Please note that Cypress is an Infineon Technologies Company.
The document following this cover page is marked as “Cypress” document as this is the company that originally developed the product. Please note that Infineon will continue to offer the product to new and existing customers as part of the Infineon product portfolio.

Continuity of document content
The fact that Infineon offers the following product as part of the Infineon product portfolio does not lead to any changes to this document. Future revisions will occur when appropriate, and any changes will be set out on the document history page.

Continuity of ordering part numbers
Infineon continues to support existing part numbers. Please continue to use the ordering part numbers listed in the datasheet for ordering.

THIS SPEC IS OBSOLETE

Spec No: 001-67541

Spec Title: AN1149 - IMPLEMENTING THE HARDWARE ASSISTED PARALLEL INTERFACE (HAPI)

Sunset Owner: Srikanth Neerella (SIRK)

Replaced By: NONE

Implementing the Hardware Assisted Parallel Interface (HAPI)

AN1149

Author: Sai Prashanth Chinnapalli
Associated Project: No
Associated Part Family: CY7C66113,CY7C66013,CY7C64113,CY7C64013
Software Version: N/A
Associated Application Notes: None

Application Note Abstract

Hardware Assisted Parallel Interface (HAPI) is a parallel interface that simplifies the parallel transfer of data at the back end. AN1149 describes how to use this interface

Introduction

The USB specification offers a highly versatile, inexpensive, and widely accepted standard for interfacing an external peripheral with a USB host (PC, Mac, embedded host, and so on). The communication between the USB host and the USB microcontroller is governed by the rules defined in the USB specification. However, the back-end transfer of data between the USB microcontroller and the peripheral device can be through any serial or parallel link.

HAPI (Hardware Assisted Parallel Interface) is a parallel interface that simplifies the parallel transfer of data at the back end. The HAPI engine interprets and generates the necessary control and handshake signals between a Cypress USB microcontroller and the external interface that sources or sinks data. The advantage of using the HAPI engine is that, because there is less firmware overhead for the USB microcontroller, the transfer throughput is improved.

HAPI functionality is offered in the CY7C64013, CY7C64113, CY7C66013, and CY7C66113 Cypress full-speed USB microcontrollers. These microcontrollers are RISC-based processors using the Cypress optimized CPU core. They are cost-effective solutions for USB applications with medium throughput requirements. The HAPI interface can sustain transfer rates of up to 1 MBps. The actual transfer rate in each implementation depends on what additional functions the Cypress USB microcontroller is to perform, in addition to reading from or writing to the HAPI interface.

It should be noted that if the HAPI interface is to be used at a data rate toward the high end of its specified bandwidth, the throughput bottleneck will be the USB FIFO size and not the HAPI interface. The Cypress USB microcontrollers that support HAPI offer a total aggregate FIFO size of 80 bytes for data endpoints. Therefore, interrupt and isochronous transfers are limited to a maximum of 80 KBps.

For bulk and control transfers, the actual throughput is unpredictable, and higher or lower throughputs may be achievable based on the available bus bandwidth. If a full-speed USB microcontroller with higher throughputs is required, consider using an EZ-USB® (AN21xx family) or an EZ-USB FX (CY7C646*xx*) part.

Table 1 offers a selector guide to help you determine which Cypress USB microcontroller with HAPI engine is most suitable for your application.

Table 1. USB Microcontrollers Supporting HAPI

Hub Requirement	I/O Pin Requirement (including HAPI)	Recommended USB Controller
Hub function required	39 or fewer pins	CY7C66113
	29 or fewer pins	CY7C66013
Hub function not required	36 or fewer pins	CY7C64113
	19 or fewer pins	CY7C64013

HAPI Functional Overview

Figure 1. HAPI/I²C Configuration Register 0x09 (Read/Write)

7	6	5	4	3	2	1	0
R/W		R/W	R/W	R	R	R/W	R/W
I²C Position	Reserved	LEMPTY Polarity	DRDY Polarity	Latch Empty	Data Ready	HAPI Port Width Bit 1	HAPI Port Width Bit 0

The HAPI function is enabled by initializing the least significant two bits of the HAPI/I²C Configuration register (0x09) to a nonzero value. These bits are cleared after a chip reset (a power-on reset or a watchdog reset), which means that the HAPI function is disabled and the I/O ports are not controlled by the HAPI engine. The HAPI engine can transfer one, two, or three bytes of data in a single HAPI Read/Write cycle. Table 2 shows the required settings for the HAPI/I²C Configuration register (0x09) to achieve single-byte or multi-byte data transfers.

