**USB-Powered Battery Charger for NiCd/NiMH Batteries****Author: Svyatoslav Paliy****Associated Project: Yes****Associated Part Family: CY8C24794****Software Version: PSoC Designer™ 5.4****Related Application Notes: For a complete list of the application notes, [click here](#).****To get the latest version of this application note, or the associated project file, please visit <http://www.cypress.com/go/AN2361>.**

This application note describes a USB-powered battery charger for NiCd/NiMH batteries that permits rapid recharging. Dedicated PC-based software has been developed to monitor and control the charging process in real time and to display data in a graphical user interface. The charger can be embedded into consumer, office, and industrial applications. It needs no drivers and starts working immediately when plugged into a USB port. A battery can be left in the charger for any length of time without the risk of overcharge.

**Introduction**

The growing popularity of wireless computer peripherals such as the wireless mouse, keyboard, and similar devices is likely to spur demand for a device that can be recharged rapidly. Rechargeable batteries are also widely used in peripheral and non-computer-related appliances.

The charger described in this application note can easily be incorporated into computer peripherals. For example, one battery can be located in a mouse or another wireless device, and a second battery inserted into a combination host/charger that is connected to the USB port of a computer. When the battery in the peripheral device is drained, you can simply swap the two batteries. Moreover, this charger can charge or discharge user batteries under manual charge control. You can control the charger from PC software, immediately stopping or starting the charge process. As an added option, it is possible to discharge the battery before charging. This allows you to control the charge level of batteries using a discharge-charge cycle.

This application note describes how the charger works, its various aspects, and how it can be modified:

- Rapid battery charging
- Charger hardware
- Charger firmware
- USB connection
- PC utilities and debugging

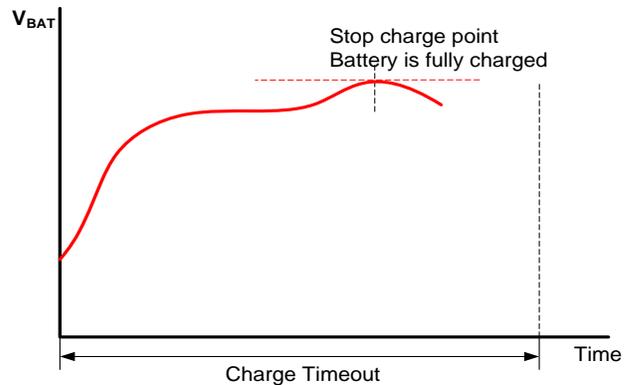

- Design modifications
- Appendixes

## Rapid Battery Charging

This charger uses the pulse method for nickel-based batteries, which makes rapid battery charging possible and preserves battery health. [Table 1](#) lists the main charger characteristics.

The battery is charged by constant current impulses of 5-second duration, alternated with 0.5-second latent periods during which no charge is applied. Then the charger measures the battery voltage. When the battery voltage stops increasing or starts decreasing, the battery is fully charged. [Figure 1](#) shows the charge termination criteria and the battery voltage upon full charge.

Figure 1. NiCd/NiMH Battery Pack Voltage in Time Graph

The charge stage should be limited by a timeout that extends for approximately 120 to 150 percent of the estimated time required to charge NiCd/NiMH batteries with expected maximal capacity.

Table 1. Main Charger Characteristics

No.	Parameter Name	Two Cells	Three Cells
1	Voltage indicating battery presence, V	0.5	0.75
2	Recharge voltage level, V	1.8	2.7
3	Emergency charger stop voltage, V	3.5	5.25
4	Discharge stop voltage, V	1.0	1.5

## Charger Hardware

The charger system is shown in [Figure 2](#). See [Appendix A. Charger Schematic](#) for more details. The acronyms used in [Figure 2](#) are defined as follows:

**USB** – Full-speed Universal Serial Bus engine used to receive control data from the PC and send data about charger status and battery states to the PC.

