

Please note that Cypress is an Infineon Technologies Company.

The document following this cover page is marked as “Cypress” document as this is the company that originally developed the product. Please note that Infineon will continue to offer the product to new and existing customers as part of the Infineon product portfolio.

Continuity of document content

The fact that Infineon offers the following product as part of the Infineon product portfolio does not lead to any changes to this document. Future revisions will occur when appropriate, and any changes will be set out on the document history page.

Continuity of ordering part numbers

Infineon continues to support existing part numbers. Please continue to use the ordering part numbers listed in the datasheet for ordering.

THIS SPEC IS OBSOLETE

Spec No: 001-66458

Spec Title: BUILDING AN EZ-HOST(TM) / EZ-OTG(TM)
PROJECT FROM START TO FINISH - AN048

Sunset Owner: Manaskant Desai (MDDD)

Replaced by: None

Building an EZ-Host™ / EZ-OTG™ Project From Start to Finish

AN048

Author: Narayana Murthy M

Associated Project: Yes

Associated Part Family: CY7C67300/CY7C67200

Software Version: None

Associated Application Notes: None

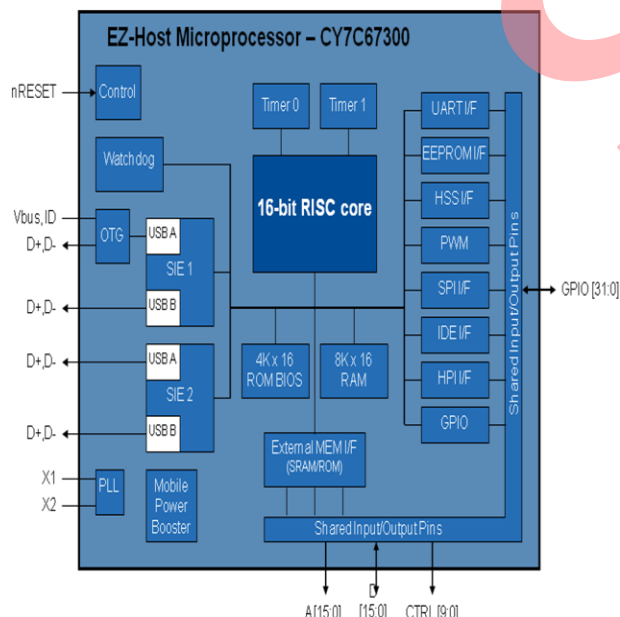

Application Note Abstract

This application note explains about a simple project to control the buttons and lights hardware present on either an EZ-HOST™ / EZ-OTG™ DVK boards. The EZ_HOST / EZ_OTG processor GNU tool chain, other cypress developed utilities are introduced and their usage in different stages of compiling the project are explained in detail.

Introduction

The EZ_HOST and EZ_OTG chipsets are Cypress USB 2.0 compliant full speed controllers. They perform functions as USB peripheral, USB Host (UHCI) and OTG. Both the chips are based on CY16, a 16-bit proprietary RISC processor. The following figure summarizes the list of all the functional blocks inside EZ_HOST chip.

Figure 1. EZ_Host (CY7C67300) Chip Block Diagram

The EZ-HOST / EZ-OTG contains several other data interfaces like UART, SPI, HSS and HPI. The EZ_HOST / EZ_OTG has the flexibility to either function independently in a standalone mode or in co-processor mode. In co-processor mode, this chip can be interfaced to external 32-bit processors (via SPI/HSS/HPI) like ARM, OMAP or any other DSP processor that does not possess USB functionality (OTG/Host/Peripheral). For more detailed

feature list, refer to datasheets of both EZ-HOST and EZ-OTG.

CY16 Tool Chain Description

The CY3663 EZ-Host and EZ-OTG Development Kit software contains a full set of standard GNU-based tools. These tools have been ported to our CY16 processor-based EZ-Host and EZ-OTG products. To build and run any firmware example projects based on CY16 these tools are essential.

- **cy16-elf-gcc:** Port of standard GNU GCC compiler. This compiles the C source files part of the project into object files.
- **cy16-elf-as:** Port of standard GNU GAS assembler. Files with assembly format and instructions are converted to object file format.
- **cy16-elf-ld:** All the object files generated from C and assembly source files will be combined with start address as mentioned in the Make file.
- **cy16-elf-objdump:** Port of standard GNU objdump. Taking object file as input the tool generates symbol table, code and data sections of the file.
- **cy16-elf-objcopy:** Copies either complete or partial information to another object file as output.
- **cy16-elf-gdb:** Port of standard GNU GDB debugger.
- **cy16-elf-libremote:** Port of standard GNU libremote.
- **scanwrap:** Cypress-developed utility to add additional header opcodes to raw firmware binary. The BIOS to perform different tasks based on opcode value.
- **qtui2c:** Cypress-developed utility to program firmware to EEPROM.
- **BASH_ENV.BAT:** Cypress-developed batch file. This acts as a front-end command line shell to invoke various CY16 GNU utilities to compile the project.

