger Quick Clear (RUQCLR = 0)
6	0x01C to 0x07F	Reserved	Dummy value
7	0x080 to 0x0F4	PPU0_PPRI	Set value
8	0x0F8	PPU0_LOCK0	Lock value (0x30004000)

The writing procedure to PPU0_PPRI and the PPU0_PURI register by the DMA forwarding is shown(Please refer to Table 3-6).

Table 3-6 Write to PPU0_PPRI, PPU0_PURI by DMA Transfer

No.	Offset	Register Name	Value
1	0x008	PPU0_UNLOCK	Unlock value (0x35AB16CC)
2	0x00C	PPU0_WPQCLR	Setting which does not trigger Quick Clear (WPQCLR = 0)
3	0x010	PPU0_WUQCLR	Setting which does not trigger Quick Clear (WUQCLR = 0)
4	0x014	PPU0_RPQCLR	Setting which does not trigger Quick Clear (RPQCLR = 0)
5	0x018	PPU0_RUQCLR	Setting which does not trigger Quick Clear (RUQCLR = 0)
6	0x01C to 0x07F	Reserved	Dummy value
7	0x080 to 0x0F4	PPU0_PPRI	Set value
8	0x0F8	PPU0_LOCK0	Dummy value (Excluding 0x30004000)
9	0x0FC	Reserved	Dummy value
10	0x100 to 0x174	PPU0_PURI	Set value
11	0x178	PPU0_LOCK1	Lock value (0x30004000)

The writing procedure to PPU0_PPRI, PPU0_PURI, and the PPU0_PPWAI register by the DMA forwarding is shown(Please refer to Table 3-7).

Table 3-7 Write to PPU0_PPRI, PPU0_PURI, PPU0_PPWAI by DMA Transfer

No.	Offset	Register Name	Value
1	0x008	PPU0_UNLOCK	Unlock value (0x35AB16CC)
2	0x00C	PPU0_WPQCLR	Setting which does not trigger Quick Clear (WPQCLR = 0)
3	0x010	PPU0_WUQCLR	Setting which does not trigger Quick Clear (WUQCLR = 0)
4	0x014	PPU0_RPQCLR	Setting which does not trigger Quick Clear (RPQCLR = 0)
5	0x018	PPU0_RUQCLR	Setting which does not trigger Quick Clear (RUQCLR = 0)
6	0x01C to 0x07F	Reserved	Dummy value
7	0x080 to 0x0F4	PPU0_PPRI	Set value
8	0x0F8	PPU0_LOCK0	Dummy value (Excluding 0x30004000)
9	0x0FC	Reserved	Dummy value
10	0x100 to 0x174	PPU0_PURI	Set value
11	0x178	PPU0_LOCK1	Dummy value (Excluding 0x30004000)
12	0x17C	Reserved	Dummy value
13	0x180 to 0x1F4	PPU0_PPWAI	Set value
14	0x1F8	PPU0_LOCK2	Lock value (0x30004000)

The writing procedure to PPU0_PPRI, PPU0_PURI, PPU0_PPWAI, and the PPU0_PUWAI register by the DMA forwarding is shown(Please refer to Table 3-8).

Table 3-8 Write to PPU0_PPRI, PPU0_PURI, PPU0_PPWAI, PPU0_PUWAI by DMA Transfer

No.	Offset	Register Name	Value
1	0x008	PPU0_UNLOCK	Unlock value (0x35AB16CC)
2	0x00C	PPU0_WPQCLR	Setting which does not trigger Quick Clear (WPQCLR = 0)
3	0x010	PPU0_WUQCLR	Setting which does not trigger Quick Clear (WUQCLR = 0)
4	0x014	PPU0_RPQCLR	Setting which does not trigger Quick Clear (RPQCLR = 0)
5	0x018	PPU0_RUQCLR	Setting which does not trigger Quick Clear (RUQCLR = 0)
6	0x01C to 0x07F	Reserved	Dummy value
7	0x080 to 0x0F4	PPU0_PPRI	Set value
8	0x0F8	PPU0_LOCK0	Dummy value (Excluding 0x30004000)
9	0x0FC	Reserved	Dummy value
10	0x100 to 0x174	PPU0_PURI	Set value
11	0x178	PPU0_LOCK1	Dummy value (Excluding 0x30004000)
12	0x17C	Reserved	Dummy value
13	0x180 to 0x1F4	PPU0_PPWAI	Set value
14	0x1F8	PPU0_LOCK2	Dummy value (Excluding 0x30004000)
15	0x1FC	Reserved	Dummy value
16	0x200 to 0x274	PPU0_PUWAI	Set value
17	0x278	PPU0_LOCK3	Lock value (0x30004000)

The writing procedure to PPU0_PPRi, PPU0_PURi, PPU0_PPWai, PPU0_PUWai and the PPU0_PFENi register by the DMA forwarding is shown(Please refer to Table 3-9).

Table 3-9 Write to PPU0_PPRi, PPU0_PURi, PPU0_PPWai, PPU0_PUWai, PPU0_PFENi by DMA Transfer

No.	Offset	Register Name	Value
1	0x008	PPU0_UNLOCK	Unlock value (0x35AB16CC)
2	0x00C	PPU0_WPQCLR	Setting which does not trigger Quick Clear (WPQCLR = 0)
3	0x010	PPU0_WUQCLR	Setting which does not trigger Quick Clear (WUQCLR = 0)
4	0x014	PPU0_RPQCLR	Setting which does not trigger Quick Clear (RPQCLR = 0)
5	0x018	PPU0_RUQCLR	Setting which does not trigger Quick Clear (RUQCLR = 0)
6	0x01C to 0x07F	Reserved	Dummy value
7	0x080 to 0x0F4	PPU0_PPRi	Set value
8	0x0F8	PPU0_LOCK0	Dummy value (Excluding 0x30004000)
9	0x0FC	Reserved	Dummy value
10	0x100 to 0x174	PPU0_PURi	Set value
11	0x178	PPU0_LOCK1	Dummy value (Excluding 0x30004000)
12	0x17C	Reserved	Dummy value
13	0x180 to 0x1F4	PPU0_PPWai	Set value
14	0x1F8	PPU0_LOCK2	Dummy value (Excluding 0x30004000)
15	0x1FC	Reserved	Dummy value
16	0x200 to 0x274	PPU0_PUWai	Set value
17	0x278	PPU0_LOCK3	Dummy value (Excluding 0x30004000)
18	0x27C	Reserved	Dummy value
19	0x280 to 0x2F4	PPU0_PFENi	Set value
20	0x2F8	PPU0_LOCK4	Lock value (0x30004000)

3.3. Access Violation

In this section explains behavior at access violation.

When violated access to the peripheral, PPU, corresponding peripheral, and the bus master (i.e. CPU) behaves as following.

- The access will cause a bus error response. The bus error response in CPU will trigger an exception.
- The access to the peripheral is blocked by the PPU. So the peripheral is not affected by the access.
- The error information is set to PPU0_SR register.

To obtain the violation information, read PPU0_SR register in the ISR for the exception at bus error response.

Figure 3-2 and Figure 3-3 are comparing behaviors for each permission.

Figure 3-2 Access Operation When the Access is Forbidden

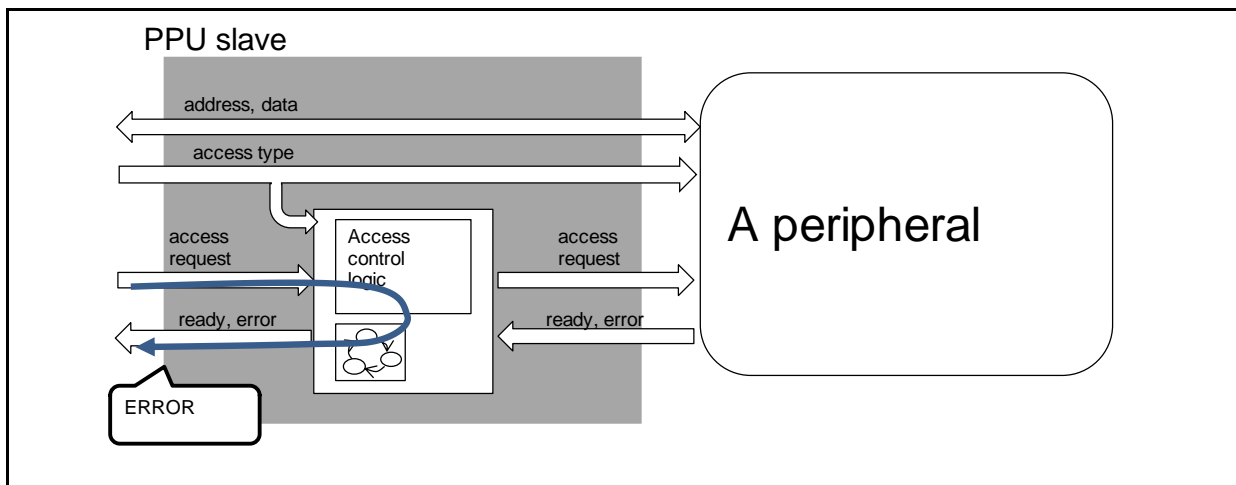

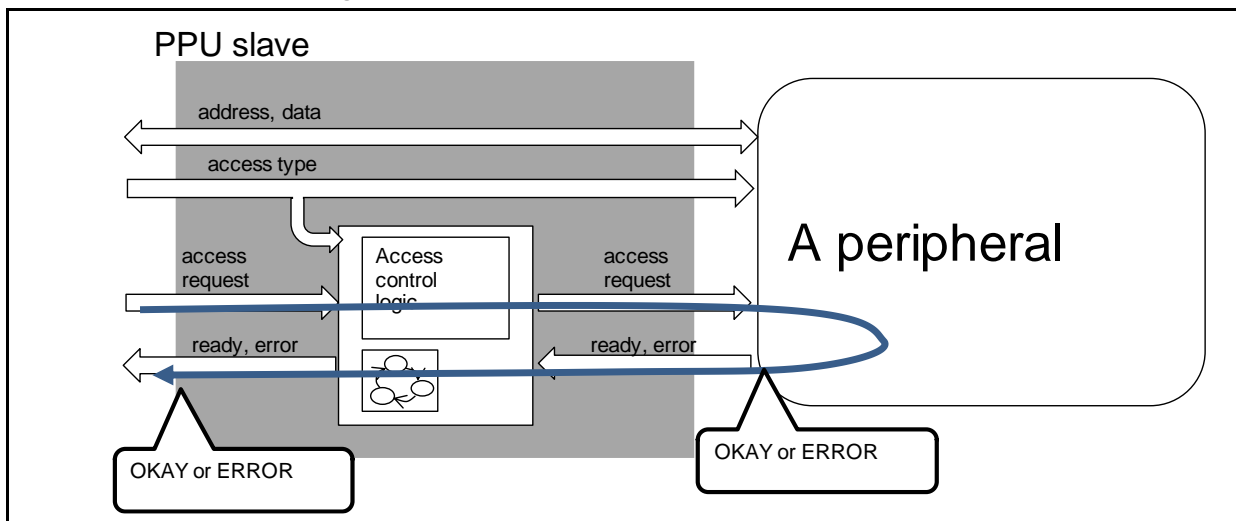

Figure 3-3 Access Operation When the Access is Permitted

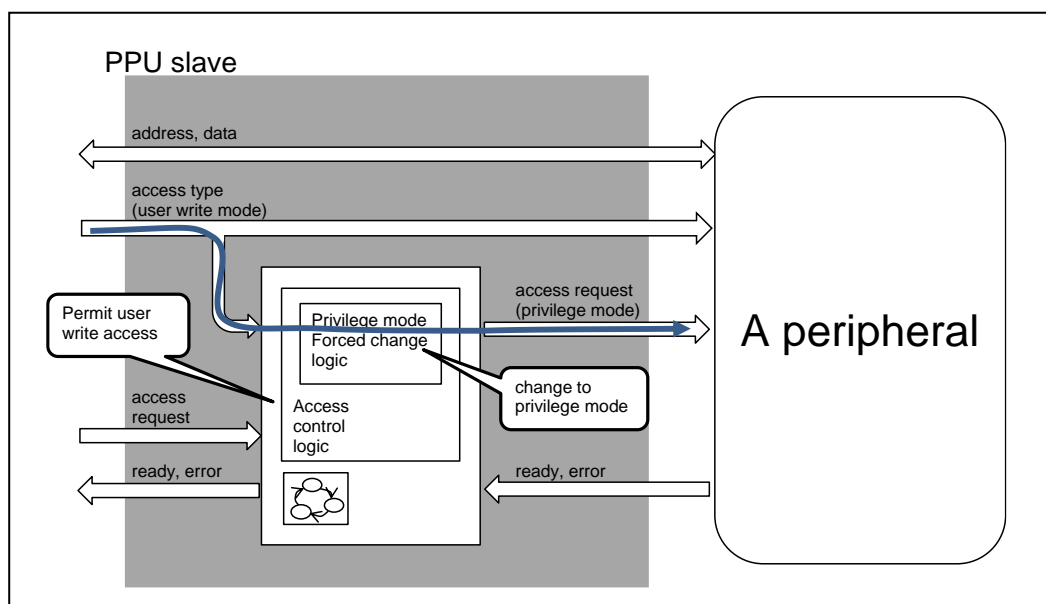

3.4. Privilege Mode Forced Change Function

In this section explains privilege mode forced change function.

The PPU supports privilege mode forced change function.

When this mode is enabled (PPU0_PFENi:PFEN[x] = 1), privilege level on a peripheral side interface is set to privilege mode as explained in Section 4.13 “PPU Privilege Mode Forced change function Enable Register (PPU0_PFENi)”. With this function, even if it is prohibited write access in user mode from bus master (i.e. CPU) to the peripherals, write access in user mode is enabled (Please refer to Figure 3-4).

Figure 3-4 Privilege Mode Forced Change Function

Note:

- When privilege mode forced change function is enabled, the PPU controls the accesses to a peripheral using the privilege level before forced change (Please refer to following table).

Access mode from the bus master	PPU0_PFENi:PFEN[x]	Access mode to the peripheral	Access mode to be used for PPU access control
User mode	0	User mode	User mode
Privilege mode	Don't care	Privilege mode	Privilege mode
User mode	1	Privilege mode	User mode

4. Registers

This section describes the registers of PPU.

Table 4-1 Register Map

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x000	PPU0_CR 00000000_00000000_00000000_00000000			
0x004	PPU0_SR 00000000_00000000_00000000_00000001			
0x008	PPU0_UNLOCK 00000000_00000000_00000000_00000000			
0x00C	PPU0_WPQCLR 00000000_00000000_00000000_00000000			
0x010	PPU0_WUQCLR 00000000_00000000_00000000_00000000			
0x014	PPU0_RPQCLR 00000000_00000000_00000000_00000000			
0x018	PPU0_RUQCLR 00000000_00000000_00000000_00000000			
0x01C 0x07F	Reserved			
0x080 0x0F4	PPU0_PPR0 - PPU0_PPR29 11111111_11111111_11111111_11111111			
0x0F8 0x0FC	PPU0_LOCK0 00000000_00000000_00000000_00000000 Reserved			
0x100 0x174	PPU0_PUR0 - PPU0_PUR29 11111111_11111111_11111111_11111111			
0x178 0x17C	PPU0_LOCK1 00000000_00000000_00000000_00000000 Reserved			
0x180 0x1F4	PPU0_PPWA0 - PPU0_PPWA29 11111111_11111111_11111111_11111111			
0x1F8 0x1FC	PPU0_LOCK2 00000000_00000000_00000000_00000000 Reserved			
0x200 0x274	PPU0_PUWA0 - PPU0_PUWA29 00000000_00000000_00000000_00000000			
0x278	PPU0_LOCK3 00000000_00000000_00000000_00000000			

Offset	Register Name / Initial Value			
	+3	+2	+1	+0
0x27C	Reserved			
0x280	PPU0_PFEN0 - PPU0_PFEN29			
0x2F4	00000000_00000000_00000000_00000000			
0x2F8	PPU0_LOCK4			
	00000000_00000000_00000000_00000000			
0x2FC	Reserved			

Accessing reserved area has no effects.

4.1. PPU Control Register (PPU0_CR)

The register controls overall of the PPU operation. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit29] MODE : PPU Mode Bit

This bit specifies the operation mode of PPU.

Bit	Description
0	Read/Write mode Read access permission can be given independently to the write access permission. Please refer to 3.1 Access Type and PPU Operation for more details.
1	Read/Access mode Write access permission always includes read access permission. Please refer to 3.1 Access Type and PPU Operation for more details.

[bit23] VCLR : PPU Violation Information Clear

Writing "1" to this bit clears VD, VP, VW and VL[4:0] bits in PPU0_SR register. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of VD, VP, VW, and VL [4:0] of the PPU0_SR register is cleared.

[bit9] FPQSET : PPU Privilege Mode Forced Change Function Quick Set

Writing "1" to this bit sets PPU0_PFENi (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PFENi (i=0 to 29) registers is set.

[bit8] FPQCLR : PPU Privilege Mode Forced Change Function Quick Clear

Writing "1" to this bit clears PPU0_PFENi (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PFENi (i=0 to 29) registers is cleared.

Notes:

- The access from the CPU to the corresponding peripheral, please go after writing to the MODE bit is completed.
- Writing to FPQSET/FPQCLR bit, please go to when access to the corresponding peripheral from the CPU does not occur.
- In case of writing "1" to FPQSET bit and FPQCLR bit at the same time, FPQCLR bit is set.

4.2. PPU Status Register (PPU0_SR)

The register shows the status of PPU.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit23] VD : Violation Detection Bit

Then violated access to the peripheral against corresponding PPU configuration is found, the bit shall be set to "1". The bit is cleared by writing "1" to PPU0_CR:VCLR.

Bit	Description
0	The violation access was not generated.
1	The violation access was generated.

[bit22] VP : Violation Privileged Level Bit

This register contains information for privilege level of the latest violated access. The bit is cleared by writing "1" to PPU0_CR:VCLR.

Bit	Description
0	The access was done in user mode.
1	The access was done in privilege mode.

[bit21] VW : Violation Write Access Bit

This register contains information for access type (read or write) of the latest violated access. The bit is cleared by writing "1" to PPU0_CR:VCLR.

Bit	Description
0	The access was read access.
1	The access was write access.

[bit20:16] VL[4:0] : Violation Location

This register contains information for access destination of the latest violated access. As application specific PPU protection area, areas of up to seven are available.

Bits	Description
00000	Reserved
00001	Violated access was done to a register in MCU Config Group.
00010	Violated access was done to a register in SYSC1.
00011	Violated access was done to a register in Memory Config Group or System SRAM.
00100	Violated access was done to a register in CPERI#0.
00101	Violated access was done to a register in CPERI#1.
00110	Violated access was done to a register in CPERI#2.
00111	Violated access was done to a register in EBI Group.
01000	Violated access was done to a register in SHE Group.
01001	Violated access was done to a register in DDRHSSPI Group.
01010	Violated access was done to a register in Application specific area #0.
01011	Violated access was done to a register in Application specific area #1.
01100	Violated access was done to a register in Application specific area #2.
01101	Violated access was done to a register in Application specific area #3.
01110	Violated access was done to a register in Application specific area #4.
01111	Violated access was done to a register in Application specific area #5.
10000	Violated access was done to a register in Application specific area #6.
Else	Reserved

[bit0] LST : Lock Status Bit

The bit has to be "0" to program the PPU. Please refer to 3.2 Access Protection to PPU Register for more details.

Bit	Description
0	Unlocked
1	Locked

Note:

- Priority of settings to PPU0_SR in the case where the access violation occurs simultaneously in several groups is as follows.

Group Name	Priorities
MCU Config Group	Highest level
SYSC1 Group	↑ (Higher)
Memory Config Group	
System SRAM	
CPERI#0	
CPERI#1	
CPERI#2	
EBI Group	
SHE Group	
DDRHSSPI Group	
Application specific area #0	
Application specific area #1	
Application specific area #2	
Application specific area #3	
Application specific area #4	
Application specific area #5	↓ (Lower)
Application specific area #6	Lowest level

4.3. PPU Unlock Register (PPU0_UNLOCK)

The register unlocks the access to PPU register. Without locking, write access to specific PPU registers results a bus error response. By writing the unlock value (0x35AB16CC), the PPU is unlocked.

BIT_OFFSET	31	30	29	28	27	26	25	24
BIT_NAME	UL[31]	UL[30]	UL[29]	UL[28]	UL[27]	UL[26]	UL[25]	UL[24]

PROT_TYPE	WP							
INITIAL_VALUE	0	0	0	0	0	0	0	0

Note:

- Writing by byte or half-word access to this register results a bus error response.

[bit31:0] UL : Unlock

By writing 0x35AB16CC, the PPU is unlocked and PPU0_SR:LST is set to "0". Writing any other value has no effect.

4.4. PPU Privileged Write Attribute Quick Clear Register (PPU0_WPQCLR)

The register clears collectively write attribute (in Read/Write mode) or access attribute (in Read/Access mode) of the corresponding peripherals in privileged mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit0] WPQCLR : PPU Privileged Write Attribute Quick Clear

Writing "1" to this bit clears PPU0_PPWAI (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PPWAI (i=0 to 29) registers is cleared.

Notes:

- The access from the CPU to the corresponding peripheral, please go after writing to the MODE bit is completed.
- Writing to WPQCLR bit, please go to when access to the corresponding peripheral from the CPU does not occur.

4.5. PPU User Write Attribute Quick Clear Register (PPU0_WUQCLR)

The register clears collectively write attribute (in Read/Write mode) or access attribute (in Read/Access mode) of the corresponding peripherals in user mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit0] WUQCLR : PPU User Write Attribute Quick Clear

Writing "1" to this bit clears PPU0_PUWAI (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PUWAI (i=0 to 29) registers is cleared.

Notes:

- The access from the CPU to the corresponding peripheral, please go after writing to the MODE bit is completed.
- Writing to WUQCLR bit, please go to when access to the corresponding peripheral from the CPU does not occur.

4.6. PPU Privileged Read Attribute Quick Clear Register (PPU0_RPQCLR)

The register clears collectively read attribute of the corresponding peripherals in privileged mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit0] RPQCLR : PPU Privileged Read Attribute Quick Clear

Writing "1" to this bit clears PPU0_PPRi (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PPRi (i=0 to 29) registers is cleared.

Notes:

- The access from the CPU to the corresponding peripheral, please go after writing to the MODE bit is completed.
- Writing to RPQCLR bit, please go to when access to the corresponding peripheral from the CPU does not occur.

4.7. PPU User Read Attribute Quick Clear Register (PPU0_RUQCLR)

The register clears collectively read attribute of the corresponding peripherals in user mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit0] RUQCLR : PPU User Read Attribute Quick Clear

Writing "1" to this bit clears PPU0_PURi (i=0 to 29) registers. Writing "0" has no effect.

Bit	Description
0	No effect.
1	Each bit of the PPU0_PURi (i=0 to 29) registers is cleared.

Notes:

- The access from the CPU to the corresponding peripheral, please go after writing to the MODE bit is completed.
- Writing to RUQCLR bit, please go to when access to the corresponding peripheral from the CPU does not occur.

4.8. PPU Privileged Read Attribute Register (PPU0_PPRi)

The register sets read attribute of the corresponding peripherals in privileged mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit31:0] PPR[x] : PPU Privileged Mode Read Attribute Bit (x=31 to 0)

Read attribute for Privileged mode access of the peripheral #(i*32+x).

PPR [x] x=31 to 0	Description
0	Read attribute in privileged mode is disabled.
1	Read attribute in privilege mode is enabled.

Note:

- The access from the CPU to the corresponding peripheral, please go after writing to the PPR[x] bit is completed.

4.9. PPU User Read Attribute Register (PPU0_PURi)

The register sets read attribute of the corresponding peripherals in user mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

[bit31:0] PUR[x] : PPU User Mode Read Attribute Bit (x=31 to 0)

Read attribute for user mode access of the peripheral #(i*32+x).

PUR [x] x=31 to 0	Description
0	Read attribute in user mode is disabled.
1	Read attribute in user mode is enabled.

Note:

- The access from the CPU to the corresponding peripheral, please go after writing to the PUR[x] bit is completed.

4.10. PPU Privileged Write or Access Attribute Register (PPU0_PPWAi)

The register sets write attribute (in Read/Write mode) or access attribute (in Read/Access mode) of the corresponding peripherals in privileged mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

[bit31:0] PPWA[x] : PPU Privileged Mode Write or Access Attribute Bit (x=31 to 0)

Write or access attribute for Privileged mode access of the peripheral #(i*32+x).

PPWA [x] x=31 to 0	Description
0	[Read/Write mode] Write attribute in privileged mode is disabled. [Read/Access mode] Access attribute in privileged mode is disabled.
1	[Read/Write mode] Write attribute in privileged mode is enabled. [Read/Access mode] Access attribute in privileged mode is enabled.

Note:

- The access from the CPU to the corresponding peripheral, please go after writing to the PPWA[x] bit is completed.

4.11. PPU User Write or Access Attribute Register (PPU0_PUWAi)

The register sets write attribute (in Read/Write mode) or access attribute (in Read/Access mode) of the corresponding peripherals in user mode access. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

[bit31:0] PUWA[x] : PPU User Mode Write or Access Attribute Bit (x=31 to 0)

Write or access attribute for User mode access of the peripheral #(i*32+x).

PUWA[x] x=31 to 0	Description
0	[Read/Write mode] Write attribute in user mode is disabled. [Read/Access mode] Access attribute in user mode is disabled.
1	[Read/Write mode] Write attribute in user mode is enabled. [Read/Access mode] Access attribute in user mode is enabled.

Note:

- The access from the CPU to the corresponding peripheral, please go after writing to the PUWA[x] bit is completed.

4.12. PPU Lock Register (PPU0_LOCKi)

The registers lock the access to PPU register by writing the lock value (0x30004000). There are several Lock register instances in PPU but all of them work in the same manner.

BIT_OFFSET	31	30	29	28	27	26	25	24

PROT_TYPE	WP							
INITIAL_VALUE	0	0	0	0	0	0	0	0

Note:

- Writing by byte or half-word access to this register results a bus error response.

[bit31:0] L : Lock

By writing 0x30004000, the PPU is locked and PPU0_SR:LST is set to "1". Writing any other values has no effect.

4.13. PPU Privilege Mode Forced Change Function Enable Register (PPU0_PFENi)

The register controls privilege mode forced change operation of the corresponding peripherals. When this mode is enabled (PPU0_PFENi= 1), privilege level to the corresponding peripherals forcibly changes to privilege mode. To write this register, you have to unlock the PPU by writing the unlock value into PPU Unlock Register.

[bit31:0] PFEN[x] : PPU Privilege Mode Forced Change Function Enable Bit (x=31 to 0)

Control of privilege mode Forced change operation of the peripheral #(i*32+x).

5. Setup Steps of PPU Register

Setup steps of the PPU register are shown below.

Figure 5-1 Setup Steps of PPU Register

Note:

- *If the setting of PPU registers is made by DMAC, before starting the access to the peripheral, CPU needs to confirm the lock value to PPU0_LOCKi register was written by DMAC (i.e. PPU0_SR:LST= 1).*

CHAPTER 52: DDR High Speed SPI Controller

This chapter explains the functionality and operation of the DDR High Speed SPI Controller (DDRHSSPI).

1. Overview
2. Configuration
3. Serial Interface
4. Operations of the DDRHSSPI
5. Registers

DDRHSSPI-TXXPT03P01R01L05-E1-XX

1. Overview

The DDRHSSPI provides various operating modes for interfacing to serial peripheral devices that use the de-facto standard SPI protocol. It supports also the Quad and Octal transfer modes to access multi-bit Serial Flash Memories. The DDRHSSPI's features are described in this section.

Features of the DDR High Speed SPI Controller

- In case of DDRHSSPI_{IN}.MID=0x00000001
 - Supports Legacy Mode and Quad Mode
 - Allows the use of up to 4 Serial Flash Memories
- In case of DDRHSSPI_{IN}.MID = 0x000000100 or 0x000000300
 - Supports Legacy Mode, Quad Mode and Octal Mode (Dual Quad, Dual Legacy)
 - Allows the use of up to 8 Serial Flash Memories
- Features a programmable transfer rate of the serial clock
- External Serial Flash Memories can be memory-mapped to the address-space of the MCU, in Command Sequencer Mode
- In Command Sequencer Mode, memory accesses initiated by the MCU and other masters are automatically converted to Serial Flash Memory read commands by the DDRHSSPI.
- In Command Sequencer Mode, access to the SPI Flash Memory is done through the Prefetch Buffer (PB)
- Direct Mode allows the DDRHSSPI to be used as a standard SPI master through a FIFO interface

Abbreviations

This section lists the terms and abbreviations used in this chapter.

Table 1-1 Terms and Abbreviations

Term	Meaning
Byte Time	Byte Time is the time required for transmission of 8 bits of data, over the SPI interface In SDR Mode, one byte time is: 1 cycle of SCLK in Octal Mode, 2 cycles of SCLK in Quad Mode and 8 cycles of SCLK in Legacy Mode. In DDR Mode one byte time is: 1/2 cycle of SCLK in Octal Mode, 1 cycle of SCLK in Quad Mode and 4 cycles of SCLK in Legacy Mode.
CSR	Control and Status Registers of DDRHSSPI.
DAP	Debug Access Port
DDR	Double Data Rate
DLP	Data Learning Pattern
DMA	Direct Memory Access
FIFO	First-In, First-Out
Half Word	16-bits of data
MCU	Micro Control Unit
on-the-fly	Switching modes of serial interface, during transferring data there
PB	Prefetch Buffer
RX	Receive
SDR	Standard Data Rate
SPI	Serial Peripheral Interface
SCLK	Serial Clock on the external port of the chip
SSEL	Serial Slave Select on the external port of the chip
SDATA	Serial Data on the external port of the chip
SW	Software
TX	Transmit
Word	32-bits of data

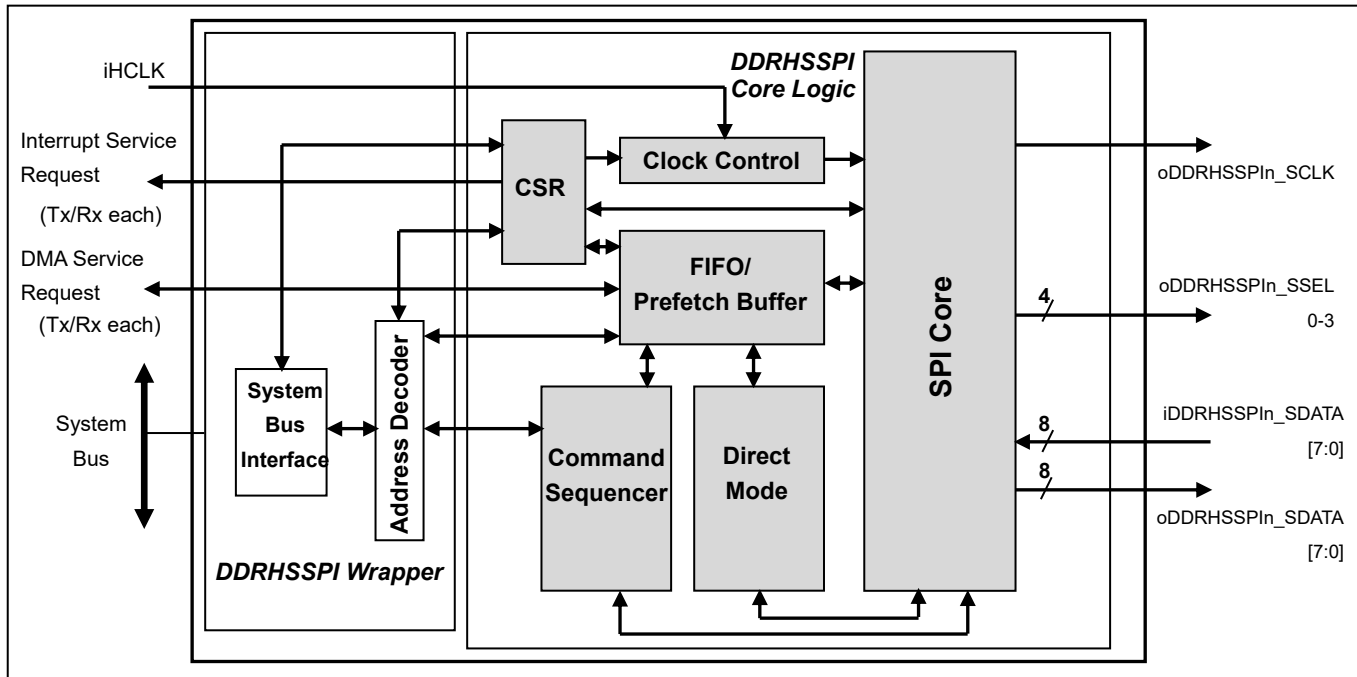

2. Configuration

This section describes a block diagram of DDRHSSPI.

Block Diagram

Figure 2-1 shows the block diagram of the DDRHSSPI, followed by the explanations of internal blocks.

Figure 2-1 DDRHSSPI Block Diagram

CSR

The CSR block holds the configuration and status registers, which are used to control and monitor the status of the DDRHSSPI.

Please refer to section 4.3 Address Map of DDRHSSPI for more detailed information about the CSR.

SPI Core and Clock Control

The SPI Core block contains the SPI protocol engine, which handles the read and write operations from/to the external serial Flash Memory. The SPI communication-related attributes like Serial Clock Frequency and Serial Clock Mode, etc., are configured via the CSR. Depending on whether the DDRHSSPI is operating in Direct Mode or in Command Sequencer Mode, the SPI Core connects with the FIFOs. The DDRHSSPI can initiate serial transfers with Serial Flash Memories, which are connected to the four Slave Select lines: oDDRHSSPIIn_SSEL0-3. An internal clock divider is used to derive the serial clock output (oDDRHSSPIIn_SCLK).

System Bus and Address Decoding

These two blocks are used as the interface to the System Bus. The masters such as MCUs are able to access the DDRHSSPI through the System Bus Interface and Address Decoder.

The Address Decoder performs the decoding of the address bus. If the System Bus access is targeted to a command or a status register, the request is sent to the CSR block. If the access is for the Command Sequencer or the Direct Mode blocks, then also access relevant info is routed to Command Sequencer or Direct Mode. When in Command Sequencer Mode, if the System Bus access is for a Serial Flash Memory which is mapped onto one of the four Slave Select lines, then the memory address is passed to the Command Sequencer block.

FIFO / Prefetch Buffer

This block can be used in two different modes based on DDRHSSPI configured mode, Command Sequencer Mode or Direct Mode. In Direct Mode, this block is used as two separate FIFOs: One for TX and one for RX. Each FIFO is 24-locations deep and has a data-width of 32 bits.

In Command Sequencer Mode this block is used as Prefetch Buffer for only receiving data from Flash Memory. The Prefetch Buffer is 48-locations deep and has data width of 32 bits.

Direct Mode

In Direct Mode DDRHSSPI internally uses FIFO/Prefetch buffer block configured as two FIFOs for temporary storage: One holds the data to be transmitted (TX-FIFO) and one stores the data to be received (RX-FIFO).

TX-FIFO and RX-FIFO are used by DDRHSSPI only in Direct Mode.

The Direct Mode block has following functions:

- Transmits data onto the Serial Interface via TX-FIFO.
- Receives data from the Serial Interface via RX-FIFO.
- DMA is available both for transmission and reception.
- Controls the data format to transmit.
 - Tri-state with variable length
 - SPI protocol on each data
 - Data Rate Mode (SDR Mode or DDR Mode) on each data

Command Sequencer

The Command Sequencer maps the external Serial Flash Memories on the address space of MCU.

In this mode the FIFO/Prefetch Buffer block is configured as Prefetch Buffer (PB) available for temporary storage and prefetch accesses, and only read operations of the Flash Memory are possible. The read data are output to the System Bus via internal Prefetch Buffer.

The Command Sequencer block has following functions:

- Watches continuity of memory access on the System Bus and determines whether it should keep current serial transfer or start a new one.
- Generates a serial transaction with
 - Decoding a Command Sequence table in CSR to output a series of data to the SPI Core.
 - Generating a serial address: it concatenates address bits from System Bus and a register value in CSR.
- Controls Prefetch Buffer to flush.
- Runs an Idle Timer (ITIMER) to control whether to close current serial transaction.

3. Serial Interface

This section describes the Serial Interface of DDRHSSPI.

3.1. Serial Clock Modes and Data Rate Modes

DDRHSSPI supports two Data Rate Modes for Serial Flash Interface, namely Single Data Rate (SDR) and Double Data Rate (DDR). In Direct Mode, the DDR is allowed only at TX-Only Mode.

Maximum output serial clock frequency in both SDR and DDR Modes, is up to 1/2 peripheral bus frequency.

Based on the programmed values of the DDRHSSPI_PCC0-3.ACES bits (valid only in SDR Mode), each peripheral can have up to 2 clock modes in SDR Mode and only 1 clock mode in DDR Mode. DDRHSSPI_PCC0-3.ACES bit setting in DDR Mode is not allowed. These bits decide the serial data input and output timings of DDRHSSPI, with respect to the serial SPI clock. This is explained in Table 3-1 and Table 3-2.

Table 3-1 Clock Modes in SDR Mode

MODE	ACES (Active Clock Edges are Same on Peripheral)	Description
Mode 0	0	Output data (oDDRHSSPI_SDATA) from DDRHSSPI are driven one half-cycle before the first positive edge of serial clock (oDDRHSSPI_SCLK) and on the subsequent negative edges of oDDRHSSPI_SCLK.
		Input data (iDDRHSSPI_SDATA) on the side of DDRHSSPI are sampled on the positive edges of oDDRHSSPI_SCLK.
Mode 4	1	Output data (oDDRHSSPI_SDATA) from DDRHSSPI are driven one half-cycle before the first positive edge of serial clock (oDDRHSSPI_SCLK) and on the subsequent negative edges of oDDRHSSPI_SCLK.
		Input data (iDDRHSSPI_SDATA) on the side of DDRHSSPI are sampled on the negative edges of oDDRHSSPI_SCLK.