Table 2. HAPI Port Configuration

Port Width Bits[1:0]	HAPI Port Width
11	24-bit transfer: P3[7:0], P1[7:0], P0[7:0]
10	16-bit transfer: P1[7:0], P0[7:0]
01	8-bit transfer: P0[7:0]
00	HAPI disabled

The following instructions show an example of how to initialize the HAPI interface for 16-bit transfers:

```
mov a, 2
iowr 09h
```

When a port is initialized to be under HAPI control, the output drivers for that port will be in CMOS output mode, regardless of the output configuration settings of the GPIO Configuration register (0x08).

Bits 2, 3, 4, and 5 of the HAPI/I²C Configuration register are also associated with the HAPI logic. Bits 4 and 5 select the active logic level of the Latch Empty and Data Ready bits. A setting of 0 for the LEMPTY Polarity bit causes the Latch Empty bit (Bit 3) to be low if the data latch is empty. A setting of 1 for the LEMPTY Polarity bit causes the Latch Empty bit to be high if the data latch is empty. As you will see later in this application note, the Latch Empty status bit is used in conjunction with a HAPI write operation.

Similarly, a setting of 0 for the DRDY Polarity bit causes the Data Ready bit to be low if new data is loaded by an external device to the data ports that are under HAPI control. The Data Ready status bit is associated with HAPI Read operations. A setting of 1 for the DRDY Polarity bit causes the Data Ready bit to be active low.

If the HAPI interface is configured to read or write multiple bytes in a single cycle (see Table 2), Port 0 must be the last port that the data is written to or read from by the Cypress microcontroller. A read or write operation on Port 0 causes an update to the Latch Empty bit or the Data Ready bit of the HAPI/I²C Configuration Register.

The major advantage of using the HAPI interface is that the HAPI engine automatically interprets the control signals and generates the handshake signals to the back-end interface. HAPI control and handshake signals are provided on Port 2. Bits [6:2] of Port 2 are used for the HAPI interface. Similar to the HAPI data ports, Port 2 HAPI pins are in CMOS output mode or open drain input mode when HAPI is active. The following sections describe control and handshake pins on Port 2.

P2[2] – Latch Empty Pin

This is an output handshake pin that is used in a HAPI write cycle. When active, this pin indicates to the external interface that the USB controller has processed the last data that was loaded in the HAPI buffers (HAPI port buffers are selected as shown in Table 2), and the HAPI engine is ready to receive more data from the back-end interface. This event tells the external interface to load more data into the HAPI FIFO. The active state of the Latch Empty pin is selected by the LEMPTY Polarity bit of the HAPI/I²C Configuration register. A setting of 0 selects an active-high state for the Latch Empty pin; a setting of 0 selects an active-low state.

Note The Latch Empty pin on Port 2 and the Latch Empty bit of the HAPI/I²C Configuration register have opposite active states.

P2[3] – Data Ready Pin

This is an output handshake pin that is used in a HAPI read cycle. When active, this pin signals to the external interface that the USB microcontroller has just loaded new data into HAPI buffers (HAPI port buffers are selected as shown in Table 2). This event tells the external device to perform a read of the HAPI FIFO. The active state of the Data Ready pin is selected by the DRDY Polarity bit of the HAPI/I²C Configuration register. A setting of 0 selects an active-high state for the Data Ready pin; a setting of 0 selects an active-low state.

Note The Data Ready pin on Port 2 and the Data Ready bit of the HAPI/I²C Configuration register have opposite active states.

P2[4] – STB (Strobe)

This is an active-low input control pin that is used in HAPI write cycles. A high-to-low transition on this pin — provided that chip select (CS) input is active — latches the data present on the HAPI data ports into the HAPI buffer. When

STB returns high, the HAPI engine signals the interrupt controller block and a HAPI interrupt is generated.

