Evaluation Adapter Board for EconoPACK™ 4 3-Level Modules in NPC2-Topology
Attention please!

THE INFORMATION GIVEN IN THIS APPLICATION NOTE IS GIVEN AS A HINT FOR THE IMPLEMENTATION OF THE INFINEON TECHNOLOGIES COMPONENT ONLY AND SHALL NOT BE REGARDED AS ANY DESCRIPTION OR WARRANTY OF A CERTAIN FUNCTIONALITY, CONDITION OR QUALITY OF THE INFINEON TECHNOLOGIES COMPONENT. THE RECIPIENT OF THIS APPLICATION NOTE MUST VERIFY ANY FUNCTION DESCRIBED HEREIN IN THE REAL APPLICATION. INFINEON TECHNOLOGIES HEREBY DISCLAIMS ANY AND ALL WARRANTIES AND LIABILITIES OF ANY KIND (INCLUDING WITHOUT LIMITATION WARRANTIES OF NON-INFRINGEMENT OF INTELLECTUAL PROPERTY RIGHTS OF ANY THIRD PARTY) WITH RESPECT TO ANY AND ALL INFORMATION GIVEN IN THIS APPLICATION NOTE.

Information
For further information on technology, delivery terms and conditions and prices please contact your nearest Infineon Technologies Office (www.infineon.com).

Warnings
Due to technical requirements components may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies Office. Infineon Technologies Components may only be used in life-support devices or systems with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system, or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body, or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

We Listen to Your Comments
Any information within this document that you feel is wrong, unclear or missing at all? Your feedback will help us to continuously improve the quality of this document. Please send your proposal (including a reference to this document) to: [WAR-IGBT-Application@infineon.com]
The board described is an evaluation board dedicated for laboratory environment only. It operates at high voltages. This board must be operated by qualified and skilled personnel familiar with all applicable safety standards.
1 Introduction

The evaluation adapter board MA3L120E12_EVAL for 3-level NPC2 EconoPACK™ 4 modules as shown in Figure 1 was developed to support customers during their first steps designing applications with EconoPACK™ 4 3-level NPC2 modules. This evaluation board was designed in addition to the module driver board F3L2020E12-F-P_EVAL¹ [1] or could be a complementary part for an existing customer driver solution. For more details about the 3-level topology, please refer to [2].

The board is available from Infineon in small quantities. The properties of this part are described in the design features chapter of this document, whereas the remaining paragraphs provide information to enable the customers to copy, modify and qualify the design for production, according to their own specific requirements.

Environmental conditions were considered in the design of the MA3L120E12_EVAL. Components qualified for a lead-free reflow soldering process were selected. The design was tested as described in this document but not qualified regarding manufacturing and operation over the whole operating temperature range or lifetime.

The boards provided by Infineon are subject to functional testing only.

Due to their purpose evaluation boards are not subject to the same procedures regarding Returned Material Analysis (RMA), Process Change Notification (PCN) and Product Discontinuation (PD) as regular products. See Legal Disclaimer and Warnings for further restrictions on Infineon’s warranty and liability.

1.1 Part Number explanation

Part number explanation:

- **MA**: Module Adapter board
- **3L**: 3-Level
- **120**: 120 V IGBT Module
- **E12**: 12 A output driver current
- **EVAL**: Evaluation Board
- **E12**: Suitable for 1200 V IGBT Module

¹ Evaluation Driver Board for 3-Level EconoPACK™4 AN2012-03 [2]
2 Design features

Electrical features of the evaluation board and mechanical dimensions including necessary interface connections are presented in the following sections.

2.1 Main features

The evaluation board is developed to work in combination with the F3L2020E12-F-P_EVAL driver board2. The MA3L120E12 adapter board provides following features:

- Electrically and mechanically suitable for 3-level NPC2 EconoPACK™4 module family
- Different gate resistor values for turning-on and -off are possible
- Active clamping protection for all IGBTs
- Desaturation output signals for short circuit monitoring
- Suitable for -8V/+15V or up to ±20V 3

2.2 Key Data

All values given in Table 1 are typical values, measured at an ambient temperature of T_amb = 25 °C.