Figure 3-1 SDR Clock Mode 0

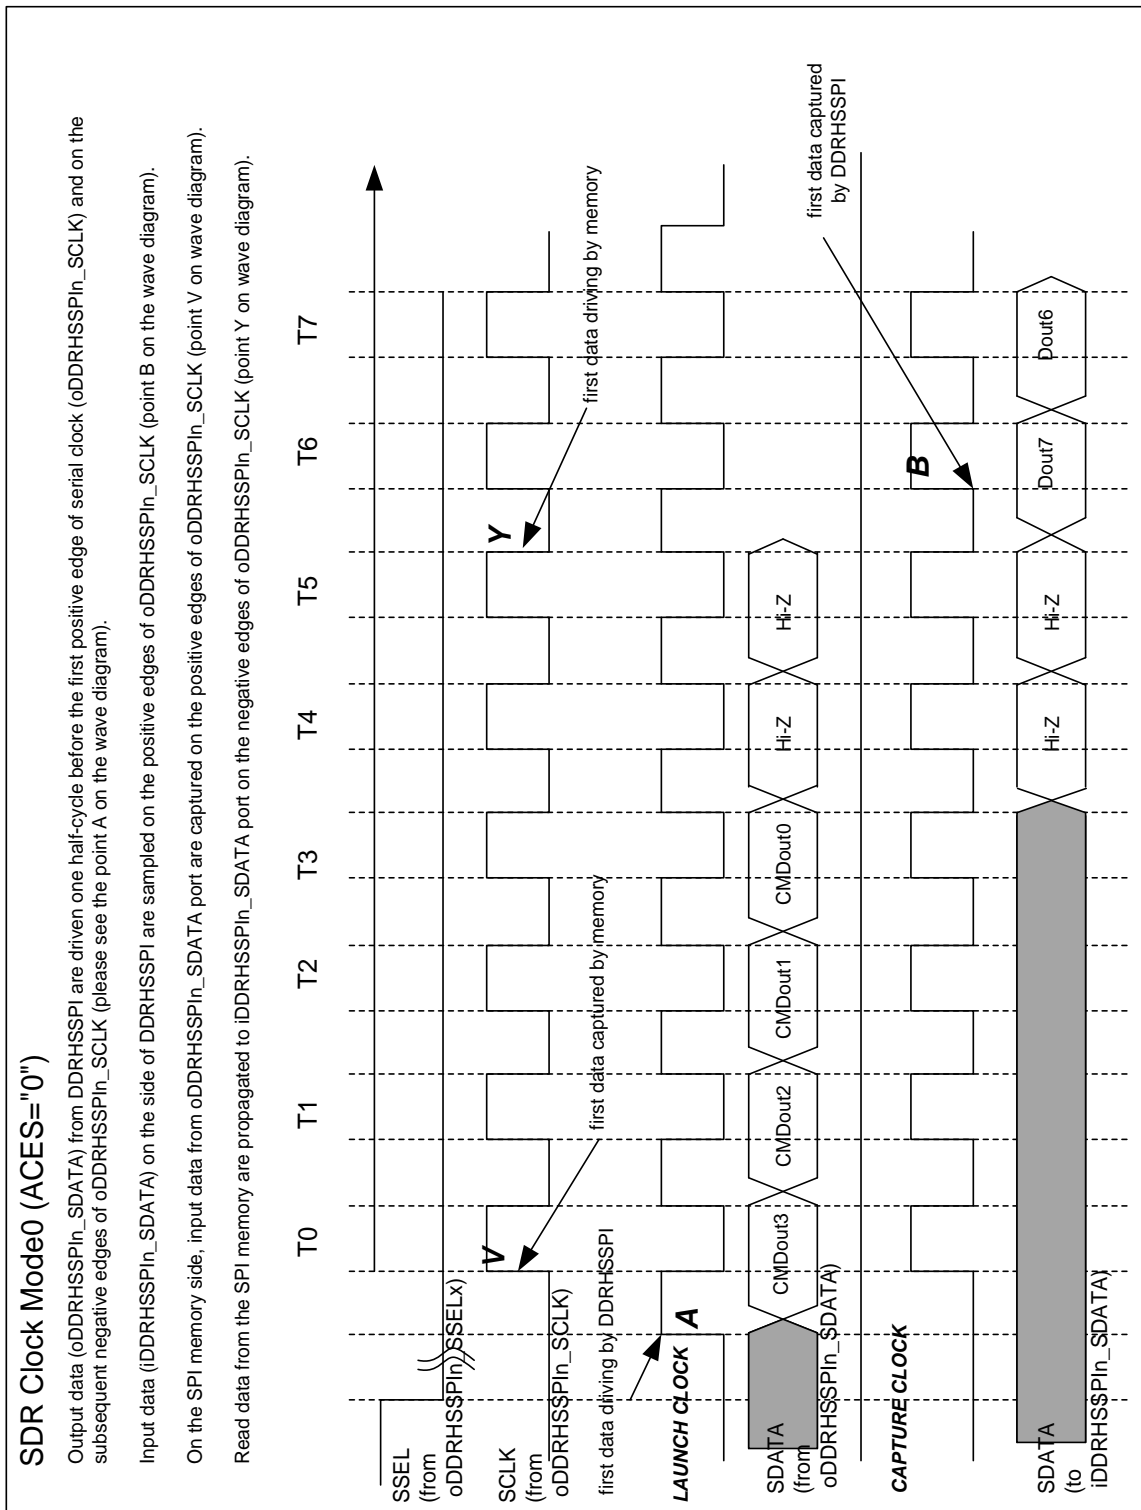

Figure 3-2 SDR Clock Mode 4

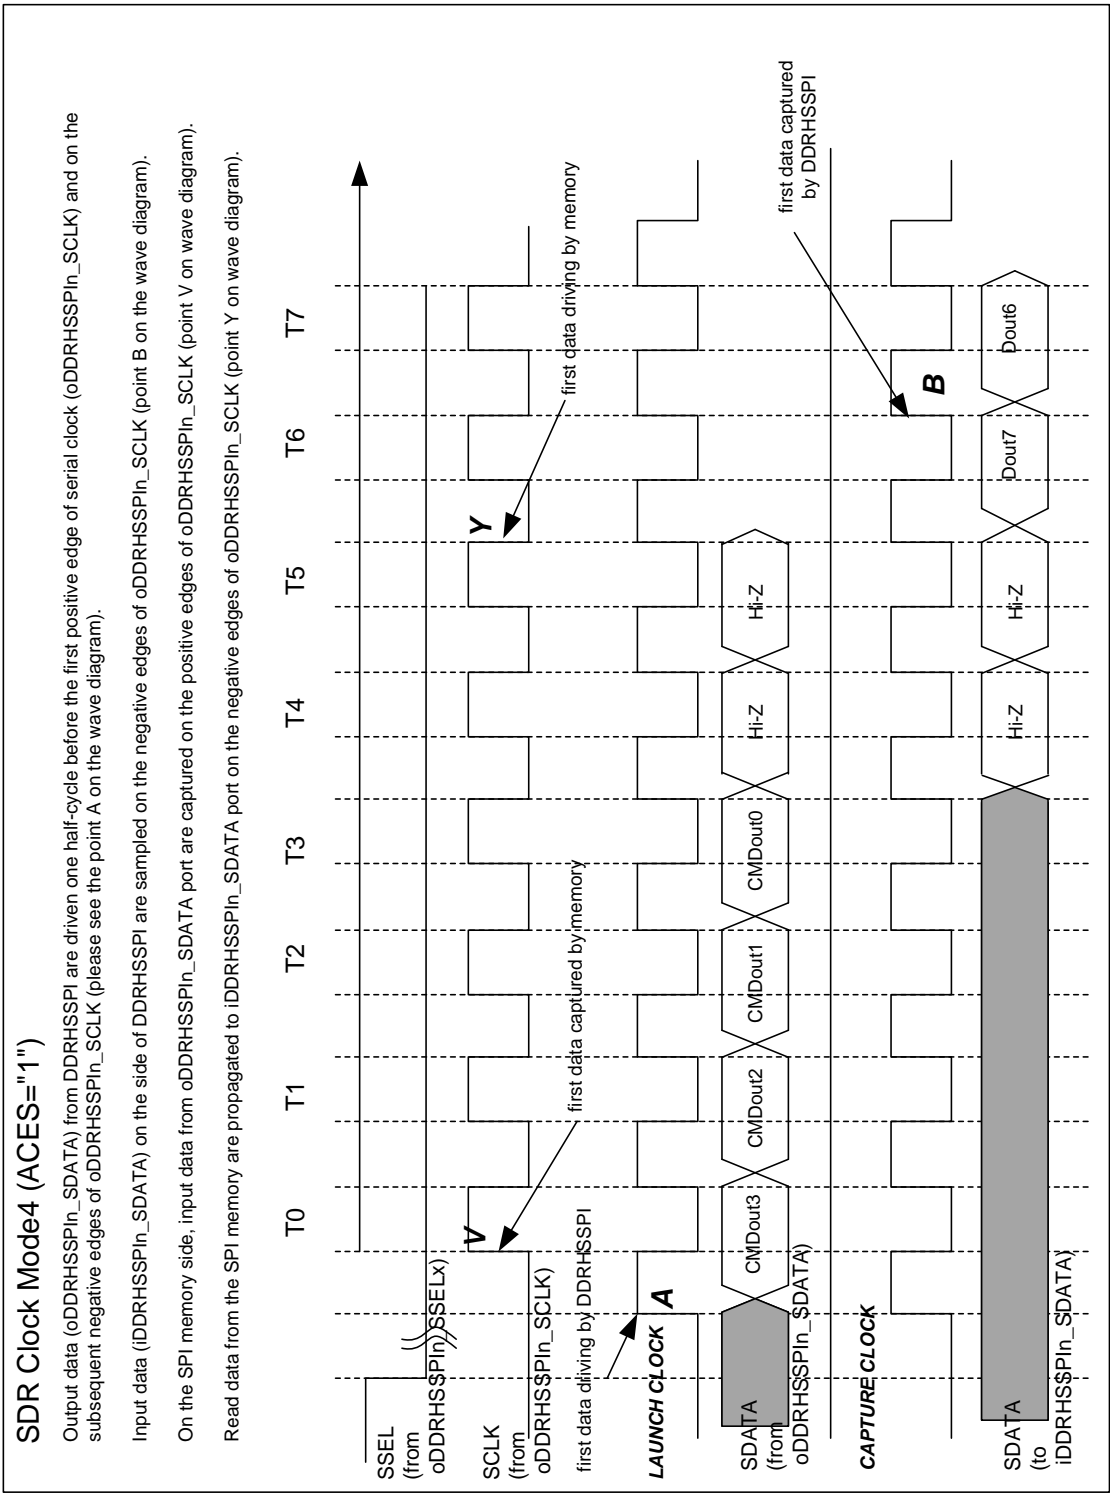

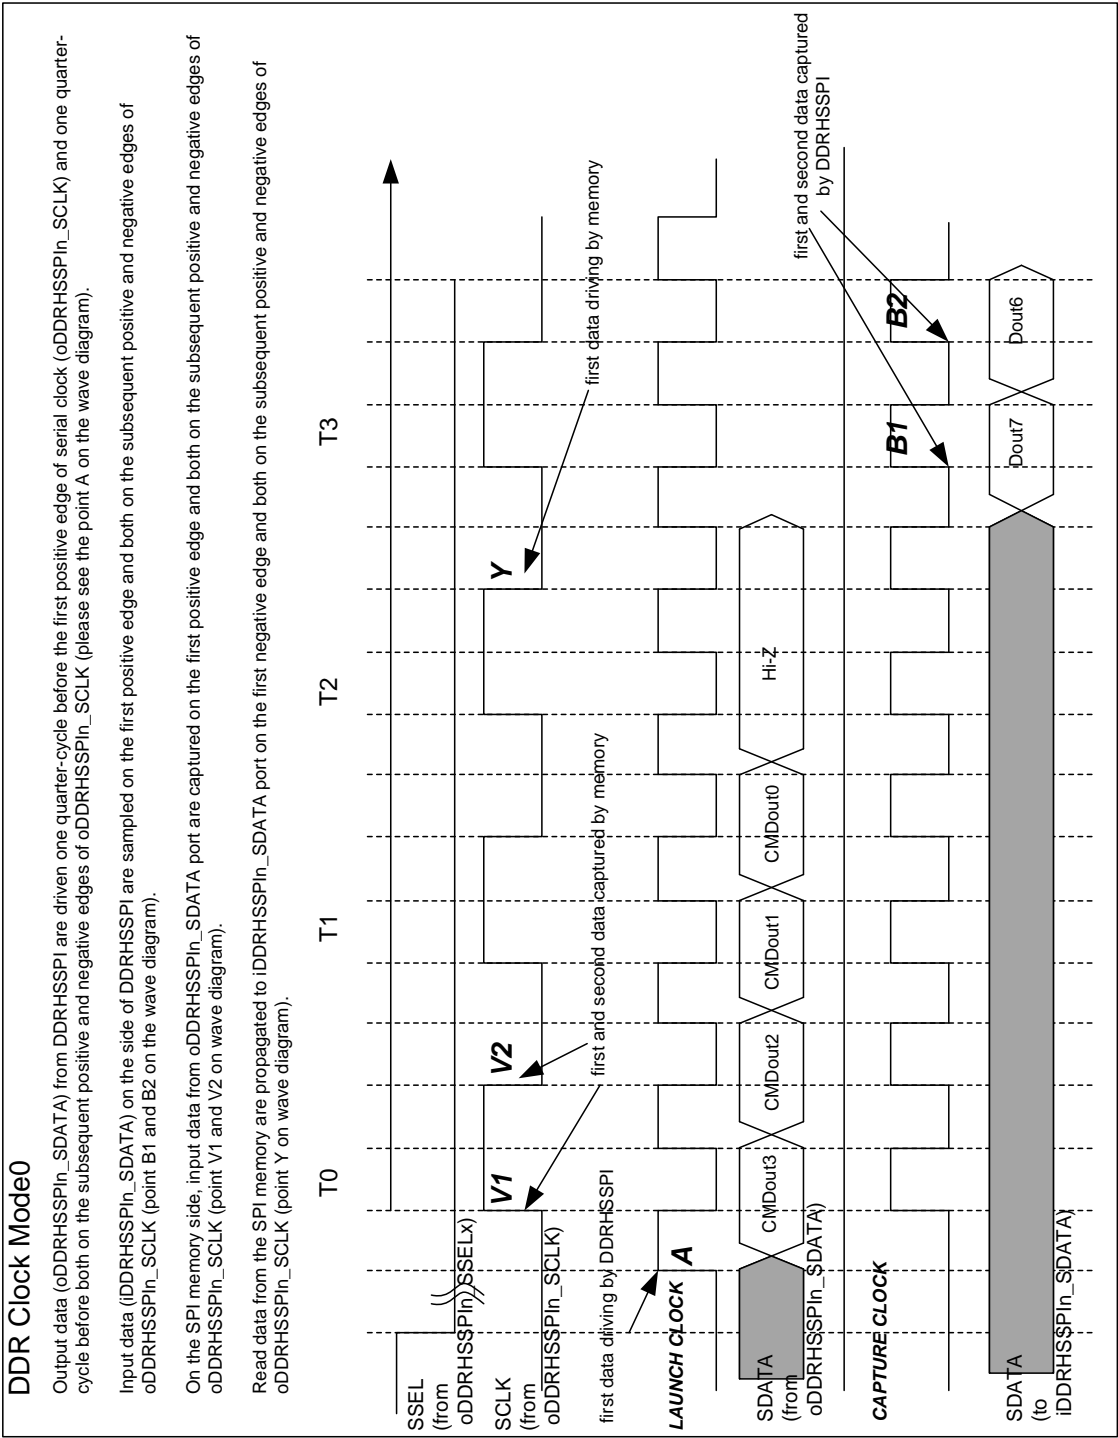

Table 3-2 Clock Modes in DDR Mode

MODE	Description
Mode 0	Output data (oDDRHSSPIIn_SDATa) from DDRHSSPI are driven one quarter-cycle before the first positive edge of serial clock (oDDRHSSPIIn_SCLK) and one quarter-cycle before both on the subsequent positive and negative edges of oDDRHSSPIIn_SCLK.
	Input data (iDDRHSSPIIn_SDATa) on the side of DDRHSSPI are sampled on the first positive edge , and both on the subsequent positive and negative edges of oDDRHSSPIIn_SCLK.

Note:

- *In Direct Mode, the DDR is allowed only at TX-Only Mode.*

Figure 3-3 DDR Clock Mode 0

3.2. SPI Clock Frequency

oDDRHSSPIn_SCLK clock is internally generated by dividing the System Bus Clock (iHCLK). The clock division ratio of the resulting internal clock-divider can be programmed in the DDRHSSPIn_PCC0-3 Registers. The DDRHSSPIn_PCC0-3.CDRS (4-bit wide) decides the clock division ratio for output serial clock frequency. Maximum clock division rate supported is 32.

For CDRS value 0 output serial clock frequency SCLK is 1/2 of iHCLK

For CDRS value 1 output serial clock frequency SCLK is 1/4 of iHCLK.

.....

For CDRS value 15 output serial clock frequency SCLK is 1/32 of iHCLK.

Output clock frequency set by CDRS is independent of Data Rate Mode (SDR Mode or DDR Mode) settings.

3.3. SPI Input Data Sampling Point

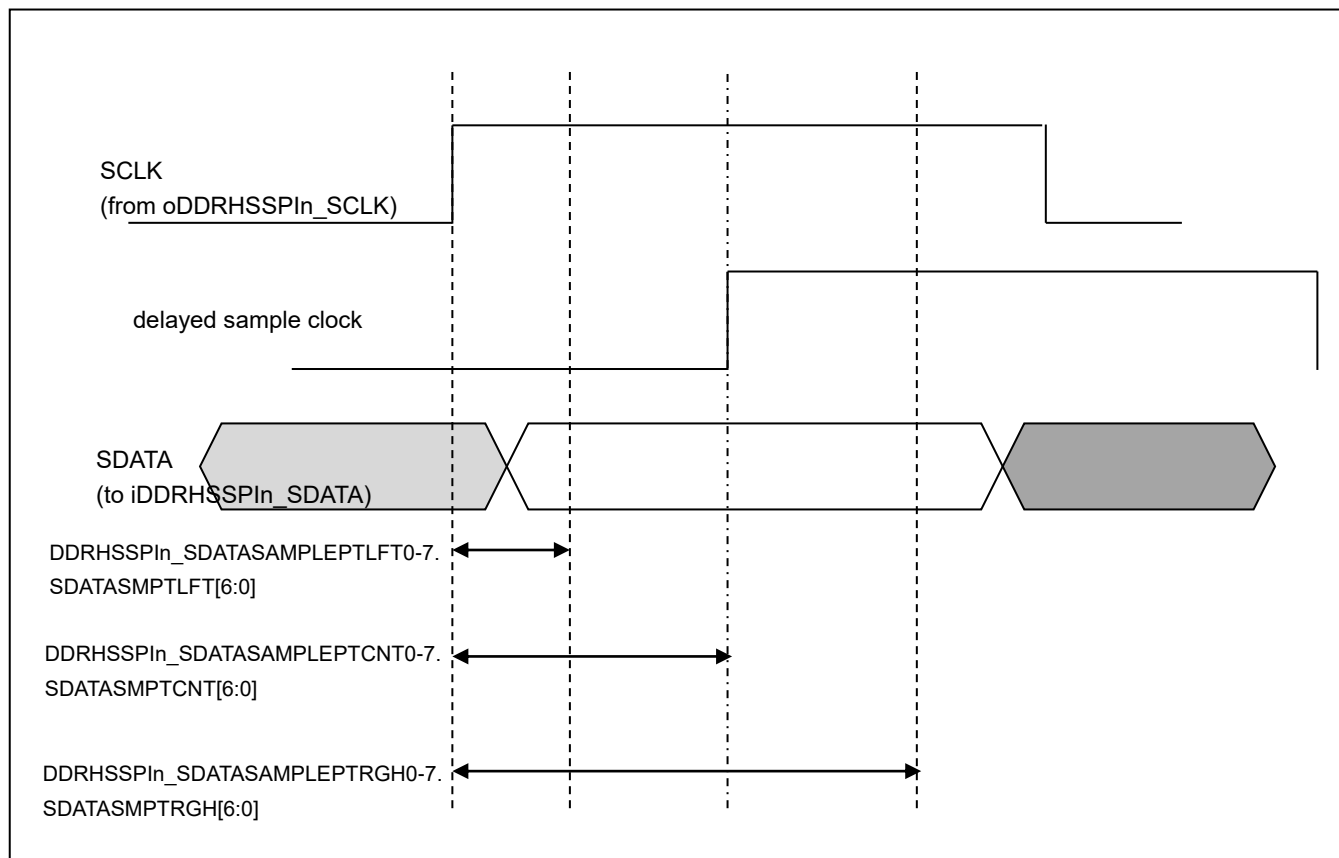

This feature is available only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300.

The delay of internal clock which samples iDDRHSSPIn_SDATA is adjustable, comparing to oDDRHSSPIn_SCLK clock. By this feature, the sampling timing of input data from Flash Memory can be finely tuned. The SPI clock sampling point per each bit line of iDDRHSSPIn_SDATA port can be programmed in the DDRHSSPIn_SDATASAMPLEPTCNT0-7 Registers.

Sampling clock fine tuning is implemented for each iDDRHSSPIn_SDATA[7:0] input line with buffers forming delay chain (on the internal clock) with programmable delay selection. It is up to SW to choose appropriate value of iDDRHSSPIn_SDATA clock sample delay point in order to provide consistency and compensate for input delay per data lines.

When in using DLP, it is possible to set additional two clock sampling points per each iDDRHSSPIn_SDATA input (so called left and right sampling point) for checking purpose only. These values are set in DDRHSSPIn_SDATASAMPLEPTLFT0-7 and DDRHSSPIn_SDATASAMPLEPTRGH0-7 Registers. Any of DLP errors at CNT/LFT/RGH will cause an error response on the System Bus. For more details, please refer to Notes of these registers before using DLP.

Please refer to Figure 3-4 explaining this in wave diagrams.

Figure 3-4 SDATA Sampling Clock Settings

Please note that setting delay is always done comparing to the rising edge of oDDRHSSPIn_SCLK clock and it is not possible to set this to be "negative" i.e. to be before oDDRHSSPIn_SCLK rising edge.

It is recommended to set values of corresponding registers such that $SDATASMPTLFT \leq SDATASMPTCNT \leq SDATASMPTRGH$.

Note:

- When in DDRHSSPIn_MID.MID is 0x00000001, all of SDATASMPTLFT, SDATASMPTCNT and SDATASMPTRGH must be fixed to 0.

3.4. SPI Data Learning Pattern

This feature is available only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300.

In case DDRHSSPI is connected with Flash Memory that has a feature outputting a Data Learning Pattern (DLP) during the dummy cycles, DDRHSSPI can check if the sampling point setting is correct.

This feature can be used only in Command Sequencer Mode and DDR Mode.

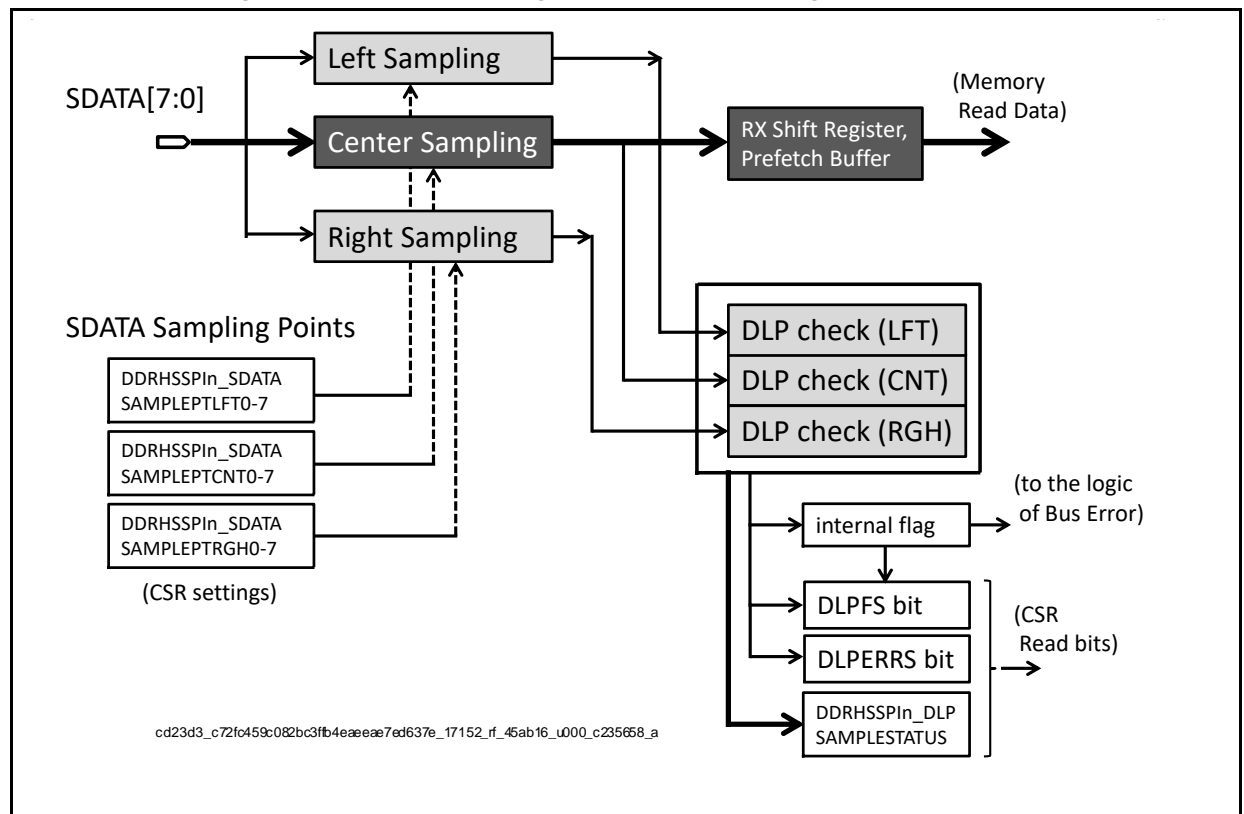

This feature is enable, when DDRHSSPIn_MCTRL.DLPEN bit is "1". This feature must be also enabled on the Flash Memory side. Please program the same value of DLP to both registers, in the Flash Memory and in DDRHSSPI (DDRHSSPIn_DLP Register). Once this feature is enabled, Flash Memory will output a Data Learning Pattern during dummy cycles, and DDRHSSPI will receive data on iDDRHSSPIn_SDATA at the same time.

Since DDRHSSPI has individual sampling points on each line of iDDRHSSPIn_SDATA, during the DLP pattern, DDRHSSPI can test neighboring (left-center-right) sampling points by registers DDRHSSPIn_SDATASAMPLEPTCNT0-7, DDRHSSPIn_SDATASAMPLEPTLFT0-7 and DDRHSSPIn_SDATASAMPLEPTRGH0-7.

All checks in iDDRHSSPIn_SDATA sampling clock settings (left-center-right) are comparing to the value of DDRHSSPIn_DLP Register as reference.

The logic related to SDATA Sampling Points and DLP is illustrated as below. The internal flag is directly invisible from the CPU, however, its status is reflected to the Bus Error and the system can detect it.

Figure 3-5 SDATA Sampling Points and Related Logics

Notes:

- Once having detected a DLP error, the following Memory Read access is affected as below.
 - (1)When a DLP error occurs, it is held on the internal flag along DDRHSSPI_{IN}_FAULTF.DLPFS bit.
 - (2)The software clears DLP-related flags (DDRHSSPI_{IN}_FAULTF.DLPFS and DDRHSSPI_{IN}_RXF.DLPERR) and adjusts the SDATA Sampling Points to proper values.
 - (3)This internal flag affects the next Memory Read access depending on the address.
 - (a)Same word-line addresses: "Error"
 - If ("new address" >> 2) = ("previous address" >> 2), the result is as below.
 - Bus Error on the System Bus
 - Internal flag = "1"
 - DDRHSSPI_{IN}_FAULTF.DLPFS = "1"
 - DDRHSSPI_{IN}_RXF.DLPERR = "0"
 - DDRHSSPI_{IN}_DLPSAMPLESTATUS = 0x00000000
 - (b)Different word-line addresses: "Success"
 - If ("new address" >> 2) ≠ ("previous address" >> 2), the result is as below.
 - No Bus Error on the System Bus
 - Internal flag = "0"
 - DDRHSSPI_{IN}_FAULTF.DLPFS = "0"
 - DDRHSSPI_{IN}_RXF.DLPERR = "0"
 - DDRHSSPI_{IN}_DLPSAMPLESTATUS 0x00000000

Figure 3-6 and Figure 3-7 illustrate these cases (a) and (b). Each diagram depicts two consecutive Memory Read accesses - the first one failing to sample SDATA, and the second one with successful sampling. The address of the second access determines the result.

 - The proposed Calibration sequence is described in the section 4.4.4 "Using the DDRHSSPI in Command Sequencer Mode of Operation".

Figure 3-6 Memory Read accesses from "FAIL" to "PASS" ((a) Same Word-line)

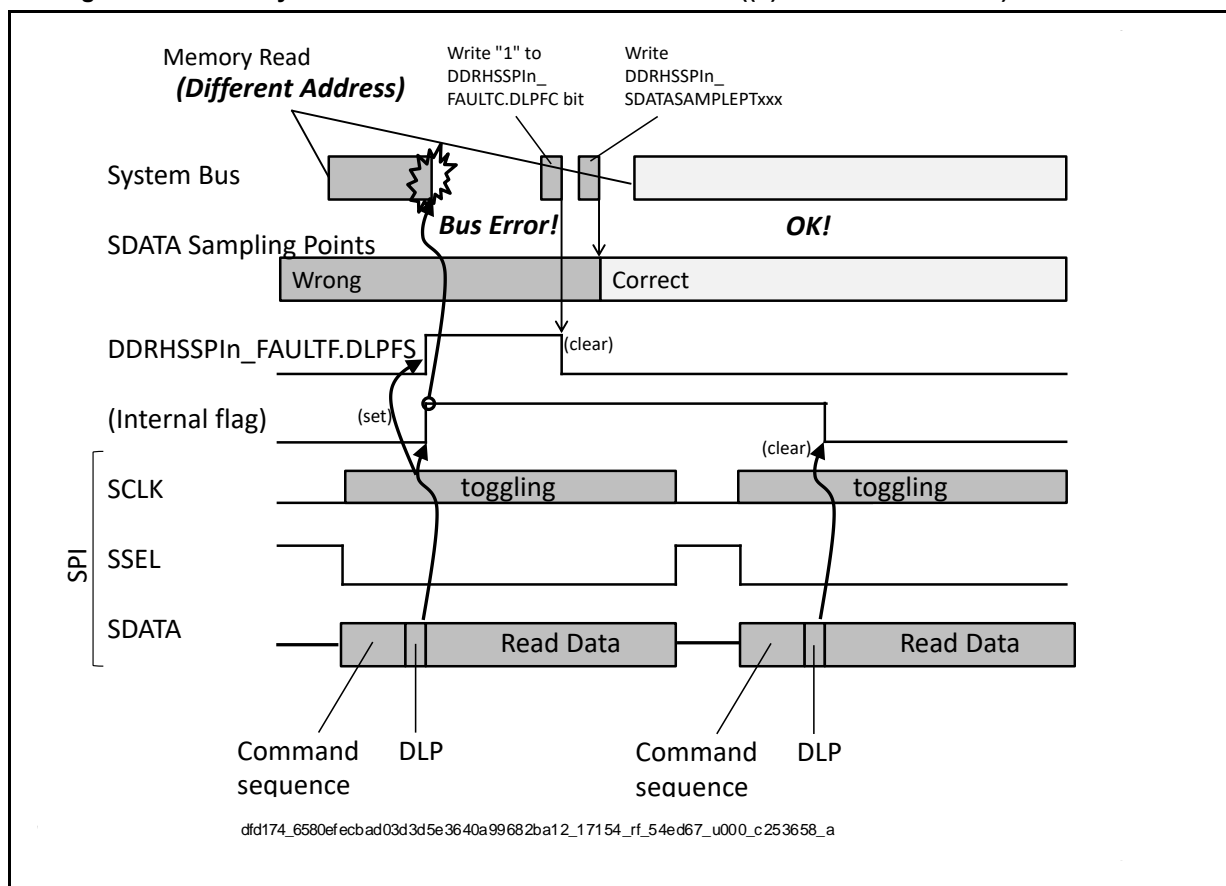

Figure 3-7 Memory Read accesses from "FAIL" to "PASS" ((b) Different Word-line)

3.5. SPI Data Protocol

DDRHSSPI supports Legacy (1-bit), Quad(4-bit) and Octal (8-bit) SPI protocols. The Quad and Octal Protocols are used for interfacing with Serial Flash Memories like Cypress FL-S series.

Legacy Protocol

The Legacy Protocol is a full-duplex protocol. When DDRHSSPI is configured with Legacy Protocol, the data can be received on a single input port (i.e. iDDRHSSPIn_SDATA[1]) and simultaneously, the data can also be transmitted on a single output port (i.e. oDDRHSSPIn_SDATA[0]). While Legacy Protocol is being used, the unused data lines (i.e. oDDRHSSPIn_SDATA[7:2]) are tri-stated by DDRHSSPI.

In Direct Mode, when DDRHSSPIn_DMTRP.TRP is configured for TX-and-RX Mode, it is allowed to use only the Legacy Mode.

In Command Sequencer Mode, the Legacy Protocol is not supported.

Quad Protocol

In Quad Protocol, four serial data lines (i.e. SDATA[3:0]) are used and SDATA[7:4] are tri-stated, in a half-duplex manner for accessing single device. Data transmission and reception cannot happen simultaneously.

In Direct Mode, when DDRHSSPIn_DMTRP.TRP is configured for "TX-Only in Quad Mode", the Quad Protocol is used.

In Command Sequencer Mode, the Quad Protocol is supported.

Octal Protocol

This feature is available only when DDRHSSPI_{IN}_MID.MID is 0x00000100 or 0x00000300.

In Octal Protocol, eight serial data lines (i.e. SDATA[7:0]) are used, in a half-duplex manner for accessing two Serial Flash Memories. Data transmission and reception cannot happen simultaneously.

In this mode DDRHSSPI is attached to two identical Flash Memories with 4 data bits each. Both of these memories also must be configured with same configuration parameters. In this mode, one memory will be attached to SDATA[3:0] and the other to SDATA[7:4]. These memories will be connected to the same SSEL signal.

The data transfer of Octal Protocol is classified as below.

- Dual Legacy

This transfer type is available only in Direct Mode (TX-Only Mode and TX-and-RX Mode). The output ports oDDRHSSPI_{IN}_SDATA[0] and oDDRHSSPI_{IN}_SDATA[4] are used at Legacy Protocol each. And the input ports iDDRHSSPI_{IN}_SDATA[1] and iDDRHSSPI_{IN}_SDATA[5] are used at Legacy Protocol each, as well. Please refer to Table 4-1 for more details.

- Dual Quad

This transfer type is available both in Direct Mode (TX-Only Mode) and Command Sequencer Mode. In Direct Mode, this transfer type is not available in TX-and-RX Mode. The output ports oDDRHSSPI_{IN}_SDATA[3:0] and oDDRHSSPI_{IN}_SDATA[7:4] are used at Quad Protocol each. And the input ports iDDRHSSPI_{IN}_SDATA[3:0] and iDDRHSSPI_{IN}_SDATA[7:4] are used at Quad Protocol each, as well. Please refer to Table 4-1 for more details. In Command Sequencer Mode, the value of address field is divided in half, since the data are located in each Serial Flash Memory at every 2 bytes.

3.6. Shift Direction

Most Significant Bit in the Shift Register is transmitted first and the first received data is shifted into the Least Significant Bit in the Shift Register. i.e. the Shift Register is shifted left. The read or write accesses to the data-registers always have Least Significant Bit of the data in bit 0.

The following figures Figure 4-7 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines. The waveforms assume DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH = 0b00 in Direct Mode. The Figures depict that the transmit data is loaded into the Shift Register from the TX-FIFO. However, the source of transmit data can be other registers, such as DDRHSSPI_{IN}_RDCSDC0-11.RDCSDATA.

When DDRHSSPI_{IN}_MID.MID is 0x00000100 or 0x00000300, DDRHSSPI is available for Dual Legacy Mode and Dual Quad Mode. Figure 3-14 and Figure 3-15 depict the direction in which the data in the Shift Register is shifted to/from the serial data lines, under Dual Legacy Mode and Dual Quad Mode.

In Command Sequencer Mode, byte ordering is always LSB first.

In Direct Mode, byte ordering is always MSB first.