**CPU** – Central processor core to implement charge algorithms and perform charge control functions.

**INA** – Switched capacitor-based instrumentation amplifier.

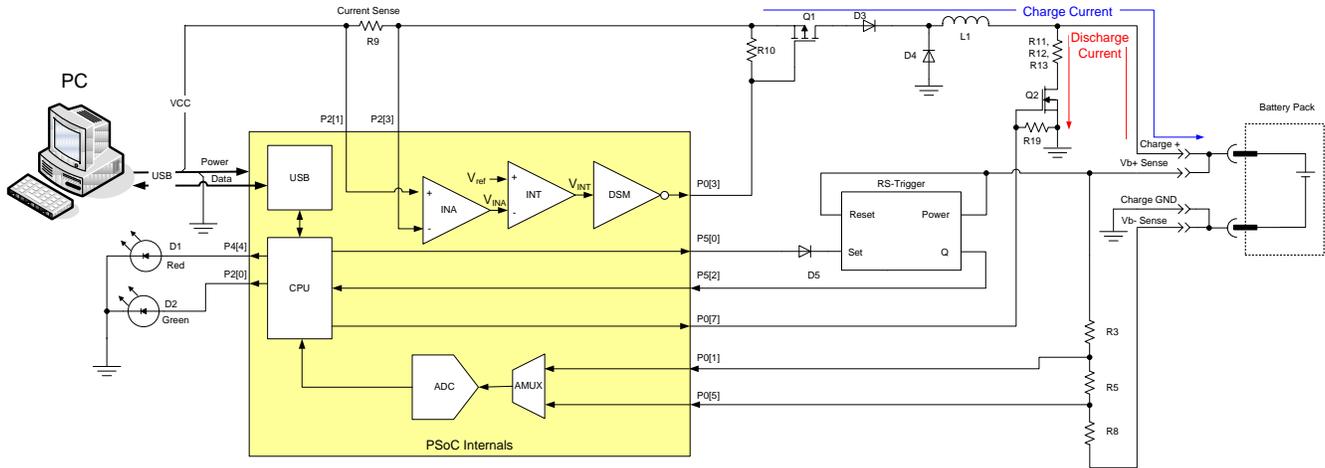

**INT** – Switched capacitor-based integrator.

**DSM** – Delta-sigma modulator for current regulator control output.

**ADC** – Incremental analog-to-digital converter used to measure battery voltage.

**AMUX** – Analog multiplexer used to switch between two analog signals for measurement.

Figure 2. Charger System with Switching Regulator

The main task of the charger is efficient use of the maximum allowed current from the USB bus (0.5 A) to minimize total charge time. The amount of the current drawn from a USB is insufficient for a fast battery charge with a fixed amount of the current. It is the current drawn from the USB that is controlled rather than the charge current. The battery charge current is determined by the instantaneous battery voltage, keeping regulator input power maintained at a constant level.

The current regulator uses a hardware control loop. The hardware control loop consists of an instrumentation amplifier (INA) to handle a current sense resistor ( $R_9$ ) signal; a differential integrator (INT), which acts as an integrating difference amplifier; and a delta-sigma modulator (DSM) as a voltage-to-pulse-density converter. This loop controls the MOSFET gate duty cycle to keep the input current constant. This hardware control loop method enables the greatest use of available USB power.

This implementation uses three configurable switched capacitor blocks: one for the instrumentation amplifier, one for the differential integrator, and one for the delta-sigma modulator. The configuration of parameters of the switched capacitor block is described in [AN2041 – Understanding Switched Capacitor Analog Blocks](#). The following equations describe the operation of the regulator:

$$V_{INA} = \frac{C_A^{INA}}{C_F^{INA}} V_{P2[1]} - \frac{C_B^{INA}}{C_F^{INA}} V_{P2[3]}; \quad \text{Equation (1)}$$

$$V_{INA} = \frac{C_A^{INA}}{C_F^{INA}} R_{sense} I_{bus}; \quad C_A^{INA} = C_B^{INA};$$

$$V_{INT} = \int \left[ \frac{C_A^{INT}}{C_F^{INT}} V_{ref} - \frac{C_B^{INT}}{C_F^{INT}} V_{INA} \right] dt; \quad \text{Equation (2)}$$

