

The following document contains information on Cypress products. The document has the series name, product name, and ordering part numbering with the prefix “MB”. However, Cypress will offer these products to new and existing customers with the series name, product name, and ordering part number with the prefix “CY”.

How to Check the Ordering Part Number

1. Go to www.cypress.com/pcn.
2. Enter the keyword (for example, ordering part number) in the **SEARCH PCNS** field and click **Apply**.
3. Click the corresponding title from the search results.
4. Download the Affected Parts List file, which has details of all changes

For More Information

Please contact your local sales office for additional information about Cypress products and solutions.

About Cypress

Cypress is the leader in advanced embedded system solutions for the world's most innovative automotive, industrial, smart home appliances, consumer electronics and medical products. Cypress' microcontrollers, analog ICs, wireless and USB-based connectivity solutions and reliable, high-performance memories help engineers design differentiated products and get them to market first. Cypress is committed to providing customers with the best support and development resources on the planet enabling them to disrupt markets by creating new product categories in record time. To learn more, go to www.cypress.com.

The following document contains information on Cypress products. Although the document is marked with the name "Spansion", the company that originally developed the specification, Cypress will continue to offer these products to new and existing customers.

Continuity of Specifications

There is no change to this document as a result of offering the device as a Cypress product. Any changes that have been made are the result of normal document improvements and are noted in the document history page, where supported. Future revisions will occur when appropriate, and changes will be noted in a document history page.

Continuity of Ordering Part Numbers

Cypress continues to support existing part numbers. To order these products, please use only the Ordering Part Numbers listed in this document.

For More Information

Please contact your local sales office for additional information about Cypress products and solutions.

About Cypress

Cypress (NASDAQ: CY) delivers high-performance, high-quality solutions at the heart of today's most advanced embedded systems, from automotive, industrial and networking platforms to highly interactive consumer and mobile devices. With a broad, differentiated product portfolio that includes NOR flash memories, F-RAM™ and SRAM, Traveo™ microcontrollers, the industry's only PSoC® programmable system-on-chip solutions, analog and PMIC Power Management ICs, CapSense® capacitive touch-sensing controllers, and Wireless BLE Bluetooth® Low-Energy and USB connectivity solutions, Cypress is committed to providing its customers worldwide with consistent innovation, best-in-class support and exceptional system value.

PREFACE

■ The Purpose and Intended Readership of This Manual

Thank you very much for your continued special support for Spansion products.

The MB95710L/770L Series is a line of products developed as general-purpose products in the New 8FX family of proprietary 8-bit single-chip microcontrollers applicable as application-specific integrated circuits (ASICs). The MB95710L/770L Series can be used for a wide range of applications from consumer products including portable devices to industrial equipment.

Intended for engineers who actually develop products using the MB95710L/770L Series of microcontrollers, this manual describes its functions, features, and operations. You should read through the manual.

For details on individual instructions, refer to "F²MC-8FX Programming Manual".

This manual is written to explain the respective configurations and operations of peripheral functions, but not to provide specifications of a device.

For detailed specifications of a device, refer to its data sheet.

■ Trademark

Note: F²MC is a trademark of Spansion LLC.

The company names and brand names in this document are the trademarks or registered trademarks of their respective owners.

■ Sample Programs

Spansion Inc. provides sample programs free of charge to operate the peripheral resources of the New 8FX family of microcontrollers. Feel free to use such sample programs to check the operational specifications and usages of Spansion microcontrollers.

Note that sample programs are subject to change without notice. As these pieces of software are offered to show standard operations and usages, evaluate them sufficiently before use with your system. Spansion Inc. assumes no liability for any damages whatsoever arising out of the use of sample programs.

How to Use This Manual

■ Finding a function

The following methods can be used to search for details of a peripheral function in this manual:

- Searching from CONTENTS
CONTENTS lists the contents in this manual in the order of description.
- Searching from registers
The address at which a register is located is not mentioned in this manual. To check the address of a register, refer to "■ I/O MAP" in the device data sheet.

■ Chapters

This manual explains one peripheral function in one chapter.

■ Terminology

This manual uses the following terminology.

Term	Explanation
Word	Indicates an access in unit of 16 bits.
Byte	Indicates an access in unit of 8 bits.

■ Notations

The notations in "■ Register Configuration" in this manual are explained below:

- bit: bit number
- Field: bit field name
- Attribute: Attributes for read access and write access of each bit
 - R: Read-only
 - W: Write-only
 - R/W: Readable/Writable
 - —: Undefined
- Initial value: Initial value of a bit after a reset
 - 0: The initial value is "0".
 - 1: The initial value is "1".
 - X: The initial value is undefined.

Multiple bits are indicated in this manual in the following way.

- Example 1: bit7:0 represents bit7 to bit0.
- Example 2: SCM[2:0] represents SCM2 to SCM0.

The values such as those indicating addresses are written in this manual in the following ways:

- Hexadecimal number: The prefix "0x" is attached to the beginning of a value (e.g.: 0xFFFF).
- Binary number: The prefix "0b" is attached to the beginning of a value (e.g.: 0b1111).
- Decimal number: Only the number is used (e.g.: 1234).

In this manual, "n" in a pin name and a register abbreviation represents the channel number.

CONTENTS

CHAPTER 1	MEMORY ACCESS MODE	1
1.1	Memory Access Mode	2
CHAPTER 2	CPU	3
2.1	Dedicated Registers	4
2.1.1	Register Bank Pointer (RP)	6
2.1.2	Direct Bank Pointer (DP)	7
2.1.3	Condition Code Register (CCR)	9
2.2	General-purpose Register	11
2.3	Placement of 16-bit Data in Memory	13
CHAPTER 3	CLOCK CONTROLLER	15
3.1	Overview	16
3.2	Oscillation Stabilization Wait Time	24
3.3	Registers	27
3.3.1	System Clock Control Register (SYCC)	28
3.3.2	PLL Control Register (PLLC)	30
3.3.3	Oscillation Stabilization Wait Time Setting Register (WATR)	31
3.3.4	Standby Control Register (STBC)	33
3.3.5	System Clock Control Register 2 (SYCC2)	35
3.4	Clock Modes	37
3.5	Operations in Low Power Consumption Mode (Standby Mode)	42
3.5.1	Notes on Using Standby Mode	43
3.5.2	Sleep Mode	46
3.5.3	Stop Mode	47
3.5.4	Time-base Timer Mode	49
3.5.5	Watch Mode	51
3.6	Clock Oscillator Circuit	52
3.7	Overview of Prescaler	53
3.8	Configuration of Prescaler	54
3.9	Operation of Prescaler	55
3.10	Notes on Using Prescaler	57
CHAPTER 4	RESET	59
4.1	Reset Operation	60
4.2	Register	64
4.2.1	Reset Source Register (RSRR)	65
4.3	Notes on Using Reset	68
CHAPTER 5	INTERRUPTS	69
5.1	Interrupts	70
5.1.1	Interrupt Level Setting Registers (ILR0 to ILR5)	71
5.1.2	Interrupt Processing	73
5.1.3	Nested Interrupts	75

5.1.4	Interrupt Processing Time	76
5.1.5	Stack Operation During Interrupt Processing	77
5.1.6	Interrupt Processing Stack Area	78
CHAPTER 6	I/O PORT	79
6.1	Overview	80
6.2	Configuration and Operations	81
CHAPTER 7	TIME-BASE TIMER	85
7.1	Overview	86
7.2	Configuration	87
7.3	Interrupt	89
7.4	Operations and Setting Procedure Example	90
7.5	Register	94
7.5.1	Time-base Timer Control Register (TBTC)	95
7.6	Notes on Using Time-base Timer	97
CHAPTER 8	HARDWARE/SOFTWARE WATCHDOG TIMER	99
8.1	Overview	100
8.2	Configuration	101
8.3	Operations and Setting Procedure Example	103
8.4	Register	106
8.4.1	Watchdog Timer Control Register (WDTC)	107
8.5	Notes on Using Watchdog Timer	109
CHAPTER 9	WATCH PRESCALER	111
9.1	Overview	112
9.2	Configuration	113
9.3	Interrupt	115
9.4	Operations and Setting Procedure Example	116
9.5	Register	119
9.5.1	Watch Prescaler Control Register (WPCR)	120
9.6	Notes on Using Watch Prescaler	122
CHAPTER 10	WATCH COUNTER	123
10.1	Overview	124
10.2	Configuration	125
10.3	Interrupt	127
10.4	Operations and Setting Procedure Example	128
10.5	Registers	130
10.5.1	Watch Counter Data Register (WCDR)	131
10.5.2	Watch Counter Control Register (WCSR)	132
10.6	Notes on Using Watch Counter	133
CHAPTER 11	WILD REGISTER FUNCTION	135
11.1	Overview	136
11.2	Configuration	137
11.3	Operations	139
11.4	Registers	140

11.4.1	Wild Register Data Setting Registers (WRDR0 to WRDR2)	141
11.4.2	Wild Register Address Setting Registers (WRAR0 to WRAR2)	142
11.4.3	Wild Register Address Compare Enable Register (WREN)	143
11.4.4	Wild Register Data Test Setting Register (WROR)	144
11.5	Typical Hardware Connection Example	145
CHAPTER 12 8/16-BIT COMPOSITE TIMER		147
12.1	Overview	148
12.2	Configuration	150
12.3	Channel	153
12.4	Pins	154
12.5	Interrupts	155
12.6	Operation of Interval Timer Function (One-shot Mode)	156
12.7	Operation of Interval Timer Function (Continuous Mode)	158
12.8	Operation of Interval Timer Function (Free-run Mode)	160
12.9	Operation of PWM Timer Function (Fixed-cycle Mode)	162
12.10	Operation of PWM Timer Function (Variable-cycle Mode)	164
12.11	Operation of PWC Timer Function	166
12.12	Operation of Input Capture Function	168
12.13	Operation of Noise Filter	170
12.14	Registers	171
12.14.1	8/16-bit Composite Timer Status Control Register 0 (Tn0CR0/Tn1CR0)	172
12.14.2	8/16-bit Composite Timer Status Control Register 1 (Tn0CR1/Tn1CR1)	175
12.14.3	8/16-bit Composite Timer Timer Mode Control Register (TMCRn)	179
12.14.4	8/16-bit Composite Timer Data Register (Tn0DR/Tn1DR)	181
12.15	Notes on Using 8/16-bit Composite Timer	184
CHAPTER 13 EXTERNAL INTERRUPT CIRCUIT		187
13.1	Overview	188
13.2	Configuration	189
13.3	Channels	190
13.4	Pin	191
13.5	Interrupt	192
13.6	Operations and Setting Procedure Example	193
13.7	Register	195
13.7.1	External Interrupt Control Register (EIC)	196
13.8	Notes on Using External Interrupt Circuit	198
CHAPTER 14 INTERRUPT PIN SELECTION CIRCUIT		199
14.1	Overview	200
14.2	Configuration	201
14.3	Pins	203
14.4	Operation	204
14.5	Register	205
14.5.1	Interrupt Pin Selection Circuit Control Register (WICR)	206
14.6	Notes on Using Interrupt Pin Selection Circuit	208
CHAPTER 15 8/12-BIT A/D CONVERTER		209
15.1	Overview	210

15.2	Configuration	211
15.3	Pins	214
15.4	Interrupt	215
15.5	Enabling Operation of 8/12-bit A/D Converter	216
15.6	Operations and Setting Procedure Example	217
15.7	Registers	220
15.7.1	8/12-bit A/D Converter Control Register 1 (ADC1)	221
15.7.2	8/12-bit A/D Converter Control Register 2 (ADC2)	223
15.7.3	8/12-bit A/D Converter Control Register 3 (ADC3)	225
15.7.4	8/12-bit A/D Converter Data Register (Upper/Lower) (ADDH/ADDL)	227
15.8	Notes on Using 8/12-bit A/D Converter	228
CHAPTER 16 LOW-VOLTAGE DETECTION CIRCUIT		231
16.1	Overview	232
16.2	Configuration	233
16.3	Pins	234
16.4	Interrupt	235
16.5	Operations	236
16.6	Register	239
16.6.1	LVD Control Register (LVDC)	240
CHAPTER 17 CLOCK SUPERVISOR COUNTER		243
17.1	Overview	244
17.2	Configuration	245
17.3	Operations	247
17.4	Registers	252
17.4.1	Clock Monitoring Data Register (CMDR)	253
17.4.2	Clock Monitoring Control Register (CMCR)	254
17.5	Notes on Using Clock Supervisor Counter	256
CHAPTER 18 8/16-BIT PPG		259
18.1	Overview	260
18.2	Configuration	261
18.3	Channel	263
18.4	Pins	264
18.5	Interrupt	265
18.6	Operations and Setting Procedure Example	266
18.6.1	8-bit PPG Independent Mode	267
18.6.2	8-bit Prescaler + 8-bit PPG Mode	269
18.6.3	16-bit PPG Mode	271
18.7	Registers	274
18.7.1	8/16-bit PPG timer n1 Control Register (PCn1)	275
18.7.2	8/16-bit PPG timer n0 Control Register (PCn0)	277
18.7.3	8/16-bit PPG timer n1/n0 Cycle Setup Buffer Register (PPSn1/PPSn0)	279
18.7.4	8/16-bit PPG timer n1/n0 Duty Setup Buffer Register (PDSn1/PDSn0)	280
18.7.5	8/16-bit PPG Start Register (PPGS)	281
18.7.6	8/16-bit PPG Output Reverse Register (REVC)	283
18.8	Notes on Using 8/16-bit PPG	285

CHAPTER 19 16-BIT RELOAD TIMER	287
19.1 Overview	288
19.2 Configuration	290
19.3 Channel	292
19.4 Pins	293
19.5 Interrupt	294
19.6 Operations and Setting Procedure Example	295
19.6.1 Internal Clock Mode	297
19.6.2 Event Count Mode	301
19.7 Registers	303
19.7.1 16-bit Reload Timer Control Status Register (Upper) ch. n (TMCSRHn)	304
19.7.2 16-bit Reload Timer Control Status Register (Lower) ch. n (TMCSRLn)	306
19.7.3 16-bit Reload Timer Timer Register (Upper/Lower) ch. n (TMRHn/TMRLn)	308
19.7.4 16-bit Reload Timer Reload Register (Upper/Lower) ch. n (TMRLRHn/TMRLRLn) ...	309
19.8 Notes on Using 16-bit Reload Timer	310
CHAPTER 20 EVENT COUNTER	311
20.1 Overview	312
20.2 Configuration	313
20.3 Operations in Even Counter Operation Mode	315
20.4 Setting Procedure Example	318
20.5 Frequency Measurement Range and Frequency Measurement Precision	321
20.6 Register	322
20.6.1 Event Counter Control Register (EVCR)	323
20.7 Notes on Using Event Counter	325
CHAPTER 21 UART/SIO	327
21.1 Overview	328
21.2 Configuration	329
21.3 Channel	331
21.4 Pins	332
21.5 Interrupts	333
21.6 Operations and Setting Procedure Example	334
21.6.1 Operations in Operation Mode 0	335
21.6.2 Operations in Operation Mode 1	342
21.7 Registers	348
21.7.1 UART/SIO Serial Mode Control Register 1 ch. n (SMC1n)	349
21.7.2 UART/SIO Serial Mode Control Register 2 ch. n (SMC2n)	351
21.7.3 UART/SIO Serial Status and Data Register ch. n (SSRn)	353
21.7.4 UART/SIO Serial Input Data Register ch. n (RDRn)	355
21.7.5 UART/SIO Serial Output Data Register ch. n (TDRn)	356
CHAPTER 22 UART/SIO DEDICATED BAUD RATE GENERATOR	357
22.1 Overview	358
22.2 Channel	359
22.3 Operations	360
22.4 Registers	361
22.4.1 UART/SIO Dedicated Baud Rate Generator Prescaler Select Register ch. n (PSSRn)	362

22.4.2	UART/SIO Dedicated Baud Rate Generator Baud Rate Setting Register ch. n (BRSRn)	363
--------	---	-----

CHAPTER 23 I²C BUS INTERFACE 365

23.1	Overview	366
23.2	Configuration	367
23.3	Channel	370
23.4	Pins	371
23.5	Interrupts	372
23.6	Operations and Setting Procedure Example	374
23.6.1	I ² C Bus Interface	375
23.6.2	Function to Wake up the MCU from Standby Mode	383
23.7	Registers	385
23.7.1	I ² C Bus Control Register 0 ch. n (IBCR0n)	386
23.7.2	I ² C Bus Control Register 1 ch. n (IBCR1n)	389
23.7.3	I ² C Bus Status Register ch. n (IBSRn)	392
23.7.4	I ² C Data Register ch. n (IDDRn)	395
23.7.5	I ² C Address Register ch. n (IAARn)	396
23.7.6	I ² C Clock Control Register ch. n (ICCRn)	397
23.8	Notes on Using I ² C Bus Interface	399

CHAPTER 24 LCD CONTROLLER (MB95710L SERIES) 401

24.1	Overview	402
24.2	Configuration	403
24.2.1	Internal Divider Resistors of LCD Controller	406
24.2.2	External Divider Resistor for LCD Controller	410
24.3	Pins	412
24.4	Display RAM	413
24.5	Interrupt	415
24.6	Operations	416
24.6.1	Output Waveform in LCD Controller Operation in 4 COM Mode (1/2 Bias, 1/2 Duty)	421
24.6.2	Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/3 Duty)	422
24.6.3	Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/4 Duty)	424
24.6.4	Output Waveform in LCD Controller Operation in 8 COM Mode (1/3 Bias, 1/8 Duty)	426
24.6.5	Output Waveform in LCD Controller Operation in 8 COM Mode (1/4 Bias, 1/8 Duty)	428
24.7	Registers	430
24.7.1	LCDC Control Register 1 (LCDCC1)	431
24.7.2	LCDC Control Register 2 (LCDCC2)	433
24.7.3	LCDC Enable Register 1 (LCDCE1)	435
24.7.4	LCDC Enable Register 2 (LCDCE2)	437
24.7.5	LCDC Enable Register 3 (LCDCE3)	439
24.7.6	LCDC Enable Register 4 (LCDCE4)	441
24.7.7	LCDC Enable Register 5 (LCDCE5)	443
24.7.8	LCDC Enable Register 6 (LCDCE6)	445
24.7.9	LCDC Enable Register 7 (LCDCE7)	447

24.7.10	LCDC Blinking Setting Register 1 (LCDCB1)	449
24.7.11	LCDC Blinking Setting Register 2 (LCDCB2)	452
24.8	Notes on Using LCD Controller	455
CHAPTER 25 LCD CONTROLLER (MB95770L SERIES)		457
25.1	Overview	458
25.2	Configuration	459
25.2.1	Internal Divider Resistors of LCD Controller	462
25.2.2	External Divider Resistor for LCD Controller	466
25.3	Pins	468
25.4	Display RAM	469
25.5	Interrupt	471
25.6	Operations	472
25.6.1	Output Waveform in LCD Controller Operation in 4 COM Mode (1/2 Bias, 1/2 Duty)	477
25.6.2	Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/3 Duty)	478
25.6.3	Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/4 Duty)	480
25.6.4	Output Waveform in LCD Controller Operation in 8 COM Mode (1/3 Bias, 1/8 Duty)	482
25.6.5	Output Waveform in LCD Controller Operation in 8 COM Mode (1/4 Bias, 1/8 Duty)	484
25.7	Registers	486
25.7.1	LCDC Control Register 1 (LCDCC1)	487
25.7.2	LCDC Control Register 2 (LCDCC2)	489
25.7.3	LCDC Enable Register 1 (LCDCE1)	491
25.7.4	LCDC Enable Register 2 (LCDCE2)	493
25.7.5	LCDC Enable Register 3 (LCDCE3)	495
25.7.6	LCDC Enable Register 4 (LCDCE4)	497
25.7.7	LCDC Enable Register 5 (LCDCE5)	499
25.7.8	LCDC Enable Register 6 (LCDCE6)	501
25.7.9	LCDC Blinking Setting Register 1 (LCDCB1)	503
25.7.10	LCDC Blinking Setting Register 2 (LCDCB2)	506
25.8	Notes on Using LCD Controller	509
CHAPTER 26 EXAMPLE OF SERIAL PROGRAMMING CONNECTION		511
26.1	Basic Configuration of Serial Programming Connection	512
26.2	Example of Serial Programming Connection	513
CHAPTER 27 DUAL OPERATION FLASH MEMORY		515
27.1	Overview	516
27.2	Sector/Bank Configuration	518
27.3	Invoking Flash Memory Automatic Algorithm	519
27.4	Checking Automatic Algorithm Execution Status	521
27.4.1	Data Polling Flag (DQ7)	523
27.4.2	Toggle Bit Flag (DQ6)	525
27.4.3	Execution Timeout Flag (DQ5)	526
27.4.4	Sector Erase Timer Flag (DQ3)	527
27.4.5	Toggle Bit2 Flag (DQ2)	528

27.5	Programming/Erasing Flash Memory	529
27.5.1	Placing Flash Memory in Read/Reset State	530
27.5.2	Programming Data to Flash Memory	531
27.5.3	Erasing All Data from Flash Memory (Chip Erase)	533
27.5.4	Erasing Specific Data from Flash Memory (Sector Erase)	534
27.5.5	Suspending Sector Erase from Flash Memory	536
27.5.6	Resuming Sector Erase of Flash Memory	537
27.5.7	Unlock Bypass Program	538
27.6	Operations	539
27.7	Flash Security	541
27.8	Registers	542
27.8.1	Flash Memory Status Register 2 (FSR2)	543
27.8.2	Flash Memory Status Register (FSR)	546
27.8.3	Flash Memory Sector Write Control Register 0 (SWRE0)	549
27.8.4	Flash Memory Status Register 3 (FSR3)	551
27.8.5	Flash Memory Status Register 4 (FSR4)	552
27.9	Notes on Using Dual Operation Flash Memory	560
CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE		561
28.1	Overview	562
28.2	Configuration	563
28.3	Registers	564
28.3.1	Main CR Clock Trimming Register (Upper) (CRTH)	565
28.3.2	Main CR Clock Trimming Register (Lower) (CRTL)	566
28.3.3	Main CR Clock Temperature Dependent Adjustment Register (CRTDA)	567
28.3.4	Watchdog Timer Selection ID Register (Upper/Lower) (WDTH/WDTL)	568
28.4	Notes on Main CR Clock Trimming	569
28.5	Notes on Using NVR Interface	571
CHAPTER 29 COMPARATOR		573
29.1	Overview	574
29.2	Configuration	575
29.3	Pins	577
29.4	Interrupt	578
29.5	Operations and Setting Procedure Example	579
29.6	Register	580
29.6.1	Comparator Control Register ch. n (CMRn)	581
CHAPTER 30 SYSTEM CONFIGURATION CONTROLLER		583
30.1	Overview	584
30.2	Registers	585
30.2.1	System Configuration Register (SYSC)	586
30.2.2	System Configuration Register 2 (SYSC2)	588
30.3	Notes on Using Controller	589
APPENDIX		591
APPENDIX A Instruction Overview		592

CHAPTER 1

MEMORY ACCESS MODE

This chapter describes the memory access mode.

1.1 Memory Access Mode

1.1 Memory Access Mode

The MB95710L/770L Series supports only one memory access mode: single-chip mode.

Single-chip Mode

In single-chip mode, only the internal RAM and the Flash memory are used, and no external bus access is executed.

Mode data

Mode data is the data used to determine the memory access mode of the CPU.
The mode data address is fixed at "0xFFFD". Always set the mode data of the Flash memory to "0x00" to select the single-chip mode.

Figure 1.1-1 Mode Data Settings

After a reset is released, the CPU fetches mode data first.
The CPU then fetches the reset vector after the mode data. It starts executing instructions from the address set in the reset vector.

CHAPTER 2

CPU

This chapter describes the functions and operations of the CPU.

- 2.1 Dedicated Registers
- 2.2 General-purpose Register
- 2.3 Placement of 16-bit Data in Memory

2.1 Dedicated Registers

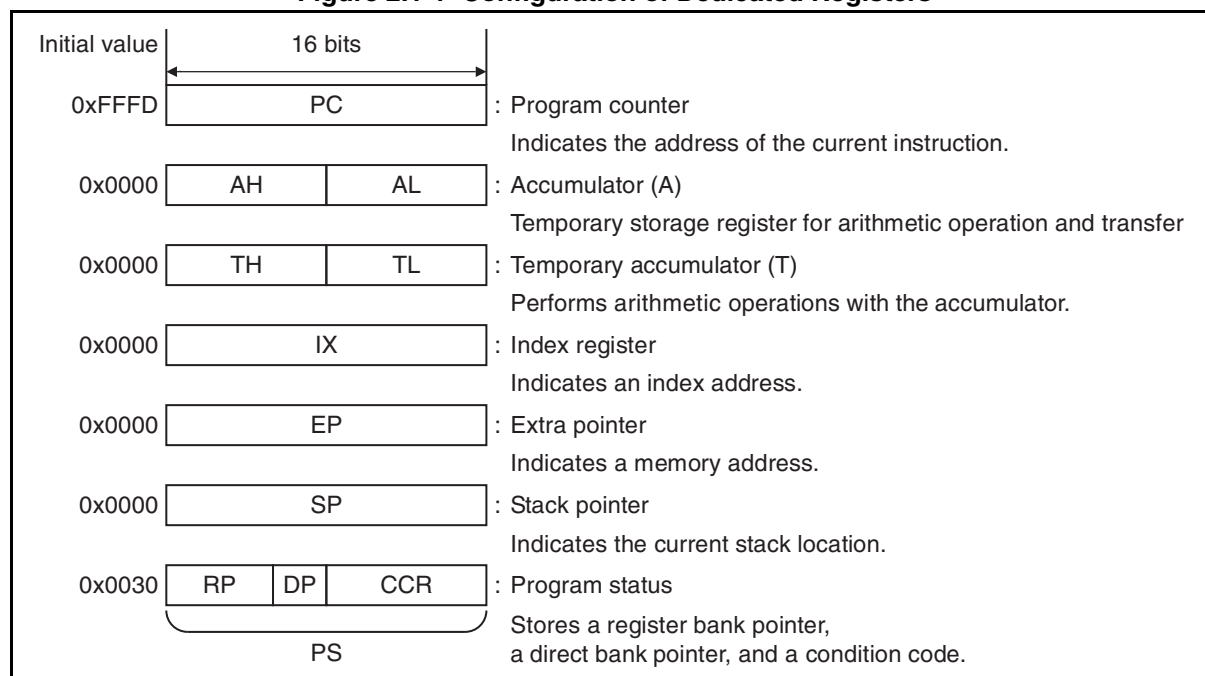

The CPU has dedicated registers: a program counter (PC), two registers for arithmetic operations (A and T), three address pointers (IX, EP, and SP), and the program status (PS) register. Each of the registers is 16 bits long. The PS register consists of the register bank pointer (RP), direct bank pointer (DP), and condition code register (CCR).

■ Configuration of Dedicated Registers

The dedicated registers in the CPU consist of seven 16-bit registers. As for the accumulator (A) and the temporary accumulator (T), using only the lower eight bits of the respective registers is also supported.

Figure 2.1-1 shows the configuration of the dedicated registers.

Figure 2.1-1 Configuration of Dedicated Registers

■ Functions of Dedicated Registers

● Program counter (PC)

The program counter is a 16-bit counter which contains the memory address of the instruction currently executed by the CPU. The program counter is updated whenever an instruction is executed or an interrupt or a reset occurs. The initial value set immediately after a reset is the mode data read address (0xFFFFD).

● Accumulator (A)

The accumulator is a 16-bit register for arithmetic operation. It is used for a variety of arithmetic and transfer operations of data in memory or data in other registers such as the temporary accumulator (T). The data in the accumulator can be handled either as word (16-bit) data or byte (8-bit) data. For byte-length arithmetic and transfer operations, only the lower eight bits (AL) of the accumulator are used with the upper eight bits (AH) left unchanged. The initial value set immediately after a reset is "0x0000".

● Temporary accumulator (T)

The temporary accumulator is an auxiliary 16-bit register for arithmetic operation. It is used to perform arithmetic operations with the data in the accumulator (A). The data in the temporary accumulator is handled as word data for word-length (16-bit) operations with the accumulator (A) and as byte data for byte-length (8-bit) operations. For byte-length operations, only the lower eight bits (TL) of the temporary accumulator are used and the upper eight bits (TH) are not used.

When a MOV instruction is used to transfer data to the accumulator (A), the previous contents of the accumulator are automatically transferred to the temporary accumulator. When transferring byte-length data, the upper eight bits (TH) of the temporary accumulator remain unchanged. The initial value after a reset is "0x0000".

● Index register (IX)

The index register is a 16-bit register used to hold the index address. The index register is used with a single-byte offset (-128 to +127). The offset value is added to the index address to generate the memory address for data access. The initial value after a reset is "0x0000".

● Extra pointer (EP)

The extra pointer is a 16-bit register which contains the value indicating the memory address for data access. The initial value after a reset is "0x0000".

● Stack pointer (SP)

The stack pointer is a 16-bit register which holds the address referenced when an interrupt or a sub-routine call occurs and by the stack push and pop instructions. During program execution, the value of the stack pointer indicates the address of the most recent data pushed onto the stack. The initial value after a reset is "0x0000".

● Program status (PS)

The program status is a 16-bit control register. The upper eight bits consists of the register bank pointer (RP) and direct bank pointer (DP); the lower eight bits consists of the condition code register (CCR).

In the upper eight bits, the upper five bits consists of the register bank pointer used to contain the address of the general-purpose register bank. The lower three bits consists of the direct bank pointer which locates the area to be accessed at high-speed by direct addressing.

The lower eight bits consists of the condition code register (CCR) which consists of flags that represent the state of the CPU.

The instructions that can access the program status are "MOVW A,PS" and "MOVW PS,A". The register bank pointer (RP) and direct bank pointer (DP) in the program status register can also be read from and written to by accessing the mirror address (0x0078).

Note that the condition code register (CCR) is a part of the program status register and cannot be accessed independently.

Refer to the "F²MC-8FX Programming Manual" for details on using the dedicated registers.

2.1.1 Register Bank Pointer (RP)

The register bank pointer (RP) in bit15 to bit11 of the program status (PS) register contains the address of the general-purpose register bank that is currently in use and is translated into a real address when general-purpose register addressing is used.

■ Configuration of Register Bank Pointer (RP)

Figure 2.1-2 shows the configuration of the register bank pointer.

Figure 2.1-2 Configuration of Register Bank Pointer

The register bank pointer contains the address of the register bank currently in use. The content of the register bank pointer is translated into a real address according to the rule shown in Figure 2.1-3.

Figure 2.1-3 Rule for Translation into Real Addresses in General-purpose Register Area

The register bank pointer specifies the register bank used as general-purpose registers in the RAM area. There are a total of 32 register banks, which are specified by setting a value between 0 and 31 in the upper five bits of the register bank pointer. Each register bank has eight 8-bit general-purpose registers which are selected by the lower three bits of the op-code.

The register bank pointer allows the space from "0x0100" to "0x01FF"(max) to be used as a general-purpose register area. However, certain products have restrictions on the size of the area available for the general-purpose register area. The initial value of the register bank pointer after a reset is "0x0000".

■ Mirror Address for Register Bank and Direct Bank Pointer

Values can be written to the register bank pointer (RP) and the direct bank pointer (DP) by accessing the program status (PS) register with the "MOVW PS,A" instruction; the two pointers can be read by accessing PS with the "MOVW A,PS" instruction. Values can also be directly written to and read from the two pointers by accessing "0x0078", the mirror address of the register bank pointer.

2.1.2 Direct Bank Pointer (DP)

The direct bank pointer (DP) in bit10 to bit8 of the program status (PS) register specifies the area to be accessed by direct addressing.

■ Configuration of Direct Bank Pointer (DP)

Figure 2.1-4 shows the configuration of the direct bank pointer.

Figure 2.1-4 Configuration of Direct Bank Pointer

The area of "0x0000 to 0x007F" and that of "0x0090 to 0x047F" can be accessed by direct addressing. Access to 0x0000 to 0x007F is specified by an operand regardless of the value in the direct bank pointer. Access to 0x0090 to 0x047F is specified by the value of the direct bank pointer and the operand.

Table 2.1-1 shows the relationship between the direct bank pointer (DP) and the access area; Table 2.1-2 lists the direct addressing instructions.

Table 2.1-1 Direct Bank Pointer and Access Area

Direct bank pointer (DP[2:0])	Operand-specified dir	Access area*
0bXXX (It does not affect mapping.)	0x0000 to 0x007F	0x0000 to 0x007F
0b000 (Initial value)	0x0090 to 0x00FF	0x0090 to 0x00FF
0b001	0x0080 to 0x00FF	0x0100 to 0x017F
0b010		0x0180 to 0x01FF
0b011		0x0200 to 0x027F
0b100		0x0280 to 0x02FF
0b101		0x0300 to 0x037F
0b110		0x0380 to 0x03FF
0b111		0x0400 to 0x047F

*: The available access area varies among products. For details, refer to the device data sheet.

2.1.3 Condition Code Register (CCR)

The condition code register (CCR) in the lower eight bits of the program status (PS) register consists of the bits (H, N, Z, V, and C) containing information about the arithmetic result or transfer data and the bits (I, IL1, and IL0) used to control the acceptance of interrupt requests.

■ Configuration of Condition Code Register (CCR)

Figure 2.1-5 Configuration of Condition Code Register (CCR)

The condition code register is a part of the program status (PS) register and therefore cannot be accessed independently.

■ Bits Showing Operation Results

● Half carry flag (H)

This flag is set to "1" when a carry from bit3 to bit4 or a borrow from bit4 to bit3 occurs due to the result of an operation. Otherwise, the flag is set to "0". Do not use this flag for any operation other than addition and subtraction as the flag is intended for decimal-adjusted instructions.

● Negative flag (N)

This flag is set to "1" when the value of the most significant bit is "1" due to the result of an operation, and is set to "0" when the value of the most significant bit is "0".

● Zero flag (Z)

This flag is set to "1" when the result of an operation is "0", and is set to "0" when the result of an operation is a value other than "0".

● Overflow flag (V)

This flag indicates whether the result of an operation has caused an overflow, with the operand used in the operation being regarded as an integer expressed as a complement of two. If an overflow occurs, the overflow flag is set to "1"; otherwise, it is set to "0".

● Carry flag (C)

This flag is set to "1" when a carry from bit7 or a borrow to bit7 occurs due to the result of an operation. Otherwise, the flag is set to "0". When a shift instruction is executed, the flag is set to the shift-out value.

Figure 2.1-6 shows how the carry flag is updated by a shift instruction.

Figure 2.1-6 Carry Flag Updated by Shift Instruction

■ Interrupt Acceptance Control Bits

● Interrupt enable flag (I)

When this flag is set to "1", interrupts are enabled and accepted by the CPU. When this flag is set to "0", interrupts are disabled and rejected by the CPU.

The initial value after a reset is "0".

The SETI and CLRI instructions set and clear the flag to "1" and "0", respectively.

● Interrupt level bits (IL[1:0])

These bits indicate the level of the interrupt currently accepted by the CPU.

The interrupt level is compared with the value of the interrupt level setting register (ILR0 to ILR5) that corresponds to the interrupt request (IRQ00 to IRQ23) of each peripheral function.

The CPU services an interrupt request only when its interrupt level is smaller than the value of these bits with the interrupt enable flag set (CCR:I = 1). Table 2.1-3 lists interrupt level priorities. The initial value after a reset is "0b11".

Table 2.1-3 Interrupt Levels

IL1	IL0	Interrupt level	Priority
0	0	0	High
0	1	1	<div style="text-align: center;"> ↑↓ Low (No interrupt) </div>
1	0	2	
1	1	3	

The interrupt level bits (IL[1:0]) are usually "0b11" when the CPU does not service an interrupt (with the main program running).

For details of interrupts, see "5.1 Interrupts".

2.2 General-purpose Register

The general-purpose registers are a memory block in which each bank consists of eight 8-bit registers. Up to 32 register banks can be used in total. The register bank pointer (RP) is used to specify a register bank.

Register banks are useful for interrupt handling, vector call processing, and sub-routine calls.

■ Configuration of General-purpose Register

- The general-purpose register is an 8-bit register and is located in a register bank in the general-purpose register area (in RAM).
- Up to 32 banks can be used, each of which consists of eight registers (R0 to R7).
- The register bank pointer (RP) specifies the register bank currently being used and the lower three bits of the op-code specify the general-purpose register 0 (R0) to the general-purpose register 7 (R7).

Figure 2.2-1 shows the configuration of the register banks.

Figure 2.2-1 Configuration of Register Banks

For information on the general-purpose register area available on each product, see "■ AREAS FOR SPECIFIC APPLICATIONS" in the device data sheet.

■ Features of General-purpose Registers

The general-purpose register has the following features.

- High-speed access to RAM with short instructions (general-purpose register addressing).
- Grouping registers into a block of register banks facilitates data protection and division of registers in terms of functions.

A general-purpose register bank can be allocated exclusively to an interrupt service routine or a vector call (CALLV #0 to #7) service routine. For instance, the fourth register bank is always assigned to the second interrupt.

Data of a general-purpose register before an interrupt can be saved to a dedicated register bank by just specifying that register bank at the beginning of an interrupt service routine. This therefore eliminates the need to save data of a general-purpose register in a stack, thereby enabling the CPU to receive interrupts at high speed.

Note:

In an interrupt service routine, include one of the following in a program to ensure that values of the interrupt level bits (CCR:IL[1:0]) of the condition code register are not modified when modifying a register bank pointer (RP) to specify a register bank.

- Read the interrupt level bits and save their values before writing a value to the RP.
 - Directly write a new value to the RP mirror address "0x0078" to update the RP.
 - As for a product whose RAM size is 256 bytes, the area available for general-purpose registers is from "0x0100" to "0x018F", which is half of that of the product whose RAM size is 512 bytes or above. Therefore, when using a program development tool such as a C compiler to set a general-purpose register area, ensure that the area used as a general-purpose register area does not exceed the size of RAM installed.
-

2.3 Placement of 16-bit Data in Memory

This section describes how 16-bit data is stored in memory.

■ Placement of 16-bit Data in Memory

● State of 16-bit data stored in RAM

When 16-bit data is written to memory, the upper byte of the data is stored at a smaller address and the lower byte is stored at the next address. When 16-bit data is read, it is handled in the same way.

Figure 2.3-1 shows how 16-bit data is placed in memory.

Figure 2.3-1 Placement of 16-bit Data in Memory

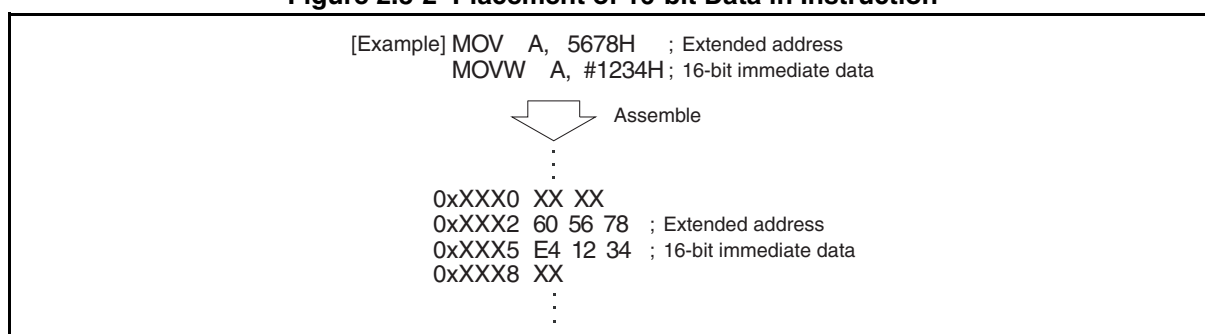

● Storage state of 16-bit data specified by an operand

Even when the operand in an instruction specifies 16-bit data, the upper byte is stored at the address closer to the op-code (instruction) and the lower byte is stored at the address next to the one at which the upper byte is stored.

That is true whether an operand is either a memory address or 16-bit immediate data.

Figure 2.3-2 shows how 16-bit data in an instruction is placed.

Figure 2.3-2 Placement of 16-bit Data in Instruction

● Storage state of 16-bit data in the stack

When 16-bit register data is saved in a stack on an interrupt, the upper byte is stored at a lower address in the same way as 16-bit data specified by an operand.

CHAPTER 3

CLOCK CONTROLLER

This chapter describes the functions and operations of the clock controller.

- 3.1 Overview
- 3.2 Oscillation Stabilization Wait Time
- 3.3 Registers
- 3.4 Clock Modes
- 3.5 Operations in Low Power Consumption Mode (Standby Mode)
- 3.6 Clock Oscillator Circuit
- 3.7 Overview of Prescaler
- 3.8 Configuration of Prescaler
- 3.9 Operation of Prescaler
- 3.10 Notes on Using Prescaler

3.1 Overview

The New 8FX family has a built-in clock controller that optimizes its power consumption. It supports both of the external main clock and the external subclock.

The clock controller enables/disables clock oscillation, enables/disables the supply of clock signals to the internal circuit, selects the clock source, and controls the PLL, the internal CR oscillator and frequency divider circuits.

■ Overview of Clock Controller

The clock controller enables/disables clock oscillation, enables/disables clock supply to the internal circuit, selects the clock source, and controls the PLL, the internal CR oscillator and frequency divider circuits.

The clock controller controls the internal clock according to the clock mode, standby mode settings and the reset operation. The clock mode is used to select an internal operating clock; the standby mode is used to enable or disable clock oscillation and signal supply.

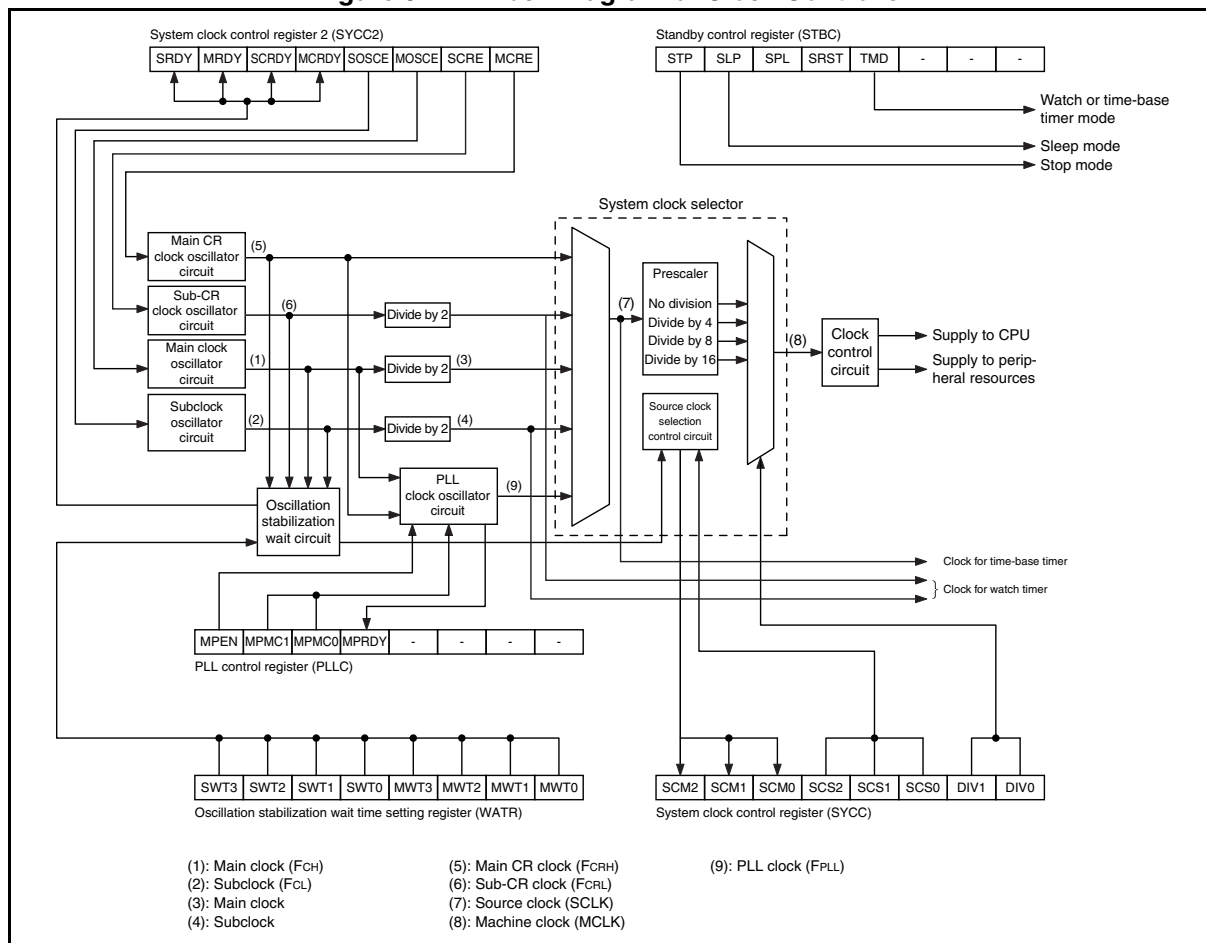

The clock controller selects the optimum power consumption and functions depending on the combination of clock mode and standby mode.

This device has six source clocks: a main clock formed by dividing the main oscillation clock by two, a main PLL clock formed by multiplying the main oscillation clock by the PLL multiplication rate, a subclock formed by dividing the suboscillation clock by two, a main CR clock, a main CR PLL clock formed by multiplying the main CR oscillation clock by the PLL multiplication rate, and a sub-CR clock formed by dividing the sub-CR oscillation clock by two.

■ Block Diagram of Clock Controller

Figure 3.1-1 is the block diagram of the clock controller.

Figure 3.1-1 Block Diagram of Clock Controller

■ Configuration of Clock Controller

- Main clock oscillator circuit

This block is the oscillator circuit for the main clock.

- Subclock oscillator circuit

This block is the oscillator circuit for the subclock.

- Main CR clock oscillator circuit

This block is the oscillator circuit for the main CR clock.

- PLL clock oscillator circuit

This block is the oscillator circuit for the PLL clock. The PLL source clock can be selected from the main clock and the main CR clock.

- Sub-CR clock oscillator circuit

This block is the oscillator circuit for the sub-CR clock.

- System clock selector

This block selects a clock according to the clock mode used from the following five types of source clock: main clock, subclock, main CR clock, PLL clock and sub-CR clock. The source clock selected is divided by the prescaler. The divided clock is called "machine clock", which is to be supplied to the clock control circuit.

- Clock control circuit

This block controls the supply of the machine clock to the CPU and each peripheral function according to the standby mode used or oscillation stabilization wait time.

- Oscillation stabilization wait circuit

This block outputs oscillation stabilization wait time signals according to clocks that are enabled to operate.

In the case of main clock, its oscillation stabilization signal can be selected from 14 types of oscillation stabilization signals created by a dedicated timer in the oscillation stabilization wait circuit. In case of subclock, its oscillation stabilization signal can be selected from 15 types of oscillation stabilization signals created by the same dedicated timer.

- System clock control register (SYCC)

This register selects a clock mode and a machine clock divide ratio, and indicates the current clock mode.

- PLL control register (PLLC)

This register controls the PLL clock multiplication rate settings.

- Standby control register (STBC)

This register controls the transition from RUN state to standby mode, the setting of pin states in stop mode, time-base timer mode, or watch mode, and the generation of software resets.

- System clock control register 2 (SYCC2)

This register enables or disables the oscillations of the main clock, main CR clock, subclock, and sub-CR clock, and displays the ready signals of main clock oscillation, main CR clock oscillation, subclock oscillation and sub-CR clock oscillation.

- Oscillation stabilization wait time setting register (WATR)

This register sets the oscillation stabilization wait times for the main clock and subclock.

■ Clock Modes

There are six clock modes:

- Main clock mode
- Main PLL clock mode
- Main CR clock mode
- Main CR PLL clock mode
- Subclock mode
- Sub-CR clock mode.

Table 3.1-1 shows the relationships between the clock modes and the machine clock (operating clock for the CPU and peripheral functions).

Table 3.1-1 Clock Modes and Machine Clock Selection

Clock mode	Machine clock
Main clock mode	The machine clock is generated by dividing the main clock by two.
Main PLL clock mode	The machine clock is generated by multiplying the main clock by a PLL multiplication rate.
Main CR clock mode	The machine clock is generated from the main CR clock.
Main CR PLL clock mode	The machine clock is generated by multiplying the main CR clock by a PLL multiplication rate.
Subclock mode	The machine clock is generated by dividing the subclock by two.
Sub-CR clock mode	The machine clock is generated by dividing the sub-CR clock by two.

In any clock mode, the frequency of a selected clock can be divided.

■ Standby Mode

The clock controller selects whether to enable or disable clock oscillation and clock supply to the internal circuitry according to the standby mode selected. With the exception of time-base timer mode and watch mode, the standby mode can be set independently of the clock mode.

Table 3.1-2 shows the relationships between standby modes and clock supply states.

Table 3.1-2 Standby Mode and Clock Supply States

Standby mode	Clock supply state
Sleep mode	Clock supply to the CPU is stopped. As a result, the CPU stops operating, but other peripheral functions continue operating.
Time-base timer mode	Clock signals are only supplied to the time-base timer and the watch prescaler, while the clock supply to other circuits is stopped. As a result, all the functions other than the time-base timer, watch prescaler, external interrupt, and low-voltage detection reset (option) are stopped. The time-base timer mode can be used in main clock mode, main PLL clock mode, main CR clock mode and main CR PLL clock mode.
Watch mode	Main clock oscillation or main PLL clock oscillation is stopped. Clock signals are supplied only to the watch prescaler, while clock supply to other circuits is stopped. As a result, all the functions other than the watch prescaler, external interrupt, and low-voltage detection reset (option) are stopped. The watch mode is the standby mode that can be used in subclock mode and sub-CR clock mode.
Stop mode	Main clock oscillation or main PLL clock oscillation, and subclock oscillation are stopped, and clock supply to all circuits is stopped. As a result, all the functions other than external interrupt and low-voltage detection reset (option) are stopped.

Note:

Clocks that are not mentioned in Table 3.1-2 are supplied under particular settings.

For example, with either main clock mode or main PLL clock being used in stop mode, when SYCC2:SOSCE or SYCC2:SCRE has been set to "1", the watch prescaler continues its operation.

In addition, with the hardware watchdog timer already started, the watchdog timer operates also in standby mode, depending on the settings of the non-volatile register (NVR) interface. For details of the non-volatile register (NVR) interface, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

■ Combinations of Clock Mode and Standby Mode

Table 3.1-3 and Table 3.1-4 list the combinations of clock mode and standby mode, and the respective operating states of different internal circuits with different combinations of clock mode and standby mode.

Table 3.1-3 Combinations of Standby Mode and Clock Mode, and Internal Operating States (1)

Function	RUN				Sleep			
	Main clock mode/ Main PLL clock mode	Main CR clock mode/ Main CR PLL clock mode	Subclock mode	Sub-CR clock mode	Main clock mode/ Main PLL clock mode	Main CR clock mode/ Main CR PLL clock mode	Subclock mode	Sub-CR clock mode

*4: The module runs when the sub-CR clock oscillation enable bit in the system clock control register 2 (SYCC2:SCRE) is set to "1".

*5: The hardware watchdog timer stops when the hardware watchdog timer is disabled by the non-volatile register (NVR) interface.

3.2 Oscillation Stabilization Wait Time

The oscillation stabilization wait time is the time after the oscillator circuit stops oscillation until the oscillator resumes its stable oscillation at its natural frequency. The clock controller obtains the oscillation stabilization wait time after the start of oscillation by counting a specific number of oscillation clock cycles. During the oscillation stabilization wait time, the clock controller stops clock supply to internal circuits.

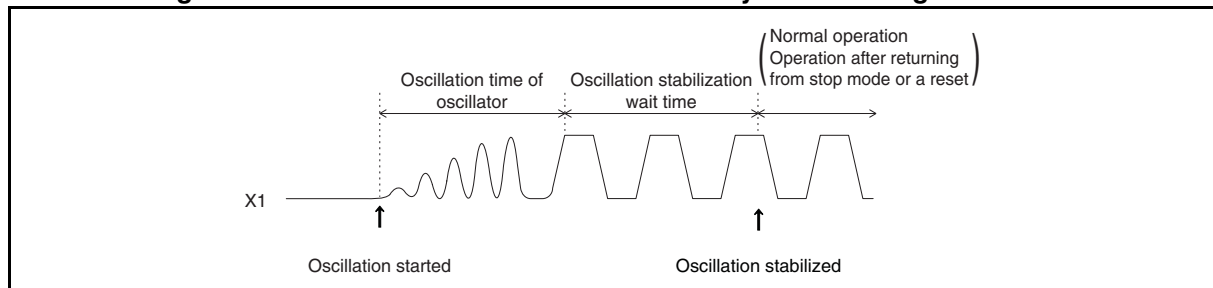

■ Oscillation Stabilization Wait Time

The clock controller obtains the oscillation stabilization wait time after the start of oscillation by counting a specific number of oscillation clock cycles. During the oscillation stabilization wait time, the clock controller stops clock supply to internal circuits.

When the power is switched on, or when a state transition request making the oscillator start from the oscillation stop state is generated due to a change of clock mode caused by a reset, by an interrupt in stop mode or by the software operation, before making the clock mode transit to another mode, the clock controller automatically waits for the oscillation stabilization wait time of the clock for that mode to elapse.

Figure 3.2-1 shows how the oscillator runs immediately after starting oscillating.

Figure 3.2-1 Behavior of Oscillator Immediately after Starting Oscillation

Oscillation stabilization wait time of main clock, subclock, main CR clock, PLL clock or sub-CR clock is counted by using a dedicated counter. The count value can be set in the oscillation stabilization wait time setting register (WATR). Set it in keeping with the oscillator characteristics.

When a power-on reset occurs, the oscillation stabilization wait time is fixed at the initial value.

Table 3.2-1 shows the length of oscillation stabilization wait time.

Table 3.2-1 Oscillation Stabilization Wait Time

Clock	Reset source	Oscillation stabilization wait time
Main clock	Power-on reset	Initial value: $(2^{14}-2)/F_{CH}$ (F_{CH} : main clock frequency)
	Other than power-on reset	Register settings (WATR:MWT[3:0])
Subclock	Power-on reset	Initial value: $(2^{15}-2)/F_{CL}$ (F_{CL} : subclock frequency)
	Other than power-on reset	Register settings (WATR:SWT[3:0])

■ PLL Clock Oscillation Stabilization Wait Time

As with the oscillation stabilization wait time of the oscillator, when a request for state transition from PLL oscillation stopped state to PLL oscillation start is generated due to an interrupt in stop mode or a change of clock mode by software, the clock controller first waits for the main clock oscillation stabilization wait time or the main CR clock oscillation stabilization wait time to elapse, and then automatically waits for the PLL clock oscillation stabilization wait time to elapse.

Table 3.2-2 shows the PLL oscillation stabilization wait time.

Table 3.2-2 PLL Oscillation Stabilization Wait Time

	PLL oscillation stabilization wait time
Main PLL clock	$2^{12}/F_{PLL}^*$
Main CR PLL clock	

*: $F_{PLL} = 16 \text{ MHz}$

■ CR Clock Oscillation Stabilization Wait Time

As with the oscillation stabilization wait time of the oscillator, when a state transition request making CR oscillation start from the CR oscillation stop state is generated due to a change of clock mode caused by an interrupt in standby mode or by the software operation, the clock controller automatically waits for the CR oscillation stabilization wait time to elapse.

Table 3.2-3 shows the CR oscillation stabilization wait time.

Table 3.2-3 CR Oscillation Stabilization Wait Time

	CR oscillation stabilization wait time
Main CR clock	$2^{10}/F_{CRH}^{*1}$
Sub-CR clock	$2^5/F_{CRL}^{*2}$

*1: $F_{CRH} = 4 \text{ MHz}$

*2: $F_{CRL} = 150 \text{ kHz}$

■ Oscillation Stabilization Wait Time and Clock Mode/Standby Mode Transition

If state transition occurs, the clock controller automatically waits for the oscillation stabilization wait time to elapse whenever necessary. Depending on the circumstances under which state transition occurs, the clock controller does not wait for the oscillation stabilization wait time to elapse even if state transition occurs.

For details on state transition, see "3.4 Clock Modes" and "3.5 Operations in Low Power Consumption Mode (Standby Mode)".

■ Order of Priority for Oscillation Stabilization Wait Times

When multiple clocks are enabled simultaneously, the clock controller counts the respective oscillation stabilization wait times of clocks according to a designated order of priority. Below are the respective orders of priority for counting different oscillation stabilization wait times in different clock modes.

- Main clock mode
Sub-CR clock > Subclock > Main PLL clock > Main CR clock > Main CR PLL clock
- Main PLL clock mode
Sub-CR clock > Subclock > Main CR clock
- Main CR clock mode
Sub-CR clock > Subclock > Main CR PLL clock > Main clock > Main PLL clock
- Main CR PLL clock mode
Sub-CR clock > Subclock > Main clock
- Subclock mode
Sub-CR clock > Main CR clock or main clock > Main CR PLL clock or main PLL clock
- Sub-CR clock mode
Main CR clock or main clock > Subclock > Main CR PLL clock or main PLL clock

Note:

Switching the clock mode from main CR PLL clock mode directly to main PLL clock mode and vice versa is prohibited. To switch the clock mode from main CR PLL clock mode to main PLL clock mode or vice versa, transit to another clock mode other than main PLL clock mode and main CR PLL clock mode once before entering main PLL clock mode or main CR PLL clock mode.

3.3 Registers

This section provides details of registers of the clock controller.

Table 3.3-1 List of Clock Controller Registers

Register abbreviation	Register name	Reference
SYCC	System clock control register	3.3.1
PLLC	PLL control register	3.3.2
WATR	Oscillation stabilization wait time setting register	3.3.3
STBC	Standby control register	3.3.4
SYCC2	System clock control register 2	3.3.5

3.3.1 System Clock Control Register (SYCC)

The system clock control register (SYCC) selects a machine clock divide ratio and a clock mode, and indicates the current clock mode.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SCM2	SCM1	SCM0	SCS2	SCS1	SCS0	DIV1	DIV0
Attribute	R	R	R	R/W	R/W	R/W	R/W	R/W
Initial value	X	X	X	1	1	0	1	1

■ Register Functions

[bit7:5] SCM[2:0]: Clock mode monitor bits

These bits indicate the current clock mode.

These bits are read-only bits. Writing values to these bits has no effect on operation.

bit7:5	Details
Reading "000"	Indicates that the current clock mode is subclock mode.
Reading "010"	Indicates that the current clock mode is main clock mode.
Reading "011"	Indicates that the current clock mode is main PLL clock mode.
Reading "100"	Indicates that the current clock mode is sub-CR clock mode.
Reading "110"	Indicates that the current clock mode is main CR clock mode.
Reading "111"	Indicates that the current clock mode is main CR PLL clock mode.

[bit4:2] SCS[2:0]: Clock mode select bits

These bits select a clock mode.

bit4:2	Details
Writing "000"	Selects subclock mode.
Writing "010"	Selects main clock mode.
Writing "011"	Selects main PLL clock mode.
Writing "100"	Selects sub-CR clock mode.
Writing "110"	Selects main CR clock mode.
Writing "111"	Selects main CR PLL clock mode.

Notes:

- Do not write to SCS[2:0] any value other than those listed in the table above.
- Switching the clock mode from main CR PLL clock mode directly to main PLL clock mode and vice versa is prohibited. To switch the clock mode from main CR PLL clock mode to main PLL clock mode or vice versa, enter another clock mode other than main PLL clock mode and main CR PLL clock mode once before entering main PLL clock mode or main CR PLL clock mode.

[bit1:0] DIV[1:0]: Machine clock divide ratio select bits

These bits select the machine clock divide ratio for the source clock.

The machine clock is generated from the source clock according to the divide ratio set by these bits.

bit1:0	Details
Writing "00"	Source clock (no division)
Writing "01"	Source clock/4
Writing "10"	Source clock/8
Writing "11"	Source clock/16

3.3.2 PLL Control Register (PLLC)

The PLL control register (PLLC) controls the PLL clock multiplication rate settings.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	MPEN	MPMC1	MPMC0	MPRDY	—	—	—	—
Attribute	R/W	R/W	R/W	R	—	—	—	—
Initial value	0	0	0	X	0	0	0	0

Register Functions

[bit7] MPEN: PLL clock enable bit

This bit enables or disables the PLL clock.

When SCS[2:0] are set to "0b011" or "0b111", this bit is automatically set to "1".

When SCS[2:0] or SCM[2:0] are set to "0b011" or "0b111", writing "0" to this bit has no effect on operation.

This bit is automatically set to "0" when the clock mode transits from one mode to another mode except main PLL clock mode and main CR PLL clock mode.

When the current clock mode is subclock mode or sub-CR clock mode, writing "1" to this bit has no effect on operation.

bit7	Details
Writing "0"	Disables the PLL clock.
Writing "1"	Enables the PLL clock.

[bit6:5] MPMC[1:0]: PLL clock multiplication rate select bits

These bits select a PLL clock multiplication rate.

The settings of these bits can be modified only when the PLL clock is stopped. Thus these bits can be modified in main clock mode, main CR clock mode, subclock mode or sub-CR clock mode.

bit6:5	Details
Writing "00"	Main clock \times 2 or main CR clock \times 2
Writing "01"	Main clock \times 2.5 or main CR clock \times 2.5
Writing "10"	Main clock \times 3 or main CR clock \times 3
Writing "11"	Main clock \times 4 or main CR clock \times 4

Note: When SCS[2:0] or SCM[2:0] are set to "0b011" or "0b111", writing values to MPMC[1:0] is prohibited.

[bit4] MPRDY: PLL clock oscillation stabilization bit

This bit indicates whether the PLL clock oscillation is ready.

bit4	Details
Reading "0"	Indicates that the PLL clock is in the oscillation stabilization wait state or that the PLL clock oscillation has stopped.
Reading "1"	Indicates that the PLL clock oscillation wait time is over.