Figure 3-9 Quad Mode / byte ordering - Command Sequencer Mode (RX Register - In Time)

Figure 3-11 Quad Mode / byte ordering - Direct Mode (RX Register - In Time)

Figure 3-12 Shift Direction (Legacy Mode and Quad Mode in Direct Mode) (Assumptions: DDRHSSPIn_DMFIFOCFG.FWIDTH= 0b00)

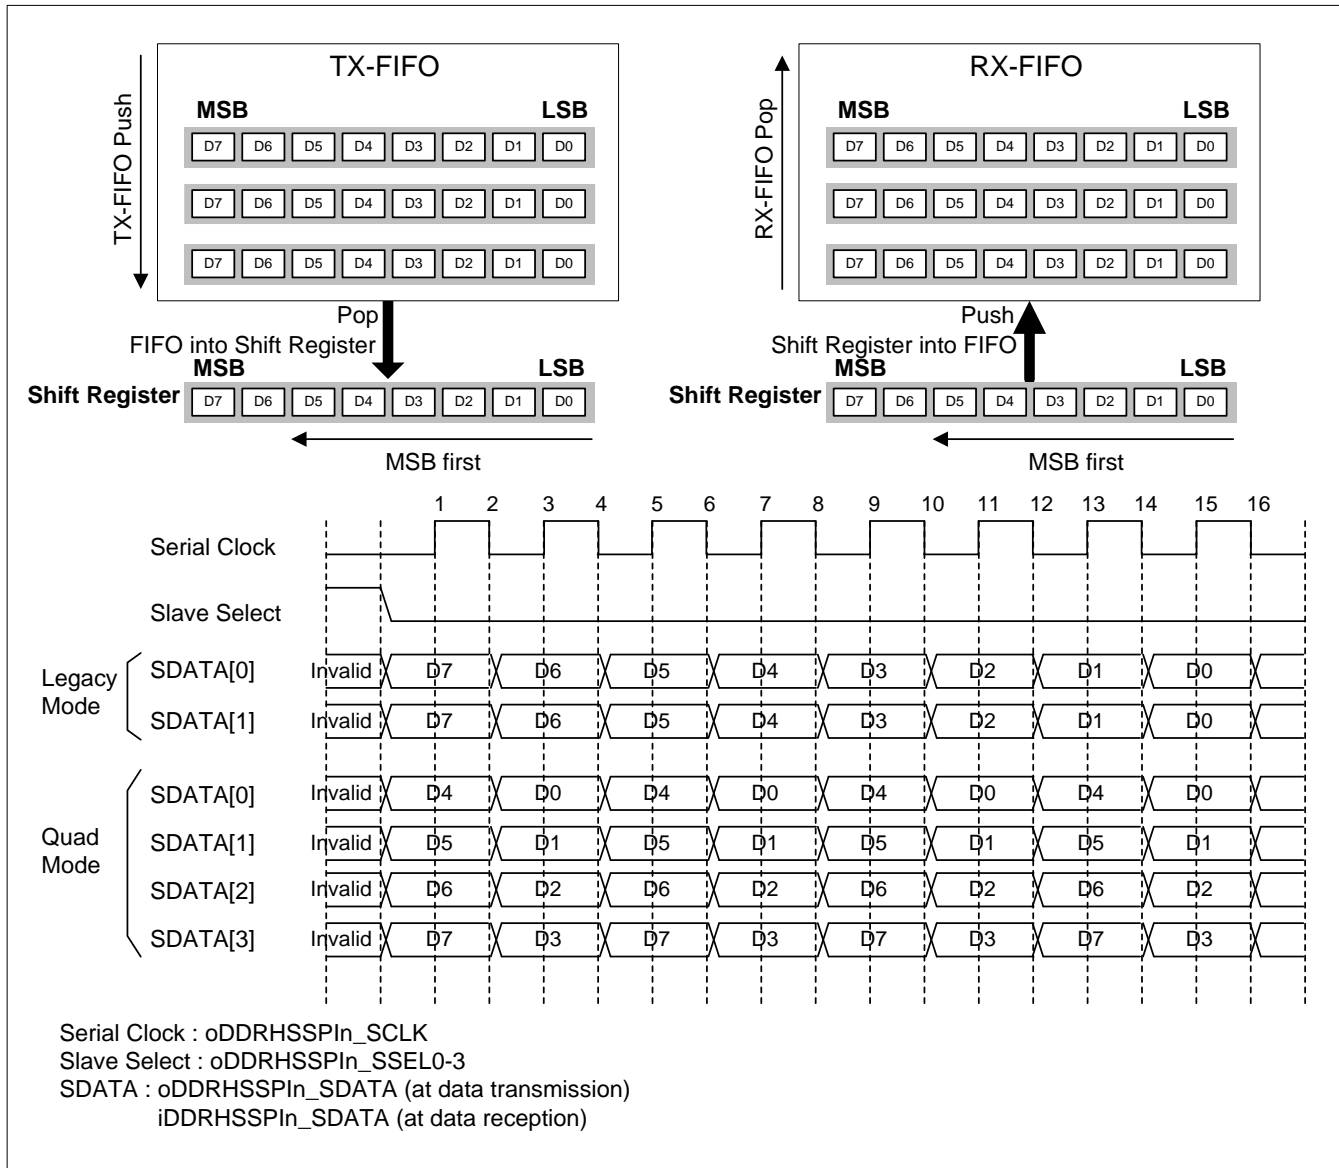

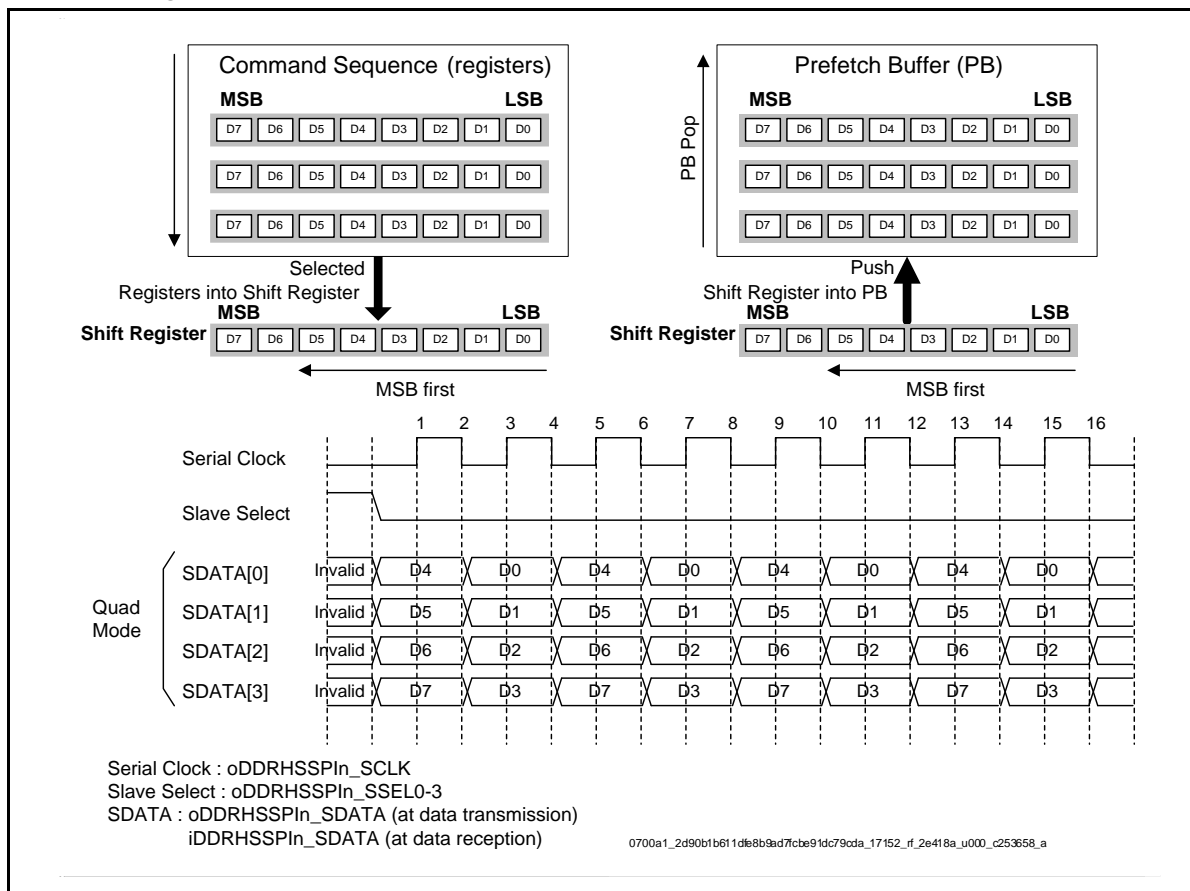

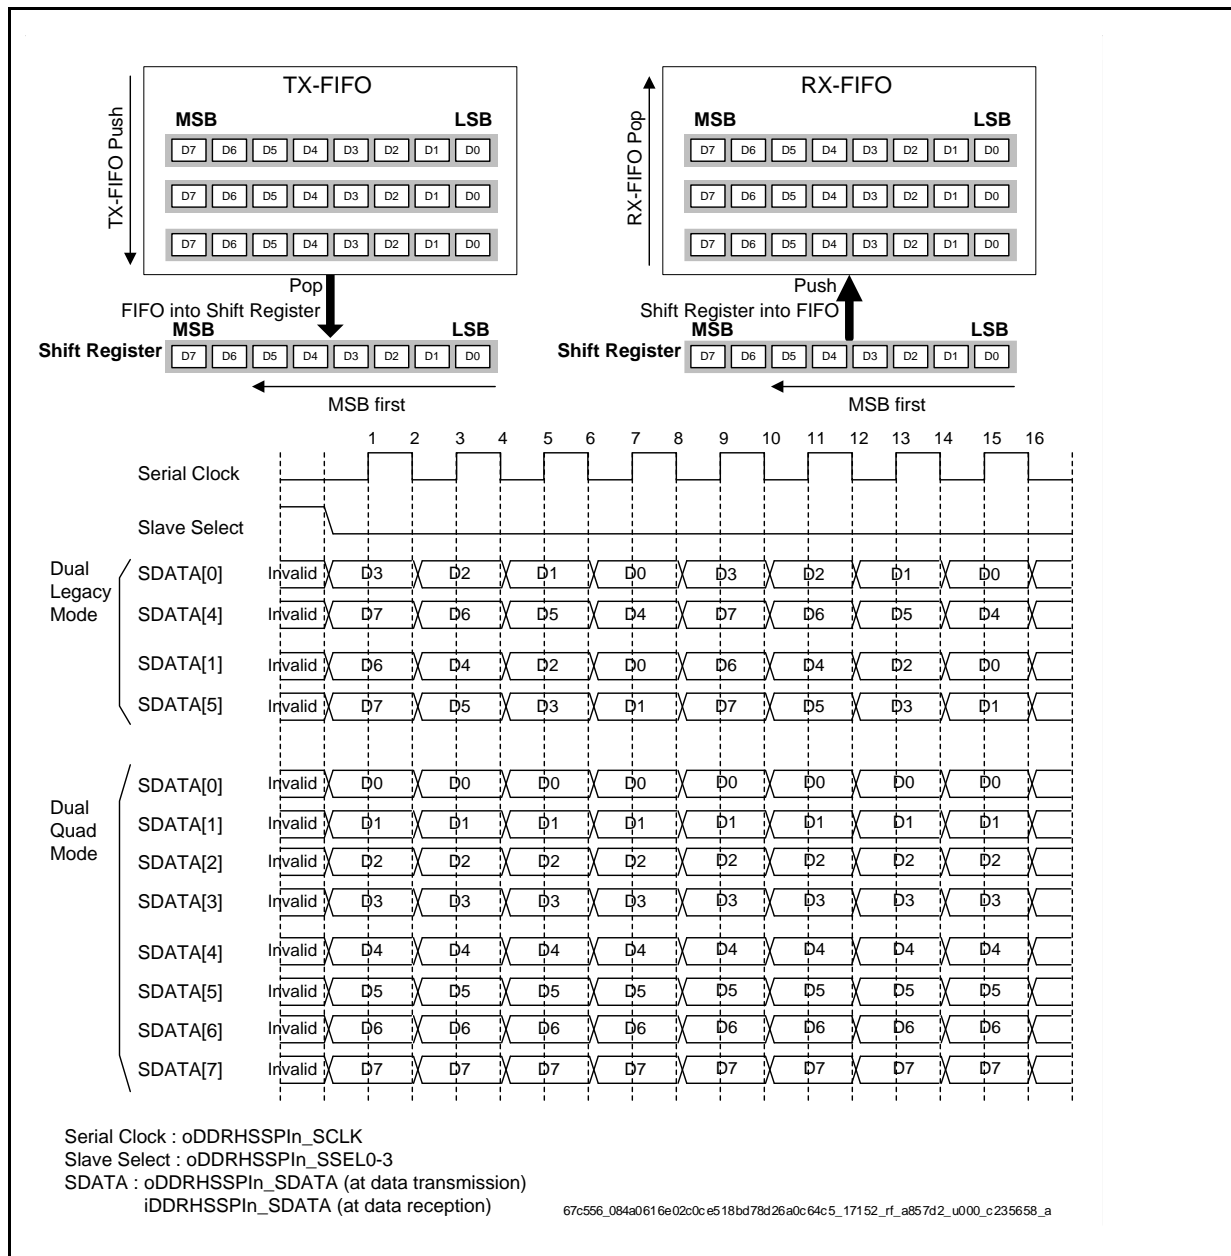

Figure 3-13 Shift Direction (Quad Mode in Command Sequencer Mode)

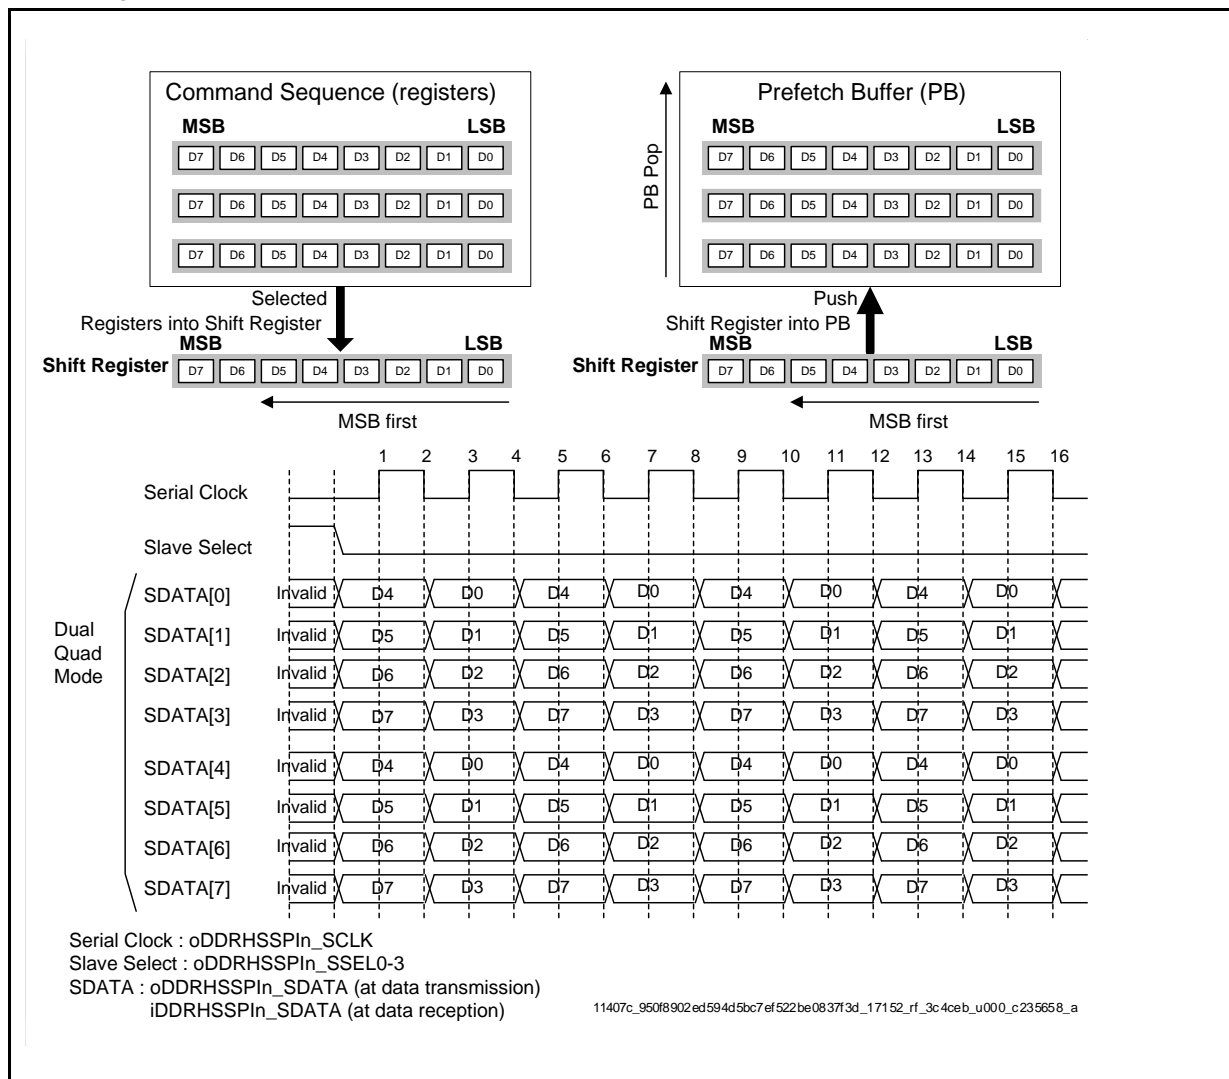

(Each line in the PB has 32-bit width, and this diagram is simplified by showing the lower 8 bits.)

Figure 3-14 Shift Direction (Dual Legacy Mode and Dual Quad Mode in Direct Mode) (Assumptions: DDRHSSPln_DMFIPOCFG.FWIDTH= 0b00)

Note:

- The bit alignment is different between TX and RX in Dual Legacy Mode. (Please refer to Table 4-1, and its TXCTRL="1" & TXDATA[12]="1" condition -> SDR mode.)

Figure 3-15 Shift Direction (Dual Quad Mode in Command Sequencer Mode)

(Each line in the PB has 32-bit width, and this diagram is simplified by showing the lower 8 bits.)

4. Operations of the DDRHSSPI

This section describes the operation of DDRHSSPI.

DDRHSSPI can be configured in one of the two operating modes: Direct Mode and Command Sequencer Mode.

In Direct Mode, the MCU can directly write data into the TX-FIFO to be transmitted to the Serial Flash Memory. Similarly, the MCU can directly read the data received from Serial Flash Memory, over the Serial Interface - from the RX-FIFO.

The SPI Core transfers the data to/from the FIFOs over the Serial Interface. The Direct Mode is described in section 4.1 Direct Mode. In Command Sequencer Mode, DDRHSSPI maps the external Serial Flash Memory onto the address space of the MCU.

In Command Sequencer Mode, only Flash Memory reads are supported. If the MCU (or any other master) initiates a System Bus transfer to access any of the mapped Serial Flash Memories, the DDRHSSPI initiates serial transfer for the corresponding memory read operation. Till the time DDRHSSPI accesses the external device, the System Bus transfer is stalled. The Command Sequencer Mode is described in section 4.2 Command Sequencer Mode.

If DDRHSSPI_{IN}.MID is 0x00000100 or 0x00000300, DDRHSSPI can be connected with up to 8 Serial Flash Memories. At the connection with 8 Serial Flash Memories, each of the 4 Slave Select outputs is connected with 2 Serial Flash Memories.

4.1. Direct Mode

In Direct Mode, the MCU (or the DMA controller) is responsible to directly control the serial transfer on the Serial Interface. Direct Mode of transfer can be enabled using the DDRHSSPI_{IN}.MCTRL.CSEN bit.

Direct Mode supports the following modes.

- TX-Only Mode

This is only to transmit data to serial interface, and supports Legacy Mode and Quad Mode. If DDRHSSPI_{IN}.MID is 0x00000100 or 0x00000300, Dual Legacy Mode and Dual Quad Mode are added. This mode supports both SDR and DDR, and is used in the following cases.

- (1) Mode setting of Serial Flash Memory
- (2) Page programming of Serial Flash Memory
- (3) Initiating Memory Read access to Serial Flash Memory

- TX-and-RX Mode

This is to receive data from serial interface with transmitting data (full-duplex), and supports Legacy Mode and Dual Legacy Mode. The transmission of one TX-FIFO level will involve receiving one RX-FIFO level. This mode does not support DDR, and is used in the following case.

- (1) Status reading from Serial Flash Memory

In Direct Mode, DDRHSSPI uses its internal TX-FIFO and RX-FIFO, for temporary storage of the data to be transmitted and the data received over the Serial Interface.

4.1.1. Internal FIFOs

In Direct Mode, DDRHSSPI internally has two FIFOs for temporary storage: One for the data to be transmitted (TX-FIFO) and one for the data to be received (RX-FIFO).

Based on whether the serial transfers in DDRHSSPI are configured as TX-Only Mode or TX-and-RX Mode in the DDRHSSPI_{IN}.DMTRP.TRP, only one or both FIFOs are used by DDRHSSPI. If DDRHSSPI

is configured for TX-Only Mode, the TX-FIFO is used. If DDRHSSPI is configured for TX-and-RX Mode, then both TX-FIFO and RX-FIFO are used.

4.1.2. FIFO Size

Each FIFO is 24-locations deep and has a data-width of 32 bits. However, the software can configure the valid data-width of the TX-FIFO and the RX-FIFO in DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH.

The Shift Register in the SPI Core is 32-bit wide. When the width of the FIFO is changed in the DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH, the usable width of the Shift Register also changes accordingly.

Please refer to Figure 4-1, for details.

Note:

- When the value of DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH is greater than 0, the value of DDRHSSPI_{IN}_DMBCC.BCC should be programmed along the boundary of bytes according to DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH, e.g. when FWIDTH is 0b11, the BCC should be a multiple of 4.

Figure 4-1 DDRHSSPI FIFO's in Direct Mode

In addition to the 32-bit of data-width, each location in TX-FIFO has a 33rd control bit (known as DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit), which decides whether

- the data from the TX-FIFO is to be transmitted by the SPI Core, OR
- the serial data lines are to be tri-stated.

4.1.3. TX-FIFO Control

If the DDRHSSPIn_DMFIPOCFG.TXCTRL bit is set to "1", the DDRHSSPI further decodes the bits[12:11] of the data in the corresponding TX-FIFO location. All possible value combinations of the DDRHSSPIn_DMFIPOCFG.TXCTRL bit and the bits[12:11] of TX-FIFO data (DDRHSSPIn_TXFIFO0-23.TXDATA) are shown in Table 4-1.

Table 4-1 Serial Data Output Control

DDRHSSPIn_DMFIPOCFG.TXCTRL	Bit 12 of TX-FIFO Data (TXDATA[12])	Bit 11 of TX-FIFO Data (TXDATA[11])	Description
0	Don't Care	Don't Care	<p>Serial data output lines are neither tri-stated nor on-the-fly while transmitting the corresponding data. Data Rate Mode (SDR Mode or DDR Mode) and SPI data width (Legacy Mode, Quad Mode or Octal Mode) are as set in DDRHSSPIn_DMTRP Register. Plus, DDRHSSPIn_DMFIPOCFG.FWIDTH affects the valid bit field of TXDATA as below.</p> <p>(1) DDRHSSPIn_DMTRP.TRP[1:0] ≠ "11"</p> <p style="padding-left: 20px;">FWIDTH TRP[1:0] SDATA</p> <p style="padding-left: 20px;">0b00 0b00 TXDATA[7:0] will be sent on SDATA[0].</p> <p style="padding-left: 40px;">0b10 TXDATA[7:0] will be sent on SDATA[3:0].</p> <p style="padding-left: 20px;">0b01 0b00 TXDATA[15:8][7:0] will be sent on SDATA[0].</p> <p style="padding-left: 40px;">0b10 TXDATA[15:8][7:0] will be sent on SDATA[3:0].</p> <p style="padding-left: 40px;">(in the order of TXDATA[15:8]->[7:0], along the SCLK edge)</p> <p style="padding-left: 20px;">0b11 0b00 TXDATA[31:24][23:16][15:8][7:0] will be sent on SDATA[0].</p> <p style="padding-left: 40px;">0b10 TXDATA[31:24][23:16][15:8][7:0] will be sent on SDATA[3:0].</p> <p style="padding-left: 40px;">(in the order of TXDATA[31:24]->[23:16]->[15:8]->[7:0] along the SCLK edge)</p> <p>In TX-and-RX Mode, it supports only Legacy Mode. So, RX-FIFO receives data from SDATA[1].</p> <p>(2) DDRHSSPIn_DMTRP.TRP[1:0] = 0b11 (Only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300)</p> <p>(2-1) SDR Mode:</p> <p style="padding-left: 20px;">FWIDTH SDATA</p> <p style="padding-left: 20px;">0b00 TXDATA[7:4] will be sent on SDATA[7:4].</p> <p style="padding-left: 40px;">TXDATA[3:0] will be sent on SDATA[3:0].</p> <p style="padding-left: 20px;">0b01 TXDATA[15:12][7:4] will be sent on SDATA[7:4].</p> <p style="padding-left: 40px;">TXDATA[11: 8][3: 0] will be sent on SDATA[3:0].</p> <p style="padding-left: 40px;">(in the order of TXDATA[15:8]->[7:0], along the SCLK edge)</p> <p style="padding-left: 20px;">0b11 TXDATA[31:28][23:20][15:12][7:4] will be sent on SDATA[7:4].</p> <p style="padding-left: 40px;">TXDATA[27:24][19:16][11: 8][3:0] will be sent on SDATA[3:0].</p> <p style="padding-left: 40px;">(in the order of TXDATA[31:24]->[23:16]->[15:8]->[7:0] along the SCLK edge).</p> <p>(2-2) DDR Mode:</p> <p style="padding-left: 20px;">FWIDTH SDATA</p> <p style="padding-left: 20px;">0b00 Not allowed.</p> <p style="padding-left: 20px;">0b01 TXDATA[31:28][23:20] will be sent on SDATA[7:4].</p>

DDRHSSPIn_ DMFIFOCFG. TXCTRL	Bit 12 of TX-FIFO Data (TXDATA[12])	Bit 11 of TX-FIFO Data (TXDATA[11])	Description
			<p>TXDATA[27:24][19:16] will be sent on SDATA[3:0]. (in the order of TXDATA[31:24]->[23:16], along the SCLK edge)</p> <p>0b11 TXDATA[31:28][23:20][15:12][7:4] will be sent on SDATA[7:4]. TXDATA[27:24][19:16][11: 8][3:0] will be sent on SDATA[3:0]. (in the order of TXDATA[31:24]->[23:16]->[15:8]->[7:0] along the SCLK edge)</p> <p>When in TXCTRL= 0, DDRHSSPI cannot transfer data at Dual Legacy Mode, since the SPI protocol is controlled just by DDRHSSPIn_DMTRP.TRP. Therefore, TX-and-RX Mode is not available for Dual Legacy Mode under this condition.</p> <p>Common in (1) and (2): The actual valid byte lane of TXDATA varies according to the lower address bits for TX-FIFO, e.g. if FWIDTH= 0b00 AND HSIZE=0x0 AND HADDR[1:0]= 0b01, TXDATA[15:8] is valid instead of TXDATA[7:0].</p>
1	0	0	<p>Serial data output lines are tri-stated for defined number of SCLK cycles . The number of dummy cycles is defined in TXDATA[7:4] bits in following way: 0b0000: Serial data output lines are tri-stated for 1 SCLK cycle 0b0001: Serial data output lines are tri-stated for 2 SCLK cycles 0b1111: Serial data output lines are tri-stated for 16 SCLK cycles Please note that maximum number of dummy cycles programmed per one TX-FIFO entry, is limited to be equivalent to sending one TX-FIFO level (with defined DDRHSSPIn_DMFIFOCFG.FWIDTH).</p> <p>The length of dummy cycles is limited as below. [Max Dummy Cycles] = [Bits per 1 FIFO entry] / [Bits per 1 SCLK cycle] For example, under the following conditions:</p> <ul style="list-style-type: none"> - Quad Mode (by DDRHSSPIn_DMTRP.TRP[1:0]) - SDR data rate - number of dummy cycles is 4 - DDRHSSPIn_DMFIFOCFG.FWIDTH is 0b01 (16 bit-wide). <p>In this example, the number of dummy cycle is within the limit. If the number of dummy cycles is larger than 4 in this example, the output serial data will be tri-stated for only 4 SCLK cycles and the rest will be ignored.</p>

DDRHSSPIn_ DMFIFOCFG. TXCTRL	Bit 12 of TX-FIFO Data (TXDATA[12])	Bit 11 of TX-FIFO Data (TXDATA[11])	Description
1	1	Don't Care	<p>SDR Mode</p> <p>In SDR Mode (DDRHSSPIn_DMTRP.DDRM = 0), TXDATA[10] is ignored, and TXDATA[7:0] will be sent in SDR Mode, depending on TXDATA[9:8]:</p> <p>0b00: Legacy Mode</p> <ul style="list-style-type: none"> - If DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300 and DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), this works as Dual Legacy Mode, and a byte data will be sent as below (4 SCLK cycles): <ul style="list-style-type: none"> - TXDATA[7:4] will be sent on SDATA[4]. - TXDATA[3:0] will be sent on SDATA[0]. <p>On the RX side of TX-and-RX Mode, a byte data will be received as below (4 SCLK cycles):</p> <ul style="list-style-type: none"> - RXDATA[7:6] is received from {SDATA[5], SDATA[1]}. (1st cycle) - RXDATA[5:4] is received from {SDATA[5], SDATA[1]}. (2nd cycle) - RXDATA[3:2] is received from {SDATA[5], SDATA[1]}. (3rd cycle) - RXDATA[1:0] is received from {SDATA[5], SDATA[1]}. (4th cycle) <p>The actual valid byte lane of RXDATA varies according to the lower address bits for RX-FIFO, e.g. if FWIDTH= 0b00 AND HSIZE=0x0 AND HADDR[1:0]= 0b01, RXDATA[15:8] is valid instead of RXDATA[7:0].</p> <ul style="list-style-type: none"> - If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then TXDATA[7:0] will be sent in Legacy Mode (8 SCLK cycles) on SDATA[0]. On the RX side of TX-and-RX Mode, a byte data will be received from SDATA[1] (8 SCLK cycles). <p>0b01: Not allowed. 0b10: Quad Mode</p> <ul style="list-style-type: none"> - If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then TXDATA[7:0] will be sent in Quad Mode (2 SCLK cycles) on SDATA[3:0]. - If DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), then it is not allowed to set TXDATA[9:8] to 0b10.

DDRHSSPIn_ DMFIFOCFG. TXCTRL	Bit 12 of TX-FIFO Data (TXDATA[12])	Bit 11 of TX-FIFO Data (TXDATA[11])	Description
1	1	Don't Care	<p>(Continued)</p> <p>0b11: Dual Quad Mode (Only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300)</p> <ul style="list-style-type: none"> – If DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), this works as Dual Quad Mode, and a byte data will be sent as below (1 SCLK cycles): <ul style="list-style-type: none"> – TXDATA[7:4] will be sent on SDATA[7:4]. – TXDATA[3:0] will be sent on SDATA[3:0]. – If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then it is not allowed to set TXDATA[9:8] to 0b11. <p>DDR Mode</p> <p>In DDR Mode (DDRHSSPIn_DMTRP.DDRM = 1), then the behavior depends on TXDATA[10]:</p> <p>(1)SDR on-the-fly</p> <p>If TXDATA[10] = 0, then TXDATA[7:0] will be sent same as SDR Mode above.</p> <p>(2)DDR on-the-fly</p> <p>If TXDATA[10] = 1, then the behavior depends on bits TXDATA[9:8]:</p> <p>0b00: Legacy Mode</p> <ul style="list-style-type: none"> – If DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), then it is not allowed to set TXDATA[9:8] to 0b00. – If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then TXDATA[7:0] will be sent in Legacy Mode (4 SCLK cycles) on SDATA[0]. <p>0b01: Not allowed.</p> <p>0b10: Quad Mode</p> <ul style="list-style-type: none"> – If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then TXDATA[7:0] will be sent in Quad Mode (1 SCLK cycles) on SDATA[3:0]. – If DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), then it is not allowed to set TXDATA[9:8] to 0b10. <p>0b11: Dual Quad Mode (Only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300)</p> <ul style="list-style-type: none"> – If DDRHSSPIn_DMTRP.TRP is configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]= 0b11), this works as Dual Quad Mode, and two bytes of data will be sent as below (1 SCLK cycles): <ul style="list-style-type: none"> – TXDATA[31:28][23:20] will be sent on SDATA[7:4]. – TXDATA[27:24][19:16] will be sent on SDATA[3:0]. (in the order of TXDATA[31:24]->[23:16] along the SCLK edge) – If DDRHSSPIn_DMTRP.TRP is not configured to Octal Mode (DDRHSSPIn_DMTRP.TRP[1:0]≠ 0b11), then it is not allowed to set TXDATA[9:8] to 0b11.

4.1.4. Available Command Formats of Serial Flash Memory

In order to apply to the command format of Serial Flash Memory, DDRHSSPI has the following features.

- Dynamic control of SPI Protocol
- Dynamic control of Data Rate Mode (SDR Mode or DDR Mode)
- Inserting dummy cycles

To realize these features, DDRHSSPI uses partial bits of TXDATA to control them. When DDRHSSPI_{DMFIFOCFG}.TXCTRL bit is "1", these features are available by decoding some bits of TXDATA. By this control, DDRHSSPI is capable of Serial Flash command formats shown in Table 4-2 and Table 4-3.

Note:

- When in writing TXDATA[12:8] for SPI control on-the-fly, it is allowed regardless the setting of DDRHSSPI_{DMFIFOCFG}.FWIDTH.

The available command formats of Serial Flash are different according to the value of DDRHSSPI_{MID}. MID bits.

(1)SDR (DDRHSSPI_{DMTRP}.DDRM= 0)

Table 4-2 The Available Serial Flash Command Format (SDR)

DDRHSSPI _{MID}		Command	Address	Mode (*1)	Dummy
0x0000 0001	0x0000 0100 or 0x00000 300				
Available	Available	Legacy (1byte)	none	none	none
Available	Available	Legacy (1byte)	Legacy (3 / 4bytes)	none / 1byte	none / greater than 0
Available	Available	Legacy (1byte)	Quad (3 / 4bytes)	none / 1byte	none / greater than 0
N/A	Available	Dual Legacy (1byte each)	none	none	none
N/A	Available	Dual Legacy (1byte each)	Dual Legacy (3 / 4bytes each)	none / 1byte each	none
N/A	Available	Dual Legacy (1byte each)	Dual Quad (3 / 4bytes each)	none / 1byte each	none / greater than 0

(*1)The "Mode" field is a control code following Address field, and the actual code of Mode field depends on the Serial Flash products.

(2)DDR (DDRHSSPI_{DMTRP}.DDRM= 1)

Table 4-3 The Available Serial Flash Command Format (DDR)

DDRHSSPIn_MID		Command	Address	Mode (*1)	Dummy
0x0000 0001	0x0000 0100 or 0x00000 300				
Available	Available	Legacy (1byte), SDR	Quad (3 / 4bytes), DDR	1byte, DDR	greater than 0
N/A	Available	Dual Legacy (1byte each), SDR	Dual Quad (3 / 4bytes each), DDR	1byte each, DDR	greater than 0

(*1)The "Mode" field is a control code following Address field, and the actual code of Mode field depends on the Serial Flash products.

For above Serial Flash command formats, DDRHSSPI supports the following SPI protocols on-the-fly.

Table 4-4 The Available Switching SPI Protocols On-the-Fly

DDRHSSPIn_MID		DDRHSSPIn_ DMTRP. TRP[1:0]	TXDATA[9:8] *1	Rx	Tx
0x0000 0001	0x0000 0100 or 0x00000 300				
Available	Available	0b00 (Legacy)	0b00 (Legacy)	SDATA[1]	SDATA[0]
N/A	N/A	0b00 (Legacy)	0b10 (Quad)	Not allowed	Not allowed
Available	Available	0b10 (Quad)	0b00 (Legacy)	SDATA[1]	SDATA[0]
Available	Available	0b10 (Quad)	0b10 (Quad)	Not allowed	SDATA[3:0]
N/A	Available	0b11 (Dual Quad)	0b00 (Dual Legacy)	SDATA[1], SDATA[5]	SDATA[0], SDATA[4]
N/A	Available	0b11 (Dual Quad)	0b10 (Quad)	Not allowed	Not allowed
N/A	Available	0b11 (Dual Quad)	0b11 (Dual Quad)	Not allowed	SDATA[7:0]

*1 With conditions of DDRHSSPIn_DMFIPOCFG.TXCTRL= 1 and TXDATA[12]= 1

4.1.5. FIFO Accesses in Direct Mode

Depending on the configured width of the FIFOs, 8-bit, 16-bit or 32-bit accesses are allowed to the DDRHSSPIn_RXFIFO0-23 and DDRHSSPIn_TXFIFO0-23 Registers.

If DDRHSSPIn_DMFIFOCFG.FWIDTH is set to 0b11 (32-bit wide mode), then only 32-bit access to the FIFO is allowed.

If DDRHSSPIn_DMFIFOCFG.FWIDTH is set to 0b01 (16-bit wide mode), then 16-bit and 32-bit accesses to the FIFO are allowed. A 32-bit access covers a whole word line for one FIFO entry. A 16-bit access with any alignment covers lower 16 bits of one FIFO entry.

If DDRHSSPIn_DMFIFOCFG.FWIDTH is set to 0b00 (8-bit wide mode), then 8-bit, 16-bit and 32-bit accesses to the FIFO are allowed. A 32-bit access covers a whole word line for one FIFO entry. A 16-bit access with any alignment covers lower 16 bits of one FIFO entry. An 8-bit access with any alignment covers the lower 8 bits of one FIFO entry.

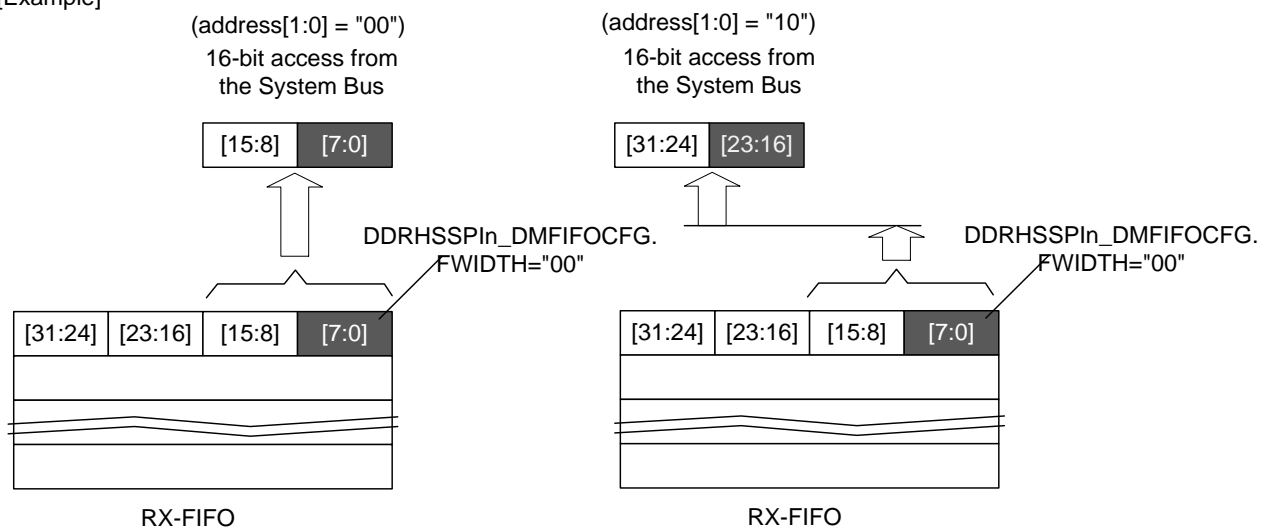

When in writing data into TX-FIFO (to any of DDRHSSPIn_TXFIFO0-23), the written data go along with DDRHSSPIn_DMFIFOCFG.TXCTRL bit, and they are written into TX-FIFO together. And when the data width is not a word size (32 bits), the data is aligned to the LSB, before written into TX-FIFO.

When the System Bus access is wider than RX-FIFO width (configured by DDRHSSPIn_DMFIFOCFG.FWIDTH), the width of read data follows FWIDTH value, and the read data is aligned to the LSB. Figure 4-2 shows this alignment and a notice of the System Bus address.

Figure 4-2 RX-FIFO Access at Greater Width

- The System Bus access wider than FIFO width is allowed.
- The read data less than 32-bit wide is aligned to the LSB.

[Example]

When the System Bus access is wider than TX-FIFO width (at DDRHSSPIn_DMFIFOCFG.TXCTRL= 0), it is allowed as well. In this case, the valid byte lane follows the System Bus address, as shown in Figure 4-3.

Figure 4-3 TX-FIFO Access at Greater Width (DDRHSSPIn_DMFIFOCFG.TXCTRL= 0)

When in DDRHSSPIn_DMFIFOCFG.TXCTRL= 1, the setting of DDRHSSPIn_DMFIFOCFG.FWIDTH is ignored at writing into TX-FIFO, and up to 32 bits could be relevant. (For details, please refer to the Table 4-1).

4.1.6. Service Requests

When operating in Direct Mode, Interrupt Service Requests to the MCU are triggered based on the current fill-levels of the TX-FIFO and the RX-FIFO, and their configured threshold values. Alternatively, the external DMA controller can be used for data transfers. When operating in Direct Mode, the DDRHSSPI has an interface with the DMA controller in the MCU for block transfers of data to/from its TX-FIFO and the RX-FIFO.

Interrupt flags are set when the current SPI transfer finishes.

Assertion of Interrupt Service Requests Based on FIFO Levels

The fill levels of both FIFOs are accessible from the system on the DDRHSSPIn_DMFIFOSTATUS.TXFLEVEL and the DDRHSSPIn_DMFIFOSTATUS.RXFLEVEL. The Interrupt Service Requests are generated by the DDRHSSPI based on (1)the FIFO fill levels and (2)their threshold values configured by the MCU.

- The DDRHSSPIn_TXF.TFLETS is set if the DDRHSSPIn_DMFIFOSTATUS.TXFLEVEL is less than or equal to DDRHSSPIn_DMFIFOCFG.TXFTH.

- The DDRHSSPI_{IN}_RXF.RFMTS is set if DDRHSSPI_{IN}_DMFIFOSTATUS.RXFLEVEL is greater than DDRHSSPI_{IN}_DMFIFOCFG.RXFTH.
- The DDRHSSPI_{IN}_TXF.TFES is set if the DDRHSSPI_{IN}_DMFIFOSTATUS.TXFLEVEL is 0, i.e. TX-FIFO is empty.
- The DDRHSSPI_{IN}_RXF.RFFS is set if the DDRHSSPI_{IN}_DMFIFOSTATUS.RXFLEVEL is 24, i.e. RX-FIFO is full. If the DDRHSSPI is configured for TX-Only operation, the RX-FIFO is not used.