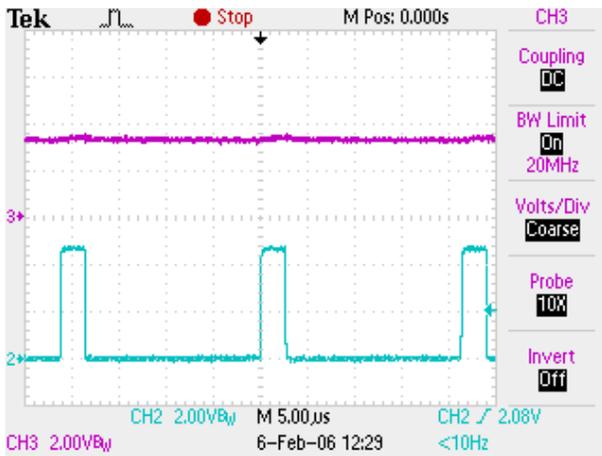

$V_{INA}$  is the output voltage of the instrumentation amplifier, and  $C_A^{INA}$ ,  $C_B^{INA}$ ,  $C_F^{INA}$ ,  $C_A^{INT}$ ,  $C_B^{INT}$ , and  $C_F^{INT}$  are values of the capacitors in the switched capacitor blocks. For correct operation,  $C_A^{INA}$  must be equal to  $C_B^{INA}$ .  $V_{P2[1]}$  and  $V_{P2[3]}$  are the voltage on the PSoC<sup>®</sup>1 pins P2[1] and P2[3], respectively.  $R_{sense}$  is the current sense resistor value.  $I_{bus}$  is the current drawn from the USB power source.  $V_{INT}$  is the differential integrator output.  $V_{ref}$  is the bandgap reference voltage. In steady state, the integrator's differential input voltage,  $V_{ref} - V_{INA}$ , is driven to zero. Thus, the target value of the regulator charging current can be calculated as follows:

$$I_{bus} = \frac{C_F^{INA} \cdot C_A^{INT} \cdot V_{ref}}{C_B^{INT} \cdot C_A^{INA} \cdot R_{sense}}; \quad \text{Equation (3)}$$

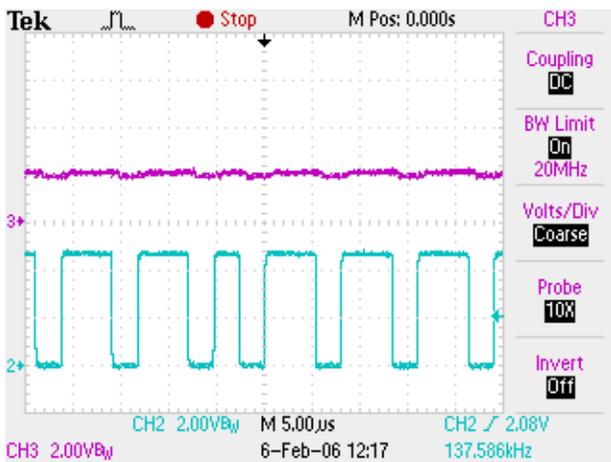

If  $C_F^{INA} = 16$ ,  $C_A^{INT} = 2$ ,  $V_{ref} = 1.3V$ ,  $C_B^{INT} = 14$ ,  $C_A^{INA} = C_B^{INA} = 31$ , and  $R_{sense} = 0.2 \Omega$ , the charging current is equal to 0.479 A. The charging current can be adjusted by changing the capacitor values. However, the USB specification enforces a 0.5-A current limitation.

The regulator's typical operating waveforms are shown in [Figure 3](#). As the battery charges up, the pulse density of the delta-sigma modulator decreases, as expected.

Figure 3. Integrator Output (Upper Trace) and Delta-Sigma Modulator Output (Lower Trace)

a) When Battery Voltage is 3.9 V

b) When Battery Voltage is 1.3 V

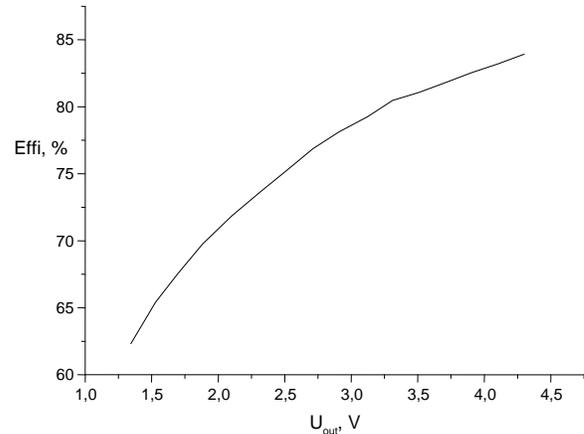

The battery charge current is determined by input current, battery voltage, and regulator efficiency. Regulator efficiency based on real measurements is shown in Figure 4.