P2[5] – OE (Output Enable)

This is an active-low input control pin that is used in HAPI read cycles. A high-to-low transition on this pin — provided that CS input is active —loads the data in the HAPI FIFO out to the port pins. When OE returns high, the HAPI engine signals the interrupt controller block and a HAPI interrupt is generated.

P2[6] – CS (Chip Select)

This is an active-low input that gates both OE and STB inputs.

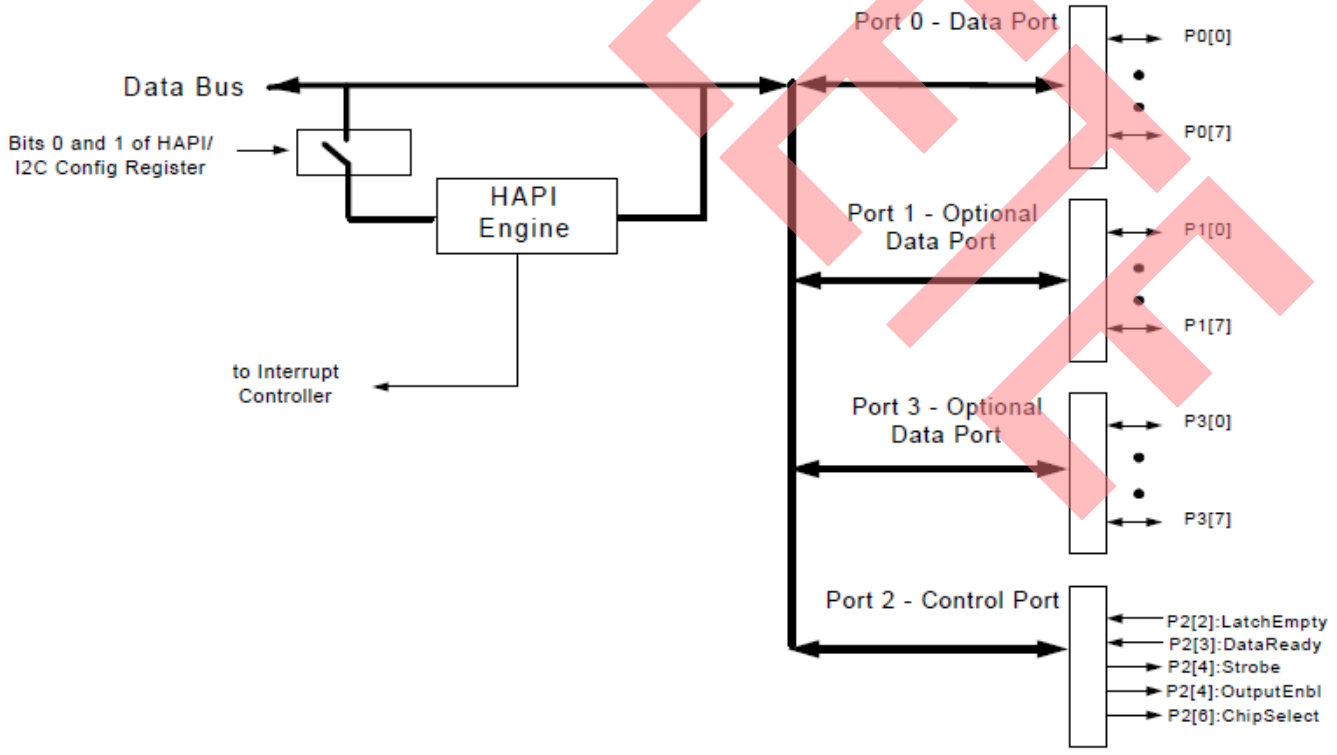
Table 3 provides a summary of HAPI port and bit definitions.

Figure 2 is a hardware block diagram of the HAPI interface. If HAPI is enabled, all of the port bits associated with HAPI operation are now accessed by the HAPI engine. Non-HAPI port bits of Port 2 are unaffected.