4  Functionality of the board

The MA3L120E12_EVAL adapter board is a complementary part of the evaluation kit to drive one 3-level IGBT module as shown in Figure 5. The adapter board should be pressed onto the EconoPACK™ 4 as described in the AN2010-06.

![Figure 5: Mounting sequence of the Evaluation Kit](image)

The IGBT module is not a part of this evaluation kit. The IGBT module needed can be purchased separately.

4.1  Power supply

The evaluation kit as shown in Figure 5 needs four external isolated power supplies of -8V/+15V. The magnitude of each power supply should not exceed the maximum allowed supply voltage of 28V\(^4\). The power supply of the evaluation kit with four isolated -8V/+15 V voltage sources can be done using a MA040E12_EVAL\(^5\) evaluation board.

If the MA3L120E12 adapter board is not used in conjunction with the F3L2020E12-F-P_EVAL driver board, it can be supplied with isolated power supplies providing up to maximum ±20V.

The input PWM voltage level should be selected according to the power supply voltage level. If an asymmetrical supply voltage of -8V/+15V is applied, the PWM signal should not exceed +15V and should not be lower than -8V.

The voltage sources are applied to the corresponding driver channels using the connectors X100, X200, X300 and X400.

![Figure 6: Principle diagram of the MA3L120E12_EVAL and 3-level EconoPACK™4](image)

\(^5\) AN2010-04 MA040E12_EVAL Isolated Gate Driver Power Supply and Logic Interface for MIPAQTM Serve
Figure 7 gives hints about the power consumption of one IGBT gate driver channel on the MA3L120E12_EVAL, as a function of the switching frequency. The whole power demand of the board is the summation of the power demand of the four gate driver channels. The conditions during the measurement were $T_{\text{case}} = 125^\circ$, $T_{\text{amb}} = 25^\circ$C. The adapter board is supplied with -8V/+15V.

![Figure 7: Power consumption of one gate driver channel on the MA3L120E12_EVAL board vs. the switching frequency](image)

4.2 Booster

Figure 8 depicts the booster circuit where three complementary pairs of transistors are used to amplify the input PWM signal. This allows to drive IGBTs that need more current than the driver IC can deliver. Three NPN transistors are used for turning-on the IGBT and three PNP transistors for turning-off the IGBT. The transistors are dimensioned to provide enough peak current to drive all EconoPACK™4 3-level IGBT modules.

![Figure 8: Schematic details of the output stage for a single IGBT driver](image)

Gate resistors are connected between the booster stage and the IGBT module's gate terminals. These resistors should have a suitable rating for repetitive pulse power to avoid degradation.
4.3 VCE monitoring for short circuit detection

The short circuit protection of the four IGBTs is based on the monitoring of the collector emitter voltage for the corresponding IGBT, using the active clamping feature as represented in Figure 9. If the IGBT conducts a current several times higher than the nominal value, the transistor desaturates and the voltage across the device increases. This behavior can be used for short circuit detection and to turn-off of the IGBT. The short circuit needs to be detected and the IGBT has to be turned off without exceeding its maximum blocking voltage, within 10µs.

When the MA3L120E12_EVAL is connected to a F3L2020E12-F-P_EVAL driver board, each 1ED020I12-F Coreless Transformer driver IC of the four IGBTs detects and handles the short circuit separately.

![Desaturation protection and active clamping diodes](image)

Figure 9: Desaturation protection and active clamping diodes

4.4 Active clamping function

Active clamping is a technique which keeps transient overvoltage below the critical limits when the IGBT turns off. The standard approach for active clamping is to use a TVS diode connected between the auxiliary collector and the gate of an IGBT module. When the Collector-Emmitter voltage exceeds the diode breakdown voltage the diode current sums up with the current from the driver output. Due to the increased Gate-Emitter voltage, the transistor is held in an active mode and the turn-off process is prolonged. The dV/dt slows down which results in a limited voltage overshoot. Avalanche diodes conduct high peak currents during the time in which the clamping is actively limiting the overvoltage.