Note that low efficiency at low voltage output is caused by voltage drops on diodes D3 and D4.

The battery voltage is measured by an ADC using a resistive divider to condition the signals to the allowed level. Correlated double sampling is used to null AD offset errors. The ADC first measures voltages on pin P0[1] and offset errors on pin P0[5]. The battery voltage is calculated as the difference between the voltages measured on P0[1] and P0[5]. The derived voltage measurement is shown in the following equation:

$$n_v = n_{max} \frac{G_v(V_{P0[1]} - V_{P0[5]})}{V_{ref}} = n_{max} \frac{G_v \beta_v V_{bat}}{V_{ref}} \quad \text{Equation (4)}$$

Figure 4. Regulator Efficiency

$V_{P0[1]}$  and  $V_{P0[5]}$  are the voltages on pins P0[1] and P0[5], respectively. The value  $\Delta n_v$  is the ADC value without the amplifier and ADC offset voltages. The value  $n_{max}$  is the maximum ADC code, with a value equal to  $2047$  for an 11-bit incremental ADC. The value  $V_{bat}$  is battery voltage, and  $G_v$  is the input amplifier gain, equal to 1. The value  $V_{ref}$  is the bandgap reference voltage (1.3 V), and  $\beta_v$  is the resistive divider coefficient, which is equal to 0.25 for  $R_3 = 150 \text{ k}\Omega$ ,  $R_5 = 100 \text{ k}\Omega$ , and  $R_8 = 150 \text{ k}\Omega$  divider resistors:

$$\beta_v = \frac{R_5}{R_3 + R_5 + R_8} \beta_v = \frac{1}{1 + \frac{R_3 + R_8}{R_5}} \quad \text{Equation (5)}$$

The ADC and regulator share comparator bus 1. Because the regulator and ADC never work simultaneously, the comparator bus reconnects by firmware to the ADC to provide measurement. The comparator bus reconnects to the delta-sigma modulator for hardware control of the charge state. See the [Charger Firmware](#) section.

The MOSFET Q4 allows the battery to be discharged before a charge. If Q2 is activated, the current from the battery flows through R11, R12, and R13, shown in schematics in Figure 2 and Figure 7, which are connected in parallel to provide greater thermal dissipation. See [Appendix A. Charger Schematic](#). This battery discharge feature can be activated only from the PC software as an option for battery training; it is not automatic.

The charger can be used in applications that require leaving the battery in the charger after the charge cycle, even if the PC power is turned off. Overcharging the battery can cause permanent damage or decrease battery capacity. To prevent battery overcharge, battery charging is initiated only after PC start when the battery voltage falls below a predefined limit. This limit is called the "charge restart condition." But if you insert the battery in the charger, the charger starts immediately, without testing the voltage.

To detect that a battery was changed when the charger was not powered from a USB, a simple RS-trigger, powered from the battery, is used. The RS-trigger automatically enters the reset state after the power goes on. Thus, changing the battery automatically resets the trigger. If the battery is not replaced in the charger, the recharge starts only if the battery voltage has fallen below a predefined limit. When the battery is changed, a charge is initiated regardless of battery voltage. The RS-trigger is built from two bipolar transistors, Q3 and Q4. As a result of nonsymmetrical resistances in bases (R4 versus R5) and collector circuits (R1 versus R2), a reset state is always triggered upon power up. Refer to [Appendix A. Charger Schematic](#).