[bit3:0] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

3.3.3 Oscillation Stabilization Wait Time Setting Register (WATR)

The oscillation stabilization wait time setting register (WATR) selects oscillation stabilization wait times.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SWT3	SWT2	SWT1	SWT0	MWT3	MWT2	MWT1	MWT0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

■ Register Functions

[bit7:4] SWT[3:0]: Subclock oscillation stabilization wait time select bits

These bits select the subclock oscillation stabilization wait time.

bit7:4	Details		
	No. of cycles	Subclock (F_{CL}) = 32.768 kHz	
Writing "1111"	$2^{15} - 2$	$(2^{15}-2)/F_{CL}$	About 1.0 s
Writing "1110"	$2^{14} - 2$	$(2^{14}-2)/F_{CL}$	About 0.5 s
Writing "1101"	$2^{13} - 2$	$(2^{13}-2)/F_{CL}$	About 0.25 s
Writing "1100"	$2^{12} - 2$	$(2^{12}-2)/F_{CL}$	About 0.125 s
Writing "1011"	$2^{11} - 2$	$(2^{11}-2)/F_{CL}$	About 62.44 ms
Writing "1010"	$2^{10} - 2$	$(2^{10}-2)/F_{CL}$	About 31.19 ms
Writing "1001"	$2^9 - 2$	$(2^9-2)/F_{CL}$	About 15.56 ms
Writing "1000"	$2^8 - 2$	$(2^8-2)/F_{CL}$	About 7.75 ms
Writing "0111"	$2^7 - 2$	$(2^7-2)/F_{CL}$	About 3.85 ms
Writing "0110"	$2^6 - 2$	$(2^6-2)/F_{CL}$	About 1.89 ms
Writing "0101"	$2^5 - 2$	$(2^5-2)/F_{CL}$	About 915.5 μ s
Writing "0100"	$2^4 - 2$	$(2^4-2)/F_{CL}$	About 427.2 μ s
Writing "0011"	$2^3 - 2$	$(2^3-2)/F_{CL}$	About 183.1 μ s
Writing "0010"	$2^2 - 2$	$(2^2-2)/F_{CL}$	About 61.0 μ s
Writing "0001"	$2^1 - 2$	$(2^1-2)/F_{CL}$	0.0 μ s
Writing "0000"	$2^1 - 2$	$(2^1-2)/F_{CL}$	0.0 μ s

The number of cycles in the above table is the minimum value. The maximum value is the number of cycles in the above table plus $1/F_{CL}$.

Note: Do not modify these bits during subclock oscillation stabilization wait time. Modify them when the subclock oscillation stabilization bit in the system clock control register 2 (SYCC2:SRDY) has been set to "1". These bits can be modified when the subclock is stopped with the subclock oscillation stop bit in the system clock control register 2 (SYCC2:SOSCE) set to "0" in main clock mode, main PLL clock mode, main CR clock mode, main CR PLL clock mode, or sub-CR clock mode.

[bit3:0] MWT[3:0]: Main clock oscillation stabilization wait time select bits

These bits select the main clock oscillation stabilization wait time.

bit3:0	Details		
	No. of cycles	Main clock (F_{CH}) = 4 MHz	
Writing "1111"	$2^{14} - 2$	$(2^{14} - 2)/F_{CH}$	About 4.10 ms
Writing "1110"	$2^{13} - 2$	$(2^{13} - 2)/F_{CH}$	About 2.05 ms
Writing "1101"	$2^{12} - 2$	$(2^{12} - 2)/F_{CH}$	About 1.02 ms
Writing "1100"	$2^{11} - 2$	$(2^{11} - 2)/F_{CH}$	About 511.5 μ s
Writing "1011"	$2^{10} - 2$	$(2^{10} - 2)/F_{CH}$	About 255.5 μ s
Writing "1010"	$2^9 - 2$	$(2^9 - 2)/F_{CH}$	About 127.5 μ s
Writing "1001"	$2^8 - 2$	$(2^8 - 2)/F_{CH}$	About 63.5 μ s
Writing "1000"	$2^7 - 2$	$(2^7 - 2)/F_{CH}$	About 31.5 μ s
Writing "0111"	$2^6 - 2$	$(2^6 - 2)/F_{CH}$	About 15.5 μ s
Writing "0110"	$2^5 - 2$	$(2^5 - 2)/F_{CH}$	About 7.5 μ s
Writing "0101"	$2^4 - 2$	$(2^4 - 2)/F_{CH}$	About 3.5 μ s
Writing "0100"	$2^3 - 2$	$(2^3 - 2)/F_{CH}$	About 1.5 μ s
Writing "0011"	$2^2 - 2$	$(2^2 - 2)/F_{CH}$	About 0.5 μ s
Writing "0010"	$2^1 - 2$	$(2^1 - 2)/F_{CH}$	0.0 μ s
Writing "0001"	$2^1 - 2$	$(2^1 - 2)/F_{CH}$	0.0 μ s
Writing "0000"	$2^1 - 2$	$(2^1 - 2)/F_{CH}$	0.0 μ s

The number of cycles in the above table is the minimum value. The maximum value is the number of cycles in the above table plus $1/F_{CH}$.

Note: Do not modify these bits during main clock oscillation stabilization wait time. Modify them when the main clock oscillation stabilization bit in the system clock control register 2 (SYCC2:MRDY) has been set to "1". These bits can be modified when the main clock is stopped with the main clock oscillation stop bit in the system clock control register 2 (SYCC2:MOSCE) set to "0" in main CR clock mode, main CR PLL clock mode, subclock mode, or sub-CR clock mode.

3.3.4 Standby Control Register (STBC)

The standby control register (STBC) controls transition from the RUN state to sleep mode, stop mode, time-base timer mode, or watch mode, sets the pin state in stop mode, time-base timer mode, and watch mode, and controls the generation of software resets.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	STP	SLP	SPL	SRST	TMD	—	—	—
Attribute	W	W	R/W	W	W	—	—	—
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] STP: Stop bit

This bit sets the transition to stop mode.

The read value of this bit is always "0".

bit7	Details
Writing "0"	Has no effect on operation.
Writing "1"	Causes the device to transit to stop mode.

Note: After an interrupt request is generated, writing "1" to this bit is ignored. For details, see "3.5.1 Notes on Using Standby Mode".

[bit6] SLP: Sleep bit

This bit sets the transition to sleep mode.

The read value of this bit is always "0".

bit6	Details
Writing "0"	Has no effect on operation.
Writing "1"	Causes the device to transit to sleep mode.

Note: After an interrupt request is generated, writing "1" to this bit is ignored. For details, see "3.5.1 Notes on Using Standby Mode".

[bit5] SPL: Pin state setting bit

This bit sets the states of external pins in stop mode, time-base timer mode, and watch mode.

bit5	Details
Writing "0"	The state (level) of an external pin in stop mode, time-base timer mode and watch mode is kept.
Writing "1"	An external pin becomes high impedance in stop mode, time-base timer mode and watch mode. (A pin for which connection to a pull-up resistor has been selected in the pull-up register is pulled up.)

[bit4] SRST: Software reset bit

This bit sets the software reset.

The read value of this bit is always "0".

bit4	Details
Writing "0"	Has no effect on operation.
Writing "1"	Generates a 3-machine clock reset signal.

[bit3] TMD: Watch bit

This bit sets transition to time-base timer mode or watch mode.

Writing "1" to this bit in main clock mode, main PLL clock mode, main CR clock mode, or main CR PLL clock mode causes the device to transit to time-base timer mode.

Writing "1" to this bit in subclock mode or sub-CR clock mode causes the device to transit to watch mode.

Writing "0" to this bit has no effect on operation.

The read value of this bit is always "0".

bit3	Details	
	In main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode	In subclock mode or sub-CR clock mode
Writing "0"	Has no effect on operation.	Has no effect on operation.
Writing "1"	Causes the device to transit to time-base timer mode.	Causes the device to transit to watch mode

Note: After an interrupt request is generated, writing "1" to this bit is ignored. For details, see "3.5.1 Notes on Using Standby Mode".

[bit2:0] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

Notes:

- Set a standby mode after making sure that the transition to clock mode has been completed by comparing the values of the clock mode monitor bits (SYCC:SCM[2:0]) and clock mode select bits (SYCC:SCS[2:0]) in the system clock control register.
- If two or more of the following bits, stop bit (STP), sleep bit (SLP), software reset bit (SRST) and watch bit (TMD), are set to "1" together, the order of priority for such bits is as follows:
 - Software reset bit (SRST)
 - Stop bit (STP)
 - Watch bit (TMD)
 - Sleep bit (SLP)

When released from standby mode, the device returns to the normal operating state.

3.3.5 System Clock Control Register 2 (SYCC2)

The system clock control register 2 (SYCC2) indicates the respective stabilization conditions of main clock oscillation, subclock oscillation, main CR clock oscillation and sub-CR clock oscillation, and controls main clock oscillation, subclock oscillation, main CR clock oscillation and sub-CR clock oscillation.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SRDY	MRDY	SCRDY	MCRDY	SOSCE	MOSCE	SCRE	MCRE
Attribute	R	R	R	R	R/W	R/W	R/W	R/W
Initial value	X	X	X	X	0	0	1	1

Register Functions

[bit7] SRDY: Subclock oscillation stabilization bit

This bit indicates whether the subclock oscillation has become stable.

This bit is read-only. Writing a value to this bit has no effect on operation.

bit7	Details
Reading "0"	Indicates that the clock controller is in the subclock oscillation stabilization wait state or that the subclock oscillation has stopped.
Reading "1"	Indicates that the subclock oscillation wait time is over.

[bit6] MRDY: Main clock oscillation stabilization bit

This bit indicates whether the main clock oscillation has become stable.

This bit is read-only. Writing a value to this bit has no effect on operation.

bit6	Details
Reading "0"	Indicates that the clock controller is in the main clock oscillation stabilization wait state or that the main clock oscillation has stopped.
Reading "1"	Indicates that the main clock oscillation wait time is over.

[bit5] SCRDY: Sub-CR clock oscillation stabilization bit

This bit indicates whether the sub-CR clock oscillation has become stable.

This bit is read-only. Writing a value to this bit has no effect on operation.

bit5	Details
Reading "0"	Indicates that the clock controller is in the sub-CR clock oscillation stabilization wait state or that the sub-CR clock oscillation has stopped.
Reading "1"	Indicates that the sub-CR clock oscillation wait time is over.

[bit4] MCRDY: Main CR clock oscillation stabilization bit

This bit indicates whether the main CR clock oscillation has become stable.

This bit is read-only. Writing a value to this bit has no effect on operation.

bit4	Details
Reading "0"	Indicates that the clock controller is in the main CR clock oscillation stabilization wait state or that the main CR clock oscillation has stopped.
Reading "1"	Indicates that the main CR clock oscillation wait time is over.

[bit3] SOSCE: Subclock oscillation enable bit

This bit enables or disables the subclock oscillation.

When SCS[2:0] are set to "0b000", this bit is automatically set to "1".

When SCS[2:0] or SCM[2:0] are set to "0b000", writing "0" to this bit has no effect on operation.

bit3	Details
Writing "0"	Disables the subclock oscillation.
Writing "1"	Enables the subclock oscillation.

[bit2] MOSCE: Main clock oscillation enable bit

This bit enables or disables the main clock oscillation.

When SCS[2:0] are set to "0b010" or "0b011", this bit is automatically set to "1".

When SCS[2:0] or SCM[2:0] are set to "0b010" or "0b011", writing "0" to this bit has no effect on operation.

This bit is automatically set to "0" when the clock mode is changed from one mode to another mode other than main clock mode.

When the current clock mode is subclock mode or sub-CR clock mode, writing "1" to this bit has no effect on operation.

bit2	Details
Writing "0"	Disables the main clock oscillation.
Writing "1"	Enables the main clock oscillation.

[bit1] SCRE: Sub-CR clock oscillation enable bit

This bit enables or disables the sub-CR clock oscillation.

When SCS[2:0] are set to "0b100", this bit is automatically set to "1".

When SCS[2:0] or SCM[2:0] are set to "0b100", writing "0" to this bit has no effect on operation.

When SCS[2:0] and SCM[2:0] are not set to "0b100", this bit can be modified independently of other bits.

bit1	Details
Writing "0"	Disables the sub-CR clock oscillation.
Writing "1"	Enables the sub-CR clock oscillation.

[bit0] MCRE: Main CR clock oscillation enable bit

This bit enables or disables the main CR clock oscillation.

When SCS[2:0] are set to "0b110" or "0b111", this bit is automatically set to "1".

When SCS[2:0] or SCM[2:0] are set to "0b110" or "0b111", writing "0" to this bit has no effect on operation.

This bit is automatically set to "0" when the clock mode is changed from one mode to another mode except main CR clock mode or from main CR PLL clock mode.

When the current clock mode is subclock mode or sub-CR clock mode, writing "1" to this bit has no effect on operation.

bit0	Details
Writing "0"	Disables the main CR clock oscillation.
Writing "1"	Enables the main CR clock oscillation.

3.4 Clock Modes

There are six clock modes: main clock mode, main PLL clock mode, subclock mode, main CR clock mode, main CR PLL clock mode, and sub-CR clock mode. The clock mode switches according to the settings in the system clock control register (SYCC).

■ Operations in Main Clock Mode and Main PLL Clock Mode

In main clock mode, the main clock is used as the machine clock for the CPU and peripheral functions. In main PLL clock mode, the main PLL clock is used as the machine clock for the CPU and peripheral functions.

The time-base timer operates using the main clock in main clock mode or using the main PLL clock in main PLL clock mode.

The watch prescaler operates using the subclock or the sub-CR clock.

While the device is operating in main clock mode or main PLL clock mode, it can be set to transit to one of the following standby mode: sleep mode, stop mode, or time-base timer mode.

After a reset, the device always enters main CR clock mode regardless of the clock mode used before that reset.

■ Operations in Subclock Mode

In subclock mode, main clock oscillation or main PLL clock oscillation is stopped* and the subclock is used as the machine clock for the CPU and peripheral functions. In this mode, the time-base timer stops as it requires the main clock for operation in main clock mode and the main PLL clock for operation in main PLL clock mode.

While the device is operating in subclock mode, it can be set to transit to one of the following standby mode: sleep mode, stop mode, or watch mode.

■ Operations in Main CR Clock Mode and Main CR PLL Clock Mode

In main CR clock mode, the main CR clock is used as the machine clock for the CPU and peripheral functions. In main CR PLL clock mode, the main CR PLL clock is used as the machine clock for the CPU and peripheral functions. The time-base timer and the watchdog timer operate using the main CR clock in main CR clock mode and the main CR PLL clock in main CR PLL clock mode.

The watch prescaler operates using the subclock or the sub-CR clock.

While the device is operating in main CR clock mode or the main CR PLL clock mode, it can be set to transit to one of the following standby mode: sleep mode, stop mode, or time-base timer mode.

■ Operations in Sub-CR Clock Mode

In sub-CR clock mode, main clock oscillation or main PLL clock oscillation is stopped* and the sub-CR clock is used as the machine clock for the CPU and peripheral functions. In this mode, the time-base timer stops as it requires the main clock for operation. The watch prescaler operates using the sub-CR clock.

While the device is operating in sub-CR clock mode, it can be set to transit to one of the following standby mode: sleep mode, stop mode, or watch mode.

*: The oscillation of the main clock, main CR clock, or PLL clock is automatically disabled (writing "0" to SYCC2:MOSCE, SYCC2:MCRE or PLLC:MPEN respectively) when the clock mode transits from main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode to subclock mode or sub-CR clock mode. In subclock mode or sub-CR clock mode, writing "1" to SYCC2:MOSCE, SYCC2:MCRE or PLLC:MPEN cannot enable the main clock, the main CR clock, or the PLL clock respectively.

There are six clock modes: main clock mode, main PLL clock mode, subclock mode, main CR clock mode, main CR PLL clock mode and sub-CR clock mode. The device can switch between these modes according to the settings in the system clock control register (SYCC).

The flowchart illustrates the sequence of events and transitions between various clock modes (Main CR clock mode, Main clock mode, Sub-CR clock mode, Subclock mode) and their associated PLL modes (Main CR PLL clock mode, Main PLL clock mode). Transitions are labeled with numbers (1) through (24). Key events include 'Power on', 'Reset state', and 'A reset occurs in any other state'. The flowchart shows the progression from power-on to the Main CR clock mode, then to the Main clock mode (or main PLL clock mode), and finally to the Sub-CR clock mode and Subclock mode. It also details the transitions between the Main CR PLL clock mode and Main PLL clock mode, and the Sub-CR clock mode and Subclock mode, including the associated oscillation stabilization wait times.

Table 3.4-1 Clock Mode State Transition Table (1 / 2)

	Current State	Next State	Description
<1>	Reset state	Main CR clock	After a reset, the device waits for the main CR clock oscillation stabilization wait time and the sub-CR clock oscillation stabilization wait time to elapse and transits to main CR clock mode. Even if that reset is a watchdog reset, software reset or external reset caused in any clock mode, the device waits for the sub-CR clock oscillation stabilization wait time and the main CR clock oscillation stabilization wait time to elapse.
(1)	Main CR clock/ Main CR PLL clock	Sub-CR clock	The device transits to sub-CR clock mode when the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b100". However, when the sub-CR has been stopped according to the setting of the sub-CR clock oscillation enable bit in the system clock control register 2 (SYCC2:SCRE), the device waits for the sub-CR clock oscillation stabilization wait time to elapse before transiting to sub-CR clock mode. In other words, when the sub-CR clock oscillation is enabled in advance, and the sub-CR clock oscillation stabilization bit in the system clock control register 2 (SYCC2:SCRDY) is "1", the device transits to sub-CR clock mode immediately after the clock mode select bits (SYCC:SCS[2:0]) are set to "0b100".
(2)			
(3)		Subclock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b000", the device transits to subclock mode after waiting for the subclock oscillation stabilization wait time. When the subclock oscillation is enabled by the setting of the subclock oscillation enable bit in the system clock control register 2 (SYCC2:SOSCE), and the subclock oscillation stabilization bit in the system clock control register 2 (SYCC2:SRDY) is "1", the device transits to subclock mode immediately after the clock mode select bits (SYCC:SCS[2:0]) are set to "0b000".
(4)			
(5)		Main clock/ Main PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b010", the device transits to main clock mode after waiting for the main clock oscillation stabilization wait time. When the main clock oscillation is enabled by the setting of the main clock oscillation enable bit in the system clock control register 2 (SYCC2:MOSCE), and the main clock oscillation stabilization bit in the system clock control register 2 (SYCC2:MRDY) is "1", the device transits to main clock mode immediately after the clock mode select bits (SYCC:SCS[2:0]) are set to "0b010".
(6)			When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b011", the device transits to main PLL clock mode after waiting for the main PLL clock oscillation stabilization wait time. Switching the clock mode from main CR PLL clock mode directly to main PLL clock mode is prohibited. To switch the clock mode from main CR PLL clock mode to main PLL clock mode, transit to another clock mode other than main PLL clock mode and main CR PLL clock mode once before entering main PLL clock mode.

Table 3.4-1 Clock Mode State Transition Table (2 / 2)

	Current State	Next State	Description
(7)	Main clock/ Main PLL clock	Main CR clock/ Main CR PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b110", the device transits to main CR clock mode after waiting for the main CR clock oscillation stabilization wait time. When the main CR clock oscillation is enabled by the setting of the main CR clock oscillation enable bit in the system clock control register 2 (SYCC2:MCRE), and the main CR clock oscillation stabilization bit in the system clock control register 2 (SYCC2:MCRDY) is "1", the device transits to main CR clock mode immediately after the clock mode select bits (SYCC:SCS[2:0]) are set to "0b110".
(8)			When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b111", the device transits to main CR PLL clock mode after waiting for the main CR PLL clock oscillation stabilization wait time. Switching the clock mode from main PLL clock mode directly to main CR PLL clock mode is prohibited. To switch the clock mode from main PLL clock mode to main CR PLL clock mode, transit to another clock mode other than main PLL clock mode and main CR PLL clock mode once before entering main CR PLL clock mode.
(9)			
(10)			Sub-CR clock
(11)			Same as (1) and (2)
(12)			Subclock
			Same as (3) and (4)
(13)	Sub-CR clock	Main CR clock/ Main CR PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b110", the device transits to main CR clock mode after waiting for the main CR clock oscillation stabilization wait time. When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b111", the device transits to main CR PLL clock mode after waiting for the main CR PLL clock oscillation stabilization wait time.
(14)		Main clock/ Main PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b010", the device transits to main clock mode after waiting for the main clock oscillation stabilization wait time. When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b011", the device transits to main PLL clock mode after waiting for the main PLL clock oscillation stabilization wait time.
(15)		Subclock	Same as (3) and (4)
(16)			
(17)	Subclock	Main CR clock/ Main CR PLL clock	Same as (13)
(18)		Main clock/ main PLL clock	Same as (14)
(19)		Sub-CR clock	Same as (1) and (2)
(20)			
(21)	Main CR clock	Main CR PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b111", the device transits to main CR PLL clock mode after waiting for the PLL clock oscillation stabilization wait time.
(22)	Main CR PLL clock	Main CR clock	Immediately after clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b110", the device transits to main CR clock mode.
(23)	Main clock	Main PLL clock	When the clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b011", the device transits to main PLL clock mode after waiting for the main PLL clock oscillation stabilization wait time.
(24)	Main PLL clock	Main clock	Immediately after clock mode select bits in the system clock control register (SYCC:SCS[2:0]) are set to "0b010", the device transits to main clock mode.

3.5 Operations in Low Power Consumption Mode (Standby Mode)

There are four standby modes: sleep mode, stop mode, time-base timer mode and watch mode.

■ Overview of Transiting to and Returning from Standby Mode

There are four standby modes: sleep mode, stop mode, time-base timer mode, and watch mode. The device transits to standby mode according to the settings in the standby control register (STBC).

The device is released from standby mode by an interrupt or a reset. Before transiting to normal operation, the device may wait for the oscillation stabilization wait time to elapse if necessary.

When the clock mode returns from standby mode due to a reset, the device returns to main CR clock mode. When the clock mode returns from standby mode due to an interrupt, the device returns to the previous clock mode before transiting to standby mode.

■ Pin States in Standby Mode

The pin state setting bit (STBC:SPL) of the standby control register can be used to keep the preceding state of an I/O port or a peripheral function pin before its transition to stop mode, time-base timer mode or watch mode, and to set an I/O port or a peripheral function pin to high impedance in stop mode, time-base timer mode or watch mode.

Refer to the device data sheet for the states of all pins in standby mode.

3.5.1 Notes on Using Standby Mode

Even if the standby control register (STBC) sets standby mode, transition to standby mode does not occur when an interrupt request has been generated from a peripheral function. When the device returns from standby mode to the normal operating state in response to an interrupt, the operation that follows varies depending on whether the interrupt request is accepted or not.

■ Insert at least three NOP instructions immediately after a standby mode setting instruction.

The device requires four machine clock cycles before entering standby mode after it is set in the standby control register. During that period, the CPU executes the program. To avoid program execution during this transition to standby mode, insert at least three NOP instructions.

The device still runs normally even if instructions other than NOP instructions are inserted after the instruction that sets the device to transit to standby mode. On this occasion, the following two events may occur. Firstly, an instruction that should be executed after the standby mode is released may be executed before the device transits to standby mode. Secondly, the device may transit to standby mode while an instruction is being executed, and the execution of that same instruction is resumed after the device is released from standby mode (increasing the number of instruction execution cycles).

■ Check that clock mode transition has been completed before setting the standby mode.

Before setting the standby mode, ensure that clock-mode transition has been completed by comparing the values of the clock mode monitor bits (SYCC:SCM[2:0]) and clock mode select bits (SYCC:SCS[2:0]) in the system clock control register.

■ An interrupt request may suppress the transition to standby mode.

When the standby mode is set with an interrupt request whose interrupt level is higher than "0b11" having been issued, the device ignores the value written to the standby control register and continues executing instructions without transiting to the standby mode set. Even after the interrupt of that interrupt request is processed, the device does not transit to the standby mode set.

The same operations are executed when interrupts are disabled by the interrupt enable flag (CCR:I) and the interrupt level bits (CCR:IL[1:0]) of the condition code register of the CPU.

■ The standby mode is also released when the CPU rejects interrupts.

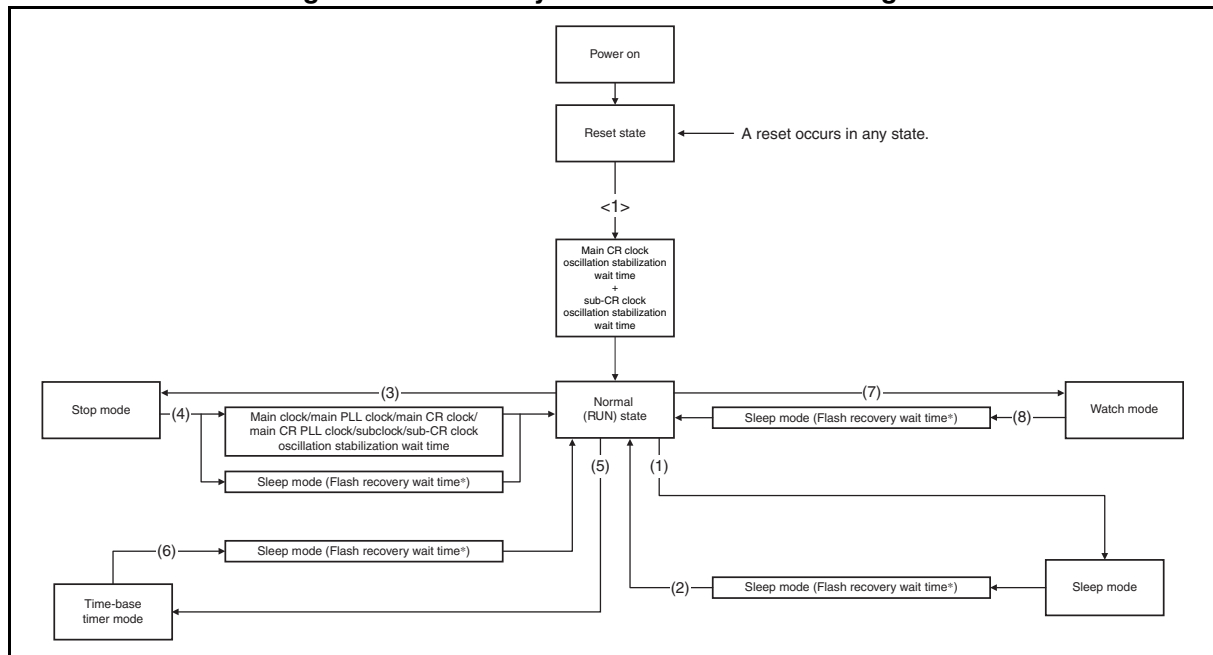

When an interrupt request whose interrupt level is higher than "0b11" is issued in standby mode, the device is released from standby mode, regardless of the settings of the interrupt enable flag (CCR:I) and the interrupt level bits (CCR:IL[1:0]) of the condition code register (CCR) of the CPU.

After being released from standby mode, the device processes interrupts if interrupts are to be accepted according to the settings of the condition code register (CCR) of the CPU. If interrupts are not to be accepted according to the settings of CCR, the device resumes instruction execution from the instruction following the one executed before the device transits to standby mode.

■ Standby Mode State Transition Diagram

Figure 3.5-1 shows a standby mode state transition diagram.

Figure 3.5-1 Standby Mode State Transition Diagram

*: Flash memory recovery wait time (SCLK: source clock, MCLK: machine clock)

- In main clock mode, main PLL clock mode, main CR clock mode, or main CR PLL clock mode
Maximum: $10 \text{ SCLK} + 150 \mu\text{s} + 6 \text{ MCLK}$
- In subclock mode or sub-CR clock mode
Maximum: $2 \text{ SCLK} + 150 \mu\text{s} + 6 \text{ MCLK}$

Table 3.5-1 Table of State Transition (Transition to and from Standby Mode)

	State transition	Description
<1>	Normal operation after reset state	After a reset, the device transits to main CR clock mode. If the reset that has occurred is a power-on reset, a watchdog reset, a software reset, or an external reset, the device always wait for the main CR clock oscillation stabilization wait time and the sub-CR clock oscillation stabilization wait time to elapse.
(1)	Sleep mode	The device transits to sleep mode when "1" is written to the sleep bit in the standby control register (STBC:SLP).
(2)		In response to an interrupt from a peripheral function, after the Flash recovery wait time elapses, the device returns to the RUN state. During the Flash recovery wait time, the device transits to sleep mode. (The CPU stops its operation; the peripheral function resumes its operation.) However, if a program is being executed on the RAM, no Flash recovery wait time occurs.
(3)	Stop mode	The device transits to stop mode when "1" is written to the stop bit in the standby control register (STBC:STP).
(4)		In response to an external interrupt, after the oscillation stabilization wait time required according to the current clock mode and the Flash recovery wait time elapse, the device returns to the RUN state. When the oscillation stabilization wait time is shorter than the Flash recovery wait time, after the oscillation stabilization wait time elapses, the device transits to sleep mode and remains in sleep mode until the Flash recovery wait time elapses. When the oscillation stabilization wait time is longer than the Flash recovery wait time, after the oscillation stabilization wait time elapses, the device returns to the RUN state. However, if a program is being executed on the RAM, no Flash recovery wait time occurs.
(5)	Time-base timer mode	The device transits to time-base timer mode when "1" is written to the watch bit in the standby control register (STBC:TMD) in main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode.
(6)		In response to an interrupt from a peripheral function, after the Flash recovery wait time elapses, the device returns to the RUN state. During the Flash recovery wait time, the device transits to sleep mode. (The CPU stops its operation; the peripheral function resumes its operation.) However, if a program is being executed on the RAM, no Flash recovery wait time occurs.
(7)	Watch mode	The device transits to watch mode when "1" is written to the watch bit in the standby control register (STBC:TMD) in subclock mode or sub-CR clock mode.
(8)		In response to an interrupt from a peripheral function, after the Flash recovery wait time elapses, the device returns to the RUN state. During the Flash recovery wait time, the device transits to sleep mode. (The CPU stops its operation; the peripheral function resumes its operation.) However, if a program is being executed on the RAM, no Flash recovery wait time occurs.

3.5.2 Sleep Mode

In sleep mode, the operations of the CPU and watchdog timer are stopped.

■ Operations in Sleep Mode

In sleep mode, the CPU and the operating clock for the watchdog timer are stopped. The CPU retains the contents of registers and RAM existing at the point immediately before the device transits to sleep mode and stops; however, all peripheral functions except the watchdog timer continue their operations.

In the case of hardware watchdog timer, if it is enabled in standby mode by the non-volatile register function, in sleep mode, the sub-CR clock does not stop and the hardware watchdog timer continues its operation. For details, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

● Transition to sleep mode

Writing "1" to the sleep bit in the standby control register (STBC:SLP) causes the device to enter sleep mode.

● Release from sleep mode

A reset or an interrupt from a peripheral function releases the device from sleep mode.

Even after a reset occurs or an interrupt is generated by a peripheral function, the device continues operating in sleep mode until the Flash recovery wait time elapses.

However, if a program is being executed on the RAM, no Flash recovery wait time occurs.

For details of the Flash recovery wait time, see Figure 3.5-1.

3.5.3 Stop Mode

In stop mode, the main clock, the main PLL clock, the main CR clock, the main CR PLL clock and the subclock are stopped.

■ Operations in Stop Mode

In stop mode, the main clock, the main PLL clock, the main CR clock, the main CR PLL clock and the subclock are stopped. In this mode, while retaining the contents of registers and RAM existing at the point immediately before the device transits to stop mode, the device stops all functions except external interrupt and low-voltage detection reset.

As for hardware watchdog timer, if it is enabled in standby mode by the non-volatile register function, in stop mode, the sub-CR clock does not stop and the hardware watchdog timer continues its operation. For details, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

● Transition to stop mode

Writing "1" to the stop bit in the standby control register (STBC:STP) causes the device to transit to stop mode. At that point, if the pin state setting bit in the standby control register (STBC:SPL) is "0", the states of the external pins are kept; if the SPL bit is "1", the states of the external pins become high impedance (a pin is pulled up if the pull-up resistor connection for that pin is selected in the pull-up register).

● Release from stop mode

The device is released from stop mode by a reset or an external interrupt. In any clock mode, if the hardware watchdog timer is enabled in standby mode by the non-volatile register function, the sub-CR clock does not stop, and the watchdog timer and the watch prescaler operate in stop mode. The device can also be released from stop mode by an interrupt from the watch prescaler. For details, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

After a reset occurs or an interrupt is generated by a peripheral function, the device executes different operations, depending on the relation between the oscillation stabilization wait time and the Flash recovery wait time as explained below.

- When the oscillation stabilization wait time is shorter than the Flash recovery wait time
After the oscillation stabilization wait time elapses, the device transits to sleep mode and remains in sleep mode until the Flash recovery wait time elapses.
- When the oscillation stabilization wait time is longer than the Flash recovery wait time
After the oscillation stabilization wait time elapses, the device returns to the RUN state.

However, if a program is being executed on the RAM, no Flash recovery wait time occurs.

For details of the Flash recovery wait time, see Figure 3.5-1.

Note:

If the device is released from stop mode by an interrupt, a peripheral function having transited to stop mode during operation resumes operating from the point at which it transited to stop mode. Therefore, some settings of that peripheral function, such as the initial interval time of the interval timer, become undefined. Initialize that peripheral function if necessary after releasing the device from stop mode.

3.5.4 Time-base Timer Mode

In time-base timer mode, only the main clock oscillator, the main PLL clock oscillator, the subclock oscillator, the time-base timer, and the watch prescaler operate. The CPU and the operating clock for peripheral functions are stopped in this mode.

■ Operations in Time-base Timer Mode

The time-base timer mode is a mode in which main clock supply and main PLL clock is stopped except the clock supply to the time-base timer. In this mode, while retaining the contents of registers and RAM existing at the point immediately before the device transits to time-base timer mode, the device stops all functions except the time-base timer, external interrupt and low-voltage detection reset.

Subclock oscillation and sub-CR clock oscillation can be enabled or disabled by the subclock oscillation enable bit and the sub-CR clock oscillation enable bit in the system clock control register 2 (SYCC2:SOSCE, SCRE) respectively. If the subclock oscillates, the watch prescaler continues its operation.

In the case of hardware watchdog timer, if it is enabled in standby mode by the non-volatile register function, in time-base timer mode, the sub-CR clock does not stop and the hardware watchdog timer continues its operation. For details, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

● Transition to time-base timer mode

If the clock mode monitor bits in the system clock control register (SYCC:SCM[2:0]) are "0b010", "0b011", "0b110", or "0b111", writing "1" to the watch bit in the standby control register (STBC:TMD) causes the device to transit to time-base timer mode.

The device can transit to time-base timer mode only when the clock mode is main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode.

After the device transits to time-base timer mode, if the pin state setting bit in the standby control register (STBC:SPL) is "0", the states of the external pins are kept; if the SPL bit is "1", the states of the external pins become high impedance (a pin is pulled up if the pull-up resistor connection for that pin is selected in the pull-up register).

● Release from time-base timer mode

The device is released from time-base timer mode by a reset, a time-base timer interrupt, or an external interrupt.

Subclock oscillation and sub-CR clock oscillation can be enabled or disabled by setting the subclock oscillation enable bit (SOSCE) and the sub-CR clock oscillation enable bit (SCRE) in the system clock control register 2 (SYCC2). When the subclock oscillates, the device can be released from time-base timer mode by an interrupt from the watch prescaler.

Even after a reset occurs or an interrupt is generated by a peripheral function, the device continues operating in sleep mode until the Flash recovery wait time elapses.

However, if a program is being executed on the RAM, no Flash recovery wait time occurs.

For details of the Flash recovery wait time, see Figure 3.5-1.

Note:

If the device is released from time-base timer mode by an interrupt, a peripheral function having transited to time-base timer mode during operation resumes operating from the point at which it transited to time-base timer mode. Therefore, some settings of that peripheral function, such as the initial interval time of the interval timer, become undefined. Initialize that peripheral function if necessary after releasing the device from time-base timer mode.

3.5.5 Watch Mode

In watch mode, only the subclock, the sub-CR clock and the watch prescaler operate. The CPU and the operating clock for peripheral functions are stopped in this mode.

■ Operations in Watch Mode

In watch mode, while retaining the contents of registers and RAM existing at the point immediately before the device transits to watch mode, the device stops all functions except the watch prescaler, external interrupt and low-voltage detection reset.

In the case of hardware watchdog timer, if it is enabled in standby mode by the non-volatile register function, in watch mode, the sub-CR clock does not stop and the hardware watchdog timer continues its operation. For details, see "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE".

● Transition to watch mode

If the clock mode monitor bits in the system clock control register (SYCC:SCM[2:0]) are "0b000" or "0b100", writing "1" to the watch bit in the standby control register (STBC:TMD) causes the device to transit to watch mode.

The device can transit to watch mode only when the clock mode is subclock mode or sub-CR clock mode.

After the device transits to watch mode, if the pin state setting bit in the standby control register (STBC:SPL) is "0", the states of the external pins are kept; if the SPL bit is "1", the states of the external pins become high impedance (a pin is pulled up if the pull-up resistor connection for that pin is selected in the pull-up register).

● Release from watch mode

The device is released from watch mode by a reset, a watch interrupt, or an external interrupt.

Even after a reset occurs or an interrupt is generated by a peripheral function, the device continues operating in sleep mode until the Flash recovery wait time elapses.

However, if a program is being executed on the RAM, no Flash recovery wait time occurs.

For details of the Flash recovery wait time, see Figure 3.5-1.

Note:

If the device is released from watch mode by an interrupt, a peripheral function having transited to watch mode during operation resumes operating from the point at which it transited to watch mode. Therefore, some settings of that peripheral function, such as the initial interval time of the interval timer, become undefined. Initialize that peripheral function if necessary after releasing the device from watch mode.

3.6 Clock Oscillator Circuit

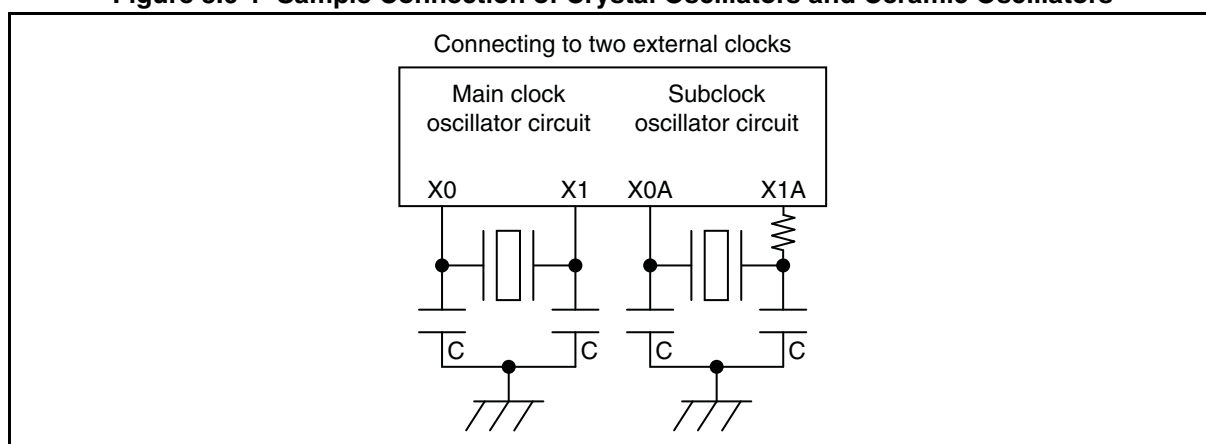

The clock oscillator circuit generates an internal clock with an oscillator connected to the clock oscillation pin or by inputting a clock signal to the clock oscillation pin.

■ Clock Oscillator Circuit

- Using crystal oscillators and ceramic oscillators

Connect crystal oscillators or ceramic oscillators as shown in Figure 3.6-1.

Figure 3.6-1 Sample Connection of Crystal Oscillators and Ceramic Oscillators

- Using external clock

As shown in Figure 3.6-2, to supply clock signals to the main clock from an external clock, connect that external clock to the X0 pin, and write "10" to the PFSEL[1:0] bits in the SYSC register; to supply clock signals to the subclock from an external clock, connect that external clock to the X0A pin, and write "10" to the PGSEL[1:0] bits in the SYSC register. For details of the SYSC register, see "CHAPTER 30 SYSTEM CONFIGURATION CONTROLLER".

Figure 3.6-2 Sample Connection of External Clocks

3.7 Overview of Prescaler

The prescaler generates the count clock source to be supplied to various peripheral functions from the machine clock (MCLK) and the count clock output from the time-base timer.

■ Prescaler

The prescaler generates the count clock source to be supplied to various peripheral functions from the machine clock (MCLK) with which the CPU operates and from the count clock ($F_{CH}/2^7$, $F_{CH}/2^8$, $F_{CRH}/2^6$, $F_{CRH}/2^7$, $F_{PLL}/2^6$, or $F_{PLL}/2^7$) output from the time-base timer. The count clock source is a clock whose frequency is divided by the prescaler or a buffered clock. The peripheral functions listed below use the clock whose frequency is divided by the prescaler as the count clock source.

The prescaler has no control register and always operates with the machine clock (MCLK) and the count clock ($F_{CH}/2^7$, $F_{CH}/2^8$, $F_{CRH}/2^6$, $F_{CRH}/2^7$, $F_{PLL}/2^6$, or $F_{PLL}/2^7$) of the time-base timer.

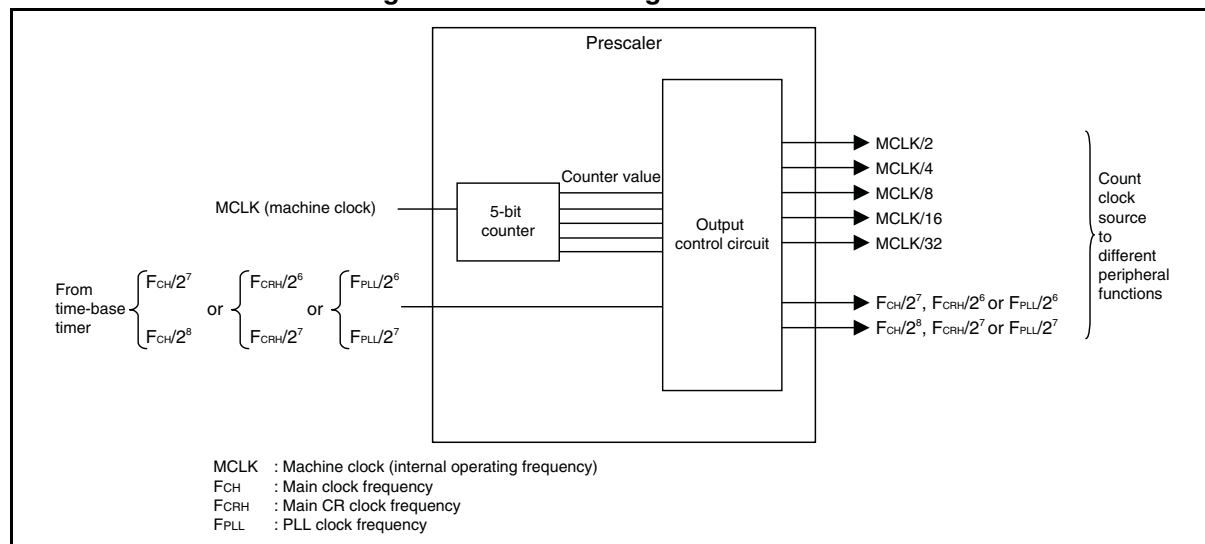

- 8/16-bit composite timer
- 8/12-bit A/D converter
- 8/16-bit PPG
- 16-bit reload timer
- UART/SIO dedicated baud rate generator

3.8 Configuration of Prescaler

Figure 3.8-1 is the block diagram of the prescaler.

■ Block Diagram of Prescaler

Figure 3.8-1 Block Diagram of Prescaler

- 5-bit counter

This counter counts the machine clock (MCLK) and outputs the count value to the output control circuit.

- Output control circuit

Based on the 5-bit counter value, this circuit supplies clocks generated by dividing the machine clock (MCLK) by 2, 4, 8, 16, or 32 to individual peripheral functions. The circuit also buffers the clock from the time-base timer ($F_{CH}/2^7$, $F_{CH}/2^8$, $F_{CRH}/2^6$, $F_{CRH}/2^7$, $F_{PLL}/2^6$, or $F_{PLL}/2^7$) and supplies it to peripheral functions.

■ Input Clock

The prescaler uses the machine clock, or the output clock of the time-base timer as the input clock.

■ Output Clock

The prescaler supplies clocks to the following peripheral functions:

- 8/16-bit composite timer
- 8/12-bit A/D converter
- 8/16-bit PPG
- 16-bit reload timer
- UART/SIO dedicated baud rate generator

3.9 Operation of Prescaler

The prescaler generates count clock sources to different peripheral functions.

■ Operation of Prescaler

The prescaler generates count clock sources from a clock whose frequency is generated by dividing the machine clock (MCLK), or from buffered signals from the time-base timer ($F_{CH}/2^7$, $F_{CH}/2^8$, $F_{CRH}/2^6$, $F_{CRH}/2^7$, $F_{PLL}/2^6$, or $F_{PLL}/2^7$), and then supplies them to different peripheral functions. The prescaler keeps operating while the machine clock and the clocks from the time-base timer are being supplied.

Table 3.9-1, Table 3.9-2 and Table 3.9-3 list the count clock sources generated by the prescaler.

Table 3.9-1 Count Clock Sources Generated by Prescaler (F_{CH})

Count clock source frequency	Frequency ($F_{CH} = 20$ MHz, MCLK = 10 MHz)	Frequency ($F_{CH} = 32$ MHz, MCLK = 16 MHz)	Frequency ($F_{CH} = 32.5$ MHz, MCLK = 16.25 MHz)
MCLK/2	5 MHz	8 MHz	8.125 MHz
MCLK/4	2.5 MHz	4 MHz	4.0625 MHz
MCLK/8	1.25 MHz	2 MHz	2.0313 MHz
MCLK/16	0.625 MHz	1 MHz	1.0156 MHz
MCLK/32	0.3125 MHz	0.5 MHz	0.5078 MHz
$F_{CH}/2^7$	156.25 kHz	250 kHz	253.9 kHz
$F_{CH}/2^8$	78.125 kHz	125 kHz	126.95 kHz

Table 3.9-2 Count Clock Sources Generated by Prescaler (F_{CRH})

Count clock source frequency	Frequency ($F_{CRH} = 4$ MHz, MCLK = 4 MHz)
MCLK/2	2 MHz
MCLK/4	1 MHz
MCLK/8	0.5 MHz
MCLK/16	0.25 MHz
MCLK/32	125 kHz
$F_{CRH}/2^6$	62.5 kHz
$F_{CRH}/2^7$	31.25 kHz

Table 3.9-3 Count Clock Sources Generated by Prescaler (F_{PLL})

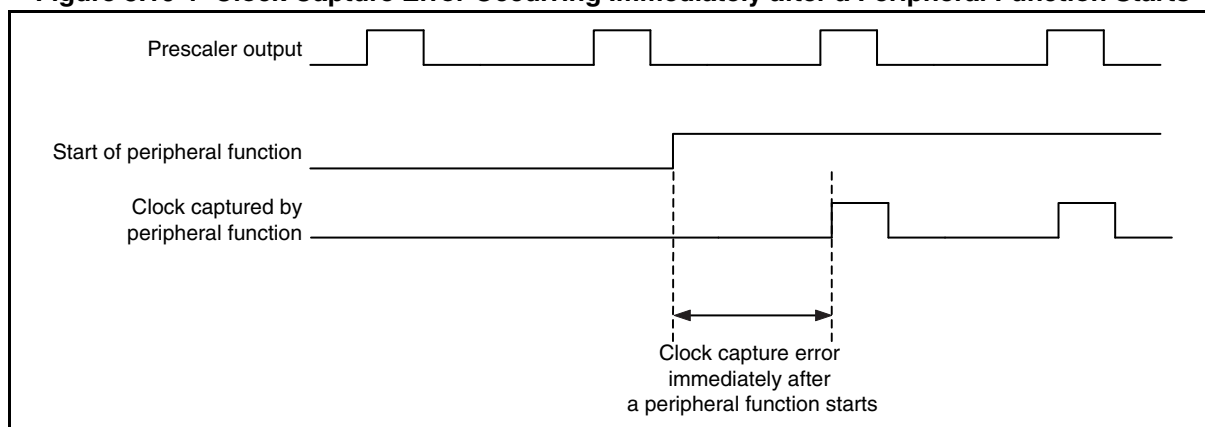

Count clock source frequency	Frequency ($F_{PLL} = 8\text{ MHz}$, $MCLK = 8\text{ MHz}$)	Frequency ($F_{PLL} = 10\text{ MHz}$, $MCLK = 10\text{ MHz}$)	Frequency ($F_{PLL} = 12\text{ MHz}$, $MCLK = 12\text{ MHz}$)	Frequency ($F_{PLL} = 16\text{ MHz}$, $MCLK = 16\text{ MHz}$)
MCLK/2	4 MHz	5 MHz	6 MHz	8 MHz
MCLK/4	2 MHz	2.5 MHz	3 MHz	4 MHz
MCLK/8	1 MHz	1.25 MHz	1.5 MHz	2 MHz
MCLK/16	0.5 MHz	0.625 MHz	0.75 MHz	1 MHz
MCLK/32	0.25 MHz	0.3125 MHz	0.375 MHz	0.5 MHz
$F_{PLL}/2^6$	125 kHz	156.25 kHz	187.5 kHz	0.25 MHz
$F_{PLL}/2^7$	62.5 kHz	78.125 kHz	93.75 kHz	125 kHz

3.10 Notes on Using Prescaler

This section provides notes on using the prescaler.

The prescaler operates with the machine clock and the clock generated from the time-base timer, and keeps operating while those clocks are being supplied. Therefore, in the operation immediately after a peripheral function is started, an error of up to one cycle of the clock source captured by that peripheral function will occur, depending on the output value of the prescaler.

Figure 3.10-1 Clock Capture Error Occurring Immediately after a Peripheral Function Starts

The prescaler count value affects the following peripheral functions:

- 8/16-bit composite timer
- 8/12-bit A/D converter
- 8/16-bit PPG
- 16-bit reload timer
- UART/SIO dedicated baud rate generator

CHAPTER 4

RESET

This section describes the reset operation.

- 4.1 Reset Operation
- 4.2 Register
- 4.3 Notes on Using Reset

4.1 Reset Operation

When a reset source occurs, the CPU immediately stops the process being executed and enters the reset release wait state. When the reset is released, the CPU reads mode data and the reset vector from the Flash memory (mode fetch). When the power is switched on or when the device is released from a reset in subclock mode, sub-CR clock mode, or stop mode, the CPU performs mode fetch after the oscillation stabilization wait time has elapsed.

■ Reset Sources

There are five reset sources for the reset.

Table 4.1-1 Reset Sources

Reset source	Reset condition
External reset	"L" level is input to the external reset pin.
Software reset	"1" is written to the software reset bit in the standby control register (STBC:SRST).
Watchdog reset	The watchdog timer overflows.
Power-on reset	The power is switched on.
Low-voltage detection reset (optional)	The supply voltage falls below the detection voltage.

● External reset

An external reset is generated if "L" level is input to the external reset pin ($\overline{\text{RST}}$).

An external input reset signal is received asynchronously with the operating clock of the microcontroller via the internal noise filter and then generates an internal reset signal that is synchronized with the machine clock to initialize the internal circuit. Therefore, the operating clock of the microcontroller is necessary for initializing the internal circuit. In order to operate with the external clock, external clock signals must be input. However, the external pins (including I/O ports and peripheral functions) are reset asynchronously. In addition, there is a standard value of the pulse width for external reset input. If the value is below the standard value, a reset signal may not be accepted.

The standard value is shown in the device data sheet. Design an external reset circuit that satisfies the standard value.

● Software reset

Writing "1" to the software reset bit of the standby control register (STBC:SRST) generates a software reset.

● Watchdog reset

After the watchdog timer starts, a watchdog reset is generated if the watchdog timer is not cleared within a predetermined period of time.

● Power-on reset

A power-on reset is generated when the power is switched on.

- Low-voltage detection reset (optional)

The circuit is only available on certain products. Check the availability of the circuit in the device data sheet.

The low-voltage detection reset circuit generates a reset if the power supply voltage falls below a predetermined level.

The logical function of the low-voltage detection reset is equivalent to that of the power-on reset. All information relating to the power-on reset of this hardware manual also applies to the low-voltage detection reset.

However, the LVD control register (LVDC) of the low-voltage detection circuit is not reset by the low-voltage detection reset.

For details of the low-voltage detection reset, see "CHAPTER 16 LOW-VOLTAGE DETECTION CIRCUIT".

■ Reset Time

The reset time varies according to the reset source.

- In the case of software reset, watchdog reset and external reset:

The reset time is affected by the number of machine cycles selected before a reset, the RAM access protection function inhibiting resets during the RAM access, and the sub-CR clock oscillation stabilization wait time. The effective time of the RAM access protection function lengthens according to the number of machine clock cycles selected before a reset.

When a reset occurs with the sub-CR clock oscillation stabilization bit in the system clock control register 2 (SYCC2:SCRDY) set to "1", the device is released from the reset state after the main CR clock oscillation stabilization wait time elapses.

When a reset occurs with the sub-CR clock oscillation stabilization bit in the system clock control register 2 (SYCC2:SCRDY) set to "0", the device is released from the reset state after both sub-CR clock oscillation stabilization wait time and main CR clock oscillation stabilization wait time elapse.

- In the case of power-on reset and low-voltage detection reset:

The device is released from the reset state after both sub-CR clock oscillation stabilization wait time and main CR clock oscillation stabilization wait time elapse.

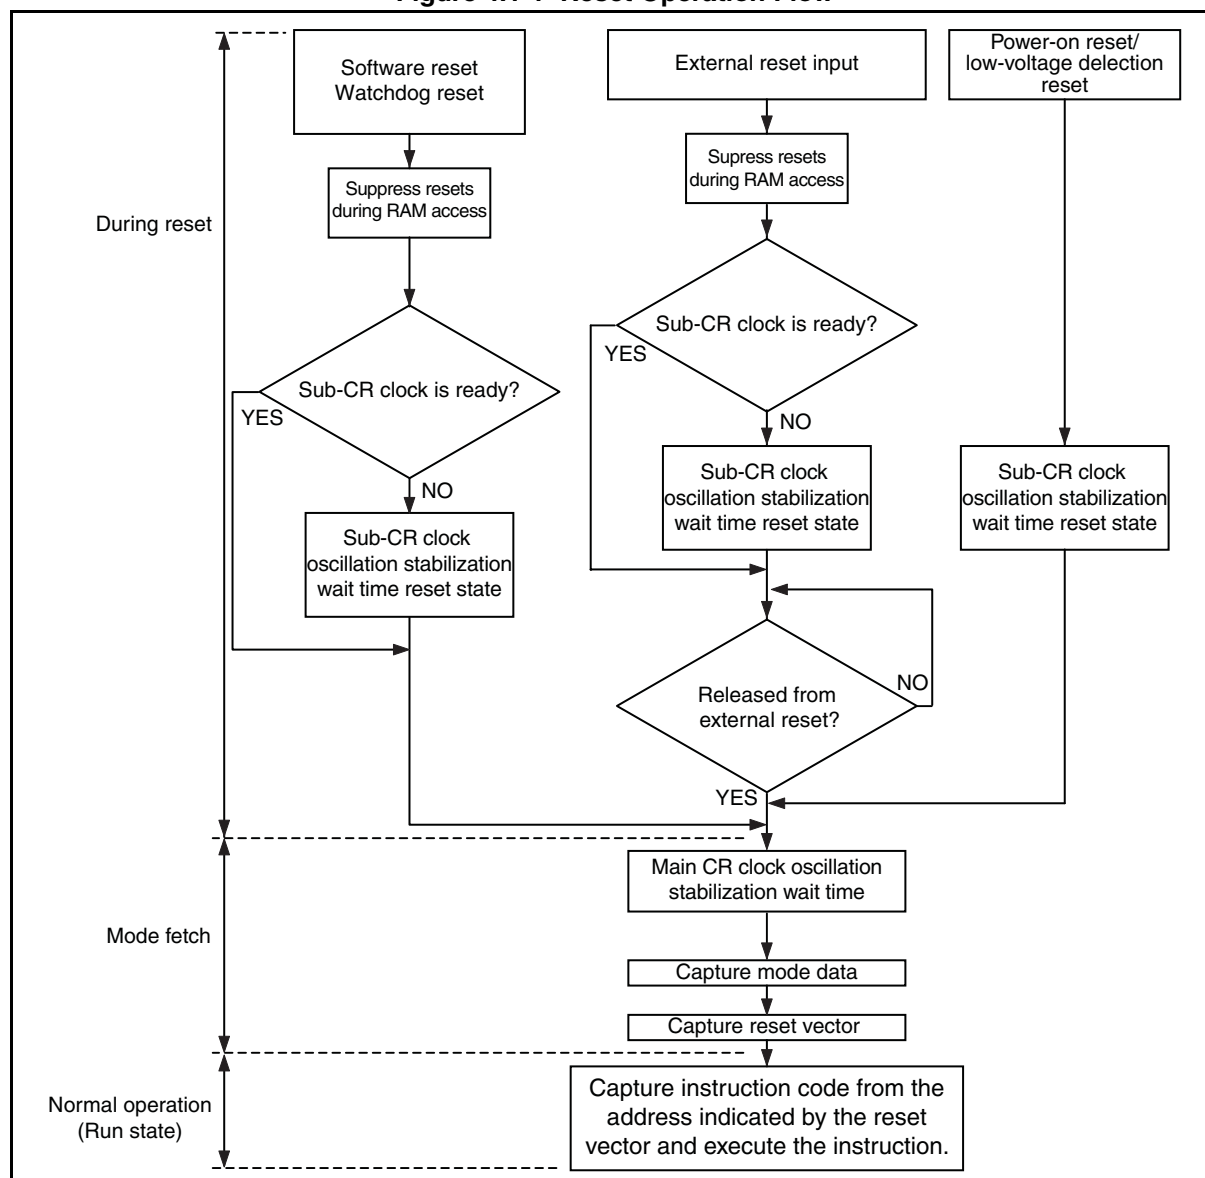

■ Reset Output

When the reset input function is effective and the reset output function is effective, the $\overline{\text{RST}}$ pin outputs "L" level while resetting it. However, the function to output "L" level is not provided for external reset in the reset pin.

For details of the reset input function and the reset output function setting, see "CHAPTER 30 SYSTEM CONFIGURATION CONTROLLER".

■ Overview of Reset Operation

Figure 4.1-1 Reset Operation Flow

In any reset, the CPU performs mode fetch after the main CR clock oscillation stabilization wait time elapses.

■ Effect of Reset on RAM Contents

When a reset occurs, the CPU halts the operation of the command currently being executed, and enters the reset state. However, during RAM access execution, in order to protect the RAM access, an internal reset signal synchronized with the machine clock is generated after an RAM access ends. This function prevents a word-data write operation from being interrupted by a reset while data of two bytes is being written.

■ Pin State During a Reset

When a reset occurs, an I/O port or a peripheral function pin remains high impedance until the setting of that I/O port or that peripheral function pin by software is executed after the reset is released.

Note:

Connect a pull-up resistor to a pin that becomes high impedance during a reset to prevent the device from malfunctioning.

For details of the states of all pins during a reset, refer to the device data sheet.

4.2 Register

This section provides details of the register for reset.

Table 4.2-1 List of Register for Reset

Register abbreviation	Register name	Reference
RSRR	Reset source register	4.2.1

4.2.1 Reset Source Register (RSRR)

The reset source register indicates the source of a reset generated.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	EXTS	WDTR	PONR	HWR	SWR
Attribute	—	—	—	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	X	X	X	X	X

■ Register Functions

[bit7:5] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit4] EXTS: External reset flag bit

When this bit is set to "1", that indicates an external reset has occurred.

When any other reset occurs, this bit retains the value that has existed before such reset occurs.

A read access or a write access (writing "0" or "1") to this bit sets it to "0".

bit4	Details
Read access	Sets this bit to "0".
Being set to "1"	Indicates that the an external reset has occurred.
Write access	Sets this bit to "0".

[bit3] WDTR: Watchdog reset flag bit

When this bit is set to "1", that indicates a watchdog reset has occurred.

When any other reset occurs, this bit retains the value that has existed before such reset occurs.

A read access or a write access (writing "0" or "1") to this bit sets it to "0".

bit3	Details
Read access	Sets this bit to "0".
Being set to "1"	Indicates that the a watchdog reset has occurred.
Write access	Sets this bit to "0".

[bit2] PONR: Power-on reset flag bit

When this bit is set to "1", that indicates a power-on reset or a low-voltage detection reset (optional) has occurred.

When any other reset occurs, this bit retains the value that has existed before such reset occurs

The circuit is only available on certain products. Check the availability of the circuit in the device data sheet.

A read access or a write access (writing "0" or "1") to this bit sets it to "0".

bit2	Details
Read access	Sets this bit to "0".
Being set to "1"	Indicates that the a power-on reset or a low-voltage detection reset (optional) has occurred.
Write access	Sets this bit to "0".

[bit1] HWR: Hardware reset flag bit

When this bit is set to "1", that indicates a hardware reset (power-on reset, low-voltage detection reset (optional), external reset or watchdog reset) other than software reset has occurred. Therefore, when any of bit4 to bit2 is set to "1", this bit is set to "1" as well.

When a software reset occurs, the bit retains the value that has existed before the software reset occurs.

A read access or a write access (writing "0" or "1") to this bit sets it to "0".

bit1	Details
Read access	Sets this bit to "0".
Being set to "1"	Indicates that the a hardware reset has occurred.
Write access	Sets this bit to "0".

[bit0] SWR: Software reset flag bit

When this bit is set to "1", that indicates a software reset has occurred.

When a hardware reset occurs, the bit retains the value that has existed before the hardware reset occurs.

A read access or a write access (writing "0" or "1") to this bit or a power-on reset sets it to "0".

bit0	Details
Read access	Sets this bit to "0".
Being set to "1"	Indicates that the a software reset has occurred.
Write access	Sets this bit to "0".

Note:

Since reading the reset source register clears its contents, save the contents of this register to the RAM before using those contents for calculation.

■ State of Reset Source Register (RSRR)

Table 4.2-2 State of Reset Source Register

Reset source	EXTS	WDTR	PONR	HWR	SWR
Power-on reset	×	×	1	1	0
Low-voltage detection reset (optional)	×	×	1	1	0
Software reset	△	△	△	△	1
Watchdog reset	△	1	△	1	△
External reset	1	△	△	1	△

1: Flag set

△: Previous state kept

×: Indeterminate

EXTS: When this bit is set to "1", that indicates an external reset has occurred.

WDTR: When this bit is set to "1", that indicates a watchdog reset has occurred.

PONR: When this bit is set to "1", that indicates a power-on reset or low-voltage detection reset (optional) has occurred.

HWR: When this bit is set to "1", that indicates one of the following reset has occurred: an external reset, a watchdog reset, a power-on reset or a low-voltage detection reset (optional).

SWR: When this bit is set to "1", that indicates that a software reset has occurred.