A typical turn-off waveform of a F3L400R12PT4_B26 module at room temperature without overvoltage limiting function can be seen in Figure 10a. Figure 10b shows the waveform with the same load conditions as Figure 10a but with active clamping function.

![Turn-off waveforms](image)

Figure 10: turn-off a) without active clamping b) with active clamping function
4.5 Maximum switching frequency

The switching frequency on the adapter board is limited either by the maximum output power of the driver power supply or by the maximum temperature of the PCB due to the power losses in the external gate resistors. These power losses in the gate resistors depend on the IGBT gate charge, gate voltage magnitude and on the switching frequency of the IGBT. Due to the power losses in the external gate resistors, heat will be generated, which leads to an increase of the PCB temperature in the neighborhood of these resistors. This temperature must not be higher than the maximum working temperature of the PCB, i.e. 105°C for a standard FR4 material.

The calculation of the power losses in the gate resistors can be done by utilizing equation (1):

\[ P_{\text{dis}} = P(R_{\text{EXT}}) + P(R_{\text{INT}}) = \Delta V_{\text{out}} \cdot f_s \cdot Q_G \]  

(1)

where:

- \( P_{\text{dis}} \) = dissipated power
- \( P(R_{\text{EXT}}) \) = dissipated power of the external gate resistors
- \( P(R_{\text{INT}}) \) = dissipated power of the IGBT module internal gate resistor
- \( \Delta V_{\text{out}} \) = voltage magnitude at the driver output
- \( f_s \) = switching frequency
- \( Q_G \) = IGBT gate charge for the given gate voltage range

The complete gate resistor consists of the internal gate resistor together with an external gate resistor and due to that, a part of the IGBT drive power losses will be dissipated directly to the PCB, whereas the other part of the losses will be dissipated to the ambient air. The ratio of the losses dissipated internally \( P(R_{\text{INT}}) \) and externally \( P(R_{\text{EXT}}) \) corresponds directly to the ratio of the mentioned \( R_{\text{INT}} \) and \( R_{\text{EXT}} \) resistors. According to \(-8/+15\)V operation, the datasheet value of \( Q_{GE} \) needs to be reduced by 20%.

Due to the PCB temperature criteria, the power dissipated in external gate resistors \( P(R_{\text{EXT}}) \) has to be considered for the thermal design.

Figure 11 illustrates the PCB board temperature around the gate resistors depending on the switching frequency. Measurement was done at \( T_{\text{case}} = 100^\circ\text{C}, T_{\text{amb}} = 25^\circ\text{C}, V_{GE} = -8/+15\)V. The high IGBT module case temperature leads elevated temperature level at the PCB. This results in a temperature rise event at a switching frequency of 0 Herz.
5 Paralleling

In contrast to the operation of one single IGBT, where the operating point is relatively simple to set up, the switching of paralleled IGBT modules on the same operation point is not trivial. This can be explained by the fact that the IGBTs have a certain variation in their characteristics. A direct consequence of this is a slight current imbalance between the IGBTs. The biggest challenge is to minimize the deviation of the leg current to achieve highly efficient systems and an improved reliability.

Two main factors have a dominant role in the current maldistribution:
- the difference between the impedance of each leg of the paralleled setup
- the difference in the output voltages of the individual leg of the paralleled setup

5.1 Static current imbalance

The static current imbalance can be caused due to:
- the variation of the Collector-Emitter voltage of each leg of the paralleled setup
- the variation of the resistance of the main current path

5.2 Dynamic current imbalance

The dynamic current imbalance can be caused by
- the variation of the transmission characteristics caused by the different $V_{GEh}$ of each IGBT
- the variation of the impedance of the main current path
- the stray inductance of the internal and external commutation path of the IGBT module
- the IGBT driver output resistance in the paralleled legs
- the transfer characteristic $I_C = f(V_{GE})$

5.3 Paralleling with MA3L120E12_EVAL

The MA3L120E12_EVAL was designed primarily to work with the evaluation driver board F3L2020E12-F-P_EVAL, which allows the parallel connection of up to three modules, each equipped with one MA3L120E12_EVAL adapter board as represented in Figure 12a. In case of paralleling, the driver board does not need to be plugged into the complementary adapter board. The connection from the driver to the adapter boards is done utilizing the connectors on the top side of the driver board as shown in Figure 12b.