Table 3. Port 2 Pin and HAPI Configuration Bit Definitions

Pin	Name	Direction	Description (Port 2 Pin)
P2[2]	LatEmptyPin	Out	Ready for more input data from external interface
P2[3]	DReadyPin	Out	Output data ready for external interface
P2[4]	STB	In	Strobe signal for latching incoming data
P2[5]	OE	In	Output Enable; causes chip to output data
P2[6]	CS	In	Chip Select; gates STB and OE
Bit	**Name**	**R/W**	**Description (HAPI/I²C Configuration Register)**
2	Data Ready	R	Asserted after firmware writes data to Port 0, until OE is driven LOW.
3	Latch Empty	R	Asserted after firmware reads data from Port 0, until STB is driven LOW.
4	DRDY Polarity	R/W	Determines polarity of Data Ready bit and DReadyPin: If 0, Data Ready is active low, DReadyPin is active high. If 1, Data Ready is active high, DReadyPin is active low
5	LEMPTY Polarity	R/W	Determines polarity of Latch Empty bit and LatEmptyPin: If 0, Latch Empty is active low, LatEmptyPin is active high. If 1, Latch Empty is active high, LatEmptyPin is active low.

Figure 2. HAPI Block Diagram



HAPI Read by an External Interface

Firmware writes the data to the General Purpose I/O (GPIO) ports. If you need a two- or three-byte transfer, Port 0 must be written last, because a write to Port 0 causes the Data Ready pin to go active, which signals to the external device that data is available. The external device then drives the OE and CS pins active (low), which causes the HAPI data to be output to the port pins.

After the external device reads the HAPI data, it returns the OE pin inactive (high). This generates a HAPI interrupt in the USB microcontroller. If there is more data to be transferred, the firmware should load it into the HAPI ports. The act of writing the data to Port 0 causes the Data Ready pin to go active, and the process repeats.

Note The Data Ready pin (P2[3]) and Data Ready bit (Bit 2 of the HAPI/I^{2}C Configuration register) have opposite active states. Figure 3 shows the timing diagram for a HAPI read cycle.

HAPI Write to an External Interface

The external interface drives STB and CS pins active (low), and drives the data to the HAPI ports. This causes the Latch Empty pin to go inactive because the HAPI latch is now full. The external device should then return the STB pin high. This would generate a HAPI interrupt in the USB microcontroller. At this time the firmware should read the data latched into the HAPI ports and process it based on the application's requirements.

If you need a two- or three-byte transfer, Port 0 must be the last port that is read by the firmware, because a read from Port 0 causes the Latch Empty pin to go active. This would signal to the external device to load the new data into the HAPI latch if there is more data to transfer.

Note The Latch Empty pin (P2[2]) and Latch Empty bit (Bit 3 of the HAPI/I^{2}C Configuration register) have opposite active states. Figure 4 shows the timing diagram for a HAPI write cycle.

Bidirectional HAPI Transfer to and from an External Interface

The sequence of events for a bidirectional HAPI interface is essentially a combination of a HAPI write and a HAPI read transfer sequence. The only additional issue is that when the HAPI interrupt is generated, the firmware must correctly identify which type of transfer caused the interrupt. The Data Ready signal will have returned to its inactive state by the time the HAPI interrupt is generated. The firmware should therefore examine the state of the Latch Empty signal; either from the HAPI/ I^{2}C Configuration register or off Port 2. If the Latch Empty signal is active, a HAPI write by an external device must have generated the interrupt. If the Latch Empty signal is active, a HAPI read by an external device must have generated the interrupt.

GPIO and HAPI Interrupt Sharing

GPIO and HAPI interrupts share the same interrupt and only one can be enabled at a time. Therefore, anytime the HAPI function is enabled, the GPIO interrupts will be disabled.