4.3 Notes on Using Reset

This section provides notes on using the reset.

■ Notes on Using Reset

- Initialization of registers and bits by reset source

Some registers and bits are initialized only by a certain reset source.

- The type of reset source determines which bit in the reset source register (RSRR) is to be initialized.
- The oscillation stabilization wait time setting register (WATR) of the clock controller can only be initialized by a power-on reset.

CHAPTER 5

INTERRUPTS

This chapter describes the interrupts.

5.1 Interrupts

5.1 Interrupts

This section describes the interrupts.

■ Overview of Interrupts

The New 8FX family has 24 interrupt request inputs for respective peripheral functions, for each of which an interrupt level can be set independently to each other.

When a peripheral function generates an interrupt request, the interrupt request is output to the interrupt controller. The interrupt controller checks the interrupt level of that interrupt request and then notifies the CPU of the generation of the interrupt. The CPU processes that interrupt according to the interrupt acceptance status. The device wakes up from standby mode by an interrupt request generated in standby mode and resumes executing instructions.

■ Interrupt Requests from Peripheral Functions

When the CPU receives an interrupt request, it branches to the interrupt service routine with the interrupt vector table address corresponding to the interrupt request as the address of the branch destination.

The priority of each interrupt request in interrupt processing can be set to one of the four levels by the interrupt level setting registers (ILR0 to ILR5).

While an interrupt is being processed in the interrupt service routine, if another interrupt whose interrupt request is of the same level or below the one of the interrupt being processed is generated, it is processed after the current interrupt service routine is completed. In addition, if multiple interrupt requests that are set to the same interrupt level are made, IRQ00 is at the top of the priority order.

For interrupt sources, refer to "■ INTERRUPT SOURCE TABLE" in the device data sheet.

5.1.1 Interrupt Level Setting Registers (ILR0 to ILR5)

The interrupt level setting registers (ILR0 to ILR5) contain 24 pairs of 2-bit data assigned to the interrupt requests of different peripheral functions. Each pair of bits (interrupt level setting bits) is used to set the interrupt level of an interrupt request.

■ Register Configuration

ILR0								
bit	7	6	5	4	3	2	1	0
Field	L03[1:0]		L02[1:0]		L01[1:0]		L00[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

ILR1								
bit	7	6	5	4	3	2	1	0
Field	L07[1:0]		L06[1:0]		L05[1:0]		L04[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

ILR2								
bit	7	6	5	4	3	2	1	0
Field	L11[1:0]		L10[1:0]		L09[1:0]		L08[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

ILR3								
bit	7	6	5	4	3	2	1	0
Field	L15[1:0]		L14[1:0]		L13[1:0]		L12[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

ILR4								
bit	7	6	5	4	3	2	1	0
Field	L19[1:0]		L18[1:0]		L17[1:0]		L16[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

ILR5								
bit	7	6	5	4	3	2	1	0
Field	L23[1:0]		L22[1:0]		L21[1:0]		L20[1:0]	
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

The interrupt level setting registers assign a pair of bits to every interrupt request. The values of interrupt level setting bits in these registers represent the priority of an interrupt request (interrupt level: 0 to 3) in interrupt processing.

The interrupt level setting bits are compared with the interrupt level bits in the condition code register (CCR:IL[1:0]).

If the interrupt level of an interrupt request is 3, the CPU ignores that interrupt request.

Table 5.1-1 shows the relationships between interrupt level setting bits and interrupt levels.

Table 5.1-1 Relationships Between Interrupt Level Setting Bits and Interrupt Levels

LXX[1:0]	Interrupt level	Priority
00	0	Highest
01	1	↑ ↓
10	2	
11	3	Lowest (No interrupt)

XX:00 to 23 Number of an interrupt request

While the main program is being executed, the interrupt level bits in the condition code register (CCR:IL[1:0]) are "0b11".

5.1.2 Interrupt Processing

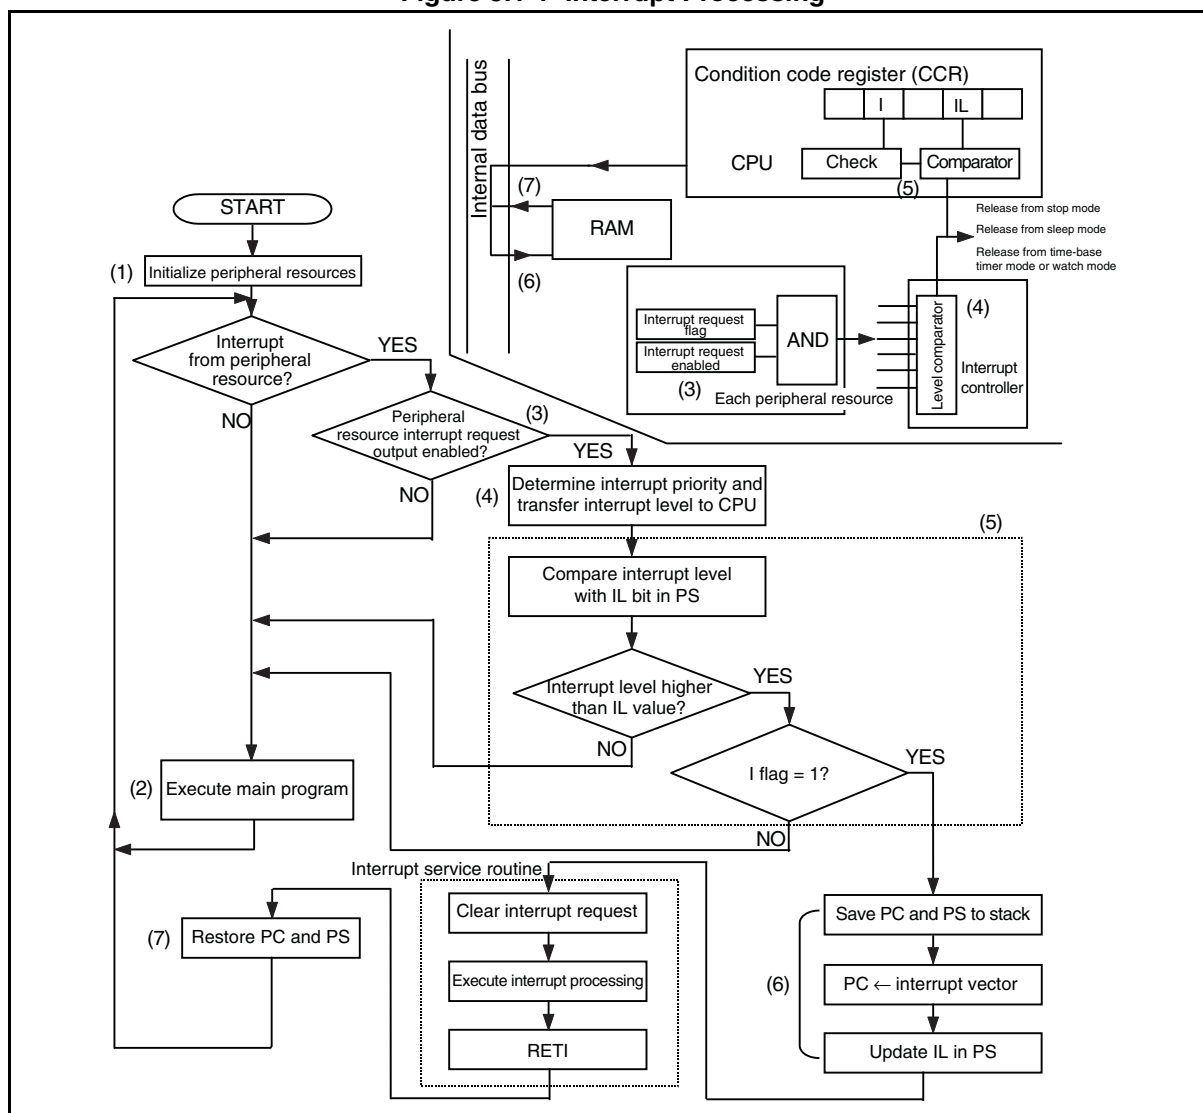

When an interrupt request is made by a peripheral function, the interrupt controller notifies the CPU of the interrupt level of that interrupt request. When the CPU is ready to accept interrupts, it halts the program it is executing and executes an interrupt service routine.

■ Interrupt Processing

The procedure for processing an interrupt is as follows: the generation of an interrupt source in a peripheral function, the execution of the main program, the setting of the interrupt request flag bit, the checking of the interrupt request enable bit, the determination of the interrupt level (ILR0 to ILR5 and CCR:IL[1:0]), the checking for interrupt requests of the same interrupt level made simultaneously, and the checking of the interrupt enable flag (CCR:I).

Figure 5.1-1 shows the interrupt processing.

Figure 5.1-1 Interrupt Processing

- (1) All interrupt requests are disabled immediately after a reset. In the peripheral function initialization program, initialize those peripheral functions that generate interrupts and set their interrupt levels in their respective interrupt level setting registers (ILR0 to ILR5) before starting operating such peripheral functions. The interrupt level can be set to 0, 1, 2, or 3. Level 0 is given the highest priority, and level 1 the second highest. Assigning level 3 to a peripheral function disables interrupts from that peripheral function.
- (2) Execute the main program (or the interrupt service routine in the case of nested interrupts).
- (3) When an interrupt source is generated in a peripheral function, the interrupt request flag bit for that peripheral function is set to "1". Provided that the interrupt request enable bit for that peripheral function has been set to the value that enables interrupts, an interrupt request of that peripheral function is output to the interrupt controller.
- (4) The interrupt controller keeps monitoring interrupt requests from individual peripheral functions and notifies the CPU of the interrupt level having priority over the others among interrupt levels already made. If there are interrupt requests having the same interrupt level, their positions in the priority order are also compared in the interrupt controller.
- (5) If the interrupt level received has priority over (smaller interrupt level number) the level set in the interrupt level bits in the condition code register (CCR:IL[1:0]), the CPU checks the content of the interrupt enable flag (CCR:I), and accepts the interrupt provided that interrupts have been enabled (CCR:I = 1).
- (6) The CPU saves the contents of the program counter (PC) and the program status (PS) to the stack, captures the start address of the interrupt service routine from the corresponding interrupt vector table address, modifies the values of the interrupt level bits in the condition code register (CCR:IL[1:0]) to the values of the interrupt level received, then starts executing the interrupt service routine.
- (7) Finally, the CPU uses the RETI instruction to restore the values of the program counter (PC) and the program status (PS) from the stack and resumes executing the instruction following the one executed just before the interrupt.

Note:

The interrupt request flag bit for a peripheral function is not automatically cleared to "0" after an interrupt request is accepted. Therefore, clear such bit to "0" by using a program (writing "0" to the interrupt request flag bit) in the interrupt service routine.

The low power consumption mode (standby mode) is released by an interrupt. For details, see "3.5 Operations in Low Power Consumption Mode (Standby Mode)".

5.1.3 Nested Interrupts

Different interrupt levels can be assigned to multiple interrupt requests from peripheral functions in the interrupt level setting registers (ILR0 to ILR5) to process nested interrupts.

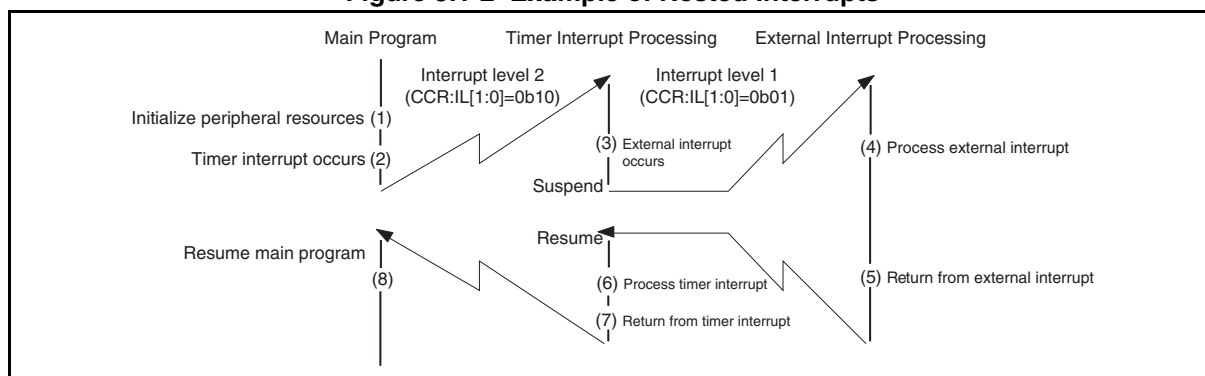

■ Nested Interrupts

During the execution of an interrupt service routine, if another interrupt request whose interrupt level has priority over the interrupt level of the interrupt being processed is made, the CPU suspends the current interrupt processing and accepts the interrupt request given priority. The interrupt level of an interrupt request can be set to 0 to 3. If it is set to 3, the CPU does not accept that interrupt request.

[Example: Nested interrupts]

In the following example of nested interrupts, assuming that the external interrupt is to be given priority over the timer interrupt, the interrupt level of the timer interrupt is set to 2 and that of the external interrupt to 1. If the external interrupt is generated while the timer interrupt is being processed, they are processed as shown in Figure 5.1-2.

Figure 5.1-2 Example of Nested Interrupts

- While the timer interrupt is being processed, the interrupt level bits in the condition code register (CCR:IL[1:0]) hold the same value as that of the interrupt level setting registers (ILR0 to ILR5) corresponding to the timer interrupt (level 2 in the above example). If an interrupt request whose interrupt level has priority over the interrupt level of the timer interrupt (level 1 in the above example) is made, that interrupt is processed first.
- To temporarily disable nested interrupts processing while the timer interrupt is being processed, disable interrupts by setting the interrupt enable flag in the condition code register (CCR:I) to "0", or set the interrupt level bits (CCR:IL[1:0]) to "0b00".
- After the interrupt processing is completed, if the interrupt return instruction (RETI) is executed, the value of the program counter (PC) and that of the program status (PS) are restored, and the CPU resumes executing the program interrupted. In addition, the values of the condition code register (CCR) return to the ones existing before the interrupt due to the restoration of the value of the program status (PS).

5.1.4 Interrupt Processing Time

Before the CPU enters the interrupt service routine after an interrupt request is made, it needs to wait for the interrupt processing time, which consists of the time between the occurrence of an interrupt request and the end of the execution of the instruction being executed, and the interrupt handling time (the time required to initiate interrupt processing) to elapse. The maximum interrupt processing time is 26 machine clock cycles.

■ Interrupt Processing Time

Before executing the interrupt service routine after an interrupt request is made, the CPU needs to wait for the interrupt request sampling wait time and the interrupt handling time to elapse.

● Interrupt request sampling wait time

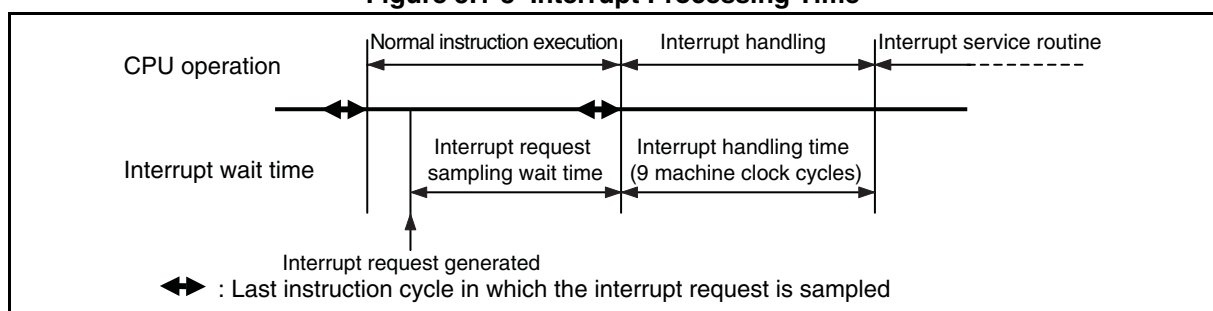

The CPU decides whether an interrupt request has occurred by sampling the interrupt request during the last cycle of each instruction. Therefore, the CPU cannot recognize interrupt requests while executing an instruction. This sampling wait time reaches its maximum when an interrupt request occurs immediately after the CPU starts executing the DIVU instruction, whose execution cycle is the longest (17 machine clock cycles).

● Interrupt handling time

After accepting an interrupt, the CPU requires nine machine clock cycles to perform the following interrupt processing setup:

- Saves the value of the program counter (PC) and that of the program status (PS) to the stack.
- Sets the PC to the start address (interrupt vector) of interrupt service routine.
- Updates the interrupt level bits (CCR:IL[1:0]) in the program status (PS).

Figure 5.1-3 Interrupt Processing Time

When an interrupt request occurs immediately after the CPU starts executing the DIVU instruction, whose execution cycle is the longest (17 machine clock cycles), the interrupt processing time spans 26 machine clock cycles.

The span of a machine clock cycle varies depending on the clock mode and main clock speed change (gear function). For details, see "CHAPTER 3 CLOCK CONTROLLER".

5.1.5 Stack Operation During Interrupt Processing

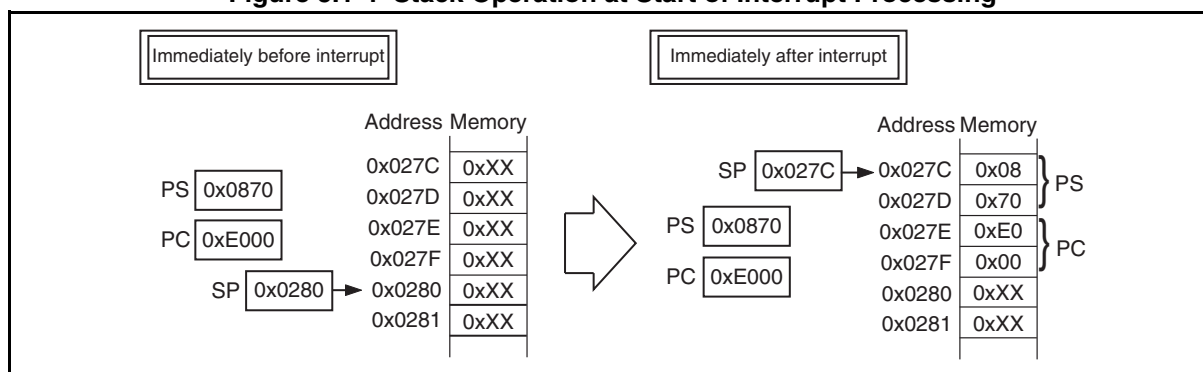

This section describes how the contents of a register are saved and restored during interrupt processing.

■ Stack Operation at the Start of Interrupt Processing

Once the CPU accepts an interrupt, it automatically saves the current value of the program counter (PC) and that of the program status (PS) values to the stack.

Figure 5.1-4 shows the stack operation at the start of interrupt processing.

Figure 5.1-4 Stack Operation at Start of Interrupt Processing

■ Stack Operation after Returning from Interrupt

When the CPU executes the interrupt return instruction (RETI) at the end of interrupt processing, it restores from the stack the value of the program status (PS) first and that of the program counter (PC), which is opposite to the sequence of saving the two values to the stack. After the restoration, both PS and PC return to their states before the start of interrupt processing.

Note:

Since the value of the accumulator (A) and that of the temporary accumulator (T) are not automatically saved to the stack, use the PUSHW and POPW instructions to save and restore the values of A and T.

5.1.6 Interrupt Processing Stack Area

The stack area in RAM is used for interrupt processing. The stack pointer (SP) contains the start address of the stack area.

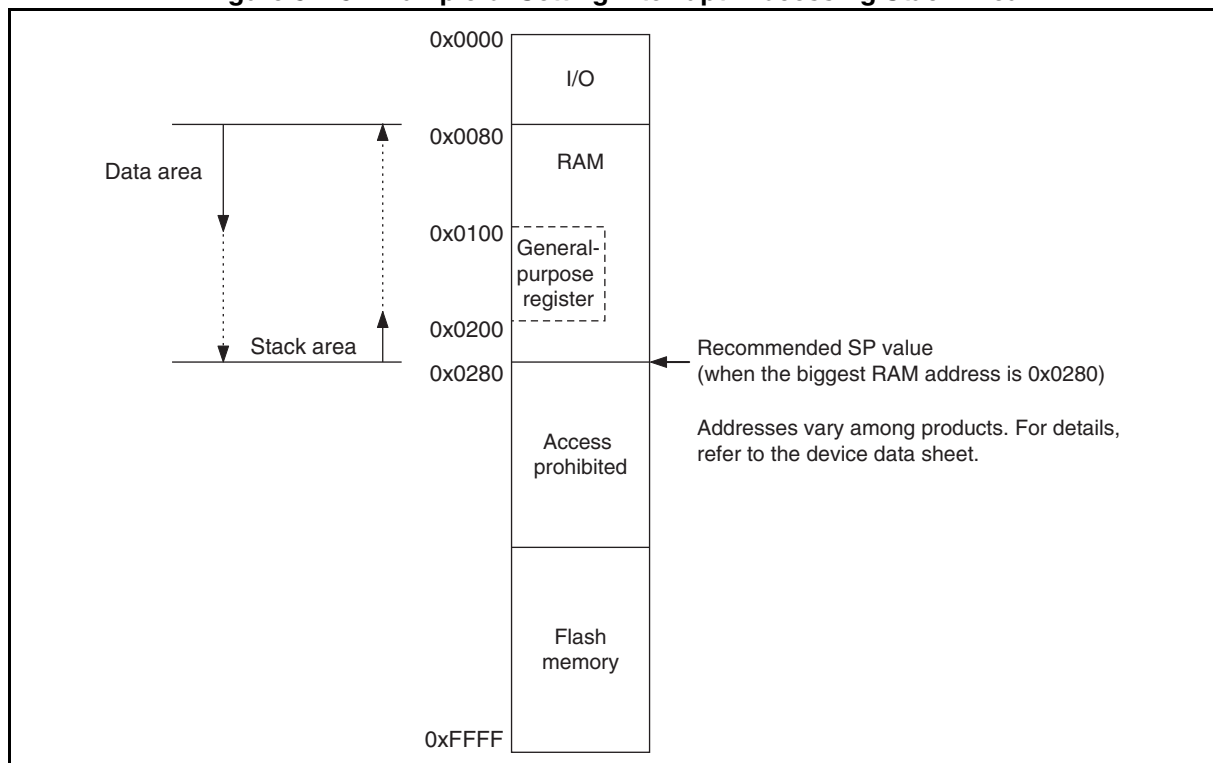

■ Interrupt Processing Stack Area

The stack area is also used for saving and restoring the program counter (PC) when the subroutine call instruction (CALL) or the vector call instruction (CALLV) is executed, and for saving temporarily and restoring register contents by the PUSHW and POPW instructions.

- The stack area is secured on the RAM together with the data area.
- Initialize the stack pointer (SP) so that it indicates the biggest RAM address and make the data area start from the smallest RAM address.

Figure 5.1-5 shows an example of setting the interrupt processing stack area.

Figure 5.1-5 Example of Setting Interrupt Processing Stack Area

Note:

The stack area is utilized by interrupts, sub-routine calls, the PUSHW instruction, etc. in descending order of addresses. It is released by return instructions (RETI, RET), the POPW instruction, etc. in ascending order of addresses. If the address value of the stack area used decreases due to nested interrupts or subroutine calls, do not let the stack area overlap the data area and the general-purpose register area, both of which retain other data.

CHAPTER 6

I/O PORT

This chapter describes the configuration and operations of the I/O port.

- 6.1 Overview
- 6.2 Configuration and Operations

6.1 Overview

The I/O port is used to control general-purpose I/O pins.

■ Overview of I/O Port

The I/O port has functions to output data from the CPU and capture input signals into the CPU with the port data register (PDR). The I/O direction of an individual I/O pin can be set as desired by using the corresponding to that I/O pin in the port direction register (DDR).

The number of I/O ports varies among products. For the exact number of I/O ports on a product, refer to the device data sheet.

In this chapter, "x" represents the port number in a register name. For details of register names and their respective abbreviations of a product, refer to the device data sheet.

Table 6.1-1 lists the registers for each port.

Table 6.1-1 List of Port Registers

Register name	Register abbreviation
Port x data register	PDRx
Port x direction register	DDRx
Port x pull-up register	PULx
A/D input disable register (upper)*	AIDRH
A/D input disable register (lower)*	AIDRL

*: Refer to "■ I/O MAP" in the device data sheet for the availability of the A/D input disable register (upper) and A/D input disable register (lower).

6.2 Configuration and Operations

This section focuses on its configuration and operations as a general-purpose I/O port.

For details of peripheral functions, see their respective chapters.

■ Configuration of I/O Port

An I/O port is made up of the following elements.

- General-purpose I/O pins/peripheral function I/O pins
- Port x data register (PDRx)
- Port x direction register (DDRx)
- Port x pull-up register (PULx)
- A/D input disable register (upper) (AIDRH)
- A/D input disable register (lower) (AIDRL)

■ Operations of I/O Port

● Operation as an output port

- A pin becomes an output port if the bit in the DDRx register corresponding to that pin is set to "1".
- For a pin shared with other peripheral functions, disable the output of such peripheral functions.
- When a pin is used as an output port, it outputs the value of the PDRx register to external pins.
- If data is written to the PDRx register, the value is stored in the output latch and is output to the pin set as an output port as it is.
- Reading the PDRx register returns the PDRx register value.
- To use a pin shared with the LCDC segment/common output pin as an output port, set a corresponding function select bit in an LCDC enable register (LCDCE:COM/SEG) to "0" to select the general-purpose I/O port function, and then set the port input control bit in the LCDC enable register 1 (LCDCE1:PICTL) to "1".
- To use a pin shared with the LCD drive power supply pin as an output port, set the bit corresponding to that pin in the VE[4:0] bits in the LCDCE1 register to "0" to select the general-purpose I/O port function.

● Operation as an input port

- A pin becomes an input port if the bit in the DDRx register corresponding to that pin is set to "0".
- For a pin shared with other peripheral functions, disable the output of such peripheral functions.
- When using a pin shared with the analog input function as an input port, set the corresponding bit in the A/D input disable register (upper/lower) (AIDRH/AIDRL) to "1".
- If data is written to the PDRx register, the value is stored in the output latch but is not output to the pin set as an input port.
- Reading the PDRx register returns the pin value. However, if the read-modify-write (RMW) type of instruction is used to read the PDRx register, the PDRx register value is returned.
- To use a pin shared with the LCDC as an input port, set a corresponding function select bit (COM/SEG) in an LCDCE register to "0" to select the general-purpose I/O port function, and then set the PICTL bit in the LCDCE1 register to "1".
- To use a pin shared with the LCD drive power supply pin as an input port, set the bit corresponding to that pin in the VE[4:0] bits in the LCDCE1 register to "0" to select the general-purpose I/O port function.

● Operation as a peripheral function output pin

- A pin becomes a peripheral function output pin if the peripheral output function is enabled by setting the output enable bit of a peripheral function corresponding to that pin.
- The pin value can be read from the PDRx register even if the peripheral function output is enabled. Therefore, the output value of a peripheral function can be read by the read operation on the PDRx register. However, if the read-modify-write (RMW) type of instruction is used to read the PDRx register, the PDRx register value is returned.

● Operation as a peripheral function input pin

- To set a pin as an input port, set the bit in the DDRx register bit corresponding to the input pin of a peripheral function to "0".
- When using a pin shared with the analog input function as another peripheral function input

pin, configure it as an input port by setting the bit in the AIDRH/AIDRL register corresponding to that pin to "1".

- Reading the PDRx register returns the pin value, regardless of whether the peripheral function uses that pin as its input pin. However, if the read-modify-write (RMW) type of instruction is used to read the PDRx register, the PDRx register value is returned.

● Operation as an LCDC segment output pin

- Set the bit in the DDRx register corresponding to an LCDC segment output pin to "0".
- To use a pin shared with a general-purpose I/O port as an LCDC segment output pin, set a corresponding function select bit (SEG) in an LCDCE register to "1" to select the LCDC segment output function, and then set the PICTL bit in the LCDCE1 register to "1".

● Operation as an LCDC common output pin

- Set the bit in the DDRx register corresponding to an LCDC segment output pin to "0".
- To use a pin shared with a general-purpose I/O port as an LCDC common output pin, set a corresponding function select bit (COM) in an LCDCE register to "1" to select the LCDC segment output function, and then set the PICTL bit in the LCDCE1 register to "1".

● Operation at reset

If the CPU is reset, all bits in the DDRx register are initialized to "0" and port input is enabled. As for a pin shared with the analog input function, its port input is disabled because the AIDRH/AIDRL register is initialized to "0".

● Operation in stop mode and watch mode

- If the pin state setting bit in the standby control register (STBC:SPL) is set to "1" and the device transits to stop mode or watch mode, the pin is compulsorily made to enter the high impedance state regardless of the DDRx register value. The input of that pin is locked at "L" level and blocked in order to prevent leaks due to input open. However, if the interrupt input is enabled for the external interrupt, the input is enabled and not blocked.
- If the pin state setting bit is "0", the state of the port I/O or that of the peripheral function I/O remains unchanged and the output level is maintained.

● Operation as an LCD drive power supply pin

- Set the bit in the DDRx register corresponding to an LCD drive power supply pin to "0".
- To use a pin shared with a general-purpose I/O port as an LCD drive power supply pin, set the bit corresponding to that pin in the VE[4:0] bits in the LCDCE1 register to "1" to select the LCD drive power supply function.

● Operation as an analog input pin

- Set the bit in the DDRx register corresponding to the analog input pin to "0" and the bit corresponding to that pin in the AIDRH/AIDRL register to "0".
- For a pin shared with other peripheral functions, disable the output of such peripheral functions. In addition, set the corresponding bit in the PULx register to "0".

● Operation as an external interrupt input pin

- Set the bit in the DDRx register corresponding to the external interrupt input pin to "0".
- For a pin shared with other peripheral functions, disable the output of such peripheral functions.
- The pin value is always input to the external interrupt circuit. When using a pin for a

function other than the interrupt, disable the external interrupt function corresponding to that pin.

- Operation of the pull-up register

Setting the bit in the PULx register to "1" makes the pull-up resistor be internally connected to the pin. When the pin output is "L" level, the pull-up resistor is disconnected regardless of the value of the PULx register.

CHAPTER 7

TIME-BASE TIMER

This chapter describes the functions and operations of the time-base timer.

- 7.1 Overview
- 7.2 Configuration
- 7.3 Interrupt
- 7.4 Operations and Setting Procedure Example
- 7.5 Register
- 7.6 Notes on Using Time-base Timer

7.1 Overview

The time-base timer is a 24-bit free-run down-counting counter. It is synchronized with the main clock divided by two, or with the main CR clock or with the PLL clock. The clock can be selected by the SCS[2:0] bits in the SYCC register. The time-base timer has an interval timer function that can repeatedly generate interrupt requests at regular intervals.

■ Interval Timer Function

The interval timer function repeatedly generates interrupt requests at regular intervals by using the main clock divided by two, or using the main CR clock or using the PLL clock as the count clock.

- The counter of the time-base timer counts down so that an interrupt request is generated every time a selected interval time elapses.
- The length of an interval time can be selected from the following 16 types.

Table 7.1-1 shows the interval times available for the time-base timer.

Table 7.1-1 Interval Times of Time-base Timer

	Interval time if the main clock is used ($2^n \times 2/F_{CH}^{*1}$)	Interval time if the main CR clock is used ($2^n \times 1/F_{CRH}^{*2}$)	Interval time if the main clock or the main CR clock is multiplied by a PLL multiplication rate of 2 ($2^n \times 1/F_{PLL}^{*3}$)
n=9	256 μ s	128 μ s	64 μ s
n=10	512 μ s	256 μ s	128 μ s
n=11	1.024 ms	512 μ s	256 μ s
n=12	2.048 ms	1.024 ms	512 μ s
n=13	4.096 ms	2.048 ms	1.024 ms
n=14	8.192 ms	4.096 ms	2.048 ms
n=15	16.384 ms	8.192 ms	4.096 ms
n=16	32.768 ms	16.384 ms	8.192 ms
n=17	65.536 ms	32.768 ms	16.384 ms
n=18	131.072 ms	65.536 ms	32.768 ms
n=19	262.144 ms	131.072 ms	65.536 ms
n=20	524.288 ms	262.144 ms	131.072 ms
n=21	1.049 s	524.288 ms	262.144 ms
n=22	2.097 s	1.049 s	524.288 ms
n=23	4.194 s	2.097 s	1.049 s
n=24	8.389 s	4.194 s	2.097 s

*1: $F_{CH} = 4 \text{ MHz}$

$\therefore 2/F_{CH} = 0.5 \text{ } \mu\text{s}$

*2: $F_{CRH} = 4 \text{ MHz}$

$\therefore 1/F_{CRH} = 0.25 \text{ } \mu\text{s}$

*3: $F_{PLL} = 8 \text{ MHz}$

PLL multiplication rate = 2

(F_{CH} or F_{CRH}) \times PLL multiplication rate = $4 \text{ MHz} \times 2 = 8 \text{ MHz}$

$\therefore 1/F_{PLL} = 0.125 \text{ } \mu\text{s}$

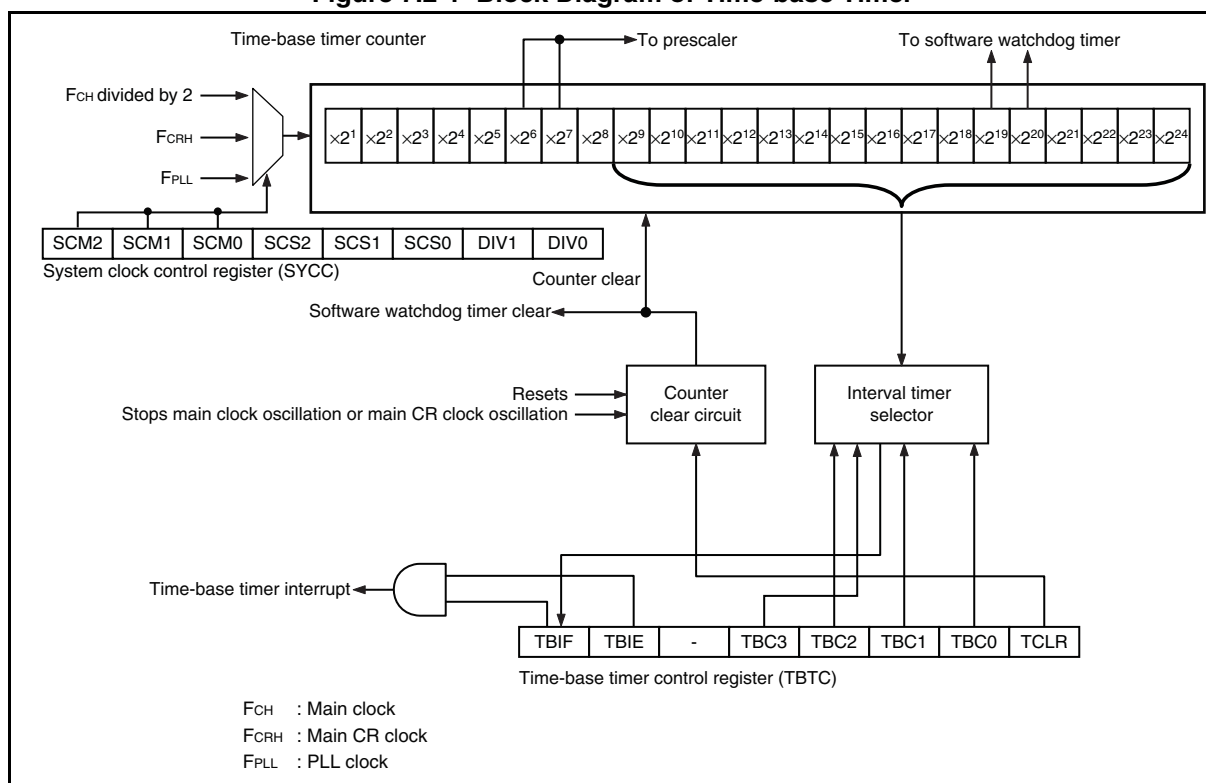

7.2 Configuration

The time-base timer consists of the following blocks:

- Time-base timer counter
- Counter clear circuit
- Interval timer selector
- Time-base timer control register (TBTC)

■ Block Diagram of Time-base Timer

Figure 7.2-1 Block Diagram of Time-base Timer

- Time-base timer counter

This is a 24-bit downcounter using the main clock divided by two, the main CR clock or the PLL clock as its count clock.

- Counter clear circuit

This circuit controls the clearing of the time-base timer counter.

- Interval timer selector

This circuit selects one bit out of 16 bits in the 24 bits of the time-base timer counter as the interval timer.

- Time-base timer control register (TBTC)

This register selects the interval time, clears the counter, controls interrupts and checks the state of the time-base timer.

■ Input Clock

The time-base timer uses the main clock divided by two, the main CR clock or the PLL clock as its input clock (count clock).

■ Output Clock

The time-base timer supplies clocks to the clock supervisor counter, the software watchdog timer and the prescaler.

7.3 Interrupt

An interrupt request is generated when the interval time selected by the time-base timer elapses (interval timer function).

■ Interrupt When Interval Function Is in Operation

When the time-base timer counter counts down by using the internal count clock and the time-base timer counter underflows due to the passage of the selected interval time, the time-base timer interrupt request flag bit (TBTC:TBIF) is set to "1". If the time-base timer interrupt request enable bit is enabled (TBTC:TBIE = 1), an interrupt request will be generated to the interrupt controller.

- Regardless of the value of the TBIE bit, the TBIF bit is set to "1" when the selected bit underflows.
- With the TBIF bit having been set to "1", if the TBIE bit is changed from the disable state to the enable state (0 → 1), an interrupt request is generated immediately.
- The TBIF bit will not be set to "1" if the counter is cleared (TBTC:TCLR = 1) at the same time as the time-base timer counter underflows.
- In the interrupt service routine, write "0" to the TBIF bit to clear an interrupt request.

Note:

When enabling the output of interrupt requests after canceling a reset (TBTC:TBIE = 1), always clear the TBIF bit at the same time (TBTC:TBIF = 0).

Table 7.3-1 Interrupt of Time-base Timer

Item	Description
Interrupt condition	The interval time set by "TBTC:TBC[3:0]" has elapsed.
Interrupt flag	TBTC:TBIF
Interrupt enable	TBTC:TBIE

7.4 Operations and Setting Procedure Example

This section describes the operations of the interval timer function of the time-base timer.

■ Operations of Time-base Timer

The counter of the time-base timer is initialized to "0xFFFFFFFF" after a reset, and starts counting while being synchronized with the main clock divided by two, the main CR clock or the PLL clock.

The time-base timer continues to count down as long as the main clock, the main CR clock or the PLL clock is oscillating. Once the main clock, the main CR clock or the PLL clock stops, the counter stops counting and is initialized to "0xFFFFFFFF".

The settings shown in Figure 7.4-1 are required to use the interval timer function.

Figure 7.4-1 Settings of Interval Timer Function

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
TBTC	TBIF	TBIE	-	TBC3	TBC2	TBC1	TBC0	TCLR
	0	1		⊙	⊙	⊙	⊙	0
⊙: Bit to be used 1: Set to "1". 0: Set to "0".								

When the time-base timer clear bit in the time-base timer control register (TBTC:TCLR) is set to "1", the counter of the time-base timer is initialized to "0xFFFFFFFF" and continues to count down. When the selected interval time has elapsed, the time-base timer interrupt request flag bit in the time-base timer control register (TBTC:TBIF) becomes "1". In other words, an interrupt request is generated at each interval time selected, based on the time when the counter was last cleared.

■ Clearing Time-base Timer

With the output of the time-base timer being used in other peripheral functions, clearing the time-base timer affects their operations in various ways such as changing the count time of a peripheral function.

When clearing the counter by using the time-base timer clear bit (TBTC:TCLR), modify the settings of other peripheral functions whenever necessary so that clearing the counter does not have any unexpected effect on them.

When the output of the time-base timer is selected as the count clock for the watchdog timer, clearing the time-base timer also clears the watchdog timer.

The time-base timer is cleared not only by the TCLR bit, but also when the main clock, the main CR clock or the PLL clock is stopped, and the oscillation stabilization wait time is necessary. The time-base timer is cleared in the following situations:

- When the device transits from main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode to stop mode
- When the device transits from the main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode to subclock mode or sub-CR clock mode
- At power-on
- At low-voltage detection reset

■ Operation Examples of Time-base Timer

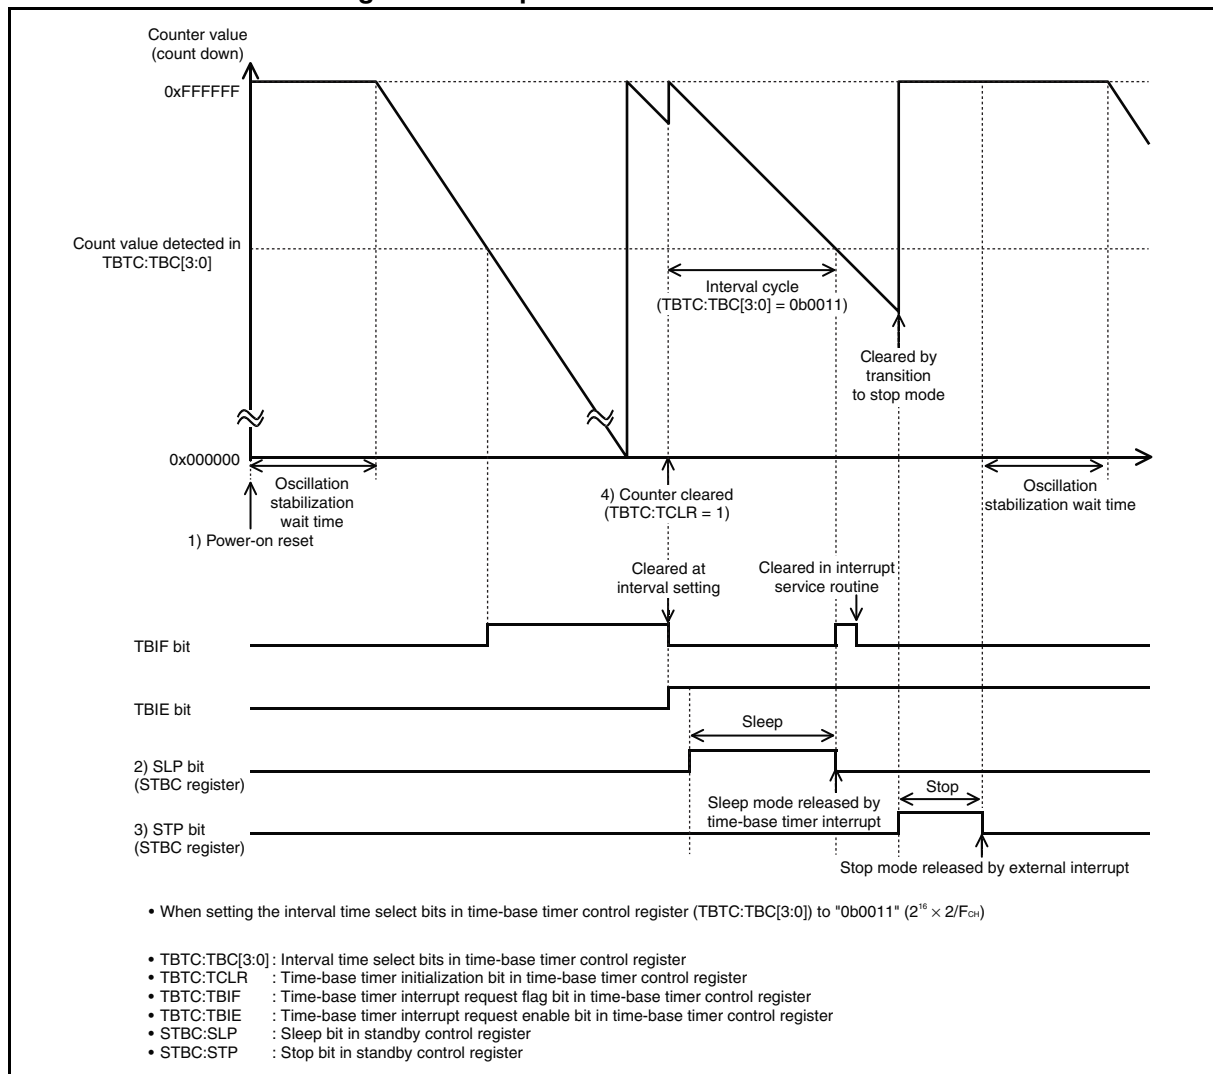

Figure 7.4-2 shows examples of operations under the following conditions:

1. When a power-on reset is generated
2. When the device enters the sleep mode during the operation of the interval timer function in main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode
3. When the device enters the stop mode during main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode
4. When a request is generated to clear the counter

If the device transits to the time-base time mode, the same operations are executed as those executed when the device transits to the sleep mode.

In stop mode in which the clock mode is subclock mode, sub-CR clock mode, main clock mode, main PLL clock mode, main CR clock mode or main CR PLL clock mode, the timer operation stops because it is cleared and the main clock stops.

Figure 7.4-2 Operations of Time-base Timer

■ Setting Procedure Example

Below is an example of procedure for setting the time-base timer.

● Initial settings

1. Set the interrupt level. (ILR*)
2. Set the interval time. (TBTC:TBC[3:0])
3. Enable interrupts and clear the interrupt request flag. (TBTC:TBIE = 1, TBTC:TBIF = 0)
4. Clear the counter. (TBTC:TCLR = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Processing interrupts

1. Clear the interrupt request flag. (TBTC:TBIF = 0)
2. Clear the counter. (TBTC:TCLR = 1)

7.5 Register

This section describes the register of the time-base timer.

Table 7.5-1 List of Time-base Timer Register

Register abbreviation	Register name	Reference
TBTC	Time-base timer control register	7.5.1

7.5.1 Time-base Timer Control Register (TBTC)

The time-base timer control register (TBTC) selects the interval time, clears the counter, controls interrupts and checks the status of the time-base timer.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	TBIF	TBIE	—	TBC3	TBC2	TBC1	TBC0	TCLR
Attribute	R/W	R/W	—	R/W	R/W	R/W	R/W	W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] TBIF: Time-base timer interrupt request flag bit

This bit is set to "1" when the interval time selected by the time-base timer has elapsed.

When this bit and the time-base timer interrupt request enable bit (TBIE) are set to "1", an interrupt request is output.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit7	Details
Reading "0"	Indicates that the interval time has not elapsed.
Reading "1"	Indicates that the interval time has elapsed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit6] TBIE: Time-base timer interrupt request enable bit

This bit enables or disables output of interrupt requests to interrupt controller.

When this bit and the time-base timer interrupt request flag bit (TBIF) are set to "1", a time-base timer interrupt request is output.

bit6	Details
Writing "0"	Disables the time-base timer interrupt request.
Writing "1"	Enables the time-base timer interrupt request.

[bit5] Undefined bit

The read value is always "0". Writing a value to this bit has no effect on operation.

[bit4:1] TBC[3:0]: Interval time select bits
These bits select interval time.

bit4:1	Details		
	Interval time (Main clock, $F_{CH} = 4 \text{ MHz}$)	Interval time (Main CR clock, $F_{CRH} = 4 \text{ MHz}$)	Interval time (Main clock or main CR clock multiplied by a PLL multiplication rate of 2, $F_{PLL} = 8 \text{ MHz}$)
Writing "0100"	$2^9 \times 2/F_{CH}$ (256 μs)	$2^9 \times 1/F_{CRH}$ (128 μs)	$2^9 \times 1/F_{PLL}$ (64 μs)
Writing "0000"	$2^{10} \times 2/F_{CH}$ (512 μs)	$2^{10} \times 1/F_{CRH}$ (256 μs)	$2^{10} \times 1/F_{PLL}$ (128 μs)
Writing "0101"	$2^{11} \times 2/F_{CH}$ (1.024 ms)	$2^{11} \times 1/F_{CRH}$ (512 μs)	$2^{11} \times 1/F_{PLL}$ (256 μs)
Writing "0001"	$2^{12} \times 2/F_{CH}$ (2.048 ms)	$2^{12} \times 1/F_{CRH}$ (1.024 ms)	$2^{12} \times 1/F_{PLL}$ (512 μs)
Writing "0110"	$2^{13} \times 2/F_{CH}$ (4.096 ms)	$2^{13} \times 1/F_{CRH}$ (2.048 ms)	$2^{13} \times 1/F_{PLL}$ (1.024ms)
Writing "0010"	$2^{14} \times 2/F_{CH}$ (8.192 ms)	$2^{14} \times 1/F_{CRH}$ (4.096 ms)	$2^{14} \times 1/F_{PLL}$ (2.048 ms)
Writing "0111"	$2^{15} \times 2/F_{CH}$ (16.384 ms)	$2^{15} \times 1/F_{CRH}$ (8.192 ms)	$2^{15} \times 1/F_{PLL}$ (4.096 ms)
Writing "0011"	$2^{16} \times 2/F_{CH}$ (32.768 ms)	$2^{16} \times 1/F_{CRH}$ (16.384 ms)	$2^{16} \times 1/F_{PLL}$ (8.192 ms)
Writing "1000"	$2^{17} \times 2/F_{CH}$ (65.536 ms)	$2^{17} \times 1/F_{CRH}$ (32.768 ms)	$2^{17} \times 1/F_{PLL}$ (16.384 ms)
Writing "1001"	$2^{18} \times 2/F_{CH}$ (131.072 ms)	$2^{18} \times 1/F_{CRH}$ (65.536 ms)	$2^{18} \times 1/F_{PLL}$ (32.768 ms)
Writing "1010"	$2^{19} \times 2/F_{CH}$ (262.144 ms)	$2^{19} \times 1/F_{CRH}$ (131.072 ms)	$2^{19} \times 1/F_{PLL}$ (65.536 ms)
Writing "1011"	$2^{20} \times 2/F_{CH}$ (524.288 ms)	$2^{20} \times 1/F_{CRH}$ (262.144 ms)	$2^{20} \times 1/F_{PLL}$ (131.072 ms)
Writing "1100"	$2^{21} \times 2/F_{CH}$ (1.049 s)	$2^{21} \times 1/F_{CRH}$ (524.288 ms)	$2^{21} \times 1/F_{PLL}$ (262.144 ms)
Writing "1101"	$2^{22} \times 2/F_{CH}$ (2.097 s)	$2^{22} \times 1/F_{CRH}$ (1.049 s)	$2^{22} \times 1/F_{PLL}$ (524.288 ms)
Writing "1110"	$2^{23} \times 2/F_{CH}$ (4.194 s)	$2^{23} \times 1/F_{CRH}$ (2.097 s)	$2^{23} \times 1/F_{PLL}$ (1.049 s)
Writing "1111"	$2^{24} \times 2/F_{CH}$ (8.389 s)	$2^{24} \times 1/F_{CRH}$ (4.194 s)	$2^{24} \times 1/F_{PLL}$ (2.097 s)

[bit0] TCLR: Time-base timer clear bit
This bit clears all bits in the counter of the time-base timer to "1".

bit0	Details
Read access	The read value is always "0".
Writing "0"	Has no effect on operation.
Writing "1"	Clears all bits in the counter of the time-base timer to "1".

Note: When the output of the time-base timer is selected as the count clock for the software watchdog timer, clear the time-base timer with this bit also clears the software watchdog timer.

7.6 Notes on Using Time-base Timer

This section provides notes on using the time-base timer.

■ Notes on Using Time-base Timer

- When setting the timer by program

The timer cannot be waken up from interrupt processing when the time-base timer interrupt request flag bit (TBTC:TBIF) is set to "1" and the interrupt request enable bit is enabled (TBTC:TBIE = 1). Always clear the TBIF bit in the interrupt service routine.

- Clearing Time-base Timer

The time-base timer is cleared not only by the time-base timer clear bit (TBTC:TCLR = 1) but also when the oscillation stabilization wait time of the main clock, of the main CR clock or of the PLL clock is required. When the time-base timer is selected as the count clock of the software watchdog timer (WDTC:CS[1:0] = 0b00 or 0b01), clearing the time-base timer also clears the software watchdog timer.

- Peripheral functions receiving clock from time-base timer

In the mode where the source oscillation of the main clock is stopped, the counter is cleared and the time-base timer stops operating. In addition, if the counter of the time-base timer is cleared with the output of the time-base timer being used in other peripheral functions, that will affect the operations of such peripheral operations such as the changing of their operating cycles.

After the counter of the time-base timer is cleared, the clock that is output from the time-base timer for the software watchdog timer returns to the initial state. However, since the software watchdog timer counter is also cleared at the same time as the clock for the software watchdog timer returns to the initial state, the software watchdog timer operates in its normal cycle.

CHAPTER 8

HARDWARE/SOFTWARE WATCHDOG TIMER

This chapter describes the functions and operations of the watchdog timer.

- 8.1 Overview
- 8.2 Configuration
- 8.3 Operations and Setting Procedure Example
- 8.4 Register
- 8.5 Notes on Using Watchdog Timer

8.1 Overview

The watchdog timer serves as a counter used to prevent programs from running out of control.

■ Watchdog Timer Function

The watchdog timer functions as a counter used to prevent programs from running out of control. Once the watchdog timer is activated, clear its counter at specified intervals regularly during a certain amount of time. A watchdog reset is generated if the timer is not cleared within a certain amount of time due to a problem such as a program entering an infinite loop.

● Count clock for the software/hardware watchdog timer

- For the software watchdog timer, the output of the time-base timer or of the watch prescaler or of the sub-CR timer can be used as the count clock.
- For the hardware watchdog timer, only the output of the sub-CR timer can be used as the count clock.

● Activation of the software/hardware watchdog timer

- The software/hardware watchdog timer is to be activated according to the values at the addresses 0xFFBE and 0xFFBF on the Flash memory, which are copied to the watchdog timer selection ID register (upper/lower) (WDTH/WDTL) (0x0FEB/0x0FEC).
- In the case of software activation (software watchdog), the watchdog timer register (WDTC) must be set to start the watchdog timer function.
- In the case of hardware activation (hardware watchdog), the watchdog timer starts automatically after a reset. It can also stop or run in stop mode according to the values at the addresses 0xFFBE and 0xFFBF on the Flash memory, which are copied to the watchdog timer selection ID register (upper/lower) (WDTH/WDTL) (0x0FEB/0x0FEC). See "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE" for details of the watchdog timer selection ID.
- The intervals of the watchdog timer are shown in Table 8.1-1. If the counter of the watchdog timer is not cleared, a watchdog reset is generated between the minimum time and the maximum time. Clear the counter of the watchdog timer within the minimum time.

Table 8.1-1 Interval Times of Watchdog Timer

Count clock type	Count clock switch bit CS[1:0], CSP	Interval time	
		Minimum time	Maximum time
Time-base timer output (main clock = 4 MHz)	0b000 (software watchdog timer)	524 ms	1.05 s
	0b010 (software watchdog timer)	262 ms	524 ms
Watch prescaler output (subclock = 32.768 kHz)	0b100 (software watchdog timer)	500 ms	1.00 s
	0b110 (software watchdog timer)	250 ms	500 ms
Sub-CR timer (sub-CR clock = 50 kHz to 150 kHz)	0bXX1* ¹ (software watchdog timer) or hardware watchdog timer* ²	437 ms	2.62 s

*1: X = 0 or 1

*2: CS[1:0] = 0b00, CSP = 1 (read-only)

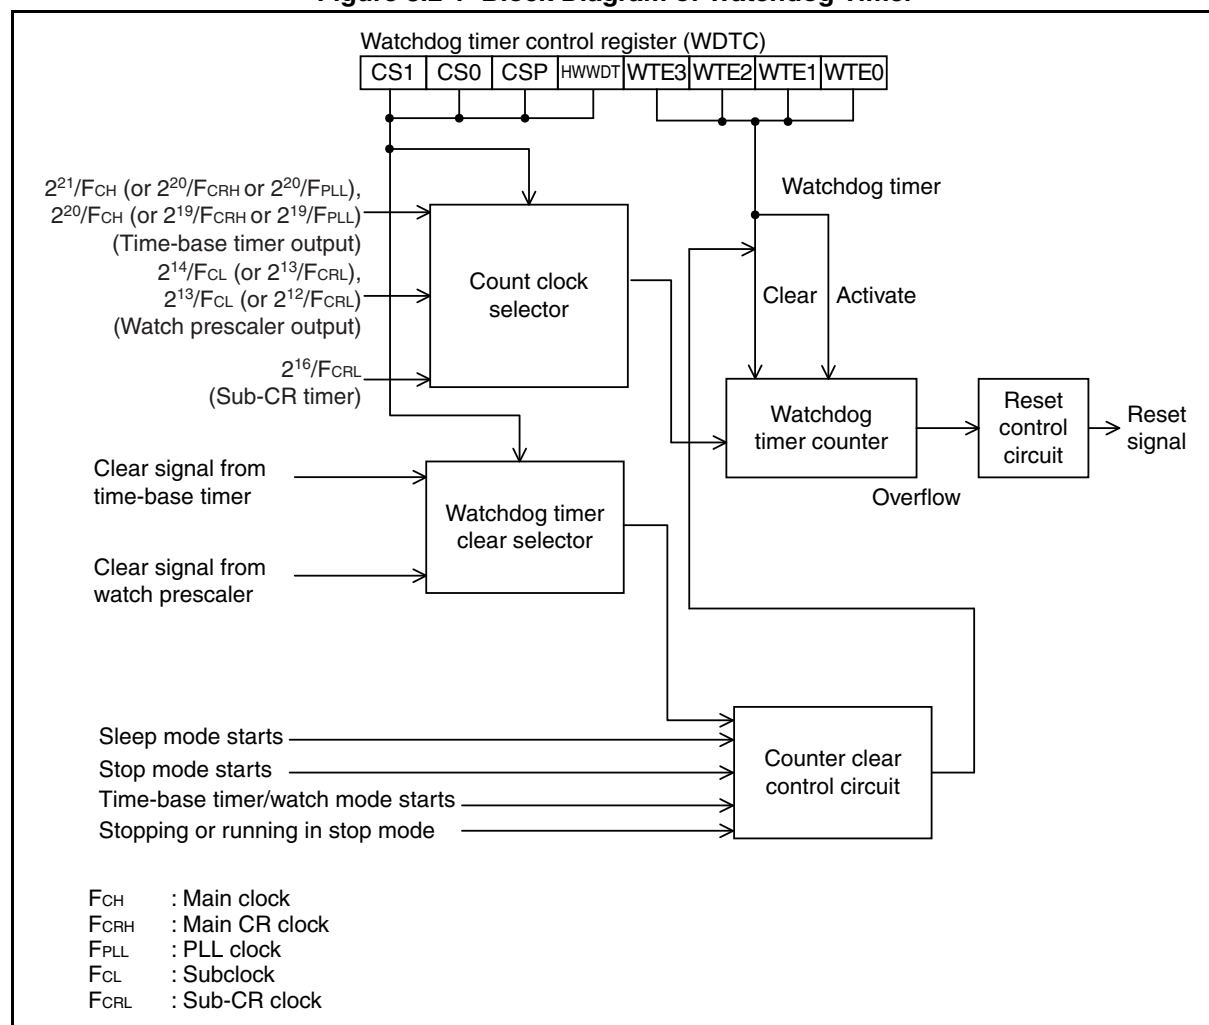

8.2 Configuration

The watchdog timer consists of the following blocks:

- Count clock selector
- Watchdog timer counter
- Reset control circuit
- Watchdog timer clear selector
- Counter clear control circuit
- Watchdog timer control register (WDTC)

■ Block Diagram of Watchdog Timer

Figure 8.2-1 Block Diagram of Watchdog Timer

- Count clock selector

This selector selects the count clock of the watchdog timer counter.

- Watchdog timer counter

This is a 1-bit counter that uses the output of the time-base timer, of the watch prescaler or of the sub-CR timer as the count clock.

- Reset control circuit

This circuit generates a reset signal when the watchdog timer counter overflows.

- Watchdog timer clear selector

This selector selects the watchdog timer clear signal.

- Counter clear control circuit

This circuit controls the clearing and stopping of the watchdog timer counter.

- Watchdog timer control register (WDTC)

This register performs setup for activating/clearing the watchdog timer counter as well as for selecting the count clock.

■ Input Clock

The watchdog timer uses the output clock of the time-base timer, of the watch prescaler or of the sub-CR timer as the input clock (count clock).

8.3 Operations and Setting Procedure Example

The watchdog timer generates a watchdog reset when the watchdog timer counter overflows.

■ Operations of Watchdog Timer

● How to activate the watchdog timer

Software watchdog

- The watchdog timer is activated when "0b0101" is written to the watchdog control bits of the watchdog timer control register (WDTC:WTE[3:0]) for the first time after a reset. The count clock switch bits of the watchdog timer control register (WDTC:CS[1:0], CSP) should also be set at the same time.
- Once the watchdog timer is activated, a reset is the only way to stop its operation.

Hardware watchdog

- To activate the hardware watchdog timer, write any value except "0xA596" to the addresses 0xFFBE and 0xFFBF on the Flash memory. After a reset, the data in 0xFFBE and 0xFFBF on the Flash memory are copied to the watchdog timer selection ID register (upper/lower) (WDTH/WDTL) (0x0FEB/0x0FEC). Writing "0xA597" to the addresses 0xFFBE and 0xFFBF on the Flash memory enables the hardware watchdog timer except in standby modes; writing any value other than "0xA596" and "0xA597" enables the hardware watchdog timer in all modes. See "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE" for details of the watchdog timer selection ID.
- Start operation after a reset is released.
- CS[1:0] and CSP bits are read-only bits fixed at "0b001".
- The counter of the watchdog timer is cleared by a reset, and the watchdog timer resumes its operation after the reset is released.

● Clearing the watchdog timer

- When the counter of the watchdog timer is not cleared within the interval time, it overflows, allowing the watchdog timer to generate a watchdog reset.
- The counter of the hardware watchdog timer is cleared when "0b0101" is written to the watchdog control bits of the watchdog timer control register (WDTC:WTE[3:0]). The counter of the software watchdog timer is cleared when "0b0101" is written to the watchdog control bits of the watchdog timer control register (WDTC:WTE[3:0]) for the second time and from the second time onward.
- The watchdog timer is cleared at the same time as the timer selected as the count clock (time-base timer or watch prescaler) is cleared.

● Operation in standby mode

- In the case of activating the software watchdog timer, or starting the hardware watchdog timer with its operation in standby mode disabled, regardless of the clock mode selected, once the device transits to standby mode, the counter of the watchdog timer is cleared and the watchdog timer stops its operation. When the device wakes up from standby mode, the watchdog timer resumes its operation.
- In the case of activating the hardware watchdog timer with its operation in standby mode enabled, whether the device transits to standby mode or wakes up from standby mode, the counter of the watchdog timer is not cleared and the watchdog timer continues its operation.