Assertion of DMA Service Requests Based on FIFO Levels

The DDRHSSPI supports block transfer mechanism in the DMA controller. The DMA Service Requests are generated by the DDRHSSPI based on (1)the FIFO fill levels and (2)their threshold values configured by the MCU. To keep track of the number of successful data transfers to/from the TX-FIFO and/or the RX-FIFO, the DDRHSSPI internally uses two down-counters: the DDRHSSPI RX Block Counter and the DDRHSSPI TX Block Counter. Each of these counters is a 5 bits down counter, which is reloaded with the DMA Block size (for the respective channel) each time the DMA Service Request for that channel is asserted. The counters are decremented with every successful read or write accesses to the RX-FIFO or TX-FIFO. In case of the RX-FIFO accesses, the RX Block Counter is decremented unless the access was from the DAP Controller. The block counters do not underflow (i.e. the counter value remains 0 even if it is decremented while it is already 0).

DMA Write Channel has DDRHSSPI_{IN}_FAULTF.DWCBSFS bit, and DMA Read Channel has DDRHSSPI_{IN}_FAULTF.DRCBSFS bit. A DMA Block Size Fault is triggered if all of the following conditions are satisfied:

- The DMA Block Counter is decremented (due to a valid System Bus access) while it is already 0, AND
- DDRHSSPI_{IN}_DMAEN.RXDMAEN or DDRHSSPI_{IN}_DMAEN.TXDMAEN for the corresponding DMA Channel is "1", AND
- DDRHSSPI_{IN}_MCTRL.MES= 1, AND
- DDRHSSPI_{IN}_MCTRL.CSEN= 0

The DMA Read Channel must be setup to perform a block transfer of "DDRHSSPI_{IN}_DMFIFOCFG.RXFTH + 1" transfers. The DMA Write Channel must be setup to perform a block transfer of "24 - DDRHSSPI_{IN}_DMFIFOCFG.TXFTH" transfers. These values are reloaded into the DDRHSSPI's internal Block Counters, each time the DMA Service Request is asserted.

The DMA Block Counter is cleared to "0" in either of the following conditions:

- The corresponding DMA channel is disabled (in DDRHSSPI_{IN}_DMAEN Register), OR
- DDRHSSPI_{IN}_MCTRL.MES= 0, OR
- The mode of operation is switched from Direct Mode to Command Sequencer Mode.

The RX DMA Service Request (for the DMA Read Channel) is asserted if all of the following conditions are satisfied:

- DDRHSSPI_{IN}_DMFIFOSTATUS.RXFLEVEL is more than DDRHSSPI_{IN}_DMFIFOCFG.RXFTH. This condition is the same as the DDRHSSPI_{IN}_RXF.RFMTS= 1, AND
- The DDRHSSPI RX Block Counter value is 0, AND

- The DMA Read Channel acknowledgement signal is de-asserted by the DMA controller, AND
- A previous DMA Read Service Request is not pending, AND
- DDRHSSPI DMAEN.RXDMAEN= 1, AND
- DDRHSSPI_FAULTF.DRCBSFS= 0, AND
- DDRHSSPI_MCTRL.MES= 1, AND
- DDRHSSPI_MCTRL.CSEN= 0, AND
- DDRHSSPI_DMTRP.TRP[3:2]= 0b00

The RX DMA Service Request (for DMA Read Channel) is de-asserted if any of the following conditions is satisfied:

- The DMA Read Channel Service Request has been acknowledged by the DMA controller, OR
- DDRHSSPI DMAEN.RXDMAEN= 0, OR
- DDRHSSPI_MCTRL.MES= 0, OR
- DDRHSSPI_MCTRL.CSEN="1"

The TX DMA Service Request (for DMA Write Channel) is asserted if all of the following conditions are satisfied:

- DDRHSSPI_DMFIHOSTATUS.TXFLEVEL is less than or equal to DDRHSSPI_DMFIHOSTATUS.TXFTH. This condition is the same as the DDRHSSPI_TXF.TFLETS= 1, AND
- The DDRHSSPI TX Block Counter value is 0, AND
- The DMA Write Channel acknowledgement signal is de-asserted by the DMA controller, AND
- The Previous DMA Write Service Request is not pending, AND
- DDRHSSPI DMAEN.TXDMAEN= 1, AND
- DDRHSSPI_FAULTF.DWCBSFS= 0, AND
- DDRHSSPI_MCTRL.MES= 1, AND
- DDRHSSPI_MCTRL.CSEN= 0, AND
- DDRHSSPI_DMTRP.TRP[2]= 0

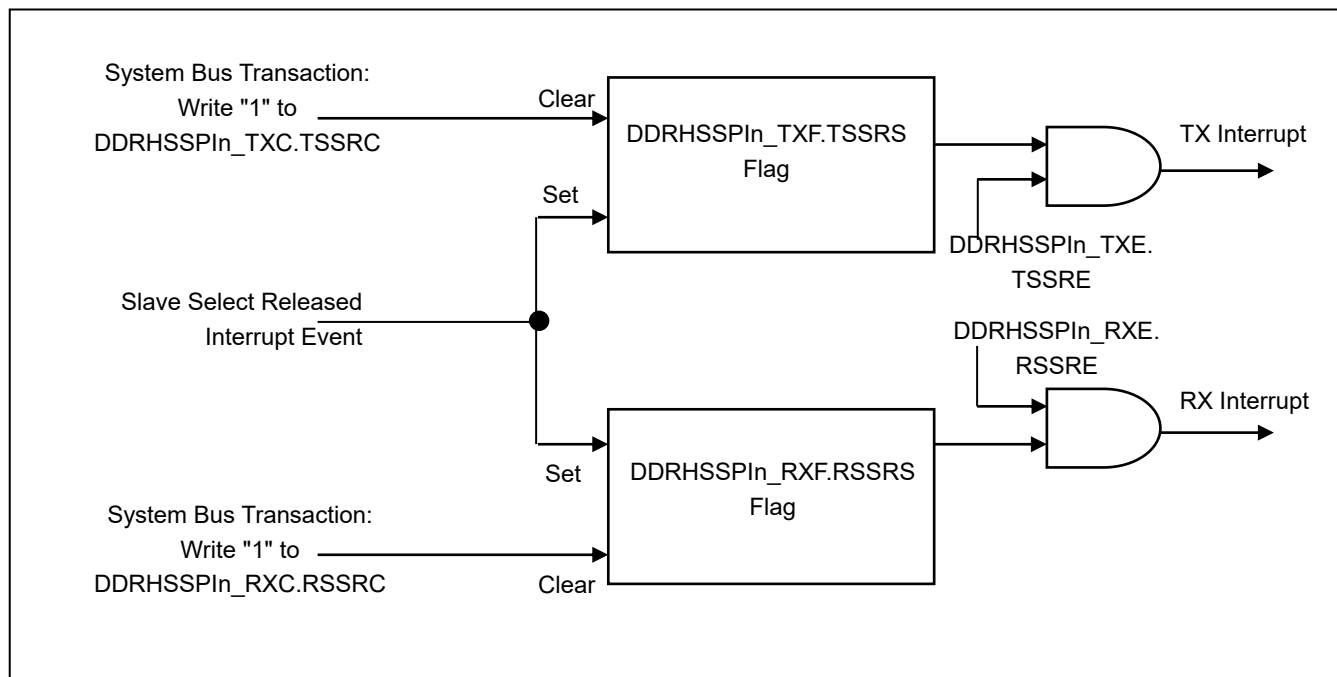

The TX DMA Service Request (for DMA Write Channel) is de-asserted if any of the following conditions is satisfied:

- The DMA Write Channel Service Request has been acknowledged by the DMA controller, OR
- DDRHSSPI DMAEN.TXDMAEN= 0, OR
- DDRHSSPI_MCTRL.MES= 0, OR
- DDRHSSPI_MCTRL.CSEN="1"

It is highly recommended that either value of DDRHSSPI_DMFIHOSTATUS.TXFTH or DDRHSSPI_DMFIHOSTATUS.RXFTH should not exceed 23.

Assertion of Service Requests on End of Transfer

While operating in Direct Mode, the DDRHSSPI also triggers interrupts when the Slave Select line is de-asserted. The Slave Select De-assertion event is routed onto two Interrupt Flags: DDRHSSPI_TXF.TSSRS and DDRHSSPI_RXF.RSSRS, which have individual Interrupt-Clear and Interrupt-Enable bits. The interrupt flags are routed onto individual Interrupt Signals. This logic is indicated in Figure 4-4.

Figure 4-4 Routing of the "Slave Select Released" Interrupt Event

4.1.7. SPI Transfers

The DDRHSSPI can initiate the transfers onto one of the four Slave Select lines, selected by the DDRHSSPIn_DMPSEL.PSEL. The following are major steps and other relevant information for initiating SPI transfers:

- Communication Attributes of the DDRHSSPI

Communication over the Serial Interface has several attributes, like: Frequency of the Serial Interface Clock, etc. These communication attributes should be same among Serial Flash Memories. When the DDRHSSPI is working in Direct Mode, it can be interfaced with up to 4 Serial Flash Memories at Legacy/Quad mode (8 at Dual Legacy/Dual Quad mode). These device-specific communication attributes can be configured in the DDRHSSPIn_PCC0-3 Registers in the CSR.
- Configuration parameter change

It is possible to switch between different bit widths and between SDR Mode and DDR Mode on-the-fly, without releasing the Slave Select line. However, it is up to the SW to take care of the timing of the switching from different SPI widths or clock modes so that data in TX-FIFO or RX-FIFO does not get lost or corrupted because of the switch.

The ability to change clock mode and access width on-the-fly is implemented in such way that the DDRHSSPI can support various Serial Flash Memories access protocols (such as command and address).
- Initiating the Serial Transfers:

When DDRHSSPIn_MCTRL.MES= 1 and DDRHSSPIn_MCTRL.CSEN= 0, serial transfers are initiated by DDRHSSPI when the DDRHSSPIn_DMSTART.START bit is set to "1".

If the DDRHSSPI_{IN}_DMTRP.TRP is programmed such that transmission is enabled, and if the TX-FIFO is empty when the DDRHSSPI_{IN}_DMSTART.START bit is set to "1"; then the DDRHSSPI delays the initiation of the serial transfer until the TX-FIFO is written by the software.

Byte Counter Mode is necessary for controlling the transfer length, and the DDRHSSPI_{IN}_DMBCS Register will be loaded with the value in DDRHSSPI_{IN}_DMBCC Register immediately when the DDRHSSPI_{IN}_DMBCC is written.

Once the DDRHSSPI_{IN}_DMSTART.START bit is set to "1", it cannot be reset by the software.

The DDRHSSPI resets the bit after it has finished the Serial Transfer.

Writing a "1" to the DDRHSSPI_{IN}_DMSTART.START bit while SSEL is asserted has no effect.

- Halting a transfer due to lack of TX-DATA or due to lack of RX-FIFO space:

In TX-Only Mode, an ongoing transfer can be halted by keeping the Slave Select asserted and by halting the Serial Clock. The DDRHSSPI automatically halts the Serial Clock, while it is waiting for the TX-FIFO to be written. The condition to halt a serial transfer in TX-Only Mode is as below.

- the TX-FIFO and the TX Shift Register are empty

And, when above condition is not satisfied while in halting, DDRHSSPI gets out of the halting status and resume the serial transfer (with starting the toggling of the Serial Clock).

In TX-and-RX Mode, halting of serial transfer must be avoided. The condition to halt a serial transfer is as below.

- the TX-FIFO and the TX Shift Register are empty, OR
- the RX-FIFO and the RX Shift Register are full

- Controlling the transfer length:

The transfer length is controlled as follows.

The MCU is supposed to initialize the DDRHSSPI_{IN}_DMBCC.BCC with the number of bytes to be transferred over the Serial Interface, before the Slave Select output is asserted. When the DDRHSSPI transfers are initiated, the DDRHSSPI counts the number of bytes that are transferred and releases the Slave Select line after the number of bytes indicated in DDRHSSPI_{IN}_DMBCC.BCC have been transferred.

When the value of DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH is greater than 0, the value of DDRHSSPI_{IN}_DMBCC.BCC should be a multiple of "DDRHSSPI_{IN}_DMFIFOCFG.FWIDTH + 1".

In TX-Only Mode, and SW sets number of dummy cycles more than 1 FIFO entry, the actual length of dummy cycles on the Serial Interface become same as 1 FIFO entry (the excessive number is ignored).

In TX-and-RX Mode, when transmitted data is for dummy cycles by

DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL= 1, the received data is input according to the dummy length.

Please refer to Table 4-1 for details. The length of dummy cycles shall not be more than 1 FIFO entry.

4.2. Command Sequencer Mode

In Command Sequencer Mode, the DDRHSSPI acts as an SPI master for interfacing with the external Serial Flash Memories. Each of the 4 Slave Select lines can be used for mapping uniform type of Serial Flash Memories such as Cypress FL-S series. Memory accesses initiated by the MCU and the other System Bus masters on the System Bus, are automatically converted to the Serial Flash Memory read commands by the DDRHSSPI.

This section describes the Command Sequencer Mode of the DDRHSSPI.

Notes:

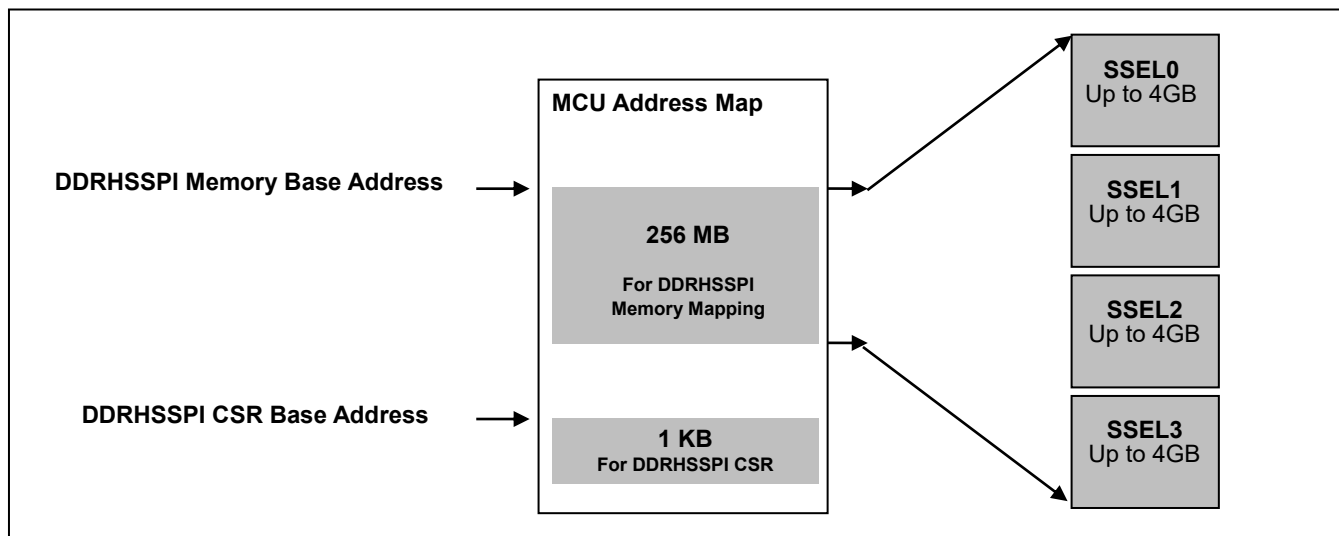

- *To use the Command Sequencer Mode, please make sure that the "Serial Flash" has a "Continuous Read Command Sequence", which skips the instruction bit field and starts with address field from the second SPI transaction. DDRHSSPI needs to work on the first SPI transaction at the Direct Mode (TX-Only Mode) to control the variable bit width on the SPI, and this feature covers the first SPI transaction. Then, the Command Sequencer Mode can be used from the second SPI transaction which continues from the first one. Since the first SPI transaction is controlled under TX-Only Mode, the read data from the Serial Flash are ignored in that transaction. Valid reading of Serial Flash is run at the Command Sequencer Mode.*
- *In memory reading, the bit width on the SPI from the address field should be constantly Quad (or Dual Quad).*

Memory Mapping

The Command Sequencer Mode can be used for memory mapping of up to 4 Slave Selects. All mapped Serial Flash Memories shall be of the same family and with the same internal configuration.

In Command Sequencer Mode, the DDRHSSPI allocates a memory space of 256MB, for mapping up to 4 external Serial Flash Memories. By using the Address Extension mechanism in Command Sequencer, each Slave Select can address a memory of up to 4GB (i.e. 32-bit address bus). The Address Extension mechanism allows concatenation of the most significant bits from a 19-bit Address Extension Register (i.e. the DDRHSSPI_{IN}_CSAEXT Register) with partial bits from the System Bus address, to form a 32-bit address to be accessed on each Slave Select. This feature is explained in detail in the subsequent sub-sections of this chapter.

Thus, the 256MB of the MCU address-space can virtually be mapped to the 16GB space of external Serial Flash Memories, as shown in Figure 4-5.

Figure 4-5 Mapping of Serial Flash Memories on the Slave Select Lines

Selection of Slaves

The `DDRHSSPIIn_CSCFG.MSEL` indicates the size of the System Bus address space associated with each Slave Select line.

Based on the value of the `DDRHSSPIIn_CSCFG.MSEL` and the address placed by the MCU (or the other System Bus Master, like the DMA Controller) on the System Bus, the DDRHSSPI Command Sequencer decides which of the 4 Slave Select lines is to be asserted. Please refer to Table 4-5 for details.

As an example, in case `DDRHSSPIIn_CSCFG.MSEL` indicates that the System Bus address space associated with each Slave Select is of 8KB. If the System Bus address is between "the DDRHSSPI Memory Base Address" and "the DDRHSSPI Memory Base Address + 8KB", then the Slave Select 0 is asserted. If the System Bus address is between "the DDRHSSPI Memory Base Address + 8KB" and "the DDRHSSPI Memory Base Address + 16KB", then the Slave Select 1 is asserted, and so on. If the System Bus Address is beyond "the DDRHSSPI Memory Base Address + 32KB", then the address is out of range and the `DDRHSSPIIn_FAULTF.UMAFS` flag is set.

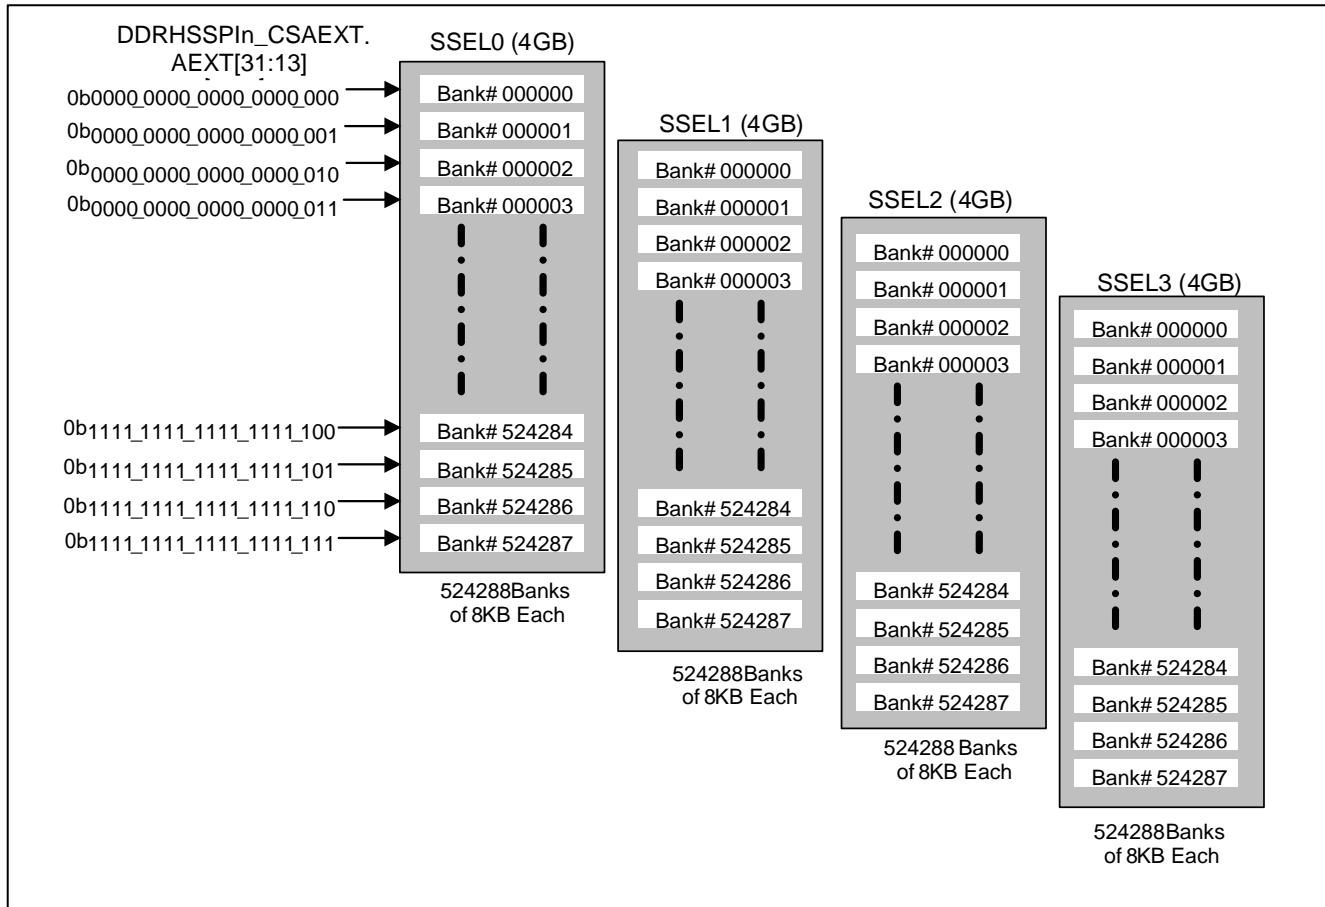

Even if the address of the System Bus access is in the valid range, if the target Slave Select is not set valid, the `DDRHSSPIIn_FAULTF.UMAFS` flag is set as well. For example, if `DDRHSSPIIn_CSCFG.SSEL0EN` is "0", any memory access corresponding to the Slave Select 0 ends up asserting an error of `DDRHSSPIIn_FAULTF.UMAFS = 1`.

Generation of 32-Bit Memory Address

The Address Extension Mechanism allows the MCU to access each Serial Flash Memory of a size of 4GB. Each Serial Flash Memory is accessible by dividing into several memory banks. The size of each bank can be programmed in the `DDRHSSPIIn_CSCFG.MSEL`. Each bank can be selected by changing the value in the `DDRHSSPIIn_CSAEXT` Register. To select a new bank, the software shall program a new value to the `DDRHSSPIIn_CSAEXT` Register. By switching banks, it is possible to address a Serial Flash Memory of 4GB size.

Please refer to Figure 4-6. It shows how each 4GB Serial Flash Memory consists of 524288 banks when the `DDRHSSPIIn_CSCFG.MSEL` is programmed to 0b0000.

Figure 4-6 Addressing 4GB Serial Flash Memories on Each Slave Select, Through Different Banks (DDRHSSPIn_CSCFG.MSEL= 0b0000)

The Least Significant Bits of the System Bus Address received by the DDRHSSPI on the System Bus are used as the offset within the bank selected by the Address Extension bits. The final 32-bit address on the SPI is generated by the following concatenation:

- Upper bits: Register bits DDRHSSPIn_CSAEXT.AEXT[31:m]
- Lower bits: Address on the System Bus[m-1:0]

(m = DDRHSSPIn_CSCFG.MSEL[3:0] + 13.)

For details, please refer to Table 4-5.

Table 4-5 MCU Address Space to Memory Address Mapping

DDRHSSPIn_CS CFG.MSEL	Size of a Memory Bank on Each Slave Select / Size of the System Bus Address Range Associated with Each Slave Select	Number of Slave Select Lines That can be Activated	Number of Bits Used from DDRHSSPIn_CSA EXT Register, for Selection of the Memory Bank on a Slave Select	Number of Bits Used from Address Bus for Addressing the Memory Location within a Bank
0000	8K Bytes	SSEL0, SSEL1, SSEL2 and SSEL3	AEXT[31:13]	HADDR[12:0]
0001	16K Bytes		AEXT[31:14]	HADDR[13:0]
0010	32K Bytes		AEXT[31:15]	HADDR[14:0]
0011	64K Bytes		AEXT[31:16]	HADDR[15:0]
0100	128K Bytes		AEXT[31:17]	HADDR[16:0]
0101	256K Bytes		AEXT[31:18]	HADDR[17:0]
0110	512K Bytes		AEXT[31:19]	HADDR[18:0]
0111	1M Bytes		AEXT[31:20]	HADDR[19:0]
1000	2M Bytes		AEXT[31:21]	HADDR[20:0]
1001	4M Bytes		AEXT[31:22]	HADDR[21:0]
1010	8M Bytes		AEXT[31:23]	HADDR[22:0]
1011	16M Bytes		AEXT[31:24]	HADDR[23:0]
1100	32M Bytes		AEXT[31:25]	HADDR[24:0]
1101	64M Bytes		AEXT[31:26]	HADDR[25:0]
1110	128M Bytes	SSEL0 and SSEL1 Only	AEXT[31:27]	HADDR[26:0]
1111	256M Bytes	SSEL0 Only	AEXT[31:28]	HADDR[27:0]

Last two columns in Table 4-5 indicate which bits from the DDRHSSPIn_CSAEXT.AEXT and the address bus (i.e. HADDR) are concatenated, to get the final 32-bit address of the Serial Flash Memory.

The output memory address on the SPI can be 32 or 24 bits according to the Serial Flash Memory products, and this is controlled by the register settings of DDRHSSPIn_RDCSDC0-11 (for details, refer to Table 4-6).

Internal Prefetch Buffer

In Command Sequencer Mode the DDRHSSPI internally has one Prefetch Buffer for a temporary storage of received data.

This Prefetch Buffer consists of 48 locations, 32-bit wide.

Prefetch Buffer shall support 32 bits, 16 bits and 8 bits reads using the following mechanism:

- When a byte or halfword is read at a random (non-sequential) address on the System Bus, the Command Sequence is generated with the address aligned to the word boundary, which covers the required data.
- In the actual Command Sequence in transmission, the two least significant address bits are fixed to "00" (i.e. these two bits from the System Bus are ignored).

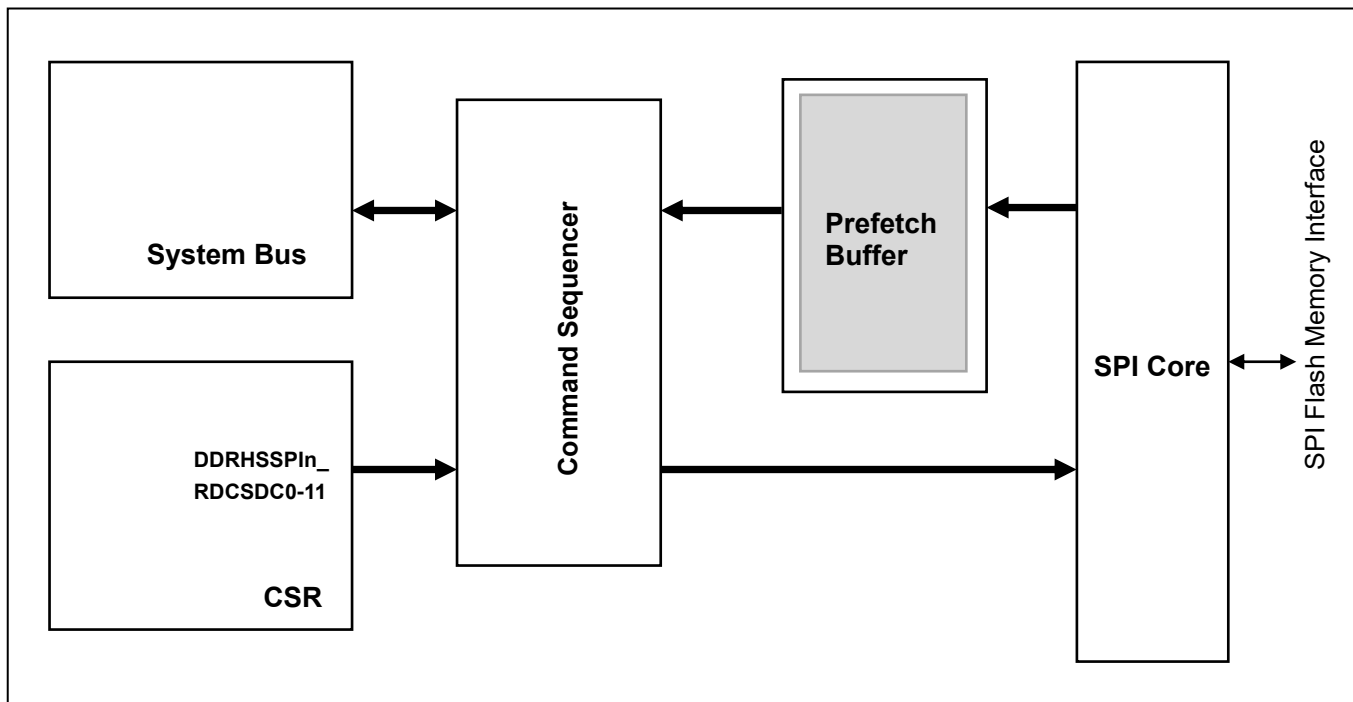

As long as the software reads a series of continuous data from the top most position of the Prefetch Buffer, there will be no additional Command Sequence on the SPI.

When the Prefetch Buffer is read, it internally works as a FIFO, and a word data in the next location pops out only when the current read data includes the last byte in the word line. The typical cases to pop the Prefetch Buffer are as below:

- When the whole aligned word is read, FIFO will be popped
- When the upper aligned halfword (word address + 2) is read, FIFO will be popped
- When the most significant byte (word address + 3) is read, FIFO will be popped
- In all other cases, FIFO will be read and will not be popped

In order to obtain the maximum throughput, word access (i.e. 32-bit access) is highly recommended.

Figure 4-7 DDRHSSPI in Command Sequencer Mode

In order to see if the requested data is already available on the top of the Prefetch Buffer, the SW can read the DDRHSSPIIn_CSPREFETCHADDR Register which keeps the first available address at the top of the Prefetch Buffer.

Initiation of Command Sequence

Whenever the Command Sequencer detects a System Bus read access for the memory mapped Serial Flash Memory, it initiates a corresponding Memory Read Command Sequence on the SPI, assembles the received data, and responds to the System Bus with the Memory Read data. The Command Sequencer Mode supports only Memory Read commands of Serial Flash Memory.

While the DDRHSSPI initiates a memory-read command and receives the read-data from the Serial Flash Memory, the DDRHSSPI inserts WAIT states on the System Bus. The DDRHSSPI keeps track of the previous address and the System Bus transfer type issued by the System Bus master. If the new transaction address is not contiguous, then a new serial transaction is issued on the Serial Interface.

Idle Timeout

After a Serial Flash Memory is accessed in the Command Sequencer Mode, the DDRHSSPI keeps asserting the Slave Select line even if the System Bus transaction is over. And DDRHSSPI can deassert the Slave Select automatically after waiting for a certain period of time. To use this feature, it is necessary to set DDRHSSPI_{IN}_CSCFG.ITIMEREN bit to "1".

If this feature is disabled, Slave Select remains asserted after any transfer on the Serial Flash Memory.

If this feature is enabled, the following part explains the Idle Timer behavior:

During idle cycles on the System Bus, DDRHSSPI continues reading the Serial Flash Memory until the prefetch Buffer reaches full. After reaching full, the Slave Select shall stay asserted, and the Idle Timer shall start running. If there are no subsequent System Bus accesses to the consecutive memory address during the programmed idle time, the DDRHSSPI deasserts the Slave Select after the Idle Timer expires. The deassertion of Slave Select indicates the termination of the transfer and flushes the Prefetch Buffer. If the consecutive memory read access resumes before the Idle Timer expires, the Idle Timer shall be cleared again. Within the predefined time period, defined by the DDRHSSPI_{IN}_CSITIME.ITIME, the DDRHSSPI determines whether to extend the current serial transaction. If the following conditions are satisfied:

- A new System Bus transaction is detected on the System Bus, AND
- The new address is contiguous with the previous transaction

the DDRHSSPI extends the current serial transfer, instead of initiating a new Command Sequence. Thus, it can reduce the access time on the Serial Interface.

If the following conditions are satisfied:

- There is a subsequent memory access during the idle time, AND
- The access is to a non-consecutive memory address, AND
- The requested read data is not ready on the top of the Prefetch Buffer

the DDRHSSPI de-asserts the Slave Select (indicating the termination of the current transfer), even before the Idle Timer expires. Then, the DDRHSSPI flushes the Prefetch Buffer and initiates a new Command Sequence.

Thus, the DDRHSSPI_{IN}_CSITIME.ITIME is used to enhance the overall performance of the memory accesses by extending the serial transaction for a programmed period.

The value of the DDRHSSPI_{IN}_CSITIME.ITIME is based on the System Bus Clock (iHCLK).

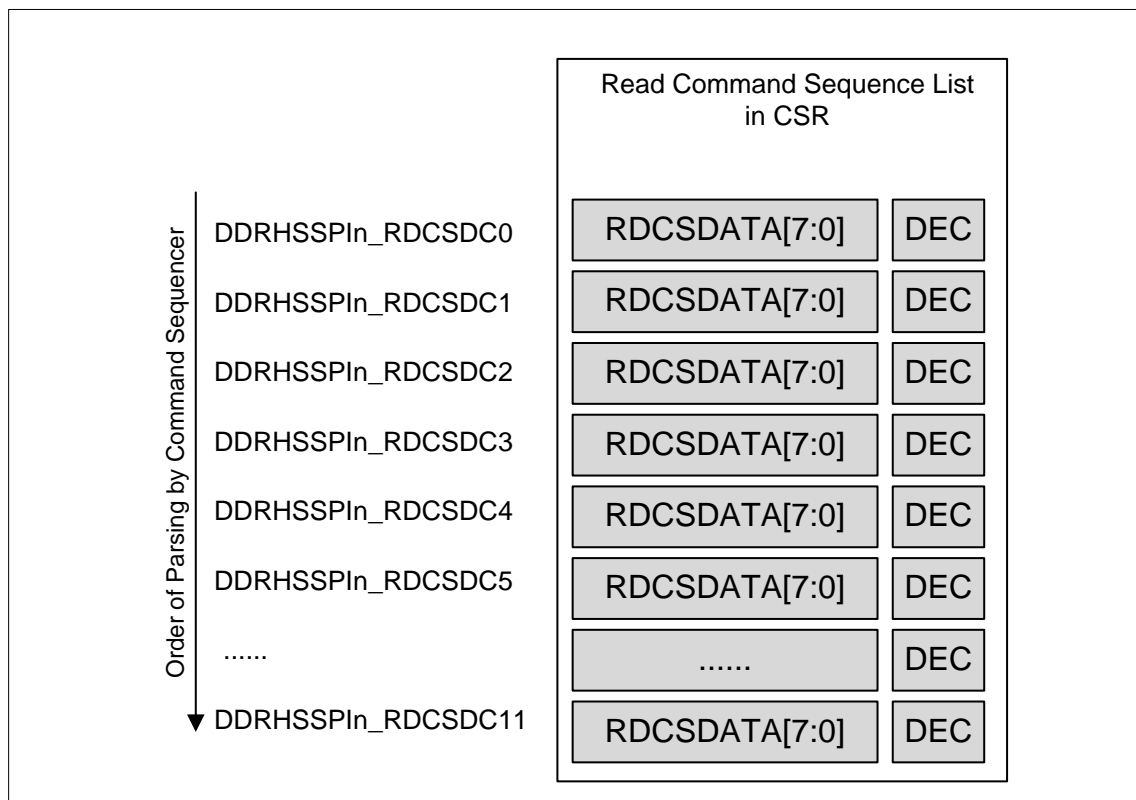

Configuration of Command Sequencer Mode in the CSR

The Command Sequencer supports memory read accesses. The sequence of command phases (i.e. command-phase, address-phase and data-phase) by the combination of Direct Mode and Command Sequencer Mode, is configured by the software (during initialization of the DDRHSSPI) in the CSR.

– Generation of Serial Flash Memory Read Command Sequence

For memory read transactions, the sequence of command phases (address-phase and data-phase) can be configured in the list of 12 registers: DDRHSSPIn_RDCSDC0-11. Starting from the DDRHSSPIn_RDCSDC0, up to the DDRHSSPIn_RDCSDC11 each of the 12 registers in the list is parsed. Please refer to Figure 4-8.

Figure 4-8 Memory Read Command Sequence List

The DEC bit in each of these registers determines whether to decode RDCSDATA[2:0] (as shown in Table 4-6). If DEC bit is "0", the data byte in RDCSDATA[7:0] is transmitted as it is.

Table 4-6 Decoding of the Read Command Sequence List

DEC	RDCSDATA [7:0]	Description
0	Don't Care	Transmit RDCSDATA[7:0] as it is.
1	0b00000000	Transmit address bits [7:0] of the Serial Flash Memory to be accessed
1	0b00000001	Transmit address bits [15:8] of the Serial Flash Memory to be accessed
1	0b00000010	Transmit address bits [23:16] of the Serial Flash Memory to be accessed
1	0b00000011	Transmit address bits [31:24] of the Serial Flash Memory to be accessed

DEC	RDCSDATA [7:0]	Description
1	0bXXXXX100	Dummy cycle(s). The bit field RDCSDATA [7:3] means the length of dummy cycles: SDATA[7:3]=0b000000 -> Generates 1 dummy cycle of the SCLK SDATA[7:3]=0b000001 -> Generates 2 dummy cycles of the SCLK Bits at "X" are for the value to control the length of dummy cycles.
1	0b00000111	End of List

The Command Sequencer switches to data-read cycles by the following conditions:

- If It gets "End of List", OR
- After the DDRHSSPIn_RDCSDC11 Register

In response to the System Bus Read transaction, during data-read cycles, the serial data on the SDATA lines is sampled, and the assembled data is returned to the System Bus master.

The actual patterns allowed in this Command Sequence List is limited in the following formats. This is based on using a Continuous Read Command Sequence, and the Command Sequence begins with Address field for the Serial FLASH Memory.

(1)24-bit Address

Table 4-7 Command Sequence List for 24-Bit Address

Register	RDCSDATA [7:0]	DEC	Description
DDRHSSPIn_RDCSDC0	0b00000010	1	address bits [23:16] of the Serial Flash Memory
DDRHSSPIn_RDCSDC1	0b00000001	1	address bits [15:8] of the Serial Flash Memory
DDRHSSPIn_RDCSDC2	0b00000000	1	address bits [7:0] of the Serial Flash Memory
DDRHSSPIn_RDCSDC3	byte data	0	Mode code *1
DDRHSSPIn_RDCSDC4	0bXXXXX100	1	Dummy cycles Bits at "X" are for the value to control the length of dummy cycles.
DDRHSSPIn_RDCSDC5	0b00000111	1	End of List

*1: The "Mode" field is a control code following Address field, and the actual code of Mode field depends on the Serial Flash products.