![Figure 12: a) Principle of parallel connection, b) Photo of the setup](image)

Figure 12b shows a parallel connection of three 3-level IGBT modules. The wires to connect the driver to the adapter boards should have the same length to avoid differences in signal run time between the gates of the three legs. Star connection of the IGBTs improves the reduction of cross flow in the auxiliary emitter paths during the switching sequence. The MA3L120E12_EVAL boards are equipped with 4.7Ω resistors in the auxiliary emitter path and other power supply lines (-8V / +15V) to reduce the current cross flow between the units of the paralleled circuits.

The MA3L120E12 adapter board is equipped with 4.7Ω decoupling resistors in the power supply lines by default. This avoids currents in the emitter path between the paralleled modules.
Figure 13a gives a hint about the balancing current flowing in the emitter paths when MA3L120E12_EVAL is equipped with 0Ω instead of 4.7Ω. Balancing currents of up to 4A can be measured after the turn-on of the IGBT. With a standard equipped adapter board, the balancing current is reduced to a few mA as depicted in Figure 13b.

Figure 13: Current distribution in the auxiliary emitter paths
a) With 0Ω as decoupling resistor  b) With 4.7Ω as decoupling resistor

Figure 14 shows the turn-on and turn-off behavior of 3 IGBT modules in parallel and their current sharing on the AC terminals.

Figure 14: Current distribution on the AC terminals of 3 parallel F3L400R12PT4_B26 modules
a) Turn-on  b) Turn-off

The $E_{on}$ and $E_{off}$ values measured with a gate resistance $R_{gon} = R_{goff} = 1.5\,\Omega$ and at an ambient temperature of 25°C are listed in Table 6.

Datasheet values of $E_{on}$ and $E_{off}$ for F3L400R07PT4_B26: $E_{on} = 8.75\,\text{mJ}$; $E_{off} = 18\,\text{mJ}$

Table 6: Overview of $E_{on}$ and $E_{off}$ of three paralleled F3L400R12PT4_B26 modules

<table>
<thead>
<tr>
<th>Device under Test</th>
<th>DUT1</th>
<th>DUT2</th>
<th>DUT3</th>
</tr>
</thead>
<tbody>
<tr>
<td>$E_{on},[\text{mJ}]$</td>

<td>12.2</td>
</tr>
<tr>
<td>$E_{off},[\text{mJ}]$</td>
<td>19.2</td>
<td>23</td>
<td>20</td>
</tr>
</tbody>
</table>

Compared to the datasheet values, the measured $E_{off}$ values are similar. The variation in $E_{on}$ is higher and in general higher than the datasheet values. Nevertheless the influence of $E_{off}$ is dominating.
6 Schematics and Layouts

To meet the individual customer requirements and to make the evaluation adapter board simple for development or modification, all necessary technical data like schematic, layout and components are included in this chapter.

6.1 Schematics

Figure 15 to Figure 19 depict the driving circuit of the IGBTs.

Figure 15: Control circuit of the high side IGBT

Figure 16: Control circuit of the inner right side IGBT
Figure 17: Control circuit of the inner left side IGBT

Figure 18: Control circuit of the low side IGBT

Figure 19: Configuration of the connectors of the MA3L120E12_EVAL
6.2 Layouts

The MA3L120E12_EVAL adapter board was designed, following the rules for the copper thickness and the space between different layers as shown in Figure 20.

Layers:

1. Copper 1: 35 µm
2. Copper 2: 35 µm
3. Copper 3: 35 µm
4. Copper 4: 35 µm