Figure 3. HAPI Read by External Interface from USB Microcontroller

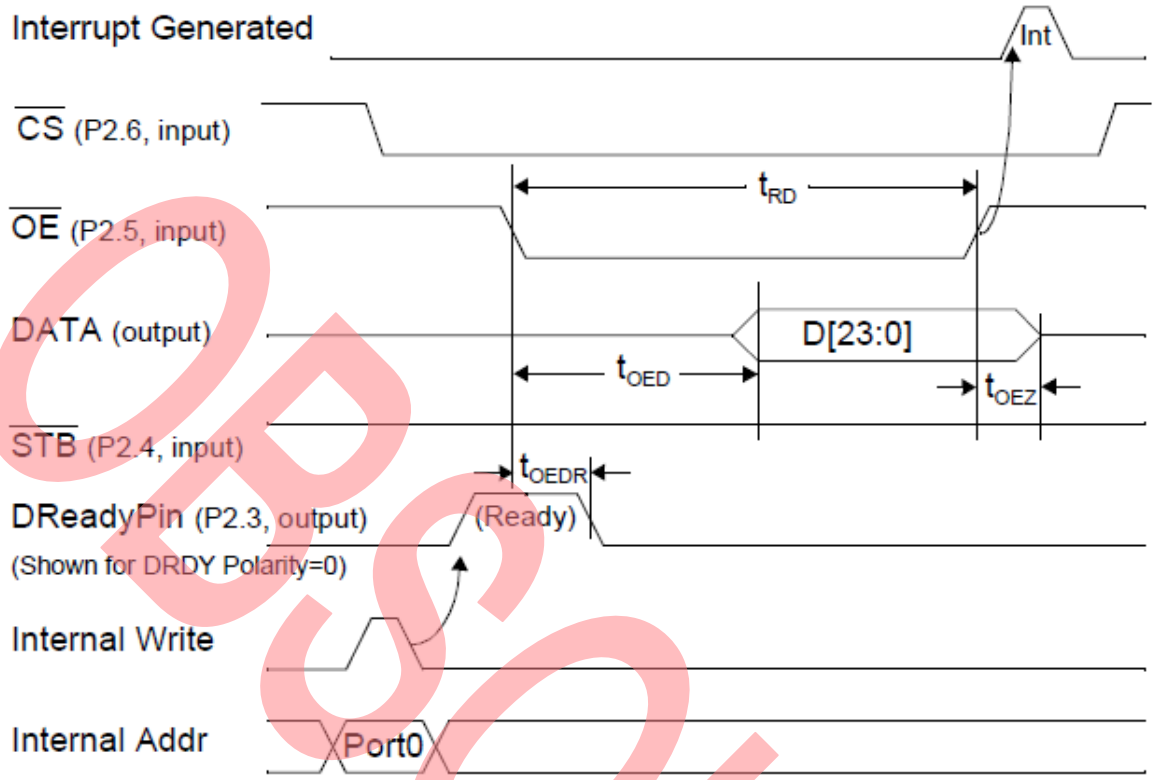


Figure 4. HAPI Write by External Device to USB Microcontroller

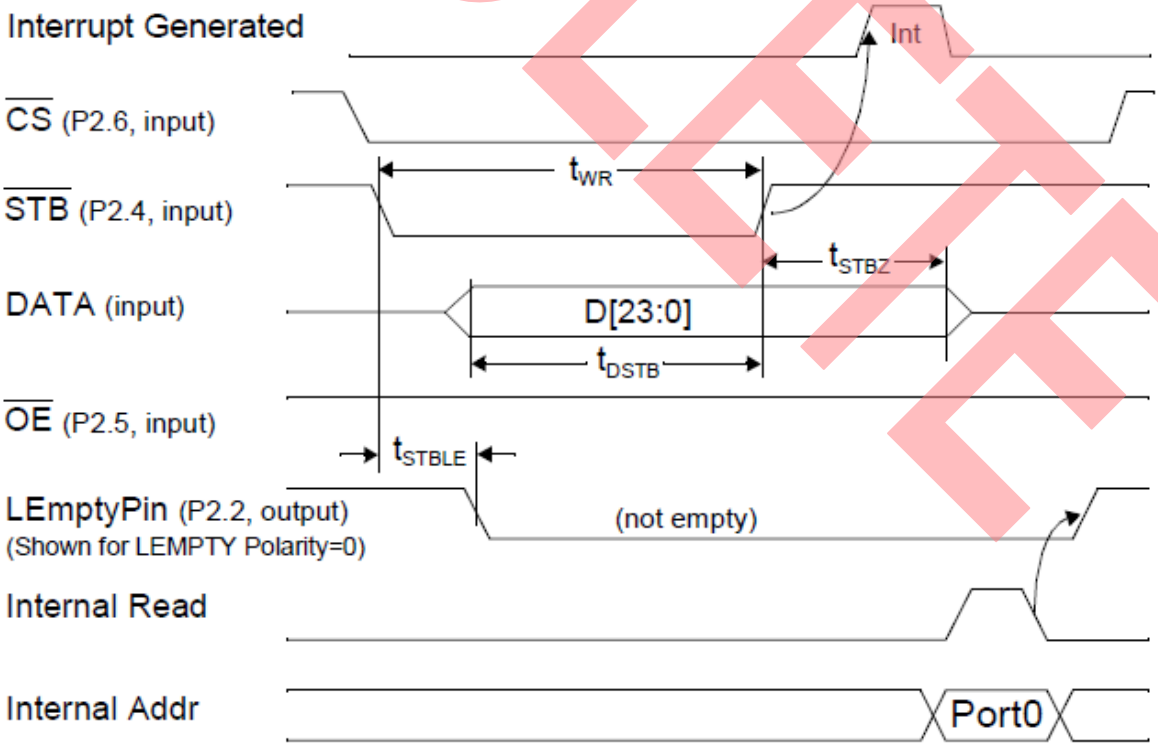

Sample Code – HAPI Read

Following is a firmware example of how to implement the HAPI interface to transfer data between any two Cypress USB controllers that support HAPI. This sample application contains two modules. The M_read.lst module is the code that should be running on the HAPI master. The HAPI master is the external device that generates the STB, OE, and CS control signals. The S_read.lst module is the code that should be running on the HAPI slave. This sample application uses a one-byte HAPI transfer mode.

29  0000             ;                        |                  |
30  0000             ;              -------------                  -------------
31  0000             ;
32  0000             ; HAPI Read Hints:
33  0000             ;
34  0000             ; The slave will write to data ports (e.g., port0 for 1 byte HAPI xfer).
The data will not appear on the common bus to which data ports are attached until both
35  0000             ; /cs and /oe go active (low). As soon as data is written to port0, DRDY
signal (either port or bit in reg 09h) will go active. When /oe is brought low by
36  0000             ; the master, DRDY pin goes inactive and data appears on the HAPI data
ports. Note that when HAPI is enabled in a device, the slave cannot write to Port 2
37  0000             ; bits under HAPI control. Only the master can write to port 2.