(2)32-bit Address

Table 4-8 Command Sequence List for 32-Bit Address

Register	RDCSDATA [7:0]	DEC	Description
DDRHSSPIn_ RDCSDC0	0b00000011	1	address bits [31:24] of the Serial Flash Memory
DDRHSSPIn_ RDCSDC1	0b00000010	1	address bits [23:16] of the Serial Flash Memory
DDRHSSPIn_ RDCSDC2	0b00000001	1	address bits [15:8] of the Serial Flash Memory
DDRHSSPIn_ RDCSDC3	0b00000000	1	address bits [7:0] of the Serial Flash Memory
DDRHSSPIn_ RDCSDC4	byte data	0	Mode code *1
DDRHSSPIn_ RDCSDC5	0bXXXXX100	1	Dummy cycles Bits at "X" are for the value to control the length of dummy cycles.
DDRHSSPIn_ RDCSDC6	0b00000111	1	End of List

*1: The "Mode" field is a control code following Address field, and the actual code of Mode field depends on the Serial Flash products.

The Operation of Memory Read Access

To perform memory read accesses to the Serial Flash Memories, it is necessary to run the following combination of Direct Mode and Command Sequencer Mode, because the Command Sequencer Mode cannot change SPI width on-the-fly.

1. Switch to Direct Mode, if it is in Command Sequencer Mode. Clear DDRHSSPIn_MCTRL.CSEN bit to "0".
2. Write a byte count of the transmission to the DDRHSSPIn_DMBCC.BCC. The byte count shall be a sum of command, address, and mode code. For example, if the address has 4 bytes, the BCC is 6.
3. Set the DDRHSSPIn_DMTRP.TRP to 0b1010 (TX-Only Mode and Quad Mode).
4. When in DDR Mode, set the DDRHSSPIn_DMTRP.DDRM bit to "1". Otherwise, clear the DDRHSSPIn_DMTRP.DDRM bit to "0".
5. Set the DDRHSSPIn_DMFIPOCFG.TXCTRL bit to "1".
6. Write a byte for the command field, into TX-FIFO. TXDATA[12] = 1, TXDATA[9:8] = 0b01 (Legacy Mode on-the-fly). TXDATA[10] = 0 (SDR Mode on-the-fly). TXDATA[7:0] is a byte for the command. Please refer to the data sheet of the Serial Flash Memory about the command code.
7. Write a byte for the address field [31:24], into TX-FIFO. TXDATA[12] = 1, TXDATA[9:8] = 0b10 (Quad Mode on-the-fly). TXDATA[10] = DDRHSSPIn_DMTRP.DDRM bit value. TXDATA[7:0] is a byte for the address[31:24].
8. Write bytes for the address field [23:16], [15:8] and [7:0] into TX-FIFO as well.
9. Write a byte for the mode field following the address field, into TX-FIFO. TXDATA[12] = 1, TXDATA[9:8] = 0b10 (Quad Mode on-the-fly). TXDATA[10] = DDRHSSPIn_DMTRP.DDRM bit value. TXDATA[7:0] is a byte for the mode. Please refer to the data sheet of the Serial Flash Memory about the mode code.
10. Write "1" to the DDRHSSPIn_TXC.TSSRC bit.

11. Set the DDRHSSPI_{IN}_TXE.TSSRE bit to "1".
12. Select a Serial Flash Memory by setting the DDRHSSPI_{IN}_DMPSEL.PSEL value.
13. Set the DDRHSSPI_{IN}_DMSTART.START bit to "1".
14. Wait for the TX Interrupt Request, or run a polling of DDRHSSPI_{IN}_TXF Register until the DDRHSSPI_{IN}_TXF.TSSRS bit to be "1".
15. Write "1" to the DDRHSSPI_{IN}_TXC.TSSRC bit.
16. Clear the DDRHSSPI_{IN}_TXE.TSSRE bit to "0".
17. Switch to Command Sequencer Mode. Set DDRHSSPI_{IN}_MCTRL.CSEN bit to "1".
18. Set the DDRHSSPI_{IN}_CSCFG.MBM same as DDRHSSPI_{IN}_DMTRP.TRP[1:0] value. Set DDRHSSPI_{IN}_CSCFG.MSEL to appropriate value. Set at least one of DDRHSSPI_{IN}_CSCFG.SSEL0EN, DDRHSSPI_{IN}_CSCFG.SSEL1EN, DDRHSSPI_{IN}_CSCFG.SSEL2EN or DDRHSSPI_{IN}_CSCFG.SSEL3EN to "1", in order to contain the Serial Flash Memory selected by DDRHSSPI_{IN}_DMPSEL.PSEL. Set DDRHSSPI_{IN}_CSCFG.DDRMODE bit same as DDRHSSPI_{IN}_DMTRP.DDRM bit.
19. Set the appropriate value to DDRHSSPI_{IN}_CSITIME.ITIME.
20. Set the appropriate value to DDRHSSPI_{IN}_CSAEXT.AEXT.
21. Write appropriate values to DDRHSSPI_{IN}_RDCSDC0-11 Registers according to Table 4-7 or Table 4-8.
22. Perform memory read accesses to the address where Serial Flash Memories are allocated. The memory accesses on the System Bus are translated to serial transactions on the Serial Interface.
23. As long as performing the memory read accesses, there is no need to change the register settings. When in issuing a new set of command, it is necessary to stop current Continuous Read Command Sequence. To stop it, go to the next step.
24. Operate steps from 1 to 16 in Direct Mode again to get out of current Continuous Read Command Sequence. In this operation, please write a different code from the step 9. About the exact code, please refer to the data sheet of the Serial Flash Memory about the mode code.
25. The SW can issue a new set of command.

Prefetch Memory Access in Command Sequencer Mode

After the DDRHSSPI is enabled and before the first access, no prefetch accesses to the Serial Flash Memory shall be performed. Once the first System Bus access is completed and if there are no new System Bus requests, the DDRHSSPI will initiate the continuous prefetch Flash Memory reads, on the Serial Interface until the Prefetch Buffer reaches full.

When there is a memory read access on the System Bus, either of two scenarios in below is expected.

a) Prefetch Buffer miss

In case of a Prefetch Buffer miss, this means that the address requested at the System Bus transaction is not same as the one available on the top of the Prefetch Buffer. This address is also readable at the DDRHSSPI_{IN}_CSPREFETCHADDR Register.

In this case, the following sequence occurs:

1. A Prefetch Buffer miss is detected
2. The Prefetch Buffer is flushed
3. A new Command Sequence to the Serial Flash Memory is generated, with a new aligned address

b) Prefetch Buffer hit

In case of a Prefetch Buffer hit, this means that the address requested at the System Bus transaction is same as the one available on the top of the Prefetch Buffer. In this case, the DDRHSSPI can immediately respond with valid data on the System Bus.

In both scenarios, a) and b), when the Prefetch Buffer is full, the SCLK will be halted and the Slave Select will work according to the following conditions.

- DDRHSSPI_{IN}_CSCFG.ITIMEREN bit = 1: The Slave Select will be released after the Idle Timer expires.
- DDRHSSPI_{IN}_CSCFG.ITIMEREN bit = 0: The Slave Select will remain asserted.

In general, PB keeps its content as long as it is not flushed or popped.

There is difference in terms for PB pop and PB read as below:

- PB pop:
Access to the PB top word results in reading-and-popping PB (as FIFO).
The internal read pointer of PB increments.
- PB read:
Access to the PB top word results in just reading.
The internal read pointer of PB does not increment.

When in reading PB, if the last byte of a word on the PB top is read, it causes a PB pop, otherwise it causes a PB read. The position of the last byte depends on the access width on the System Bus.

4.3. Address Map of DDRHSSPI

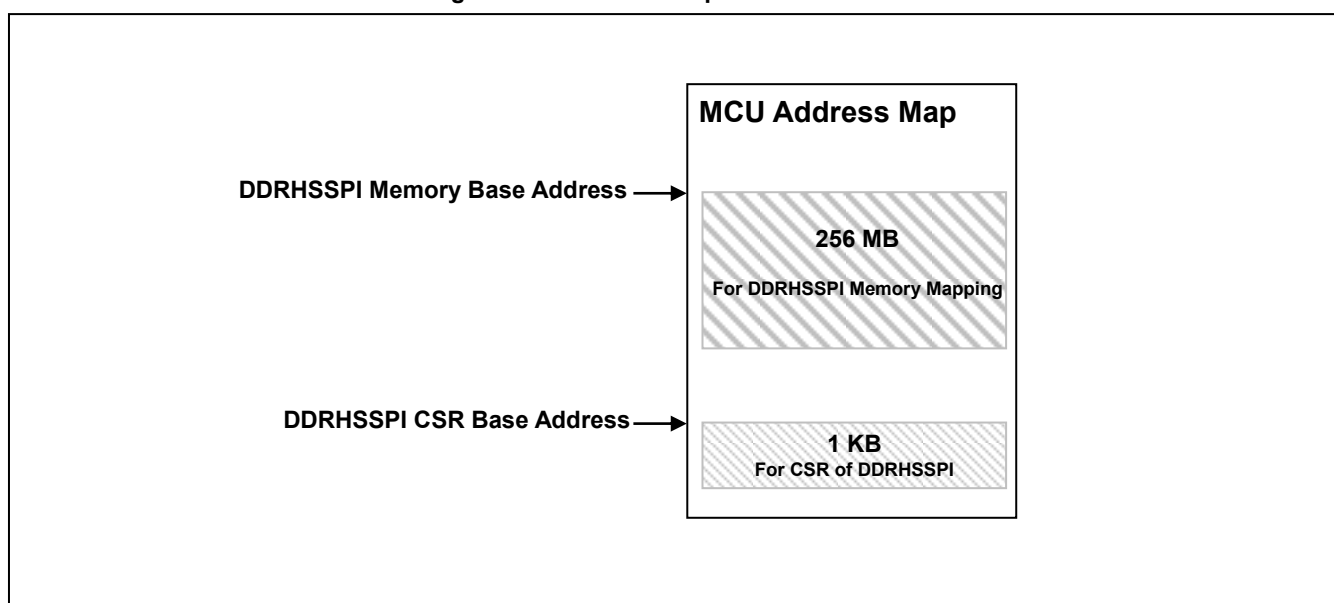

With DDRHSSPI, a memory area of 256MB is allocated in the MCU's address space. This memory area is mapped to the external Serial Flash Memories, using Command Sequencer Mode. An additional 1KB of MCU's address space is mapped to the internal Configuration and Status Registers (i.e. CSRs) of the DDRHSSPI.

The address area allocated to the DDRHSSPI is explained in this section.

Arrangement of DDRHSSPI Address Space in Memory

Figure 4-9 shows the allocation of DDRHSSPI address space in the MCU's address space.

Figure 4-9 Address Map of DDRHSSPI

4.4. General Use Case Guidelines for DDRHSSPI

This section lists up the guidelines for programming the DDRHSSPI. It is strongly recommended to read these guidelines before programming.

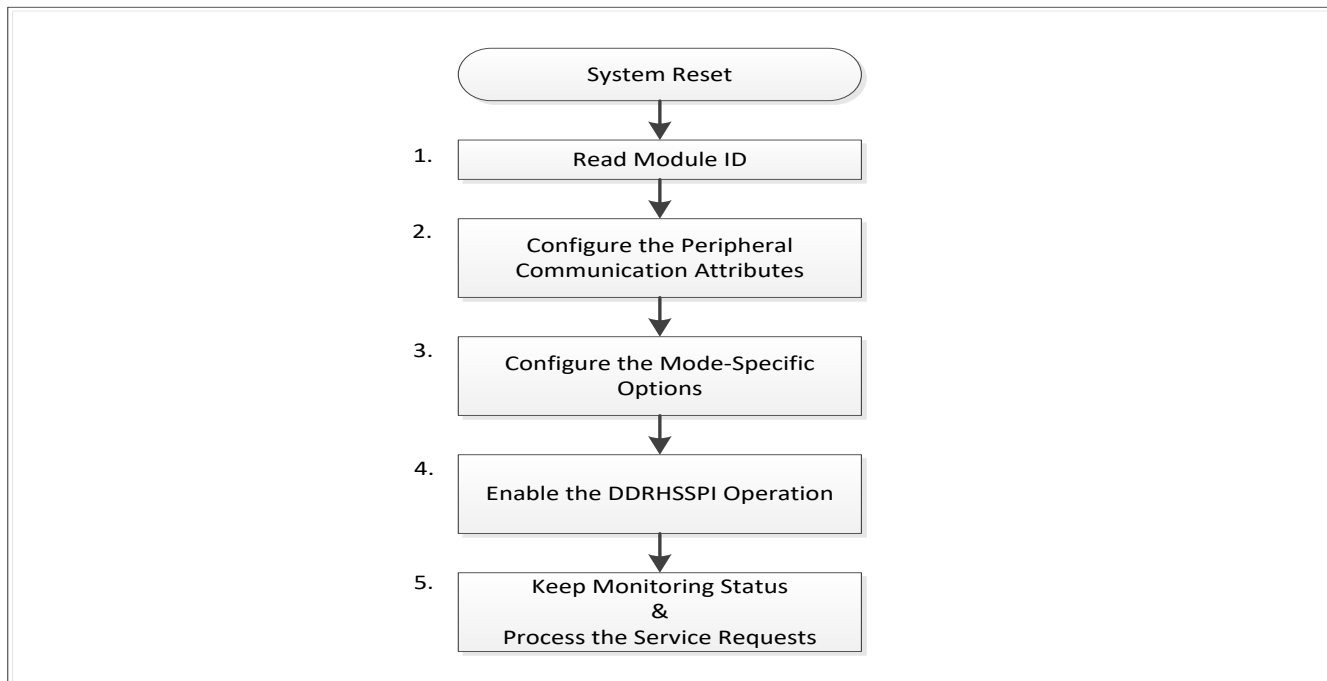

4.4.1. Guidelines on Typical Use Cases of DDRHSSPI

- Any serial-transaction-related parameters and control bits (DDRHSSPI_{IN}_DMCFG, DDRHSSPI_{IN}_DMBCC, DDRHSSPI_{IN}_DMBCS, DDRHSSPI_{IN}_DMTRP, DDRHSSPI_{IN}_DMPSEL and DDRHSSPI_{IN}_DMFIFOCFG) should not be changed while a serial transaction is in progress. Any such changes should be performed only after the current serial transfer has ended (i.e. DDRHSSPI_{IN}_TXF.TSSRS= 1 or DDRHSSPI_{IN}_RXF.RSSRS= 1). To ensure that the DDRHSSPI has finished all of its transfers, the software can read the DDRHSSPI_{IN}_DMFIFOSTATUS.SSACTIVE.
- Direct Mode and Command Sequencer Mode have different configurations of the FIFO, which is the common resource in DDRHSSPI. Hence, when switching from one mode to another, all FIFO data will be lost.
- When the Serial Flash Memory has a command format with changing SPI protocols, DDRHSSPI supports it by Direct Mode. In the Direct Mode, it can transfer the initial set of byte(s) in Legacy Mode using SDR clock, and then transfer the remaining sets of data bytes using the Quad Mode. In such cases, software needs to use DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit and write TX-FIFO data with additional control such as Data Rate Mode (SDR Mode or DDR Mode) and SPI data width (Legacy Mode, Quad Mode or Octal Mode). Thus, for example, it is possible to transmit the first byte in Legacy Mode with SDR clock, and the following bytes in Quad Mode with DDR clock.
- When Direct Mode is used, the software shall be responsible to take care that the internal FIFOs of DDRHSSPI do not get overrun or underrun. In case the FIFOs get overrun or underrun, the FIFO fill-levels (i.e. DDRHSSPI_{IN}_DMFIFOSTATUS.TXFLEVEL and DDRHSSPI_{IN}_DMFIFOSTATUS.RXFLEVEL) are no longer pertinent and the software would have to flush the FIFOs.
- The DDRHSSPI_{IN}_DMFIFOCFG.RXFLSH and DDRHSSPI_{IN}_DMFIFOCFG.TXFLSH bits shall be used by the software to flush the corresponding FIFOs and Shift Registers before using them for any serial transfer. Flushing a FIFO and Shift Registers ensures that they are not pre-loaded with any garbage data (possibly from the previous transfer).
- In Direct Mode with TX-and-RX Mode, whenever the transfer ends, the data from the RX Shift Register is pushed into the RX-FIFO; provided that the RX-FIFO is not full.
 - If the RX-FIFO is already full while a serial transfer is terminating, the serial transfer halts and the RX Shift Register holds the last data as long as DDRHSSPI is halted. As soon as the RX-FIFO is not full anymore, DDRHSSPI comes out of the halt state and the data in the RX Shift Register is pushed into the RX-FIFO before DDRHSSPI releases the Slave Select line. The last data is pushed into the RX-FIFO irrespective of whether the RX Shift Register is filled completely or partially. Thus, in Direct Mode, the received data never remains in the RX Shift Register.
 - In Direct Mode when DDRHSSPI is configured in SDR Mode (when DDRHSSPI_{IN}_DMTRP.DDRM bit is set to "0"), it is not allowed to switch to DDR Mode while module is enabled.

4.4.2. Steps in Programming the DDRHSSPI Module

Figure 4-10 gives the general steps a programmer shall follow while using the DDRHSSPI.

Figure 4-10 Programmer's Flowchart: General Steps

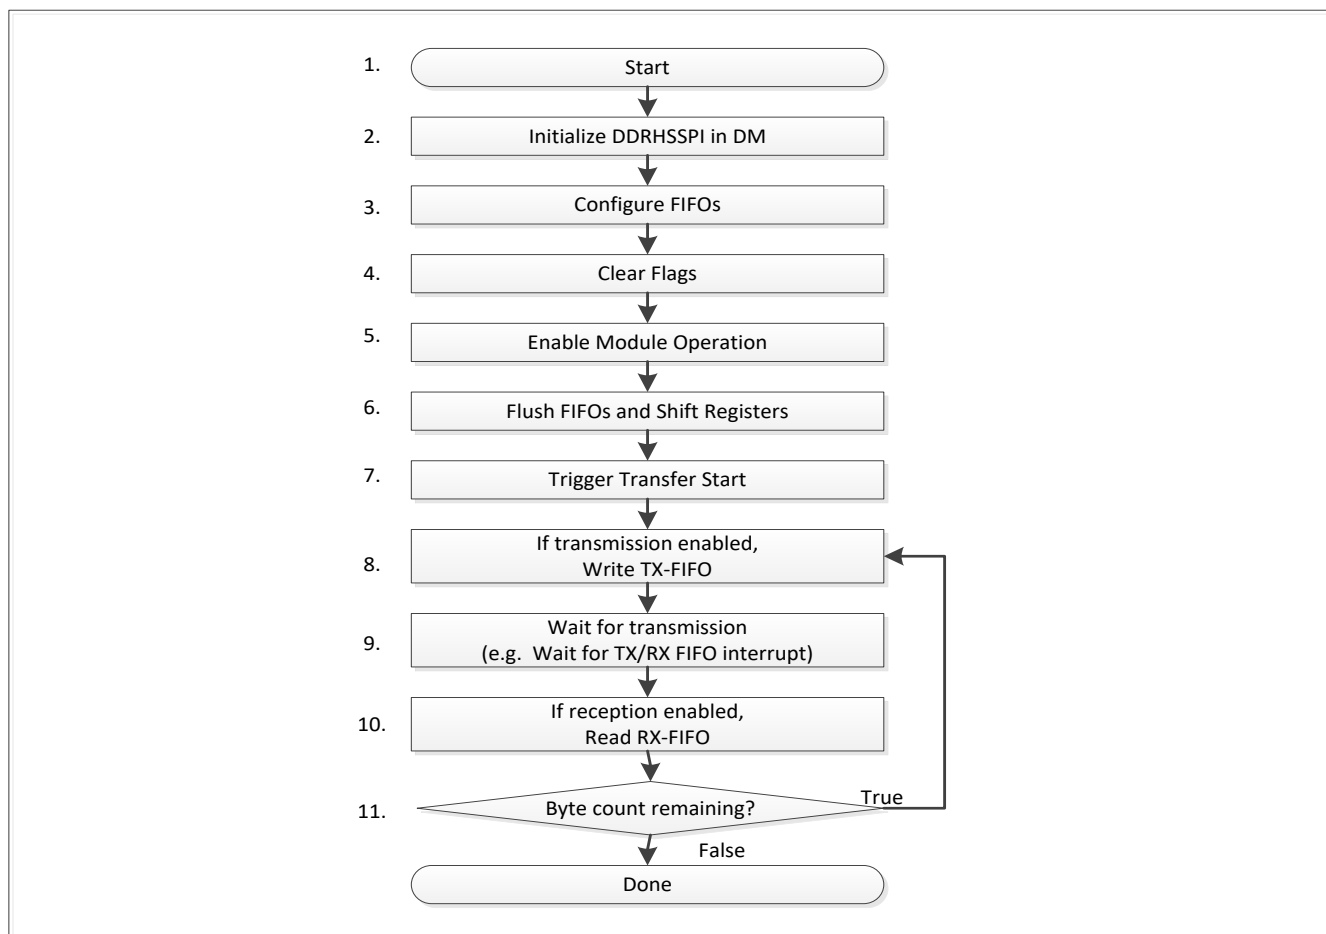

1. After the System Reset, the software shall confirm the Module ID number of DDRHSSPI, by reading the DDRHSSPI_{MID} Register. This would help it in identifying the attributes and capabilities supported by the DDRHSSPI.
2. The next step is to configure the Attributes related to the Peripheral Communication with the Serial Flash Memory(Memories) connected with DDRHSSPI. DDRHSSPI can be interfaced with up to 4 Serial Flash Memories at Legacy/Quad mode (8 at Dual Legacy/Dual Quad mode). Serial communication related attributes like Transfer Frequency (i.e. Clock Division Ratio bits), etc. shall be configured in the registers: DDRHSSPI_{PCC0-3}. It is very important that these attributes shall be identical among the Serial Flash Memories connected with DDRHSSPI. These configurations shall not be modified while the DDRHSSPI is active. In case the software has to re-program any of these values, the software shall first disable the DDRHSSPI and wait until the current serial transfer is finished.
3. DDRHSSPI can be configured either in Direct Mode or in Command Sequencer Mode, by the DDRHSSPI_{MCTRL.CSEN} bit. Depending on which mode is to be used, the software shall configure the mode-specific registers. The registers specific to the Direct Mode are: (DDRHSSPI_{DMCFG}, DDRHSSPI_{DMBCC}, DDRHSSPI_{DMBCS}, DDRHSSPI_{DMTRP}, DDRHSSPI_{DMPSEL} and DDRHSSPI_{DMFIFOCFG}) and the registers specific to the Command Sequencer Mode are: (DDRHSSPI_{RDCSDC0-11}, DDRHSSPI_{CSCFG}, DDRHSSPI_{CSITIME}, DDRHSSPI_{CSAEXT} and DDRHSSPI_{CSPBUFFERCFG}). When DDRHSSPI_{MID.MID} is 0x00000300, there are additional registers (DDRHSSPI_{SDATASAMPLEPT{CNT/LFT/RGH}0-7}, DDRHSSPI_{DLP}) in Command Sequencer Mode.
4. Only after all module-specific configurations are programmed, the DDRHSSPI can be enabled (by setting the DDRHSSPI_{MCTRL.MEN} to "1").
5. Once the DDRHSSPI is enabled, its normal operation begins. The software shall keep monitoring the status of the DDRHSSPI using the various status bits. If the DDRHSSPI is configured for initiating the service requests, it would periodically trigger the service requests (i.e. Interrupts and/or DMA Service Requests). The software would respond to those requests, in order to ensure the normal operation of DDRHSSPI.

4.4.3. Using the DDRHSSPI in Direct Mode of Operation

Figure 4-11 gives the general steps which the SW shall follow while using the DDRHSSPI in Direct Mode.

Figure 4-11 Programmer's Flowchart: DDRHSSPI in Direct Mode of Operation

1. After the System Reset, the software shall initialize the DDRHSSPI by reading the DDRHSSPI_{In}_MID Register and setting the Peripheral Communication related attributes in the DDRHSSPI_{In}_PCC0-3 Registers. Please make sure that the DDRHSSPI_{In}_MCTRL.CSEN bit is cleared to "0".
2. The next step is to configure the transfer protocol (i.e. whether the DDRHSSPI serial transfers use the Legacy or the Quad Protocol and whether the DDRHSSPI would be used only for transmission, or for both transmission and reception) in the DDRHSSPI_{In}_DMTRP.TRP. DDRHSSPI loads the DDRHSSPI_{In}_DMBCC.BCC to know the number of bytes in the serial transfer.
3. Configure the DDRHSSPI_{In}_DMFIFOCFG Register, to set the FIFO threshold levels. By programming these levels, the assertion of the service requests can be controlled. Also configure the DDRHSSPI_{In}_DMFIFOCFG.FWIDTH, to select the width of the FIFOs. Configure the service requests: DDRHSSPI supports both Interrupt Service Request and DMA Service Request, for the normal data read operations from RX-FIFO or write operations to TX-FIFO. For normal operation, either the Interrupt Service Requests or the DMA Service Requests shall be enabled by the software. To enable the Interrupt Service Requests for writing TX-FIFO, please program the bits in the DDRHSSPI_{In}_TXE Register. To enable the Interrupt Service Requests for reading RX-FIFO, please program the bits in the DDRHSSPI_{In}_RXE Register. To enable the DMA Service Request (for writing

- and/or reading), please program either/both of the DDRHSSPI_{IN}_DMAEN.TXDMAEN and the DDRHSSPI_{IN}_DMAEN.RXDMAEN bits. The DMA Read Channel must be setup to perform a block transfer of "DDRHSSPI_{IN}_DMFIFOCFG.RXFTH + 1" transfers. The DMA Write Channel must be setup to perform a block transfer of "24 - DDRHSSPI_{IN}_DMFIFOCFG.TXFTH" transfers. Select the peripheral (in DDRHSSPI_{IN}_DMPSEL.PSEL) on which DDRHSSPI shall initiate the transfer
4. Clear all relevant flags. This finishes the steps in initialization of DDRHSSPI for Direct Mode.
 5. Set the DDRHSSPI_{IN}_MCTRL.MEN bit, to enable the module.
 6. Flush FIFOs to ensure data consistency and avoid any data corruption from previous transfers.
 7. When DDRHSSPI is configured, setting the DDRHSSPI_{IN}_DMSTART.START bit triggers the start of the serial transaction. Once the serial transaction starts, if the transmit data is available in the TX-FIFO, the DDRHSSPI reads data from TX-FIFO and loads them to the Shift Register. The Shift Register is shifted left and the transmit data is shifted-out onto the Serial Interface. If DDRHSSPI is enabled for Receive operation (in DDRHSSPI_{IN}_DMTRP.TRP), the DDRHSSPI receives the serial data with shifting the Shift Register. The received data assembled in the Shift Register is pushed into the RX-FIFO.
 8. Write the transmit data to the TX-FIFO via any of DDRHSSPI_{IN}_TXFIFO0-23 Registers. Before writing to the DDRHSSPI_{IN}_TXFIFO0-23 Register, modify the value of the DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit appropriately. Generally (i.e. when the write data to the TX-FIFO is to be transmitted as it is), the DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit shall be "0". Only when in adding some kind of controls such as dummy cycles, the DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit shall be set to "1". The write access to DDRHSSPI_{IN}_TXFIFO0-23 shall be performed after the control of the DDRHSSPI_{IN}_DMFIFOCFG.TXCTRL bit.
 9. Service Requests are asserted by DDRHSSPI whenever the TX-FIFO level is below the threshold or whenever the DDRHSSPI RX-FIFO level is above the threshold. The software shall write TX-FIFO or read RX-FIFO, to ensure the serial data transfer of DDRHSSPI. After writing or reading the relevant FIFO, the software shall clear the Interrupt Service Requests by writing the DDRHSSPI_{IN}_TXC or the DDRHSSPI_{IN}_RXC Register. DMA Service Requests are cleared by the handshake responses from the DMA Controller. When the data transfer is not by DMA, the Service Requests can be asserted also by TX-FIFO's empty or RX-FIFO's full status. The software can select the conditions.
 10. If reception is enabled in DDRHSSPI_{IN}_DMTRP Register (when in TX-and-RX Mode), then the software fetches the received data from the RX-FIFO.
 11. Software judges if current serial transfer has finished, by checking (1) the DDRHSSPI_{IN}_TXF.TSSRS bit to be "1" or (2)the DDRHSSPI_{IN}_DMBCS Register value to be 0x0000. In the normal course of operation, the software usually keeps repeating steps from 8 to 11 until the end of serial transfer.

When the software initiates a new serial transfer again, it starts this flow from step 2.

To switch between the Direct Mode and Command Sequencer Mode, or to re-program any of the parameters that directly affect the serial transfer, the software shall first stop the current transfer and disable the DDRHSSPI (by clearing DDRHSSPI_{IN}_MCTRL.MEN bit to "0"). The software can check the status bit DDRHSSPI_{IN}_TXF.TSSRS, to see if the current transfer has finished.

4.4.4. Using the DDRHSSPI in Command Sequencer Mode of Operation

- Using the Memory Mapped Memories

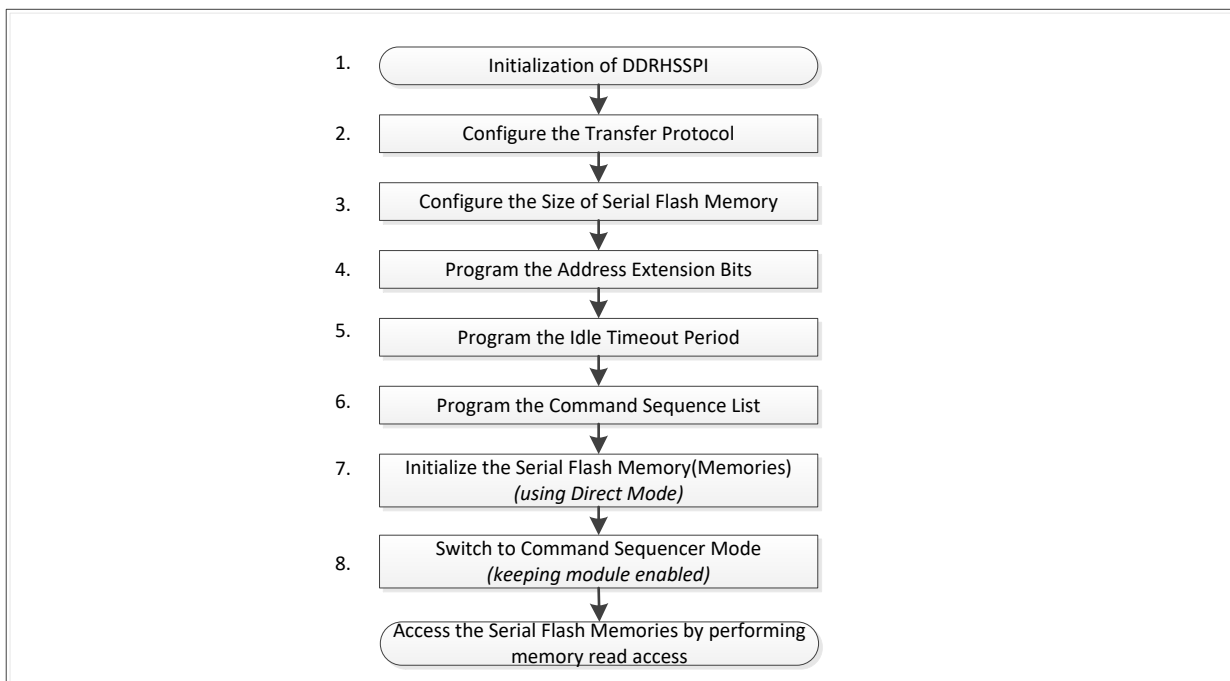

Following usage rules shall be followed, when interfacing Serial Flash Memories, for memory-mapped accesses in Command Sequencer Mode.

- Usage Rules and Notes

- In Command Sequencer Mode, all Serial Flash Memories interfaced with DDRHSSPI shall be of same family. Do not mix Serial Flash Memories from different vendor families.
- If Serial Flash Memories of the same family in different memory sizes are to be interfaced, then while deciding the suitable value of the DDRHSSPI_{IN}_CSCFG.MSEL, the Serial Flash Memory with maximum size must be considered. However, it shall be noted here, that the number of bytes from the final memory address that will be transmitted by DDRHSSPI to the Serial Flash Memory is programmed in the Command Sequence lists (in DDRHSSPI_{IN}_RDCSDC0-11). Interfacing Serial Flash Memories mixing 32-bit addressing and 24-bit addressing is not allowed in Command Sequencer Mode. This is because the Serial Flash Memory in 24-bit addressing cannot be extended to 32-bit addressing - the address phase in 24-bit addressing is of 3 bytes only.
- In Command Sequencer Mode, it is impossible to change the SPI width while in the serial transfer. For this reason, for some types of the Serial Flash Memories - the Command Sequencer can be enabled only after the Serial Flash Memory has transitioned to work in the "Continuous Read Command Sequence". This transition is needed before the first Memory Read access, using the Direct Mode operation of DDRHSSPI.
- When Command Sequencer Mode is used, internal Prefetch Buffer will be used. Since the Command Sequencer Mode supports only Memory Read accesses, there is only Prefetch Buffer available in Command Sequencer Mode. This buffer is 48 locations deep, 32-bit wide.
- In Command Sequencer Mode - prefetch of read data is used in order to streamline data reads. This means that during System Bus idle cycles - DDRHSSPI is performing speculative reads from Flash Memory until it gets internal Prefetch Buffer full. There is separate register DDRHSSPI_{IN}_CSPREFETCHADDR [31:0] which stores next available prefetch address. In case of address miss-hit on the System Bus, the Prefetch Buffer is flushed automatically.
- On-the-fly switching of Data Rate Mode (SDR/DDR Mode programmed in DDRHSSPI_{IN}_CSCFG.DDRMODE) is not allowed in Command Sequencer Mode while module is enabled.

- Programmer's Flowchart

Figure 4-12 shows the general steps how to allocate the Serial Flash Memories onto the address space of MCU.

Figure 4-12 Programmer's Flowchart: Memory Mapping of Serial Flash Memories

1. After the System Reset, the software shall initialize the DDRHSSPI by setting the Peripheral Communication related attributes in the DDRHSSPI_n_PCC0-3 Registers. It is very important that these attributes shall be identical among Serial Flash Memories interfaced with the DDRHSSPI. When Serial Flash Memories are to be memory-mapped using Command Sequencer Mode, all Serial Flash Memories shall be of the same family. Therefore, all of DDRHSSPI_n_PCC0-3 Registers shall have same configuration values.
2. The next step is to configure the transfer protocol (i.e. whether the DDRHSSPI serial transfers use the Quad or Octal Protocol in the DDRHSSPI_n_CSCFG.MBM). The DDRHSSPI_n_CSCFG.DDRMODE bit shall be set same as DDRHSSPI_n_DMTRP.DDRM bit.
3. Program the DDRHSSPI_n_CSCFG.MSEL, according to
 - The address space on the System Bus for mapping the Serial Flash Memory (Memories)
 - The number of Serial Flash Memories interfaced with DDRHSSPI
 Please refer to Section 4.2 for details of the Slave Select.
4. To cover the physical address space in the Serial Flash Memories (up to 16GB), the DDRHSSPI_n_CSAEXT Register value gives the upper bits of the address. Please refer to Section 4.2 for details of address generation.
5. The DDRHSSPI_n_CSITIME.ITIME helps DDRHSSPI enhance the performance of memory accesses, by continuing previous serial transfer. If DDRHSSPI detects a consecutive memory access during ITIMER period (Slave Select is kept asserted and SCLK is halted), it extends the data transfer without de-asserting current Slave Select. This feature reduces the access time by omitting a new Command Sequence. Program the DDRHSSPI_n_CSITIME.ITIME with appropriate idle time-out value.
6. Program the list of Read Command Sequence Registers (i.e. DDRHSSPI_n_RDCSDC0-11) with the sequence of the memory read command for the Serial Flash Memory which is interfaced. Please refer to the data sheet of the Serial Flash Memory for details of the Read Command Sequence.

7. The next step is to initialize the Serial Flash Memory that is to be memory mapped. The initialization is specific to the Serial Flash Memory product, including the setting of some control or status bits in its register set. e.g. To use a Serial Flash Memory in a high-performance Quad Mode. Please refer to the data sheet of the Serial Flash Memory to be interfaced. This initialization of the Serial Flash Memory shall be performed using Direct Mode of DDRHSSPI.
8. With this, DDRHSSPI has been configured for accessing the memory-mapped devices (Serial Flash Memories). Switch the DDRHSSPI to Command Sequencer Mode, so that it starts generating the Read Command Sequences on the Serial Interface, by mapping the System Bus accesses to the memory-mapped locations.

Calibration of SDATA Sampling Points

Before running the main process, the software shall adjust the SDATA Sampling Points by setting up registers `DDRHSSPIIn_SDATASAMPLEPT{LFT/CNT/RGH}0-7`. To determine the best sampling points on each bit lane of `SDATA[7:0]`, the software has to run a flow (1)~(3) as below. This flow is an example. The overview of this flow is also illustrated in Figure 4-13.

(1) Calibration sequence

First of all, the software needs to prepare arrays to store the result of Calibration. Each array has a size corresponding to SDATA Sampling Points (=128). It is recommended to prepare 8 arrays to store results for each bit lane of `SDATA[7:0]`.

The software runs the following sequence:

- a) Set `DDRHSSPIIn_MCTRL.DLPEN` bit to "1".
 - The Calibration sequence goes with causing Bus Errors, and these errors have to be ignored by the system. Please make the settings on the system for it.
- b) Set all {R/C/L} of SDATA Sampling Points to 0.
 - The target registers are for current bit lane of `SDATA[7:0]`.
 - E.g. If current bit lane is `SDATA[0]`, write 0x00 to registers `DDRHSSPIIn_SDATASAMPLEPT{LFT/CNT/RGH}0`.
- c) Run a Memory Read access at 32-bits width.
 - From the second round in the loop, the software shall increment the address at least +8.
 - If any of SDATA Sampling Points is not in the valid bit range, the DLP checking results in error and causes a Bus Error.
- d) Check the status of `DDRHSSPIIn_DLPSAMPLESTATUS` register.
 - The software shall check the bit fields for current bit lane of `SDATA[7:0]`, and store the result to the corresponding array.
- e) Clear the `DLPFS` bit by writing "1" to `DDRHSSPIIn_FAULTC.DLPFC`.
- f) Increment all {R/C/L} of SDATA Sampling Points (+1 on each).
- g) Repeat (c)~(f) until the max value of SDATA Sampling Points (128 rounds).
- h) Repeat (b)~(g) until completing all bit lanes of `SDATA[7:0]` (8 rounds).
- i) At this moment, DDRHSSPI is expected to be in the status as below:
 - SDATA Sampling Points are the max value.
 - The last Memory Read access has ended in Bus Error.
 - `DDRHSSPIIn_FAULTF.DLPFS`="1"
 - `DDRHSSPIIn_RXF.DLPERR`="1"

- The software holds all arrays of "PASS"/"FAIL" results for each bit lane of SDATA[7:0].

(2) Setting SDATA Sampling Points

Set the registers DDRHSSPIn_SDATASAMPLEPTCNT0-7 to the center positions in respective "PASS" ranges. If there is no "PASS" range in the array, the DDRHSSPI hereafter cannot serve Memory Read access. Else if the "PASS" range is divided by "FAIL(s)", choose the longest "PASS" range and take the center position of it.

DDRHSSPIn_SDATASAMPLEPTLFT0-7 shall be set to less values than DDRHSSPIn_SDATASAMPLEPTCNT0-7 (for each bit lane of SDATA[7:0]).