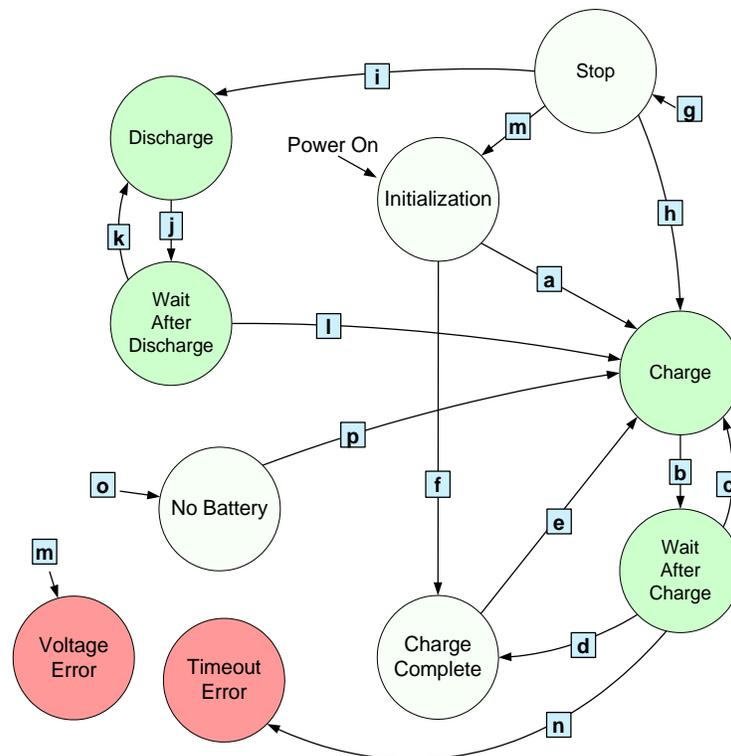

One digital block and interrupt-based firmware are used for charge-time control. The PSoC Timer8 User Module generates an interrupt with a frequency of 20 Hz and clocks from VC3 (5,859 kHz).

Two LEDs, green and red, are used to indicate the charger state. When the charger is connected to the USB, both LEDs are switched on. After device enumeration, the LEDs indicate the charger state. A green LED means a charge is in process. When both LEDs are turned off, everything is functioning properly but no charge is being applied to the battery at this time, possibly because the battery is fully charged or there is no battery in the charger. A red light indicates an error condition. The following section provides more information about the charger state.

## Charger Firmware

The firmware is constructed as a state machine. [Figure 5](#) shows the state diagram, in which active charge states are highlighted in green and error states are highlighted in red.

Figure 5. Charger State Diagram

In [Figure 5](#), state transitions are indicated by lines and squares labeled with letters. See [State Transition Descriptions](#) for explanations of the transitions. The states in circles in [Figure 5](#) are defined as follows:

**Initialization** – Both LEDs are off. Test for battery presence and state based on battery voltage.

**Charge** – Green LED is on. Charge for 5 seconds.

**Wait After Charge** – Green LED is on. No charge, for 0.5 seconds.

**Charge Complete** – Both LEDs are off. No charge. Battery is fully charged.

**Stop** – Both LEDs are off. No charge. This state occurs when the device gets a stop command from the PC. Wait for the next command.

**Discharge** – Green LED is on. Discharge is in progress for 5 seconds.

**Wait After Discharge** – Green LED is on. No charge, no discharge, wait 0.5 seconds.

**No Battery** – Both LEDs are off. Charger is turned off. Wait for battery to be inserted.

**Voltage Error** – Red LED is on. Stop charging. Battery voltage has reached the maximum permitted safe level. The battery or charger may be damaged. Wait for battery to be removed.

**Timeout Error** – Red LED is on. Charging is stopped. Charger has attempted to charge the battery for a predefined period but detects that the battery has failed to take a full charge. The battery may be damaged. Wait for the battery to be removed.

### State Transition Descriptions

The state transitions shown in [Figure 5](#) are described as follows:

- a) IF  $V_{NO-BATT} < V_{BATT} \leq V_{RE-CH}$   
or BatteryChanged flag is set  
THEN Charge

If a battery is detected and the battery is not already charged, then the green LED is turned on, and transition to the Charge state occurs.

- b) IF 5 seconds have elapsed  
THEN Wait After Charge

Charge the battery for 5 seconds.

- c) IF battery voltage increasing  
THEN Charge Complete

The charge termination criteria are that the voltage is decreasing during a charge, or that the voltage remains constant (no longer increasing) during a charge. If either criterion is not met, then the battery charge continues.

- d) IF battery voltage not increasing  
THEN Charge Complete

If termination criteria are met, the green LED is turned off and the charge is stopped. Transition to the Charge Complete state occurs.

- e) IF  $V_{NO-BATT} < V_{BATT} \leq V_{RE-CH}$

THEN Charge

If the battery voltage has fallen below the recharge voltage level (possibly because the battery is self-discharging), the battery charge is resumed.