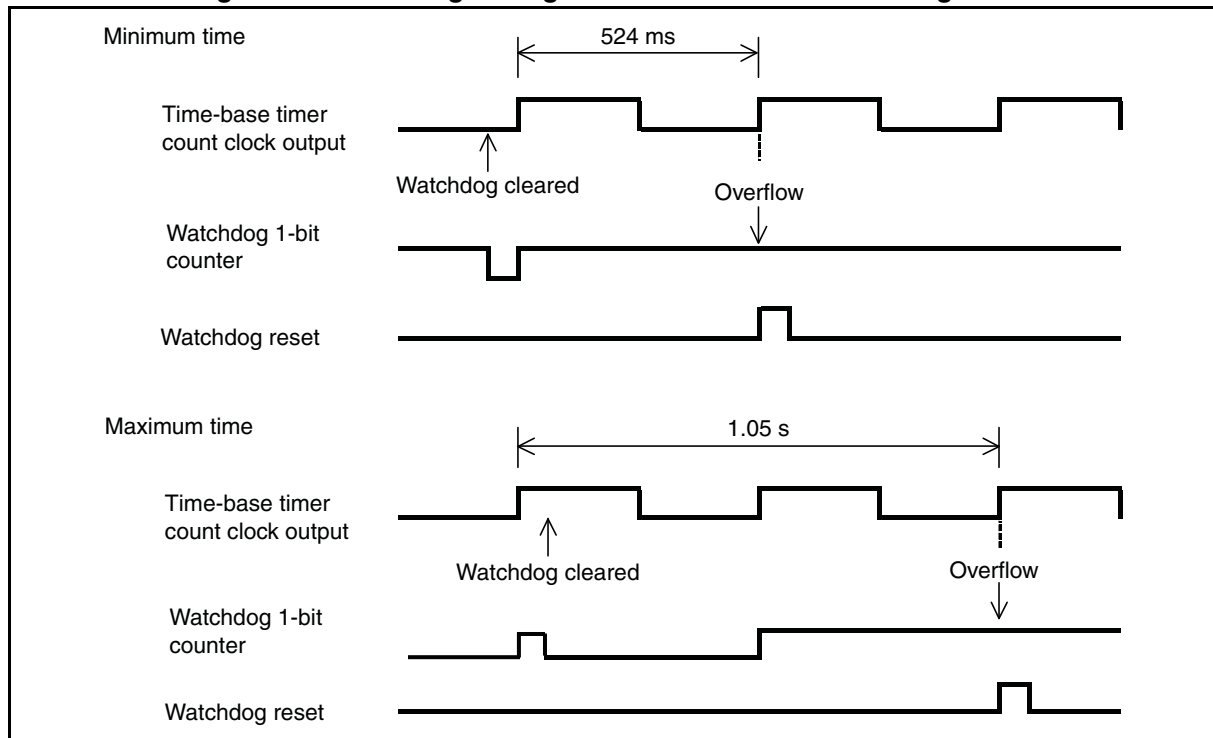

Note:

The watchdog timer is also cleared when the timer selected as the count clock (time-base timer or watch prescaler) is cleared. For this reason, the watchdog timer cannot function if the software is set to repeatedly clear the timer selected as the count clock of the watchdog timer at the interval time selected for the watchdog timer.

● Interval time

The interval time varies depending on the timing of clearing the watchdog timer. Figure 8.3-1 shows the correlation between the timing of clearing the watchdog timer and the interval time when the time-base timer output $F_{CH}/2^{21}$ (F_{CH} : main clock) is selected as the count clock (main clock = 4 MHz).

Figure 8.3-1 Clearing Timing and Interval Time of Watchdog Timer

● Operation in subclock mode

When a watchdog reset is generated in subclock mode, the timer starts operating in main clock mode after the oscillation stabilization wait time has elapsed. The reset signal is output during this oscillation stabilization wait time.

■ Setting Procedure Example

Below is the procedure for setting the software watchdog timer.

1. Select the count clock. (WDTC:CS[1:0], CSP)
2. Activate the watchdog timer. (WDTC:WTE[3:0] = 0b0101)
3. Clear the watchdog timer. (WDTC:WTE[3:0] = 0b0101)

Below is the procedure for setting the hardware watchdog timer.

1. Write any value except "0xA596" to the addresses 0xFFBE and 0xFFBF on the Flash memory. After a reset, the data in 0xFFBE and 0xFFBF on the Flash memory are copied to the watchdog timer selection ID register (upper/lower) (WDTH/WDTL) (0x0FEB/0x0FEC). Writing "0xA597" to the addresses 0xFFBE and 0xFFBF on the Flash memory enables the hardware watchdog timer except in standby modes; writing any value other than "0xA596" and "0xA597" enables the hardware watchdog timer in all modes. See "CHAPTER 28 NON-VOLATILE REGISTER (NVR) INTERFACE" for details of the watchdog timer selection ID.
2. Clear the watchdog timer. (WDTC:WTE[3:0] = 0b0101)

8.4 Register

This section describes the register of the watchdog timer.

Table 8.4-1 List of Watchdog Timer Register

Register abbreviation	Register name	Reference
WDTC	Watchdog timer control register	8.4.1

8.4.1 Watchdog Timer Control Register (WDTC)

The watchdog timer control register (WDTC) activates or clears the watchdog timer.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	CS1	CS0	CSP	HWWDT	WTE3	WTE2	WTE1	WTE0
Attribute and initial values for software watchdog timer								
Attribute	R/W	R/W	R/W	R	W	W	W	W
Initial value	0	0	0	0	0	0	0	0
Attribute and initial values for hardware watchdog timer								
Attribute	R	R	R	R	W	W	W	W
Initial value	0	0	1	1	0	0	0	0

Register Functions

[bit7:6] CS[1:0]: Count clock switch bits

[bit5] CSP: Count clock select sub-CR selector bit

These bits select the count clock of the watchdog timer.

Write to these bits at the same time as activating the watchdog timer by the watchdog control bits.

No change can be made once the watchdog timer is activated.

	bit7	bit6	bit5	Details (F _{CH} : main clock, F _{CRH} : main CR clock, F _{PLL} : PLL clock, F _{CL} : subclock, F _{CRL} : sub-CR clock)
Writing	0	0	0	Output cycle of time-base timer ($2^{21}/F_{CH}$, $2^{20}/F_{CRH}$ or $2^{20}/F_{PLL}$)
Writing	0	1	0	Output cycle of time-base timer ($2^{20}/F_{CH}$, $2^{19}/F_{CRH}$ or $2^{19}/F_{PLL}$)
Writing	1	0	0	Output cycle of watch prescaler ($2^{14}/F_{CL}$ or $2^{13}/F_{CRL}$)
Writing	1	1	0	Output cycle of watch prescaler ($2^{13}/F_{CL}$ or $2^{12}/F_{CRL}$)
Writing	0/1	0/1	1	Output cycle of sub-CR timer ($2^{16}/F_{CRL}$)

Note: Since the time-base timer is stopped in subclock mode or sub-CR clock mode, always select the output of the watch prescaler in subclock mode.

[bit4] HWWDT: Hardware watchdog timer start bit

This is a read-only bit used to confirm the start/stop of the hardware watchdog timer.

bit4	Details
Reading "0"	Indicates that the hardware watchdog timer has stopped (The software watchdog timer can be activated).
Reading "1"	Indicates that the hardware watchdog timer has been activated.

[bit3:0] WTE[3:0]: Watchdog control bits

These bits controls the watchdog timer.

The read value of these bits is always "0b0000".

bit3:0	Details
Writing "0101"	Activates the watchdog timer (in the first write access after a reset) or clears it (from the second write access after a reset). <ul style="list-style-type: none"> • In the case of activating the watchdog timer Writing "0101" to these bits in the first write access after a reset starts the software watchdog timer. • In the case of clearing the watchdog timer Writing "0101" to these bits in the first write access or later after a reset clears the hardware watchdog timer. Writing "0101" to these bits in the second write access or later after a reset clears the software watchdog timer.
Writing a value other than "0101"	Has no effect on operation.

Note:

Using the read-modify-write (RMW) type of instruction to access the WDTC register is prohibited.

8.5 Notes on Using Watchdog Timer

This section provides notes on using the watchdog timer.

■ Notes on Using Watchdog Timer

● Stopping the watchdog timer

Software watchdog timer

Once activated, the watchdog timer cannot be stopped until a reset is generated.

● Selecting the count clock

Software watchdog timer

The count clock switch bits (WDTC:CS[1:0], CSP) can be modified only when the watchdog control bits (WDTC:WTE[3:0]) are set to "0b0101" after the activation of the watchdog timer. The count clock switch bits cannot be set by a bit manipulation instruction. Moreover, the bit settings should not be changed once the timer is activated.

In subclock mode or sub-CR clock mode, the time-base timer does not operate because the main clock, the main CR clock, or the PLL clock stops oscillating.

In order to make the watchdog timer operate in subclock mode or sub-CR clock mode, select the watch prescaler as the count clock beforehand and set WDTC:CS[1:0], CSP to "0b100" or "0b110" or "0bXX1" (X = 0 or 1).

● Clearing the watchdog timer

Clearing the timer (time-base timer, watch prescaler or sub-CR timer) used as the count clock of the watchdog timer also clears the counter of the watchdog timer.

The counter of the watchdog timer is cleared when the watchdog timer transits to sleep mode, stop mode, or watch mode, except in the case of activating hardware watchdog timer whose operation in standby mode has been enabled.

● Programming precaution

When creating a program in which the watchdog timer is cleared repeatedly in the main loop, set the processing time of the main loop including the interrupt processing time to the minimum watchdog timer interval time or shorter.

● Hardware watchdog timer (operation in standby mode has been enabled)

The hardware watchdog timer does not stop in stop mode, sleep mode, time-base timer mode or watch mode. Therefore, the hardware watchdog timer is not cleared by the CPU even if the internal clock stops. (in stop mode, sleep mode, time-base timer mode or watch mode).

Regularly release the device from standby mode and clear the watchdog timer. However, depending on the setting of the oscillation stabilization wait time setting register, a watchdog reset may be generated after the CPU wakes up from stop mode in subclock mode or sub-CR clock mode.

Take account of the setting of the subclock stabilization wait time when selecting the subclock.

CHAPTER 9

WATCH PRESCALER

This chapter describes the functions and operations of the watch prescaler.

- 9.1 Overview
- 9.2 Configuration
- 9.3 Interrupt
- 9.4 Operations and Setting Procedure Example
- 9.5 Register
- 9.6 Notes on Using Watch Prescaler

9.1 Overview

The watch prescaler is a 16-bit down-counting, free-run counter, which is synchronized with the subclock divided by two or the sub-CR clock divided by two. It has an interval timer function that continuously generates interrupt requests at regular intervals.

■ Interval Timer Function

The interval timer function continuously generates interrupt requests at regular intervals, using the subclock divided by two or the sub-CR clock divided by two as its count clock.

- The counter of the watch prescaler counts down and an interrupt request is generated whenever the selected interval time has elapsed.
- The interval time can be selected from the following eight types:

Table 9.1-1 shows the interval times of the watch prescaler.

Table 9.1-1 Interval Times of Watch Prescaler

	Interval time (Sub-CR clock) ($2^n \times 2/F_{CRL}^{*1}$)	Interval time (Subclock) ($2^n \times 2/F_{CL}^{*2}$)
n=10	20.48 ms	62.5 ms
n=11	40.96 ms	125 ms
n=12	81.92 ms	250 ms
n=13	163.84 ms	500 ms
n=14	327.68 ms	1 s
n=15	655.36 ms	2 s
n=16	1.311 s	4 s
n=17	2.621 s	8 s

*1: $2/F_{CRL}=20\ \mu\text{s}$ when $F_{CRL}=100\ \text{kHz}$

*2: $2/F_{CL}=61.035\ \mu\text{s}$ when $F_{CL}=32.768\ \text{kHz}$

Note:

Refer to the device data sheet for the accuracy of the sub-CR clock frequency.

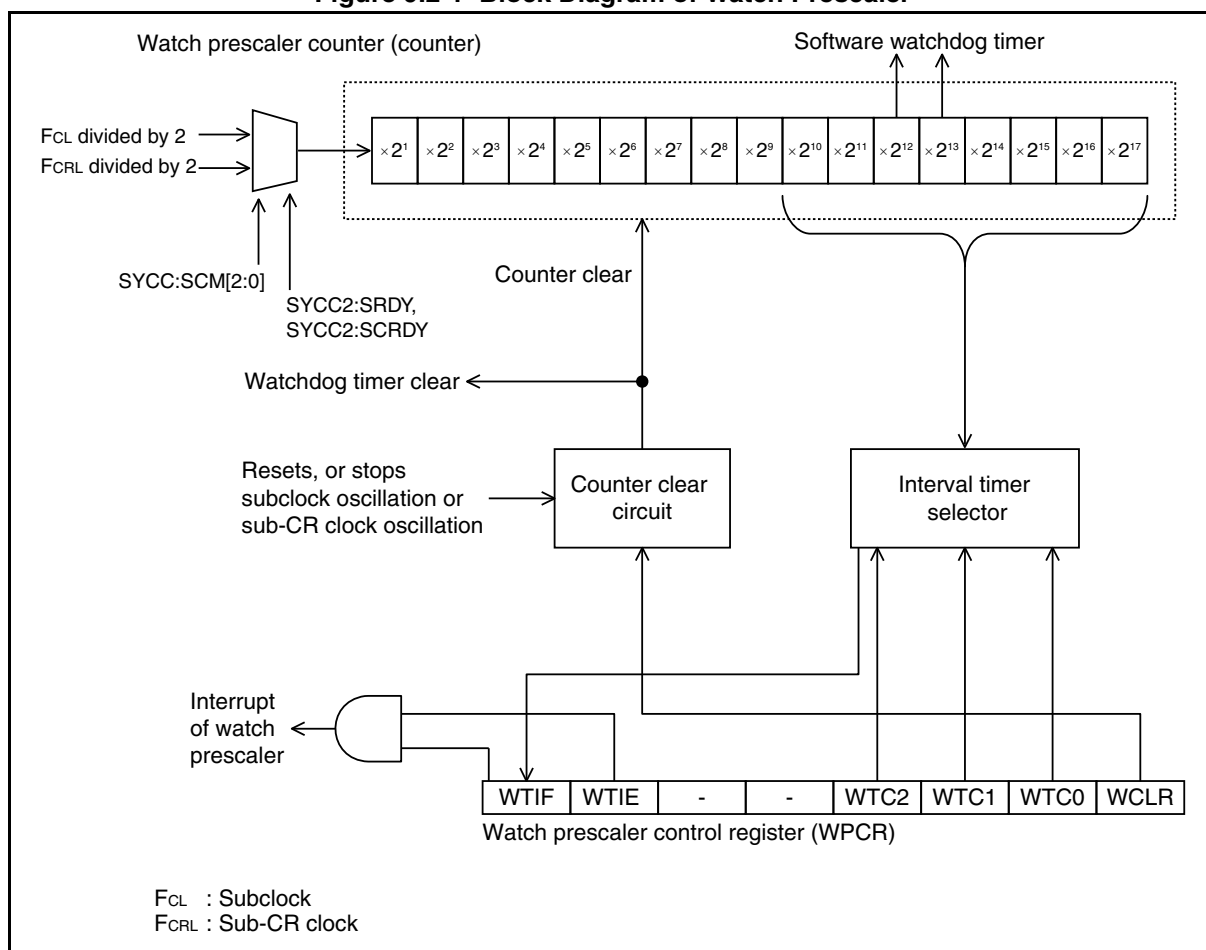

9.2 Configuration

The watch prescaler consists of the following blocks:

- **Watch prescaler counter**
- **Counter clear circuit**
- **Interval timer selector**
- **Watch prescaler control register (WPCR)**

■ Block Diagram of Watch Prescaler

Figure 9.2-1 Block Diagram of Watch Prescaler

- Watch prescaler counter (counter)

This is a 16-bit downcounter that uses the subclock divided by two or the sub-CR clock divided by two as its count clock.

- Counter clear circuit

This circuit controls the clearing of the watch prescaler.

- Interval timer selector

This circuit selects one out of the eight bits used for the interval timer among 17 bits available in the watch prescaler counter.

- Watch prescaler control register (WPCR)

This register selects the interval time, clears the counter, controls interrupts and checks the status.

■ Input Clock

The watch prescaler uses the subclock divided by two or the sub-CR clock divided by two as its input clock (count clock).

■ Output Clock

The watch prescaler supplies its clock to the software watchdog timer.

9.3 Interrupt

An interrupt request is generated when the selected interval time of the watch prescaler has elapsed (interval timer function).

■ Interrupts in Operation of Interval Timer Function (Watch Prescaler Interrupts)

In any mode except the stop mode in which the subclock mode or the sub-CR clock mode is used, if the watch prescaler counter counts down using the subclock divided by two or the sub-CR clock divided by two and the selected interval time elapses, the watch prescaler interrupt request flag bit is set to "1" (WPCR:WTIF = 1). At that time, if the watch prescaler interrupt request enable bit has been enabled (WPCR:WTIE = 1), an interrupt request is output from the watch prescaler to the interrupt controller.

- Regardless of the value in the WTIE bit, the WTIF bit is set to "1" as soon as the time set by the watch prescaler interrupt interval time select bits has elapsed.
- When the WTIF bit is set to "1", changing the WTIE bit from the disable state to the enable state (WPCR:WTIE = 0 → 1) immediately generates an interrupt request.
- The WTIF bit will not be set to "1" if the counter is cleared (WPCR:WCLR = 1) at the same time as the selected bit overflows.
- Write "0" to the WTIF bit in the interrupt service routine to clear an interrupt request.

Note:

To enable the output of interrupt requests after releasing a reset, set the WTIE bit in the WPCR register to "1" and clear the WTIF bit in the same register simultaneously.

Table 9.3-1 Interrupt of Watch Prescaler

Item	Description
Interrupt condition	Interval time set by "WPCR:WTC[2:0]" has elapsed.
Interrupt flag	WPCR:WTIF
Interrupt enable	WPCR:WTIE

9.4 Operations and Setting Procedure Example

The watch prescaler operates as an interval timer.

■ Operations of Interval Timer Function (Watch Prescaler)

The counter of the watch prescaler continues to count down using the subclock divided by two or the sub-CR clock divided by two as its count clock as long as the subclock or the sub-CR clock oscillates.

When cleared (WPCR:WCLR = 1), the counter starts counting down from "0xFFFF". Once it reaches "0x0000", it returns to "0xFFFF" to continue counting. As soon as the time set by the interrupt interval time select bits has elapsed during the counting down, the watch prescaler interrupt request flag bit (WPCR:WTIF) is set to "1" in any mode except the stop mode in which the subclock mode or the sub-CR clock mode is used. In other words, a watch interrupt request is generated at every selected interval time, based on the time when the counter was last cleared.

■ Clearing Watch Prescaler

If the watch prescaler is cleared, other peripheral functions that are using the watch prescaler output are affected by changes in count time and by other factors.

When clearing the counter using the watch prescaler clear bit (WPCR:WCLR), modify the settings of other peripheral functions so that clearing the counter does not have any unexpected effect on them.

When the output of the watch prescaler is selected as the count clock, clearing the watch prescaler also clears the watchdog timer.

The watch prescaler is cleared not only by the watch prescaler clear bit (WPCR:WCLR) but also when the subclock or the sub-CR clock is stopped and the oscillation stabilization wait time is necessary. The watch prescaler is cleared in the following situations:

- The device transits from the subclock mode or sub-CR clock mode to the stop mode.
- The subclock oscillation enable bit or the sub-CR clock oscillation enable bit in the system clock control register 2 (SYCC2:SOSCE or SCRE) is set to "0" in main clock mode, main PLL clock mode, main CR clock mode, or main CR PLL clock mode.

In addition, the counter of the watch prescaler is cleared and stops operating when a reset is generated.

■ Input Clock Selection for Watch Prescaler

Below are the clocks selected as input clocks of the watch prescaler in different clock modes.

- In main clock mode, main PLL clock mode, main CR clock mode, and main CR PLL clock mode

When the subclock oscillation is enabled and the subclock oscillation stabilization wait time elapses, the subclock is selected as the input clock of the watch prescaler.

When the sub-CR clock oscillation is enabled and the sub-CR clock oscillation stabilization wait time elapses, the sub-CR clock is selected as the input clock of the watch prescaler.

When the subclock oscillation and the sub-CR clock oscillation are enabled, and the oscillation stabilization wait time elapses, the subclock is selected as the input clock of the watch prescaler.

- In subclock mode

Only the subclock is used as the input clock of the watch prescaler.

- In sub-CR clock mode

Only the sub-CR clock is used as the input clock of the watch prescaler.

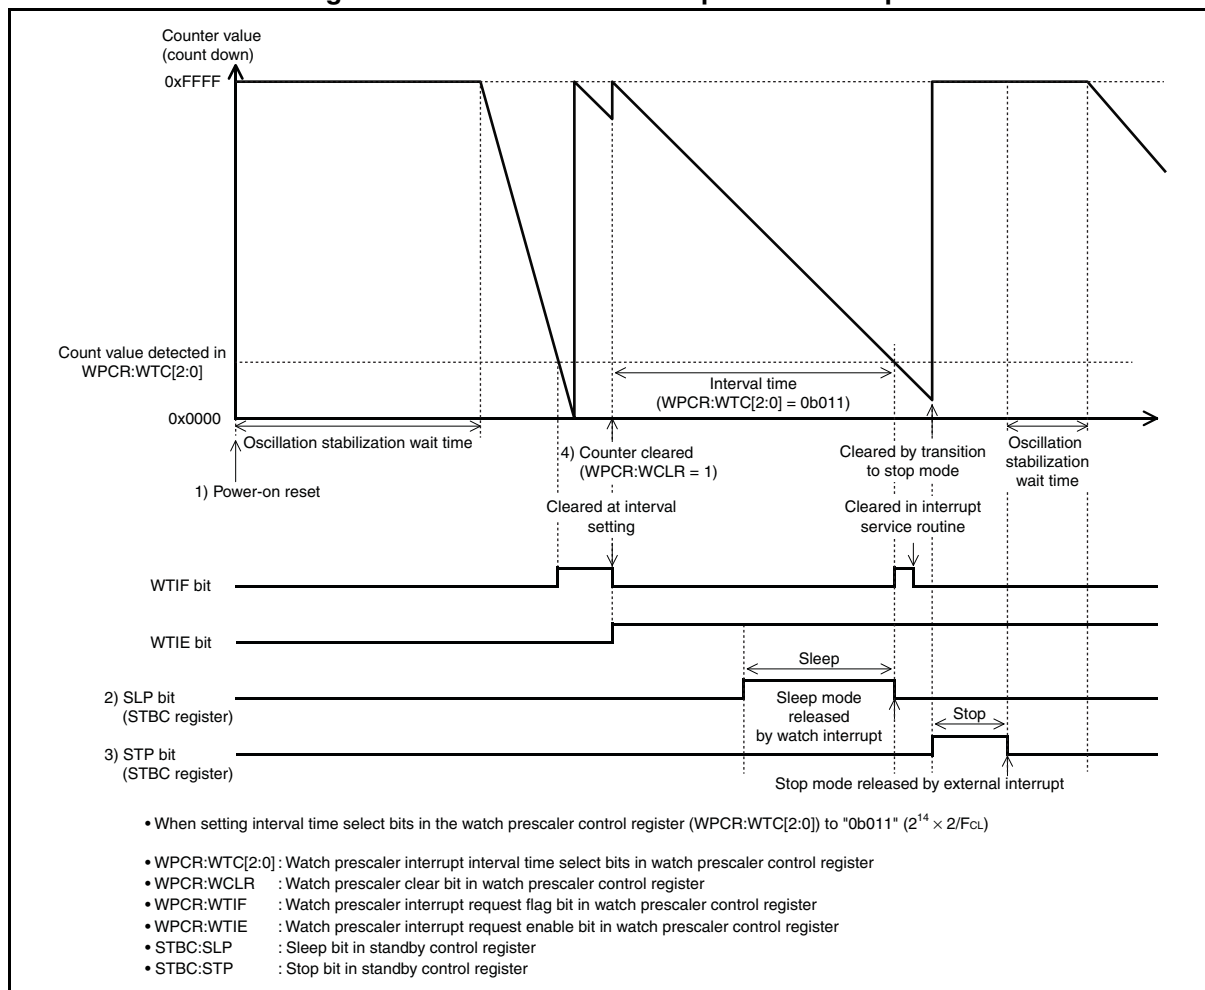

■ Operation Example of Watch Prescaler

Figure 9.4-1 shows an operation example under the following conditions:

1. When a power-on reset occurs
2. When the device transits to the sleep mode during the operation of the interval timer function in subclock mode or sub-CR clock mode
3. When the device transits to the stop mode during the operation of the interval timer function in subclock mode or sub-CR clock mode
4. When a request for clearing the counter is issued

The same operation is performed when changing to the watch mode as for when changing to the sleep mode.

Figure 9.4-1 Watch Prescaler Operation Example

■ Setting Procedure Example

Below is an example of procedure for setting the watch prescaler.

● Initial settings

1. Set the interrupt level. (ILR*)
2. Set the interval time. (WPCR:WTC[2:0])
3. Enable interrupts and clear the interrupt request flag. (WPCR:WTIE = 1, WPCR:WTIF = 0)
4. Clear the counter. (WPCR:WCLR = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Processing interrupts

1. Clear the interrupt request flag. (WPCR:WTIF = 0)
2. Clear the counter. (WPCR:WCLR = 1)

9.5 Register

This section describes the register of the watch prescaler.

Table 9.5-1 List of Watch Prescaler Register

Register abbreviation	Register name	Reference
WPCR	Watch prescaler control register	9.5.1

9.5.1 Watch Prescaler Control Register (WPCR)

The watch prescaler control register (WPCR) is a register used to select the interval time, clear the counter, control interrupts and check the status of the watch prescaler.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	WTIF	WTIE	—	—	WTC2	WTC1	WTC0	WCLR
Attribute	R/W	R/W	—	—	R/W	R/W	R/W	W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] WTIF: Watch prescaler interrupt request flag bit

This bit is set to "1" when the interval time selected by the watch prescaler has elapsed.

When this bit and the watch prescaler interrupt request enable bit (WTIE) are set to "1", a watch prescaler interrupt request is output.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit7	Details
Reading "0"	Indicates that the interval time has not elapsed.
Reading "1"	Indicates that the interval time has elapsed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit6] WTIE: Watch prescaler interrupt request enable bit

This bit enables or disables output of interrupt requests to interrupt controller.

When this bit and the watch prescaler interrupt request flag bit (WTIF) are set to "1", a watch prescaler interrupt request is output.

bit6	Details
Writing "0"	Disables the watch prescaler interrupt request.
Writing "1"	Enables the watch prescaler interrupt request.

[bit5:4] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit3:1] WTC[2:0]: Watch prescaler interrupt interval time select bits

These bits select the interval time.

bit3:1	Details	
	Interval time (Subclock, $F_{CL} = 32.768 \text{ kHz}$)	Interval time (Sub-CR clock, $F_{CRL} = 100 \text{ kHz}$)
Writing "100"	$2^{10} \times 2/F_{CL}$ (62.5 ms)	$2^{10} \times 2/F_{CRL}$ (20.48 ms)
Writing "000"	$2^{11} \times 2/F_{CL}$ (125 ms)	$2^{11} \times 2/F_{CRL}$ (40.96 ms)
Writing "001"	$2^{12} \times 2/F_{CL}$ (250 ms)	$2^{12} \times 2/F_{CRL}$ (81.92 ms)
Writing "010"	$2^{13} \times 2/F_{CL}$ (500 ms)	$2^{13} \times 2/F_{CRL}$ (163.84 ms)
Writing "011"	$2^{14} \times 2/F_{CL}$ (1 s)	$2^{14} \times 2/F_{CRL}$ (327.68 ms)
Writing "101"	$2^{15} \times 2/F_{CL}$ (2 s)	$2^{15} \times 2/F_{CRL}$ (655.36 ms)
Writing "110"	$2^{16} \times 2/F_{CL}$ (4 s)	$2^{16} \times 2/F_{CRL}$ (1.311 s)
Writing "111"	$2^{17} \times 2/F_{CL}$ (8 s)	$2^{17} \times 2/F_{CRL}$ (2.621 s)

[bit0] WCLR: Watch prescaler clear bit

This bit clears all bits in the counter of the watch prescaler to "1".

bit0	Details
Read access	The read value is always "0".
Writing "0"	Has no effect on operation.
Writing "1"	Clears all bits in the counter of the watch prescaler to "1".

Note: When the output of the watch prescaler is selected as the count clock of the software watchdog timer, clearing the watch prescaler with this bit also clears the software watchdog timer.

9.6 Notes on Using Watch Prescaler

This section provides notes on using the watch prescaler.

■ Notes on Using Watch Prescaler

- When setting interrupt processing in a program

The watch prescaler cannot be waken up from interrupt processing if the watch prescaler interrupt request flag bit (WPCR:WTIF) is set to "1" and the interrupt request is enabled (WPCR:WTIE = 1). Always clear the WTIF bit in the interrupt routine.

- Clearing the watch prescaler

When the watch prescaler is selected as the count clock of the software watchdog timer (WDTC:CS[1:0], CSP = 0b100 or 0b110), clearing the watch prescaler also clears the software watchdog timer.

- Watch prescaler interrupts

In stop mode in which the main clock, the main PLL clock, the main CR clock, or the main CR PLL clock is used, the watch prescaler performs counting, and can generate the watch prescaler interrupt.

- Peripheral functions receiving clock from the watch prescaler

If the counter of the watch prescaler is cleared when the output of the watch prescaler is used in other peripheral functions, the operations of such peripheral functions may be affected such as the changing of their operating cycles.

After the counter of the watch prescaler is cleared, the clock for the software watchdog timer output from the watch prescaler returns to the initial state. However, since the software watchdog timer counter is also cleared at the same time as the clock for the software watchdog timer returns to the initial state, the software watchdog timer operates in its normal cycle.

CHAPTER 10

WATCH COUNTER

This chapter describes the functions and operations of the watch counter.

- 10.1 Overview
- 10.2 Configuration
- 10.3 Interrupt
- 10.4 Operations and Setting Procedure Example
- 10.5 Registers
- 10.6 Notes on Using Watch Counter

10.1 Overview

The watch counter generates interrupt requests at intervals from 40.96 ms (min.) to 63 s (max.).

■ Function of Watch Counter

The watch counter performs counting for the number of times specified in the watch counter data register (WCDR) by using a selected count clock and generates an interrupt request. The count clock can be selected from eight types shown in Table 10.1-1. The count value can be set to any number from "0" to "63". No interrupt request is generated when "0" is selected as the count value.

When the count clock is set to 1 s and the count value "60", an interrupt request is generated every one minute.

Table 10.1-1 Count Clock Types

	Count clock (Sub-CR clock) ($2^n \times 2/F_{CRL}^{*1}$)	Count clock (Subclock) ($2^n \times 2/F_{CL}^{*2}$)
n = 11	40.96 ms	125 ms
n = 12	81.92 ms	250 ms
n = 13	163.84 ms	500 ms
n = 14	327.68 ms	1 s

*1: $2/F_{CRL} = 20 \mu\text{s}$ when $F_{CRL} = 100 \text{ kHz}$

*2: $2/F_{CL} = 61.035 \mu\text{s}$ when $F_{CL} = 32.768 \text{ kHz}$

Note:

Refer to the device data sheet for the accuracy of the sub-CR clock frequency.

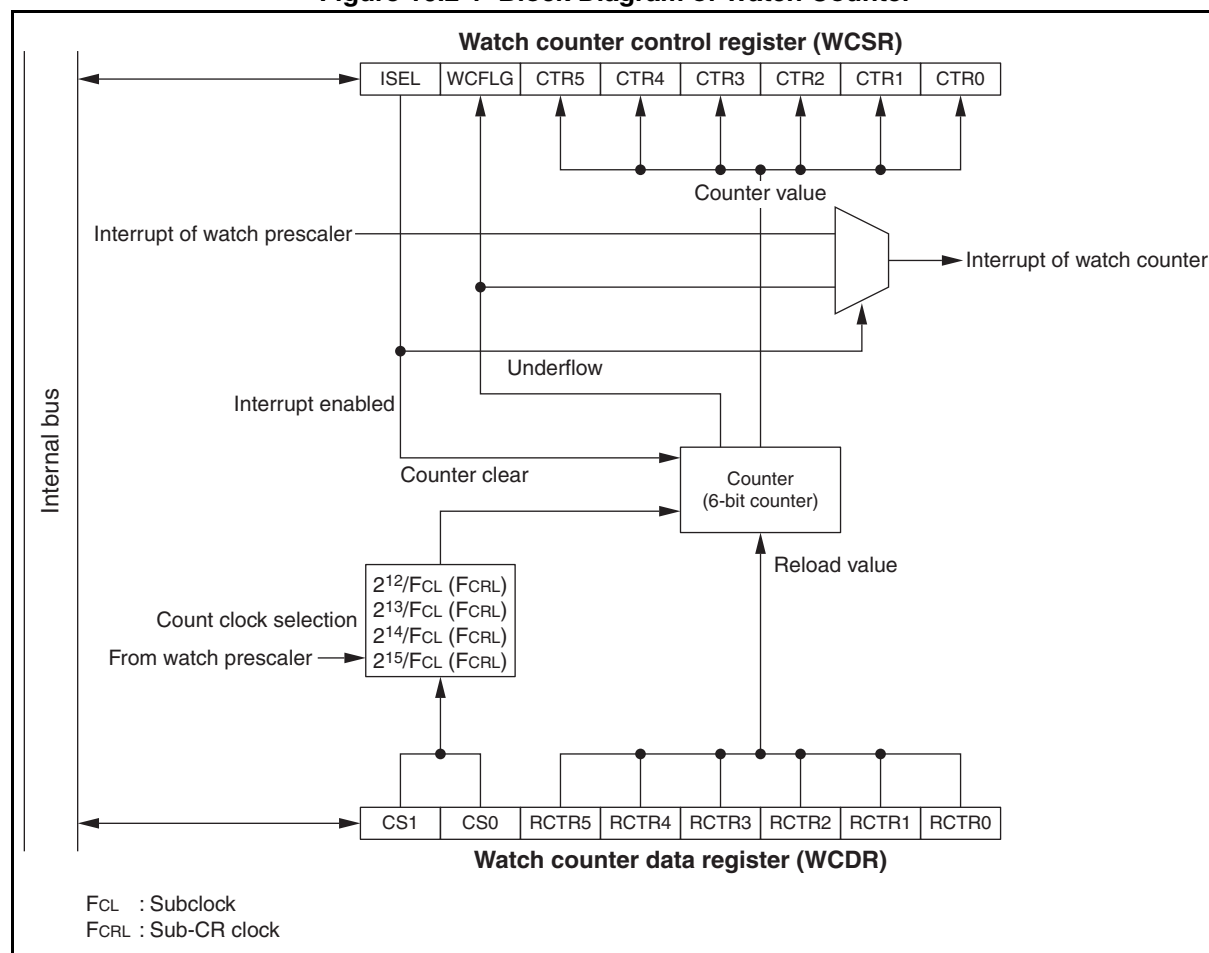

10.2 Configuration

The watch counter consists of the following blocks:

- Counter
- Watch counter control register (WCSR)
- Watch counter data register (WCDR)

■ Block Diagram of Watch Counter

Figure 10.2-1 Block Diagram of Watch Counter

- Counter

This is a 6-bit downcounter using the output clock of the watch prescaler as its count clock.

- Watch counter control register (WCSR)

This register controls interrupts, checks interrupt status and reads the count value.

- Watch counter data register (WCDR)

This register selects the count clock and sets the counter reload value.

- **Input Clock**

The watch counter uses the output clock of the watch prescaler as its input clock (count clock).

10.3 Interrupt

The watch counter outputs an interrupt request when the counter underflows (counter value = 0b000001).

■ Watch Counter Interrupt

When the counter of the watch counter underflows, the watch counter interrupt request flag bit (WCFLG) in the watch counter control register (WCSR) is set to "1". Provided that the watch counter start and interrupt request enable bit (ISEL) in the WCSR register has also been set to "1", the watch counter outputs an interrupt request to the interrupt controller.

Table 10.3-1 shows the interrupt control bits and interrupt sources of the watch counter.

Table 10.3-1 Interrupt Control Bits and Interrupt Sources of Watch Counter

Item	Details
Interrupt request flag bit	WCSR:WCFLG
Interrupt request enable bit	WCSR:ISEL
Interrupt source	Counter underflow

10.4 Operations and Setting Procedure Example

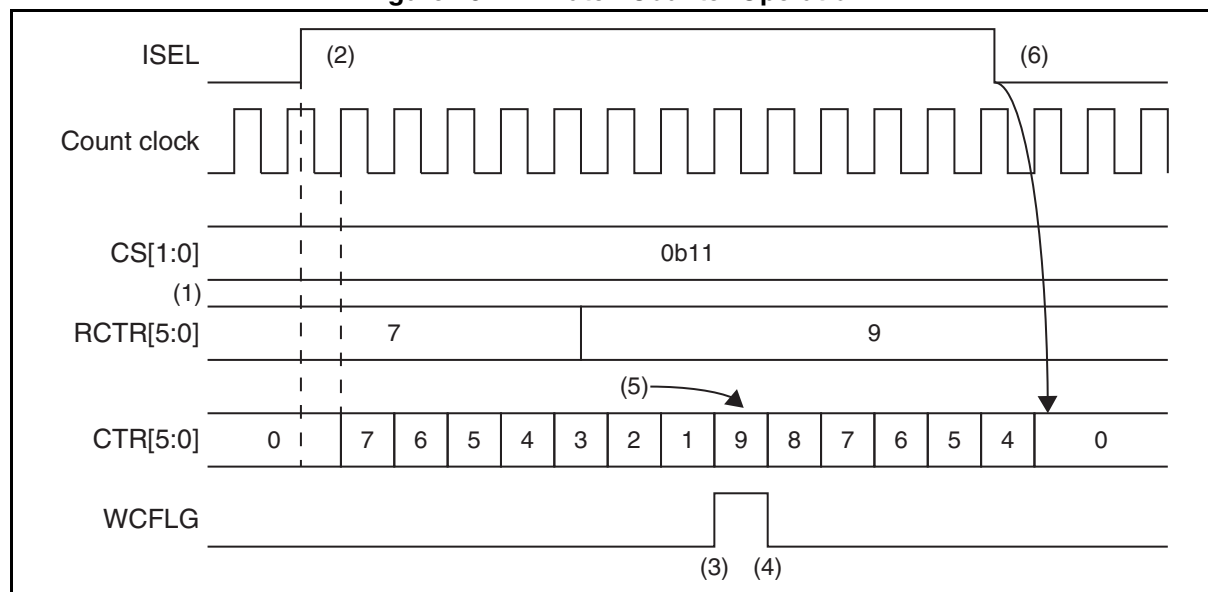

With the ISEL bit in the WCSR register set to "1", the watch counter counts down for the number of times specified as a count value in the RCTR[5:0] bits in the WCDR register with the count clock selected in the CS[1:0] bits in the WCDR register. When the counter underflows, the WCFLG bit in the WCSR register is set to "1", and the watch counter generates an interrupt request.

■ Setup Procedure of Watch Counter

Below is the procedure for setting up the watch counter.

1. Select the count clock (CS[1:0]) and set the counter reload value (RCTR[5:0]).
2. Set the ISEL bit to "1" to start a down count and enable interrupts. In addition, disable interrupts of the watch prescaler.
The watch counter performs counting by using a divided clock (asynchronous) from the watch prescaler. An error of up to one count clock may occur at the beginning of a count cycle, depending on the time at which the ISEL bit is set to "1".
3. When the counter underflows, the WCFLG bit is set to "1", causing the watch counter to generate an interrupt request.
4. Write "0" to the WCFLG bit to clear it.
5. When the RCTR[5:0] bits are modified during counting, the reload value is updated at a reload occurring after the counter is set to "1".
6. When "0" is written to the ISEL bit, the counter becomes "0" and stops operating.

Figure 10.4-1 Watch Counter Operation

Note:

Before restarting the counter by setting the ISEL bit to "0" stop the counter, read the CTR[5:0] bits in the WCSR register twice and ensure that the CTR[5:0] bits have been cleared to "0b000000".

■ Operation in Substop Mode and Sub-CR Clock Stop Mode

When the device enters substop mode or sub-CR clock stop mode, the watch counter stops the count operation and the watch prescaler is also cleared. Therefore, the watch counter cannot count the correct value after the device exits substop mode or sub-CR clock stop mode. After the device exits substop mode or sub-CR clock stop mode, always write "0" to the ISEL bit in the WCSR register to clear the counter. In any other standby mode except the substop mode and sub-CR clock stop mode, the watch counter keeps operating.

■ Operation in Main Stop Mode and Main CR Clock Stop Mode

In main stop mode or main CR clock stop mode, though the watch counter continues the count operation, no interrupt is generated. The watch counter stops when the subclock oscillation enable bit (SOSCE) and sub-CR clock oscillation enable bit (SCRE) in the system clock control register 2 (SYCC2) are both set to "0".

■ Setting Procedure Example

Below is an example of procedure for setting the watch counter.

● Initial settings

1. Set the interrupt level. (ILR*)
2. Select the count clock. (WCDR:CS[1:0])
3. Set the counter reload value. (WCDR:RCTR[5:0])
4. Activate the watch counter and enable interrupts. (WCSR:ISEL = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

1. Clear the interrupt request flag. (WCSR:WCFLG = 0)
2. Process any interrupt.

10.5 Registers

This section describes the registers of the watch counter.

Table 10.5-1 List of Watch Counter Registers

Register abbreviation	Register name	Reference
WCDR	Watch counter data register	10.5.1
WCSR	Watch counter control register	10.5.2

10.5.1 Watch Counter Data Register (WCDR)

The watch counter data register (WCDR) selects the count clock and sets the counter reload value.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	CS1	CS0	RCTR5	RCTR4	RCTR3	RCTR2	RCTR1	RCTR0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	1	1	1	1	1	1

■ Register Functions

[bit7:6] CS[1:0]: Watch counter count clock select bits

These bits select the count clock of the watch counter.

Ensure that the ISEL bit in the WCSR register has been set to "0" before modifying these bits.

bit7:6	Details	
	Count clock (Subclock, $F_{CL} = 32.768 \text{ kHz}$)	Count clock (Sub-CR clock, $F_{CRL} = 100 \text{ kHz}$)
Writing "00"	$2^{12}/F_{CL}$ (125 ms)	$2^{12}/F_{CRL}$ (40.96 ms)
Writing "01"	$2^{13}/F_{CL}$ (250 ms)	$2^{13}/F_{CRL}$ (81.92 ms)
Writing "10"	$2^{14}/F_{CL}$ (500 ms)	$2^{14}/F_{CRL}$ (163.84 ms)
Writing "11"	$2^{15}/F_{CL}$ (1 s)	$2^{15}/F_{CRL}$ (327.68 ms)

[bit5:0] RCTR[5:0]: Watch counter counter reload value setting bits

These bits set the counter reload value.

When the counter reload value is modified during the count operation, the new value becomes effective at a reload after the counter underflows.

When the RCTR[5:0] bits are set to "0", no interrupt request is to be generated.

When the counter reload value is modified at the same time as an interrupt request is generated (WCSR:WCFLR = 1), the value to be reloaded is not correct. Therefore, modifying the counter reload value should be done before an interrupt request is generated, i.e. during the interrupt service routine or after the stopping of the watch counter (WCSR:ISEL = 0).

10.5.2 Watch Counter Control Register (WCSR)

The watch counter control register (WCSR) controls the watch counter operation and the interrupt of the watch counter, and reads the counter value.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	ISEL	WCFLG	CTR5	CTR4	CTR3	CTR2	CTR1	CTR0
Attribute	R/W	R/W	R	R	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] ISEL: Watch counter start and interrupt request enable bit

This bit starts the watch counter, and enables or disables the interrupt request of the watch counter and that of the watch prescaler.

Always disable the interrupt request of the watch prescaler before setting this bit to "1" to enable the interrupt request of the watch counter.

The watch counter counts with the asynchronous clock from the watch prescaler. Therefore, an error of up to one count clock may occur at the beginning of counting, depending on the time of setting the ISEL bit to "1".

bit7	Details
Writing "0"	Stops the watch counter and disables the interrupt request of the watch counter (enables the interrupt request of the watch prescaler).
Writing "1"	Starts the watch counter and enables the interrupt request of the watch counter (disables the interrupt request of the watch prescaler).

[bit6] WCFLG: Watch counter interrupt request flag bit

This bit is set to "1" when the counter underflows.

When this bit and the ISEL bit are both set to "1", a watch counter interrupt request is generated.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit6	Details
Reading "0"	Indicates that no watch counter interrupt request has been generated.
Reading "1"	Indicates that a watch counter interrupt request has been generated.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit5:0] CTR[5:0]: Watch counter counter read bits

These bits read the value of the counter that is counting.

While the counter value is being changed, the counter value that these bits read may not be correct. Therefore, before using the counter value these bits read, ensure that the counter reads the same value in times of reading by reading these bits twice.

Writing values to these bits has no effect on operation.

10.6 Notes on Using Watch Counter

This section provides notes on using the watch counter

- When the watch prescaler is cleared while the watch counter is running, the watch counter may not be able to run normally. Before clearing the watch prescaler, write "0" to the ISEL bit in the WCSR register to stop the watch counter.
- Before writing "1" to the ISEL bit to restart the watch counter after stopping it, read the CTR[5:0] bits in the WCSR register twice to ensure that the CTR[5:0] bits have been cleared to "0b000000".

CHAPTER 11

WILD REGISTER FUNCTION

This chapter describes the functions and operations of the wild register function.

- 11.1 Overview
- 11.2 Configuration
- 11.3 Operations
- 11.4 Registers
- 11.5 Typical Hardware Connection Example

11.1 Overview

The wild register function can be used to patch bugs in a program with addresses and modification data, both of which are to be set in built-in registers. This section describes the wild register function.

■ Wild Register Function

The wild register consists of three wild register data setting registers, three wild register address setting registers, a 1-byte address compare enable register and a 1-byte wild register data test setting register. If addresses and data that are to be modified are set to these registers, ROM data can be replaced with modification data set in the registers. Data of up to three different addresses can be modified.

The wild register function can be used to debug a program after creating the mask and to patch bugs in the program.

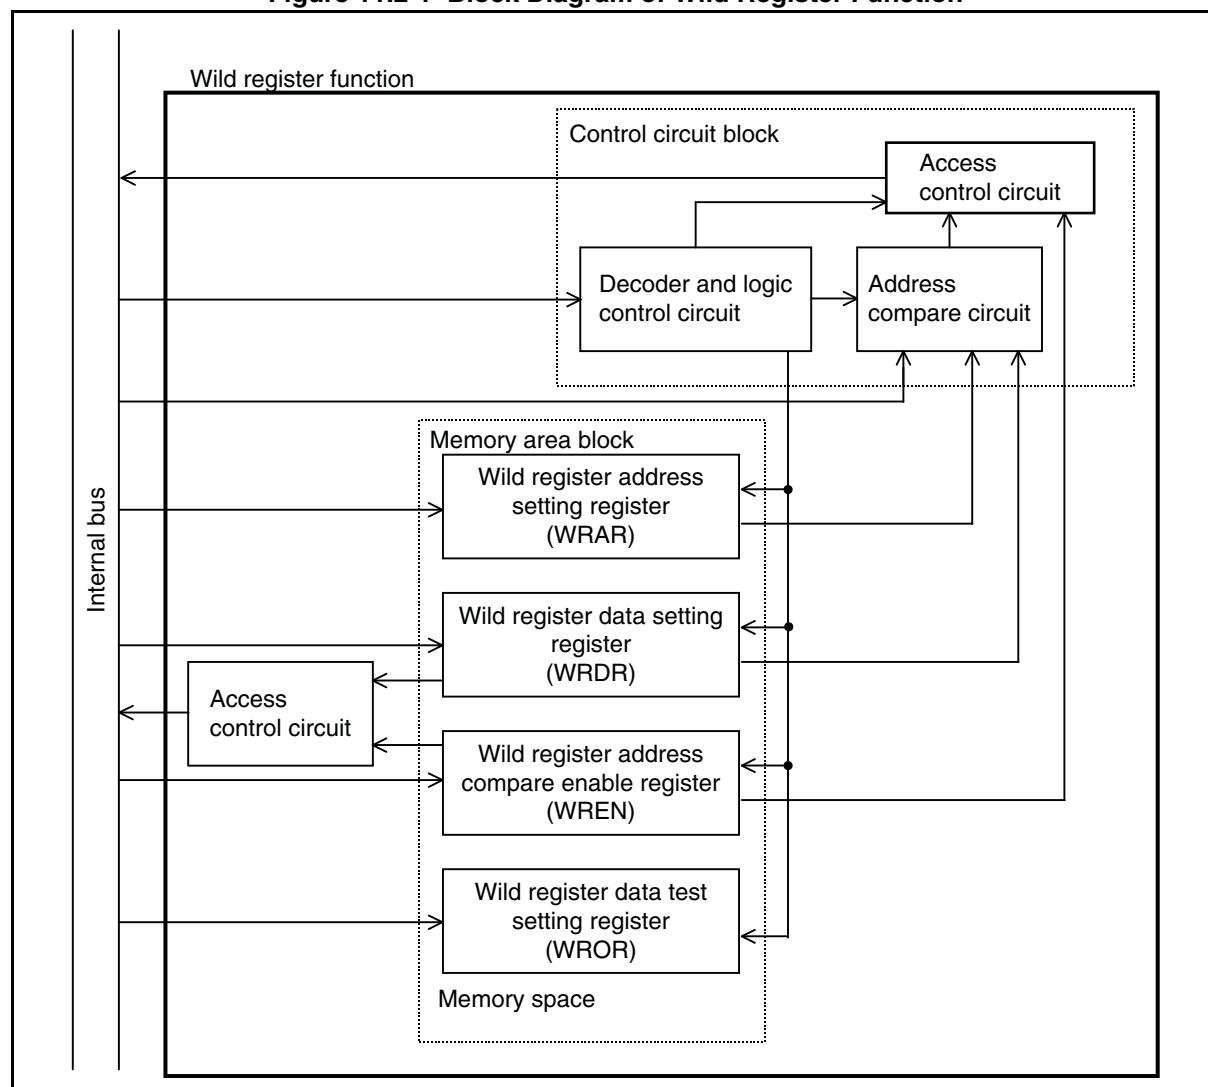

11.2 Configuration

The block diagram of the wild register is shown below. The wild register consists of the following blocks:

- Memory area block
 - Wild register data setting register (WRDR0 to WRDR2)
 - Wild register address setting register (WRAR0 to WRAR2)
 - Wild register address compare enable register (WREN)
 - Wild register data test setting register (WROR)
- Control circuit block

■ Block Diagram of Wild Register Function

Figure 11.2-1 Block Diagram of Wild Register Function

- Memory area block

The memory area block consists of the wild register data setting registers (WRDR), wild register address setting registers (WRAR), wild register address compare enable register (WREN) and wild register data test setting register (WROR). The wild register function is used to specify the addresses and data that need to be replaced. The wild register address compare enable register (WREN) enables the wild register function for each wild register data setting register (WRDR). In addition, the wild register data test setting register (WROR) enables the normal read function for each wild register data setting register (WRDR).

- Control circuit block

This circuit compares the actual address data with addresses set in the wild register address setting registers (WRAR). If they match, the circuit outputs the data from the wild register data setting register (WRDR) to the data bus. The operation of the control circuit block is controlled by the wild register address compare enable register (WREN).

11.3 Operations

This section describes the procedure for setting the wild register function.

■ Procedure for Setting Wild Register Function

Prepare a program that can read the value to be set in the wild register from external memory (e.g. EEPROM or FRAM) in the user program before using the wild register function. The setting method for the wild register is shown below.

This section does not include information on the method of communications between the external memory and the device.

- Write the address of the built-in ROM code that will be modified to the wild register address setting register (WRAR0 to WRAR2).
- Write a new code to the wild register data setting register (WRDR0 to WRDR2) corresponding to the wild register address setting register to which the address has been written.
- Write "1" to the EN bit in the wild register address compare enable register (WREN) corresponding to the wild register number to enable the wild register function represented by that wild register number.

Table 11.3-1 shows the procedure for setting the registers of the wild register function.

Table 11.3-1 Procedure for Setting Registers of Wild Register Function

Step	Operation	Operation example
1	Read replacement data from a peripheral function outside through a certain communication method.	Suppose the built-in ROM code to be modified is at the address 0xF011 and the data to be modified is "0xB5", and there are three built-in ROM codes to be modified.
2	Write the replacement address to a wild register address setting register (WRAR0 to WRAR2).	Set wild register address setting registers (WRAR0 = 0xF011, WRAR1 = ..., WRAR2 = ...).
3	Write a new ROM code (replacement for the built-in ROM code) to a wild register data setting register (WRDR0 to WRDR2).	Set the wild register data setting registers (WRDR0 = 0xB5, WRDR1 = ..., WRDR2 = ...).
4	Enable the EN bit in the wild register address compare enable register (WREN) corresponding to the wild register number of the wild register function used.	Setting bit0 of the address compare enable register (WREN) to "1" enables the wild register function of the wild register number 0. If the address matches the value set in the wild register address setting register (WRAR), the value of the wild register data setting register (WRDR) will be replaced with the built-in ROM code. When replacing more than one built-in ROM code, enable the related EN bits in the wild register address compare enable register (WREN) corresponding to respective built-in ROM codes.

■ Wild Register Function Applicable Addresses

The wild register function can be applied to all address space except the address "0x0078".

Since the address "0x0078" is used as a mirror address for the register bank pointer and the direct bank pointer, this address cannot be patched.

11.4 Registers

This section describes the registers of the wild register function.

Table 11.4-1 List of Hardware/software Watchdog Timer Register

Register abbreviation	Register name	Reference
WRDR0	Wild register data setting register 0	11.4.1
WRDR1	Wild register data setting register 1	11.4.1
WRDR2	Wild register data setting register 2	11.4.1
WRAR0	Wild register address setting register 0	11.4.2
WRAR1	Wild register address setting register 1	11.4.2
WRAR2	Wild register address setting register 2	11.4.2
WREN	Wild register address compare enable register	11.4.3
WROR	Wild register data test setting register	11.4.4

■ Wild Register Number

A wild register number is assigned to each wild register address setting register (WRAR) and each wild register data setting register (WRDR).

Table 11.4-2 Wild Register Numbers Corresponding to Wild Register Address Setting Registers and Wild Register Data Setting Registers

Wild register number	Wild register address setting register (WRAR)	Wild register data setting register (WRDR)
0	WRAR0	WRDR0
1	WRAR1	WRDR1
2	WRAR2	WRDR2

11.4.1 Wild Register Data Setting Registers (WRDR0 to WRDR2)

The wild register data setting registers (WRDR0 to WRDR2) use the wild register function to specify the data to be modified.

■ Register Configuration

WRDR0

bit	7	6	5	4	3	2	1	0
Field	RD7	RD6	RD5	RD4	RD3	RD2	RD1	RD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

WRDR1

bit	7	6	5	4	3	2	1	0
Field	RD7	RD6	RD5	RD4	RD3	RD2	RD1	RD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

WRDR2

bit	7	6	5	4	3	2	1	0
Field	RD7	RD6	RD5	RD4	RD3	RD2	RD1	RD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:0] RD[7:0]: Wild register data setting bits

These bits specify the data to be modified by the wild register function.

These bits are used to set the modification data at the address assigned by the wild register address setting register (WRAR). Data is valid at an address corresponding to one of the wild register numbers.

The read access to one of these bits is enabled only when the data test setting bit in the wild register data test setting register (WROR) corresponding to the bit to be read is set to "1".

11.4.2 Wild Register Address Setting Registers (WRAR0 to WRAR2)

The wild register address setting registers (WRAR0 to WRAR2) set the address to be modified by the wild register function.

■ Register Configuration

WRAR0

bit	15	14	13	12	11	10	9	8
Field	RA15	RA14	RA13	RA12	RA11	RA10	RA9	RA8

Initial value	0	0	0	0	0	0	0	0

WRAR2

bit	15	14	13	12	11	10	9	8
Field	RA15	RA14	RA13	RA12	RA11	RA10	RA9	RA8
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

bit	7	6	5	4	3	2	1	0
Field	RA7	RA6	RA5	RA4	RA3	RA2	RA1	RA0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit15:0] RA[15:0]: Wild register address setting bits

These bits set the address to be modified by the wild register function.

The address to be assigned to modification data is set to these bits. The address is to be specified according to the wild register number corresponding to a wild register address setting register.

11.4.3 Wild Register Address Compare Enable Register (WREN)

The wild register address compare enable register (WREN) enables or disables the operations of wild register functions using their respective wild register numbers.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	Reserved	Reserved	Reserved	EN2	EN1	EN0
Attribute	—	—	W	W	W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5:3] Reserved bits

Always set these bits to "0".

[bit2:0] EN[2:0]: Wild register address compare enable bits

These bits enable or disable the operation of the wild register.

- EN0 corresponds to wild register number 0.
- EN1 corresponds to wild register number 1.
- EN2 corresponds to wild register number 2.

bit2/bit1/bit0	Details
Writing "0"	Disables the operation of the wild register function.
Writing "1"	Enables the operation of the wild register function.

11.4.4 Wild Register Data Test Setting Register (WROR)

The wild register data test setting register (WROR) enables or disables data reading from the corresponding wild register data setting register (WRDR0 to WRDR2).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	Reserved	Reserved	Reserved	DRR2	DRR1	DRR0
Attribute	—	—	W	W	W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5:3] Reserved bits

Always set these bits to "0".

[bit2:0] DRR[2:0]: Wild register data test setting bits

These bits enable or disable the normal reading from the corresponding data setting register of the wild register.

- DRR0 corresponds to wild register number 0.
- DRR1 corresponds to wild register number 1.
- DRR2 corresponds to wild register number 2.

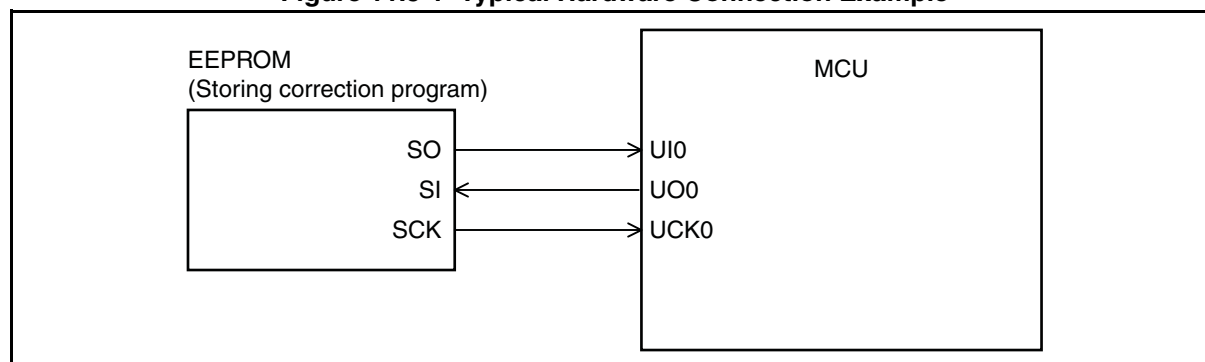

bit2/bit1/bit0	Details
Writing "0"	Disables reading from the wild register data setting register.
Writing "1"	Enables reading from the wild register data setting register.

11.5 Typical Hardware Connection Example

Below is an example of typical hardware connection for the application of the wild register function.

■ Hardware Connection Example

Figure 11.5-1 Typical Hardware Connection Example

CHAPTER 12

8/16-BIT COMPOSITE TIMER

This chapter describes the functions and operations of the 8/16-bit composite timer.

- 12.1 Overview
- 12.2 Configuration
- 12.3 Channel
- 12.4 Pins
- 12.5 Interrupts
- 12.6 Operation of Interval Timer Function (One-shot Mode)
- 12.7 Operation of Interval Timer Function (Continuous Mode)
- 12.8 Operation of Interval Timer Function (Free-run Mode)
- 12.9 Operation of PWM Timer Function (Fixed-cycle Mode)
- 12.10 Operation of PWM Timer Function (Variable-cycle Mode)
- 12.11 Operation of PWC Timer Function
- 12.12 Operation of Input Capture Function
- 12.13 Operation of Noise Filter
- 12.14 Registers
- 12.15 Notes on Using 8/16-bit Composite Timer

12.1 Overview

The 8/16-bit composite timer consists of two 8-bit counters. It can be used as two 8-bit timers, or as a 16-bit timer if the two counters are connected in cascade.

The 8/16-bit composite timer has the following functions:

- Interval timer function
- PWM timer function
- PWC timer function (pulse width measurement)
- Input capture function

■ Interval Timer Function (One-shot Mode)

When the interval timer function (one-shot mode) is selected, the counter starts counting from "0x00" as the timer is started. When the counter value matches the value of the 8/16-bit composite timer data register, the timer output is inverted, an interrupt request occurs, and the counter stops counting.

■ Interval Timer Function (Continuous Mode)

When the interval timer function (continuous mode) is selected, the counter starts counting from "0x00" as the timer is started. When the counter value matches the value of the 8/16-bit composite timer data register, the timer output is inverted, an interrupt request occurs, and the counter counts from "0x00" again. The timer outputs square wave as a result of this repeated operation.

■ Interval Timer Function (Free-run Mode)

When the interval timer function (free-run mode) is selected, the counter starts counting from "0x00". When the counter value matches the value of the 8/16-bit composite timer data register, the timer output is inverted and an interrupt request occurs. Under these conditions, if the counter continues to count and reaches "0xFF", it restarts counting from "0x00". The timer outputs square wave as a result of this repeated operation.

■ PWM Timer Function (Fixed-cycle Mode)

When the PWM timer function (fixed-cycle mode) is selected, a PWM signal with a variable "H" pulse width is generated in fixed cycles. The cycle is fixed at "0xFF" in 8-bit operation or at "0xFFFF" in 16-bit operating mode. The time is determined by the count clock selected. The "H" pulse width is specified by setting a specific register.

■ PWM Timer Function (Variable-cycle Mode)

When the PWM timer function (variable-cycle mode) is selected, two 8-bit counters are used to generate an 8-bit PWM signal of variable cycle and duty depending on the cycle and "L" pulse width specified by registers.

In this operating mode, since the two 8-bit counters have to be used separately, the composite timer cannot operate as a 16-bit counter.