DDRHSSPIn_SDATASAMPLEPTRGH0-7 shall be set to greater values than DDRHSSPIn_SDATASAMPLEPTCNT0-7 (for each bit lane of SDATA[7:0]).

These register settings for {"LFT", "RGH"} are actually not used in the data reception, and they are just used for detecting the violation of sampling.

The degree of 'less' and 'greater' depends on the window size of "PASS" range, and these differences are used in the re-adjustment of SDATA Sampling Points afterward.

(3) To the main process

The software shall clear DDRHSSPIn_MCTRL.DLPEN bit to "0", if it is not allowed to lose the Memory Read data in the main process by the occurrence of DLP error.

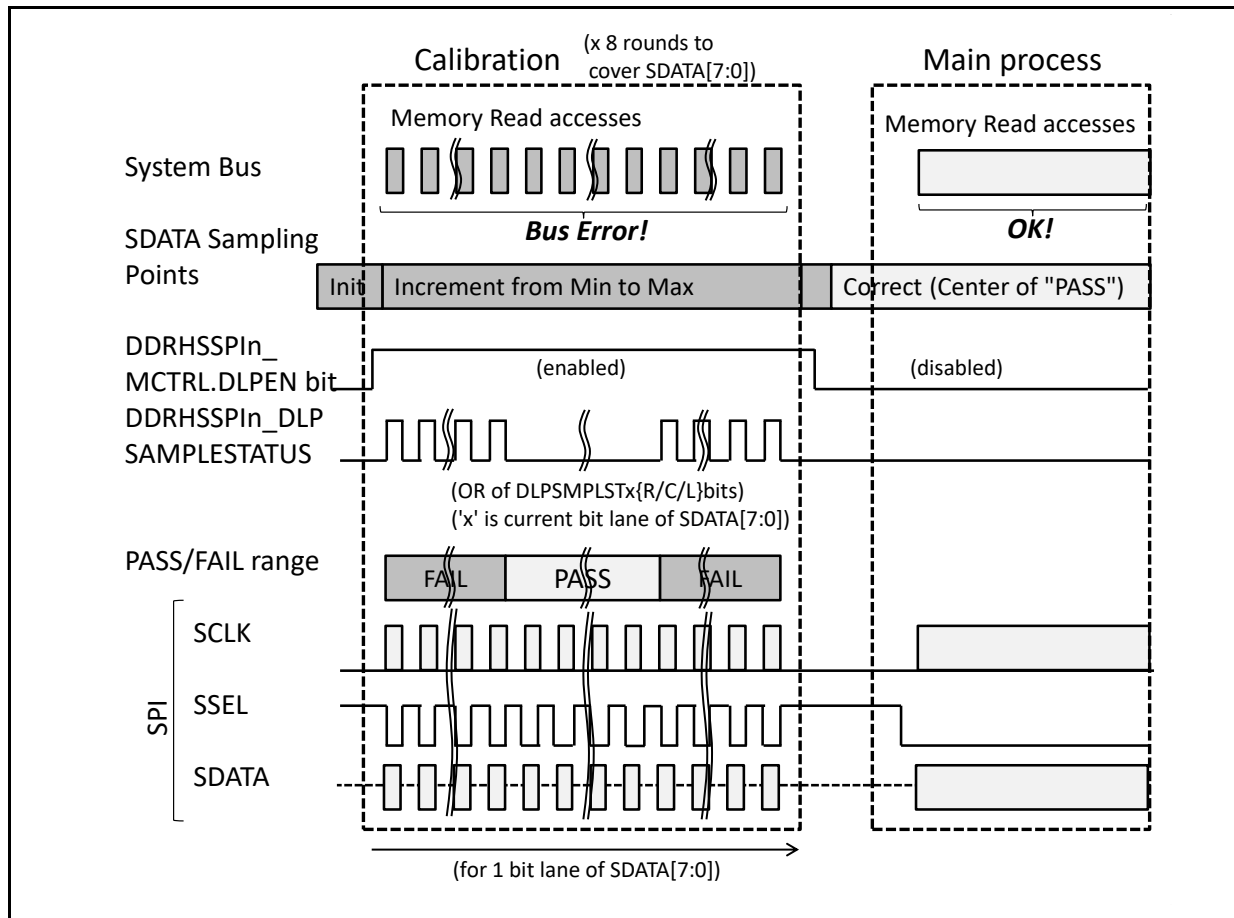

Now the DDRHSSPI is ready for the Memory Read access in the main process. During the main process, the software is required to run a periodical adjustment of SDATA

Sampling Points, and this operation is described later in this section.

Notes:

- *If the Serial Flash Memory does not support the DLP function, please change following points.*
 - *DDRHSSPIn_MCTRL.DLPEN should be "0".*
 - *DLP-related status bits are not used.*
 - *All Serial Flash Memories have to store certain data in certain addresses in advance. These data are used for pattern matching instead of DLP, and shall have bit-toggling pattern on each bit lane of SDATA[7:0] as well as DLP. Please consider the "bit pattern" and "bit alignment" according to the intended SPI protocol (Quad or Dual-Quad).*
 - *The software has to do pattern-matching checks with the read data, since there is no automatic checking like DLP. Please note that the read data work instead of DLP by the process of software. Therefore, the software shall recognize how many data to read in the DLP-like operation, and gather byte data by re-arranging bits from the read data. [e.g. Memory Read at "DDR & Dual-Quad" protocol] For the pattern matching check, it is assumed to use 8 consecutive bits on each bit lane of SDATA[7:0] as the substitute for DLP. The sum of these pattern-matching bits becomes 64 bits. In this case, the software has to read 2 words (assuming 32-bits access) to check all of these bits.*
 - *Although the SDATA[7:0] is sampled in parallel, the software has to check the serial bits on each bit lane of SDATA[7:0] individually. The main loop flow is basically same as the case of DLP.*
 - *The SPI transaction goes on regardless the sampling condition of SDATA[7:0], different from the case using DLP.*

The overview of Calibration sequence is shown in the following diagram.

Figure 4-13 Calibration Sequence before the Main Process

Before starting the main process, please read carefully the Notes of 3.4 SPI Data Learning Pattern.

Re-adjustment of SDATA Sampling Points

After setting the best position of SDATA Sampling Points, these points can gradually drift and get close to the edge of SDATA as time passes (e.g. due to the fluctuation of temperature), and the sampling may begin to fail. To avoid the miss-sampling, the software shall periodically adjust the SDATA Sampling Points. The actual interval depends on the system, however, it is expected that the software does not have to run a full Calibration sequence each time.

If the periodical adjustment is frequent enough, each adjustment can change the SDATA Sampling Points ± 1 [tap] at a time. This operation will not take time compared to the full Calibration, and it is expected that the system can insert this re-adjustment operation in the moment while the main process does not access the Serial Flash Memories. Furthermore, the system can determine the degree of adjustment not only within ± 1 [tap].

The software runs the following sequence:

- a) Set DDRHSSPIn_MCTRL.DLPEN bit to "1".

The handling of Bus Error is same as Calibration. Please make sure that the main process will not access Serial Flash Memories during (a)~(f) in this flow.

- b) Run a Memory Read access (at 32-bits width).

The software shall increment the address +8 each time.

- c) Check the status of following registers:

DDRHSSPIn_FAULTF.DLPFS bit (optional)

If this bit is "0", go to (f).

DDRHSSPIn_RXF.DLPERR bit (optional)

If this bit is "0", go to (f).

DDRHSSPIn_DLPSAMPLESTATUS register (must)

For each bit lane of SDATA[7:0], the software shall check the status of sampling and update the corresponding SDATA Sampling Point. These judgments are based on the register settings of DDRHSSPIn_SDATASAMPLEPT{LFT/CNT/RGH}0-7 in the Calibration ($L < C < R$).

- DLPSMPLSTx{R/C/L} = "100": --> Decrease the SDATA Sampling Point.

- DLPSMPLSTx{R/C/L} = "001": --> Increase the SDATA Sampling Point.

- DLPSMPLSTx{R/C/L} = "000": --> No need to change the SDATA Sampling Point.

If the value of DDRHSSPIn_DLPSAMPLESTATUS register is 0x00000000, go to (f).

- Otherwise: --> Outside the re-adjustable range.

This situation requires a full Calibration and the system shall stop the main process for a moment.

When increasing/decreasing the SDATA Sampling Points, the "CNT" shall be adjusted to the center between "LFT" and "RGH", so as to ensure the PASS range as much as possible. e.g. If

DLPSMPLST0{R/C/L} = "100", the software shall decrease only the value of

DDRHSSPIn_SDATASAMPLEPTRGH0 registers, then calculate the "CNT" as the average value between "LFT" and "RGH".

- d) If DLPFS = "1", write "1" to DDRHSSPIn_FAULTC.DLPFC to clear it.

If DLPERR = "1", write "1" to DDRHSSPIn_RXC.DLPERRC to clear it.

- e) Repeat (b)~(d) until DDRHSSPIn_DLPSAMPLESTATUS = 0x00000000.

If the period to run this operation is frequent enough against the fluctuation of SDATA timing, this loop is not always necessary.

- f) Clear DDRHSSPIn_MCTRL.DLPEN bit to "0", if it is not allowed to lose the Memory Read data in the main process by the occurrence of DLP error.

- g) Main process can access Serial Flash Memories.

Notes:

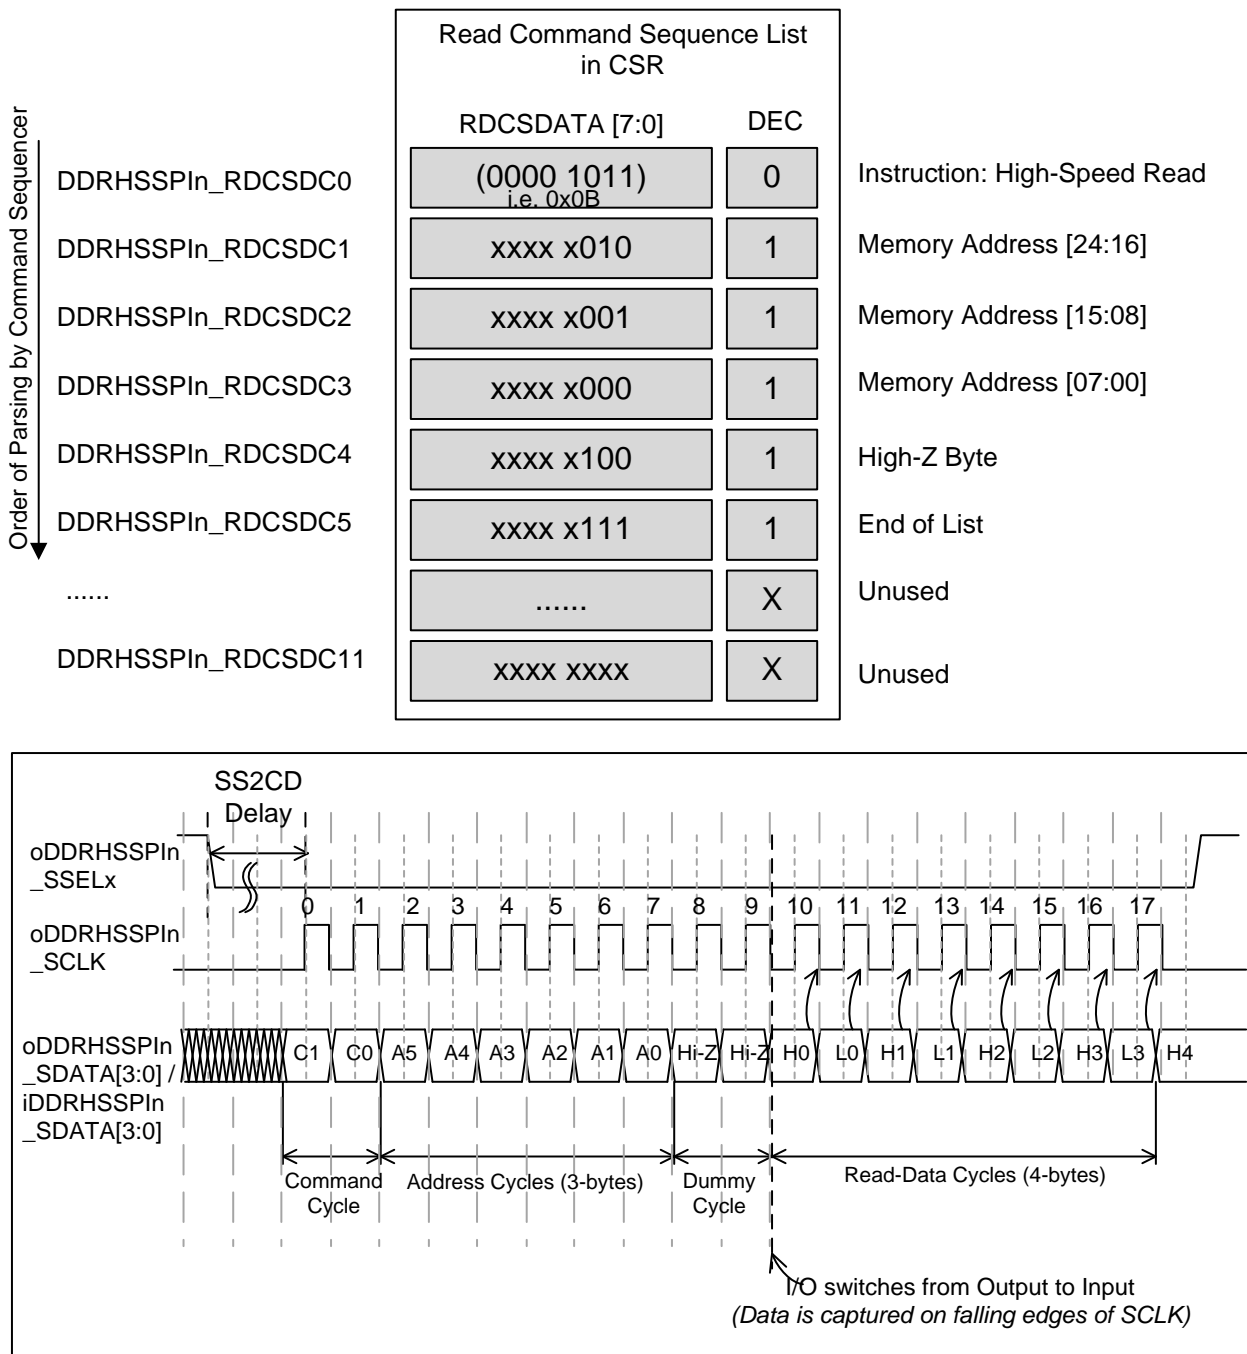

- If the Serial Flash Memory does not support the DLP function, the software has to check the result of Memory Read access as well as Calibration sequence (please refer to its Notes).
- The system has to ensure the timing for this Re-adjustment operation.

Before starting the main process, please read carefully the Notes of 3.4 SPI Data Learning Pattern.

Timing Diagram for Command Sequencer

Figure 4-14 illustrates with an example, how the Command Sequencer generates the Serial Flash Memory Read Command Sequence. Assuming that the Read Command Sequence list is programmed in DDRHSSPIn_RDCSDC0-11 Registers, as shown in the figure, the Command Sequencer parses the list, starting from DDRHSSPIn_RDCSDC0 Register, and executes the commands as explained in Section 4.2 Command Sequencer Mode.

Figure 4-14 shows also the corresponding timing diagram for a Read Command Sequence, for Mode 4.

Figure 4-14 Read Command Sequence Illustration With Timing Diagram (Mode4)

Note:

- The above example is to illustrate the relation between the Command Sequence List and the serial transmission, and it does not mean the actual example of the SPI transaction for Serial Flash Memory.

5. Registers

The DDRHSSPI contains various registers to configure its operation, to monitor its status and to read or write the data to be transferred over the Serial Interface.

All registers in DDRHSSPI are explained in this section.

List of DDRHSSPI Registers in Memory

Abbreviation	Register Name	See
DDRHSSPIIn_MCTRL	DDRHSSPI Module Control Register	5.1
DDRHSSPIIn_PCC0	DDRHSSPI Peripheral Communication Configuration Register 0	5.2
DDRHSSPIIn_PCC1	DDRHSSPI Peripheral Communication Configuration Register 1	
DDRHSSPIIn_PCC2	DDRHSSPI Peripheral Communication Configuration Register 2	
DDRHSSPIIn_PCC3	DDRHSSPI Peripheral Communication Configuration Register 3

Note:

- *The initial register value after reset indicates as follows:*
 - "1": Initial value "1"
 - "0": Initial value "0"
 - "X": Initial value undefined
 - "-": Reserved bit/Undefined bit
 - "*": Initial value "0" or "1" according to the setting

5.1. DDRHSSPI Module Control Register (DDRHSSPIIn_MCTRL)

The DDRHSSPI Module Control Register controls the DDRHSSPI. It contains vital bits like the Module Enable bit, the Command Sequencer Mode Enable bit and Data Learning Pattern Enable bit.

The Software can enable/disable the DDRHSSPI operation by using this register.

[bit31:6] Reserved: Reserved**[bit5] DLPEN: Data Learning Pattern Enable**

This bit enables when the sampling point of receiving data is checked to use the command with DLP.

This bit shall be fixed to "0" when DDRHSSPI_{IN_MID}.MID is 0x00000001.

This bit is valid in DDR Mode of the Command Sequencer Mode.

Bit	Description
0	DLP is disabled.
1	DLP is enabled.

Notes:

- Under the condition of DLPEN="1", any DLP error in the DDRHSSPI_{IN_DLPSAMPLESTATUS} register results in the system bus error, and this is common among {LFT/CNT/RGH}. In that case, the Memory Read data is invalid.
- Even if the CNT is sampled correctly, any error on the LFT or RGH leads to the error.

[bit4] MES: Module Enable Status

This bit shows the status of the DDRHSSPI.

Bit	Description
0	DDRHSSPI is completely disabled and it has entered the power saving mode.
1	DDRHSSPI is enabled.

[bit3:2] Reserved: Reserved**[bit1] CSEN: Command Sequencer Mode Enable**

This bit selects the operating mode(Direct Mode or Command Sequencer Mode).

Bit	Description
0	Direct Mode is enabled. Command Sequencer Mode is disabled.
1	Command Sequencer Mode is enabled. Direct Mode is disabled.

[bit0] MEN: Module Enable

This bit enables DDRHSSPI operation.

Bit	Description
0	DDRHSSPI is disabled. DDRHSSPI enters power saving mode.
1	DDRHSSPI is enabled.

After configuring the DDRHSSPI, Software must set this bit to "1", to enable DDRHSSPI in operating mode.

When Software resets this bit:

- In Direct Mode: DDRHSSPI aborts current SPI transfer and Slave Select is released. After the Slave Select is released, it internally enters a power saving mode.

b) In Command Sequencer Mode: DDRHSSPI generates an unmapped memory access fault interrupt if any further access to memory mapped Serial Flash Memories is received. It aborts ongoing transaction on the Serial Interface and release Slave Select. After the Slave Select has been released, it internally enters a power saving mode.

5.2. DDRHSSPI Peripheral Communication Configuration Registers (DDRHSSPI_n_PCC0-3)

The DDRHSSPI Peripheral Communication Configuration Registers 0-3 control the attributes related to the serial communication on Slave Select 0-3. The Software must initialize these registers with the attributes that match the communication attributes of the Serial Flash Memory that is to be interfaced on the corresponding Slave Select line 0-3 of DDRHSSPI. When DDRHSSPI is configured in Direct Mode or in Command Sequencer Mode, each of the 4 registers is used and must be same value.

Only DDRHSSPI_n_PCC0 Register is described here. Other registers (i.e. DDRHSSPI_n_PCC1-3) have same bit fields.

[bit31:21] Reserved: Reserved

[bit20:16] SSELDEASRT[4:0]: Slave Selection De-Assertion Timeout

It defines the time period after SSEL de-assertion when a new SSEL assertion can not occur.

Bits	Description	
	SDR Mode	DDR Mode
00000	Setting this value is prohibited.	
00001	De-assertion time = 4 x SCLK cycle	De-assertion time = 3.5 x SCLK cycle
00010	De-assertion time = 5 x SCLK cycle	De-assertion time = 4.0 x SCLK cycle
...
00111	De-assertion time = 10 x SCLK cycle	De-assertion time = 6.5 x SCLK cycle
...
11111	De-assertion time = 34 x SCLK cycle	De-assertion time = 18.5 x SCLK cycle

[bit15:13] Reserved: Reserved

[bit12:9] CDRS[3:0]: Clock Division Ratio Select for Peripheral

This field decides the Clock Division Ratio for the SCLK.

Bits	Description
0000	Divide by 2
0001	Divide by 4.
0010	Divide by 6.
...	...
0111	Divide by 16.
...	...
1111	Divide by 32.

[bit8:7] Reserved: Reserved

[bit6:5] SS2CD[1:0]: Slave Select to Clock Delay

It defines a setup time for the Serial Flash Memory. By delaying the toggling of SCLK, DDRHSSPI delays the start of data transfer from the Slave Select active edge by a multiple of SCLK cycles.

The delay between the assertion of Slave Select and the first edge on the SCLK is given by:

$$(SS2CD + 0.50) \times \text{SCLK cycle} \quad [\text{SDR mode}]$$

$$(SS2CD + 0.75) \times \text{SCLK cycle} \quad [\text{DDR mode}]$$

When the Slave Select becomes active, the Serial Flash Memory has to prepare data transfer within the delay time defined by SS2CD bits.

Note:

- *SS2CD[1:0] = "00" must not be used when all the following conditions are met:*
 - *DDRHSSPI_{in}_DMTRP.TRP[3:0] = "1011"*
 - *DDRHSSPI_{in}_DMTRP.DDRM = "1"*
 - *DDRHSSPI_{in}_DMFIFOCFG.TXCTRL = "1"*
 - *DDRHSSPI_{in}_TXFIFOx.TXDATA[12][10][9:8] = "1000"*

[bit4:3] Reserved: Reserved

[bit2] ACES: Active Clock Edges are Same on Peripheral

This bit decides whether the active edges of the clock used for launching of data and for capturing of data are same or not. This bit takes effect both in Direct Mode and Command Sequencer Mode. This bit is only valid in SDR Mode.

Bit	Description
0	Launching of data and capturing of data is done on alternate (i.e. opposite) edges of clock.
1	Launching of data and capturing of data is done on same edges of clock.

[bit1:0] Reserved: Reserved

5.3. DDRHSSPI TX Interrupt Flag Register (DDRHSSPIn_TXF)

The DDRHSSPI TX Interrupt Flag Register indicates the status of the TX interrupt flags. These interrupt flags except TSSRS flag are set in Direct Mode only. When Command Sequencer Mode is selected, these flags except TSSRS flag are automatically cleared. The interrupt flags except TSSRS flag can be active also while the DDRHSSPI is disabled (DDRHSSPIn_MCTRL.MES = 0).

Software can enable these interrupts and wait for their assertion, or it can also use them in polling mode.

[bit31:7] Reserved: Reserved

[bit6] TSSRS: Slave Select Released

This interrupt flag indicates that the Slave Select line is released by the DDRHSSPI.

Bit	Description
0	DDRHSSPI does not generate the event which SSEL signal is de-asserted.
1	DDRHSSPI generates the event which SSEL signal is de-asserted.

This interrupt flag triggers the TX Interrupt Service Request if it is enabled in DDRHSSPI_{IN}.TXE.TSSRE.

This interrupt flag is cleared when DDRHSSPI_{IN}.TXC.TSSRC bit is written "1".

[bit5] TFMTS: TX-FIFO Fill Level is More Than Threshold

This interrupt flag indicates whether the TX-FIFO Fill Level is more than the configured TX-FIFO threshold value or not.

Bit	Description
0	The TX-FIFO fill level is not more than the configured TX-FIFO threshold value.
1	The TX-FIFO fill level is more than the configured TX-FIFO threshold value. This bit is always set while this condition is satisfied.

i.e. DDRHSSPI_{IN}.DMFIFOSTATUS.TXFLEVEL is greater than DDRHSSPI_{IN}.DMFIFOCFG.TXFTH.

This interrupt flag triggers the TX Interrupt Service Request if it is enabled in DDRHSSPI_{IN}.TXE.TFMTE. This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPI_{IN}.TXC.TFMTC bit is written "1".

[bit4] TFLETS: TX-FIFO Fill Level is Less Than or Equal to Threshold

This interrupt flag indicates whether the TX-FIFO Fill Level is less than or equal to the configured TX-FIFO threshold value or not.

Bit	Description
0	The TX-FIFO fill level is not less than or equal to the configured TX-FIFO threshold value.
1	The TX-FIFO fill level is less than or equal to the configured TX-FIFO threshold value. This bit is always set while this condition is satisfied.

i.e. DDRHSSPI_{IN}.DMFIFOSTATUS.TXFLEVEL is less than or equal to DDRHSSPI_{IN}.DMFIFOCFG.TXFTH.

This interrupt flag triggers the TX Interrupt Service Request if it is enabled in DDRHSSPI_{IN}.TXE.TFLETE. This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPI_{IN}.TXC.TFLETC bit is written "1".

Note:

- After System Reset, this bit is set to "1".

[bit3] Reserved: Reserved

[bit2] TFOS: TX-FIFO Overrun

This interrupt flag indicates that the TX-FIFO is overrun.

Bit	Description
0	Any of DDRHSSPIn_TXFIFO0-23 Registers is not written by the Software when the TX-FIFO is full.
1	Any of DDRHSSPIn_TXFIFO0-23 Registers is written by the Software when the TX-FIFO is full.

This interrupt flag triggers the TX Interrupt Service Request if it is enabled in DDRHSSPIn_TXE.TFOE. This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_TXC.TFOC bit is written "1".

[bit1] TFES: TX-FIFO and Shift Register are Empty

This interrupt flag indicates whether the TX-FIFO and TX Shift Register are empty or not.

Bit	Description
0	The TX-FIFO or the TX Shift Register (in SPI Core) are not empty.
1	The TX-FIFO and the TX Shift Register (in SPI Core) are empty. This bit is always set while this condition is satisfied.

This interrupt flag triggers the TX Interrupt Service Request if it is enabled in DDRHSSPIn_TXE.TFEE. This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_TXC.TFEC bit is written "1".

Note:

- After System Reset, this bit is set to "1".

[bit0] TFFS: TX-FIFO Full

This interrupt flag indicates whether the TX-FIFO is full or not.

Bit	Description
0	The TX-FIFO is not full.
1	The TX-FIFO is full. This bit is always set while this condition is satisfied.

This interrupt flag triggers the TX Interrupt Service Request, if it is enabled in DDRHSSPIn_TXE.TFFE. This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_TXC.TFFC bit is written "1".

5.4. DDRHSSPI TX Interrupt Enable Register (DDRHSSPIn_TXE)

The DDRHSSPI TX Interrupt Enable Register decides whether the interrupt flags in DDRHSSPIn_TXF Register trigger the TX Interrupt Service Request or not.

The Software must enable these bits if it wants to wait for the assertion of the TX Interrupt Service Request.

[bit31:7] Reserved: Reserved

[bit6] TSSRE: Slave Select Released Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TSSRS interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TSSRS interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TSSRS interrupt flag triggers the TX Interrupt Service Request.

[bit5] TFMTE: TX-FIFO Fill Level is More Than Threshold Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TFMTS interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TFMTS interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TFMTS interrupt flag triggers the TX Interrupt Service Request.

[bit4] TFLETE: TX-FIFO Fill Level is Less Than or Equal To Threshold Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TFLETS interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TFLETS interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TFLETS interrupt flag triggers the TX Interrupt Service Request.

[bit3] Reserved: Reserved

[bit2] TFOE: TX-FIFO Overrun Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TFOS interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TFOS interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TFOS interrupt flag triggers the TX Interrupt Service Request.

[bit1] TFEE: TX-FIFO Empty Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TFES interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TFES interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TFES interrupt flag triggers the TX Interrupt Service Request.

[bit0] TFFE: TX-FIFO Full Interrupt Enable

This bit decides whether the DDRHSSPIn_TXF.TFFS interrupt flag is routed on TX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_TXF.TFFS interrupt flag does not trigger the TX Interrupt Service Request.
1	The DDRHSSPIn_TXF.TFFS interrupt flag triggers the TX Interrupt Service Request.

5.5. DDRHSSPI TX Interrupt Clear Register (DDRHSSPIn_TXC)

The DDRHSSPI TX Interrupt Clear Register is used to clear the interrupt flags in the DDRHSSPIn_TXF Register.

By writing "1" to a bit in this register, the Software can clear the corresponding flag in the DDRHSSPIn_TXF Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit31:7] Reserved: Reserved

[bit6] TSSRC: Slave Select Released Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TSSRS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TSSRS interrupt flag

The read value is "0".

[bit5] TFMTC: TX-FIFO Fill Level More Than Threshold Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TFMTC interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TFMTS interrupt flag.

The read value is "0".

[bit4] TFLETC: TX-FIFO Fill Level Less Than or Equal to Threshold Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TFLETS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TFLETS interrupt flag.

The read value is "0".

[bit3] Reserved: Reserved

[bit2] TFOC: TX-FIFO Overrun Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TFOS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TFOS interrupt flag.

The read value is "0".

[bit1] TFEC: TX-FIFO Empty Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TFES interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TFES interrupt flag.

The read value is "0".

[bit0] TFFC: TX-FIFO Full Interrupt Clear

This bit is used to clear the DDRHSSPIn_TXF.TFFS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_TXF.TFFS interrupt flag.

The read value is "0".

5.6. DDRHSSPI RX Interrupt Flag Register (DDRHSSPIIn_RXF)

The DDRHSSPI RX Interrupt Flag Register indicates the status of the RX interrupt flags. The interrupt flags can be active also while the DDRHSSPI is disabled (DDRHSSPIIn_MCTRL.MES = 0).

Software can enable these interrupts and wait for their assertion, or it can also use them in polling mode.

[bit31:9] Reserved: Reserved

[bit8] TEST: Test

This is a test flag. The read value is not defined. Writing to this bit does not influence other functions.

[bit7] DLPERR: Data Learning Pattern Reception Error

This bit is available only when DDRHSSPIIn_MID.MID is 0x00000100 or 0x00000300.

This interrupt flag indicates that the one or more SDATA input ports received incorrect DLP from Flash Memory which is caused by wrong sample clock settings in one or more registers among DDRHSSPIIn_SDATASAMPLEPTCNT0-7, DDRHSSPIIn_SDATASAMPLEPTLFT0-7 and DDRHSSPIIn_SDATASAMPLEPTRGH0-7.

Bit	Description
0	DDRHSSPIn_DLP.DLP matches the received DLP data, or DDRHSSPI does not check the DLP data.
1	DDRHSSPIn_DLP.DLP does not match the received DLP data.

This interrupt flag triggers the RX Interrupt Service Request, if it is enabled in DDRHSSPIn_RXE.DLPERRE.

DDRHSSPIn_DLPSAMPLESTATUS Register has information which SDATA input pins detected problems with data sampling. This flag can be used only in DDR Mode of the Command Sequencer Mode.

This interrupt flag is cleared when DDRHSSPIn_RXC.DLPERRC bit is written "1".

[bit6] RSSRS: Slave Select Released

This interrupt flag indicates that the Slave Select is released by the DDRHSSPI.

Bit	Description
0	DDRHSSPI does not generate the event which SSEL signal is de-asserted.
1	DDRHSSPI generates the event which SSEL signal is de-asserted.

This interrupt flag triggers the RX Interrupt Service Request if it is enabled in DDRHSSPIn_RXE.RSSRE.

This interrupt flag is cleared when DDRHSSPIn_RXC.RSSRC bit is written "1".

[bit5] RFMTS: RX-FIFO Fill Level is More Than Threshold

This interrupt flag indicates whether the RX-FIFO Fill Level is more than the configured RX-FIFO threshold value or not.

Bit	Description
0	The RX-FIFO fill level is not more than the configured RX-FIFO threshold value.
1	The RX-FIFO fill level is more than the configured RX-FIFO threshold value. This bit is always set while this condition is satisfied.

i.e. DDRHSSPIn_DMFIFOSTATUS.RXFLEVEL is greater than DDRHSSPIn_DMFIFOCFG.RXFTH.

This interrupt flag triggers the RX Interrupt Service Request, if it is enabled in DDRHSSPIn_RXE.RFMTE.

This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_RXC.RFMTC bit is written "1".

[bit4] RFLETS: RX-FIFO Fill Level is Less Than or Equal to Threshold

This interrupt flag indicates whether the RX-FIFO Fill Level is less than or equal to the configured RX-FIFO threshold value or not.

Bit	Description
0	The RX-FIFO fill level is not less than or equal to the configured RX-FIFO threshold value.

Bit	Description
1	The RX-FIFO fill level is less than or equal to the configured RX-FIFO threshold value. This bit is always set while this condition is satisfied.

i.e. DDRHSSPIn_DMFIFOSTATUS.RXFLEVEL is less than or equal to DDRHSSPIn_DMFIFOCFG.RXFTH.

This interrupt flag triggers the RX Interrupt Service Request, if it is enabled in DDRHSSPIn_RXE.RFLETE.

This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_RXC.RFLETC bit is written "1".

Note:

- After System Reset, this bit is set to "1".

[bit3] RFUS: RX-FIFO Under Run

This interrupt flag indicates that the RX-FIFO is under run.

Bit	Description
0	Any of DDRHSSPIn_RXFIFO0-23 Registers is not read by the Software when the RX-FIFO is empty.
1	Any of DDRHSSPIn_RXFIFO0-23 Registers is read by the Software when the RX-FIFO is empty.

This interrupt flag triggers the RX Interrupt Service Request if it is enabled in DDRHSSPIn_RXE.RFUE.

This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_RXC.RFUC bit is written "1".

Note:

- This flag is not set when the DAP controller reads the DDRHSSPIn_RXFIFO0-23 Registers while the RX-FIFO is empty.

[bit2] Reserved: Reserved

[bit1] RFES: RX-FIFO Empty

This interrupt flag indicates whether the RX-FIFO is empty or not.

Bit	Description
0	The RX-FIFO is not empty.
1	The RX-FIFO is empty. This bit is always set while this condition is satisfied.

This interrupt flag triggers the RX Interrupt Service Request if it is enabled in DDRHSSPIn_RXE.RFEE.

This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_RXC.RFEC bit is written "1".

Note:

- After System Reset, this bit is set to "1".

[bit0] RFFS: RX-FIFO Full

This interrupt flag indicates whether the RX-FIFO is full or not.

Bit	Description
0	The RX-FIFO is not full.
1	The RX-FIFO is full. This bit is always set while this condition is satisfied.

This interrupt flag triggers the RX Interrupt Service Request if it is enabled in DDRHSSPIn_RXE.RFFE.

This interrupt flag shall be used in Direct Mode only. If Command Sequencer Mode is selected, this flag is automatically cleared.

This interrupt flag is cleared when DDRHSSPIn_RXC.RFFC bit is written "1".

5.7. DDRHSSPI RX Interrupt Enable Register (DDRHSSPIn_RXE)

The DDRHSSPI RX Interrupt Enable Register decides whether the interrupt flags in DDRHSSPIn_RXF Register trigger the RX Interrupt Service Request or not.

The Software must enable these bits if it wants to wait for the assertion of the RX Interrupt Service Request.

[bit31:8] Reserved: Reserved

[bit7] DLPERRE: Data Learning Pattern Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.DLPERR interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.DLPERR interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.DLPERR interrupt flag triggers the RX Interrupt Service Request.

[bit6] RSSRE: Slave Select Released Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RSSRS interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RSSRS interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RSSRS interrupt flag triggers the RX Interrupt Service Request.

[bit5] RFMTE: RX-FIFO Fill Level is More Than Threshold Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RFMTS interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RFMTS interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RFMTS interrupt flag triggers the RX Interrupt Service Request.

[bit4] RFLETE: RX-FIFO Fill Level is Less Than or Equal To Threshold Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RFLETS interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RFLETS interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RFLETS interrupt flag triggers the RX Interrupt Service Request.

[bit3] RFUE: RX-FIFO Under Run Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RFUS interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RFUS interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RFUS interrupt flag triggers the RX Interrupt Service Request.

[bit2] Reserved: Reserved
[bit1] RFEE: RX-FIFO Empty Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RFES interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RFES interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RFES interrupt flag triggers the RX Interrupt Service Request.

[bit0] RFFE: RX-FIFO Full Interrupt Enable

This bit decides whether the DDRHSSPIn_RXF.RFFS interrupt flag is routed on RX Interrupt Service Request or not.

Bit	Description
0	The DDRHSSPIn_RXF.RFFS interrupt flag does not trigger the RX Interrupt Service Request.
1	The DDRHSSPIn_RXF.RFFS interrupt flag triggers the RX Interrupt Service Request.

5.8. DDRHSSPI RX Interrupt Clear Register (DDRHSSPIn_RXC)

The DDRHSSPI RX Interrupt Clear Register is used to clear the interrupt flags in the DDRHSSPIn_RXF Register.

By writing "1" to a bit in this register, the Software can clear the corresponding flag in the DDRHSSPIn_RXF Register.

BITS_OFFSET	31	30	29	28	27	26	25	24

[bit31:8] Reserved: Reserved

[bit7] DLPERRC: DLP Error Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.DLPERR interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.DLPERR interrupt flag.

The read value is "0".

[bit6] RSSRC: Slave Select Released Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RSSRS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RSSRS interrupt flag.

The read value is "0".

[bit5] RFMTC: RX-FIFO Fill Level More Than Threshold Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RFMTS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RFMTS interrupt flag.

The read value is "0".

[bit4] RFLETC: RX-FIFO Fill Level Less Than or Equal to Threshold Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RFLETS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RFLETS interrupt flag.

The read value is "0".

[bit3] RFUC: RX-FIFO Under Run Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RFUS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RFUS interrupt flag.

The read value is "0".

[bit2] Reserved: Reserved

[bit1] RFEC: RX-FIFO Empty Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RFES interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RFES interrupt flag.

The read value is "0".

[bit0] RFFC: RX-FIFO Full Interrupt Clear

This bit is used to clear the DDRHSSPIn_RXF.RFFS interrupt flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_RXF.RFFS interrupt flag.

The read value is "0".

5.9. DDRHSSPI Fault Status Flag Register (DDRHSSPIn_FAULTF)

The DDRHSSPI Fault Status Flag Register indicates the status of the FAULT flag.

Once a fault occurs, the Software needs to take a corrective action. Whenever one of these flags gets set, the corresponding bus access returns with a bus error response.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit31:7] Reserved: Reserved

[bit6] DLPFS: DLP Error Fault

This status flag indicates that the DLP error fault has occurred on the data received on Serial Interface.

Bit	Description
0	DDRHSSPI does not detect the DLP error.
1	DDRHSSPI detects the DLP error.

The DLP error fault occurs if the DDRHSSPI receives 8 bit DLP value that is not matched DDRHSSPI_{in}_DLP.DLP.

This status flag is cleared when DDRHSSPI_{in}_FAULTC.DLPFC bit is written "1".

[bit5] Reserved: Reserved
[bit4] DRCBSFS: DMA Read Channel Block Size Fault

This status flag indicates that the block size fault has occurred on DMA read channel.

Bit	Description
0	DDRHSSPI does not detect the DMA read channel block size fault.
1	DDRHSSPI detects the DMA read channel block size fault.

The DMA read channel block size fault occurs if the DDRHSSPI RX block counter is 0 and there is a valid read access to the RX-FIFO (except for from the DAP controller).

This status flag is cleared when DDRHSSPI_{in}_FAULTC.DRCBSFC bit is written "1".