- f) IF  $V_{RE-CH} < V_{BATT}$   
THEN Charge Complete

If a battery is detected and is fully charged, transition to the Charge Complete state occurs.

- g) IF Stop command received  
THEN Stop

If a stop command has been received from the PC, then stop charging immediately, regardless of the current state.

- h) IF Charge command received  
THEN Charge

If a charge command has been received from the PC, then charging starts immediately, regardless of the battery voltage.

- i) IF Discharge command received  
THEN Discharge

If the discharge command is received from the PC, then discharging starts immediately. This is the only way to discharge the battery.

- j) IF  $T_{BATT} \leq T_{COLD\_STOP}$   
THEN Wait After Discharge

Permits discharge of the battery for 5 seconds.

- k) IF  $V_{BATT} > V_{DISCH}$   
THEN Discharge

If batteries are not discharged, then discharge resumes after 0.5 second.

- l) IF  $V_{BATT} \leq V_{DISCH}$   
THEN Charge

If the battery is fully discharged, transition to the Charge state occurs.

- m) IF  $V_{BATT} > V_{ERR}$   
THEN Voltage Error

If battery voltage exceeds the  $V_{ERR}$  level, transition to the Voltage Error state occurs regardless of the present state.

- n) IF duration of charge exceeds predefined limit  
THEN Timeout Error

If the battery time charge exceeds a predefined limit, then charging stops. The battery may be damaged.

- o) IF  $V_{BATT} \leq V_{NO-BATT}$   
THEN No Battery

Exit from the current state and transition to No Battery state if the battery has been removed.

- p) IF  $V_{BATT} > V_{NO-BATT}$   
THEN Charge

If a newly inserted battery is detected, a charge starts. A charge always starts after a battery is inserted.

Note that if a battery is removed, then the charger goes to the No Battery state from any other state except the Stop state.

A time-based interrupt handler is used to implement sleep mode (Suspend state of the USB). The interrupt handler checks the bus activity bit. If the bus enters USB Suspend mode, the charger goes into CPU sleep mode. The CPU stays in sleep mode until it receives a wake-up event from the USB. Sleep mode support is required for full compliance with USB standards.

## USB Connection

The charger uses USB for two purposes:

- To receive and manually control data that relates to the charge process.
- As a power source for the charger

Logically, the charger is represented as a Human Interface Device (HID). The charger requires only a low data rate. An HID is very useful in this case. The advantage of an HID is that no special driver is needed and software support is simplified.

The supporting documents (see supporting files in the project .zip) contain tables of the USB descriptors and HID report descriptors. Both descriptors are represented in PSoC style, corresponding to the USB Setup Wizard tables.

## PC Utilities and Debugging

Dedicated charger control software has been developed to monitor the charge process. The user interface (UI) is very simple, as shown in Figure 6.

The UI consists of a chart that displays battery voltage, labels indicating the present charger state (Stopped, in Figure 6), battery voltage (2.79 V), and four buttons to manually control the charge process.

The software is optional and not required for charger operation.

Table 2 shows the data packets that are sent from the charger to the PC and from the PC to the charger. The data packet from the charger to the PC contains the charger state and battery voltage. This package has a length of 3 bytes, as specified in Table 2. Using this data, the software builds a chart and prints the actual battery voltage. The battery voltage is calculated in Equation (6) from the returned ADC code by the inverse function of Equation (4):

$$V_{BATT} = \frac{V_{ref} n_{V_{BATT}}}{G_V \beta_V n_{max}}; \text{ Equation (6)}$$

$n_{V_{BATT}}$  is the battery voltage in ADC code from the data packet.

The data packet from the PC to the charger contains a single 1-byte command.

