

## Objective

This code example demonstrates peripheral-to-peripheral data transfer using the PSoC direct memory access (DMA) controller. Analog-to-digital converter (ADC) sampled data is transferred to a digital-to-analog converter (DAC) output register.

## Overview

This code example shows how the PSoC 3 and PSoC 5LP DMA controller is used to transfer data to and from various peripherals, including the ADC and DAC, without using the CPU. The ADC continually samples an analog input pin. At the end of each sample, it generates a DMA request signal. The DMA transfers data from an ADC output data register to a DAC input data register.

The ADC resolution is configured to be 8 bits; however, it can produce a 16-bit signed value to handle analog input overflow and underflow. The DAC is 8-bit. The DMA transfers the 8 least significant bits (LSb) of data from the ADC to the DAC.

The firmware continuously displays the ADC signed 16-bit register and the 8-bit DAC data register on a kit LCD for monitoring. You can also monitor the ADC input and DAC output pins with a multimeter or oscilloscope.

## Requirements

**Tool:** PSoC Creator™ 3.1 or later

**Programming Language:** C (DP8051 Keil 9.51, ARM GCC 4.8.4, and ARM MDK compilers)

**Associated Parts:** All PSoC 3 and PSoC 5LP parts

**Related Hardware:** [CY8CKIT-030](#), [CY8CKIT-050](#)

## Design

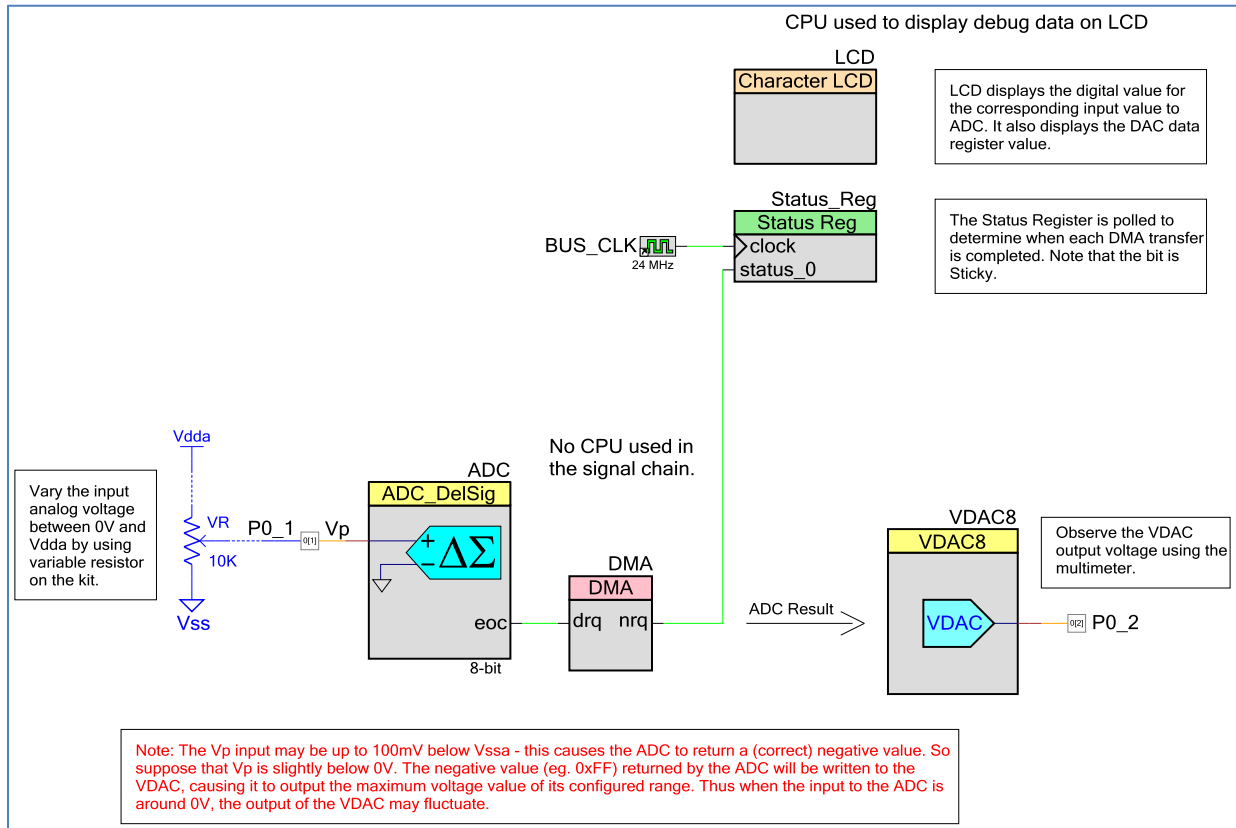

[Figure 1](#) shows the PSoC Creator schematic design of the code example.