■ PWC Timer Function

When the PWC timer function is selected, the width and cycle of an external input pulse can be measured.

In this operating mode, the counter starts counting from "0x00" immediately after a count start edge of an external input signal is detected. Afterward, when a count end edge is detected, the counter transfers its value to a register to generate an interrupt.

■ Input Capture Function

When the input capture function is selected, the counter value is stored in a register immediately after the detection of an edge of an external input signal.

This function is available in either free-run mode or clear mode for count operation.

In clear mode, the counter starts counting from "0x00", and transfers its value to a register to generate an interrupt after an edge is detected. Afterward, the counter restarts counting from "0x00".

In free-run mode, the counter transfers its value to a register to generate an interrupt immediately after the detection of an edge. Afterward, unlike in clear mode, the counter continues to count without being cleared to "0x00".

12.2 Configuration

The 8/16-bit composite timer consists of the following blocks:

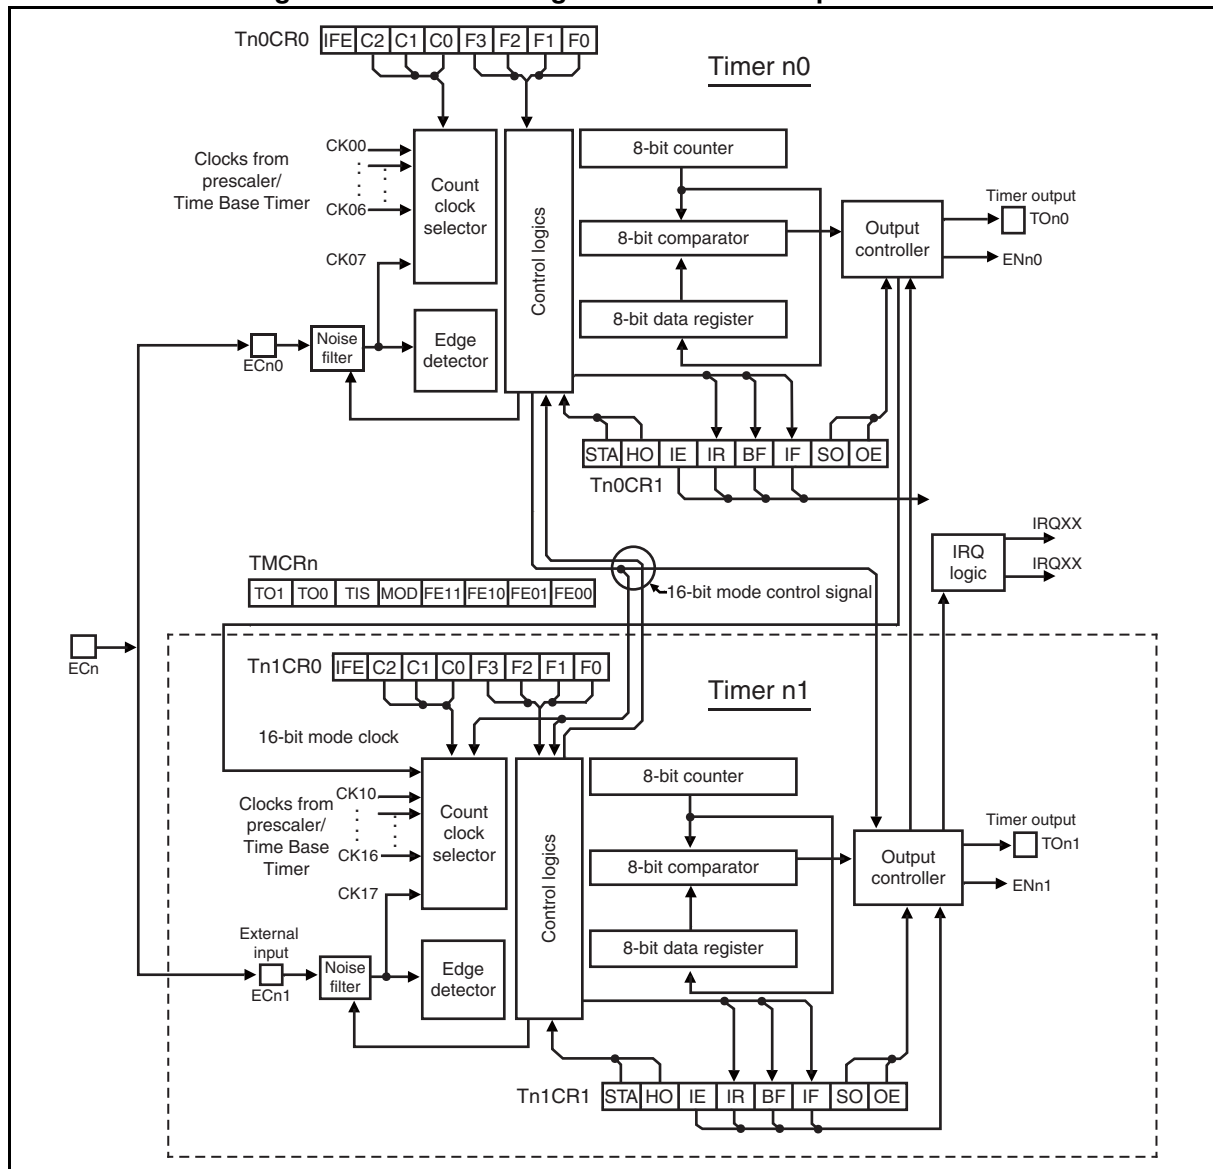

- 8-bit counter
 - 8-bit comparator (including a temporary latch)
 - 8/16-bit composite timer data register (Tn0DR/Tn1DR)
 - 8/16-bit composite timer status control register 0 (Tn0CR0/Tn1CR0)
 - 8/16-bit composite timer status control register 1 (Tn0CR1/Tn1CR1)
 - 8/16-bit composite timer timer mode control register (TMCRn)
 - Output controller
 - Control logic
 - Count clock selector
 - Edge detector
 - Noise filter
-

The number of pins and that of channels of the 8/16-bit composite timer vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of 8/16-bit Composite Timer

Figure 12.2-1 Block Diagram of 8/16-bit Composite Timer

● 8-bit counter

This counter serves as the basis for various timer operations. It can be used either as two 8-bit counters or as a 16-bit counter.

● 8-bit comparator

The comparator compares the value in the 8/16-bit composite timer data register and that in the counter. It incorporates a latch that temporarily stores the 8/16-bit composite timer data register value.

- 8/16-bit composite timer data register (Tn0DR/Tn1DR)

These registers are used to write the maximum value counted during interval timer operation or PWM timer operation and to read the count value during PWC timer operation or input capture operation.

- 8/16-bit composite timer status control register 0 (Tn0CR0/Tn1CR0)

These registers are used to select the timer operating mode and the count clock, and to enable or disable IF flag interrupts.

- 8/16-bit composite timer status control register 1 (Tn0CR1/Tn1CR1)

These registers are used to control interrupt flags, timer output, and timer operation.

- 8/16-bit composite timer timer mode control register (TMCRn)

This register is used to select the noise filter function, 8-bit or 16-bit operating mode, and signal input to timer n0/n1 and to indicate the timer output value.

- Output controller

The output controller controls timer output. The timer output is supplied to the external pin when the pin output has been enabled.

- Control logic

The control logic controls timer operation.

- Count clock selector

The selector selects the counter operating clock signal from different prescaler output signals (divided machine clock signal and time-base timer output signal).

- Edge detector

The edge detector selects the edge of an external input signal to be used as an event for PWC timer operation or input capture operation.

- Noise filter

This filter serves as a noise filter for external input signals. The filter function can be selected from "H" pulse noise elimination, "L" pulse noise elimination, and "H"/"L"-pulse noise elimination.

■ Input Clock

The 8/16-bit composite timer uses the output clock from the prescaler as its input clock (count clock).

12.3 Channel

This section describes the channels of the 8/16-bit composite timer.

■ Channel of 8/16-bit Composite Timer

On a channel, there are two 8-bit counters. They can be used as two 8-bit timers or one 16-bit timer. Table 12.3-1 lists the external pins on a channel.

Table 12.3-1 External Pins of 8/16-bit Composite Timer

Pin name	Pin function
TOn0	Timer n0 output
TOn1	Timer n1 output
ECn	Timer n0 input and timer n1 input

12.4 Pins

This section describes the pins of the 8/16-bit composite timer.

■ Pins of 8/16-bit Composite Timer

The external pins of the 8/16-bit composite timer are TOn0, TOn1 and ECn.

- TOn0 pin

TOn0:

This pin serves as the timer output pin for timer n0 in 8-bit operation or for timers n0 and n1 in 16-bit operating mode. When the output is enabled ($Tn0CR1:OE = 1$) in the interval timer function, PWM timer function, or PWC timer function, this pin becomes an output pin automatically regardless of the port direction register (DDR) and functions as the timer output TOn0 pin.

The output becomes undetermined if output is enabled with the input capture function in use.

- TOn1 pin

TOn1:

This pin serves as the timer output pin for timer n1 in 8-bit operation. When the output is enabled ($Tn1CR1:OE = 1$) in interval timer function, PWM timer function (fixed-cycle mode), or PWC timer function, the pin becomes an output pin automatically regardless of the port direction register (DDR) and functions as the timer output TOn1 pin.

In 16-bit operating mode, if output is enabled with the PWM timer function (variable-cycle mode) or input capture function in use, the output becomes undetermined.

- ECn pin

The ECn pin is connected to the ECn0 and ECn1 internal pins.

ECn0 internal pin:

This pin serves as the external count clock input pin for timer n0 when the interval timer function or PWM timer function is selected, or as the signal input pin for timer n0 when the PWC timer function or input capture function is selected. The pin cannot be set to serve as the external count clock input pin when the PWC timer function or input capture function is selected.

To use the input function mentioned above, set the bit in the port direction register corresponding to ECn pin to "0" to make the pin as an input port.

ECn1 internal pin:

This pin serves as the external count clock input pin for timer n1 when the interval timer function or PWM timer function is selected, or as the signal input pin for timer n1 when the PWC timer function or input capture function is selected. The pin cannot be set to serve as the external count clock input pin when the PWC timer function or input capture function is selected.

In 16-bit operating mode, the input function of this pin is not used. If the PWM timer function (variable-cycle mode) is selected, the input function of this pin can also be used.

To use the input function mentioned above, set the bit in the port direction register corresponding to ECn pin to "0" to make the pin as an input port.

12.5 Interrupts

The 8/16-bit composite timer generates the following types of interrupts. An interrupt number and an interrupt vector are assigned to each type of interrupts.

- Timer n0 interrupt
- Timer n1 interrupt

■ Timer n0 Interrupt

Table 12.5-1 shows the timer n0 interrupt and its sources.

Table 12.5-1 Timer n0 Interrupt

Item	Description		
Interrupt generating source	Comparison match in the interval timer operation or the PWM timer operation (variable-cycle mode)	Overflow in the PWC timer operation or the input capture operation	Completion of measurement in the PWC timer operation or edge detection in the input capture operation
Interrupt flag	Tn0CR1:IF	Tn0CR1:IF	Tn0CR1:IR
Interrupt enable	Tn0CR1:IE and Tn0CR0:IFE	Tn0CR1:IE and Tn0CR0:IFE	Tn0CR1:IE

■ Timer n1 Interrupt

Table 12.5-2 shows the timer n1 interrupt and its sources.

Table 12.5-2 Timer n1 Interrupt

Item	Description		
Interrupt generating source	Comparison match in the interval timer operation or the PWM timer operation (variable-cycle mode), except in 16-bit operating mode	Overflow in the PWC timer operation or the input capture operation, except in 16-bit operating mode	Completion of measurement in the PWC timer operation or edge detection in the input capture operation, except in 16-bit operating mode
Interrupt flag	Tn1CR1:IF	Tn1CR1:IF	Tn1CR1:IR
Interrupt enable	Tn1CR1:IE and Tn1CR0:IFE	Tn1CR1:IE and Tn1CR0:IFE	Tn1CR1:IE

12.6 Operation of Interval Timer Function (One-shot Mode)

This section describes the operation of the interval timer function (one-shot mode) of the 8/16-bit composite timer.

■ Operation of Interval Timer Function (One-shot Mode)

To use the interval timer function (one-shot mode), do the settings shown in Figure 12.6-1.

Figure 12.6-1 Settings of Interval Timer Function (One-shot Mode)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
Tn0CR0/Tn1CR0	IFE	C2	C1	C0	F3	F2	F1	F0
	○	○	○	○	0	0	0	0
Tn0CR1/Tn1CR1	STA	HO	IE	IR	BF	IF	SO	OE
	1	○	○	x	x	○	○	○
TMCRn	TO1	TO0	TIS	MOD	FE11	FE10	FE01	FE00
	○	○	x	○	○	○	○	○
Tn0DR/Tn1DR	Sets interval time (counter compare value)							
	○: Used bit							
	x: Unused bit							
	1: Set to "1"							
	0: Set to "0"							

As for the interval timer function (one-shot mode), enabling timer operation (Tn0CR1/Tn1CR1:STA = 1) causes the counter to start counting from "0x00" at the rising edge of a selected count clock signal. When the counter value matches the value of the 8/16-bit composite timer data register (Tn0DR/Tn1DR), the timer output (TMCRn:TO0/TO1) is inverted, the interrupt flag (Tn0CR1/Tn1CR1:IF) is set to "1", the timer operation enable bit (Tn0CR1/Tn1CR1:STA) is set to "0", and the counter stops counting.

The value of the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is transferred to the temporary storage latch (comparison data storage latch) in the comparator when the counter starts counting. Do not write "0x00" to the 8/16-bit composite timer data register.

Figure 12.6-2 shows the operation of the interval timer function in 8-bit operation.

Figure 12.6-2 Operation of Interval Timer Function in 8-bit Operation (One-shot Mode)

12.7 Operation of Interval Timer Function (Continuous Mode)

This section describes the interval timer function (continuous mode operation) of the 8/16-bit composite timer.

■ Operation of Interval Timer Function (Continuous Mode)

To use interval timer function (continuous mode), do the settings shown in Figure 12.7-1.

Figure 12.7-1 Settings for Interval Timer Function (Continuous Mode)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
Tn0CR0/Tn1CR0	IFE	C2	C1	C0	F3	F2	F1	F0
	○	○	○	○	0	0	0	1
Tn0CR1/Tn1CR1	STA	HO	IE	IR	BF	IF	SO	OE
	1	○	○	x	x	○	○	○
TMCRn	TO1	TO0	TIS	MOD	FE11	FE10	FE01	FE00
	○	○	x	○	○	○	○	○
Tn0DR/Tn1DR	Sets interval time (counter compare value)							
	○: Bit to be used							
	x: Unused bit							
	1: Set to "1"							
	0: Set to "0"							

As for the interval timer function (continuous mode), enabling timer operation (Tn0CR1/Tn1CR1:STA = 1) causes the counter to start counting from "0x00" at the rising edge of a selected count clock signal. When the counter value matches the value in the 8/16-bit composite timer data register (Tn0DR/Tn1DR), the timer output bit (TMCRn:TO0/TO1) is inverted, the interrupt flag (Tn0CR1/Tn1CR1:IF) is set to "1", and the counter returns to "0x00" and restarts counting. The timer outputs square wave as a result of this continuous operation.

The value of the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is transferred to the temporary storage latch (comparison data storage latch) in the comparator either when the counter starts counting or when a counter value comparison match is detected. Do not write "0x00" to the 8/16-bit composite timer data register while the counter is counting.

When the timer stops operating, the timer output bit (TMCRn:TO0/TO1) holds the last value.

Figure 12.7-2 Operation Diagram of Interval Timer Function (Continuous Mode)

12.8 Operation of Interval Timer Function (Free-run Mode)

This section describes the operation of the interval timer function (free-run mode) of the 8/16-bit composite timer.

■ Operation of Interval Timer Function (Free-run Mode)

To use the interval timer function (free-run mode), do the settings shown in Figure 12.8-1.

Figure 12.8-1 Settings for Interval Timer Function (Free-run Mode)

Figure 12-17 Settings for Interval Timer Function (Free Run Mode)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
Tn0CR0/Tn1CR0	IFE	C2	C1	C0	F3	F2	F1	F0
	○	○	○	○	0	0	1	0
Tn0CR1/Tn1CR1	STA	HO	IE	IR	BF	IF	SO	OE
	1	○	○	x	x	○	○	○
TMCRn	TO1	TO0	TIS	MOD	FE11	FE10	FE01	FE00
	○	○	x	○	○	○	○	○
Tn0DR/Tn1DR	Sets interval time (counter compare value)							

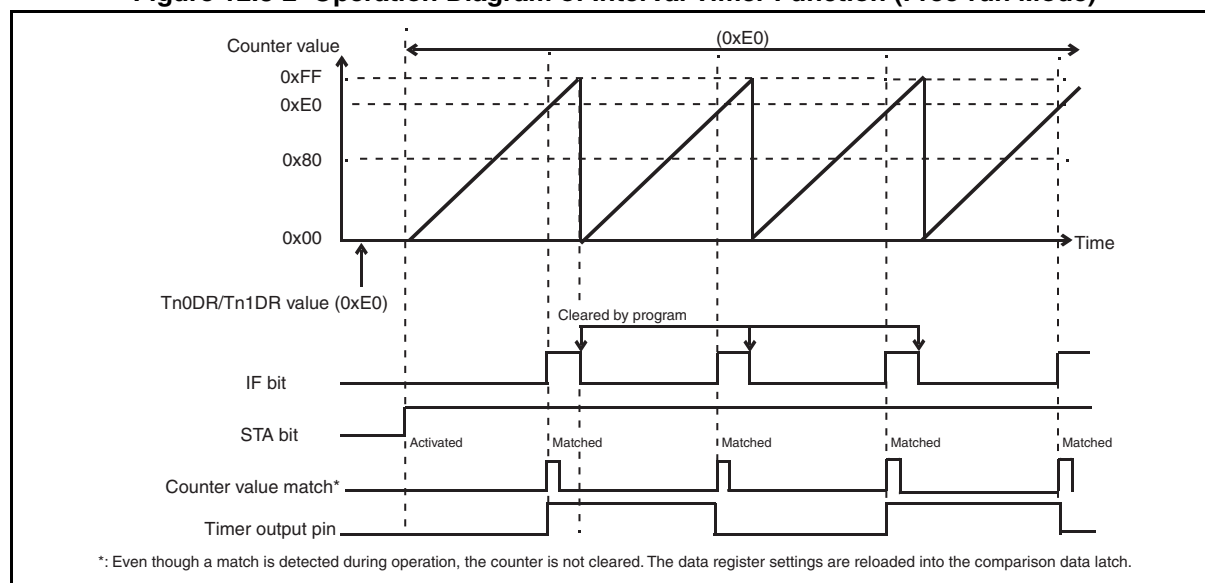

○: Bit to be used
x: Unused bit
1: Set to "1"
0: Set to "0"

As for the interval timer function (free-run mode), enabling timer operation (Tn0CR1/Tn1CR1:STA = 1) causes the counter to start counting from "0x00" at the rising edge of a selected count clock signal. When the counter value matches the value in the 8/16-bit composite timer data register (Tn0DR/Tn1DR), the timer output bit (TMCRn:TO0/TO1) is inverted and the interrupt flag (Tn0CR1/Tn1CR1:IF) is set to "1". If the counter continues to count with the above settings and then reaches "0xFF", it returns to "0x00" and restarts counting. The timer outputs square wave as a result of this continuous operation.

The value of the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is transferred to the temporary storage latch (comparison data storage latch) in the comparator either when the counter starts counting or when a counter value comparison match is detected. Do not write "0x00" to the 8/16-bit composite timer data register.

When the timer stops operation, the timer output bit (TMCRn:TO0/TO1) holds the last value.

Figure 12.8-2 Operation Diagram of Interval Timer Function (Free-run Mode)

12.9 Operation of PWM Timer Function (Fixed-cycle Mode)

This section describes the operation of the PWM timer function (fixed-cycle mode) of the 8/16-bit composite timer.

■ Operation of PWM Timer Function (Fixed-cycle Mode)

To use the PWM timer function (fixed-cycle mode), do the settings shown in Figure 12.9-1.

Figure 12.9-1 Settings for PWM Timer Function (Fixed-cycle Mode)

Tn0DR/Tn1DR	Sets "H" pulse width (compare value)							

○: Bit to be used
x: Unused bit
1: Set to "1"
0: Set to "0"

As for the PWM timer function (fixed-cycle mode), PWM signal that has a fixed cycle and variable "H" pulse width is output from the timer output pin (TON0/TOn1). The cycle is fixed at "0xFF" in 8-bit operation or "0xFFFF" in 16-bit operating mode. The time is determined by the count clock selected. The "H" pulse width is specified by the value in the 8/16-bit composite timer data register (Tn0DR/Tn1DR).

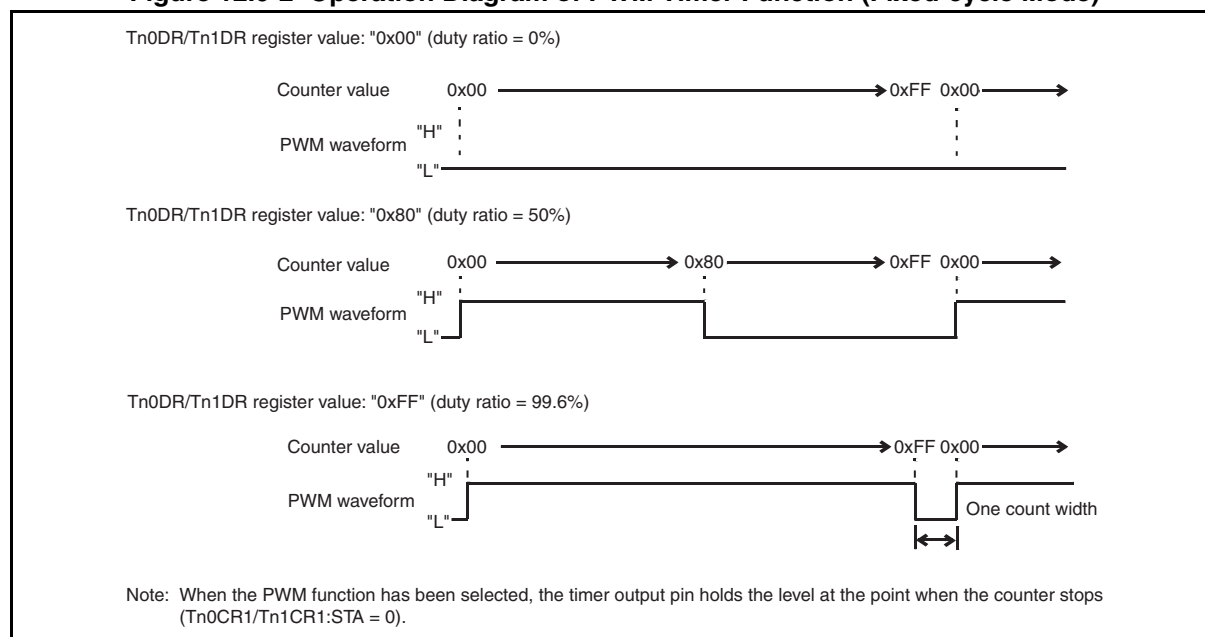

This function has no effect on the interrupt flag (Tn0CR1/Tn1CR1:IF). Since each cycle always starts with "H" pulse output, the timer output initial value setting bit (Tn0CR1/Tn1CR1:SO) has no effect on operation.

The value of the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is transferred to the temporary storage latch (comparison data storage latch) in the comparator either when the counter starts counting or when a counter value comparison match is detected.

When the timer stops operation, the timer output bit (TMCRn:TO0/TO1) holds the last value.

In the output waveform immediately after activation of the timer (write "1" to the STA bit), the "H" pulse is one count clock shorter than the value set in the Tn0DR/Tn1DR register.

Figure 12.9-2 Operation Diagram of PWM Timer Function (Fixed-cycle Mode)

12.10 Operation of PWM Timer Function (Variable-cycle Mode)

This section describes the operation of the PWM timer function (variable-cycle mode) of the 8/16-bit composite timer.

■ Operation of PWM Timer Function (Variable-cycle Mode)

To use the PWM timer function (variable-cycle mode), do the settings shown in Figure 12.10-1.

Figure 12.10-1 Settings for PWM Timer Function (Variable-cycle Mode)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0

Tn0DR	Sets "L" pulse width (compare value)							
Tn1DR	Sets the cycle of PWM waveform (compare value)							
○: Bit to be used								
x: Unused bit								
1: Set to "1"								
0: Set to "0"								

As for the PWM timer function (variable-cycle mode), both timers n0 and n1 are used. PWM signal of any cycle and of any duty is output from the timer output pin (TON0). The cycle is specified by the 8/16-bit composite timer n1 data register (Tn1DR), and the "L" pulse width is specified by the 8/16-bit composite timer n0 data register (Tn0DR).

Since both the 8-bit counters are used for this function, the composite timer cannot form a 16-bit counter.

Enabling timer operation (Tn0CR1/Tn1CR1:STA = 1) sets the mode bit (TMCRn:MOD) to "0". As the first cycle always begins with "L" pulse output, the timer initial value setting bit (Tn0CR1/Tn1CR1:SO) has no effect on operation.

An interrupt flag (Tn0CR1/Tn1CR1:IF) is set when the 8-bit counter corresponding to that interrupt flag matches the value in its corresponding 8/16-bit composite timer data register (Tn0DR/Tn1DR).

The 8/16-bit composite timer data register value is transferred to the temporary storage latch (comparison data storage latch) in the comparator either when the counter starts counting or when a comparison match with each counter value is detected.

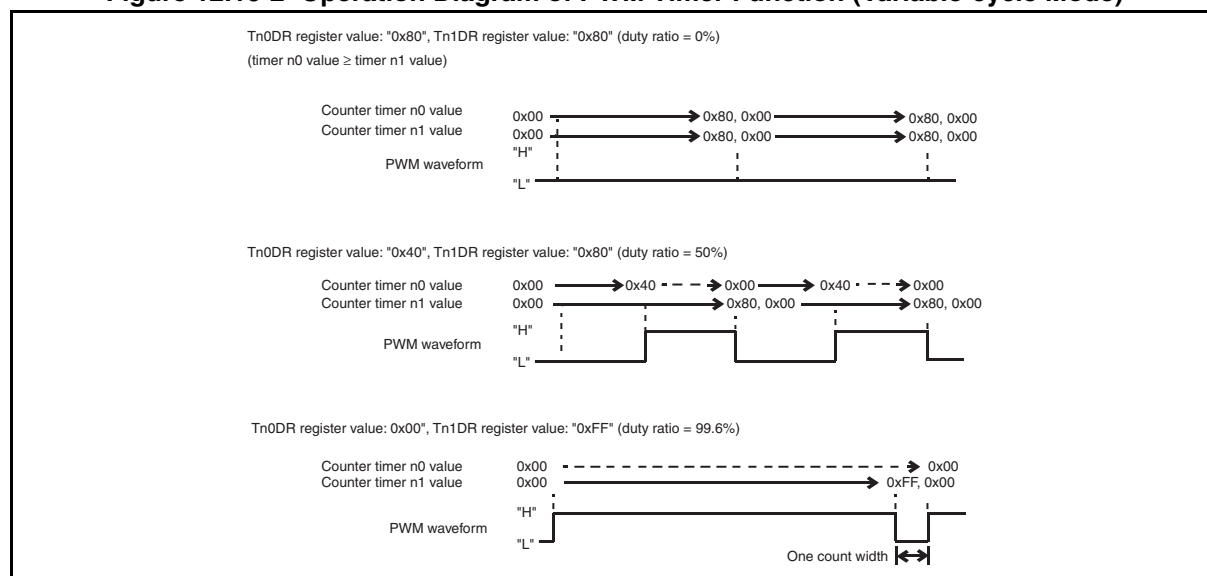

"H" is not output when the "L" pulse width setting value is greater than the cycle setting value.

The count clock must be selected for both timers n0 and n1. Selecting different count clocks for the two timers is prohibited.

When the timer stops operating, the timer output bit (TMCRn:TO0) holds the last output value.

If the 8/16-bit composite timer data register is modified during operation, the data written will become valid from the cycle immediately after the detection of a synchronous match.

Figure 12.10-2 Operation Diagram of PWM Timer Function (Variable-cycle Mode)

12.11 Operation of PWC Timer Function

This section describes the operation of the PWC timer function of the 8/16-bit composite timer.

■ Operation of PWC Timer Function

To use the PWC timer function, do the settings shown in Figure 12.11-1.

Figure 12.11-1 Settings for PWC Timer Function

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0

	○	○	○	○	○	○	○	○
Tn0DR/Tn1DR	Holds pulse width measurement value							
○: Bit to be used								
x: Unused bit								
1: Set to "1"								

When the PWC timer function is selected, the width and cycle of an external input pulse can be measured. The edges at which counting starts and ends are selected by the timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]).

In the operation of this function, the counter starts counting from "0x00" immediately after a specified count start edge of an external input signal is detected. Upon the detection of a specified count end edge, the count value is transferred to the 8/16-bit composite timer data register (Tn0DR/Tn1DR), and the interrupt flag (Tn0CR1/Tn1CR1:IR) and the buffer full flag (Tn0CR1/Tn1CR1:BF) are set to "1". The buffer full flag is set to "0" when the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is read.

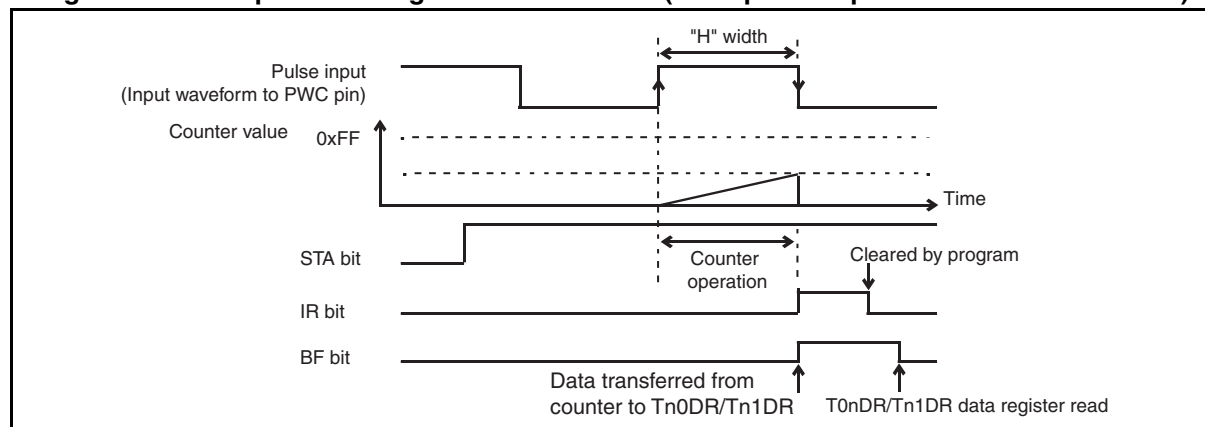

If the buffer full flag is set to "1", the 8/16-bit composite timer data register holds data. Even if the next edge is detected during that time, the next measurement result is lost since the count value has not been transferred to the 8/16-bit composite timer data register.

There is an exception. With the F3 bit to F0 bit in the Tn0CR0/Tn1CR0 register having been set to "0b1001", even though the BF bit is set to "1", the "H" pulse measurement result is transferred to the 8/16-bit composite timer data register, while the cycle measurement result is not transferred to the 8/16-bit composite timer data register. Therefore, in order to perform cycle measurement, the "H" pulse measurement result must be read before a cycle is completed. In addition, the result of "H" pulse measurement and that of cycle measurement are lost if they are not read before the completion of the next "H" pulse.

The time exceeding the range of the counter can be measured by counting the number of counter overflows using the software. When the counter overflows, the interrupt flag (Tn0CR1/Tn1CR1:IF) is set to "1". The interrupt service routine can therefore be used to count the number of overflows. In addition, the timer output is inverted due to the overflow. The timer output initial value can be set by the timer output initial value bit (Tn0CR1/Tn1CR1:SO).

When the timer stops operating, the timer output bit (TMCRn:TO1/TO0) holds the last value.

Figure 12.11-2 Operation Diagram of PWC Timer (Example of H-pulse Width Measurement)

12.12 Operation of Input Capture Function

This section describes the operation of the input capture function of the 8/16-bit composite timer.

■ Operation of Input Capture Function

To use the input capture function, do the settings shown in Figure 12.12-1.

Figure 12.12-1 Settings for Input Capture Function

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
Tn0CR0/Tn1CR0	IFE	C2	C1	C0	F3	F2	F1	F0
	○	○	○	○	○	○	○	○
Tn0CR1/Tn1CR1	STA	HO	IE	IR	BF	IF	SO	OE
	1	○	○	○	x	○	x	x
TMCRn	TO1	TO0	TIS	MOD	FE11	FE10	FE01	FE00
	x	x	○	○	○	○	○	○
Tn0DR/Tn1DR	Holds pulse width measurement value							
○: Bit to be used								
x: Unused bit								
1: Set to "1"								

When the input capture function is selected, the counter value is stored to the 8/16-bit composite timer data register (Tn0DR/Tn1DR) immediately after an edge of the external signal input is detected. The target edge to be detected is selected by the timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]).

This function is available in free-run mode and clear mode, which can be selected by the timer operating mode select bits.

In clear mode, the counter starts counting from "0x00". When an edge is detected, the counter value is transferred to the 8/16-bit composite timer data register (Tn0DR/Tn1DR), the interrupt flag (Tn0CR1/Tn1CR1:IR) is set to "1", and the counter returns to "0x00" and restarts counting.

In free-run mode, when an edge is detected, the counter value is transferred to the 8/16-bit composite timer data register (Tn0DR/Tn1DR) and the interrupt flag (Tn0CR1/Tn1CR1:IR) is set to "1". In this case, the counter continues to count without being cleared.

This function has no effect on the buffer full flag (Tn0CR1/Tn1CR1:BF).

The time exceeding the range of the counter can be measured by counting the number of counter overflows using the software. When the counter overflows, the interrupt flag (Tn0CR1/Tn1CR1:IF) is set to "1". The interrupt service routine can therefore be used to count the number of overflows. In addition, the timer output is inverted due to the overflow. The timer output initial value can be set by the timer output initial value bit (Tn0CR1/Tn1CR1:SO).

Note:

See "12.15 Notes on Using 8/16-bit Composite Timer" for notes on using the input capture function.

Figure 12.12-2 Operating Diagram of Input Capture Function

12.13 Operation of Noise Filter

This section describes the operation of the noise filter of the 8/16-bit composite timer.

When the input capture function or PWC timer function is selected, a noise filter can be used to eliminate the pulse noise of the signal from the external input pin (ECn). H-pulse noise, L-pulse noise, or H/L-pulse noise elimination can be selected by the FE11, FE10, FE01 and FE00 bits in the TMCRn register. The maximum pulse width that can be eliminated is three machine clock cycles. If the noise filter function is activated, the signal input will be delayed for four machine clock cycles.

Figure 12.13-1 Operation of Noise Filter

12.14 Registers

This section describes the registers of the 8/16-bit composite timer.

Table 12.14-1 List of 8/16-bit Composite Timer Registers

Register abbreviation	Register name	Reference
Tn0CR0	8/16-bit composite timer n0 status control register 0	12.14.1
Tn1CR0	8/16-bit composite timer n1 status control register 0	12.14.1
Tn0CR1	8/16-bit composite timer n0 status control register 1	12.14.2
Tn1CR1	8/16-bit composite timer n1 status control register 1	12.14.2
TMCRn	8/16-bit composite timer timer mode control register	12.14.3
Tn0DR	8/16-bit composite timer n0 data register	12.14.4
Tn1DR	8/16-bit composite timer n1 data register	12.14.4

12.14.1 8/16-bit Composite Timer Status Control Register 0 (Tn0CR0/Tn1CR0)

The 8/16-bit composite timer status control register 0 (Tn0CR0/Tn1CR0) selects the timer operation mode, selects the count clock, and enables or disables IF flag interrupts. The Tn0CR0 and Tn1CR0 registers correspond to timers n0 and n1 respectively.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	IFE	C2	C1	C0	F3	F2	F1	F0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] IFE: IF flag interrupt enable bit

This bit enables or disables IF flag interrupts.

During timer operation (Tn0CR1/Tn1CR1:STA = 1), the write access to this bit has no effect on operation. Ensure that the timer has stopped before modifying this bit.

With this bit set to "1", an IF flag interrupt request is output when both the IE bit (Tn0CR1/Tn1CR1:IE) and the IF flag (Tn0CR1/Tn1CR1:IF) are set to "1".

bit7	Details
Writing "0"	Disables the IF flag interrupt.
Writing "1"	Enables the IF flag interrupt.

[bit6:4] C[2:0]: Count clock select bits

These bits select the count clock.

The count clock is generated by the prescaler. See "3.9 Operation of Prescaler".

During timer operation (Tn0CR1/Tn1CR1:STA = 1), the write access to these bits has no effect on operation in timer operation.

The clock selection of Tn1CR0 (timer n1) is nullified in 16-bit operating mode.

These bits cannot be set to "0b111" when the PWC function or input capture function is used. An attempt to write "0b111" with the PWC function or input capture function in use resets the bits to "0b000". The bits are also reset to "0b000" if the timer enters the input capture operation mode with the bits set to "0b111".

When these bits are set to "0b110", the count clock from the time-base timer is used as the count clock. Depending on the settings of the SYCC register, the count clock from the time-base timer can be generated from the main clock, the main CR clock, or the PLL clock. In the case of using the count clock from the time-base timer as the count clock, resetting the time-base timer by writing "1" to the time-base timer clear bit in the time-base timer control register (TBTC:TCLR) affects the count time.

bit6:4	Details (MCLK: machine clock, F _{CH} : main clock, F _{CRH} : main CR clock, F _{PLL} : PLL clock)
Writing "000"	1 MCLK
Writing "001"	MCLK/2
Writing "010"	MCLK/4
Writing "011"	MCLK/8
Writing "100"	MCLK/16
Writing "101"	MCLK/32
Writing "110"	F _{CH} /2 ⁷ , F _{CRH} /2 ⁶ or F _{PLL} /2 ⁶ *
Writing "111"	External clock

*: The value to be used as the count clock depends on the settings of the SCS[2:0] bits in the SYCC register.

[bit3:0] F[3:0]: Timer operating mode select bits

These bits select the timer operating mode.

The PWM timer function (variable-cycle mode; F[3:0] = 0b0100) is set by either the Tn0CR0 (timer n0) register or Tn1CR0 (timer n1) register. If one of the timers starts operating (Tn0CR1/Tn1CR1: STA = 1), the F[3:0] bits of the other timer are automatically set to "0b0100".

With the 16-bit operating mode having been selected (TMCRn:MOD = 1), if the composite timer starts operating using the PWM timer function (variable-cycle mode) (Tn0CR1/Tn1CR1:STA = 1), the MOD bit is set to "0" automatically.

Write access to these bits is nullified in timer operation (Tn0CR1/Tn1CR1:STA = 1).

bit3:0	Details
Writing "0000"	Interval timer (one-shot mode)
Writing "0001"	Interval timer (continuous mode)
Writing "0010"	Interval timer (free-run mode)
Writing "0011"	PWM timer (fixed-cycle mode)
Writing "0100"	PWM timer (variable-cycle mode)
Writing "0101"	PWC timer (H pulse = rising edge to falling edge)
Writing "0110"	PWC timer (L pulse = falling edge to rising edge)
Writing "0111"	PWC timer (cycle = rising edge to rising edge)
Writing "1000"	PWC timer (cycle = falling edge to falling edge)
Writing "1001"	PWC timer (H pulse = rising edge to falling edge; cycle = rising edge to rising edge)
Writing "1010"	Input capture (rising edge, free-run counter)
Writing "1011"	Input capture (falling edge, free-run counter)
Writing "1100"	Input capture (both edges, free-run counter)
Writing "1101"	Input capture (rising edge, counter clear)
Writing "1110"	Input capture (falling edge, counter clear)
Writing "1111"	Input capture (both edges, counter clear)

12.14.2 8/16-bit Composite Timer Status Control Register 1 (Tn0CR1/Tn1CR1)

The 8/16-bit composite timer status control register 1 (Tn0CR1/Tn1CR1) controls the interrupt flag, timer output, and timer operations. Tn0CR1 and Tn1CR1 registers correspond to timers n0 and n1 respectively.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	STA	HO	IE	IR	BF	IF	SO	OE
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] STA: Timer operation enable bit

This bit enables or stops the timer operation.

Writing "0": stops the timer operation and sets the count value to "0x00".

- With the PWM timer function (variable-cycle mode) in use (Tn0CR0/Tn1CR0:F[3:0] = 0b0100), the STA bit in either the Tn0CR1 (timer n0) or the Tn1CR1 (timer n1) register can be used to enable or disable the timer operation. If the STA bit in one of the registers is set to "0", the STA bit in the other one is automatically set to the same value.
- In 16-bit operating mode (TMCRn:MOD = 1), use the STA bit in the Tn0CR1 (timer n0) register to enable or disable timer operation. If the STA bit of one of the timers is set to "0", the STA bit in the other one is automatically set to the same value.

Writing "1": starts the timer operation from the count value "0x00".

- Before setting this bit to "1", set the count clock select bits (Tn0CR0/Tn1CR0:C[2:0]), timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]), timer output initial value bit (Tn0CR1/Tn1CR1:SO), 8-bit/16-bit operating mode select bit (TMCRn:MOD), and filter function select bits (TMCRn:FEn1, FEn0).

bit7	Details
Writing "0"	Stops the timer operation.
Writing "1"	Enables the timer operation.

[bit6] HO: Timer suspend bit

This bit suspends or resumes the timer operation.

Writing "1" to this bit during timer operation suspends the timer operation.

When the timer operation has been enabled (Tn0CR1/Tn1CR1:STA = 1), writing "0" to the bit resumes the timer operation.

With the PWM timer function (variable-cycle mode) in use (Tn0CR0/Tn1CR0:F[3:0] = 0b0100), the HO bit in either Tn0CR1 (timer n0) or Tn1CR1 (timer n1) can be used to suspend or resume timer operation. If the HO bit in one of the registers is set to "0" or "1", the HO bit in the other one is automatically set to the same value.

In 16-bit operation (TMCRn:MOD = 1), use the HO bit in the Tn0CR1 (timer n0) register to suspend or resume timer operation. If the HO bit in one of the registers is set to "0" or "1", the HO bit in the other one is automatically set to the same value.

bit6	Details
Writing "0"	Resumes the timer operation.
Writing "1"	Suspends the timer operation.

[bit5] IE: Interrupt request enable bit

This bit enables or disables the output of interrupt requests.

Writing "0" to this bit disables the interrupt request.

Writing "1" to this bit outputs an interrupt request when the pulse width measurement completion/edge detection flag (Tn0CR1/Tn1CR1:IR) or timer reload/overflow flag (Tn0CR1/Tn1CR1:IF) is set to "1".

However, an interrupt request from the timer reload/overflow flag (Tn0CR1/Tn1CR1:IF) is not output unless the IF flag interrupt enable bit (Tn0CR0/Tn1CR0:IFE) is also set to "1".

bit5	Details
Writing "0"	Disables the interrupt request.
Writing "1"	Enables the interrupt request.

[bit4] IR: Pulse width measurement completion/edge detection flag

This bit indicates the completion of pulse width measurement or the detection of an edge.

Writing "0" to this bit sets it to "0".

Writing "1" to this bit has no effect on operation.

With the PWC timer function in use, this bit is set to "1" immediately after pulse width measurement is complete.

With the input capture function in use, this bit is set to "1" immediately after an edge is detected.

The bit is set to "0" when the function of the composite timer selected is neither the PWC timer function nor the input capture function.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

The IR bit in the Tn1CR1 (timer n1) register is set to "0" in 16-bit operating mode.

bit4	Details
Reading "0"	Indicates that the pulse width measurement has been completed or no edge has been detected.
Reading "1"	Indicates that the pulse width measurement has been completed or an edge has been detected.
Writing "0"	Clears this flag.
Writing "1"	Has no effect on operation.

[bit3] BF: Data register full flag

With the PWC timer function in use, this bit is set to "1" when a count value is stored in the 8/16-bit composite timer data register (Tn0DR/Tn1DR) immediately after pulse width measurement is complete.

In 8-bit operation, this bit is set to "0" when the 8/16-bit composite timer data register (Tn0DR/Tn1DR) is read.

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) holds data if this bit is set to "1". With this bit being "1", even when the next edge is detected, the count value is not transferred to the Tn0DR/Tn1DR register, and the next measurement result is thus lost. Nonetheless, there is an exception. With the F[3:0] bits in the Tn0CR0/Tn1CR0 register having been set to "0b1001", even though the BF bit is set to "1", the "H" pulse measurement result is transferred to the Tn0DR/Tn1DR register, while the cycle measurement result is not transferred to the Tn0DR/Tn1DR register. Therefore, in order to perform cycle measurement, the "H" pulse measurement result must be read before a cycle is completed. In addition, the result of "H" pulse measurement and that of cycle measurement are lost if they are not read before the completion of the next "H" pulse.

The BF bit in the Tn0CR1 (timer n0) register is set to "0" when the Tn1DR (timer n1) register is read during 16-bit operation.

The BF bit in the Tn1CR1 (timer n1) register is set to "0" during 16-bit operation.

This bit is "0" when any timer function other than the PWC timer function is selected.

Writing a value to this bit has no effect on operation.

bit3	Details
Reading "0"	Indicates that there is no measurement data in the 8/16-bit composite timer data register (Tn0DR/Tn1DR).
Reading "1"	Indicates that there is measurement data in the 8/16-bit composite timer data register (Tn0DR/Tn1DR).

[bit2] IF: Timer reload/overflow flag

This bit detects the count value match and the counter overflow.

With the interval timer function (one-shot or continuous) or the PWM timer function (variable-cycle mode) in use, this bit is set to "1" if the 8/16-bit composite timer data register (Tn0DR/Tn1DR) value matches the count value.

With the PWC timer function or the input capture function in use, this bit is set to "1" if a counter overflow occurs.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1". Writing "0" to this bit sets it to "0".

Writing "1" to this bit has no effect on operation.

This bit becomes "0" if the PWM function (variable-cycle mode) is selected.

The IF bit in the Tn1CR1 (timer n1) register is "0" in 16-bit operating mode.

bit2	Details
Reading "0"	Indicates that neither timer reload nor overflow has occurred.
Reading "1"	Indicates that a timer reload or an overflow has occurred.
Writing "0"	Clears this flag.
Writing "1"	Has no effect on operation.

[bit1] SO: Timer output initial value bit

The timer output (TMCRn:TO1/TO0) initial value is set by writing a value to this bit. The value in this bit is reflected in the timer output when the timer operation enable bit (Tn0CR1/Tn1CR1:STA) changes from "0" to "1".

In 16-bit operating mode (TMCRn:MOD = 1), use the SO bit in the Tn0CR1 (timer n0) register to set the timer output initial value. In this case, the value of the SO bit in the other one has no effect on operation.

During timer operation (Tn0CR1/Tn1CR1:STA = 1), the write access to this bit is invalid. However, in 16-bit operating mode, although a value can be written to the SO bit in the Tn1CR1 (timer n1) register even during timer operation, the value written has no direct effect on the timer output.

When the PWM timer function (fixed cycle mode or variable cycle mode) or the input capture function is in use, the value of this bit has no effect on operation.

bit1	Details
Writing "0"	Sets "0" as the timer output initial value.
Writing "1"	Sets "1" as the timer output initial value.

[bit0] OE: Timer output enable bit

This bit enables or disables timer output.

Writing "0" to this bit disables outputting the timer value (TMCRn:TO1/TO0) to the external pin. In this case, the external pin serves as a general-purpose port.

Writing "1" to this bit enables outputting the timer value to the external pin.

bit0	Details
Writing "0"	Disables timer output.
Writing "1"	Enables timer output.

12.14.3 8/16-bit Composite Timer Timer Mode Control Register (TMCRn)

The 8/16-bit composite timer timer mode control register (TMCRn) selects the filter function, 8-bit or 16-bit operating mode, and signal input to timer n0 and indicates the timer output value. This register serves both timer n0 and timer n1.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	TO1	TO0	TIS	MOD	FE11	FE10	FE01	FE00
Attribute	R	R	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] TO1: Timer n1 output bit

This bit indicates the output value of timer n1. When the timer starts operation (Tn0CR1/Tn1CR1:STA = 1), the value in the bit changes depending on the timer function selected.

Writing a value to this bit has no effect on operation.

In 16-bit operating mode, if the PWM timer function (variable-cycle mode) or the input capture function is selected, the value in the bit becomes undefined.

With the interval timer function or the PWC timer function having been selected, if the timer stops operating (Tn0CR1/Tn1CR1:STA = 0), this bit holds the last value.

With the PWM timer function (variable-cycle mode) having been selected, if the timer stops operating (Tn0CR1/Tn1CR1:STA = 0), this bit holds the last value.

When the timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]) are modified with the timer stopping operating, this bit indicates the last value of timer operation if the same timer operation has been performed; otherwise it indicates its initial value "0".

[bit6] TO0: Timer n0 output bit

This bit indicates the output value of timer n0. When the timer starts operation (Tn0CR1/Tn1CR1:STA = 1), the value in the bit changes depending on the selected timer function.

Writing a value to this bit has no effect on operation.

If the input capture function is selected, the value in the bit becomes undefined.

With the interval timer function or the PWC timer function having been selected, if the timer stops operating (Tn0CR1/Tn1CR1:STA = 0), this bit holds the last value.

With the PWM timer function (variable-cycle mode) having been selected, if the timer stops operating (Tn0CR1/Tn1CR1:STA = 0), this bit holds the last value.

When the timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]) are modified with the timer stopping operating, this bit indicates the last value of timer operation if the same timer operation has been performed; otherwise it indicates its initial value "0".

[bit5] TIS: Timer n0 internal signal select bit

This bit selects the signal input to timer n0 when the PWC timer function or input capture function is selected.

bit5	Details
Writing "0"	Selects the external signal (ECn) as the signal input for timer n0.
Writing "1"	Setting prohibited.

[bit4] MOD: 8-bit/16-bit operating mode select bit

This bit selects 8-bit or 16-bit operating mode.

Writing "0" to this bit allows timers n0 and n1 to operate as separate 8-bit timers.

Writing "1" to this bit allows timers n0 and n1 to operate as a 16-bit timer.

While this bit is "1", if the timer starts operating (Tn0CR1/Tn1CR1:STA = 1) with the PWM timer function (variable-cycle mode), this bit is automatically set to "0".

During timer operation (Tn0CR1/Tn1CR1:STA = 1), the write access to this bit is invalid.

bit4	Details
Writing "0"	Selects the 8-bit operating mode.
Writing "1"	Selects the 16-bit operating mode.

[bit3:2] FE1[1:0]: Timer n1 filter function select bits

These bits select the filter function for the external signal (ECn) to timer n1 when the PWC timer function or the input capture function is selected.

During timer operation (Tn1CR1:STA = 1), the write access to these bits is invalid.

The settings of the bits have no effect on operation when the interval timer function or the PWM timer function is selected (the filter function does not operate.).

bit3:2	Details
Writing "00"	Disables the filter function.
Writing "01"	Filters out "H" pulse noise.
Writing "10"	Filters out "L" pulse noise.
Writing "11"	Filters out both "H" pulse noise and "L" pulse noise.

[bit1:0] FE0[1:0]: Timer n0 filter function select bits

These bits select the filter function for the external signal (ECn) to timer n0 when the PWC timer function or the input capture function is selected.

During timer operation (Tn0CR1:STA = 1), the write access to these bits is invalid.

The settings of the bits have no effect on operation when the interval timer function or the PWM timer function is selected (the filter function does not operate.).

bit1:0	Details
Writing "00"	Disables the filter function.
Writing "01"	Filters out "H" pulse noise.
Writing "10"	Filters out "L" pulse noise.
Writing "11"	Filters out both "H" pulse noise and "L" pulse noise.

12.14.4 8/16-bit Composite Timer Data Register (Tn0DR/Tn1DR)

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) is used to set the maximum count value during the interval timer operation or the PWM timer operation and to read the count value during the PWC timer operation or the input capture operation. The Tn0DR and Tn1DR registers correspond to timers n0 and n1 respectively.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	TDR7	TDR6	TDR5	TDR4	TDR3	TDR2	TDR1	TDR0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

● Interval timer function

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) is used to set the interval time. When the timer starts operating (Tn0CR1/Tn1CR1:STA = 1), the value of this register is transferred to the latch in the 8-bit comparator and the counter starts counting. When the count value matches the value held in the latch in the 8-bit comparator, the value of this register is transferred again to the latch, and the counter returns to "0x00" and continues to count.

The current count value can be read from this register.

An attempt to write "0x00" to this register is disabled in interval timer function.

In 16-bit operating mode, write the upper timer data to Tn1DR and lower timer data to Tn0DR, and write or read Tn1DR first and then Tn0DR.

● PWM timer function (fixed-cycle)

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) is used to set "H" pulse width time. When the timer starts operating (Tn0CR1/Tn1CR1:STA = 1), the value of this register is transferred to the latch in the 8-bit comparator and the counter starts counting from timer output "H". When the count value matches the value transferred to the latch, the timer output becomes "L" and the counter continues to count until the count value reaches "0xFF". When an overflow occurs, the value of this register is transferred again to the latch in the 8-bit comparator and the counter performs the next cycle of counting.

The current value can be read from this register. In 16-bit operating mode, write the upper timer data to Tn1DR and lower timer data to Tn0DR, and write or read Tn1DR first and then Tn0DR.

- PWM timer function (variable-cycle)

The 8/16-bit composite timer n0 data register (Tn0DR) and 8/16-bit composite timer n1 data register (Tn1DR) are used to set "L" pulse width time and cycle respectively. When the timer starts operating (Tn0CR1/Tn1CR1:STA = 1), the value of each register is transferred to the latch in the 8-bit comparator and the two counters start counting from timer output "L". When the Tn0DR value transferred to the latch matches the timer n0 counter value, the timer output becomes "H" and the counting continues until the Tn1DR value transferred to the latch matches the timer n1 counter value. When the Tn1DR value transferred to the latch of the 8-bit comparator matches the timer n1 counter value, the values of the Tn0DR register and the T01DR register are transferred again to the latch and the counter performs the next PWM cycle of counting.

The current count value can be read from this register. In 16-bit operating mode, write the upper timer data to Tn1DR and lower timer data to Tn0DR, and read Tn1DR first and then Tn0DR.

- PWC timer function

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) is used to read PWC measurement results. When PWC measurement is completed, the counter value is transferred to this register and the BF bit is set to "1".

When the 8/16-bit composite timer data register is read, the BF bit is set to "0". While the BF bit is "1", no data is transferred to the 8/16-bit composite timer data register.

There is an exception. With the F[3:0] bits in the Tn0CR0/Tn1CR0 register having been set to "0b1001", even though the BF bit is set to "1", the "H" pulse measurement result is transferred to the 8/16-bit composite timer data register, while the cycle measurement result is not transferred to the 8/16-bit composite timer data register. Therefore, in order to perform cycle measurement, the "H" pulse measurement result must be read before a cycle is completed. In addition, the result of "H" pulse measurement and that of cycle measurement are lost if they are not read before the completion of the next "H" pulse.

When reading the 8/16-bit composite timer data register, ensure that the BF bit is not cleared accidentally.

If new data is written to the 8/16-bit composite timer data register, the stored measurement data is replaced with the new data. Therefore, do not write data to the register. In 16-bit operating mode, write the upper timer data to Tn1DR and lower timer data to Tn0DR, and read Tn1DR first and then Tn0DR.

- Input capture function

The 8/16-bit composite timer data register (Tn0DR/Tn1DR) is used to read input capture results. When an edge specified is detected, the counter value is transferred to the 8/16-bit composite timer data register.

If new data is written to the 8/16-bit composite timer data register, the stored measurement data is replaced with the new data. Therefore, do not write data to the register. In 16-bit operating mode, write the upper timer data to Tn1DR and lower timer data to Tn0DR, and read Tn1DR first and then Tn0DR.

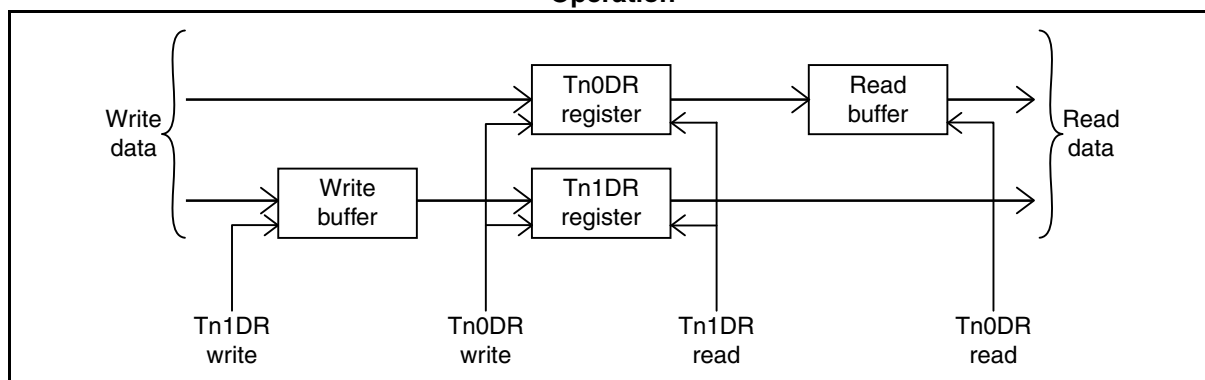

● Read and write operations

Read and write operations of Tn0DR and Tn1DR are performed in the following manner in 16-bit operating mode or when the PWM timer function (variable-cycle) is selected.

- Read from Tn1DR: In addition to the read access to Tn1DR, the value of Tn0DR is also stored in the internal read buffer at the same time.
- Read from Tn0DR: The internal read buffer is read.
- Write to Tn1DR: Data is written to the internal write buffer.
- Write to Tn0DR: In addition to the write access to Tn0DR, the value of the internal write buffer is stored in Tn1DR at the same time.

Figure 12.14-1 shows the Tn0DR and Tn1DR registers read from and written to during 16-bit operation.

Figure 12.14-1 Read and Write Operations of Tn0DR and Tn1DR Registers during 16-bit Operation

12.15 Notes on Using 8/16-bit Composite Timer

This section provides notes on using the 8/16-bit composite timer.

■ Notes on Using 8/16-bit Composite Timer

- To switch the timer function with the timer operating mode select bits (Tn0CR0/Tn1CR0:F[3:0]), stop the timer operation first (Tn0CR1/Tn1CR1:STA = 0), then clear the interrupt flag (Tn0CR1/Tn1CR1:IF, IR), the interrupt enable bits (Tn0CR1/Tn1CR1:IE, Tn0CR0/Tn1CR0:IFE) and the buffer full flag (Tn0CR1/Tn1CR1:BF).
- In the case of using the input capture function, when both edges of the external input signal is selected as the timing at which the 8/16-bit composite timer captures a counter value (Tn0CR0/Tn1CR0:F[3:0] = 0b1100 or 0b1111) while "H" level external input signal is being input, the first falling edge will be ignored, no counter value will be transferred to the data register (Tn0DR/Tn1DR), and pulse width measurement completion/edge detection flag (Tn0CR1/Tn1CR1:IR) will not be set either.
 - In counter clear mode, the counter will not be cleared at the first falling edge and no data will be transferred to the data register either. The 8/16-bit composite timer will start the input capture operation from the next rising edge.
 - In counter free-run mode, no data will be transferred to the data register at the first falling edge. The 8/16-bit composite timer will start the input capture operation from the next rising edge.
- In 8-bit operating mode (TMCRn:MOD = 0) of the PWM timer function (variable-cycle mode), when modifying the 8/16-bit composite timer data registers (Tn0DR and Tn1DR) during counter operation, modify Tn1DR first and then Tn0DR.
- When the event counter operates in event counter operation mode, 8/16-bit composite timer ch. 1 is used by the event counter, therefore the 8/16-bit composite timer can no longer use 8/16-bit composite timer ch. 1. For details of the event counter, see "CHAPTER 20 EVENT COUNTER".
- The counter stops operating while holding the value when the microcontroller transits to stop mode or watch mode. When the stop mode or watch mode is released by an interrupt, the counter resumes operating with the last value that it holds (see Figure 12.15-1 and Figure 12.15-2). Therefore, the first interval time or the initial external clock count value is incorrect. Always initialize the counter value after the microcontroller is released from stop mode or watch mode.