Figure 6. Charger Monitoring Software

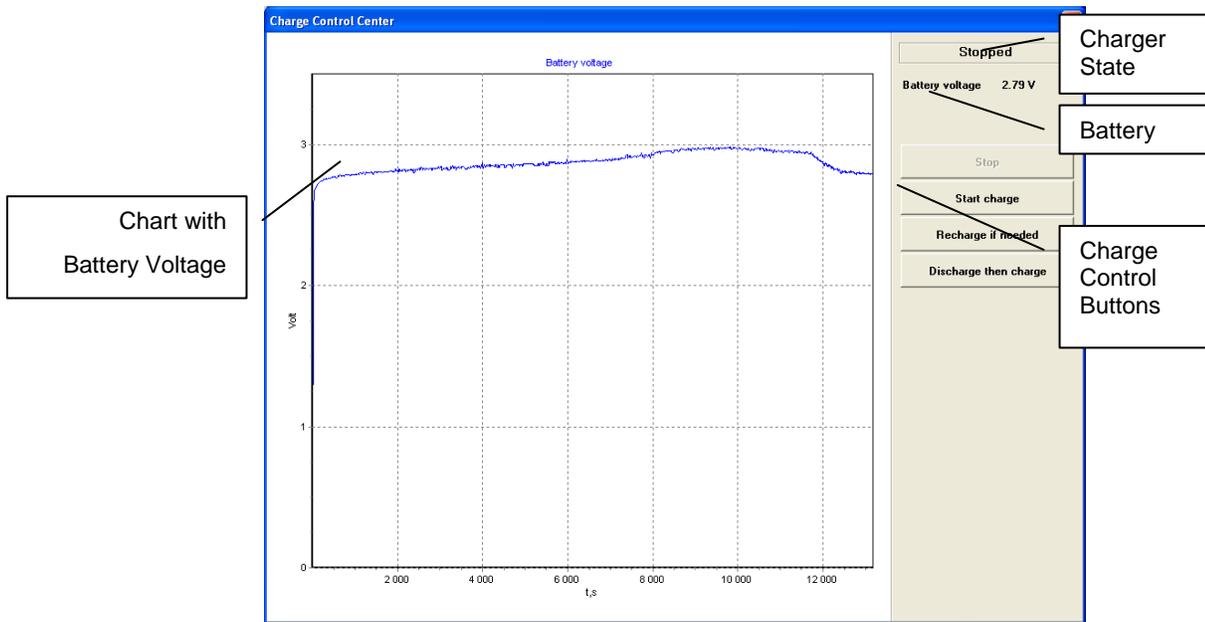

Table 2. Data Packets

Item No.	Length in Bytes	Reference	Description
<b>a) Data Packet from Charger to PC</b>			
1	1	State	Charger State • INITIALIZATION = 0 • WAIT AFTER CHARGE = 2 • NO BATTERY = 4 • WAIT AFTER DISCHARGE = 6 • VOLTAGE ERROR = 8 • CHARGE = 1 • CHARGER COMPLETE = 3 • DISCHARGE = 5 • STOP = 7 • TIMEOUT ERROR = 9
2	2	$n_{V_{BATT}}$	Battery voltage in ADC code
<b>b) Data Packet from PC to Charger</b>			
1	1	Cmd	Command to Charger • STOP = 1 • RECHARGE = 3 • SET TIMEOUT = 5 • CHARGE = 2 • DISCHARGE = 4

## Design Modifications

It is possible to decrease the cost of the charger by eliminating the coil and Schottky diode and substituting a pulse regulator with a linear current source. However, this alternative increases the charge time because if a linear regulator is used, the charge current is not greater than 0.5 A. The constant current source consists of an instrumentation amplifier to sense the current and a differential integrator.

Figure 7 shows the structure of a charger with a linear current source. The DSM is eliminated, and the differential integrator directly drives the MOSFET gate. The differential amplifier inputs are swapped to obtain an inverted signal on the output. The inverted signal is required to form negative feedback in order to drive a P-channel MOSFET. In contrast to a switching regulator, the MOSFET in a linear regulator operates in linear mode. As a result, the power dissipation on the MOSFET is higher, so a small heat sink may be necessary. A PCB plane is suitable for this role.