All of the required tools listed above, including many other tools, are installed automatically when the CY3663 software is installed. In fact, these tools have many environmental dependencies in order to work properly that are also automatically handled by the install, so properly install the [CY3663 Development Kit software](#) before attempting to build an EZ-Host or EZ-OTG project. For complete documentation on all utilities, including standard RedHat GNUPro documentation, refer to the CY3663 documentation folder (C:\Cypress\USB\OTG-Host\Docs\OTG-Host Tools) and the tool binaries (C:\Cypress\USB\OTG-Host\Tools\cy16-020830\H-i686-pc-cygwin\bin).

EZ-HOST / EZ-OTG Frameworks

The EZ-HOST and EZ-OTG firmware examples are a set of examples developed by cypress. After installing CY3663 development kit software all the firmware examples that are part of the kit are copied under directory path: \Cypress\USB\OTG-Host\Source\stand-alone. Following is the snapshot view of the examples folder:

Figure 2. CY3663 DVK Firmware Examples Directory View

From the figure, the firmware examples of CY3663 are classified into two main directories

- **Simple Examples: (se1-10):** These examples demonstrate the USB and several other functionalities.
- **Design Examples: (de1-4):** These examples demonstrate USB and additionally support co-processor mode functionality of EZ-HOST/EZ-OTG.

The simple and design examples are base references for customers to start their firmware design for commercial purpose. Both set of examples rely on **/common** directory usually termed as EZ-HOST/EZ-OTG frameworks. This **/common** directory contains set of source files to allow low-level access to each of the interfaces available inside EZ-HOST/EZ-OTG. For more details on the content of frameworks, refer to *OTG-Host Frameworks Reference Guide.pdf* under C:\Cypress\USB\OTG-Host\Docs.

Buttons and Lights Example Description

The buttons and Lights example project presented in this note works on common hardware available on both EZ-HOST and EZ-OTG boards. Following is the picture of EZ-HOST development board supplied in the CY3663 development kit.

Figure 3. CY3663 Kit-EZ-HOST Development Board

The EZ-HOST/EZ-OTG can control the Dipswitch, Push-buttons, 7-segment display and LED's through CPLD present on the board. The Buttons and Lights example presented here can run on either the EZ-Host or EZ-OTG stand-alone boards shipped with the CY3663 development kit. This example should not be confused with Buttons and Lights Examples (se3-se10) explained in *USB Multi-Role Device Design By Example* book. The EZ-Host and EZ-OTG stand-alone boards indirectly memory map these LEDs and buttons through the U8 CPLD. Therefore, this example bit bangs a standard memory interface to RD/WR the CPLD. A complete description of these boards, including the CPLD indirect memory map, is included in the *CY3663 Hardware Users Manual* included with the CY3663 kit.

Buttons and Lights Project Files

Below is a short list of the files that make up this Buttons and Lights example.

- BAL.c
- StartupNoBIOS.s or StartupWithBIOS.s
- cy7c67200_300.h
- BAL.ld

BAL.c File Description

This file contains a simple main routine along with functions to read and write the CPLD. Using the GPIO pins mapped to address, these peripherals can communicate with each other. Following are the code snippets on how EZ-HOST or EZ-OTG can access the peripherals connected through CPLD

```
void writeCPLD(int address, int data)
{
    writeCPLDADX(address);
    writeCPLDDATA(data);
}

int readCPLD(int address)
{
    writeCPLDADX(address);
    return readCPLDDATA();
}
```

The main routine defined in this file is just a “while(1)” loop that looks for button presses. Pressing the S5 button will turn ON LEDs D1, and D9:D7. When button S1 is pressed, these LEDs will turn off. Following is the relevant code snippet.

```
while(1)    {

    button_read = readCPLD(0x0000);
                /* Read Buttons */

    if((button_read & 0x01) == 0)    {
        /* If Button S1 (PB_UP) is
        pressed, turn LEDs OFF */
        writeCPLD(0x7, 0xFF);
        writeCPLD(0x1, 0xFF);
        /* Clear Button S1
        Status */
    }

    if((button_read & 0x08) == 0)    {
        /* If Button S5 (PB_DN) is
        pressed, turn LEDs ON */
        writeCPLD(0x7, 0x00);
        writeCPLD(0x4, 0xFF);
        /* Clear Button S5
        Status */
    }

}
```

Complete code of this file can be found in the later sections of the note titled “Source code”.