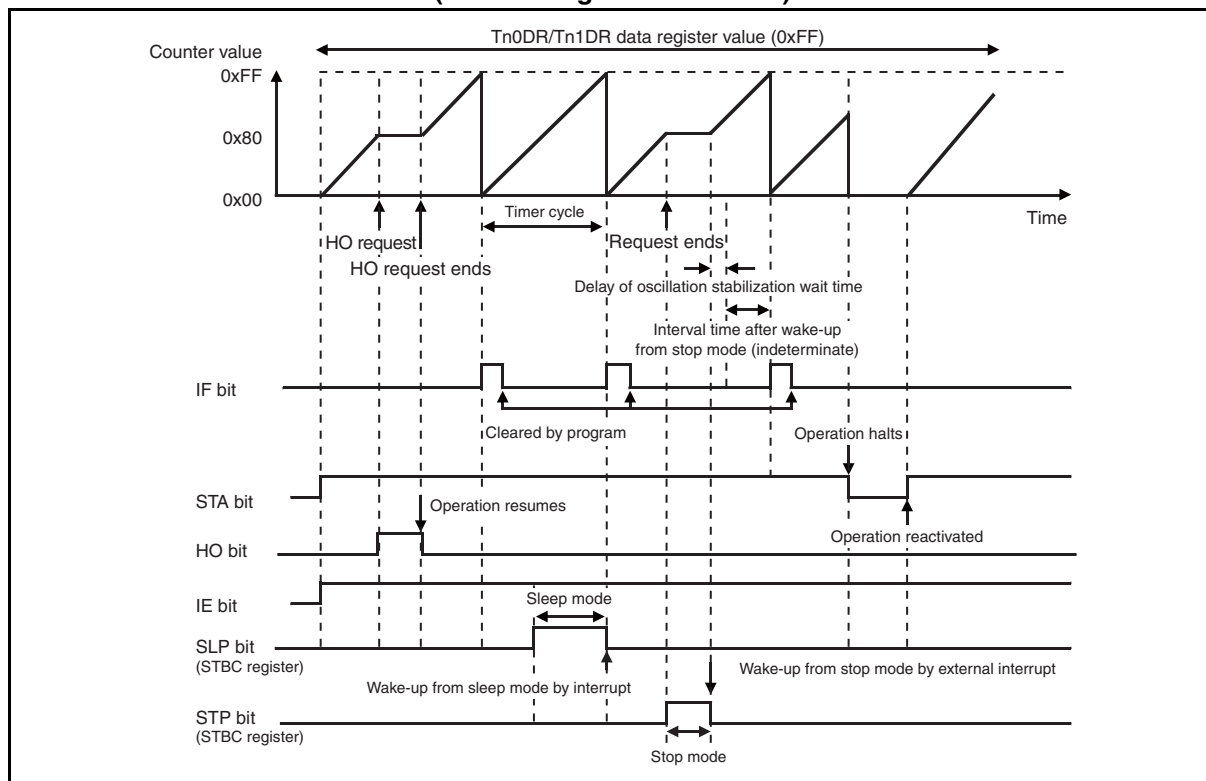

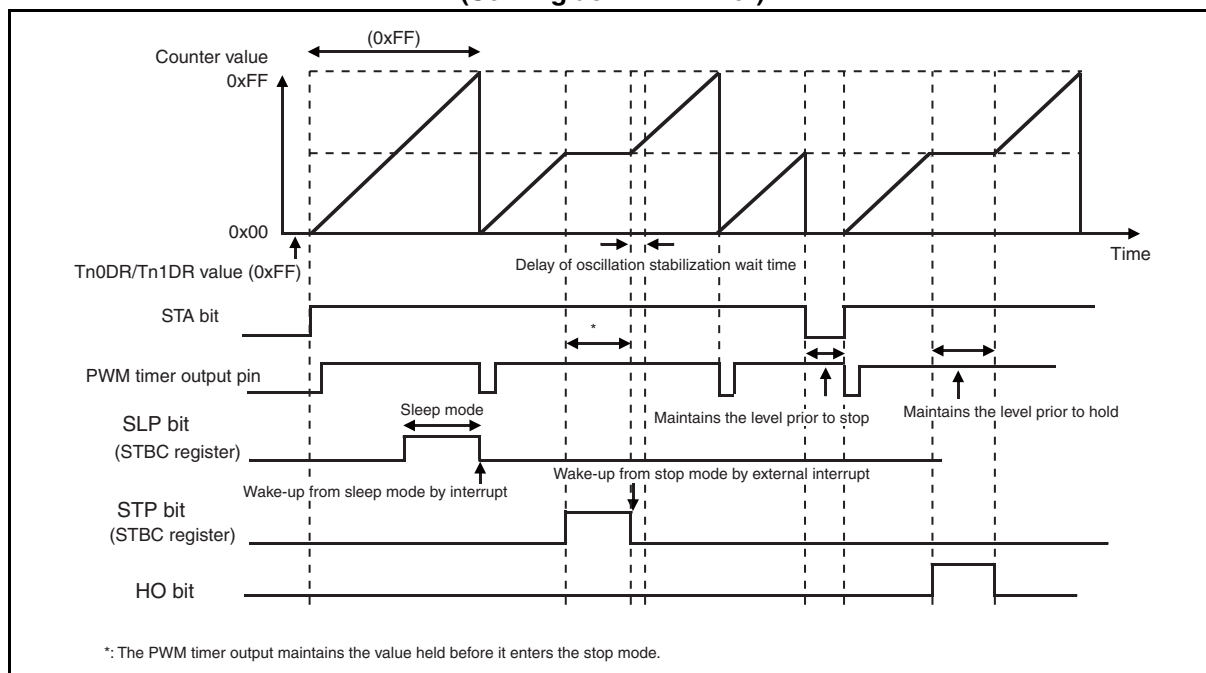

Figure 12.15-2 Operations of Counter in Standby Mode or in Pause (Serving as PWM Timer)

CHAPTER 13

EXTERNAL INTERRUPT CIRCUIT

This chapter describes the functions and operations of the external interrupt circuit.

- 13.1 Overview
- 13.2 Configuration
- 13.3 Channels
- 13.4 Pin
- 13.5 Interrupt
- 13.6 Operations and Setting Procedure Example
- 13.7 Register
- 13.8 Notes on Using External Interrupt Circuit

13.1 Overview

The external interrupt circuit detects edges on the signal that is input to the external interrupt pin, and outputs interrupt requests to the interrupt controller.

■ Function of External Interrupt Circuit

The external interrupt circuit detects any edge of a signal that is input to an external interrupt pin and generates interrupt requests to the interrupt controller. The interrupt generated according to this interrupt request can cause the device to wake up from standby mode and return to its normal operating state. Therefore, the operating mode of the device can be changed when a signal is input to the external interrupt pin.

13.2 Configuration

The external interrupt circuit consists of the following blocks:

- Edge detection circuit
- External interrupt control register

■ Block Diagram of External Interrupt Circuit

Figure 13.2-1 is the block diagram of the external interrupt circuit.

Figure 13.2-1 Block Diagram of External Interrupt Circuit

● Edge detection circuit

When the polarity of the edge detected on a signal input to an external interrupt circuit pin (INT) matches the polarity of the edge selected in the interrupt control register (EIC), a corresponding external interrupt request flag bit (EIR) is set to "1".

● External interrupt control register (EIC)

This register is used to select an edge, enable or disable interrupt requests, check for interrupt requests, etc.

13.3 Channels

This section describes the channels of the external interrupt circuit.

■ Channels of External Interrupt Circuit

Table 13.3-1 shows the pins and their corresponding registers of the external interrupt.

Table 13.3-1 Pins and Register of External Interrupt Circuit

Pin name	Pin function	Corresponding register
INTn	External interrupt input ch. n	External interrupt control register (EIC)
INTn+1	External interrupt input ch. n+1	
INTn+2	External interrupt input ch. n+2	
INTn+3	External interrupt input ch. n+3	

The number of external interrupt circuit units varies among products. For the number of external interrupt circuit units in an individual product, refer to the device data sheet.

13.4 Pin

This section provides details of the pin of the external interrupt circuit.

■ Pin of External Interrupt Circuit

● INT pin

This pin serves both as an external interrupt input pin and as a general-purpose I/O port.

If the INT pin is set as an input port by the port direction register (DDR) and the corresponding external interrupt input is enabled by the external interrupt control register (EIC), that pin functions as an external interrupt input pin (INT).

The state of a pin can always be read from the port data register (PDR) when that pin is set as an input port. The value of PDR can be read by using the read-modify-write (RMW) type of instruction.

13.5 Interrupt

The interrupt source for the external interrupt circuit is the detection of the specified edge of the signal input to an external interrupt pin.

■ Interrupt during Operation of External Interrupt Circuit

When the specified edge of external interrupt input is detected, the corresponding external interrupt request flag bit (EIC:EIR0 or EIR1) is set to "1". In this case, if the interrupt request enable bit (EIC:EIE0 or EIE1 = 1) corresponding to that external interrupt request flag bit is enabled, an interrupt request is generated to the interrupt controller. In an interrupt service routine, write "0" to the external interrupt request flag bit corresponding to that interrupt request generated to clear the interrupt request.

13.6 Operations and Setting Procedure Example

This section describes the operations of the external interrupt circuit.

■ Operations of External Interrupt Circuit

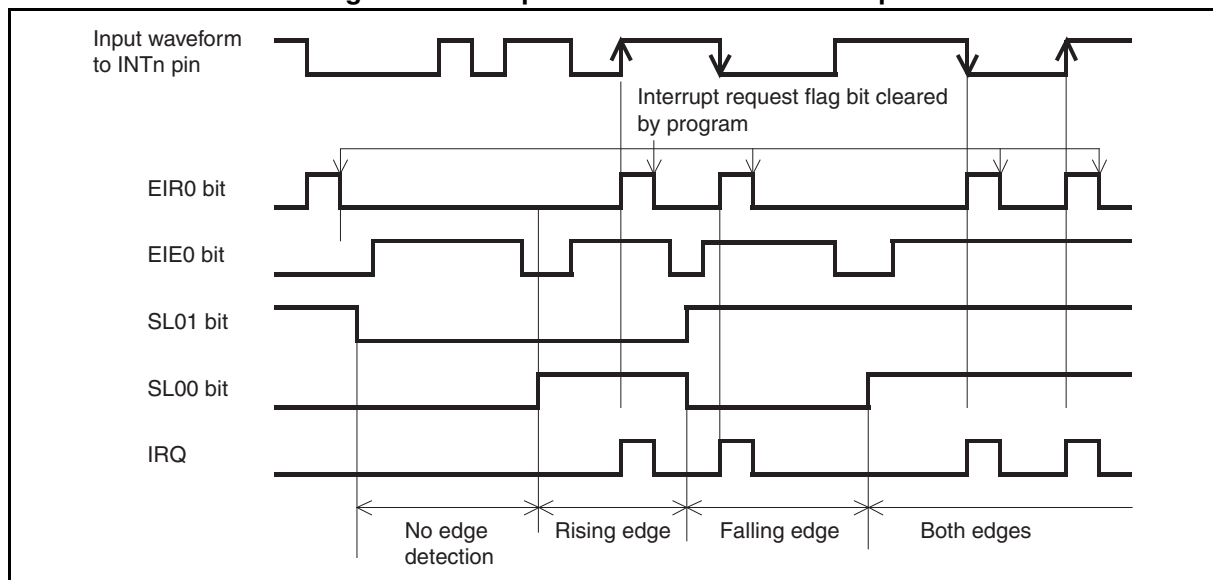

When the polarity of an edge of a signal input from one of the external interrupt pins (INTn, INTn+1) matches the polarity of the edge selected by the external interrupt control register (EIC:SL0[1:0] or SL1[1:0]), the corresponding external interrupt request flag bit (EIC:EIR0 or EIR1) is set to "1" and the interrupt request is generated.

Always set the interrupt request enable bit to "0" when not using an external interrupt to wake up the device from standby mode.

When setting the edge polarity select bit (SL00, SL01 or SL10, SL11), set the interrupt request enable bit (EIE0 or EIE1) to "0" to prevent the interrupt request from being generated accidentally. Also clear the interrupt request flag bit (EIR0 or EIR1) to "0" after changing the edge polarity.

Figure 13.6-1 shows the operations for setting the INTn pin as an external interrupt input.

Figure 13.6-1 Operations of External Interrupt

■ Setting Procedure Example

Below is an example of procedure for setting the external interrupt circuit.

● Initial settings

1. Set the interrupt level. (ILR*)
2. Select the edge polarity. (EIC:SL0[1:0])
3. Enable interrupt requests. (EIC:EIE0 = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

1. Clear the interrupt request flag. (EIC:EIR0 = 0)
2. Process any interrupt.

Note:

An external interrupt input port shares the same pin with a general-purpose I/O port. Therefore, when using the pin as an external interrupt input port, set the bit in the port direction register (DDR) corresponding to that pin to "0" (input).

13.7 Register

This section describes the register of the external interrupt circuit.

Table 13.7-1 List of External Interrupt Circuit Register

Register abbreviation	Register name	Reference
EIC	External interrupt control register	13.7.1

13.7.1 External Interrupt Control Register (EIC)

The external interrupt control register (EIC) is used to select the edge polarity for the external interrupt input and control interrupts.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	EIR1	SL11	SL10	EIE1	EIR0	SL01	SL00	EIE0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

Register Functions

[bit7] EIR1: External interrupt request flag bit 1

This flag is set to "1" when the edge selected by the edge polarity select bits 1 (SL1[1:0]) is input to the external interrupt pin INTn+1.

When this bit and the interrupt request enable bit 1 (EIE1) are set to "1", an interrupt request is output.

Writing "0" clears this bit. Writing "1" has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit7	Details
Reading "0"	Indicates that the specified edge has not been input.
Reading "1"	Indicates that the specified edge has been input.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit6:5] SL1[1:0]: Edge polarity select bits 1

These bits select the polarity of an edge of the pulse input to the external interrupt pin INTn+1. The edge selected is to be the interrupt source.

If these bits are set to "0b00", no edge detection is performed and no interrupt request is made.

If these bits are set to "0b01", rising edges are to be detected; if "0b10", falling edges are to be detected; if "0b11", both edges are to be detected.

bit6:5	Details
Writing "00"	No edge detection
Writing "01"	Rising edge
Writing "10"	Falling edge
Writing "11"	Both edges

[bit4] EIE1: Interrupt request enable bit 1

This bit enables or disables outputting the interrupt request to the interrupt controller. When this bit and the external interrupt request flag bit 1 (EIR1) are "1", an interrupt request is output.

When using an external interrupt pin, write "0" to the corresponding bit in the port direction register (DDR) to set the pin as an input port.

The status of the external interrupt pin can be read directly from the port data register, regardless of the status of the interrupt request enable bit.

bit4	Details
Writing "0"	Disables outputting the interrupt request.
Writing "1"	Enables outputting the interrupt request.

[bit3] EIR0: External interrupt request flag bit 0

This flag is set to "1" when the edge selected by the edge polarity select bits 0 (SL0[1:0]) is input to the external interrupt pin INTn.

When this bit and the interrupt request enable bit 0 (EIE0) are set to "1", an interrupt request is output.

Writing "0" clears this bit. Writing "1" has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit3	Details
Reading "0"	Indicates that the specified edge has not been input.
Reading "1"	Indicates that the specified edge has been input.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit2:1] SL0[1:0]: Edge polarity select bits 0

These bits select the polarity of an edge of the pulse input to the external interrupt pin INTn. The edge selected is to be the interrupt source.

If these bits are set to "0b00", no edge detection is performed and no interrupt request is made.

If these bits are set to "0b01", rising edges are to be detected; if "0b10", falling edges are to be detected; if "0b11", both edges are to be detected.

bit2:1	Details
Writing "00"	No edge detection
Writing "01"	Rising edge
Writing "10"	Falling edge
Writing "11"	Both edges

[bit0] EIE0: Interrupt request enable bit 0

This bit enables or disables outputting the interrupt request to the interrupt controller. When this bit and the external interrupt request flag bit 0 (EIR0) are "1", an interrupt request is output.

When using an external interrupt pin, write "0" to the corresponding bit in the port direction register (DDR) to set the pin as an input port.

The status of the external interrupt pin can be read directly from the port data register, regardless of the status of the interrupt request enable bit.

bit0	Details
Writing "0"	Disables outputting the interrupt request.
Writing "1"	Enables outputting the interrupt request.

13.8 Notes on Using External Interrupt Circuit

This section provides notes on using the external interrupt circuit.

■ Notes on Using External Interrupt Circuit

- Before setting the edge polarity select bits (SL0[1:0] or SL1[1:0]), set the interrupt request enable bit (EIE0 or EIE1) to "0" (disabling interrupt requests). In addition, clear the external interrupt request flag bit (EIR0 or EIR1) to "0" after setting the edge polarity.
- The device cannot wake up from the interrupt service routine if the external interrupt request flag bit is "1" and the interrupt request enable bit is enabled. In the interrupt service routine, always clear the external interrupt request flag bit.

CHAPTER 14

INTERRUPT PIN SELECTION CIRCUIT

This chapter describes the functions and operations of the interrupt pin selection circuit.

- 14.1 Overview
- 14.2 Configuration
- 14.3 Pins
- 14.4 Operation
- 14.5 Register
- 14.6 Notes on Using Interrupt Pin Selection Circuit

14.1 Overview

The interrupt pin selection circuit selects pins to be used as interrupt input pins from among various peripheral input pins.

■ Interrupt Pin Selection Circuit

The interrupt pin selection circuit is used to select interrupt input pins from among various peripheral inputs (EC0, INT00, UCK0 and UI0). The input signal from each peripheral function pin is selected by this circuit and the signal is used as the INT00 (ch. 0) input of external interrupt. This enables the input signal from each peripheral function pin to also serve as an external interrupt pin.

14.2 Configuration

Figure 14.2-1 and Figure 14.2-2 show the block diagrams of the interrupt pin selection circuit.

■ Block Diagrams of Interrupt Pin Selection Circuit

Figure 14.2-1 Block Diagram of Interrupt Pin Selection Circuit (MB95710L Series)

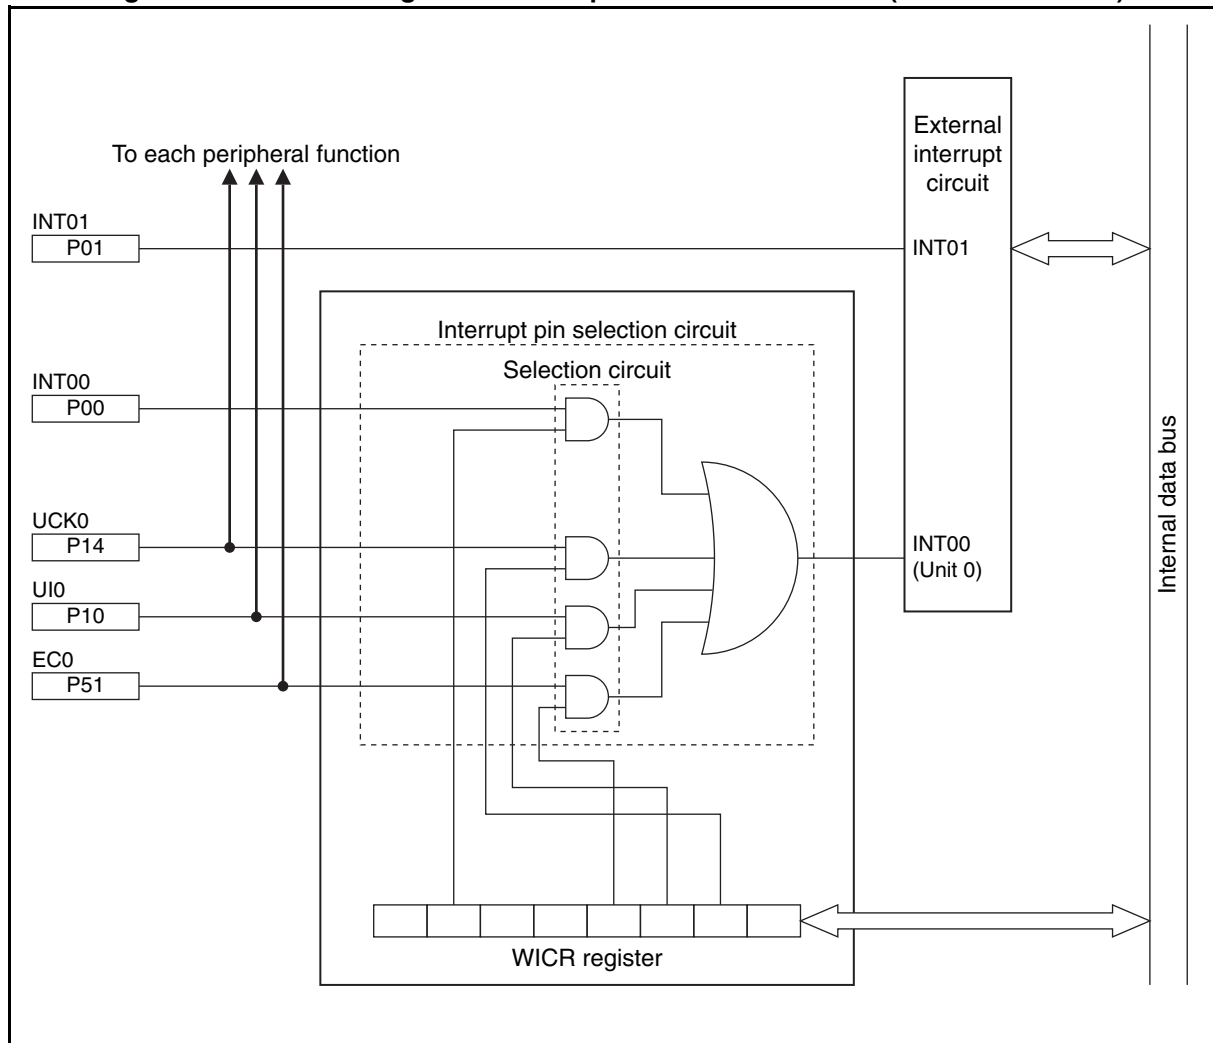

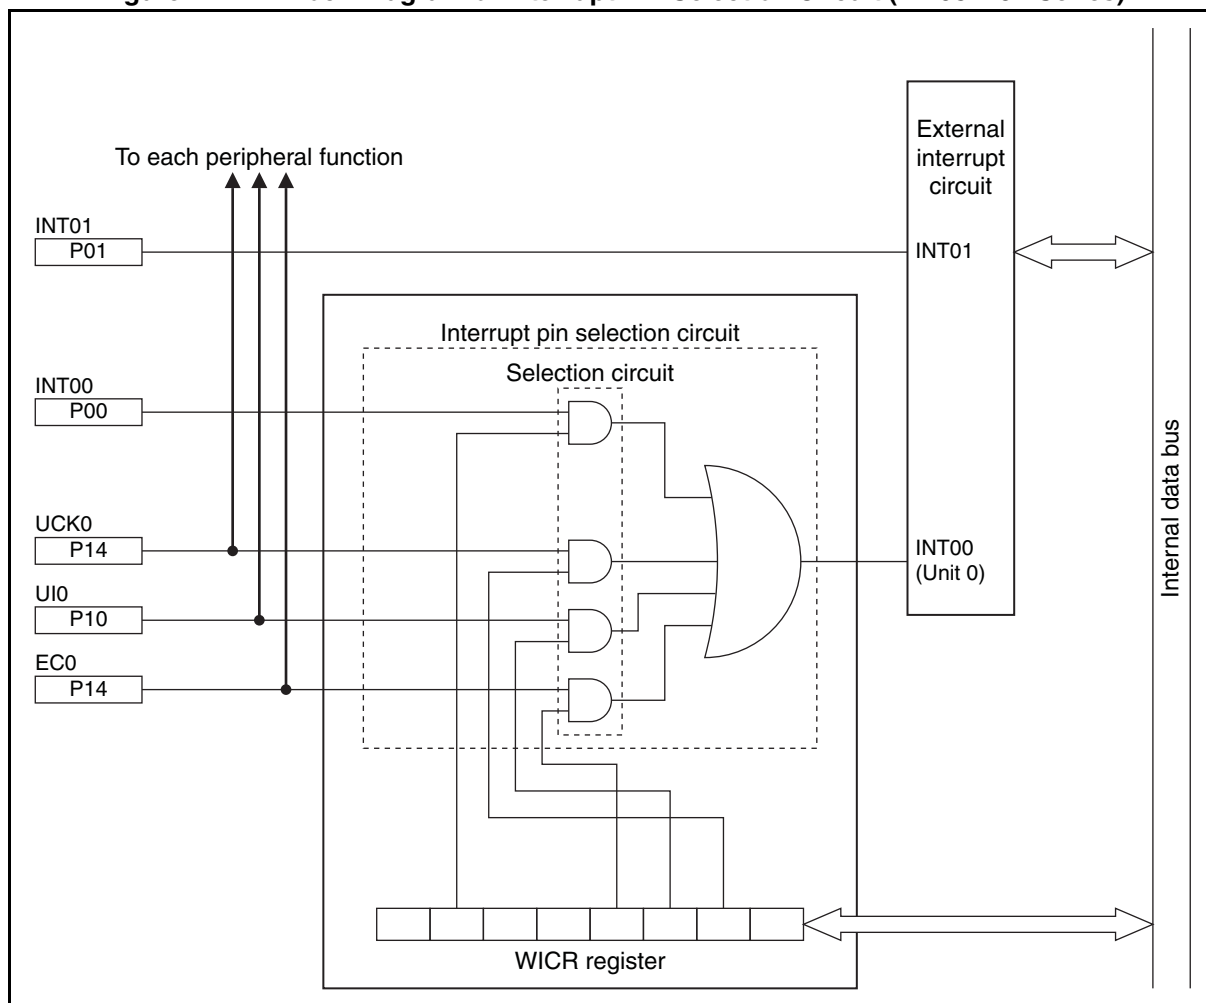

Figure 14.2-2 Block Diagram of Interrupt Pin Selection Circuit (MB95770L Series)

- **WICR register (interrupt pin selection circuit control register)**
This register is used to determine which of the available peripheral input pins should be output to the interrupt circuit and which interrupt pins they should serve as.
- **Selection circuit**
This circuit outputs the input from the pin selected by the WICR register to the INT00 input of the external interrupt circuit (ch. 0).

14.3 Pins

This section describes the pins of the interrupt pin selection circuit.

■ Pins of Interrupt Pin Selection Circuit

The peripheral function pins of the interrupt pin selection circuit are the EC0, INT00, UCK0 and UI0 pins. These input pins (except INT00) are also connected to their respective peripheral units in parallel and can be used for both functions simultaneously. Table 14.3-1 shows the correspondence between the peripheral functions and peripheral input pins.

Table 14.3-1 Correspondence between Peripheral Functions and Peripheral Input Pins

Peripheral input pin name	Peripheral functions name
EC0	8/16-bit composite timer (event input)
INT00	Interrupt pin selection circuit
UCK0	UART/SIO (clock I/O)
UI0	UART/SIO (data input)

14.4 Operation

The interrupt pins are selected by setting the WICR register.

■ Operation of Interrupt Pin Selection Circuit

The WICR register selects the input pins to be input to INT00 of the external interrupt circuit (ch. 0). Below is a setup procedure for the interrupt pin selection circuit and external interrupt circuit (ch. 0), which must be followed when selecting the UCK0 pin as an interrupt pin.

1. Write "0" to the corresponding bit in the port direction register (DDR) to set the pin as an input.
2. Select the UCK0 pin as an interrupt input pin in the WICR register.
 - Write "0x02" to the WICR register. At this point, write "0" to the EIE0 bit in the EIC00 register of the external interrupt circuit to disable the operation of the external interrupt circuit.
3. Enable the operation of INT00 of the external interrupt circuit (ch. 0).
 - Set the SLO[1:0] bits in the EIC00 register to any value other than "0b00" in the external interrupt circuit to select the valid edge. Also write "1" to the EIE0 bit to enable interrupts.
4. The subsequent interrupt operation is the same as that of the external interrupt circuit.
 - When a reset is released, the WICR register is initialized to "0x40" and the INT00 bit is selected as the only available interrupt pin. To use any pins other than the INT00 pin as external interrupt pins, modify the settings of this register before enabling the operation of the external interrupt circuit.

14.5 Register

This section describes the register of the interrupt pin selection circuit.

Table 14.5-1 List of External Interrupt Circuit Register

Register abbreviation	Register name	Reference
WICR	Interrupt pin selection circuit control register	14.5.1

14.5.1 Interrupt Pin Selection Circuit Control Register (WICR)

This register is used to determine which of the available peripheral input pins should be output to the interrupt circuit and which interrupt pins they should serve as.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	INT00	—	—	EC0	UI0	UCK0	—
Attribute	—	R/W	—	—	R/W	R/W	R/W	—
Initial value	0	1	0	0	0	0	0	0

■ Register Functions

[bit7] Undefined bit

The read value is always "0". Writing a value to this bit has no effect on operation.

[bit6] INT00: INT00 interrupt pin select bit

This bit determines whether to select the INT00 pin as an interrupt input pin.

Writing "0" to this bit deselects the INT00 pin as an interrupt input pin, and the interrupt pin selection circuit treats the INT00 pin input as being fixed at "0".

Writing "1" to this bit selects the INT00 pin as an interrupt input pin and the circuit passes the INT00 pin input to INT00 (ch. 0) of the external interrupt circuit. In this case, the input signal to the INT00 pin can generate an external interrupt if INT00 (ch. 0) operation is enabled in the external interrupt circuit.

bit6	Details
Writing "0"	Deselects the INT00 pin as an interrupt input pin.
Writing "1"	Selects the INT00 pin as an interrupt input pin.

[bit5:4] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit3] EC0: EC0 interrupt pin select bit

This bit determines whether to select the EC0 pin as an interrupt input pin.

Writing "0" to this bit deselects the EC0 pin as an interrupt input pin, and the interrupt pin selection circuit treats the EC0 pin input as being fixed at "0".

Writing "1" to this bit selects the EC0 pin as an interrupt input pin and the circuit passes the EC0 pin input to INT00 (ch. 0) of the external interrupt circuit. In this case, the input signal to the EC0 pin can generate an external interrupt if INT00 (ch. 0) operation is enabled in the external interrupt circuit.

bit3	Details
Writing "0"	Deselects the EC0 pin as an interrupt input pin.
Writing "1"	Selects the EC0 pin as an interrupt input pin.

[bit2] UI0: UI0 interrupt pin select bit

This bit determines whether to select the UI0 pin as an interrupt input pin.

Writing "0" to this bit deselects the UI0 pin as an interrupt input pin, and the interrupt pin selection circuit treats the UI0 pin input as being fixed at "0".

Writing "1" to this bit selects the UI0 pin as an interrupt input pin and the circuit passes the UI0 pin input to INT00 (ch. 0) of the external interrupt circuit. In this case, the input signal to the UI0 pin can generate an external interrupt if INT00 (ch. 0) operation is enabled in the external interrupt circuit.

bit2	Details
Writing "0"	Deselects the UI0 pin as the interrupt input pin.
Writing "1"	Selects the UI0 pin as the interrupt input pin.

[bit1] UCK0: UCK0 interrupt pin select bit

This bit determines whether to select the UCK0 pin as an interrupt input pin.

Writing "0" to this bit deselects the UCK0 pin as an interrupt input pin, and the interrupt pin selection circuit treats the UCK0 pin input as "0".

Writing "1" to this bit selects the UCK0 pin as an interrupt input pin and the circuit passes the UCK0 pin input to INT00 (ch. 0) of the external interrupt circuit. In this case, the input signal to the UCK0 pin can generate an external interrupt if INT00 (ch. 0) operation is enabled in the external interrupt circuit.

bit1	Details
Writing "0"	Deselects the UCK0 pin as the interrupt input pin.
Writing "1"	Selects the UCK0 pin as the interrupt input pin.

[bit0] Undefined bit

The read value is always "0". Writing a value to this bit has no effect on operation.

When any of these bits (except undefined bits) is set to "1" and the operation of INT00 (ch. 0) of the external interrupt circuit is enabled in standby mode of this device, the selected pin is enabled to perform input operation. The device wakes up from the standby mode when a valid edge pulse is input to the selected pin. For detail of the standby mode, see "3.5 Operations in Low Power Consumption Mode (Standby Mode)".

Note:

The input signals to the peripheral pins do not generate an external interrupt even when "1" is written to these bits if the INT00 (ch. 0) of the external interrupt circuit is disabled.

Do not modify the values of these bits while the INT00 (ch. 0) of the external interrupt circuit is enabled. If modified, the external interrupt circuit may detect a valid edge, depending on the pin input level.

If multiple interrupt pins are selected in the WICR register simultaneously and the operation of INT00 (ch. 0) of the external interrupt circuit is enabled (the values other than "0b00" are written to the SL0[1:0] bits in the EIC register of the external interrupt circuit.), the selected pins will remain enabled to perform input so as to accept interrupts even in standby mode.

14.6 Notes on Using Interrupt Pin Selection Circuit

This section provides notes on using the interrupt pin selection circuit.

- If multiple interrupt pins are selected in the WICR register simultaneously and the operation of INT00 (ch. 0) of the external interrupt circuit is enabled (a value other than "0b00" is written to the SL0[1:0] bits in the EIC register of the external interrupt circuit to select a valid edge, and "1" is written to the EIE0 bit to enable the interrupt request.), the input to the selected pins will remain enabled so as to accept interrupts even in standby mode.
- If multiple interrupt pins are selected in the WICR register simultaneously, an input to INT00 (ch. 0) of the external interrupt circuit is treated as "H" if any of the selected input signals is "H" (It becomes "OR" of the signals input to the selected pins).

CHAPTER 15

8/12-BIT A/D CONVERTER

This chapter describes the functions and operations of the 8/12-bit A/D converter.

- 15.1 Overview
- 15.2 Configuration
- 15.3 Pins
- 15.4 Interrupt
- 15.5 Enabling Operation of 8/12-bit A/D Converter
- 15.6 Operations and Setting Procedure Example
- 15.7 Registers
- 15.8 Notes on Using 8/12-bit A/D Converter

15.1 Overview

The 8/12-bit A/D converter is a 12-bit successive approximation type of 8/12-bit A/D converter. It can be started by the software and internal clock, with one input signal selected from multiple analog input pins.

■ A/D Conversion Function

The 8/12-bit A/D converter converts analog voltage (input voltage) input through an analog input pin to an 8-bit or 12-bit digital value.

- The input signal can be selected from multiple analog input pins.
- The conversion speed can be set in a program. (can be selected according to operating voltage and frequency).
- An interrupt is generated when A/D conversion is completed.
- The completion of conversion can be determined according to the ADI bit in the ADC1 register.

To activate the A/D conversion function, use one of the following methods.

- Activation using the AD bit in the ADC1 register
- Continuous activation using the 8/16-bit composite timer output TO00

15.2 Configuration

The 8/12-bit A/D converter consists of the following blocks:

- Clock selector (input clock selector for starting A/D conversion)
 - Analog channel selector
 - Sample-and-hold circuit
 - Control circuit
 - 8/12-bit A/D converter operation enable state transition time counter
 - 8/12-bit A/D converter data register (upper/lower) (ADDH/ADDL)
 - 8/12-bit A/D converter control register 1 (ADC1)
 - 8/12-bit A/D converter control register 2 (ADC2)
 - 8/12-bit A/D converter control register 3 (ADC3)
-

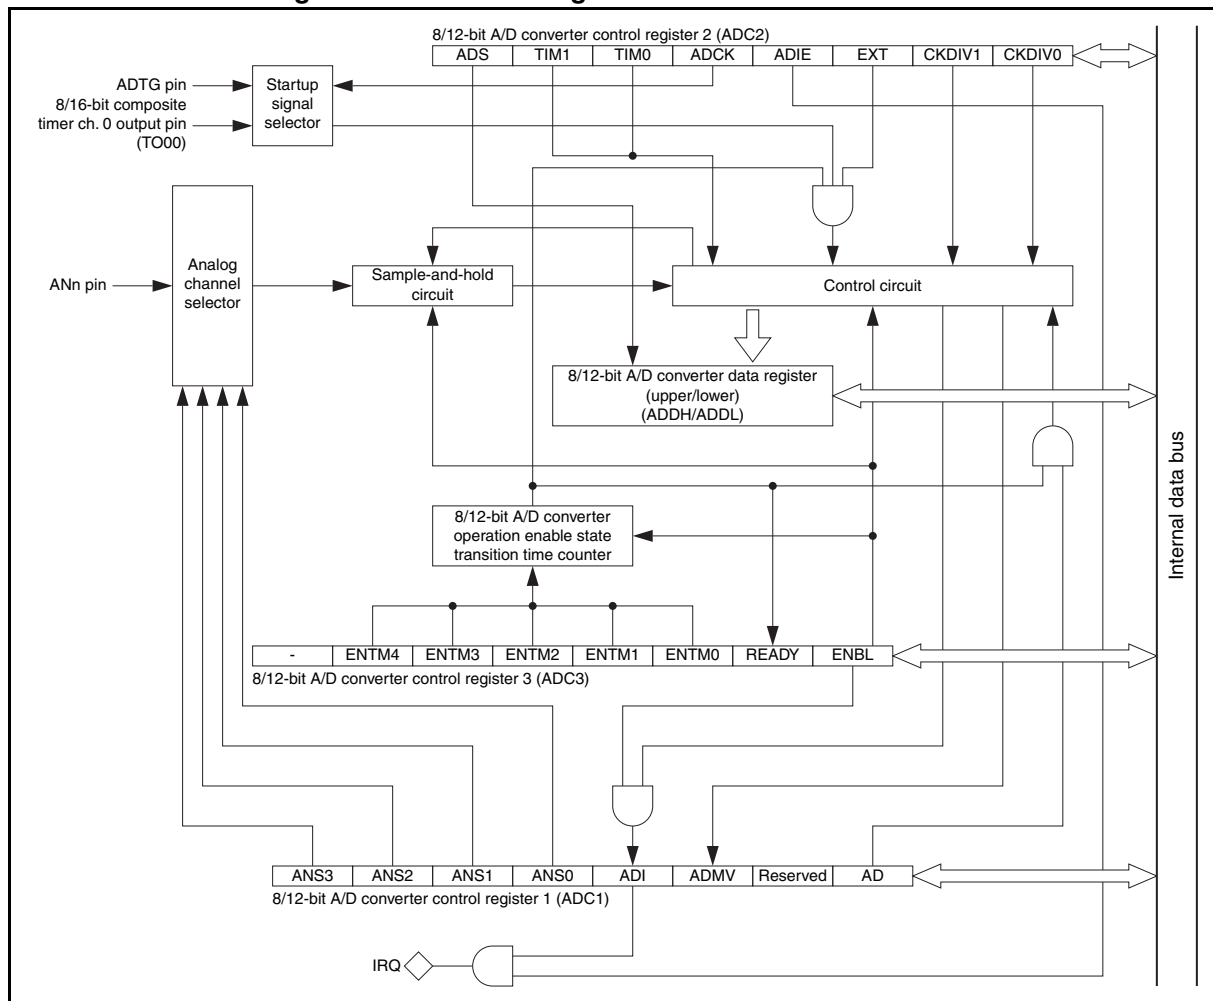

The number of analog input pins and that of analog channels of the 8/12-bit A/D converter vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name represents the analog input pin number. For details of pin names of a product, refer to the device data sheet.

■ Block Diagram of 8/12-bit A/D Converter

Figure 15.2-1 is the block diagram of the 8/12-bit A/D converter.

Figure 15.2-1 Block Diagram of 8/12-bit A/D Converter

- **Clock selector**

This selects the A/D conversion clock with continuous activation having been enabled (ADC2:EXT = 1).

- **Analog channel selector**

This is the circuit selecting an input channel from several analog input pins.

- **Sample-and-hold circuit**

This circuit holds input voltage selected by the analog channel selector. By sampling the input voltage and holding it immediately after A/D conversion starts, this circuit prevents A/D conversion from being affected by the fluctuation in input voltage during the conversion (comparison).

- **Control circuit**

The A/D conversion function determines the values in the 12-bit A/D data register sequentially from MSB to LSB based on the voltage compare signal from the comparator. When A/D

conversion is completed, the A/D conversion function sets the interrupt request flag bit (ADC1:ADI) to "1".

- 8/12-bit A/D converter data register (upper/lower) (ADDH/ADDL)

The upper two bits of 12-bit A/D data are stored in the ADDH register; the lower eight bits in the ADDL register.

If the A/D conversion precision bit (ADC2:AD8) is set to "1", the A/D conversion precision becomes 8-bit precision, and the upper eight bits of 12-bit A/D data are to be stored in the ADDL register.

- 8/12-bit A/D converter control register 1 (ADC1)

This register enables or disables different functions, selects an analog input pin and checks the status of the 8/12-bit A/D converter.

- 8/12-bit A/D converter control register 2 (ADC2)

This register selects an input clock, enables or disables interrupts and controls different functions of the 8/12-bit A/D converter.

- 8/12-bit A/D converter control register 3 (ADC3)

This register switches the 8/12-bit A/D converter between the operation enable state and the operation disable state.

- 8/12-bit A/D converter operation enable state transition time counter

This is the dedicated counter for counting the time of the 8/12-bit A/D converter transiting from the operation disable state to the operation enable state. The transition time can be adjusted by modifying the value of the ENTM[4:0] bits in the ADC3 register.

■ Input Clock

The 8/12-bit A/D converter uses an output clock from the prescaler as the input clock (operating clock).

15.3 Pins

This section describes the pins of the 8/12-bit A/D converter.

■ Pins of 8/12-bit A/D Converter

- ANn pin

When using the A/D conversion function, input to the ANn pin the analog voltage to be converted. To use an ANn pin as an analog input pin, write "0" to the bit in the port direction register (DDR) corresponding to that pin, and the value corresponding to that pin to the analog input pin select bits (ADC1:ANS[3:0]). A pin not used as an analog input pin can be used as a general-purpose I/O port even when the 8/12-bit A/D converter is in use.

- ADTG pin

This is a pin used to activate the A/D conversion function with an external trigger. Before using the ADTG pin to activate the A/D conversion function with an external trigger, set the pin as an input port using the corresponding DDR register.

15.4 Interrupt

The completion of conversion during the operation of the 8/12-bit A/D converter is an interrupt source of the 8/12-bit A/D converter.

■ Interrupt During 8/12-bit A/D Converter Operation

When A/D conversion is completed, the interrupt request flag bit (ADC1:ADI) is set to "1". Then if the interrupt request enable bit has been enabled (ADC2:ADIE = 1), an interrupt request is made to the interrupt controller. Write "0" to the ADI bit using the interrupt service routine to clear the interrupt request.

The ADI bit is set to "1" when A/D conversion is completed, irrespective of the value of the ADIE bit.

The CPU cannot return from interrupt processing if the interrupt request flag bit (ADC1:ADI) is "1" with interrupt requests having been enabled (ADC2:ADIE = 1). Always clear the ADI bit in the interrupt service routine.

15.5 Enabling Operation of 8/12-bit A/D Converter

This section describes details of enabling the operation of the 8/12-bit A/D converter.

Before executing A/D conversion, the 8/12-bit A/D converter must be in the operation enable state. Writing "1" to the ENBL bit in the ADC3 register makes the 8/12-bit A/D converter, after the operation enable state transition time elapses, transit from the operation disable state to the operation enable state. Writing "0" to the ENBL bit makes the 8/12-bit A/D converter immediately transit to the operation disable state.

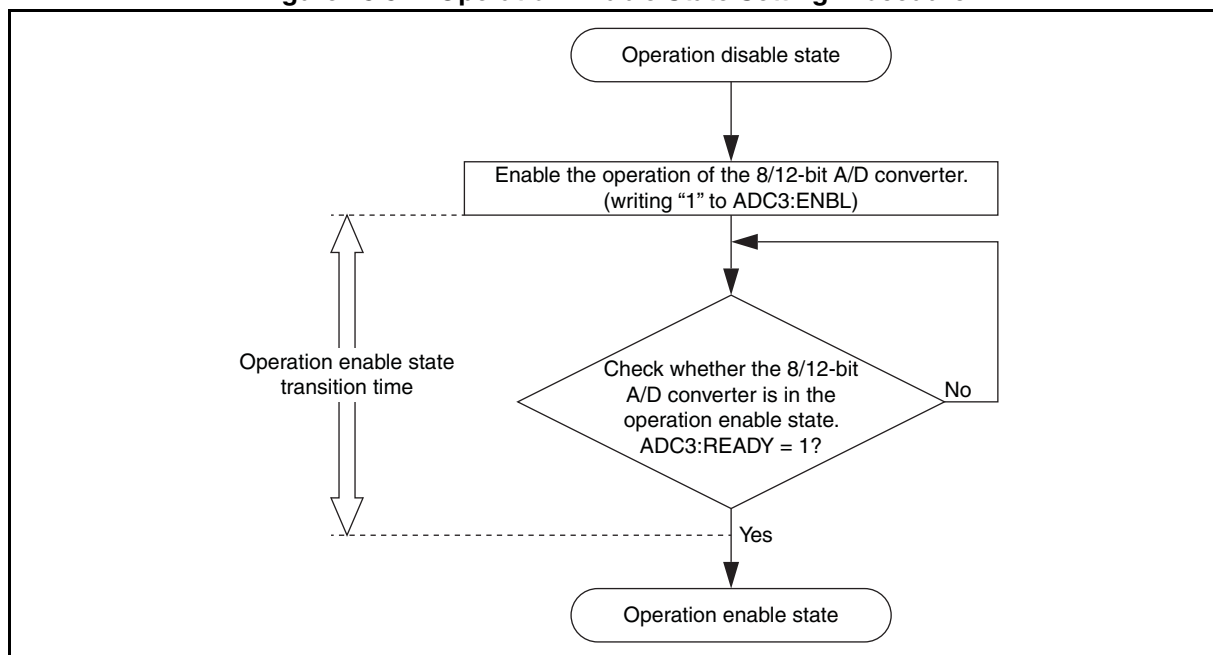

Only in the operation enable state can the 8/12-bit A/D converter execute A/D conversion.

In the operation disable state, all A/D conversion requests are ignored.

Reading the READY bit in the ADC3 register can check whether the 8/12-bit A/D converter is in the operation enable state.

Figure 15.5-1 shows the procedure for setting the operation enable state.

Figure 15.5-1 Operation Enable State Setting Procedure

Note:

The operation enable state transition time can be adjusted by modifying the value of the ENTM[4:0] bits in the ADC3 register. Select an appropriate transition time in relation to the machine clock (MCLK) cycle following the specifications shown in "■ ELECTRICAL CHARACTERISTICS" in the device data sheet.

15.6 Operations and Setting Procedure Example

The 8/12-bit A/D converter can activate A/D conversion with the software or activate A/D conversion continuously according to the setting of the EXT bit in the ADC2 register.

■ Operations of 8/12-bit A/D Converter Conversion Function

● Software activation

To activate the A/D conversion function with the software, do the settings shown in Figure 15.6-1.

Figure 15.6-1 Settings for A/D Conversion Function (Software Activation)

Figure 10-3-1 Settings for A/D Conversion Function (Software Activation)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
ADC1	ANS3	ANS2	ANS1	ANS0	ADI	ADMV	Reserved	AD
	⊙	⊙	⊙	⊙	⊙	⊙	0	1
ADC2	AD8	TIM1	TIM0	ADCK	ADIE	EXT	CKDIV1	CKDIV0
	⊙	⊙	⊙	x	⊙	0	⊙	⊙
ADC3	-	ENTM4	ENTM3	ENTM2	ENTM1	ENTM0	READY	ENBL
	0	⊙	⊙	⊙	⊙	⊙	1	1
ADDH	-	-	-	-	A/D converted value retained			
ADDL	A/D converted value retained							

⊙: Bit to be used
x : Unused bit
0 : Set to "0"
1 : Set to "1"

When the A/D conversion function is activated, A/D conversion starts. In addition, the A/D conversion function can be re-activated even during conversion.

● Continuous activation

To execute continuous activation of the A/D conversion function, do the settings shown in Figure 15.6-2.

Figure 15.6-2 Settings for A/D Conversion Function (Continuous Activation)

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
ADC1	ANS3	ANS2	ANS1	ANS0	ADI	ADMV	Reserved	AD
	⊙	⊙	⊙	⊙	⊙	⊙	0	x
ADC2	AD8	TIM1	TIM0	ADCK	ADIE	EXT	CKDIV1	CKDIV0
	⊙	⊙	⊙	⊙	⊙	1	⊙	⊙
ADC3	-	ENTM4	ENTM3	ENTM2	ENTM1	ENTM0	READY	ENBL
	0	⊙	⊙	⊙	⊙	⊙	1	1
ADDH	-	-	-	-	A/D converted value retained			
ADDL	A/D converted value retained							

⊙ : Bit to be used
x : Unused bit
0 : Set to "0"
1 : Set to "1"

When continuous activation is enabled, the A/D conversion function is activated at the rising edge of the input clock selected to start A/D conversion. Continuous activation is stopped when disabled (ADC2:EXT = 0).

■ Operations of A/D Conversion Function

This section explains the operations of 8/12-bit A/D converter.

1. When A/D conversion is started, the conversion flag bit is set (ADC1:ADMV = 1) and the selected analog input pin is connected to the sample-and-hold circuit.
2. The voltage in the analog input pin is loaded into a sample-and-hold capacitor in the sample-and-hold circuit during the sampling cycle. This voltage is held until A/D conversion is completed.
3. The comparator in the control circuit compares the voltage loaded into sample-and-hold capacitor with the A/D conversion reference voltage, from the most significant bit (MSB) to the least significant bit (LSB), and then transfers the results to the ADDH and ADDL registers.

After the results have been transferred to the two registers, the conversion flag bit is cleared (ADC1:ADMV = 0) and the interrupt request flag bit is set to "1" (ADC1:ADI = 1).

Notes:

- The contents of the ADDH and ADDL registers are saved at the end of A/D conversion. Therefore, during A/D conversion, the values resulting from last conversion will be returned if the two registers are read.
- Do not change the analog input pin select bits (ADC1:ANS[3:0]) while AD conversion function is being used. During continuous activation in particular, disable continuous activation (ADC2:EXT = 0) before changing the analog input pin.
- A reset, or the start of the stop mode or watch mode causes the 8/12-bit A/D converter to stop and the ADMV bit to be cleared to "0".

■ Setting Procedure Example

Below is an example of procedure for setting the 8/12-bit A/D converter:

● Initial settings

1. Set the input port. (DDR)
2. Set the interrupt level. (ILR*)
3. Enable the operation of the 8/12-bit A/D converter. (ADC3:ENTM[4:0], ADC3:ENBL = 1)
4. Select an A/D input pin. (ADC1:ANS[3:0])
5. Set the sampling time. (ADC2:TIM[1:0])
6. Select the clock. (ADC2:CKDIV[1:0])
7. Set A/D conversion precision. (ADC2:AD8)
8. Select the operating mode. (ADC2:EXT)
9. Select the start trigger. (ADC2:ADCK)
10. Enable interrupts. (ADC2:ADIE = 1)
11. Check that the 8/12-bit A/D converter is in the operation enable state. (ADC3:READY = 1)
12. Activate the A/D conversion function. (ADC1:AD = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

1. Clear the interrupt request flag to "0". (ADC1:ADI = 0)
2. Read converted values. (ADDH, ADDL)
3. Activate the A/D conversion function. (ADC1:AD = 1)

15.7 Registers

This section describes the registers of the 8/12-bit A/D converter.

Table 15.7-1 List of 8/12-bit A/D Converter Registers

Register abbreviation	Register name	Reference
ADC1	8/12-bit A/D converter control register 1	15.7.1
ADC2	8/12-bit A/D converter control register 2	15.7.2
ADC3	8/12-bit A/D converter control register 3	15.7.3
ADDH	8/12-bit A/D converter data register (upper)	15.7.4
ADDL	8/12-bit A/D converter data register (lower)	15.7.4

15.7.1 8/12-bit A/D Converter Control Register 1 (ADC1)

The 8/12-bit A/D converter control register 1 (ADC1) enables or disables individual functions of the 8/12-bit A/D converter, selects an analog input pin and checks the status of the 8/12-bit A/D converter.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	ANS3	ANS2	ANS1	ANS0	ADI	ADMV	Reserved	AD
Attribute	R/W	R/W	R/W	R/W	R/W	R	W	W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:4] ANS[3:0]: Analog input pin select bits

These bits select an analog input pin.

When A/D conversion is started (AD = 1) by the software (ADC2: EXT = 0), these bits can be modified simultaneously.

bit7:4	Details*
Writing "0000"	AN00 pin
Writing "0001"	AN01 pin
Writing "0010"	AN02 pin
Writing "0011"	AN03 pin
Writing "0100"	AN04 pin
Writing "0101"	AN05 pin
Writing "0110"	AN06 pin
Writing "0111"	AN07 pin
Writing "1000"	AN08 pin
Writing "1001"	AN09 pin
Writing "1010"	AN10 pin
Writing "1011"	AN11 pin

*: The number of analog input pins vary among products. For the number of analog input pins of a product, refer to its data sheet.

Notes:

- Do not write to ANS[3:0] any value other than those listed in the table above.
- When the ADMV bit is "1", do not modify these bits. Pins not used as analog input pins can be used as general-purpose I/O ports.

[bit3] ADI: Interrupt request flag bit

This bit detects the completion of A/D conversion.

When the A/D conversion function is used, the bit is set to "1" immediately after A/D conversion is complete.

Interrupt requests are output when this bit and the interrupt request enable bit (ADC2: ADIE) are both set to "1".

When "0" is written to this bit, it is cleared. Writing "1" to this bit does not change it or affect other bits.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit3	Details
Reading "0"	Indicates that A/D conversion has not been completed.
Reading "1"	Indicates that A/D conversion has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit2] ADMV: Conversion flag bit

This bit indicates that A/D conversion is in progress.

The bit is set to "1" during A/D conversion.

This bit is read-only. Writing a value to this bit has no effect on operation.

bit2	Details
Reading "0"	Indicates that A/D conversion is not executed.
Reading "1"	Indicates that A/D conversion is in progress.

[bit1] Reserved bit

Always set this bit to "0".

[bit0] AD: A/D conversion start bit

This bit starts the A/D conversion function with the software.

Writing "1" to the bit starts the A/D conversion function.

When the continuous start enable bit in the ADC2 register (ADC2:EXT) is "1", starting the A/D conversion with this bit is disabled.

With the EXT bit set to "0", when "1" is written to this bit while A/D conversion is in progress, A/D conversion restarts.

bit0	Details
Writing "0"	Has no effect on operation.
Writing "1"	Starts the A/D conversion function.

Note: Writing "0" to this bit cannot stop the operation of the A/D conversion function. The read value of this bit is always "0".

15.7.2 8/12-bit A/D Converter Control Register 2 (ADC2)

The 8/12-bit A/D converter control register 2 (ADC2) controls different functions of the 8/12-bit A/D converter, selects the input clock, and enables or disables interrupts.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	AD8	TIM1	TIM0	ADCK	ADIE	EXT	CKDIV1	CKDIV0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] AD8: Precision select bit

This bit selects the resolution of A/D conversion.

Writing "0" to this bit selects 12-bit precision.

Writing "1" to this bit selects 8-bit precision. Reading the ADDL register can obtain 8-bit data.

bit7	Details
Writing "0"	12-bit precision
Writing "1"	8-bit precision

Note: The data bits to be used are different depending on the resolution selected. Modify this bit only when the A/D converter has stopped operating.

[bit6:5] TIM[1:0]: Sampling time select bits

These bits select the sampling time.

Modify the sampling time according to operating conditions (voltage and frequency).

The CKIN value is determined by the clock select bits (ADC2:CKDIV[1:0]).

bit6:5	Details
Writing "00"	$CKIN \times 2$
Writing "01"	$CKIN \times 5$
Writing "10"	$CKIN \times 8$
Writing "11"	$CKIN \times 14$

Note: Modify these bits only when the A/D converter has stopped operating.

[bit4] ADCK: External start signal select bit

This bit selects the start signal for external start (ADC2:EXT = 1).

bit4	Details
Writing "0"	Selects the ADTG pin as the pin used to start the A/D conversion function.
Writing "1"	Selects the 8/16-bit composite timer ch. 0 output pin (TO00) as the pin used to start the A/D conversion function.

[bit3] ADIE: Interrupt request enable bit

This bit enables or disables outputting the interrupt request to the interrupt controller.

When both this bit and the interrupt request flag bit (ADC1: ADI) have been set to "1", an interrupt request is output.

bit3	Details
Writing "0"	Disables outputting the interrupt request.
Writing "1"	Enables outputting the interrupt request.

[bit2] EXT: Continuous start enable bit

This bit selects whether to start the A/D conversion function with the software, or to continuously start the A/D conversion function whenever a rising edge of the input clock is detected.

bit2	Details
Writing "0"	Starts the A/D conversion function with the AD bit in the ADC1 register.
Writing "1"	Continuously start the A/D conversion function according to the clock selected by the ADCK bit in the ADC2 register.

[bit1:0] CKDIV[1:0]: Clock select bits

These bits select the clock (CKIN) to be used for A/D conversion. The input clock is generated by the prescaler. See "3.9 Operation of Prescaler" for details.

The sampling time varies according to the clock selected by these bits.

Modify these bits according to operating conditions (voltage and frequency).

bit1:0	Details (MCLK: machine clock)
Writing "00"	1 MCLK
Writing "01"	MCLK/2
Writing "10"	MCLK/4
Writing "11"	MCLK/8

Note: Modify these bits only when the A/D converter has stopped operating.

15.7.3 8/12-bit A/D Converter Control Register 3 (ADC3)

The 8/12-bit A/D converter control register 3 (ADC3) sets the 8/12-bit A/D converter to the operation enable state.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	ENTM4	ENTM3	ENTM2	ENTM1	ENTM0	READY	ENBL
Attribute	—	R/W	R/W	R/W	R/W	R/W	R	R/W
Initial value	0	1	1	1	1	1	0	0

■ Register Functions

[bit7] Undefined bit

The read value of this bit is always "0". Writing a value to this bit has no effect on operation.

[bit6:2] ENTM[4:0]: Operation enable state transition cycle select bits

These bits select the number of operation enable state transition time cycles.

Operation enable state transition time = machine clock (MCLK) cycle × (value of ENTM[4:0] + 1)

Example:

MCLK = 16.25 MHz (61 ns)

ENTM[4:0] = 0x1F

Operation enable state transition time = 61 ns × (31 + 1) = 1925 ns

[bit1] READY: A/D converter operation enable state bit

This bit indicates whether the 8/12-bit A/D converter is in the operation enable state.

Only in the operation enable state can the 8/12-bit A/D converter execute A/D conversion.

In the operation disable state, all A/D conversion requests are ignored.

When the 8/12-bit A/D converter transits to the operation disable state during A/D conversion, A/D conversion stops after the conversion sequence ends (ADC1:ADMV = 0).

bit1	Details
Reading "0"	Indicates that the 8/12-bit A/D converter is in the operation disable state.
Reading "1"	Indicates that the 8/12-bit A/D converter is in the operation enable state.

[bit0] ENBL: A/D converter operation enable/disable bit

This bit enables or disables the operation of the 8/12-bit A/D converter.

Writing "1" to this bit makes the 8/12-bit A/D converter, after the operation enable state transition time elapses, transit from the operation disable state to the operation enable state. Writing "0" to this bit makes the 8/12-bit A/D converter immediately transit to the operation disable state.

bit0	Details
Writing "0"	Disables the operation of the 8/12-bit A/D converter.
Writing "1"	Enables the operation of the 8/12-bit A/D converter.

Notes:

- Modifying the value of the ENTM[4:0] bits is prohibited during the period between writing "1" to the ENBL bit and the READY bit changing to "1". To modify the value of the ENTM[4:0] bits with "1" already written to the ENBL bit, check that the READY bit has been set to "1" beforehand.
 - When a reset is generated or when the stop mode or the watch mode starts, the 8/12-bit A/D converter immediately stops, and the ADMV bit in the ADC1 register, the READY bit and the ENBL bit are cleared to "0".
 - A/D conversion continues for a while after "0" is written to the ENBL bit during A/D conversion. Before enabling the operation of the 8/12-bit A/D converter again by writing "1" to the ENBL bit, check the ADMV bit in the ADC1 register to ensure that the previous A/D conversion has been completed (ADC1:ADMV = 0).
 - During A/D conversion, when the 8/12-bit A/D converter is stopped due to one of the following actions: writing "0" to the ENBL bit, setting the stop mode, and setting the watch mode, the interrupt request flag bit in the ADC1 register may indicate that A/D conversion has been completed (ADC1:ADI = 1), but the values stored in the 8/12-bit A/D converter data register (upper) (ADDH) and the 8/12-bit A/D converter data register (lower) (ADDL) are undefined. Therefore, in the interrupt sequence, do not refer to the values of the ADDH and ADDL registers.
-

15.7.4 8/12-bit A/D Converter Data Register (Upper/Lower) (ADDH/ADDL)

The 8/12-bit A/D converter data register (upper/lower) (ADDH/ADDL) store the results of 12-bit A/D conversion during 12-bit A/D conversion.

The upper four bits of 12-bit data are stored in the ADDH register and the lower eight bits the ADDL register.

■ Register Configuration

ADDH								
bit	7	6	5	4	3	2	1	0
Field	—	—	—	—	SAR11	SAR10	SAR9	SAR8
Attribute	—	—	—	—	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

ADDL								
bit	7	6	5	4	3	2	1	0
Field	SAR7	SAR6	SAR5	SAR4	SAR3	SAR2	SAR1	SAR0
Attribute	R	R	R	R	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

The upper four bits of 12-bit A/D data correspond to bit3 to bit0 in the ADDH register and the lower eight bits bit7 to bit0 in the ADDL register.

If the AD8 bit in the ADC2 register is set to "1", 8-bit precision is selected. Reading the ADDL register can obtain 8-bit data.

These two registers are read-only registers. Writing data to them has no effect on operation.

In A/D conversion in which 8-bit precision is selected, the SAR[11:8] bits in the ADDH register become "0".

● A/D conversion function

When A/D conversion is started, the results of conversion are finalized and stored in the ADDH and ADDL registers after the conversion time according to the register settings elapses. After A/D conversion is completed and before the next A/D conversion is completed, read the A/D data registers (conversion results), and clear the interrupt request flag bit (ADI) in the ADC1 register. During A/D conversion, the values of the ADDH and ADDL registers are results of the last A/D conversion.

15.8 Notes on Using 8/12-bit A/D Converter

This section provides notes on using the 8/12-bit A/D converter.

■ Notes on Using 8/12-bit A/D Converter

● Note on setting the 8/12-bit A/D converter with a program

- The values of the ADDH and ADDL registers are saved at the end of A/D conversion. Therefore, during A/D conversion, the values resulting from last conversion will be returned if the two registers are read.
- Do not change the analog input pin select bits (ADC1:ANS[3:0]) while AD conversion function is being used. During continuous activation in particular, disable continuous activation (ADC2: EXT = 0) before changing the analog input pin.
- A reset, or the start of the stop mode or watch mode causes the 8/12-bit A/D converter to stop and the ADMV bit to be cleared to "0".
- The CPU cannot return from interrupt processing if the interrupt request flag bit (ADC1:ADI) is "1" with interrupt requests having been enabled (ADC2:ADIE = 1). Always clear the ADI bit in the interrupt service routine.

● Note on interrupt requests

If the restart of A/D conversion (ADC1:AD = 1) and the completion of A/D conversion occur simultaneously, the interrupt request flag bit (ADC1:ADI) is set.

● A/D conversion error

As $|V_{CC} - V_{SS}|$ decreases, the A/D conversion error increases proportionately.

● 8/12-bit A/D converter analog input sequences

Turn on the analog input (ANn) and the digital power supply (V_{CC}) simultaneously, or turn on the analog input (ANn) after turning on the digital power supply (V_{CC}).

Turn off the digital power supply (V_{CC}) and the analog input (ANn) simultaneously, or turn off the digital power supply (V_{CC}) after turning off the analog input (ANn).

Ensure that the analog input voltage does not exceed the voltage of the digital power supply (V_{CC}) when turning on or off the power supply of the 8/12-bit A/D converter.

● Conversion time

The conversion speed of A/D conversion function is affected by clock mode, main clock oscillation frequency and main clock speed switching (gear function).

Example:

Sampling time = $CKIN \times (\text{settings of ADC2:TIM}[1:0])$

Compare time = $CKIN \times 13$ (fixed value) + MCLK

8/12-bit A/D converter startup time: minimum = $MCLK \times 2 + CKIN \times 2$

maximum = $MCLK + CKIN \times 3$

Conversion time = 8/12-bit A/D converter startup time + sampling time + compare time

- The conversion time may have an error of up to $(1 \text{ CKIN} - 1 \text{ MCLK})$, depending on the time at which A/D conversion starts.
- When setting the 8/12-bit A/D converter in software, ensure that the settings satisfy all timing specifications of the 8/12-bit A/D converter mentioned in the device data sheet.