The example project features the following:

- Delta Sigma ADC Component for sampling an input voltage. The input voltage to the ADC may be adjusted between 0 V and  $V_{dda}$  by using a variable resistor on the [CY8CKIT-030](#), [CY8CKIT-50](#), or an external analog voltage source.
- DMA Component triggered by the ADC end-of-conversion (EOC) terminal. For a detailed description of PSoC 3 and PSoC 5LP DMA, see the DMA-specific application notes listed in [Related Documents](#).
  - The source address of the DMA's transfer descriptor points to the ADC sample register.
  - The destination address of the DMA's transfer descriptor points to the DAC data register.
  - The DMA transfers one byte on every burst.
  - The DMA generates a pulse on the `nrq` terminal at the end of each transfer.
  - A sticky status register captures the completion of a DMA transfer.
- Eight-bit DAC Component configured to drive a voltage signal between 0 V and 1.020 V.
- A display Component (Character LCD) to show the ADC sample value and the DAC data register.
  - The first LCD line shows the raw 16-bit ADC output.
  - The second LCD line shows the 8-bit DAC input value.
  - The LCD is updated when a DMA transfer is complete.

Note that a status register, with the sticky bit option set, is used to detect the end of a DMA transfer. The firmware polls the status register to detect the DMA transfer completion and then updates the LCD with the ADC and DAC data.

Figure 1. PSoC 3 and PSoC 5LP Peripheral-to-Peripheral Data Transfer Using DMA

## Design Considerations

The ADC, even when it is configured with 8 bits, can produce a 16-bit value to handle voltages below V<sub>ssa</sub> (underflow). It reports voltages below V<sub>ssa</sub> as 16-bit negative values. Writing these values to the DAC causes it to output about the maximum DAC voltage. Thus, when the input to the ADC is about 0 V, the DAC output may fluctuate.

Similar behavior occurs when the measured voltage is higher than 1.020 V (overflow). The ADC returns a 16-bit value greater than 255. When the LS<sub>b</sub> is written to the DAC, the output fluctuates at approximately the minimum DAC voltage. Thus, when the input to the ADC is about 1.020 V, the DAC output may also fluctuate.

## Hardware Setup

For the basic kit board setup, see the corresponding [kit user guide](#).

This example project is designed to run on the CY8CKIT-030 (by default) and CY8CKIT-050. To use the latter, change the project's device from CY8C3866AXI-40 to CY8C586AXI-LP035 with the Device Selector (see demonstration [video](#)).

The only instruction is to connect a jumper wire between the P0[1] pin and the VR pin from the P6 connector. You use a multimeter to observe the DAC output pin voltage (P0[2]).

## Software Setup

No special software setup is required. You can use all supported compilers, with any optimization.

## Components

Table 1 lists the PSoC Creator Components used in this example, as well as the resources used by each one.

Table 1. PSoC Creator Components

Component	Hardware Resources
Delta Sigma ADC	PSoC 3 or PSoC 5LP Delta Sigma ADC
DMA	1 DMA channel, 1 transaction descriptor
Status Register	UDB (1 status register)
Clock	Bus clock
Character LCD	7 pins
VDAC8	1 DAC block
Pin	2 analog pins

## Parameter Settings

Table 2 lists the parameter settings for the PSoC Creator Components used in the code example. Only the parameters that vary from the default are listed.

Table 2. PSoC Creator Component Parameter Settings

Component	Non-Default Parameter Settings
Delta Sigma ADC	Conversion mode: Continuous Input range: Vssa to 1.024 V Buffer mode: Bypass buffer Input mode: Single ended Resolution: 8 bits
DMA	Hardware request: Level
Status Register	Sticky mode
Clock	Source: BUS_CLK
Character LCD	None
VDAC8	None
Pin	ADC input pin: Analog VDAC output pin: Analog

## Design-Wide Resources

Figure 2 shows the pin assignments for the examples. No other Design-Wide Resources need to be changed from their default settings.

Figure 2. Pin Assignments for PSoC 3 and PSoC 5LP Example

Alias	Name	Port	Pin	Lock
	\LCD:LCDPort[6:0]\	P2 [6:0]	95..99,1..2	<input checked="" type="checkbox"/>
	P0_1	P0 [1] OpAmp0:vout	72	<input checked="" type="checkbox"/>
	P0_2	P0 [2] OpAmp0:vplus, SAR1:ext_pin	73	<input checked="" type="checkbox"/>

## Operation

After building and installing the code example in the appropriate kit, test the code example as follows:

- Use the potentiometer to change the voltage at the ADC input pin. Observe the character LCD.
  - Observe that the top row displays “ADC Output: XXXX.” The 16-bit hexadecimal value represents the 8-bit ADC sample value. Confirm that the values below zero show “0xFFFF” and the values above 1.020 V show a number greater than 0x00FF.
  - Observe that the bottom row displays “DAC Input: XX.” The 8-bit hexadecimal value represents the 8 LSb of the ADC sample.
- Use a multimeter to measure the output voltage at the P0[2] pin. Confirm that the value is 1.020 V when the DAC input is 0xFF and 0 V when the DAC input is 0x00. Confirm that the numbers between 0x00 and 0xFF are linearly proportional.

## Upgrade Information