[bit3] DWCBSFS: DMA Write Channel Block Size Fault

This status flag indicates that the block size fault has occurred on DMA write channel.

Bit	Description
0	DDRHSSPI does not detect the DMA write channel block size fault.
1	DDRHSSPI detects the DMA write channel block size fault.

The DMA write channel block size fault occurs if the DDRHSSPI TX block counter is 0 and there is a valid write access to the TX-FIFO.

This status flag is cleared when DDRHSSPI_{in}_FAULTC.DWCBSFC bit is written "1".

[bit2] PVFS: Protection Violation Fault

This status flag indicates that a protection violation fault has occurred.

Bit	Description
0	DDRHSSPI does not detect the protection violation fault.
1	DDRHSSPI detects the protection violation fault.

The protection violation fault includes following cases:

- Access to a reserved register except some reserved registers.
- Write access to a read-only register.

This status flag is cleared when DDRHSSPI_{in}_FAULTC.PVFC bit is written "1".

[bit1] Reserved: Reserved

[bit0] UMAFS: Unmapped Memory Access Fault

This status flag indicates that an unmapped memory access fault has occurred.

This bit is set by DDRHSSPI when any of the following event occurs.

- In Direct Mode (i.e. DDRHSSPI_MCTRL.CSEN = 0), a System Bus access within the 256 MB address range starting from the DDRHSSPI base address is detected.
- In Command Sequencer Mode (i.e. DDRHSSPI_MCTRL.CSEN = 1), an access to a Serial Flash Memory which is not enabled (in DDRHSSPI_CSCFG.SSEL0EN-SSEL3EN bits) is detected.
- In Command Sequencer Mode (i.e. DDRHSSPI_MCTRL.CSEN = 1), a System Bus access to a memory location which is outside the memory range being mapped onto the four Slave Selects (configured through the DDRHSSPI_CSCFG.MSEL) is detected.
- While the module is disabled (i.e. DDRHSSPI_MCTRL.MES = 0), an access to a mapped memory is detected.

This status flag is cleared when DDRHSSPI_FAULTC.UMAF bit is written "1".

5.10. DDRHSSPI Fault Status Clear Register (DDRHSSPIn_FAULTC)

The DDRHSSPI Fault Status Clear Register is used to clear the status flags in the DDRHSSPIn_FAULTF Register.

By writing "1" to a bit in this register, the Software can clear the corresponding flag in the DDRHSSPIn_FAULTF Register.

BIT_OFFSET	31	30	29	28	27	26	25	24

[bit31:7] Reserved: Reserved

[bit6] DLPFC: DLP Error Fault Clear

This bit is used to clear the DDRHSSPIn_FAULTF.DLPFS status flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_FAULTF.DLPFS interrupt flag.

The read value is "0".

[bit5] Reserved: Reserved**[bit4] DRCBSFC: DMA Read Channel Block Size Fault Status Clear**

This bit is used to clear the DDRHSSPIn_FAULTF.DRCBSFS status flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_FAULTF.DRCBSFS interrupt flag.

The read value is "0".

[bit3] DWCBSFC: DMA Write Channel Block Size Fault Status Clear

This bit is used to clear the DDRHSSPIn_FAULTF.DWCBSFS status flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_FAULTF.DWCBSFS status flag.

The read value is "0".

[bit2] PVFC: Protection Violation Fault Status Clear

This bit is used to clear the DDRHSSPIn_FAULTF.PVFS status flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_FAULTF.PVFS status flag.

The read value is "0".

[bit1] Reserved: Reserved**[bit0] UMAFC: Unmapped Memory Access Fault Interrupt Clear**

This bit is used to clear the DDRHSSPIn_FAULTF.UMAFS status flag.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit clears the DDRHSSPIn_FAULTF.UMAFS status flag.

The read value is "0".

5.11. DDRHSSPI Direct Mode Configuration Register (DDRHSSPI_{IN}_DMCFG)

The DDRHSSPI Direct Mode Configuration Register configures the following operational parameter of DDRHSSPI:

- Byte Counter Mode of Slave Select De-assertion

This register is used only when DDRHSSPI is in Direct Mode.

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	SSDC	Reserved
ACCESS_TYPE	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R/W	R0,W0
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit7:2] Reserved: Reserved

[bit1] SSDC: Slave Select De-Assertion Control

The SSDC bit decides how the Slave Select is de-asserted:

Bit	Description
0	This is prohibited when DDRHSSPI is operated in Direct Mode.
1	Byte Counter Mode. DDRHSSPI _{IN} _DMBCC.BCC is used to decide when to de-assert the Slave Select.

[bit0] Reserved: Reserved

5.12. DDRHSSPI DMA Enable Register (DDRHSSPIn_DMAEN)

The DDRHSSPI DMA Enable Register can be used by the Software, for enabling/disabling of the DMA Service Requests generated by DDRHSSPI.

This register is used in Direct Mode only.

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	TXDMAEN	RXDMAEN
ACCESS_TYPE	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R/W	R/W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit7:2] Reserved: Reserved

[bit1] TXDMAEN: TX DMA Enable

This bit enable or disable the TX DMA channel(DMA write channel side).

Bit	Description
0	TX DMA channel is disabled.
1	TX DMA channel is enabled.

This bit is valid in Direct Mode.

[bit0] RXDMAEN: RX DMA Enable

This bit enable or disable the RX DMA channel(DMA read channel side).

Bit	Description
0	RX DMA channel is disabled.
1	RX DMA channel is enabled.

This bit is valid in Direct Mode.

5.13. DDRHSSPI Direct Mode Start Register (DDRHSSPIIn_DMSTART)

The DDRHSSPI Direct Mode Start Register can be used by the Software, for triggering the start of the serial transfer.

This register is used only in Direct Mode.

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	START
ACCESS_TYPE	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R,W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit7:1] Reserved: Reserved

[bit0] START: Start Transfer

This bit is a trigger to start a new serial transfer in Direct Mode.

Bit	Description
0	Writing "0" to this bit has no effect.
1	Writing "1" to this bit sets this bit. This bit can be only set by Software and it is cleared by Hardware.

DDRHSSPI resets this bit to "0" in any of following conditions:

- Serial transfer ends.
- Module is disabled (DDRHSSPIIn_MCTRL.MES= 0)
- DDRHSSPI is switched from Direct Mode to Command Sequencer Mode.

Writing "1" to this bit when the bit is already set to "1" has no effect on the current serial transfer (in any cases).

5.14. DDRHSSPI Direct Mode Peripheral Select Register (DDRHSSPIIn_DMPSEL)

The DDRHSSPI Direct Mode Peripheral Select Register can be used by the Software to select one of 4 Slave Selects for initiating the serial transfer.

This register is used only when DDRHSSPI is in Direct Mode.

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	PSEL[1]	PSEL[0]
ACCESS_TYPE	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R0,W0	R/W	R/W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit7:2] Reserved: Reserved

[bit1:0] PSEL[1:0]: Peripheral Select

The PSEL bits decide which of the 4 Slave Selects in oDDRHSSPIIn_SSEL3-0 is asserted for the current serial transfer.

Bits	Description
00	oDDRHSSPIIn_SSEL0 is asserted.
01	oDDRHSSPIIn_SSEL1 is asserted.
10	oDDRHSSPIIn_SSEL2 is asserted.
11	oDDRHSSPIIn_SSEL3 is asserted.

5.15. DDRHSSPI Direct Mode Transfer Protocol Register (DDRHSSPI_{IN}_DMTRP)

The DDRHSSPI Direct Mode Transfer Protocol Register configures the transfer protocol of the serial transfer.

This register is used only when DDRHSSPI is in Direct Mode.

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	Reserved	Reserved	DDRM	Reserved	TRP[3]	TRP[2]	TRP[1]	TRP[0]
ACCESS_TYPE	R0,W0	R0/W0	R/W	R0,W0	R/W	R/W	R/W	R/W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit7:6] Reserved: Reserved

[bit5] DDRM: DDR Mode

This bit indicates whether DDRHSSPI is in DDR Mode or SDR Mode, in Direct Mode.

Bit	Description
0	DDRHSSPI is in Single Data Rate (SDR) Mode.
1	DDRHSSPI is in Dual Data Rate (DDR) Mode.

[bit4] Reserved: Reserved

[bit3:0] TRP[3:0]: Transfer Protocol

Bits TRP[3:2] indicate the Duplex Configuration: TX-and-RX or TX-Only.

Bits TRP[1:0] indicate the using protocol: Legacy, Quad or Octal.

Bits	Description
0000	TX-and-RX in Legacy Mode is configured.
0011	This value is available only when DDRHSSPI _{IN} _MID.MID is 0x00000100 or 0x00000300. TX-and-RX in Octal Mode is configured.
1000	TX-Only in Legacy Mode is configured.
1010	TX-Only in Quad Mode is configured.
1011	This value is available only when DDRHSSPI _{IN} _MID.MID is 0x00000100 or 0x00000300. TX-Only in Octal Mode is configured.

All other combinations are RESERVED and prohibited.

5.16. DDRHSSPI Byte Count Control Register (DDRHSSPIn_DMBCC)

The DDRHSSPI Byte Count Control Register configures the number of bytes that would be transferred in the serial transfer.

This register is used in Direct Mode only.

BIT_OFFSET	15	14	13	12	11	10	9	8
BIT_NAME	BCC[15]	BCC[14]	BCC[13]	BCC[12]	BCC[11]	BCC[10]	BCC[9]	BCC[8]
ACCESS_TYPE	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	BCC[7]	BCC[6]	BCC[5]	BCC[4]	BCC[3]	BCC[2]	BCC[1]	BCC[0]
ACCESS_TYPE	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit15:0] BCC[15:0]: Byte Count Control

This field is used by DDRHSSPI in Direct Mode and when DDRHSSPIn_DMCFG.SSDC= 1.

BCC must be programmed by the Software with the number of bytes to be transmitted/received/both.

The value in this field is loaded in a down-counter immediately after it is written in this register, and the counter is decremented when a byte is serially transferred. DDRHSSPI completes the transaction and de-asserts the Slave Select when this down-counter reaches zero.

5.17. DDRHSSPI Byte Count Status Register (DDRHSSPIIn_DMBCS)

The DDRHSSPI Byte Count Status Register is a read-only register, which can be used by the Software, to know how many bytes are yet to be transferred, in the current serial transfer.

This register is valid only when DDRHSSPI is configured so that Byte Counter Mode is selected (i.e. if DDRHSSPIIn_DMCFG.SSDC= 1 in Direct Mode).

BIT_OFFSET	15	14	13	12	11	10	9	8
BIT_NAME	BCS[15]	BCS[14]	BCS[13]	BCS[12]	BCS[11]	BCS[10]	BCS[9]	BCS[8]
ACCESS_TYPE	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

BIT_OFFSET	7	6	5	4	3	2	1	0
BIT_NAME	BCS[7]	BCS[6]	BCS[5]	BCS[4]	BCS[3]	BCS[2]	BCS[1]	BCS[0]
ACCESS_TYPE	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit15:0] BCS[15:0]: Byte Count Status

This read-only field is valid only when DDRHSSPI is in Direct Mode and when DDRHSSPIIn_DMCFG.SSDC= 1.

BCS indicates the number of bytes in the current serial transfer that are not yet serially transmitted/received/both. Counter is updated with a new value only when current byte is considered to be transferred i.e. when last bit has been sent to memory or last bit from the memory has been received and put into FIFO.

For each FIFO entry where the number of cycles is less than a number of complete bytes, the BCS will be decremented by upper rounded value. For each FIFO entry where the number of cycles is less than a byte, the BCS will be decremented by one.

For FIFO entries where the number of cycles is more than one byte and less than two bytes, then the BCS will be decremented by two etc.

5.18. DDRHSSPI Direct Mode FIFO Status Register (DDRHSSPI_{DMFIFOSTATUS})

The DDRHSSPI Direct Mode FIFO Status Register contains the status bits like current fill-level of the TX/RX-FIFOs and whether the TX/RX path is active/idle i.e. Slave Select is asserted. This register is used only in Direct Mode.

[bit31:17] Reserved: Reserved

[bit16] SSACTIVE: Slave Select Active

This flag indicates whether a Slave Select is active.

Bit	Description
0	Slave Select is not active.
1	Slave Select is active.

[bit15:13] Reserved: Reserved

[bit12:8] TXFLEVEL[4:0]: Current Fill Level of TX-FIFO

This field indicates the current fill level of the TX-FIFO.

[bit7:5] Reserved: Reserved**[bit4:0] RXFLEVEL[4:0]: Current Fill Level of RX-FIFO**

This field indicates the current fill level of the RX-FIFO.

5.19. DDRHSSPI Direct Mode FIFO Configuration Register (DDRHSSPI_{DMFIFOCFG})

The DDRHSSPI FIFO Configuration Register configures the operation of the TX-FIFO and the RX-FIFO. The Software can configure the FIFO threshold levels and the FIFO width.

The Software can also initialize the FIFOs using the TXFLSH and RXFLSH bits in this register.

[bit31:21] Reserved: Reserved

[bit20] TXFLSH: TX-FIFO Flush

This bit can be used by the Software to flush the TX-FIFO and TX Shift Register.

Bit	Description
0	Writing "0" has no effect.
1	Writing "1" flushes the TX-FIFO and TX Shift Register. Please do not write "1" to this bit, while DDRHSSPIn_DMFIHOSTATUS.SSACTIVE bit is "1".

The read value is "0".

[bit19] RXFLSH: RX-FIFO Flush

This register can be used by the Software to flush the RX-FIFO and RX Shift Register.

Bit	Description
0	Writing "0" has no effect.
1	Writing "1" flushes the RX-FIFO and RX Shift Register. Please do not write "1" to this bit, while DDRHSSPIn_DMFIHOSTATUS.SSACTIVE bit is "1".

This read value is "0".

[bit18] TXCTRL: TXCTRL Bit to be Written to TX-FIFO

When one of the DDRHSSPIn_TXFIFO0-23 Registers is written, the 33rd bit (TXCTRL bit) in TX-FIFO word takes this value.

Before writing to one of the DDRHSSPIn_TXFIFO0-23 Registers, the Software must update this bit, to control the next entry of TX-FIFO. Please refer to Section 4.1.3 for details of TXCTRL.

[bit17:16] FWIDTH[1:0]: FIFO Width

This field indicates the FIFO Width. Depending on the configured width of the FIFO, the available size of the Shift-Register in the SPI-Core also changes.

Bits	Description
00	TX-FIFO, RX-FIFO and Shift-Register are 8-bit wide.
01	TX-FIFO, RX-FIFO and Shift-Register are 16-bit wide.
11	TX-FIFO, RX-FIFO and Shift-Register are 32-bit wide.

All other combinations are RESERVED and prohibited.

[bit15:13] Reserved: Reserved

[bit12:8] TXFTH[4:0]: TX-FIFO Threshold Level

Software must program this field with the threshold level of the TX-FIFO. The Maximum allowed value is 24 that is equal to TX-FIFO depth.

[bit7:5] Reserved: Reserved

[bit4:0] RXFTH[4:0]: RX-FIFO Threshold Level

Software must program this field with the threshold level of the RX-FIFO. The Maximum allowed value is 24 that is equal to RX-FIFO depth.

5.20. DDRHSSPI TX-FIFO Registers (DDRHSSPIn_TXFIFO0-23)

The DDRHSSPI TX-FIFO Registers are used to push the data into the TX-FIFO. There are 24 registers for the input of the TX-FIFO, and they are all consecutively placed in the register-map. Each of these 24 registers is identical in function and fields. This is because the System Bus protocol does not support burst transfers to the same address. Only DDRHSSPIn_TXFIFO0 Register is described here. Other registers (i.e. DDRHSSPIn_TXFIFO1-23) have same bit fields.

Only 8-bit, 16-bit or 32-bit accesses are allowed to these registers. A write access to these registers by the Software pushes 33-bits into the TX-FIFO. This 33rd bit corresponds to the DDRHSSPIn_DMFIFOCFG.TXCTRL bit. These registers are used only in Direct Mode.

PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit31:0] TXDATA[31:0]: TX-FIFO Data

Writing to this 32-bit register pushes the data into the next location of TX-FIFO, and increments the write pointer of TX-FIFO. In addition, the DDRHSSPIn_DMFIFOCFG.TXCTRL bit is internally written as the 33rd bit of a TX-FIFO entry.

When the Shift Register width is 32 bits (DDRHSSPIn_DMFIFOCFG.FWIDTH=0b11), only 32-bit access is possible.

When the Shift Register width is 16 bits (DDRHSSPI_n_DMFIFOCFG.FWIDTH=0b01), both 16-bit and 32-bit access are possible.

- a) 32-bit access shall access the full width of FIFO, but only the lower 16 bits are valid.
- b) 16-bit access with any alignment shall access the lower 16 bits of the FIFO.

When the Shift Register width is 8 bits (DDRHSSPI_n_DMFIFOCFG.FWIDTH=0b00), then 8-bit, 16-bit and 32-bit access are possible.

- a) 32-bit access shall access the full width of FIFO, but only the lower 8 bits are valid.
- b) 16-bit access with any alignment shall access the lower 16 bits of the FIFO, but only the lower 8 bits are valid.
- c) 8-bit access with any alignment shall access the lower 8 bits of the FIFO.

Other conditions (e.g. 8-bit write access in 32-bit wide setting) will cause a bus error response.

While the TX-FIFO is full, a write access to this register pushes the new data into the TX-FIFO and triggers a TX-FIFO overrun(DDRHSSPI_n_TXF.TFOS) event. When the TX-FIFO overrun condition occurs, the integrity of the data transmitted over the Serial Interface is not guaranteed. Before writing to this register, the Software must ensure that the TX-FIFO is not full to avoid an overrun.

5.21. DDRHSSPI RX-FIFO Registers (DDRHSSPIn_RXFIFO0-23)

The DDRHSSPI RX-FIFO Registers are used to pop the data out of the RX-FIFO. There are 24 registers for the output of the RX-FIFO, and they are all consecutively placed in the register-map. Each of these 24 registers is identical in function and fields. This is because the System Bus protocol does not support burst transfers to the same address. Only DDRHSSPIn_RXFIFO0 Register is described here. Other registers (i.e. DDRHSSPIn_RXFIFO1-23) have same bit fields.

8-bit, 16-bit and 32-bit read accesses are allowed to these registers. By reading these registers, the Software can pop the data out of the RX-FIFO. These registers are used in Direct Mode.

ACCESS_TYPE	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
PROT_TYPE	-							
INITIAL_VALUE	0	0	0	0	0	0	0	0

[bit31:0] RXDATA[31:0]: RX-FIFO Data

Reading this register returns a word of data from the RX-FIFO location pointed by the RX-FIFO read pointer. After a read access to this register, the RX-FIFO read pointer is incremented, if the read cycle was initiated by the System Bus master (not the DAP controller). If the DAP controller reads this register, the RX-FIFO read pointer is not incremented.

When the Shift Register width is 32 bits (DDRHSSPIn_DMFIFOCFG.FWIDTH=0b11), only 32-bit access is possible.

When the Shift Register width is 16 bits (DDRHSSPIn_DMFIFOCFG.FWIDTH=0b01), both 16-bit and 32-bit access are possible.

- a) 32-bit access shall access the full width of FIFO, but only the lower 16 bits are valid.
- b) 16-bit access with any alignment shall access the lower 16 bits of the FIFO.

When the Shift Register width is 8 bits (DDRHSSPIn_DMFIFOCFG.FWIDTH= 0b00), then 8-bit, 16-bit and 32-bit access are possible.

- a) 32-bit access shall access the full width of FIFO, but only the lower 8 bits are valid.
- b) 16-bit access with any alignment shall access the lower 16 bits of the FIFO, but only the lower 8 bits are valid.
- c) 8-bit access with any alignment shall access the lower 8 bits of the FIFO.

Other conditions (e.g. 8-bit write access in 32-bit wide setting) will cause a bus error response.

When the bus width to access the FIFO is greater than the width of FIFO, the upper redundant bits of the read data on the System Bus are filled with "0". For example, if configured FIFO width is 8 bits (DDRHSSPIn_DMFIFOCFG.FWIDTH= 0b00), and the read access of the FIFO is on 32 bits, then

- Only the bits RXDATA[7:0] are valid, AND
- The other bits RXDATA[31:8] are all "0".

The Software must not use any data from the unused most significant bits.

While the RX-FIFO is empty, a read access to this register pops invalid data out of the RX-FIFO. A RX-FIFO under run interrupt (DDRHSSPIn_RXF.RFUS) event is triggered if the read cycle was initiated by the System Bus master other than the DAP controller. If the DAP controller reads this register while the RX-FIFO is empty, the DDRHSSPIn_RXF.RFUS flag is not set.

5.22. DDRHSSPI Read Command Sequencer Data/Control Registers (DDRHSSPI_n_RDCSDC0-11)

The DDRHSSPI Read Command Sequencer Data/Control Registers 0-11 are the list of Data/Control registers which configure the phases of the serial transaction generated by the Command Sequencer for Memory Read operations. These registers are used only in Command Sequencer Mode.

Only the DDRHSSPIn_RDCSDC0 Register is explained here. Other registers have identical fields.

BIT_OFFSET	15	14	13	12	11	10	9	8

[bit15:8] RDCSDATA[7:0]: Command Sequencer Data or Control Byte for Memory-Read Transactions

This field contains either a command code or a control code according to the setting of DEC bit.

- When DEC bit is "0":
The RDCSDATA contains the 8-bit data to be transmitted on the Serial Interface.
- When DEC bit is "1":
The RDCSDATA[7:0] is decoded as follows.

RDCSDATA[2:0] = 0b000: Transmit address bits [7:0] of the Serial Flash Memory address.
RDCSDATA[2:0] = 0b001: Transmit address bits [15:8] of the Serial Flash Memory address.
RDCSDATA[2:0] = 0b010: Transmit address bits [23:16] of the Serial Flash Memory address.
RDCSDATA[2:0] = 0b011: Transmit address bits [31:24] of the Serial Flash Memory address.
RDCSDATA[2:0] = 0b100: Dummy cycle(s) on the SDATA output lines for RDCSDATA [7:3]
 number of SCLK cycles.

- RDCSDATA[7:3]= 0b00000 -> Dummy cycle for 1 SCLK cycle.
- RDCSDATA[7:3]= 0b00001 -> Dummy cycles for 2 SCLK cycles.

.....

RDCSDATA[2:0] = **0b**111: End of list.

All other values of RDCSDATA[2:0] are reserved and must not be used.

[bit7:1] Reserved: Reserved

[bit0] DEC: Decode

This bit controls whether to decode RDCSDATA[2:0].

Bit	Description
0	Transmit the RDCSDATA[7:0] as it is.
1	Decode the RDCSDATA[2:0] to decide the further action.

Notes:

- *The Command Sequencer Mode can use only a Continuous Read Command Sequence of the Serial FLASH Memory.*
- *The transmitted address bits of the Serial Flash Memory address must be registered in the DDRHSSPIn_RDCSDC0 Register.*

5.23. DDRHSSPI Module ID Register (DDRHSSPI_{IN}_MID)

This is a read-only register with a unique Module Identification Number which identifies the version of the DDRHSSPI used in the MCU.

[bit31:0] MID[31:0]: Module ID

This read-only register gives the unique module identification number of DDRHSSPI.

The unique module ID number identifies the version of the DDRHSSPI used in the MCU.

Bits	Description
0x00000001	<p>This version has limitations as below.</p> <ul style="list-style-type: none"> - Octal protocol (Dual Quad and Dual Legacy) is not supported. <ul style="list-style-type: none"> ➤ DDRHSSPIn_DMTRP.TRP[1:0] shall not be 0b11. ➤ DDRHSSPIn_CSCFG.MBM[1:0] shall not be 0b11. - Sample Point Control function is not supported. <ul style="list-style-type: none"> ➤ DDRHSSPIn_SDATASAMPLEPTCNT0-7.SDATASMPTCNT shall be fixed to 0. ➤ DDRHSSPIn_SDATASAMPLEPTLFT0-7.SDATASMPTLFT shall be fixed to 0. ➤ DDRHSSPIn_SDATASAMPLEPTRGH0-7.SDATASMPTRGH shall be fixed to 0. - DLP function is not supported. <ul style="list-style-type: none"> ➤ DDRHSSPIn_MCTRL.DLPEN shall be fixed to "0".
0x00000100	<p>This version supports the following features.</p> <ul style="list-style-type: none"> - Octal protocol (Dual Quad and Dual Legacy) - Sample Point Control function - DLP function
0x00000300	<p>The DDRHSSPIn_SDATASAMPLEPT* registers have been extended from six ([5:0]) to seven ([6:0]) bits, All other features are exactly the same as MID = 0x00000100.</p>

5.24. DDRHSSPI Command Sequencer Prefetch Address Register (DDRHSSPI_n_CSPREFETCHADDR)

The DDRHSSPI Command Sequencer Prefetch Address Register is used to keep the next available address of memory that is available in Command Sequencer Mode Prefetch Buffer.

This register is used only in Command Sequencer Mode.

[bit31:0] PRFADDR[31:0]: Prefetch Buffer Address

This register is used in Command Sequencer Mode.

Reading this register returns address available at the top of the Prefetch Buffer.

Writing to this register is not allowed.

5.25. DDRHSSPI SDATA Center Clock Sample Point Registers (DDRHSSPIn_SDATASAMPLEPTCNT0-7)

This feature is available only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300.

The DDRHSSPI SDATA Center Clock Sample Point Registers 0-7 are used for fine tuning and configuring of the clock center sampling point for all incoming SDATA ports. Each SDATA[7:0] input port has one register.

Only the DDRHSSPIn_SDATASAMPLEPTCNT0 Register is explained here. Other registers have identical fields.

[bit5:0] SDATASMP TCNT[5:0]: SDATA Sample Point Center Control

This field defines, for an incoming SDATA port, sample clock delay.

Clock is delayed through a series of buffers and each buffer output from delay chain, can be selected by putting corresponding value into this register.

Notes:

- About the actual use cases, refer to the 4.4.4 Using the DDRHSSPI in Command Sequencer Mode of Operation
-> "Calibration of SDATA Sampling Points", and "Re-adjustment of SDATA Sampling Points".
- When in using the DLP check function, please read the Notes of DDRHSSPIn_MCTRL.DLPEN bit carefully.

5.26. DDRHSSPI SDATA Left Clock Sample Point Registers (DDRHSSPIn_SDATASAMPLEPTLFT0-7)

This feature is available only when DDRHSSPIn_MID.MID is 0x00000100 or 0x00000300.

The DDRHSSPI SDATA Left Clock Sample Point Registers 0-7 are used for fine tuning and configuring of the clock left sampling point for all incoming SDATA ports. Each SDATA[7:0] input port has one register.

Only the DDRHSSPIn_SDATASAMPLEPTLFT0 Register is explained here. Other registers have identical fields.

[bit7:0] DLP[7:0]: Data Learning Pattern

This field is used to specify the data pattern of DLP function, and can be used only in Command Sequencer Mode.

Programming this register is possible only if DDRHSSPI_n_MCTRL.DLPEN= 1 and DLP is enabled on the Serial Flash Memory side.

It is necessary to write an expected DLP value to this field, before receiving a DLP from the Serial Flash Memory.

Results of comparing DLP data received from the Serial Flash Memory with DLP Register will be stored in DDRHSSPI_n_DLPSAMPLESTATUS Register.

Note:

- *When in using the DLP check function, please read the Notes of DDRHSSPIn_MCTRL.DLPEN bit carefully.*

5.29. DDRHSSPI Data Learning Pattern Sample Status Register (DDRHSSPI_n_DLPSAMPLESTATUS)

This feature is available only when DDRHSSPI_n_MID.MID is 0x00000100 or 0x00000300.

The DDRHSSPI Data Learning Pattern Status Register indicates status of DLP patterns recorded on each SDATA[7:0] input ports.

0	Indicates 8-bit data compare match: - Sampled data on the SDATA[0] port, at the sampling point DDRHSSPIn_SDATASAMPLEPTLFT0, WITH - DDRHSSPIn_DLP[7:0] value
1	Indicates 8-bit data compare miss: - Sampled data on the SDATA[0] port, at the sampling point DDRHSSPIn_SDATASAMPLEPTLFT0, WITH - DDRHSSPIn_DLP[7:0] value

Notes:

- When in using the DLP check function, please read the Notes of DDRHSSPIn_MCTRL.DLPEN bit carefully.
- These status bits are set along with DDRHSSPIn_FAULTF.DLPFS bit, however, the 'clear' conditions are different as below.
 - DDRHSSPIn_FAULTF.DLPFS bit:
 - Cleared by writing DDRHSSPIn_FAULTC.DLPFC="1".
 - DDRHSSPIn_DLPSAMPLESTATUS DLPSMPLSTxx bits:
 - Updated at the next Memory Read access (with discontinuous address).
 - 'Set'/'Clear' depends on the latest result of the DLP check in the SPI transaction.

5.30. DDRHSSPI Command Sequencer Configuration Register (DDRHSSPI_{IN}_CSCFG)

The DDRHSSPI Command Sequencer Configuration Register configures the Command Sequencer in DDRHSSPI.

This register must be programmed by the Software before enabling the Command Sequencer Mode. Attributes like Transfer Protocol, Slave Select enable/disable and Size of Serial Flash Memory interfaced with DDRHSSPI can be configured in this register.

[bit23] ITIMEREN: Idle Timer Enable

This bit is set whether Idle Timer is enabled or not.

Bit	Description
0	ITIMER is disabled. SSEL remains asserted after transfers are finished. The programmed value in DDRHSSPI _{IN} _CSITIME Register is ignored.
1	ITIMER is enabled. SSEL is de-asserted after the time expiration, that has been programmed in DDRHSSPI _{IN} _CSITIME Register.

[bit22:20] Reserved: Reserved

[bit19:16] MSEL[3:0]: Memory Selection Bits

This field indicates the range of the address space associated with each Slave Select. It also indicates the size of each memory banks in the selected Serial Flash Memory.

This field is used by Command Sequencer Mode for two things:

- To assert one of 4 Slave Selects for the memory mapped serial transfer
- To select the size of each memory bank in the selected Serial Flash Memory

Please refer to the Section 4.2 for more details.

[bit15:12] Reserved: Reserved

[bit11] SSEL3EN: Slave Select 3 Enable

This bit enables Slave Select 3 for Command Sequencer Mode.

Bit	Description
0	Access to the Serial Flash Memory mapped on Slave Select 3 is disabled.
1	Access to the Serial Flash Memory mapped on Slave Select 3 is enabled.

[bit10] SSEL2EN: Slave Select 2 Enable

This bit enables Slave Select 2 for Command Sequencer Mode.

Bit	Description
0	Access to the Serial Flash Memory mapped on Slave Select 2 is disabled.
1	Access to the Serial Flash Memory mapped on Slave Select 2 is enabled.

[bit9] SSEL1EN: Slave Select 1 Enable

This bit enables Slave Select 1 for Command Sequencer Mode.

Bit	Description
0	Access to the Serial Flash Memory mapped on Slave Select 1 is disabled.
1	Access to the Serial Flash Memory mapped on Slave Select 1 is enabled.

[bit8] SSEL0EN: Slave Select 0 Enable

This bit enables Slave Select 0 for Command Sequencer Mode.

Bit	Description
0	Access to the Serial Flash Memory mapped on Slave Select 0 is disabled.
1	Access to the Serial Flash Memory mapped on Slave Select 0 is enabled.

[bit7:4] Reserved: Reserved

[bit3] DDRMODE: DDR Mode

This bit indicates whether DDRHSSPI is in DDR Mode or SDR Mode, in Command Sequencer Mode.

Bit	Description
0	DDRHSSPI is in Single Data Rate (SDR) Mode.
1	DDRHSSPI is in Dual Data Rate (DDR) Mode.

[bit2:1] MBM[1:0]: Multi Bit Mode

This field decides the bit width on the Serial Interface in Command Sequencer Mode.

Bits	Description
00	This setting is prohibited.
01	This setting is prohibited.
10	Serial transfer works at Quad Protocol. Read data is sampled on SDATA[3:0]. Memory instruction, address, and other control information are transmitted on SDATA[3:0].
11	This value is available only when DDRHSSPI _{IN} .MID is 0x00000100 or 0x00000300. Serial transfer works at Dual Quad Protocol. Read data is sampled on SDATA[7:0]. Memory instruction, address, and other control information are transmitted on SDATA[7:0].

[bit0] Reserved: Reserved

5.31. DDRHSSPI Command Sequencer Idle Time Register (DDRHSSPI_{IN}_CSITIME)

The DDRHSSPI Command Sequencer Idle Time Register configures the idle-time-out period of Command Sequencer Mode in the DDRHSSPI.

The Software must program this timeout value before enabling the Command Sequencer Mode. This register is used only in Command Sequencer Mode.

[bit31:16] Reserved: Reserved

[bit15:0] ITIME[15:0]: Idle Time

This field decides the idle timeout period after a memory access in Command Sequencer Mode.

The idle timeout is available when DDRHSSPI_{IN}_CSCFG.ITIMEREN is "1".

Once DDRHSSPI completes the required number of memory read access on the Serial Interface and fills Prefetch Buffer, it keeps the Slave Select asserted. If no more access to the Serial Flash Memory is detected within the idle timeout period, then DDRHSSPI de-asserts the Slave Select. The value of ITIME is based on the system clock (iHCLK).

5.32. DDRHSSPI Command Sequencer Address Extension Register (DDRHSSPI_{IN}_CSAEXT)

The DDRHSSPI Command Sequencer Address Extension Register is used to extend the usable size of Serial Flash Memory, which is mapped by the Command Sequencer.

The Software must program this register if the Address Extension feature is required, in order to virtually access a Serial Flash Memory up to 16GB. If Address Extension is not to be used, the Software must reset all bits in this register to "0".

[bit31:13] AEXT[18:0]: Address Extension Bits

This field is used to extend the address of Serial Flash Memory in Command Sequencer Mode.

The DDRHSSPI_{IN}_CSAEXT Register contains the 19 most significant bits [31:13] of the memory address which are generated by the Command Sequencer. The generated memory address on each Slave Select is a concatenation of the appropriate number of bits from the DDRHSSPI_{IN}_CSAEXT Register and bits from the address bus. Please refer to the Section 4.2 for more details.

If the address extension is not used, the Software should reset this field to 0x00000.

[bit12:0] Reserved: Reserved

5.33. DDRHSSPI Command Sequencer Prefetch Buffer Configuration Register (DDRHSSPIn_CSPBUFFERCFG)

The DDRHSSPI Prefetch Buffer Configuration Register configures the operation of the Prefetch Buffer. The Software can also flush the Prefetch Buffer using the PBFLSH bit in this register.

[bit19] PBFLSH: Prefetch Buffer Flush

This bit can be used by the Software to flush the Prefetch Buffer and RX Shift Register.

Bit	Description
0	Writing "0" has no effect.
1	Writing "1" flushes the Prefetch Buffer and RX Shift Register. Please do not write "1" to this bit, while DDRHSSPIn_CSPBUFFERSTATUS.SSACTIVE bit is "1".

The read value is "0".

[bit18:4] Reserved: Reserved

[bit3:0] Reserved: Reserved

5.34. DDRHSSPI Command Sequencer Prefetch Buffer Status Register (DDRHSSPI_n_CSPBUFFERSTATUS)

The DDRHSSPI Command Sequencer Prefetch Buffer Status Register contains the status bits like current fill-level of the Prefetch Buffer or whether the Serial Flash Memory access is in progress or not, i.e. Slave Select is still asserted. This register is used only in Command Sequencer Mode.

[bit31:17] Reserved: Reserved

[bit16] SSACTIVE: Slave Select Active

This flag indicates whether a Slave Select is active.

Bit	Description
0	Slave Select is not active.
1	Slave Select is active.

[bit15:6] Reserved: Reserved

[bit5:0] PBLEVEL[5:0]: Current Fill Level of Prefetch Buffer

This field indicates the current fill level of the Prefetch Buffer.

CHAPTER 53: System SRAM Module (SRAM_IF)

This chapter explains the functions and operations of System SRAM module (SRAM_IF).

1. "Outline of SRAM_IF"
2. "Configuration and Block Diagram"
3. "Operation of SRAM_IF"
4. "SRAM_IF Register Set"
5. "How to use SRAM_IF"

SRAMIF-TXXPT03P01R01L06-E1-XX

1. Outline of SRAM_IF

The System SRAM module interacts with System SRAM Macro. It has an ECC logic which can generate interrupts during bit-error detection in SRAM read data. The ECC logic is made testable with the option of injecting bit errors into SRAM read data.

Feature List

- Integrates synchronous static RAM.
- Implements Single-bit error correcting ECC logic
- Generates Interrupt during Single-bit error detection.
- Sends error response on double-bit error detection.
- Error injection by changing both the data bits and ECC bits read from the SRAM to test the ECC functionality.
- Wait state insertion during the SRAM read and write operation to allow adjustment of the memory access time to higher operating frequencies.
- Power management capability to support power gating.
- Parallel read and write either to two different SRAM banks or to a single SRAM bank and register set is supported.
- LRG (Least Recently Granted) priority scheme is used in case of simultaneous read and write requests to the same SRAM bank or register set.

Abbreviations

This section lists the terms and abbreviations used in this chapter.