CHAPTER 16

LOW-VOLTAGE DETECTION CIRCUIT

This chapter describes the function and operation of the low-voltage detection circuit.

- 16.1 Overview
- 16.2 Configuration
- 16.3 Pins
- 16.4 Interrupt
- 16.5 Operations
- 16.6 Register

16.1 Overview

The low-voltage detection circuit monitors the power supply voltage, and generates a reset signal when the power supply voltage falls below the detection voltage. In addition, when the power supply voltage fluctuates above or below a selected threshold voltage, the low-voltage detection circuit can generate an interrupt.

■ Low-voltage Detection Circuit

The low-voltage detection circuit monitors the power supply voltage, and generates a reset signal when the power supply voltage falls below the detection voltage. In addition, when the power supply voltage fluctuates above or below the selected threshold level, the low-voltage detection circuit can generate an interrupt. The interrupt threshold voltage can be selected from six options through the LVD control register (LVDC).

At power-on, the lowest interrupt threshold voltage is selected in the LVDC register.

The circuit is only available on certain products. Check the availability of the circuit in the device data sheet.

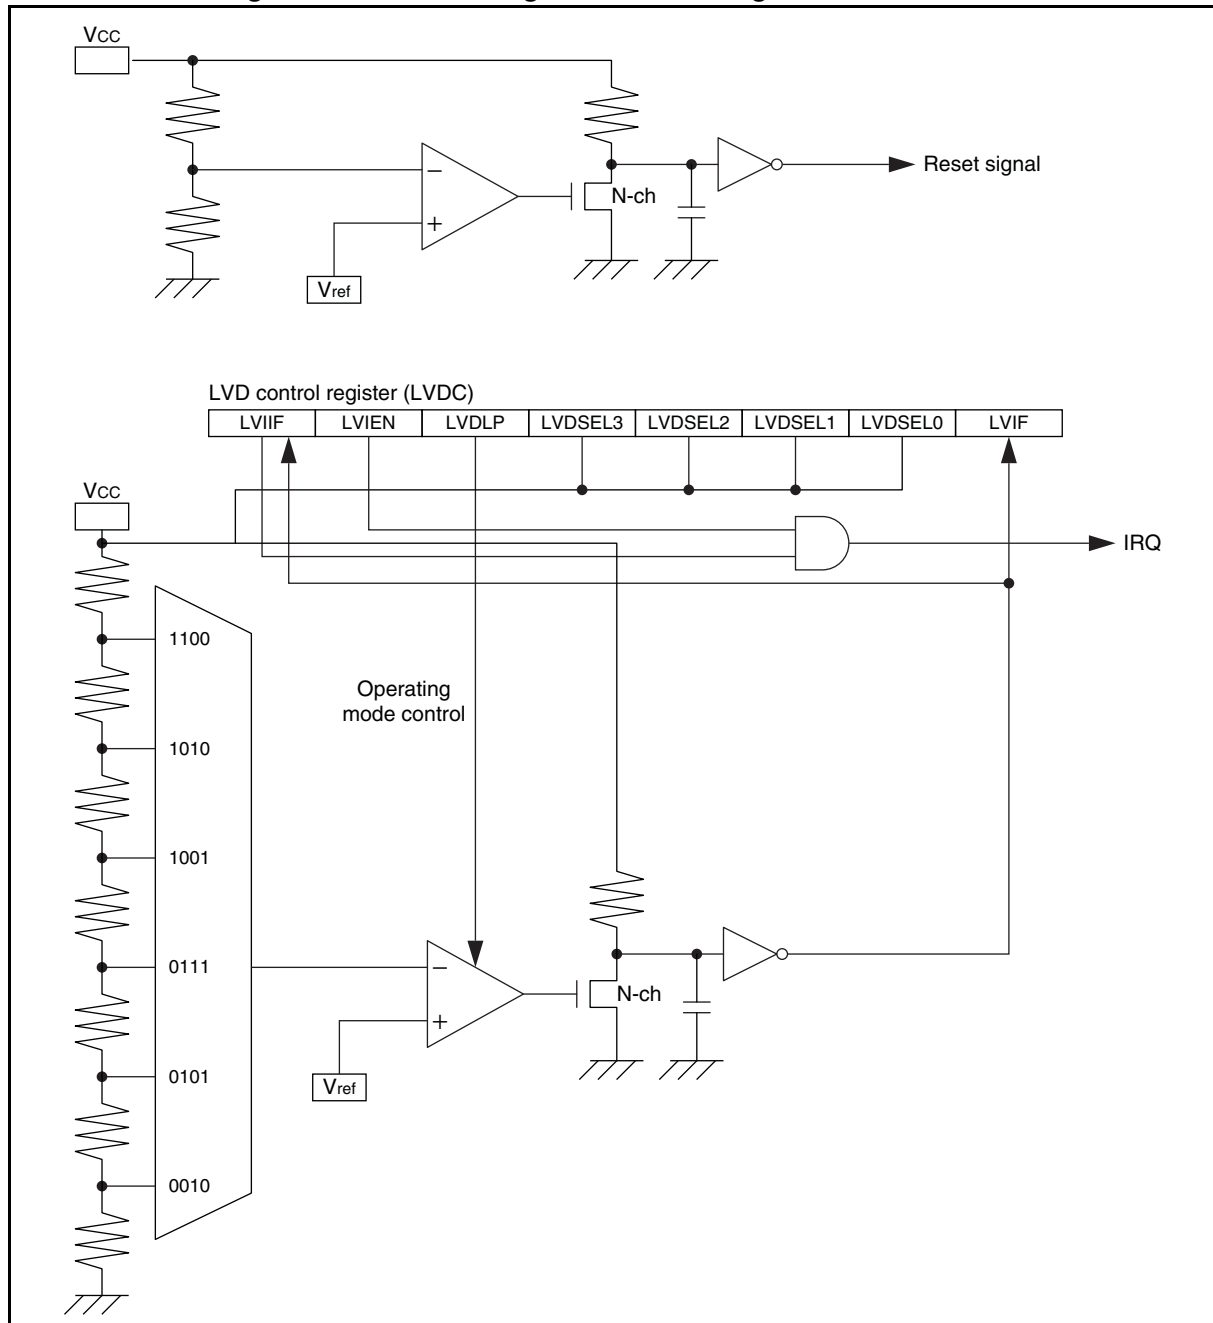

Refer also to the device data sheet for details of the electrical characteristics.

16.2 Configuration

Figure 16.2-1 is the block diagram of the low-voltage detection circuit.

■ Block Diagram of Low-voltage Detection Circuit

Figure 16.2-1 Block Diagram of Low-voltage Detection Circuit

16.3 Pins

This section describes the pins of the low-voltage detection circuit.

■ Pins of Low-voltage Detection Circuit

- V_{CC} pin

The low-voltage detection circuit monitors the voltage of this pin.

- V_{SS} pin

This is the GND pin serving as the reference for voltage detection.

- \overline{RST} pin

The low-voltage detection reset signal is output inside the microcontroller and to this pin.

16.4 Interrupt

The low-voltage detection circuit outputs an interrupt request when the power supply voltage fluctuates above or below the threshold selected in the low-voltage interrupt threshold voltage select bits in the LVD control register (LVDC:LVDSEL[3:0]).

■ Interrupt of Low-voltage Detection Circuit

Table 16.4-1 shows details of the registers and bits related to the interrupt of the low-voltage detection circuit.

Table 16.4-1 Details of Registers and Bits Related to Interrupt of Low-voltage Detection Circuit

Item	Details
Interrupt request flag bit	LVDC:LVIIF
Interrupt request enable bit	LVDC:LVIEN
Interrupt source	The power supply voltage fluctuates above or below the threshold voltage selected in the low-voltage interrupt threshold voltage select bits in the LVD control register (LVDC:LVDSEL[3:0]).

The CPU cannot return from the interrupt processing when the low-voltage interrupt request flag bit (LVDC:LVIIF) is set to "1" and the low-voltage interrupt request is enabled (LVDC:LVIEN = 1). Always clear the LVIIF bit in the interrupt service routine.

16.5 Operations

The low-voltage detection circuit generates a reset signal when the power supply voltage falls below the detection voltage, and an interrupt signal when the power supply voltage fluctuates above or below the selected threshold voltage.

■ Changing Interrupt Threshold Voltage

When the interrupt threshold voltage in the LVDC register is changed, the new threshold voltage does not start to take effect until the interrupt threshold voltage transition stabilization time (t_{stb}) elapses. For details of t_{stb} , refer to the device data sheet. In addition, to prevent misdetections, follow the procedure below when changing the interrupt threshold voltage.

1. Disable the interrupt by writing "0" to the low-voltage interrupt request enable bit (LVDC:LVIEN).
2. Change the value of the low-voltage interrupt threshold voltage select bits (LVDC:LVDSEL[3:0]).
3. Wait for the interrupt threshold voltage transition stabilization time (t_{stb}), the interrupt detection delay time (t_{di2} or t_{diL2}) and the interrupt release delay time (t_{di1} or t_{diL1}) to elapse. Mask any misdetected low-voltage.
4. Clear the low-voltage interrupt request flag bit (LVDC:LVIIF) by writing "0" to it.
5. Enable the interrupt by writing "1" to the LVIEN bit.

For details of t_{di1} , t_{diL1} , t_{di2} and t_{diL2} , refer to the device data sheet.

■ Switching Operating Modes of Low-voltage Detection Circuit for Interrupt

The operating mode of the low-voltage detection circuit for interrupt can be switched between normal mode and low power consumption mode by using the LVD for interrupt low power consumption switch bit in the LVDC register (LVDC:LVDLP).

Compared with normal mode, in low power consumption mode, while the interrupt detection voltage and the interrupt release voltage are less accurate, and the interrupt detection delay time and the interrupt release delay time become longer, there is less power consumption.

When the operating mode is changed, the new operating mode does not take effect until the interrupt low-voltage detection mode switch time (t_{mdsw}) elapses.

For details of t_{mdsw} , refer to the device data sheet.

■ Operation of Low-voltage Detection Reset Circuit

The low-voltage detection reset circuit generates a reset signal if the power supply voltage falls below the low-voltage detection voltage. Afterward, when the low-voltage detection reset circuit detects the low-voltage detection reset release voltage, it outputs a reset signal lasting for the oscillation stabilization wait time and then releases the reset.

For details of the electrical characteristics, refer to the device data sheet.

Figure 16.5-1 Operation of Low-voltage Detection Reset Circuit

■ Operation of Low-voltage Detection Interrupt Circuit

When the power supply voltage fluctuates above or below the threshold selected in the low-voltage interrupt threshold voltage select bits in the LVD control register (LVDC:LVDSEL[3:0]), the low-voltage interrupt request flag bit in the LVD control register (LVDC:LVIIF) is set to "1".

Figure 16.5-2 Operation of Low-voltage Detection Interrupt Circuit

■ Operation in Standby Mode

The low-voltage detection circuit keeps operating even in standby mode (stop mode, sleep mode, subclock mode and watch mode).

16.6 Register

This section describes the register of the low-voltage detection circuit.

Table 16.6-1 List of Low-voltage Detection Circuit Register

Register abbreviation	Register name	Reference
LVDC	LVD control register	16.6.1

16.6.1 LVD Control Register (LVDC)

The LVD control register (LVDC) selects the interrupt threshold voltage, indicates the voltage condition, controls the interrupt and checks the low-voltage interrupt flag status.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	LVIIF	LVIEN	LVDLP	LVDSSEL3	LVDSSEL2	LVDSSEL1	LVDSSEL0	LVIF
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R
Initial value	0	0	0	0	0	1	0	0

■ Register Functions

[bit7] LVIIF: Low-voltage interrupt request flag bit

This flag bit is set to "1" when the power supply voltage fluctuates above or below the threshold voltage selected in the low-voltage interrupt threshold voltage select bits (LVDSSEL[3:0]).

When this bit and the low-voltage interrupt request enable bit (LVIEN) are both set to "1", a low-voltage interrupt request is output.

After power-on, this bit remains "0" as long as the power supply voltage keeps staying below the lowest interrupt detection voltage. In this case, check the power supply voltage by polling the LVIF bit.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit7	Details
Reading "0"	Indicates that the power supply voltage has not fluctuated above or below the threshold voltage selected in the LVDSSEL[3:0] bits.
Reading "1"	Indicates that the power supply voltage has fluctuated above or below the threshold voltage selected in the LVDSSEL[3:0] bits.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit6] LVIEN: Low-voltage interrupt request enable bit

This bit enables or disables outputting the low-voltage interrupt request to the interrupt controller.

When this bit and the low-voltage interrupt request flag bit (LVIIF) are both set to "1", a low-voltage interrupt request is output.

bit6	Details
Writing "0"	Disables outputting the low-voltage interrupt request.
Writing "1"	Enables outputting the low-voltage interrupt request.

[bit5] LVDLP: LVD for interrupt low power consumption switch bit

This bit selects the operating mode (normal mode or low power consumption mode) for the low-voltage detection circuit for interrupt.

Below are the differences between two operating modes.

- Power consumption
The normal mode has higher power consumption than the low power consumption mode.
- Accuracy of detection voltage and release voltage
The normal mode has higher accuracy than the low power consumption mode.

For details of power consumption and of the accuracy of detection voltage and release voltage, refer to the device data sheet.

bit5	Details
Writing "0"	Selects the normal mode.
Writing "1"	Selects the low power consumption mode.

[bit4:1] LVDSEL[3:0]: Low-voltage interrupt threshold voltage select bits

These bits select the interrupt threshold voltage.

bit4:1	Details	
	At power supply voltage fall	At power supply voltage rise
Writing "0010"	2.2 V	2.3 V
Writing "0101"	2.5 V	2.6 V
Writing "0111"	2.8 V	2.9 V
Writing "1001"	3.2 V	3.3 V
Writing "1010"	3.6 V	3.7 V
Writing "1100"	4 V	4.1 V

Note: Writing a value other than those listed in the table above to the LVDSEL[3:0] bits is prohibited.

[bit0] LVIF: Low-voltage status bit

This bit indicates the relation between the power supply voltage and the threshold voltage.

bit0	Details
Reading "0"	Indicates that the power supply voltage is higher than the threshold voltage selected in the LVDSEL[3:0] bits.
Reading "1"	Indicates that the power supply voltage is lower than the threshold voltage selected in the LVDSEL[3:0] bits.

Note:

The LVDC register can be reset only by the power-on reset. The low-voltage detection reset has no effect on this register.

CHAPTER 17

CLOCK SUPERVISOR COUNTER

This chapter describes the functions and operations of the clock supervisor counter.

- 17.1 Overview
- 17.2 Configuration
- 17.3 Operations
- 17.4 Registers
- 17.5 Notes on Using Clock Supervisor Counter

17.1 Overview

The clock supervisor counter checks the external clock frequency to detect the abnormal state of the external clock.

■ Overview of Clock Supervisor Counter

The clock supervisor counter checks the external clock frequency to detect the abnormal state of the external clock.

The clock supervisor counter automatically counts up the counter based on the external clock input within the time-base timer interval time selected from eight options.

The main oscillation clock or the suboscillation clock can be selected as the count clock of this module.

Note:

Operate the clock supervisor counter in main CR clock mode together with the hardware watchdog timer (running in standby mode).

Otherwise, it cannot detect the abnormal state of the external clock correctly and will hang up if the external clock stops.

See "CHAPTER 8 HARDWARE/SOFTWARE WATCHDOG TIMER" for the hardware watchdog timer (running in standby mode).

17.2 Configuration

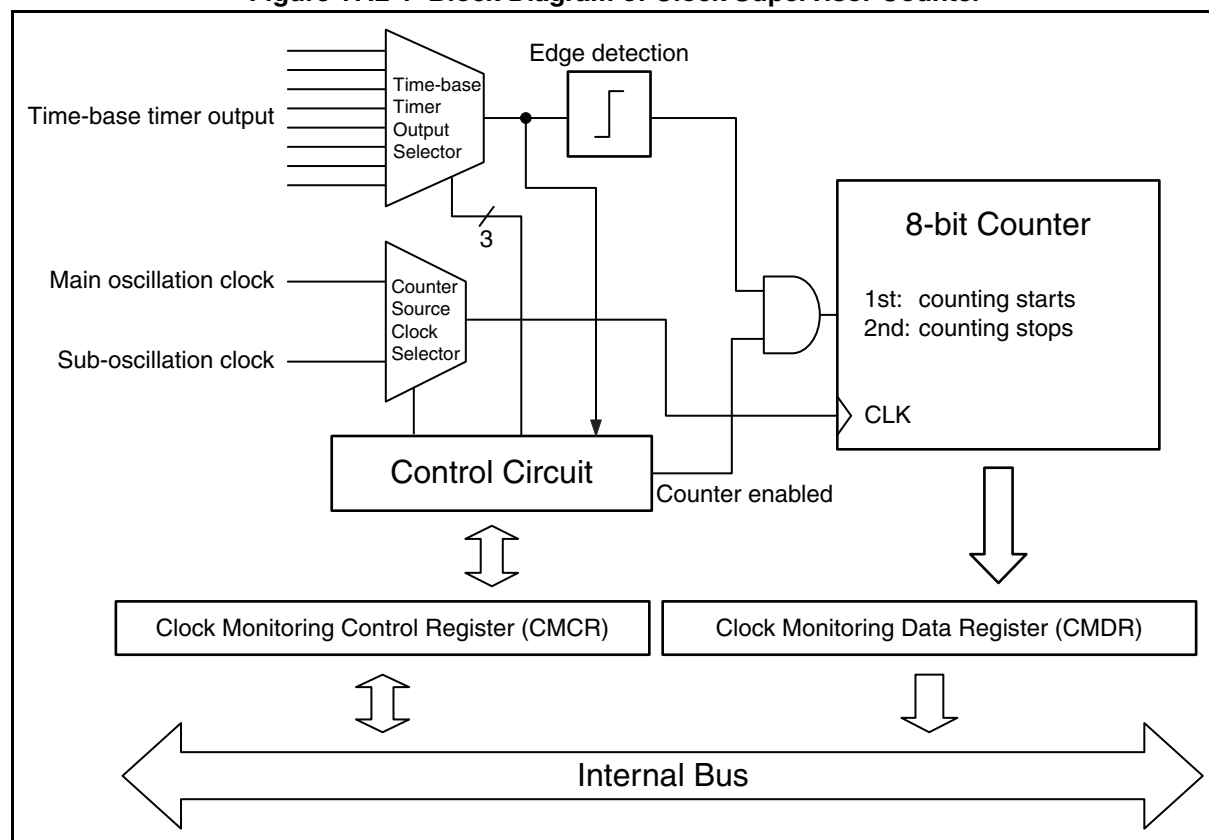

The clock supervisor counter consists of the following blocks:

- Control circuit
- Clock Monitoring Control Register (CMCR)
- Clock Monitoring Data Register (CMDR)
- Time-base timer output selector
- Counter source clock selector

■ Block Diagram of Clock Supervisor Counter

Figure 17.2-1 is the block diagram of the clock supervisor counter.

Figure 17.2-1 Block Diagram of Clock Supervisor Counter

- Control circuit

This block controls the start and stop of the counter, the counter clock source, and the counter enable period based on the settings of the clock monitoring control register (CMCR).

- Clock Monitoring Control Register (CMCR)

This register is used to select a counter source clock, select a counter enable period from eight different time-base timer intervals, start the counter and check whether the counter is operating or not.

- Clock Monitoring Data Register (CMDR)

This register block is used to read the counter value after the counter stops. The software determines whether the external clock frequency is correct or not according to the contents of this register.

- Time-base timer interval selector

This block is used to select the counter enable period from eight different time-base timer intervals.

- Counter source clock selector

This block is used to select the counter source clock from the main oscillation clock and the suboscillation clock.

17.3 Operations

This section describes the operations of the clock supervisor counter.

■ Clock Supervisor Counter

● Clock Supervisor Counter Operation 1

The clock supervisor counter is first enabled by the software (CMCEN = 1), and then the clock supervisor counter operates with the time-base timer interval selected from eight options by the TBTSEL[2:0] bits. Between two rising edges of the time-base timer interval selected, the internal counter is clocked by the external clock.

The count clock of this module can be selected from the main oscillation clock and the suboscillation clock.

Figure 17.3-1 Clock Supervisor Counter Operation 1

● Clock Supervisor Counter Operation 2

The CMDR register is cleared when the CMCEN bit changes from "0" to "1".

Figure 17.3-2 Clock Supervisor Counter Operation 2

● Clock Supervisor Counter Operation 3

The counter stops counting if it reaches "255". It cannot count further than "255".

Figure 17.3-3 Clock Supervisor Counter Operation 3

● Clock Supervisor Counter Operation 4

If the external clock selected stops, the counter stops counting. According to this counter stop, the software identifies that the external clock selected is in the abnormal state.

Figure 17.3-4 Clock Supervisor Counter Operation 4

● Clock Supervisor Counter Operation 5

The counter is cleared to "0" by the software if the CMCEN is set to "0" while the counter is operating.

Figure 17.3-5 Clock Supervisor Counter Operation 5

■ Table of Time-base Timer Intervals & Clock Supervisor Counter Values

Table 17.3-1 shows time-base timer intervals suitable for using different main CR clock frequencies to measure different external clocks.

Table 17.3-1 Table of Counter Values in Relation to TBTSEL Settings

Main CR (FCRH) [MHz]	Main/Sub-crystal oscillation [MHz]	Main CR error	Measurement error	TBTSEL2 to TBTSEL0							
				"000"	"001"	"010"	"011"	"100"	"101"	"110"	"111"
				$(2^3 \times 1 / F_{CRH})$	$(2^5 \times 1 / F_{CRH})$	$(2^7 \times 1 / F_{CRH})$	$(2^9 \times 1 / F_{CRH})$	$(2^{11} \times 1 / F_{CRH})$	$(2^{13} \times 1 / F_{CRH})$	$(2^{15} \times 1 / F_{CRH})$	$(2^{17} \times 1 / F_{CRH})$
4	0.03277	+2%	-1	0	0	0	1	7	31	130	525
		-2%	+1	1	1	1	3	9	35	137	548
	0.5	+2%	-1	0	0	6	30	124	500	2006	8030
		-2%	+1	1	3	9	33	131	523	2090	8360
	1	+2%	-1	0	2	14	61	249	1002	4014	16061
		-2%	+1	2	5	17	66	262	1045	4180	16719
	4	+2%	-1	2	14	61	249	1002	4014	16061	64249
		-2%	+1	5	17	66	262	1045	4180	16719	66874
	6	+2%	-1	4	22	93	375	1504	6022	24093	96375
		-2%	+1	7	25	98	392	1568	6270	25078	100311
	10	+2%	-1	8	38	155	626	2508	10038	40155	160626
		-2%	+1	11	41	164	654	2613	10449	41796	167184
	20	+2%	-1	18	77	312	1253	5018	20077	80312	321253
		-2%	+1	21	82	327	1307	5225	20898	83592	334368
	32.5	+2%	-1	30	126	508	2038	8155	32626	130508	522038
		-2%	+1	34	133	531	2123	8490	33960	135837	543347

 : Recommended setting

 : The counter value becomes "0" or "255".

Table 17.3-1 is calculated by the following equation:

$$\text{Counter value} = \frac{\left\{ \begin{array}{l} 2^2 \times 1/F_{\text{CRH}}(\text{TBTSEL}=000) \\ 2^1 \times 1/F_{\text{CRH}}(\text{TBTSEL}=001) \\ 2^0 \times 1/F_{\text{CRH}}(\text{TBTSEL}=010) \\ 2^3 \times 1/F_{\text{CRH}}(\text{TBTSEL}=011) \\ 2^4 \times 1/F_{\text{CRH}}(\text{TBTSEL}=100) \\ 2^5 \times 1/F_{\text{CRH}}(\text{TBTSEL}=101) \\ 2^6 \times 1/F_{\text{CRH}}(\text{TBTSEL}=110) \\ 2^7 \times 1/F_{\text{CRH}}(\text{TBTSEL}=111) \end{array} \right\} \times \text{Main/Sub-Oscillation Clock Frequency}}{2} \pm 1 \text{ (Measurement error)}$$

*Omit the decimal places of "Counter value".

Selected time-base timer interval

Within this period, the "Counter value" in the above equation is counted by the main/sub oscillation clock.

If the time-base timer interrupt is used to make the clock supervisor counter wait for the oscillation stabilization time, please satisfy the following condition:

$$\text{Time-base Timer Interval} > \text{Main Oscillation / Suboscillation Stabilization Time} \times 1.05$$

e.g. $F_{\text{CH}} = 4 \text{ MHz}$, $F_{\text{CRH}} = 1 \text{ MHz}$, $\text{MWT}[3:0] = 0b1111$ (in WATR register)

$$\text{Time-base Timer Interval} > \frac{(2^{14} - 2)}{4 \times 10^6} \times 1.05 \approx 4.3 \text{ ms}$$

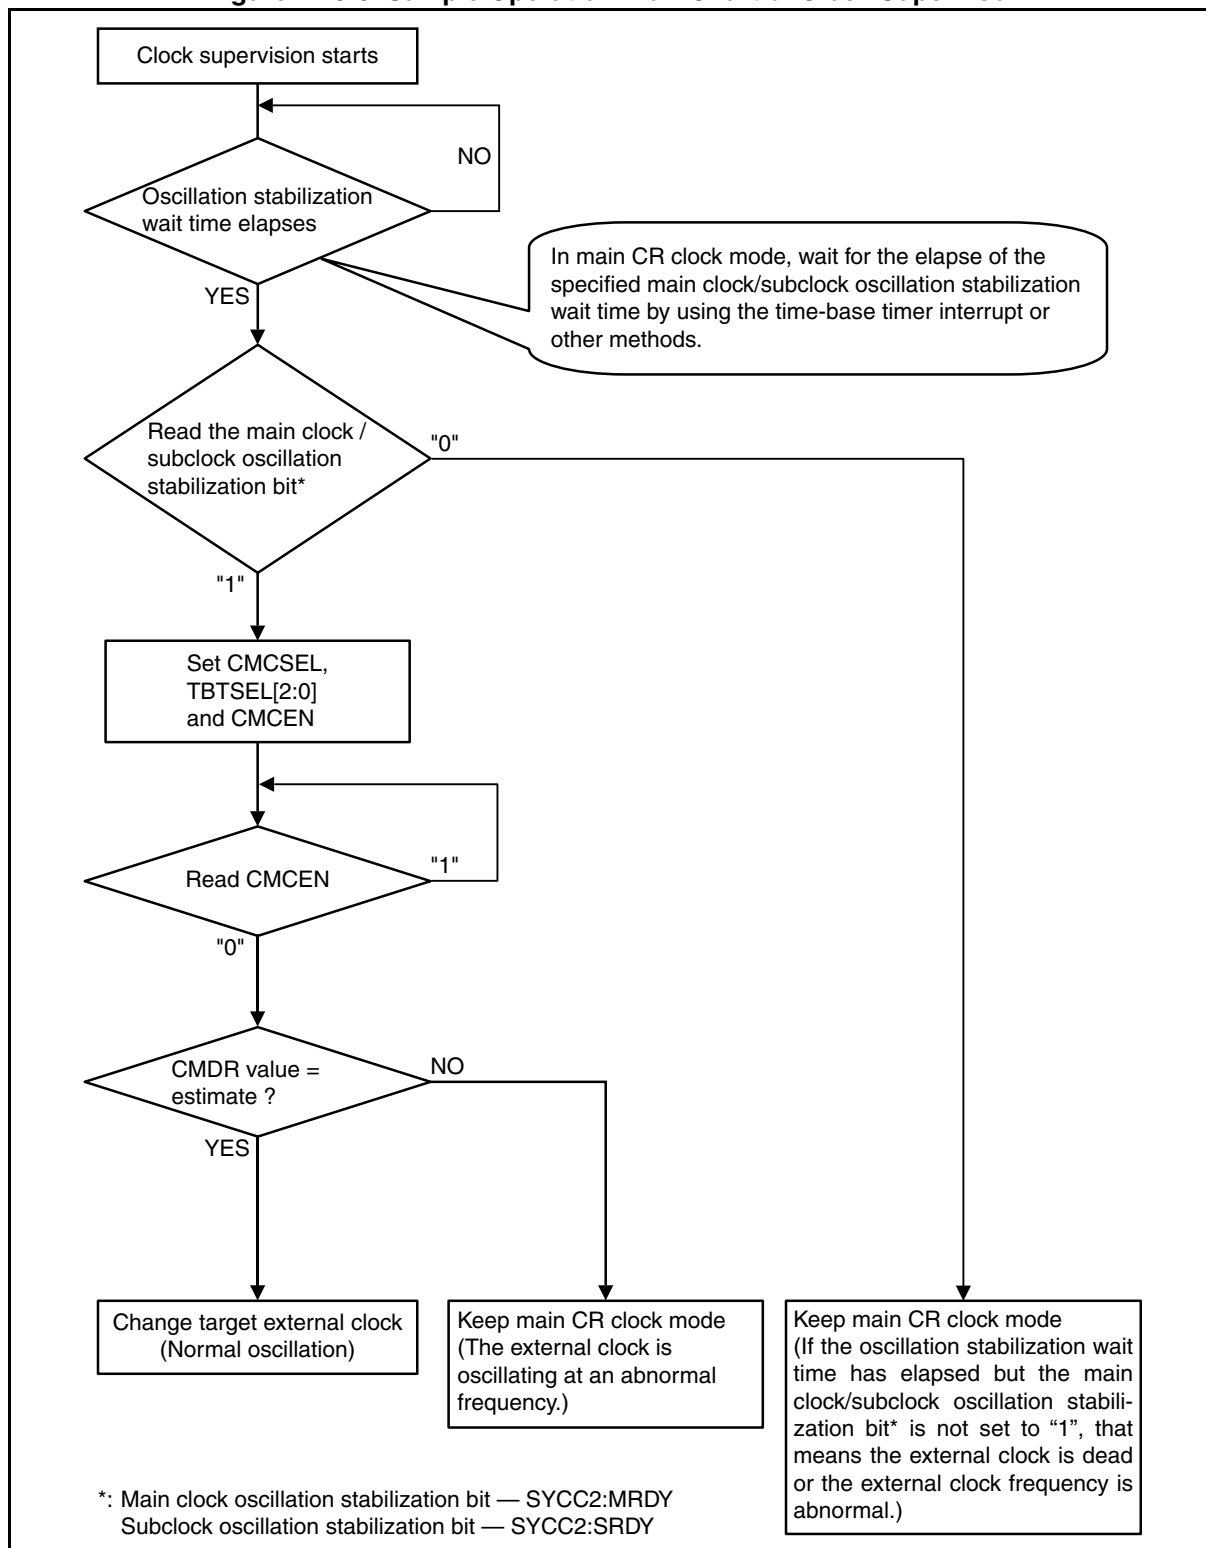

$$\text{TBC}[3:0] = 0b0110 (2^{13} \times 1/F_{\text{CRH}})$$

Notes:

- See "7.1 Overview" for time-base timer interval settings.
- See "3.3.3 Oscillation Stabilization Wait Time Setting Register (WATR)" for main/sub-oscillation stabilization time settings.

■ Sample Operation Flow Chart of Clock Supervisor

Figure 17.3-6 Sample Operation Flow Chart of Clock Supervisor

17.4 Registers

This section describes the registers of the clock supervisor counter.

Table 17.4-1 List of Clock Supervisor Counter Registers

Register abbreviation	Register name	Reference
CMDR	Clock monitoring data register	17.4.1
CMCR	Clock monitoring control register	17.4.2

17.4.1 Clock Monitoring Data Register (CMDR)

The clock monitoring data register (CMDR) is used to read the count value after the clock supervisor counter stops. The software can check whether the external clock frequency is correct or not according to the content of this register.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	CMDR7	CMDR6	CMDR5	CMDR4	CMDR3	CMDR2	CMDR1	CMDR0
Attribute	R	R	R	R	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

The clock monitoring data register (CMDR) is used to read the counter value after the clock supervisor counter stops.

- The counter value can be read from the clock monitoring data register (CMDR). The software can check whether the external clock frequency is correct or not according to the counter value read and the time-base timer interval selected.

[bit7:0] CMDR[7:0]: Clock monitoring data bits

These bits indicate the clock supervisor counter value after the counter stops.

These bits are cleared if one of the following events occurs:

- Reset
- The CMCEN bit in the CMCR register (CMCR:CMCEN) is modified from "0" to "1" by the software.
- The CMCEN bit is modified from "1" to "0" by the software while the counter is running.
- After the external clock stops, the falling edge of the selected time-base timer clock is detected twice. (See Figure 17.5-2.)

Note:

The value of this register is "0b00000000" as long as the counter is operating (CMCR:CMCEN = 1).

17.4.2 Clock Monitoring Control Register (CMCR)

The clock monitoring control register (CMCR) is used to select the counter source clock, select a time-base timer interval as the counter enable period, start the counter and check whether the counter is running or not.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	Reserved	CMCSEL	TBTSEL2	TBTSEL1	TBTSEL0	CMCEN
Attribute	—	—	W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] Reserved bit

Always set this bit to "0".

[bit4] CMCSEL: Counter clock select bit

This bit selects the counter source clock.

bit4	Details
Writing "0"	Selects the external main oscillation clock as the counter source clock.
Writing "1"	Selects the external suboscillation clock as the counter source clock.

[bit3:1] TBTSEL[2:0]: Time-base timer counter output select bits

These bits select the time-base timer interval.

The operation of the clock supervisor counter is enabled and disabled at specific times according to the time-base timer counter output selected by these bits.

The first rising edge of the interval selected enables the counter operation and the second rising edge of the same output disables the counter operation.

bit3:1	Details (F _{CRH} : main CR clock)
Writing "000"	$2^3 \times 1/F_{CRH}$
Writing "001"	$2^5 \times 1/F_{CRH}$
Writing "010"	$2^7 \times 1/F_{CRH}$
Writing "011"	$2^9 \times 1/F_{CRH}$
Writing "100"	$2^{11} \times 1/F_{CRH}$
Writing "101"	$2^{13} \times 1/F_{CRH}$
Writing "110"	$2^{15} \times 1/F_{CRH}$
Writing "111"	$2^{17} \times 1/F_{CRH}$

[bit0] CMCEN: Counter enable bit

This bit enables or disables the clock supervisor counter.

Writing "0" to this bit stops the counter and clears the CMDR register to "0b00000000".

Writing "1" to this bit enables the counter. The counter starts counting when detecting the rising edge of the time-base timer interval. It stops counting when detecting the second rising edge of the same interval.

This bit is automatically set to "0" when the counter stops.

bit0	Details
Writing "0"	Disables the counter operation.
Writing "1"	Enables the counter operation.

Notes:

- Do not modify the CMCSEL bit when the CMCEN bit is "1".
- Do not modify the TBTSEL[2:0] bits when the CMCEN bit is "1".

17.5 Notes on Using Clock Supervisor Counter

This section provides notes on using the clock supervisor counter.

■ Notes on Using Clock Supervisor Counter

● Restrictions

- Operate the clock supervisor counter in main CR clock mode together with the hardware watchdog timer (running in standby mode). Otherwise, it cannot detect the abnormal state of the external clock correctly and will hang up if the external clock stops. See "CHAPTER 8 HARDWARE/SOFTWARE WATCHDOG TIMER" for the hardware watchdog timer (running in standby mode).
- Use main CR clock mode only. Do not use any other clock mode.
- If the time-base timer stops, the internal counter stops working. Do not clear the time-base timer while the clock supervisor counter is counting with the external clock.
- Select a time-base timer interval that is sufficiently long for the clock supervisor counter to operate. See Table 17.3-1 for time-base timer intervals.
- Read the CMDR register when CMCEN = 0. (The value of CMDR remains "0b00000000" while the clock supervisor counter is operating (CMCEN = 1).)
- When using the clock supervisor counter, ensure that the machine clock cycle is shorter than half the time-base timer interval selected. If the machine clock cycle is longer than half the time-base timer interval selected, CMCEN may remain "1" even after the clock supervisor counter stops.

Table 17.5-1 shows the appropriate clock gear setting for each TBTSEL setting.

Table 17.5-1 Appropriate Clock Gear Setting for Respective TBTSEL Settings

DIV[1:0] (clock gear setting)	TBTSEL[2:0]		
	000	001	010 to 111
	$2^3 \times 1/F_{CRH}$	$2^5 \times 1/F_{CRH}$	$2^7 \times 1/F_{CRH}$ to $2^{17} \times 1/F_{CRH}$
00 ($1 \times 1/F_{CRH}$)	○	○	○
01 ($4 \times 1/F_{CRH}$)	x	○	○
10 ($8 \times 1/F_{CRH}$)	x	○	○
11 ($16 \times 1/F_{CRH}$)	x	x	○

○ : Recommended

x : Prohibited

- If the external clock stops while the clock supervisor counter is operating, and it restarts after the second rising edge of the time-base timer interval selected, CMCEN is set to "0" after the external clock restarts.

Figure 17.5-1 Clock Supervisor Counter Operation 1

- With the clock supervisor counter running, if the external clock stops, CMCEN is set to "0" when a falling edge of the time-base timer interval selected is detected after the second rising edge of the same interval. The counter is cleared at the same falling edge.

Figure 17.5-2 Clock Supervisor Counter Operation 2

CHAPTER 18

8/16-BIT PPG

This chapter describes the functions and operations of the 8/16-bit PPG.

- 18.1 Overview
- 18.2 Configuration
- 18.3 Channel
- 18.4 Pins
- 18.5 Interrupt
- 18.6 Operations and Setting Procedure Example
- 18.7 Registers
- 18.8 Notes on Using 8/16-bit PPG

18.1 Overview

The 8/16-bit PPG is an 8-bit reload timer module that uses pulse output control based on timer operation to perform PPG output. The 8/16-bit PPG also operates in cascade (8 bits + 8 bits) as 16-bit PPG.

■ Overview of 8/16-bit PPG

The number of pins and that of channels of the 8/16-bit PPG vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

The 8/16-bit PPG functions are summarized as follows.

- 8-bit PPG output independent operation mode

In this mode, the unit can operate as two 8-bit PPG (PPG timer n0 and PPG timer n1).

- 8-bit prescaler + 8-bit PPG output operation mode

The rising and falling edge detection pulses from the PPG timer n1 output can be input to the downcounter of the PPG timer n0 to enable variable-cycle 8-bit PPG output.

- 16-bit PPG output operation mode

The unit can also operate in cascade (PPG timer n1 (upper 8 bits) + PPG timer n0 (lower 8 bits)) as 16-bit PPG output.

- PPG output operation

In this operation, a variable-cycle pulse waveform is output in any duty ratio.

The unit can also be used as a D/A converter in conjunction with an external circuit.

- Output inversion mode

This mode can invert the PPG output value.

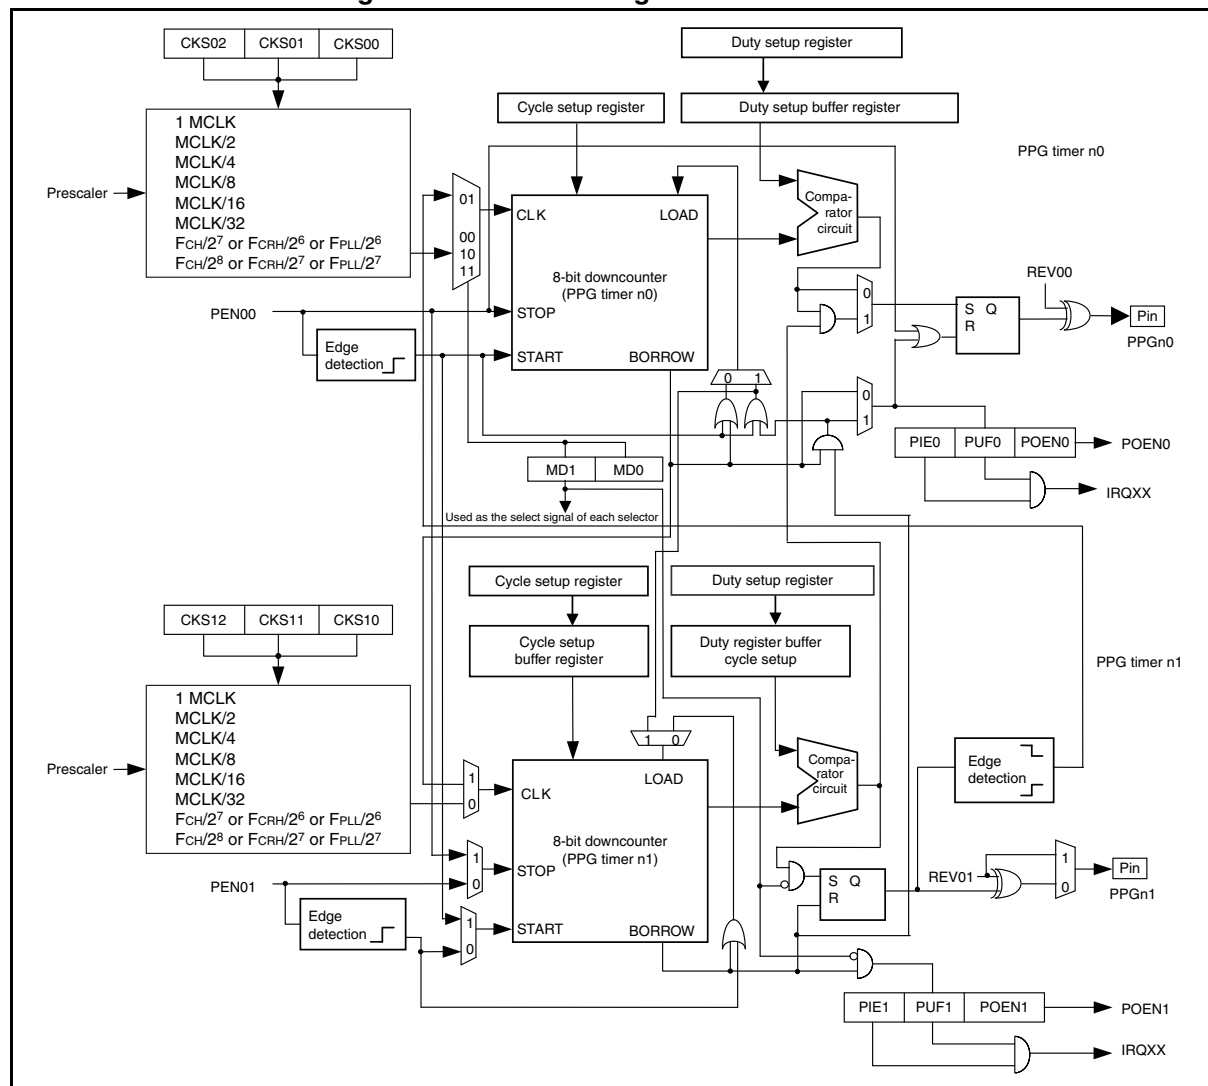

18.2 Configuration

This section shows the block diagram of the 8/16-bit PPG.

■ Block Diagram of 8/16-bit PPG

Figure 18.2-1 shows the block diagram of the 8/16-bit PPG.

Figure 18.2-1 Block Diagram of 8/16-bit PPG

- Counter clock selector

The clock for the countdown of 8-bit downcounter is selected from eight types of internal count clocks.

- 8-bit downcounter

It counts down with the count clock selected with the count clock selector.

- Comparator circuit

The output is kept "H" level until the value of 8-bit downcounter is corresponding to the value of 8/16-bit PPG duty setup buffer register from the value of 8/16-bit set buffer register of PPG cycle.

Afterwards, after keep "L" level the output until the counter value is corresponding to "1", it keeps counting 8-bit downcounter from the value of 8/16-bit PPG cycle setup buffer register.

- 8/16-bit PPG timer n1 control register (PCn1)

The operation condition on the PPG timer n1 side of 8/16-bit PPG timer is set.

- 8/16-bit PPG timer n0 control register (PCn0)

The operation mode of 8/16-bit PPG timer and the operation condition on the PPG timer n0 side are set.

- 8/16-bit PPG timer n1/n0 cycle setup buffer register (PPSn1/PPSn0)

The compare value for the cycle of 8/16-bit PPG timer is set.

- 8/16-bit PPG timer n1/n0 duty setup buffer register (PDSn1/PDSn0)

The compare value for "H" width of 8/16-bit PPG timer is set.

- 8/16-bit PPG start register

The start or the stop of 8/16-bit PPG timer is set.

- 8/16-bit PPG output inversion register

An initial level also includes the output of 8/16-bit PPG timer and it is reversed.

■ Input Clock

The 8/16-bit PPG uses the output clock from the prescaler as its input clock (count clock).

18.3 Channel

This section describes the channel of the 8/16-bit PPG.

■ Channel of 8/16-bit PPG

The 8/16-bit PPG consists of 8-bit PPG timer n0 and 8-bit PPG timer n1. They can be used respectively as two 8-bit PPGs or as a single 16-bit PPG.

Table 18.3-1 shows the pins and Table 18.3-2 the registers.

Table 18.3-1 Pins of 8/16-bit PPG

Pin name	Pin function
PPGn0	PPG timer n0 output (8-bit PPG (n0), 16-bit PPG)
PPGn1	PPG timer n1 output (8-bit PPG (n1), 8-bit prescaler)

Table 18.3-2 Registers of 8/16-bit PPG

Register abbreviation	Corresponding register (Name in this manual)
PCn1	8/16-bit PPG timer n1 control register
PCn0	8/16-bit PPG timer n0 control register
PPSn1	8/16-bit PPG timer n1 cycle setup buffer register
PPSn0	8/16-bit PPG timer n0 cycle setup buffer register
PDSn1	8/16-bit PPG timer n1 duty setup buffer register
PDSn0	8/16-bit PPG timer n0 duty setup buffer register
PPGS	8/16-bit PPG start register
REVC	8/16-bit PPG output inversion register

18.4 Pins

This section describes the pins of the 8/16-bit PPG.

■ Pins of 8/16-bit PPG

- PPGn0 pin and PPGn1 pin

These pins function both as general-purpose I/O ports and 8/16-bit PPG outputs.

PPGn0, PPGn1: A PPG waveform is output to these pins. The PPG waveform can be output by enabling the output by the 8/16-bit PPG timer n1/n0 control registers (PCn0: POEN0 = 1, PCn1: POEN1 = 1).

18.5 Interrupt

The 8/16-bit PPG outputs an interrupt request when a counter borrow is detected.

■ Interrupt of 8/16-bit PPG

Table 18.5-1 shows the interrupt control bits and interrupt sources of the 8/16-bit PPG.

Table 18.5-1 Interrupt Control Bits and Interrupt Sources of 8/16-bit PPG

Item	Description	
	PPG timer n1 (8-bit PPG, 8-bit prescaler)	PPG timer n0 (8-bit PPG, 16-bit PPG)
Interrupt request flag bit	PUF1 bit in PCn1	PUF0 bit in PCn0
Interrupt request enable bit	PIE1 bit in PCn1	PIE0 bit in PCn0
Interrupt source	Counter borrow of PPG cycle downcounter	

When a counter borrow occurs on the downcounter, the 8/16-bit PPG sets the counter borrow detection flag bit (PUF) in the 8/16-bit PPG timer n0/n1 control register (PC) to "1". When the interrupt request enable bit is enabled (PIE = 1), an interrupt request is output to the interrupt controller.

In 16-bit PPG mode, the 8/16-bit PPG timer n0 control register (PCn0) is available.

18.6 Operations and Setting Procedure Example

This section describes the operations of the 8/16-bit PPG.

The 8/16-bit PPG has the following three operating modes:

- 8-bit PPG independent mode
- 8-bit prescaler + 8-bit PPG mode
- 16-bit PPG mode

18.6.1 8-bit PPG Independent Mode

In this mode, the 8/16-bit PPG operates as two channels (PPG timer n0 and PPG timer n1) of the 8-bit PPG.

■ Setting 8-bit PPG Independent Mode

The 8/16-bit PPG requires the register settings shown in Figure 18.6-1 to operate in 8-bit PPG independent mode.

Figure 18.6-1 8-bit PPG Independent Mode

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
PCn1	-	-	PIE1	PUF1	POEN1	CKS12	CKS11	CKS10

	*	*	*	*	*	*	⊙	⊙

⊙ : Used bit
 0 : Set to "0"
 * : The bit status depends on the number of channels provided.

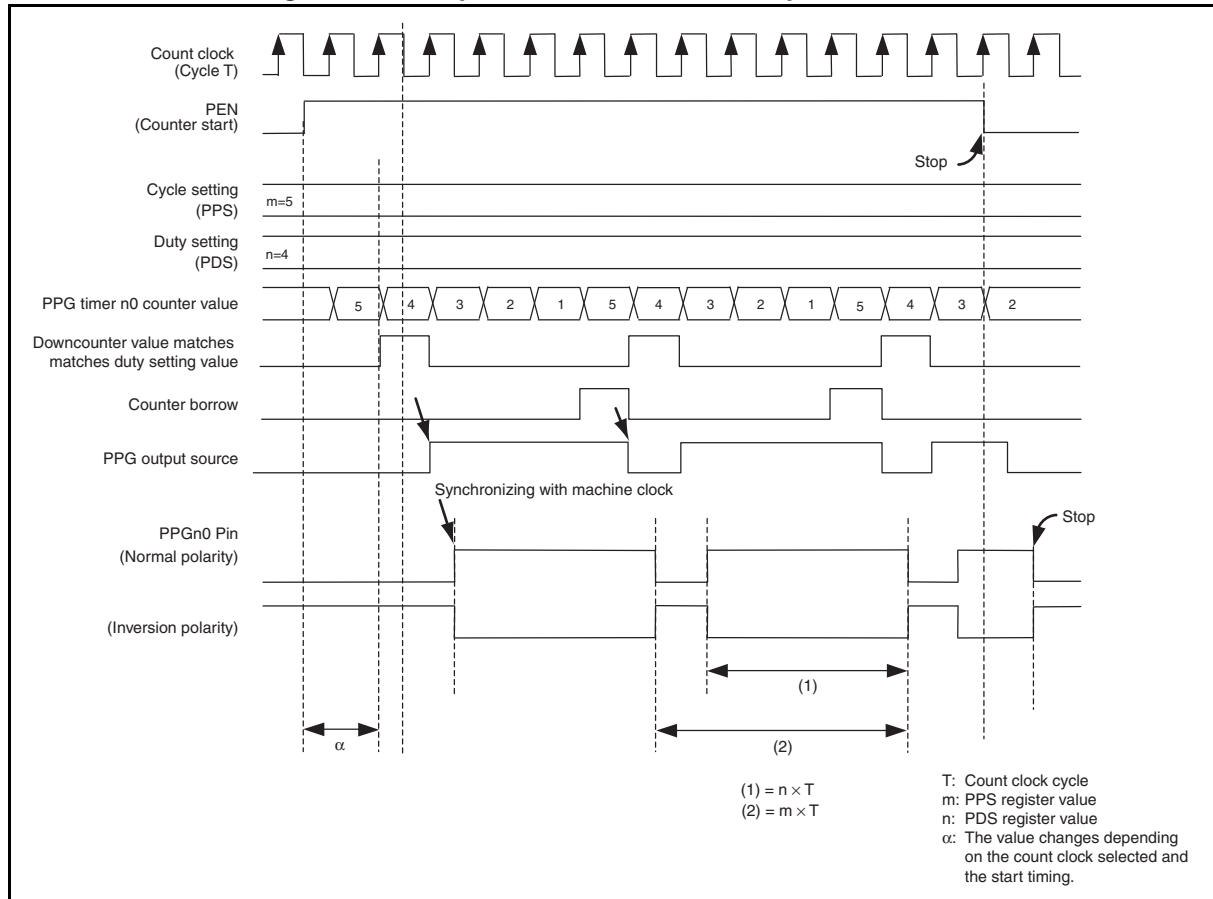

■ Operation of 8-bit PPG Independent Mode

- This mode is selected when the operation mode select bits (MD[1:0]) in the 8/16-bit PPG timer n0 control register (PCn0) are set to "0b00".
- When the corresponding bit (PEN) in the 8/16-bit PPG start register (PPGS) is set to "1", the value in the 8/16-bit PPG cycle setup buffer register (PPS) is loaded to start down-count operation. When the count value reaches "1", the value in the cycle setup register is reloaded to repeat the counting.
- "H" is output to the PPG output synchronizing with the count clock. When the downcounter value matches the value in the 8/16-bit PPG timer n1/n0 duty setup buffer register (PDS). After "H" which is the value of duty setting is output, "L" is output to the PPG output.

If, however, the PPG output level reverse bit is set to "1", the PPG output is set and reset inversely from the above process.

Figure 18.6-2 shows the operation of the 8-bit PPG independent mode.

Figure 18.6-2 Operation of 8-bit PPG Independent Mode

Example for setting the duty to 50%

When PDS is set to "0x02" with PPS set to "0x04", the PPG output is set at a duty ratio of 50% (PPS setting value / 2 set to PDS).

18.6.2 8-bit Prescaler + 8-bit PPG Mode

In this mode, the rising and falling edge detection pulses from the PPG timer n1 output can be used as the count clock of the PPG timer n0 downcounter to allow variable-cycle 8-bit PPG output from PPG timer n0.

■ Setting 8-bit Prescaler + 8-bit PPG Mode

The 8/16-bit PPG requires the register settings shown in Figure 18.6-3 to operate in 8-bit prescaler + 8-bit PPG mode.

Figure 18.6-3 Setting 8-bit Prescaler + 8-bit PPG Mode

REVC	-	-	REV21	REV20	REV11	REV10	REV01	REV00
	*	*	*	*	*	*	⊙	⊙

⊙ : Used bit
 0 : Set to "0"
 1 : Set to "1"
 x : Setting nullified
 * : The bit status varies depending of the number of channels implemented

■ Operation of 8-bit Prescaler + 8-bit PPG Mode

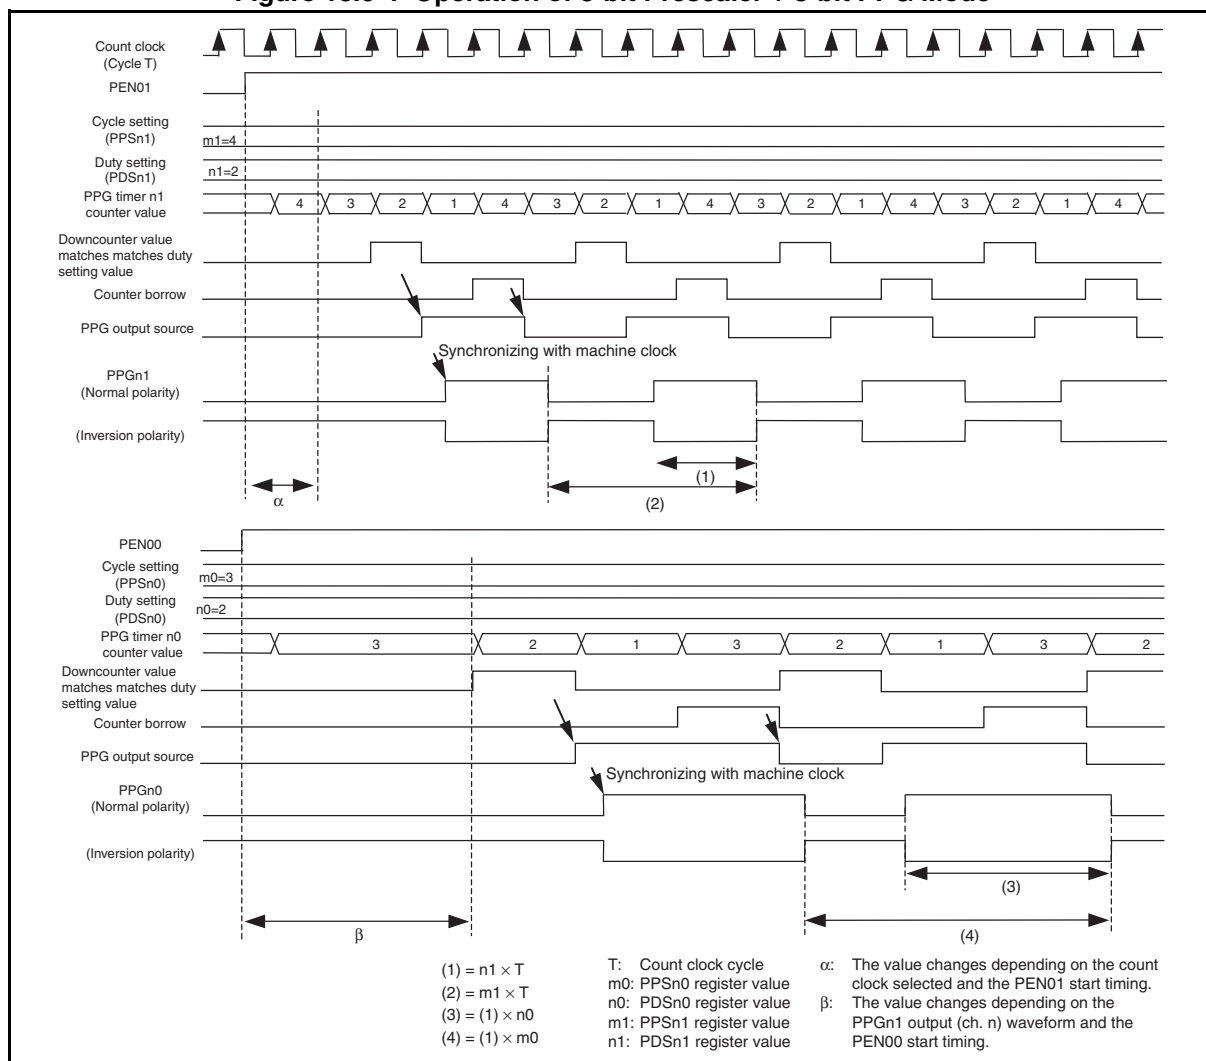

- This mode is selected by setting the operation mode select bits (MD[1:0]) in the 8/16-bit PPG timer n0 control register (PCn0) to "0b01". This allows PPG timer n1 to be used as an 8-bit prescaler and PPG timer n0 to be used as an 8-bit PPG.
- When the PPG timer n1 (ch. n) downcounter operation enable bit (PEN01) is set to "1", the 8-bit prescaler (PPG timer n1) loads the value in the 8/16-bit PPG timer n1 cycle setup buffer register (PPSn1) and starts down-count operation. When the value of the downcounter matches the value in the 8/16-bit PPG timer n1 duty setup buffer register (PDSn1), the PPGn1 output is set to "H" synchronizing with the count clock. After "H" which is the value of duty setting is output, the PPGn1 output is set to "L". If the output level reverse signal (REV01) is "0", the polarity remains the same. If it is "1", the polarity is

reversed and the signal is output to the PPGn1 pin.

- When the PPG timer n0 (ch. n) downcounter operation enable bit (PEN00) is set to "1", the 8-bit PPG (PPG timer n0) loads the value in the 8/16-bit PPG timer n0 cycle setup buffer register (PPSn0) and starts down-count operation (count clock = rising and falling edge detection pulses of PPGn1 output after PPG timer n1 operation is enabled). When the count value reaches "1", the value in the PPSn0 register is reloaded to repeat the counting. When the value of the downcounter matches the value in the 8/16-bit PPG timer n0 duty setup buffer register (PDSn0), the PPGn0 output is set to "H" synchronizing with the count clock. After "H" which is the value of duty setting is output, the PPGn0 output is reset to "L". If the output level reverse bit (REV00) is "0", the polarity remains the same. If it is "1", the polarity is reversed and the signal is output to the PPGn0 pin.
- Set that the duty of the 8-bit prescaler (PPG timer n1) output to 50%.
- When PPG timer n0 is started with the 8-bit prescaler (PPG timer n1) being stopped, PPG timer n0 does not count.
- When the duty of the 8-bit prescaler (PPG timer n1) is set to 0% or 100%, PPG timer n0 does not perform counting as the 8-bit prescaler (PPG timer n1) output does not toggle.

Figure 18.6-4 shows the operation of 8-bit prescaler + 8-bit PPG mode.

Figure 18.6-4 Operation of 8-bit Prescaler + 8-bit PPG Mode

18.6.3 16-bit PPG Mode

In this mode, the 8/16-bit PPG can operate as a 16-bit PPG when PPG timer n1 and PPG timer n0 are assigned to the upper and lower bits respectively.

■ Setting 16-bit PPG Mode

The 8/16-bit PPG requires the register settings shown in Figure 18.6-5 to operate in 16-bit PPG mode.

Figure 18.6-5 Setting 16-bit PPG Mode

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
PCn1	-	-	PIE1	PUF1	POEN1	CKS12	CKS11	CKS10

⊙ : Used bit
 0 : Set to "0"
 1 : Set to "1"
 x : Setting nullified
 * : The bit status changes depending on the number of channels implemented.