StartupNoBIOS.s / StartupWithBIOS.s File Description

The default GNU start-up code is generally contained within crt0.s. The crt0.s file contains a lot of code overhead in functions that are rarely used for embedded applications. Therefore, we will supply our own start-up code in a.s file and instruct the compiler to use it instead of the default crt0.s file. This will save quite a bit of code space. For more information on minimizing code space by not using crt0.s, please see the *OTG-Host Boot Code Design* white paper included in the CY3663 kit. The most important portion of

our start-up file is the _start routine. This routine is intended to be run before main and is loaded at the ORG location specified in the BAL.ld file. In its simplest form, the _start code is just a jump to main. Code at this location or the start of main will generally determine how the task or main function interacts with the BIOS.

BAL.ld File Description

A default linker script can be automatically generated by typing “cy16-elf-ld --verbose > BAL.ld.” This command will generate a default linker script file called BAL.ld that contains everything our project needs and more. There are a few simple changes that must be made to this default script for our project (and other EZ-Host/OTG projects).

These small changes are listed as follows.

1. Change the base address for our code to start at. This can be done by changing the “.” =” statement following SECTIONS to 0x1000. The 0x1000 location ensures that we allow enough room for the GDB stub to be loaded when in debug mode.
2. Anything that is not code in the file must be commented out, because otherwise a parse error will occur when linking. This includes the GNU version information in the top of the default file and the “=====” lines at the top and bottom of the file.

Buttons and Lights Without BIOS

The StartupNoBIOS.s file never returns control of the processor to the BIOS. The BIOS first executes some initialization routines such as setting up the stack and loading the program. Then program execution begins at “_start” as defined in the StartupNoBIOS.s file. StartupNoBIOS.s contains a jump to main at “_start”.

Buttons and Lights With BIOS

Our Buttons and Lights example does not require the BIOS to be running in the background (except initialization). However, there are still some debug benefits to having the BIOS running. When the BIOS is running, we can use some simple Cypress-developed utility programs such as qtsdump/qtudump to dump memory and qtsarena/qtuarena to give memory usage information.

If BIOS is not running in the background, the BIOS IDLE chain will not execute. This means BIOS will never look for any SCAN vectors on the UART or USB port. It is a requirement for the BIOS to execute and look for SCAN vectors over the UART or USB in order to use qtuload/qtsload or qtuarena/qtsarena (see Binary Utilities Reference for more information on these utilities).

There are many different ways to design our Buttons and Lights application to run concurrently with BIOS running in the background. Most of the suggested ways such as adding the Buttons and Lights task into the IDLE chain are described in *USB Multi-Role Device Design by Example*. We execute the BIOS IDLE Task in a periodic Timer0 Interrupt.

To allow Timer0 to properly interrupt at a given interval and vector to the proper ISR code, *StartupWithBIOS.s* makes the appropriate initialization in “_start” before returning to BIOS to complete initialization. In this example, we return to

BIOS instead of jumping directly to main. This is required so that BIOS will finish initialization of the UART and USB. Instead of jumping to main, our start-up code replaces the `IDLER_ISR` vector address with main. The `IDLER_ISR` (now main) is automatically called by BIOS upon finishing initialization.

Building the Example for Running with the Debugger (GDB)

If a program is built to run with the debugger, then the build process is different from code being built to run out of an EEPROM.

Running code with GDB will allow for breakpoints, single stepping, and other standard debug activities, in addition to running Insight, the graphical user interface for GDB. To run code with GDB, an Executable Linker Format (ELF) must be generated. This is the default format of the GCC compiler and is file-extension-independent. The only requirement is that debug symbols need to be turned on. The following command line instruction will generate a proper ELF file for use with GDB. It is assumed that the CY3663 CD has been installed and that `BASH_ENV.BAT` has been invoked to create a bash shell environment.

In addition, change the working directory to that containing the Buttons and Lights files. Full details of how to actually run the debugger are listed in both the CY16.PDF and the *USB Multi-Role Device Design by Example* book.

It should be noted that even though `StartupNoBios.s` is used, the GDB stub that is loaded will still execute the BIOS IDLE chain. This is required to allow debug communication over USB or UART.

```
[cy]$ cy16-elf-gcc -nostartfiles -g -TBAL.ld
StartupNoBIOS.s BAL.c -o BAL
```

- The above command will generate a file called “BAL” in the ELF format. This file can then be used as an input when invoking GDB.
- The “-nostartfiles” parameter tells the compiler/linker not to use the default start-up code. Instead, we will supply `StartupWithBIOS.s` as the start-up code to be used.
- The “-g” parameter instructs the compiler to turn on debug symbols.
- The “-T” parameter tells the linker to use our supplied linker script instead of the default.
- The “-o” parameter is followed by the output file name.