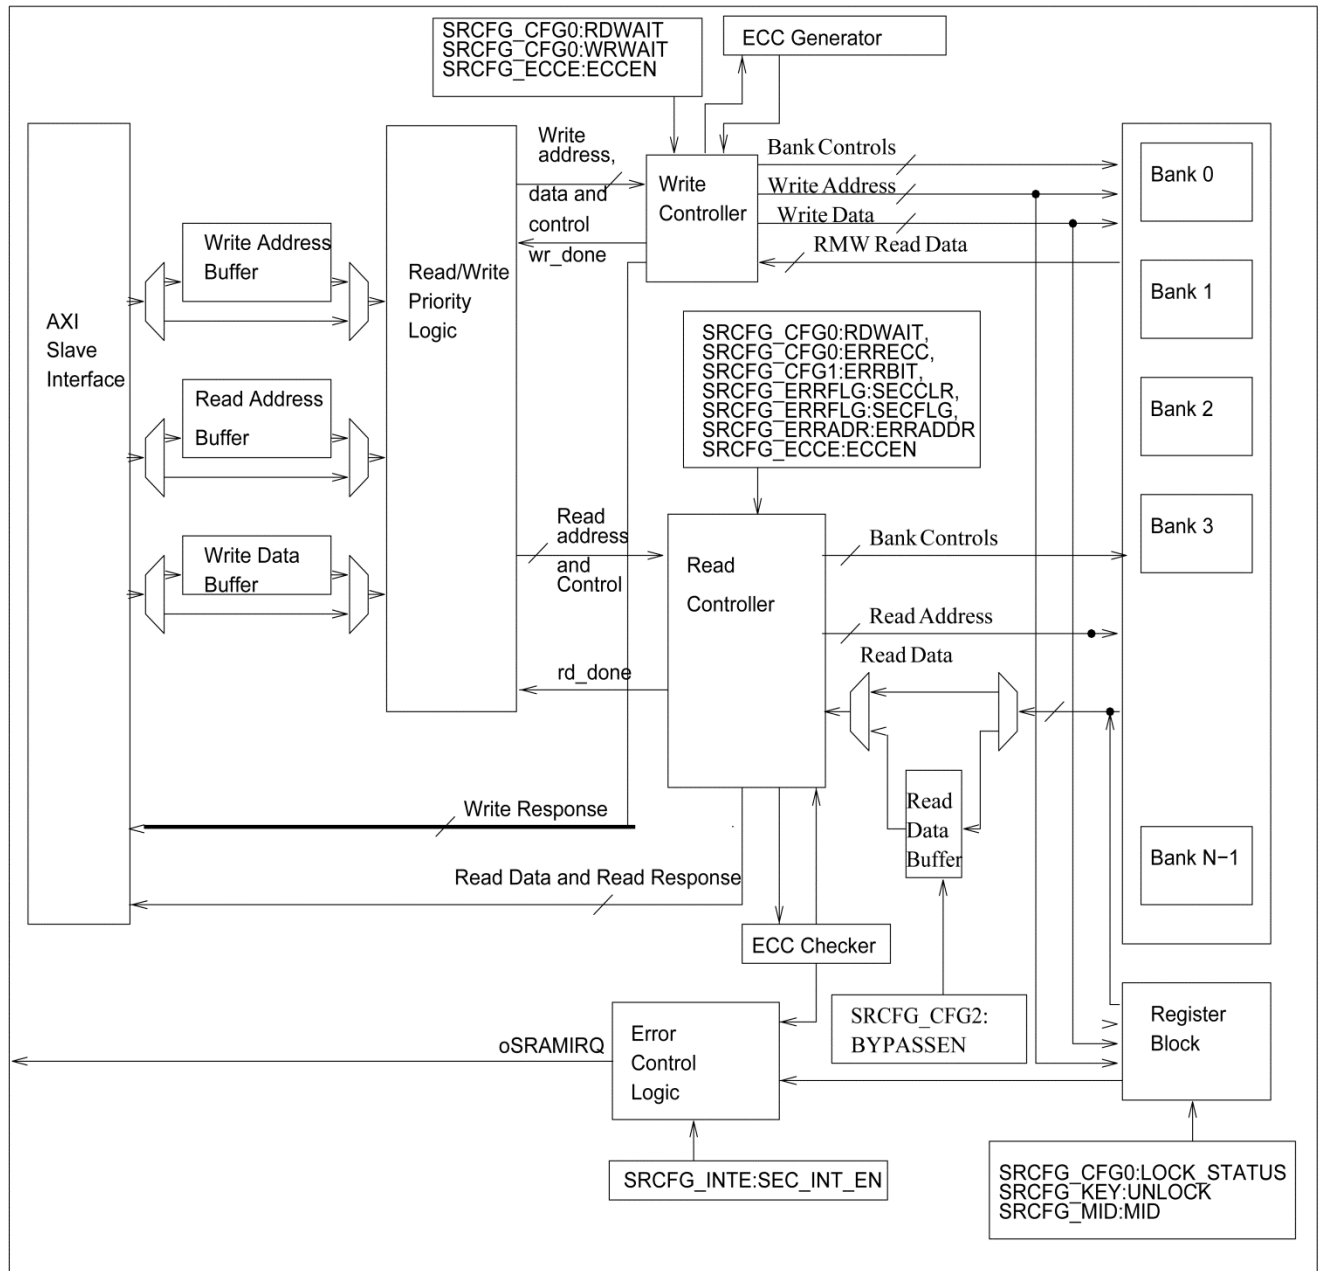

Table 1-1 Terms and Abbreviations

Term	Meaning
SRAM	Static Random Access Memory
ECC	Error Checking and Correcting
AXI	Advanced eXtensible Interface

2. Configuration and Block Diagram

The Figure 2-1 shows the block diagram of SRAM_IF.

Figure 2-1 SRAM_IF Block Diagram

3. Operation of SRAM_IF

This chapter describes the operation of SRAM_IF.

Description of Features Supported

WAIT States

Wait states can be configured for this module by writing to the SRCFG_CFG0 register through AXI Slave interface in privileged mode and only when the SRCFG_CFG0:LOCK_STATUS bit is Zero. An error response will be generated if there is a write to SRCFG_CFG0:RDWAIT or to SRCFG_CFG0:WRWAIT when SRCFG_CFG0:LOCK_STATUS is 1. The range of the wait states that can be configured range from 0 to 3. By default, maximum number of wait states (i.e., 3 wait states) is configured, which means the data will be latched in the fourth clock cycle after the address is given on memory interface for read transaction. Similarly, the write transaction will be on memory interface for configured number of clock cycles in SRCFG_CFG0:WRWAIT.

The read-data from the SRAM is used only after the configured number of wait states is completed. Once the WAIT states are configured, they continue to apply until they are again changed by writing into the configuration registers.

The SRCFG_CFG0:RDWAIT is used by write controller in case of RMW (read-modified writes) and by read controller for read transactions. These blocks will generate the wait states as per configuration and latch the memory data accordingly.

ECC Operation

When ECC checks are enabled, the checks for ECC will be done for every read data from SRAM. In this case, the single-bit errors would be detected and corrected while double-bit errors would be detected and an error response would be given to the master. Similarly, ECC will be calculated for every write transaction if ECC is enabled.

Partial writes are the write transactions that writes only part of the memory address (8-bit or 16-bit) and ECC for these writes will be calculated after merging the new data with old valid data in memory (other than the 8-bit or 16-bit write data). This operation is called read-modified write (RMW). The memory data will be read for the partial write address and will be written after merging the partial write data and recalculating the ECC.

Disabling the ECC will improve the performance for partial writes as it will save the clock cycles which would have been used to read the data from memory and recalculating the ECC. The write will be done in one cycle when ECC is disabled.

ECC generator calculates the ECC for write transactions and ECC checker checks the ECC for read transactions.

ECC Self-Test

This feature is implemented to test the 32-bit ECC logic. This is done by injecting bit-flips either at only the data or at the ECC data or at both that is read from the SRAM.

This is achieved by writing the required data into the SRAM_IF configuration register when the SRCFG_CFG0:LOCK_STATUS bit is Zero. The access to register space when SRCFG_CFG0:LOCK_STATUS=1 will generate an error response. If the errors are to be injected in the data then 32-bit ERRBIT data has to be written to SRCFG_CFG1 and if the errors are to be injecting in the ECC data then 7-bit ERRECC data has to be written to SRCFG_CFG0 register.

Note:

- *The data (32-bit data and 7-bit ECC data) read from RAM locations are always flipped for positions in the configuration registers SRCFG_CFG0:ERRECC and SRCFG_CFG1:ERRBIT having 1. So if this feature is not required, the register values have to be Zero. However, the default value is Zero.*

Error Generation

Error response will be generated when SRAM_IF configuration registers are accessed before unlocking condition or write a value other than the UNLOCK or LOCK value to the SRCFG_KEY register or non-privileged access to the SRAM_IF configuration registers. Also, access to the reserved space of the module generates this error response. Refer: Figure 5-1 for flow chart on usage of SRCFG_KEY:UNLOCK to access the register space.

Interrupt Generation

SRAM_IF generates interrupts in the following conditions:

ECC Checker has detected a Single-bit error in the SRAM Read data (SRCFG_ERRFLG:SECFLG is Set) and SRCFG_INTE:SEC_INT_EN bit is Set.

SRAM_IF also stores the address of the SRAM location where Single-bit error has occurred in SRCFG_ERRADR:ERRADDR register.

Parallel Read/Write Access and Priority Scheme

The AXI interface of SRAM_IF is shared for memory and register accesses. SRAM_IF supports parallel read and write access either to two different SRAM banks or to a single SRAM bank and register set. In case of simultaneous read and write requests to the same SRAM bank or register set, LRG (Least Recently Granted) priority scheme is used to grant one of these transactions. If the last granted request was a read, then write request will be given priority and vice-versa.

4. SRAM_IF Register Set

All registers in SRAM_IF are explained in this section.

SRAM_IF Registers

Table 4-1 Register Map

Offset	Register Name / Initial Value								Block
	+7	+6	+5	+4	+3	+2	+1	+0	
0x00000000	SRCFG_CFG1 00000000_00000000_00000000_00000000				SRCFG_CFG0 00000011_00000011_00000001_00000000				SRAM_IF

4.1. SRAM_IF Configuration Register 0 (SRCFG_CFG0)

The SRAM_IF Configuration Register 0 contains 7-bit ERR ECC bit data which is used to inject errors in the ECC data read from SRAM. It also contains 2-bit WAIT state values and a LOCK_STATUS bit.

Bit	31	30	29	28	27	26	25	24

[bit31:26] Reserved: Reserved Bits

[bit25:24] RDWAIT[1:0]: Read Data Wait State Value

These 2 bits are used to configure the number of data wait states for SRAM read transaction.

Bits	Description
00	0 wait State
01	1 wait State
10	2 wait States
11	3 wait States (default)

[bit23:18] Reserved: Reserved Bits

[bit25:24] WRWAIT[1:0]: Write Data Wait State Value

These 2 bits are used to configure the number of data wait states for SRAM write transaction.

Bits	Description
00	0 wait State
01	1 wait State
10	2 wait States
11	3 wait States (default)

[bit15:9] Reserved: Reserved Bits**[bit8] LOCK_STATUS: SRAM_IF Lock Status**

This bit provides locked or unlocked status of SRAM_IF.

Bit	Description
0	SRAM_IF is unlocked and therefore the configuration registers are accessible for write or read
1	SRAM_IF is locked and therefore the configuration registers are not accessible for write (default)

[bit7] Reserved: Reserved Bit**[bit6:0] ERRECC[6:0]: ECC ERBIT Value**

Each bit set in this register will cause an emulated bit-flip in the corresponding bit of read-data ECC bits.

Note:

- *SRCFG_CFG0:ERRECC[6:0] bits have no effect when ECC is disabled (SRCFG_ECCE:ECCEN = 0).*

4.2. SRAM_IF Configuration Register 1 (SRCFG_CFG1)

The SRAM_IF Configuration Register 1 contains the 32-bit ERRBIT data used to corrupt the data read from the SRAM.

Bit	31	30	29	28	27	26	25	24
Field	ERRBIT[31]	ERRBIT[30]	ERRBIT[29]	ERRBIT[28]	ERRBIT[27]	ERRBIT[26]	ERRBIT[25]	ERRBIT[24]
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	ERRBIT[23]	ERRBIT[22]	ERRBIT[21]	ERRBIT[20]	ERRBIT[19]	ERRBIT[18]	ERRBIT[17]	ERRBIT[16]
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Field	ERRBIT[15]	ERRBIT[14]	ERRBIT[13]	ERRBIT[12]	ERRBIT[11]	ERRBIT[10]	ERRBIT[9]	ERRBIT[8]
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	ERRBIT[7]	ERRBIT[6]	ERRBIT[5]	ERRBIT[4]	ERRBIT[3]	ERRBIT[2]	ERRBIT[1]	ERRBIT[0]
R/W Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] ERRBIT[31:0]: ERRBIT Value

Each bit set in this register causes an emulated bit-flip in the corresponding bit of 32-bit read data.

Notes:

- All subsequent accesses will fail in case ECC injection is configured.
- SRCFG_CFG1:ERRBIT[31:0] bits have no effect when ECC is disabled (SRCFG_ECCE:ECCEN = 0).

4.3. SRAM_IF Configuration Register 2 (SRCFG_CFG2)

The SRAM_IF Configuration Register 2 contains the 1-bit BYPASSEN used to enable the Read Data Buffer (RDB) Bypass path of data read from the SRAM.

Bit	31	30	29	28	27	26	25	24
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX

Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	BYPASSEN
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R/W
Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	0

[bit31:1] Reserved: Reserved Bits

[bit0] BYPASSEN: RDB Bypass Disable or Enable

RDB Bypass will be enabled in case this bit is 1.

Bit	Description
0	RDB Bypass path is disabled (default)
1	RDB Bypass path is enabled

Notes:

- Enabling RDB Bypass path (SRCFG_CFG2:BYPASSEN = 1) will reduce read latency since the read data from SRAM will be directly output to the Bus interface without buffering in RDB (Refer Figure 2-1).
- Although the default value of this bit is 0, it is not required to configure this bit to 0.

4.4. SRAM_IF Unlock/Lock Key Register (SRCFG_KEY)

The SRAM_IF Unlock/Lock Key Register has to be written to Unlock or Lock all accesses to SRAM_IF configuration registers.

Bit	31	30	29	28	27	26	25	24
Field	UNLOCK [31]	UNLOCK [30]	UNLOCK [29]	UNLOCK [28]	UNLOCK [27]	UNLOCK [26]	UNLOCK [25]	UNLOCK [24]

Field	UNLOCK [15]	UNLOCK [14]	UNLOCK [13]	UNLOCK [12]	UNLOCK [11]	UNLOCK [10]	UNLOCK [9]	UNLOCK [8]
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W
Protection Attribute	WP							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	UNLOCK [7]	UNLOCK [6]	UNLOCK [5]	UNLOCK [4]	UNLOCK [3]	UNLOCK [2]	UNLOCK [1]	UNLOCK [0]
R/W Attribute	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W	R0,W
Protection Attribute	WP							
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] UNLOCK[31:0]: SRAM_IF Unlock or Lock Key

If the correct unlock key is written into this register, the SRCFG_CFG0:LOCK_STATUS is set to '0' (unlocked) and all the configuration registers can be written. If the correct lock key is written into this register, the SRCFG_CFG0:LOCK_STATUS is set to '1' (locked) and the configuration registers will not be accessible. Illegal access to static configuration registers or writing value other than lock or unlock value to this register will cause protection error, an error response will be given back.

Locked registers are as follows.

- SRCFG_CFG0
- SRCFG_CFG1
- SRCFG_CFG
- SRCFG_ERRFLG
- SRCFG_INTE

- SRCFG_ECCE
- SRCFG_ERRADR

Note:

- *The "Unlock/Lock" Key values are specified as followings.*
SRAM_IF UNLOCK_VALUE = 0x5ECC551F
SRAM_IF LOCK_VALUE = 0x551FB10C

4.5. SRAM_IF Error Flag Register (SRCFG_ERRFLG)

The SRAM_IF Error Flag Register has the flags to indicate Single errors in SRAM Read data. It also contains the bits to clear these flags.

Bit	31	30	29	28	27	26	25	24
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved

[bit31:9] Reserved: Reserved Bits

[bit8] SECCLR: Single-Bit Error Flag Clear

If this bit is 1, it clears the flag SRCFG_ERRFLG:SECFLG. This bit always returns 0 on read.

[bit7:1] Reserved: Reserved Bits

[bit0] SECFLG: Single-Bit Error Detection Flag

This bit is set if single-bit error is detected in SRAM read data.

This also causes a maskable interrupt to be sent to CPU. If SRCFG_INTE:SEC_INT_EN bit is 0, no interrupt occurs.

Note:

- ECC Check is performed in parallel to both the upper and lower 32-bit of SRAM read data. Irrespective of the access size, SRCFG_ERRFLG:SECFLG is set when Single-bit error is detected in either the lower or the upper 32-bit of SRAM read data.

4.6. SRAM_IF Interrupt Enable Register (SRCFG_INTE)

The SRAM_IF Interrupt Enable Register contains the Interrupt Enable bits.

Bit	31	30	29	28	27	26	25	24
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX

Initial Value	0	0	0	0	0	0	0	0

[bit31:1] Reserved: Reserved Bits

[bit0] SEC_INT_EN: Single-Bit Error Interrupt Enable Bit

Bit	Description
0	Interrupt will not be generated even if SRCFG_ERRFLG:SECFLG bit is set (default)
1	Interrupt will be generated if SRCFG_ERRFLG:SECFLG bit is set (single error detection)

4.7. SRAM_IF ECC Enable Register (SRCFG_ECCE)

The SRAM_IF ECC Enable Register contains the ECC enable bits.

Bit	31	30	29	28	27	26	25	24
Field	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved	Reserved
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX

Protection Attribute	WPS							
Initial Value	0	0	0	0	0	0	0	1

[bit31:1] Reserved: Reserved Bits

[bit0] ECCEN: ECCEN Value

This bit enables or disables ECC logic in SRAM_IF. This bit is writable only once by software and all further writes to this byte will be signaled as protection error. An error response will be given back in that scenario.

Bit	Description
0	ECC logic is disabled
1	ECC logic is enabled (default)

4.8. SRAM_IF Error Address Register (SRCFG_ERRADR)

The SRAM_IF Error Address Register contains the absolute SRAM location address value where Single-bit error has occurred. Always ECC check is performed in parallel to both upper and lower 32-bit of SRAM read data and independent of the error location, the 64-bit aligned address is stored in this register.

Bit	31	30	29	28	27	26	25	24
Field	ERRADDR [31]	ERRADDR [30]	ERRADDR [29]	ERRADDR [28]	ERRADDR [27]	ERRADDR [26]	ERRADDR [25]	ERRADDR [24]
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	ERRADDR [23]	ERRADDR [22]	ERRADDR [21]	ERRADDR [20]	ERRADDR [19]	ERRADDR [18]	ERRADDR [17]	ERRADDR [16]
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX	R,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8
Field	ERRADDR [15]	ERRADDR [14]	ERRADDR [13]	ERRADDR [12]	ERRADDR [11]	ERRADDR [10]	ERRADDR [9]	ERRADDR [8]

Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	7	6	5	4	3	2	1	0
Field	ERRADDR [7]	ERRADDR [6]	ERRADDR [5]	ERRADDR [4]	ERRADDR [3]	ERRADDR [2]	ERRADDR [1]	ERRADDR [0]
R/W Attribute	R,WX	R,WX	R,WX	R,WX	R,WX	R0,WX	R0,WX	R0,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] ERRADDR[31:0]: ECC Error Address

This read-only register contains the absolute SRAM location address where single-bit ECC error has occurred. It will be updated with the latest SRAM address location where single-bit ECC error has occurred.

4.9. SRAM_IF Module Identification Register (SRCFG_MID)

The SRAM_IF Module Identification register contains the SRAM_IF module ID.

Bit	31	30	29	28	27	26	25	24
Field	MID[31]	MID[30]	MID[29]	MID[28]	MID[27]	MID[26]	MID[25]	MID[24]
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

Bit	23	22	21	20	19	18	17	16
Field	MID[23]	MID[22]	MID[21]	MID[20]	MID[19]	MID[18]	MID[17]	MID[16]
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R1,WX	R0,WX	R0,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	1	0	0

Field	MID[15]	MID[14]	MID[13]	MID[12]	MID[11]	MID[10]	MID[9]	MID[8]
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R1,WX	R1,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	1	1

Bit	7	6	5	4	3	2	1	0
Field	MID[7]	MID[6]	MID[5]	MID[4]	MID[3]	MID[2]	MID[1]	MID[0]
R/W Attribute	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX	R0,WX
Protection Attribute	-							
Initial Value	0	0	0	0	0	0	0	0

[bit31:0] MID[31:0]: Module ID

This read-only register gives the unique module identification number of SRAM_IF module.

The unique module ID number identifies the version of the SRAM_IF module used in the MCU.

Refer to the specific device datasheet for the module identification number of SRAM_IF.

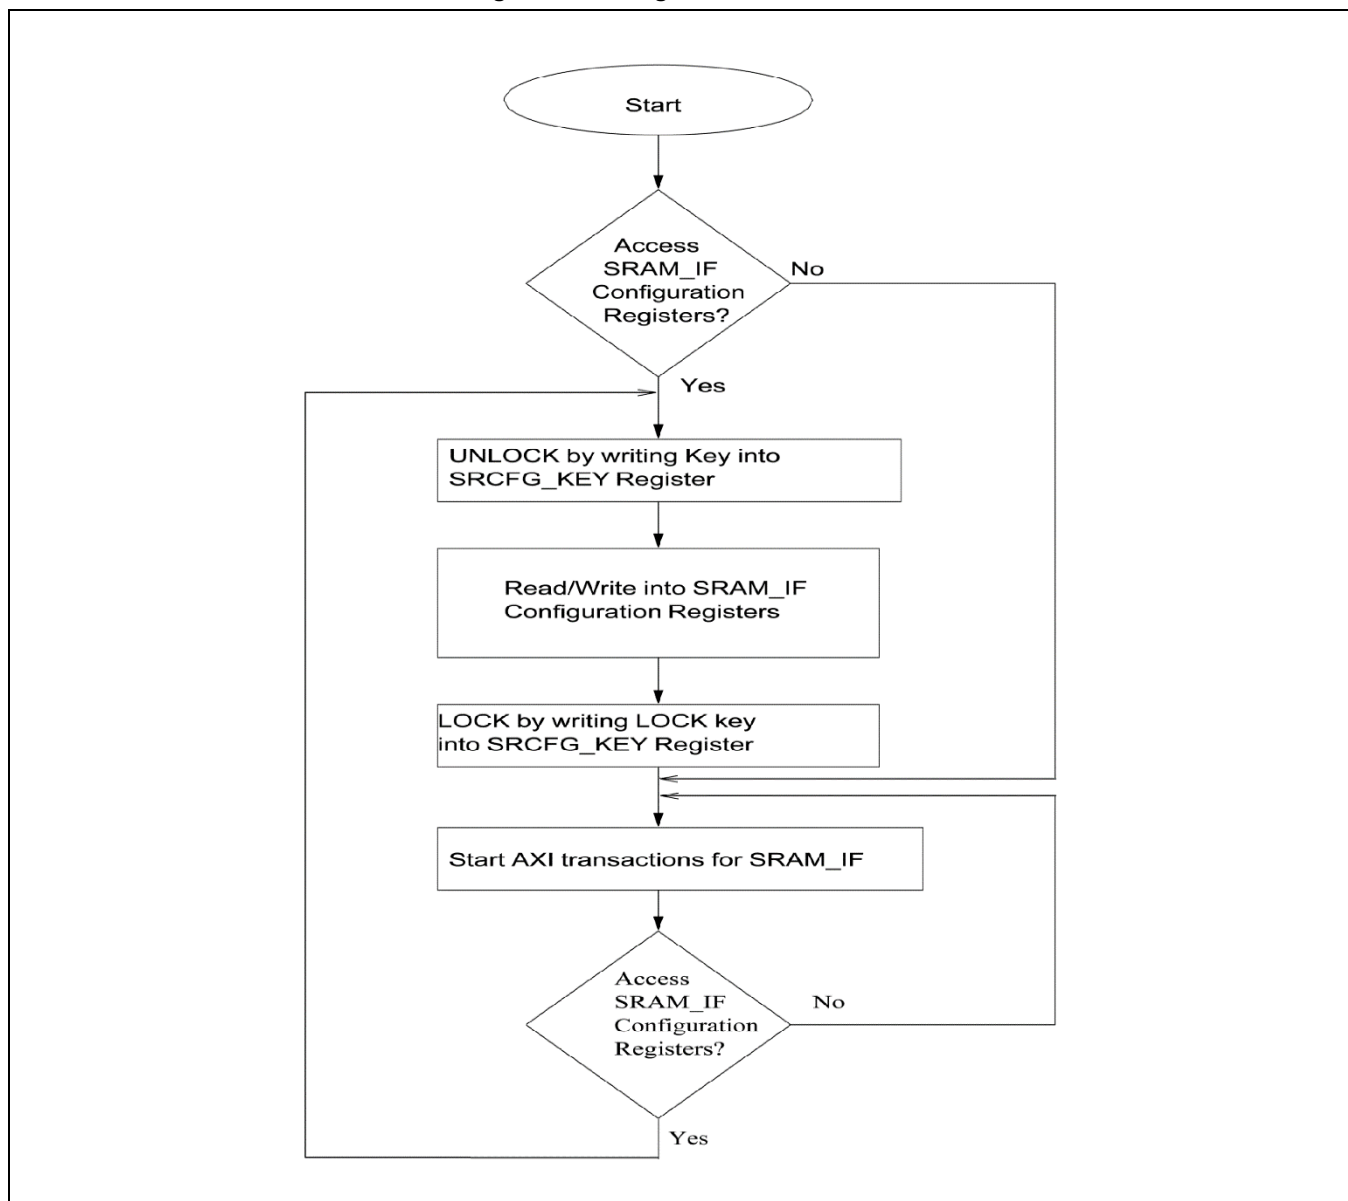

5. How to use SRAM_IF

The following flowchart shows the sequence of steps to be followed to configure the SRAM_IF Registers.

Typical SRAM_IF Configuration Flow

Figure 5-1 shows the steps to write to SRAM_IF Configuration Registers.

Figure 5-1 Configuration Flowchart

CHAPTER 54: Bit-Band Unit

This chapter provides an overview and notes on bit-band unit.

1. Overview
2. Explanation of Operation

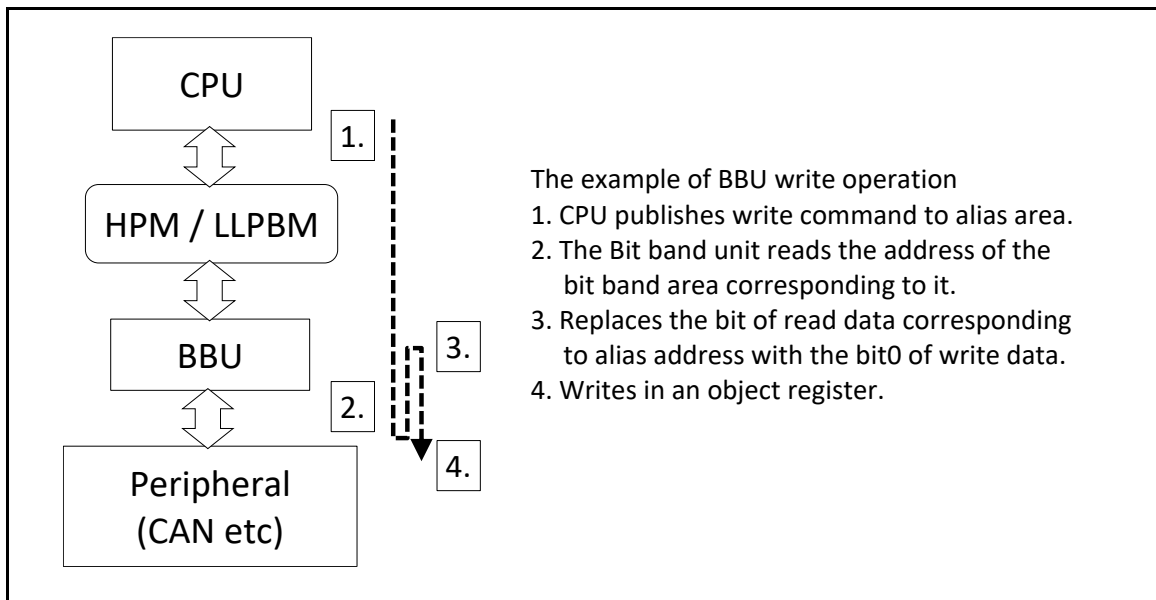

BBU-TXXPT03P01R01L07-E1-XX

1. Overview

This section shows the features of bit-band unit.

The memory map of this device has an address area called "bit-band alias area" and an address area named "bit-band area". Bit-band unit has a function, by writing 1 byte in bit-band alias area, to set or clear 1 bit corresponding to bit-band area. Also, by reading 1 byte in bit-band alias area, the corresponding 1 bit in bit-band area is read to bit[0] of the read value through bit-band unit. Bit-band area is mapped over resource area. To set or clear only a specific bit in the register, it is possible to process bit manipulation faster than reading and writing the register.

Figure 1-1 Bit-Band Alias Unit Operations (Write)

2. Explanation of Operation

This section provides an explanation of bit-band unit operation.

Bit-band Area and Bit-band Alias Area

The relationship between bit-band alias area and bit-band area is shown in Figure 2-1. 1 byte of bit-band alias area corresponds to 1 bit of bit-band area. The correspondence between bit-band alias area and bit-band area is shown in Table 2-1.

Figure 2-1 Bit-Band Alias Area and Bit-Band Area

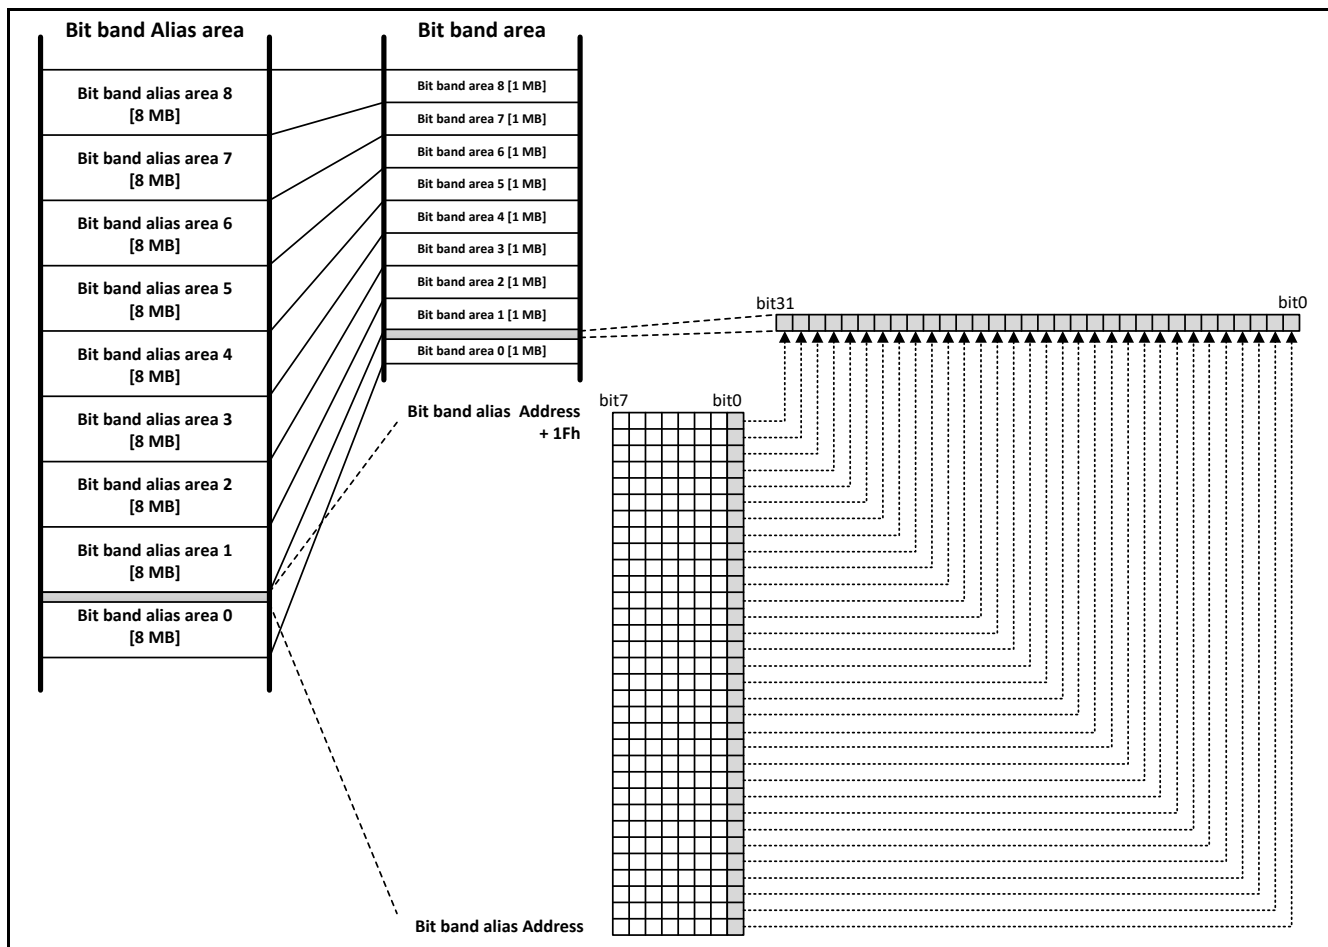

Table 2-1 Correspondence between Bit-band Alias Area and Bit-band Area

Bit-band Area	Group	Bit-band Alias Area
0xB030_0000 to 0xB031_FFFF	SYSC1 Group	0xB100_0000 to 0xB10F_FFFF
0xB040_0000 to 0xB041_FFFF	Memory & Config Group	0xB110_0000 to 0xB11F_FFFF
0xB060_0000 to 0xB06F_FFFF	MCU Config Group	0xB080_0000 to 0xB0FF_FFFF
0xB470_0000 to 0xB47F_FFFF	Common Peripheral Group #2	0xB700_0000 to 0xB77F_FFFF
0xB480_0000 to 0xB487_FFFF	Common Peripheral Group #0	0xB780_0000 to 0xB7BF_FFFF
0xB488_0000 to 0xB48F_FFFF	Common Peripheral Group #1	0xB7C0_0000 to 0xB7FF_FFFF
0xB490_0000 to 0xB497_FFFF	Common Peripheral Group#0 (MCAN)	0xB4C0_0000 to 0xB4FF_FFFF

Bit Set and Bit Clear by Bit-band Unit

If "1" is written in bit[0] in address in bit-band alias area, the corresponding bit in bit-band area is set to "1". Also, if "0" is written, corresponding bit in bit-band area is cleared to "0". The value of bit[7:1] is not affected.

Notes:

- In the following case, writing is ignored and a bus error is returned.
 - When a value other than byte size is written in bit-band alias area
- Following registers do not support write operations via bit-band unit. If write operations via bit-band unit are performed on them, either a bus error will be returned or an incorrect value will be written.
 - Registers to which byte accesses are prohibited
 - Registers protected by Keycode

Reading Bit by Bit-band Unit

The corresponding bit of bit-band area is read in bit[0] by reading using the corresponding address of bit-band in bit-band alias domain.

Notes:

- In the following case, a bus error is returned.
 - When a value other than byte size is read for bit-band alias area
- Following registers do not support read operations via bit-band unit. If read operations via bit-band unit are performed on them, either a bus error will be returned or an incorrect value will be read.
 - Registers to which byte accesses are prohibited

Details of Address Correspondence

The address of bit-band alias single bit manipulation area is calculated using the following formula

$$(1) + 8 * [(3) - (2)] + (4)$$

- (1) ...Base address of bit-band alias single bit manipulation area corresponding to each group
- (2) ...Base address of bit-band area of each group
- (3) ...Register address to manipulate in bit-band area for each group
- (4) ...Bit position to manipulate

Table 2-2 shows an example of SYSC1 Group. Groups other than SYSC1 Group are calculated in the same way.

Table 2-2 Details of Address Correspondence (An Example of SYSC1 Group)

Register Address of Bit-band Area (SYSC1 Group)	Bit Position	Register Address of Bit-band Alias Single Bit Manipulation Area
0xB0300000 (2)	bit[0]	0xB1000000 (1)
	bit[1]	0xB1000001
	bit[2]	0xB1000002
	...	
0xB0300010 (3)	bit[0]	0xB1000080
	bit[1]	0xB1000081
	bit[2]	0xB1000082
	bit[3] (4)	0xB1000083 (= (1) + 8 * ((3) - (2)) + (4))
	...

CHAPTER6:Low Power Consumption 4. Operation Procedure 4.2.Transition from RUN to PSS	<p>Features of "For details" should be corrected as indicated by the shading below.</p> <p>(Error)</p> <p>The following figure is a flowchart of RUN to PSS transition operations.</p> <p>(Correct)</p> <p>■Prepare Wakeup from PSS Mode by Interrupt</p> <p>There are multiple ways to setup interrupts for wakeup from PSS mode. The major steps that apply in most cases are described in the following list.</p> <p>Table 4-1 Steps to prepare Wakeup from PSS by Interrupt</p> <table><tr><th>Step</th><th>Purpose</th><th>Action</th></tr><tr><td>S1</td><td>Make sure that the CPU accepts interrupts.</td><td>Set the I-flag in PSR of the CPU core to "0". This enables any interrupt that might occur.</td></tr><tr><td>S1</td><td>If it is intended to finish pending interrupts before PSS mode, wait for the indication from IRCn.</td><td>Poll the IRCn_IRQST:nIRQ flag. While reading "0", not all ISRs are finished. Once the logic value "1" is read, the IRC will not accept any subsequent interrupts. (*1)</td></tr><tr><td>S1</td><td>Configure the desired wake-up sources.</td><td>Enable the interrupts that are intended for wake-up, disable others. (*2)</td></tr><tr><td>S1</td><td>Remove the lock from IRC.</td><td>Write to any of the registers that are listed in the description of IRCn_IRQST:nIRQ. - IRCn_IRQVAr - IRCn_IRQPL0-127 - IRCn_IRQS0-15 - IRCn_IRQR0-15 - IRCn_IRQCES0-15 - IRCn_IRQCEC0-15 - IRCn_IRQCE0-15 - IRCn_IRQHC - IRCn_IRQPLM - IRCn_CSR</td></tr><tr><td>S1</td><td>Prepare the transition from RUN to PSS mode</td><td>Follow the steps for transition to PSS mode as described above.</td></tr><tr><td>S1</td><td>Transition to PSS mode</td><td>Execute the WFI instruction.</td></tr></table> <p>Notes:</p> <p>– (*1): If the read access in step S2 returns a pending interrupt request, the processor will execute the interrupt service routine. After return from interrupt, the IRQ interrupt status bit nIRQ will show "end of return from interrupt instruction".</p> <p>– (*2): If the interrupt should be used for wakeup without a specific interrupt service routine, this can be achieved by setting the I-Flag to "1" before S3. It must be considered that any write access to one of the registers listed in S4 will remove the lock from the IRC.</p>	Step	Purpose	Action	S1	Make sure that the CPU accepts interrupts.	Set the I-flag in PSR of the CPU core to "0". This enables any interrupt that might occur.	S1	If it is intended to finish pending interrupts before PSS mode, wait for the indication from IRCn.	Poll the IRCn_IRQST:nIRQ flag. While reading "0", not all ISRs are finished. Once the logic value "1" is read, the IRC will not accept any subsequent interrupts. (*1)	S1	Configure the desired wake-up sources.	Enable the interrupts that are intended for wake-up, disable others. (*2)	S1	Remove the lock from IRC.	Write to any of the registers that are listed in the description of IRCn_IRQST:nIRQ. - IRCn_IRQVAr - IRCn_IRQPL0-127 - IRCn_IRQS0-15 - IRCn_IRQR0-15 - IRCn_IRQCES0-15 - IRCn_IRQCEC0-15 - IRCn_IRQCE0-15 - IRCn_IRQHC - IRCn_IRQPLM - IRCn_CSR	S1	Prepare the transition from RUN to PSS mode	Follow the steps for transition to PSS mode as described above.	S1	Transition to PSS mode	Execute the WFI instruction.
Step	Purpose	Action																				
S1	Make sure that the CPU accepts interrupts.	Set the I-flag in PSR of the CPU core to "0". This enables any interrupt that might occur.																				
S1	If it is intended to finish pending interrupts before PSS mode, wait for the indication from IRCn.	Poll the IRCn_IRQST:nIRQ flag. While reading "0", not all ISRs are finished. Once the logic value "1" is read, the IRC will not accept any subsequent interrupts. (*1)																				
S1	Configure the desired wake-up sources.	Enable the interrupts that are intended for wake-up, disable others. (*2)																				
S1	Remove the lock from IRC.	Write to any of the registers that are listed in the description of IRCn_IRQST:nIRQ. - IRCn_IRQVAr - IRCn_IRQPL0-127 - IRCn_IRQS0-15 - IRCn_IRQR0-15 - IRCn_IRQCES0-15 - IRCn_IRQCEC0-15 - IRCn_IRQCE0-15 - IRCn_IRQHC - IRCn_IRQPLM - IRCn_CSR																				
S1	Prepare the transition from RUN to PSS mode	Follow the steps for transition to PSS mode as described above.																				
S1	Transition to PSS mode	Execute the WFI instruction.