Also, if the Monitor program is used to check the state of the registers, the reading of
data ports
38  0000             ; on the slave is done at some internal stage of the port and NOT at the
external interface. For that reason, writes to HAPI data ports can only be verified
39  0000             ; by reading the HAPI data regs at the master side and not on the
slave 3652.

Sample Code - HAPI Write

Following is a firmware example of how to implement the HAPI interface to transfer data between any two Cypress USB controllers that support HAPI. This sample application contains two modules. The M_write.lst module is the code that should be running on the HAPI master. The HAPI master is the external device that generates the STB, OE, and CS control signals. The S_write.lst module is the code that should be running on the HAPI slave.

```

Document History

Document Title: AN1149 - Implementing the Hardware Assisted Parallel Interface (HAPI)

Document Number: 001-67541

Revision	ECN	Orig. of Change	Submission Date	Description of Change
**	3179839	CSAI	2/24/2011	OLD APP. NOTE: Obtained spec. # for note to be added to spec. system. Updated copyright. Added source disclaimer, revision disclaimer. Applied new template. Copy edit. **This note had no technical updates.**
*A	3198844	DSG	3/17/2011	Minor Change: Fixed footer
*B	4184440	RSKV	11/06/2013	Obsolete document.

In March of 2007, Cypress recatalogued all of its Application Notes using a new documentation number and revision code. This new documentation number and revision code (001-xxxxx, beginning with rev. **), located in the footer of the document, will be used in all subsequent revisions.