Building the Example for Running out of the EEPROM

The build process is slightly more involved to create an image that is ready to run out of an EEPROM. All of the steps are listed below and can be entered at the command line in a bash shell, or included in a script or Makefile. Since this project is so small, a Makefile is not needed. For a Makefile example, please see the CY3663 design examples that use Makefiles that contain similar calls as those listed below.

Following is a list of the steps required to build an EEPROM-ready image.

It should be noted that `StartupNoBIOS` is used as the default startup file in this example but `StartupWithBIOS` may be used without any additional changes.

1. Open a bash shell.
Run `BASH_ENV.bat` by clicking on the shortcut created under Programs/Cypress/OTG-Host
2. Assemble the start-up file into a linkable object file.

```
[cy]$ cy16-elf-as StartupNoBIOS.s -o
StartupNoBIOS.o.
```
3. Compile the .C file into a linkable object file (ELF file).

```
[cy]$ cy16-elf-gcc -c -nostartfiles BAL.c
-o BAL.o.
```
4. Link both of the object files

```
[cy]$ cy16-elf-ld -TBAL.ld
StartupNoBIOS.o BAL.o -o BAL.
```
5. Obtain a Listing file (optional).

```
[cy]$ cy16-elf-objdump -D -z -t --source
BAL > BAL.lst.
```
6. Convert the ELF file format to a Binary file format.

```
[cy]$ cy16-elf-objcopy -O binary BAL
BAL.bin.
```
7. Add appropriate SCAN signatures to the Binary file.

```
[cy]$ scanwrap BAL.bin BAL_Scan.bin
0x00001000.
```
8. Download the Binary file to the EEROM.

```
[cy]$ qtui2c BAL_Scan.bin -f.
```

Below is a detailed description of each of the above command

1. `BASH_ENV.bat`.
 - `BASH_ENV.bat` will set up all of the required environment variables and then invoke a bash shell
2. `cy16-elf-as -StartupNoBIOS.s -o StartupNoBIOS.o`
 - The “-o” parameter specifies the desired output file name.
3. `cy16-elf-gcc -c -nostartfiles BAL.c -o BAL.o`
 - The “-c” parameter causes a compile/assemble without running the linker.
 - The “-nostartfiles” parameter tells the compiler/linker not to use the default start-up code.
 - The “-o” parameter specifies the desired output file name.

4. `cy16-elf-ld -TBAL.ld StartupNoBIOS.o
BAL.o -o BAL`

- The “-T” parameter tells the linker to use our supplied linker script instead of the default.
- The “-o” parameter specifies the desired output file name.

5. `cy16-elf-objdump -D -z -t --source BAL >
BAL.lst.`

- This step is not required, but is nice to have.
- The “-D” parameter causes the contents of all sections to be disassembled.
- The “-z” parameter causes blocks of zeros to be disassembled.
- The “-t” parameter prints the symbols table entries of the file.
- The “--source” parameter displays source code intermixed with disassembly, if possible.
- The “>” parameter directs the output to a file with name provided after the “>” parameter.
- `cy16-elf-objcopy -O binary BAL BAL.bin.`
- The “-O” parameter writes an output file in the format specified after the “-O” parameter. In this case, we specify the “binary” format.

6. `scanwrap BAL.bin BAL_Scan.bin 0x00001000.`

- The address parameter is the base address where the program is to be loaded. This is the same address that was added into to *.ld file and needs to be the address where the _start routine in the start-up file resides.

7. `qtui2c BAL_Scan.bin -f.`

- Please see the *Binary Utilities Reference* document for detailed instructions on how to run this utility. Basically, the EZ-Host or EZ-OTG mezzanine card should have all DIP switches OFF and then the board should be powered with the USB cable plugged into peripheral port 2A. Next, the DIP switches should be set to select the appropriate

EEPROM to download code to. An example is to set switches [6:3] ON and [2:1] OFF (0bXX111100) which selects EEPROM # 4. Finally, qtui2c should

be run followed by a board reset. At this point the Buttons and Lights code should be running.

- The “-f” parameter specifies that the EEPROM is 4K-64K. If the EEPROM is 256-2K, no “-f” parameter is required.

Conclusion

Once you have built and run the Buttons and Lights example presented in this application note, you should have a basic understanding of how to get up and running with the CY16 toolset. The next step is to start learning about the EZ-Host and EZ-OTG BIOS and Frameworks. These two items will provide a very comprehensive foundation on which to build your application code. In addition, Frameworks relies heavily on Make files that in turn use some of the basic commands discussed throughout this application note.