Figure 7. Charger Structure with Linear Regulator

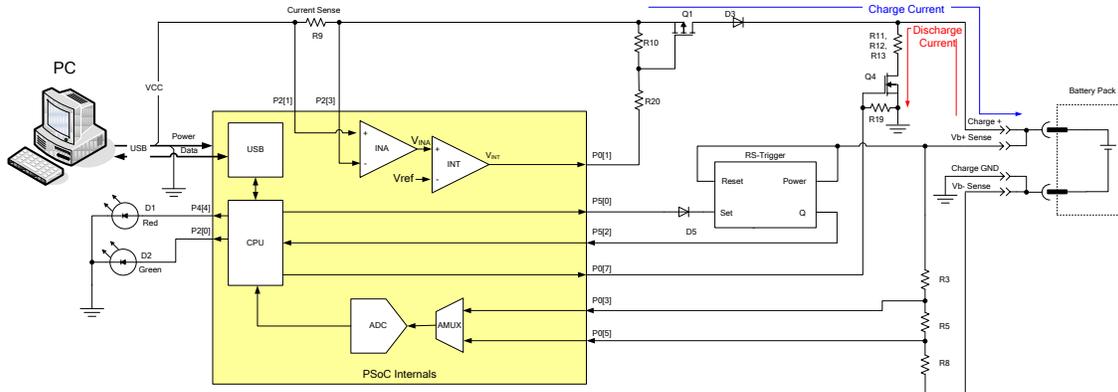

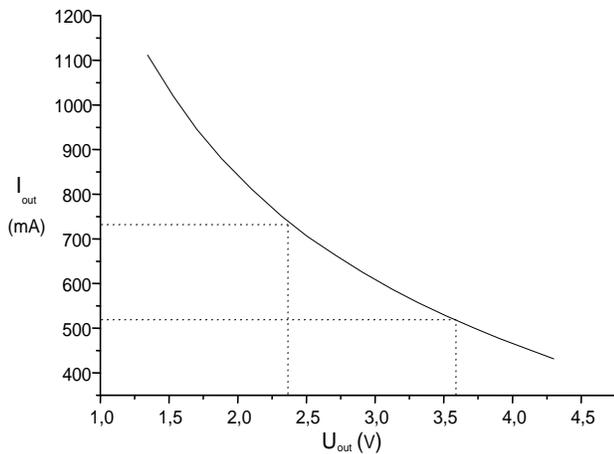

Figure 8 shows the charge current versus battery voltage for the switching regulator.

Figure 8. Charge Current Versus Battery Voltage

For the linear regulator, the current is constant and does not exceed 0.5 A. So when a switching regulator is used to charge two batteries (2.6 V in a charged state), the charge current is significantly greater than the charge current when a linear current source is used. For three batteries with 3.9 V in a charged state, the charge current is about the same for both kinds of regulators. For deeply discharged batteries (2.4 V), the charge current is greater.

However, the overall benefit is not great when a switching regulator is used to charge three NiCd/NiMH batteries. So in this case, a linear regulator can be used with a very small loss of efficiency. Figure 9 shows switching and linear regulator efficiencies against battery voltage.

Figure 9. Switching and Linear Regulator Output Power Versus Battery Voltage

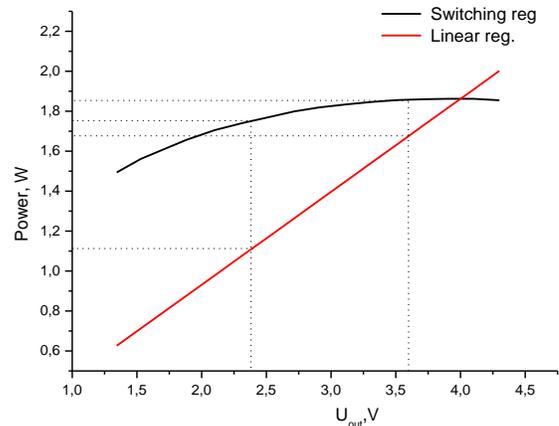

Table 3 lists the time required to charge different batteries when the two regulator types are used.

Table 3. Charge Time Examples

No.	Case	Time
1	Two cells by 1400 mAh using switching regulator	189 min
2	Two cells by 1400 mAh using linear regulator	323 min
3	Three cells by 1800 mAh using switching regulator	384 min
4	Three cells by 1800 mAh using linear regulator	426 min

The USB charger is designed to be part of a more complex system. Additional resources can be allocated to the unused digital blocks. For example, the SPIM User Module can be added for communication with the WUSB User Module. The size of the firmware code is small, about 4.5 KB (less than 30 percent of flash). A total of 104 bytes of SRAM is used for variables—13 percent using the large memory model (LMM), 40 percent without. Resources are thus available to combine this charger onto one PSoC device with the user's own design.

## Summary

This application note demonstrated the USB-powered NiCd/NiMH battery charger using the PSoC CY8C24794 device. It described both switching and linear regulator methods, which you can select depending on cost and efficiency requirements.