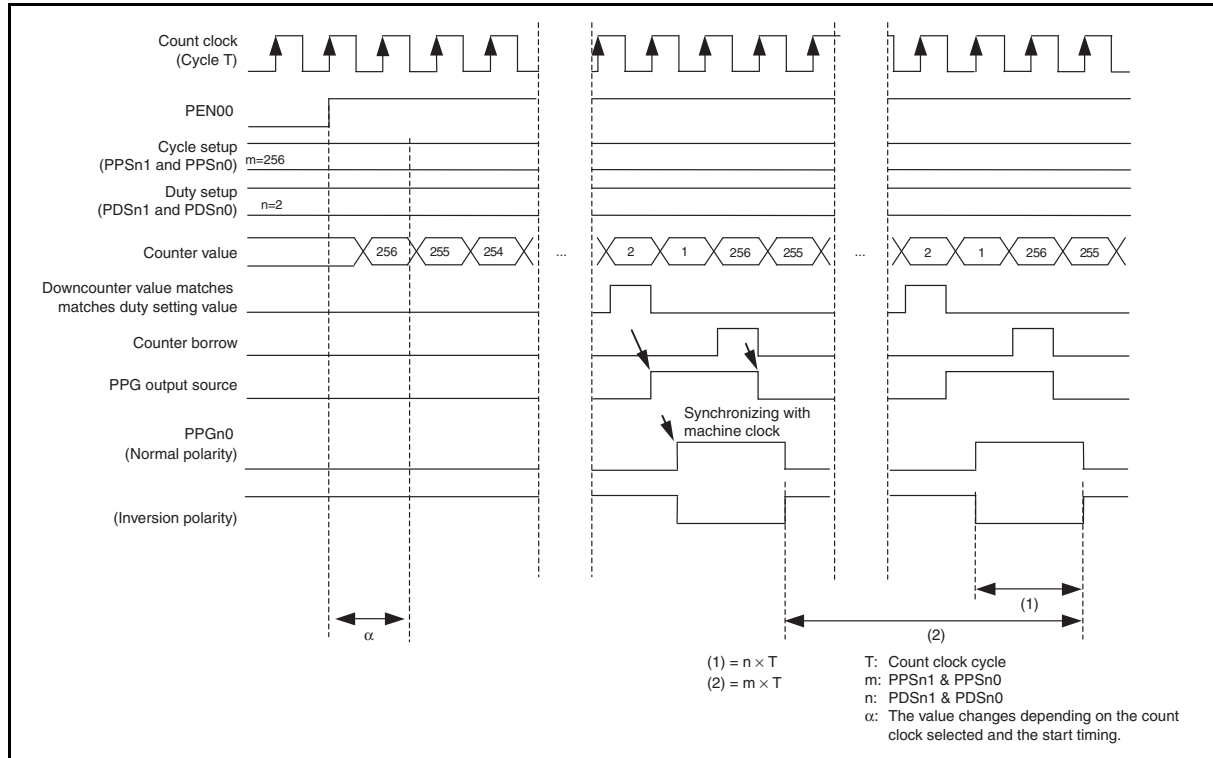

■ Operation of 16-bit PPG Mode

- This mode is selected by setting the operation mode select bits (MD[1:0]) in the PPG timer n0 control register (PCn0) to "0b10" or "0b11".
- When the PPG timer n0 (ch. n) downcounter operation enable bit (PEN00) is set to "1" in 16-bit PPG mode, the 8-bit downcounters (PPG timer n0) and 8-bit downcounter (PPG timer n1) load the values in the 8/16-bit PPG timer n1/n0 cycle setup buffer registers (PPSn1 for PPG timer n1 and PPSn0 for PPG timer n0) and start down-count operation. When the count value reaches "1", the values in the cycle setup register are reloaded and the counters repeat the counting.
- When the values of the downcounters match the values in the 8/16-bit PPG timer duty setup buffer registers (both the value in PDSn1 for PPG timer n1 and the value in PDSn0 for PPG timer n0), the PPGn0 pin is set to "H" synchronizing with the count clock. After "H" which

is the value of duty setting is output, the PPGn0 pin is set to "L". If the output level reverse bit (REV00) is "0", the signal is output to the PPGn0 pin with the polarity unchanged. If it is set to "1", the polarity is reversed and the signal is output to the PPGn0 pin.

Figure 18.6-6 shows the operation of 16-bit PPG mode.

Figure 18.6-6 Operation of 16-bit PPG Mode

■ Setting Procedure Example

Below is an example of procedure for setting the 8/16-bit PPG ch. n.

● Initial setup

1. Set the port output. (DDR)
2. Set the interrupt level. (ILR*)
3. Select the operating clock, enable the output and interrupt. (PCn1)
4. Select the operating clock, enable the output and interrupt, select the operation mode. (PCn0)
5. Set the cycle. (PPS)
6. Set the duty. (PDS)
7. Set the 8/16-bit PPG output reverse register. (REVC)
8. Start the 8/16-bit PPG. (PPGS)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

1. Process any interrupt.
2. Clear the interrupt request flag. (PCn1:PUF1, PCn0:PUF0)
3. Start the 8/16-bit PPG. (PPGS)

18.7 Registers

This section describes the registers of the 8/16-bit PPG.

Table 18.7-1 List of 8/16-bit PPG Registers

Register abbreviation	Register name	Reference
PCn1	8/16-bit PPG timer n1 control register	18.7.1
PCn0	8/16-bit PPG timer n0 control register	18.7.2
PPSn1	8/16-bit PPG timer n1 cycle setting buffer register	18.7.3
PPSn0	8/16-bit PPG timer n0 cycle setting buffer register	18.7.3
PDSn1	8/16-bit PPG timer n1 duty setting buffer register	18.7.4
PDSn0	8/16-bit PPG timer n0 duty setting buffer register	18.7.4
PPGS	8/16-bit PPG start register	18.7.5
REVC	8/16-bit PPG output reverse register	18.7.6

18.7.1 8/16-bit PPG timer n1 Control Register (PCn1)

The 8/16-bit PPG timer n1 control register (PCn1) sets the operating conditions for PPG timer n1.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	PIE1	PUF1	POEN1	CKS12	CKS11	CKS10
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] PIE1: Interrupt request enable bit

This bit controls interrupts of PPG timer n1.

The bit outputs an interrupt request (IRQ) when the counter borrow detection bit (PUF1) and the PIE1 bit are both set to "1".

bit5	Details
Writing "0"	Disables the PPG timer n1 interrupt.
Writing "1"	Enables the PPG timer n1 interrupt.

[bit4] PUF1: Counter borrow detection flag bit for PPG cycle downcounter

This bit serves as the counter borrow detection flag for the PPG cycle downcounter of the PPG timer n1.

This bit is set to "1" when a counter borrow occurs in 8-bit PPG independent mode or 8-bit prescaler + 8-bit PPG mode.

In 16-bit PPG mode, this bit is not set to "1" even when a counter borrow occurs.

Writing "1" to this bit has no effect on operation. Writing "0" to this bit clears it.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit4	Details
Reading "0"	Indicates that no counter borrow of PPG timer n1 has been detected.
Reading "1"	Indicates that a counter borrow of PPG timer n1 has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit3] POEN1: Output enable bit

This bit enables or disables the PPG timer n1 pin output.

Setting this bit to "1" in 16-bit PPG mode sets the PPG timer n1 pin as an output pin. (The setting value of REV01 is output. "L" output is supplied when REV01 is "0".)

bit3	Details
Writing "0"	The PPG timer n1 pin functions as a general-purpose I/O port.
Writing "1"	The PPG timer n1 pin functions as a PPG output pin.

[bit2:0] CKS1[2:0]: Operating clock select bits

These bits select the operating clock for 8-bit downcounter of the PPG timer n1.

The operating clock is generated from the prescaler. For details, see "3.9 Operation of Prescaler".

In 16-bit PPG mode, the settings of these bits have no effect on the operation.

bit2:0	Details (MCLK: machine clock, F _{CH} : main clock, F _{CRH} : main CR clock, F _{PLL} : PLL clock)
Writing "000"	1 MCLK
Writing "001"	MCLK/2
Writing "010"	MCLK/4
Writing "011"	MCLK/8
Writing "100"	MCLK/16
Writing "101"	MCLK/32
Writing "110"	F _{CH} /2 ⁷ or F _{CRH} /2 ⁶ or F _{PLL} /2 ⁶
Writing "111"	F _{CH} /2 ⁸ or F _{CRH} /2 ⁷ or F _{PLL} /2 ⁷

Note: In subclock mode or sub-CR clock mode, since the time-base timer stops operating, setting CKS1[2:0] to "0b110" or "0b111" is prohibited.

18.7.2 8/16-bit PPG timer n0 Control Register (PCn0)

The 8/16-bit PPG timer n0 control register (PCn0) sets the operating conditions and the operation mode for PPG timer n0.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	MD1	MD0	PIE0	PUF0	POEN0	CKS02	CKS01	CKS00
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] MD[1:0]: Operating mode bits

These bits select the PPG operation mode.

Do not modify the settings of these bits during counting.

bit7:6	Details
Writing "00"	8-bit PPG independent mode
Writing "01"	8-bit prescaler + 8-bit PPG mode
Writing "10"	16-bit PPG mode
Writing "11"	

[bit5] PIE0: Interrupt request enable bit

This bit controls interrupts of PPG timer n0.

In 16-bit PPG mode, use this bit to control the interrupt request of the 8/16-bit PPG.

The bit outputs an interrupt request (IRQ) when the counter borrow detection bit (PUF0) and the PIE0 bit are both set to "1".

bit5	Details
Writing "0"	Disables the PPG timer n0 interrupt.
Writing "1"	Enables the PPG timer n0 interrupt.

[bit4] PUF0: Counter borrow detection flag bit for PPG cycle downcounter

This bit serves as the counter borrow detection flag for the PPG cycle downcounter of the PPG timer n0.

In 16-bit PPG mode, only this bit is effective and the PUF1 bit in the PCn1 register has no effect on operation.

Note: In 8-bit PPG independent mode or 8-bit prescaler + 8-bit PPG mode, counter borrow detection is always enabled.

Writing "1" to this bit has no effect on operation. Writing "0" to this bit clears it.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit4	Details
Reading "0"	Indicates that no counter borrow of PPG timer n0 has been detected.
Reading "1"	Indicates that a counter borrow of PPG timer n0 has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit3] POEN0: Output enable bit

This bit enables or disables the PPG timer n0 pin output.

In 16-bit PPG mode, since the 8/16-bit PPG outputs pulse wave through the PPG timer n0 pin, this bit controls the 8/16-bit PPG output.

bit3	Details
Writing "0"	The PPG timer n0 pin functions as a general-purpose I/O port.
Writing "1"	The PPG timer n0 pin functions as a PPG output pin.

[bit2:0] CKS0[2:0]: Operating clock select bits

These bits select the operating clock for 8-bit downcounter of the PPG timer n0.

The operating clock is generated from the prescaler. For details, see "3.9 Operation of Prescaler".

In 8-bit prescaler + 8-bit PPG mode, the rising and falling edge detection pulses from the PPG timer n1 output are used as the count clock for PPG timer n0. Therefore, the settings of these bits have no effect on operation.

In 16-bit PPG mode, use these bits to select the operating clock.

bit2:0	Details (MCLK: machine clock, F_{CH} : main clock, F_{CRH} : main CR clock, F_{PLL} : PLL clock)
Writing "000"	1 MCLK
Writing "001"	MCLK/2
Writing "010"	MCLK/4
Writing "011"	MCLK/8
Writing "100"	MCLK/16
Writing "101"	MCLK/32
Writing "110"	$F_{CH}/2^7$ or $F_{CRH}/2^6$ or $F_{PLL}/2^6$
Writing "111"	$F_{CH}/2^8$ or $F_{CRH}/2^7$ or $F_{PLL}/2^7$

Note: In subclock mode or sub-CR clock mode, since the time-base timer stops operating, setting CKS0[2:0] to "0b110" or "0b111" is prohibited.

18.7.3 8/16-bit PPG timer n1/n0 Cycle Setup Buffer Register (PPSn1/PPSn0)

The 8/16-bit PPG timer n1/n0 cycle setup buffer register (PPSn1/PPSn0) sets the PPG output cycle.

■ Register Configuration

PPSn1								
bit	7	6	5	4	3	2	1	0
Field	PH7	PH6	PH5	PH4	PH3	PH2	PH1	PH0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

PPSn0								
bit	7	6	5	4	3	2	1	0
Field	PL7	PL6	PL5	PL4	PL3	PL2	PL1	PL0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

■ Register Functions

The PPSn1 and PPSn0 registers set the PPG output cycle.

- In 16-bit PPG mode, PPSn1 serves as the upper 8 bits, while PPSn0 serves as the lower 8 bits.
- In 16-bit PPG mode, write the upper bits before the lower bits. When only the upper bits are written, the previously written value is reused in the next load.
- 8-bit mode: Cycle = max. 255 (0xFF) × Input clock cycle
- 16-bit mode: Cycle = max. 65535 (0xFFFF) × Input clock cycle
- Initialized at reset.
- Do not set the cycle to "0x00" or "0x01" when using the unit in 8-bit PPG independent mode or 8-bit prescaler mode + 8-bit PPG mode
- Do not set the cycle to "0x0000" or "0x0001" when using the unit in 16-bit PPG mode.
- If the cycle settings are modified during the operation, the modified settings will be effective from the next PPG cycle.

18.7.4 8/16-bit PPG timer n1/n0 Duty Setup Buffer Register (PDSn1/PDSn0)

The 8/16-bit PPG timer n1/n0 duty setup buffer register (PDSn1/PDSn0) sets the duty of the PPG output.

■ Register Configuration

PDSn1								
bit	7	6	5	4	3	2	1	0
Field	DH7	DH6	DH5	DH4	DH3	DH2	DH1	DH0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

PDSn0								
bit	7	6	5	4	3	2	1	0
Field	DL7	DL6	DL5	DL4	DL3	DL2	DL1	DL0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	1	1	1	1	1	1	1	1

■ Register Functions

The PDSn1 and PDSn0 registers set the duty of the PPG output ("H" pulse width when normal polarity).

- In 16-bit PPG mode, PDSn1 serves as the upper 8 bits while PDSn0 serves as the lower 8 bits.
- In 16-bit PPG mode, write the upper bits before the lower bits. When only the upper bits are written, the previously written value is reused in the next load. By writing to PDSn0, PDSn1 is updated.
- Initialized at reset.
- To set the duty to 0%, select "0x00".
- To set the duty to 100%, set it to the same value as the 8/16-bit PPG timer n1/n0 cycle setup register (PPSn0, PPSn1).
- When the 8/16-bit PPG timer n0/n1 duty setup register (PDS) is set to a larger value than the setting value of the 8/16-bit PPG cycle setup buffer register (PPS), the PPG output becomes "L" output in the normal polarity (when the output level inversion bit of 8/16-bit PPG output inversion register is "0").
- If the duty settings are modified during operation, the modified value will be effective from the next PPG cycle.

18.7.5 8/16-bit PPG Start Register (PPGS)

The 8/16-bit PPG start register (PPGS) starts or stops the downcounter. The operation enable bit of each channel is assigned to the PPGS register, allowing simultaneous activation of the PPG channels.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	PEN21*	PEN20*	PEN11*	PEN10*	PEN01	PEN00
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

*: Since the number of channels of the 8/16-bit PPG varies among products, these bits may become undefined bits on certain products. For details, refer to the device data sheet.

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] PEN21: PPG timer 21 (ch. 2) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 21 (ch. 2).

bit5	Details
Writing "0"	Stops the downcounter operation of PPG timer 21 (ch. 2).
Writing "1"	Enables the downcounter operation of PPG timer 21 (ch. 2).

[bit4] PEN20: PPG timer 20 (ch. 2) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 20 (ch. 2).

bit4	Details
Writing "0"	Stops the downcounter operation of PPG timer 20 (ch. 2).
Writing "1"	Enables the downcounter operation of PPG timer 20 (ch. 2).

[bit3] PEN11: PPG timer 11 (ch. 1) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 11 (ch. 1).

bit3	Details
Writing "0"	Stops the downcounter operation of PPG timer 11 (ch. 1).
Writing "1"	Enables the downcounter operation of PPG timer 11 (ch. 1).

[bit2] PEN10: PPG timer 10 (ch. 1) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 10 (ch. 1).

bit2	Details
Writing "0"	Stops the downcounter operation of PPG timer 10 (ch. 1).
Writing "1"	Enables the downcounter operation of PPG timer 10 (ch. 1).

[bit1] PEN01: PPG timer 01 (ch. 0) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 01 (ch. 0).

bit1	Details
Writing "0"	Stops the downcounter operation of PPG timer 01 (ch. 0).
Writing "1"	Enables the downcounter operation of PPG timer 01 (ch. 0).

[bit0] PEN00: PPG timer 00 (ch. 0) downcounter operation enable bit

This bit enables or stops the downcounter operation of PPG timer 00 (ch. 0).

bit0	Details
Writing "0"	Stops the downcounter operation of PPG timer 00 (ch. 0).
Writing "1"	Enables the downcounter operation of PPG timer 00 (ch. 0).

18.7.6 8/16-bit PPG Output Reverse Register (REVC)

The 8/16-bit PPG output reverse register (REVC) reverses the PPG output including the initial level.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	REV21*	REV20*	REV11*	REV10*	REV01	REV00
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

*: Since the number of channels of the 8/16-bit PPG varies among products, these bits may become undefined bits on certain products. For details, refer to the device data sheet.

Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] REV21: PPG timer 21 (ch. 2) output level reverse bit

This bit selects the output level of PPG timer 21 (ch. 2).

bit5	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

[bit4] REV20: PPG timer 20 (ch. 2) output level reverse bit

This bit selects the output level of PPG timer 20 (ch. 2).

bit4	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

[bit3] REV11: PPG timer 11 (ch. 1) output level reverse bit

This bit selects the output level of PPG timer 11 (ch. 1).

bit3	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

[bit2] REV10: PPG timer 10 (ch. 1) output level reverse bit

This bit selects the output level of PPG timer 10 (ch. 1).

bit2	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

[bit1] REV01: PPG timer 01 (ch. 0) output level reverse bit
This bit selects the output level of PPG timer 01 (ch. 0).

bit1	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

[bit0] REV00: PPG timer 00 (ch. 0) output level reverse bit
This bit selects the output level of PPG timer 00 (ch. 0).

bit0	Details
Writing "0"	Selects normal polarity.
Writing "1"	Selects reverse polarity.

18.8 Notes on Using 8/16-bit PPG

This section provides notes on using the 8/16-bit PPG.

■ Notes on Using 8/16-bit PPG

- Note on operation

Depending on the timing between the activation of PPG and count clock, an error may occur in the first cycle of the PPG output immediately after the activation. The error varies depending on the count clock selected. The output, however, is performed properly in the succeeding cycles.

- Note on interrupts

A PPG interrupt is generated when the interrupt enable bit (PIE1/PIE0) is set to "1" and the interrupt request flag bit (PUF1/PUF0) in the 8/16-bit PPG timer n1/n0 control register (PCn1/PCn0) is also set to "1". Always clear the interrupt request flag bit (PUF1/PUF0) to "0" in the interrupt service routine.

CHAPTER 19

16-BIT RELOAD TIMER

This chapter describes the functions and operations of the 16-bit reload timer.

- 19.1 Overview
- 19.2 Configuration
- 19.3 Channel
- 19.4 Pins
- 19.5 Interrupt
- 19.6 Operations and Setting Procedure Example
- 19.7 Registers
- 19.8 Notes on Using 16-bit Reload Timer

19.1 Overview

The 16-bit reload timer has two counter operating modes in each of the two clock modes.

The 16-bit reload timer can be used as an interval timer by generating an interrupt when an underflow occurs in the timer.

■ Operation Modes of 16-bit Reload Timer

Table 19.1-1 shows the operation modes of the 16-bit reload timer.

Table 19.1-1 Operation Modes of 16-bit Reload Timer

Clock mode	Counter operating mode	Trigger operation mode
Internal clock mode	Reload mode	Software trigger operation External trigger input operation External gate input operation
	One-shot mode	
Event count mode (external clock mode)	Reload mode	Software trigger operation
	One-shot mode	

■ Internal Clock Mode

Internal clock mode is selected when any value other than "0b111" is set to the count clock setting bits (CSL[2:0]) in the 16-bit reload timer control status register (upper) ch. n (TMCSR_{Hn}).

In internal clock mode, the following three trigger operation modes are available.

● Software trigger operation

The count starts when the count enable bit (CNTE) in the 16-bit reload timer control status register (lower) ch. n (TMCSRL_n) is set to "1" and the software trigger bit (TRG) is set to "1".

● External trigger input operation

When the count enable bit (CNTE) in the 16-bit reload timer control status register (lower) ch. n (TMCSRL_n) is set to "1", the count will start if a valid edge (rising, falling, or both selectable) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin.

● External gate input operation

When the count enable bit (CNTE) in the 16-bit reload timer control status register (lower) ch. n (TMCSRL_n) is set to "1", the count will start if a valid trigger input level ("L" or "H" selectable) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin.

■ Event Count Mode (External Clock Mode)

When the count clock setting bits (CSL[2:0]) in the 16-bit reload timer control status register (upper) ch. n (TMCSR_{Hn}) are set to "0b111", the count will start if a valid edge of trigger input (rising, falling, or both) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin. When an external clock is input in regular cycles, the reload timer can also be used as an interval timer.

■ Counter Operating Mode

- Reload mode

When an underflow occurs in the 16-bit downcounter ("0x0000" → "0xFFFF"), the value of the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) is loaded to the 16-bit downcounter and the 16-bit reload timer continues counting. In addition, since the interrupt request is output by an underflow, the 16-bit reload timer can be used as the interval timer.

- One-shot mode

An interrupt is generated when an underflow occurs on the 16-bit downcounter.

During counter operation, the TOn pin outputs a square waveform indicating that the counter is currently running.

19.2 Configuration

The 16-bit reload timer consists of the following blocks:

- Count clock generation circuit
- Reload control circuit
- Output control circuit
- Operation control circuit
- 16-bit reload timer timer register ch. n (TMRHn, TMRLn)
- 16-bit reload timer reload register ch. n (TMRLRHn, TMRLRLn)
- 16-bit reload timer control status register ch. n (TMCSRHn, TMCSRLn)

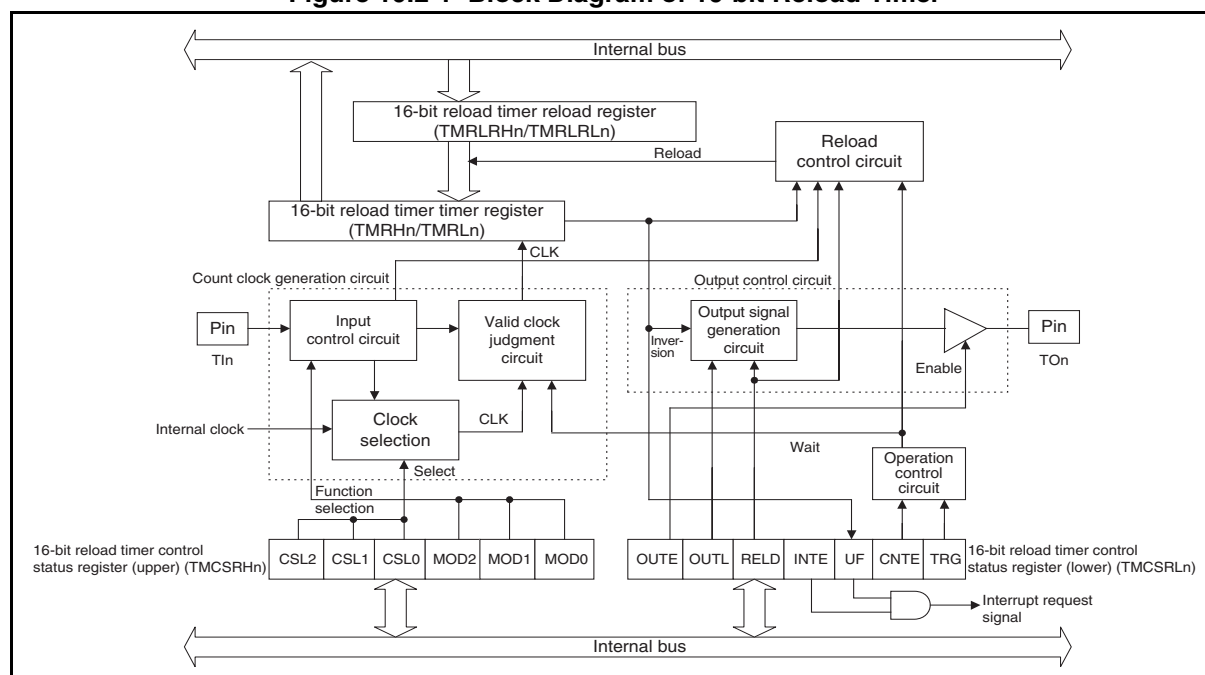

The number of pins and that of channels of the 16-bit reload timer vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of 16-bit Reload Timer

Figure 19.2-1 shows the block diagram of the 16-bit reload timer.

Figure 19.2-1 Block Diagram of 16-bit Reload Timer

- Count clock generation circuit

The count clock for the 16-bit reload timer is generated from the internal clock or TIn pin input signal.

- Reload control circuit

This circuit controls reload operation when the timer is started or an underflow occurs.

- Output control circuit

This circuit controls the inversion of TOn pin output by an underflow of the 16-bit downcounter and the enabling and disabling of TOn pin output.

- Operation control circuit

This circuit controls the starting and stopping of the 16-bit downcounter.

- 16-bit reload timer timer register (upper/lower) ch. n (TMRHn/TMRLn)

TMRHn and TMRLn form a 16-bit downcounter. Reading these registers returns the current count value.

- 16-bit reload timer reload register (upper/lower) ch. n (TMRLRHn/TMRLRLn)

This register sets the load value to the 16-bit downcounter. The register loads the setting value of the 16-bit reload timer reload register to the 16-bit downcounter to down count.

- 16-bit reload timer control status register (upper/lower) ch. n (TMCSRHn/TMC SRLn)

This register controls the count clock, operating mode, clock selection, interrupts, and other aspects of the 16-bit reload timer as well as indicates the current operation status.

■ Input Clock

The 16-bit reload timer uses the output clock from the prescaler or the input signal from the TIn pin as its input clock (count clock).

When the event counter operates in event counter operation mode, external clock input from the TIn pin is gated by the PWM signal generated by 8/16-bit composite timer ch. 1, and is then input to the 16-bit reload timer as a count clock for the 16-bit reload timer. For details of the event counter, see "CHAPTER 20 EVENT COUNTER".

19.3 Channel

This section describes the channel of the 16-bit reload timer.

■ Channel of 16-bit Reload Timer

Table 19.3-1 and Table 19.3-2 show the pins and registers on a channel of the 16-bit reload timer respectively.

Table 19.3-1 Pins of 16-bit Reload Timer

Pin name	Pin function
TOn	Timer output
TIn	Timer input

Table 19.3-2 Registers of 16-bit Reload Timer

Register abbreviation	Corresponding register (Name in this manual)
TMCSRHn	16-bit reload timer control status register (upper) ch. n
TMCSRLn	16-bit reload timer control status register (lower) ch. n
TMRHn	16-bit reload timer timer register (upper) ch. n
TMRLn	16-bit reload timer timer register (lower) ch. n
TMRLRHn	16-bit reload timer reload register (upper) ch. n
TMRLRLn	16-bit reload timer reload register (lower) ch. n

19.4 Pins

This section describes the pins of the 16-bit reload timer.

■ Pins of 16-bit Reload Timer

The pins of the 16-bit reload timer are namely the TIn and TOn pins.

- TIn pin

This pin is used both as a general-purpose I/O port and as the external pulse input pin for the counter (TIn).

TIn: Any pulse edge input to this pin is counted during counter operation. To use it as the external pulse input pin in counter operation, set the corresponding bit in the port direction register (DDR) to "0".

- TOn pin

This pin is used both as a general-purpose I/O port and as the output pin of the 16-bit reload timer (TOn).

TOn: This pin outputs waveforms of the 16-bit reload timer.

When this pin is used as the 16-bit reload timer output pin, regardless of the setting of the port direction register (DDR), enabling 16-bit reload timer output (TMCSRLn:OUTE = 1) automatically makes this pin function as the 16-bit reload timer output pin to output the waveforms.

19.5 Interrupt

The 16-bit reload timer outputs an interrupt request when an underflow occurs on the 16-bit downcounter.

■ Interrupt of 16-bit Reload Timer

Table 19.5-1 shows the interrupt control bit and interrupt source of the 16-bit reload timer.

Table 19.5-1 Interrupt Control Bits and Interrupt Sources of 16-bit Reload Timer

Item	Description
Interrupt request flag bit	UF bit in TMC SRLn register
Interrupt request enable bit	INTE bit in TMC SRLn register
Interrupt source	Underflow of downcounter (TMRHn/TMRLn)

The 16-bit reload timer sets the underflow interrupt request flag bit (UF) in the 16-bit reload timer control status register (lower) ch. n (TMC SRLn) to "1" when an underflow occurs in the 16-bit downcounter ("0x0000" → "0xFFFF"). If the underflow interrupt request has been enabled (TMC SRLn:INTE = 1), the interrupt request will be output to the interrupt controller.

19.6 Operations and Setting Procedure Example

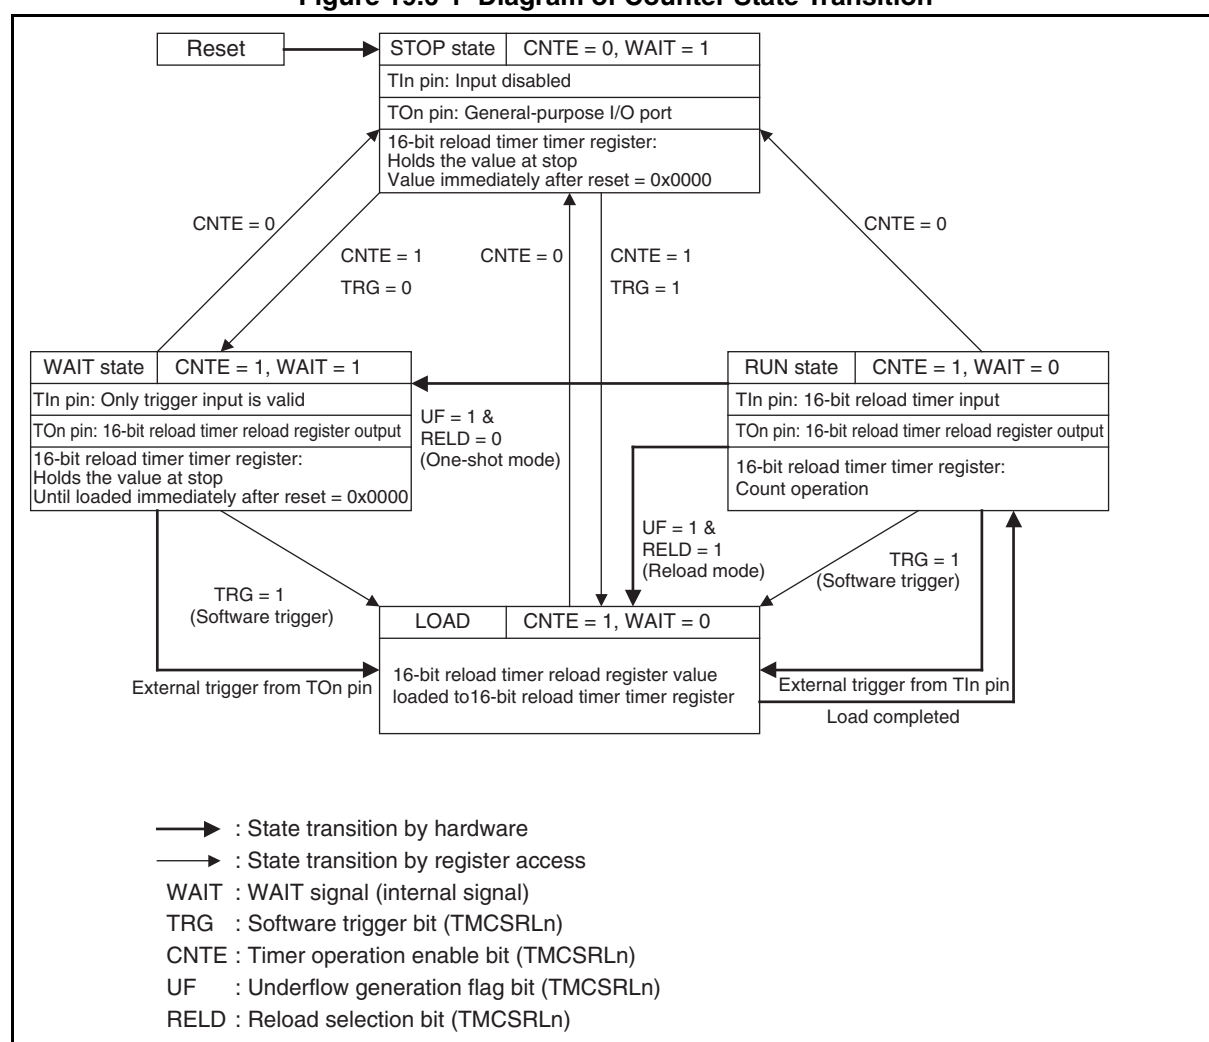

This section describes the operating status of the 16-bit reload timer counter.

■ Operating Status of Counter

The counter status is determined by the value of the count enable bit (CNTE) in the 16-bit reload timer control status register (lower) ch. n (TMCSRLn) and the internal signal start trigger wait signal (WAIT). The STOP state (halted), WAIT state (waiting for a start trigger) and RUN state (operating state) can be set.

Figure 19.6-1 shows the status transition of these counters.

Figure 19.6-1 Diagram of Counter State Transition

■ Setting Procedure Example

Below is an example of procedure for setting the 16-bit reload timer.

● Initial setup

1. Set the interrupt level. (ILR*)
2. Set the reload value. (TMRHn/TMRLn)
3. Select the clock. (TMCSRHn:CSL[2:0])
4. Select the operating mode. (TMCSRHn:MOD[2:0])
5. Enable the output. (TMCSRLn:OUTE = 1)
6. Select the output level. (TMCSRLn:OUTL)
7. Select reload. (TMCSRLn:RELD)
8. Enable a count. (TMCSRLn:CNTEN = 1)
9. Perform the software trigger. (TMCSRLn:TRG = 1)
10. Enable underflow interrupt. (TMCSRLn:INTE = 1).

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

1. Clear the underflow interrupt request flag. (TMCSRLn:UF=0)
2. Disable underflow interrupt. (TMCSRLn:INTE = 0)
3. Process any interrupt.
4. Enable underflow interrupt. (TMCSRLn:INTE = 1)

19.6.1 Internal Clock Mode

In this mode, the 16-bit downcounter counts down while being synchronized with the internal count clock, and outputs an interrupt request to the interrupt controller every time an underflow occurs ("0x0000" → "0xFFFF"). In addition, the TOn pin can output the toggle waveform.

■ Setting Internal Clock Mode

The timer requires the register settings shown in Figure 19.6-2 to operate as an interval timer.

Figure 19.6-2 Internal Clock Mode Setup

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
TMCSRHn	-	-	CSL2	CSL1	CSL0	MOD2	MOD1	MOD0
			Other than "0b111"			0	⊙	⊙
	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
TMCSRLn	-	OUTE	OUTL	RELD	INTE	UF	CNTE	TRG
	0	⊙	⊙	⊙	⊙	⊙	1	⊙
	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
TMRLRHn	D15	D14	D13	D12	D11	D10	D9	D8
	Set initial value of counter (reload value) (upper)							
	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
TMRLRLn	D7	D6	D5	D4	D3	D2	D1	D0
	Set initial value of counter (reload value) (lower)							

⊙ : Used bit
 0 : Set to "0"
 1 : Set to "1"

■ Operation of Internal Clock Mode (Reload Mode)

When "1" is set to the count enable bit (CNTE) to enable counting, and the timer is started by setting "1" to the software trigger bit (TRG) or by an external trigger, the value set in the 16-bit reload timer reload register (upper/lower) ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit downcounter and downcounting starts. If counting is enabled when the count enable bit (CNTE) and software trigger bit (TRG) are set to "1" at the same time, the counting starts at the same time.

If the reload select bit (RELD) is "1", the value of the 16-bit reload timer reload register (upper/lower) ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit downcounter and the count continues when the 16-bit counter underflows ("0x0000" → "0xFFFF"). If the underflow interrupt request flag bit (UF) is "1" when the underflow interrupt request enable bit (INTE) is set to "1", an interrupt request is output.

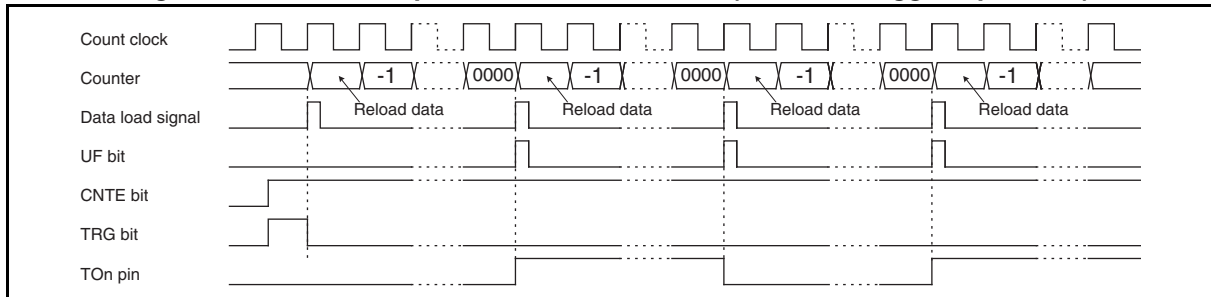

The TOn pin can output a toggle waveform that is inverted every time an underflow occurs.

● Software trigger operation

When the count enable bit (CNTE) is set to "1", setting "1" to the software trigger bit (TRG) starts counting.

Figure 19.6-3 shows the software trigger operation in reload mode.

Figure 19.6-3 Count Operation in Reload Mode (Software Trigger Operation)

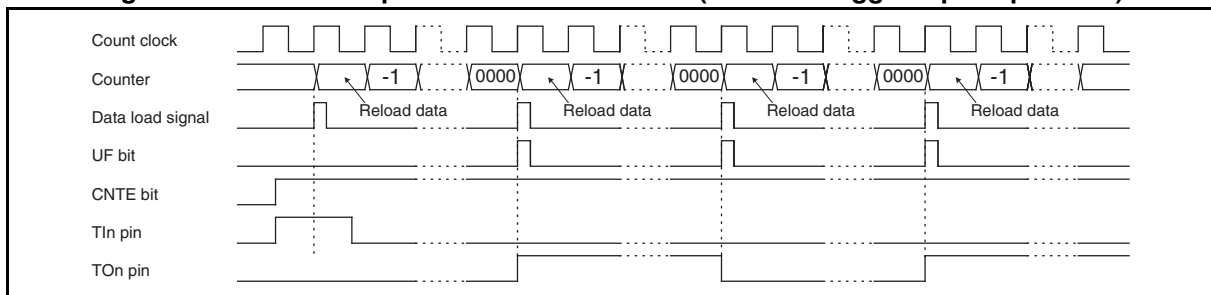

● External trigger input operation

The count starts when the count enable bit (CNTE) is set to "1" and a valid edge of trigger input (rising, falling, or both selectable) set by the operating mode select bits (MOD[2:0]) is input to the TIn pin.

The timer start with the software trigger becomes effective as well as the one with an external trigger.

Figure 19.6-4 shows the external trigger input operation in reload mode.

Figure 19.6-4 Count Operation in Reload Mode (External Trigger Input Operation)

● Gate input operation

The count starts when the count enable bit (CNTE) is set to "1" and the software trigger bit (TRG) is also set to "1".

The timer continues counting while the valid gate input level ("L" or "H" selectable) set by the operating mode select bits (MOD[2:0]) is being input to the TIn pin.

The timer start with the software trigger becomes effective as well as the one with an external trigger.

Figure 19.6-5 shows the gate input operation in reload mode.

Figure 19.6-5 Count Operation in Reload Mode (External Gate Input Operation)

■ Operation of Internal Clock Mode (One-shot Mode)

When the count enable bit (CNTE) is set to "1" and the software trigger bit (TRG) is set to "1" or the valid edge (rising, falling or both edges selectable) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin, the value set in the 16-bit reload timer reload register is reloaded to the 16-bit downcounter and down-counting starts. When the count enable bit (CNTE) and software trigger bit (TRG) are set to "1" at the same time and then counting is enabled, the count is started simultaneously.

If the reload select bit (RELD) is "0", the 16-bit counter halts at "0xFFFF" when the 16-bit counter underflows ("0x0000" → "0xFFFF"). In this case, the underflow interrupt request flag bit (UF) is set to "1" and if the underflow interrupt request enable bit (INTE) is "1", an interrupt request is output.

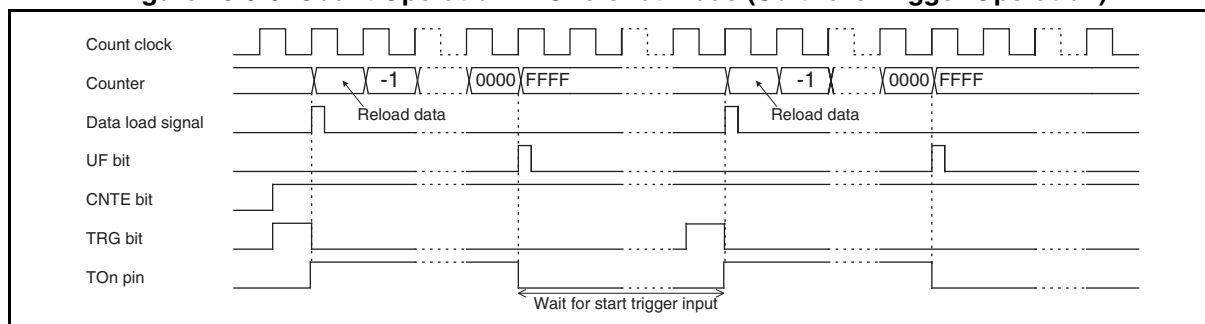

A square waveform can be output from the TOn pin to indicate that the count is in progress.

● Software trigger operation

The count starts when the count enable bit (CNTE) is "1" and the software trigger bit (TRG) is set to "1".

Figure 19.6-6 shows the software trigger operation in one-shot mode.

Figure 19.6-6 Count Operation in One-shot Mode (Software Trigger Operation)

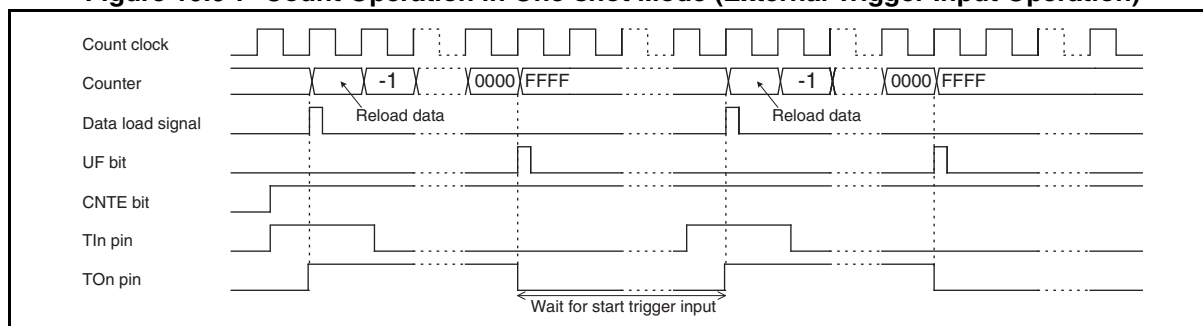

● External trigger input

The count starts when the count enable bit (CNTE) is "1" and the valid edge of trigger input (rising, falling, or both edges) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin.

Figure 19.6-7 shows the external trigger input operation in one-shot mode.

Figure 19.6-7 Count Operation in One-shot Mode (External Trigger Input Operation)

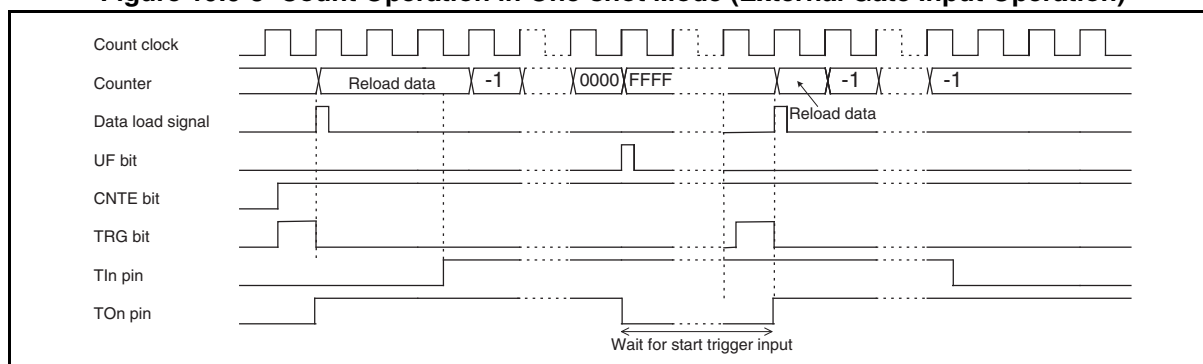

● Gate input operation

The count starts when the count enable bit (CNTE) is "1" and the software trigger bit (TRG) is also set to "1".

The timer continues counting as long as the trigger input enable level ("L" or "H" selectable) specified by the operating mode select bits (MOD[2:0]) is input to the TIn pin.

Figure 19.6-8 shows the external gate input operation in one-shot mode.

Figure 19.6-8 Count Operation in One-shot Mode (External Gate Input Operation)

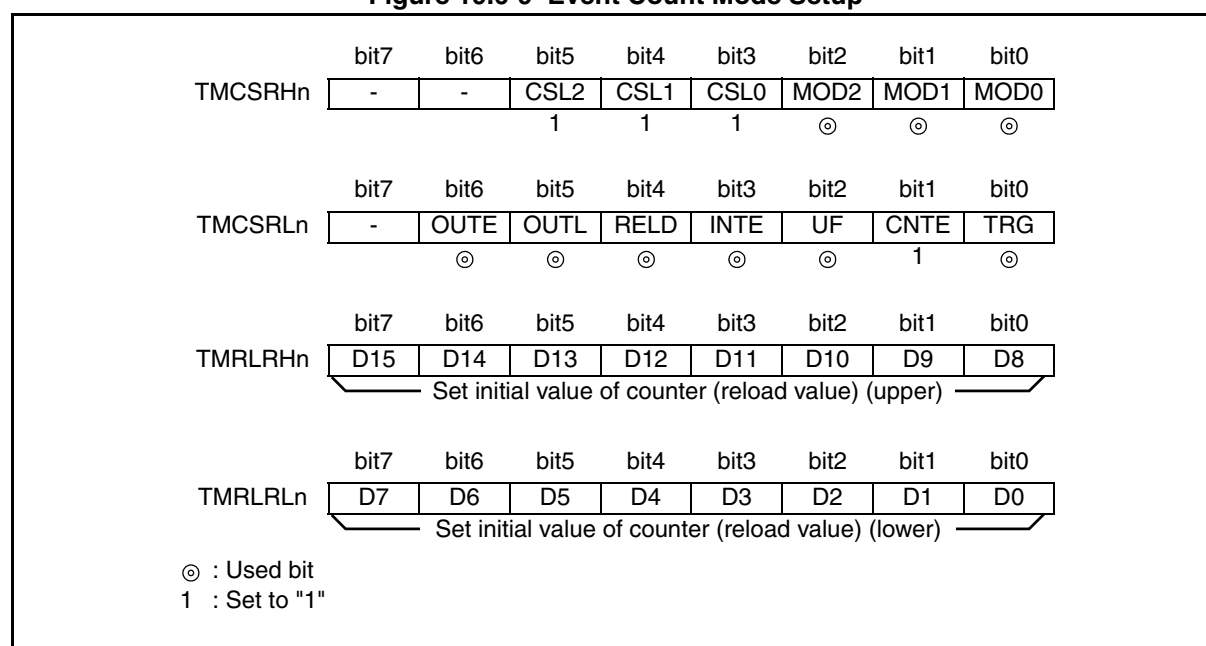

19.6.2 Event Count Mode

In this mode, the 16-bit downcounter counts down each time the valid edge is detected on the pulses input to the TIn pin, and an interrupt request is output to the interrupt controller when an underflow occurs ("0x0000" → "0xFFFF"). In addition, a toggle waveform or square waveform can be output from the TOn pin.

■ Event Count Mode Setup

The timer requires the register settings shown in Figure 19.6-9 to operate as an event counter.

Figure 19.6-9 Event Count Mode Setup

■ Event Count Mode

The value set in the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit counter when the count enable bit (CNTE) is set to "1" and the software trigger bit (TRG) is set to "1". The counter counts each time the valid edge (rising, falling, or both edges selectable) is detected on the pulses input to the TIn pin (external count clock).

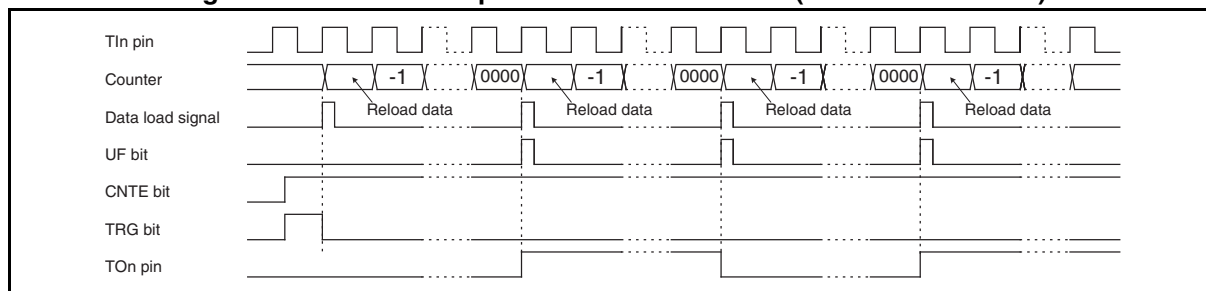

● Operation of reload mode

If the reload select bit (RELD) is "1", the value set in the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit counter and the count continues when the 16-bit counter underflows ("0x0000" → "0xFFFF").

The underflow interrupt request flag bit (UF) in the 16-bit reload timer control status register (lower) ch. n (TMCSRLn) is set to "1" when an underflow occurs ("0x0000" → "0xFFFF") in the 16-bit counter, and an interrupt request is output if the underflow interrupt enable bit (INTE) is set to "1".

The TOn pin can output a toggle waveform that is inverted each time an underflow occurs. Figure 19.6-10 shows the count operation in reload mode.

Figure 19.6-10 Count Operation in Reload Mode (Event Count Mode)

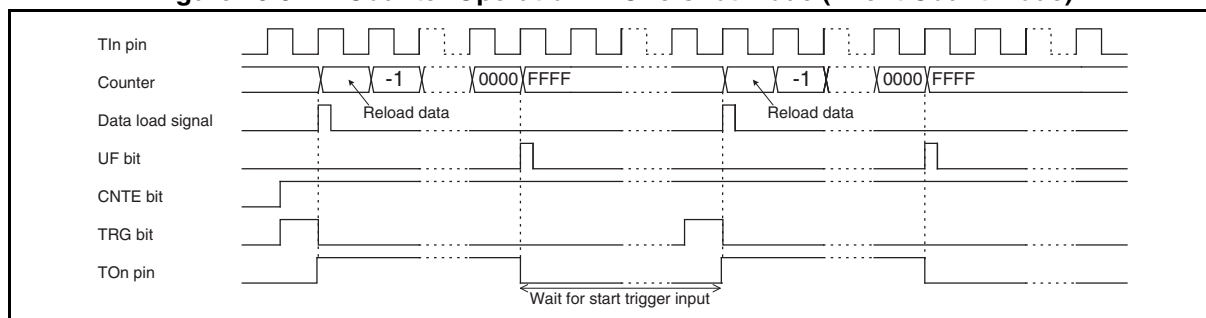

● Operation of one-shot mode

If the reload select bit (RELD) is "0", the value of the 16-bit counter halts at "0xFFFF" when the 16-bit counter underflows ("0x0000" → "0xFFFF").

An interrupt request is output when the underflow request flag bit (UF) in the 16-bit reload timer control status register (lower) ch. n (TMCSRLn) is set to "1" with the underflow interrupt enable bit (INTE) set to "1".

The TOn pin outputs a square waveform indicating that counting is in progress. Figure 19.6-11 shows the count operation in one-shot mode.

Figure 19.6-11 Counter Operation in One-shot Mode (Event Count Mode)

19.7 Registers

This section describes the registers of the 16-bit reload timer.

Table 19.7-1 List of 16-bit Reload Timer Registers

Register abbreviation	Register name	Reference
TMCSRHn	16-bit reload timer control status register (upper) ch. n	19.7.1
TMCSRLn	16-bit reload timer control status register (lower) ch. n	19.7.2
TMRHn	16-bit reload timer timer register (upper) ch. n	19.7.3
TMRLn	16-bit reload timer timer register (lower) ch. n	19.7.3
TMRLRHn	16-bit reload timer reload register (upper) ch. n	19.7.4
TMRLRLn	16-bit reload timer reload register (lower) ch. n	19.7.4

19.7.1 16-bit Reload Timer Control Status Register (Upper) ch. n (TMCSRHn)

The 16-bit reload timer control status register (upper) ch. n (TMCSRHn) sets the operating mode and operating conditions of the 16-bit reload timer.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	CSL2	CSL1	CSL0	MOD2	MOD1	MOD0
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation,

[bit5:3] CSL[2:0]: Count clock select bits

These bits select the count clock for the 16-bit reload timer.

When a value between "0b000" and "0b110" inclusive is written to these bits, the 16-bit reload timer counts with the internal clock (internal clock mode). The internal clock is generated by the prescaler. For details, see "3.9 Operation of Prescaler".

When "0b111" is written to these bits, the 16-bit reload timer counts with the edge of the external event clock (event count mode).

bit5:3	Details	
	Operating mode	Count clock*
Writing "000"	Internal clock mode	1 MCLK
Writing "001"		MCLK/2
Writing "010"		MCLK/4
Writing "011"		MCLK/8
Writing "100"		MCLK/16
Writing "101"		MCLK/32
Writing "110"		$F_{CH}/2^7$ or $F_{CRH}/2^6$ or $F_{PLL}/2^6$
Writing "111"	Event count mode	External clock

*: MCLK: machine clock

F_{CH} : main clock

F_{CRH} : main CR clock

F_{PLL} : PLL clock

[bit2:0] MOD[2:0]: Operating mode select bits

These bits set the operating conditions of the 16-bit reload timer.

- Internal clock mode (CSL[2:0] = any value between 0b000 and 0b110 inclusive)
 - Select the input pin function with the MOD2 bit.
 - When the MOD2 bit is "0",
 - The TIn pin functions as a trigger input pin.
 - Select the edge to be detected using the MOD[1:0] bits.
 - When the edge selected in MOD[1:0] is detected, the value set to the 16-bit reload timer reload register (upper/lower) ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit reload timer timer register (upper/lower) ch. n (TMRHn/TMRLn), and the 16-bit reload counter starts counting using TMRHn/TMRLn.
 - When the MOD2 bit is "1",
 - The TIn pin functions as a gate input pin.
 - The setting of the MOD1 bit is invalid.
 - Select the valid signal level ("H" or "L") with the MOD0 bit. The 16-bit reload timer counts using TMRHn/TMRLn only while the valid signal level is being input.

Note: When the MOD[2:0] bits are "0b000", external pin input becomes invalid. In this case, use the TRG bit to start the 16-bit reload timer by using the software.

bit2:0	Details (Internal clock mode)	
	TIn pin function	Valid edge/level
Writing "000"	External pin input invalid	—
Writing "001"	Trigger input	Rising edge
Writing "010"		Falling edge
Writing "011"		Both edges
Writing "100"	Gate input	"L" level
Writing "101"		"H" level
Writing "110"		"L" level
Writing "111"		"H" level

- Event count mode (CSL[2:0] = 0b111)
 - The MOD2 bit is always set to "0".
 - The external event clock is input from the TIn pin.
 - Select the edge to be detected using the MOD[1:0] bits.

bit2:0	Details (Event count mode)	
	TIn pin function	Valid edge/level
Writing "000"	External pin input invalid	—
Writing "001"	Trigger input	Rising edge
Writing "010"		Falling edge
Writing "011"		Both edges
Writing "100"	Setting prohibited	
Writing "101"		
Writing "110"		
Writing "111"		

19.7.2 16-bit Reload Timer Control Status Register (Lower) ch. n (TMCSRLn)

The 16-bit reload timer control status register (lower) ch. n (TMCSRLn) sets the operating conditions of the 16-bit reload timer, enables or disables counting, controls interrupts, and checks the interrupt request status.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	OUTE	OUTL	RELD	INTE	UF	CNTE	TRG
Attribute	—	R/W	R/W	R/W	R/W	R/W	R/W	W
Initial value	0	0	0	0	0	0	0	0

Register Functions

[bit7] Undefined bit

The read value is always "0". Writing a value to this bit has no effect on operation.

[bit6] OUTE: Timer output enable bit

This bit sets the TOn pin function of the 16-bit reload timer.

bit6	Details
Writing "0"	The TOn pin functions as a general-purpose I/O port.
Writing "1"	The TOn pin functions as the 16-bit reload timer output pin.

[bit5] OUTL: Pin output level select bit

This bit selects the output level of the output pin of the 16-bit reload timer.

bit5	Details	
	One-shot mode (TMCSRLn:RELD = 0)	Reload mode (TMCSRLn:RELD = 1)
Writing "0"	The output pin outputs "H" level square waveform while the 16-bit reload timer is counting.	The output pin outputs "L" when the 16-bit reload timer is started, and then toggles whenever an underflow occurs.
Writing "1"	The output pin outputs "L" level square waveform while the 16-bit reload timer is counting.	The output pin outputs "H" when the 16-bit reload timer is started, and then toggles whenever an underflow occurs.

[bit4] RELD: Reload select bit

This bit selects the reload operation to be executed when an underflow occurs.

When "0" is written to this bit, the 16-bit reload timer enters one-shot mode. In one-shot mode, when an underflow occurs, the 16-bit reload timer stops counting.

When "1" is written to this bit, the 16-bit reload timer enters reload mode. In reload mode, when an underflow occurs, the value set to the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) is loaded to the 16-bit reload timer timer register ch. n (TMRHn/TMRLn), and the 16-bit reload timer continues counting.

bit4	Details
Writing "0"	One-shot mode
Writing "1"	Reload mode

[bit3] INTE: Underflow interrupt request enable bit

This bit enables or disables the underflow interrupt.

bit3	Details
Writing "0"	Disables the underflow interrupt.
Writing "1"	Enables the underflow interrupt.

[bit2] UF: Underflow interrupt request flag bit

This bit indicates whether an underflow has occurred in the 16-bit reload timer.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit2	Details
Reading "0"	Indicates that no underflow has occurred in the 16-bit reload timer.
Reading "1"	Indicates that an underflow has occurred in the 16-bit reload timer.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit1] CNTE: Count enable bit

This bit enables or disables the counting operation of the 16-bit reload timer.

When "0" is written to this bit, the 16-bit reload timer stops counting.

When "1" is written to this bit, the 16-bit reload timer enters the start trigger wait state. When a start trigger is input, the 16-bit reload counter starts counting.

bit1	Details
Writing "0"	Stops the 16-bit reload timer counting operation.
Writing "1"	Enables the 16-bit reload timer counting operation (start trigger wait state).

[bit0] TRG: Software trigger bit

This bit enables using the software to start the 16-bit reload timer, and is valid only when the 16-bit reload timer operation is enabled (CNTE = 1).

Writing "0" to this bit has no effect on operation.

When "1" is written to this bit, the value set to the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) is reloaded to the 16-bit reload timer timer register ch. n (TMRHn/TMRLn), and then the 16-bit reload timer starts counting from the next count clock input.

Note: Writing "1" to this bit and the CNTE bit simultaneously starts the 16-bit reload timer counting operation.

The read value of this bit is always "0". However, this bit keeps reading "1" from the point at which "1" is written to this bit to start the 16-bit reload timer to the point at which the 16-bit reload timer starts counting.

bit0	Details
Read access	The read value is always "0".
Writing "0"	Has no effect on operation.
Writing "1"	The 16-bit reload timer starts counting from the next count clock input after the value set in TMRLRHn/TMRLRLn is reloaded to TMRHn/TMRLn.

19.7.3 16-bit Reload Timer Timer Register (Upper/Lower) ch. n (TMRHn/TMRLn)

The 16-bit reload timer timer register (upper/lower) ch. n (TMRHn/TMRLn) reads the count value of the 16-bit downcounter.

■ Register Configuration

TMRHn								
bit	7	6	5	4	3	2	1	0
Field	D15	D14	D13	D12	D11	D10	D9	D8
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

TMRLn								
bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

The 16-bit reload timer timer register ch. n reads the count value of the 16-bit downcounter.

If the counting operation has already been enabled (TMCSRLn:CNTE = 1) when the 16-bit reload timer starts counting, the value set to the 16-bit reload timer reload register is reloaded to the 16-bit reload timer timer register ch. n, and then the 16-bit reload timer starts downcounting.

Notes:

- This register can read the count value even during the counting operation of the 16-bit reload timer. To read this register, use a word transfer instruction, or read the upper byte of this register first and then its lower byte. The circuit of the 16-bit reload timer timer register ch. n is configured so that the lower byte value is saved when the upper byte value is read.
- This register is read-only and located at the same address as the 16-bit reload timer reload register ch. n. Therefore, a write access to this register becomes a write access to the 16-bit reload timer reload register ch. n.

19.7.4 16-bit Reload Timer Reload Register (Upper/Lower) ch. n (TMRLRHn/TMRLRLn)

The 16-bit reload timer reload register (upper/lower) ch.n (TMRLRHn/TMRLRLn) sets the reload value for the 16-bit downcounter. The value written to this register is reloaded to the 16-bit downcounter for downcounting.

■ Register Configuration

TMRLRHn

bit	7	6	5	4	3	2	1	0
Field	D15	D14	D13	D12	D11	D10	D9	D8
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

TMRLRLn

bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

The 16-bit reload timer reload register ch. n sets the reload value to be reloaded to the 16-bit downcounter.

The value set to the 16-bit reload timer reload register ch. n is reloaded to the 16-bit downcounter for downcounting when the 16-bit reload timer starts or when an underflow occurs. In addition, the value of this register can be modified during the counting operation of the 16-bit reload timer.

Notes:

- A value can be written to this register even during the counting operation of the 16-bit reload timer. To write a value to this register, use a word transfer instruction, or write the upper byte of this register first and then its lower byte. The 16-bit reload timer reload register ch. n has a circuit configured so that the upper byte value becomes valid when a value is written to the lower byte.
- This register is write-only and located at the same address as the 16-bit reload timer timer register ch. n. Therefore, a read access to this register becomes a read access to the 16-bit reload timer timer register ch. n.

19.8 Notes on Using 16-bit Reload Timer

This section provides notes on using the 16-bit reload timer.

■ Notes on Using 16-bit Reload Timer

● Notes on setting the program

- The 16-bit reload timer timer register ch. n (TMRHn/TMRLn) can read the count value even during the counting operation of the 16-bit reload timer. To read this register, use a word transfer instruction, or read the upper byte of this register first and then its lower byte.
- A value can be written to the 16-bit reload timer reload register ch. n (TMRLRHn/TMRLRLn) even during the counting operation of the 16-bit reload timer. To write a value to this register, use a word transfer instruction, or write the upper byte of this register first and then its lower byte.

● Notes on interrupts

With the underflow interrupt request enabled (TMCSRLn:INTE = 1), if the underflow interrupt request flag bit (UF) in the 16-bit reload timer control status register (lower) ch. n (TMCSRLn) is set to "1", the CPU cannot wake up from the interrupt service routine. Therefore, always clear the UF bit in the interrupt service routine.

● Note on the event counter operating in event counter operation mode

When the event counter operates in event counter operation mode, the 16-bit reload timer cannot be used.

CHAPTER 20

EVENT COUNTER

This chapter describes the functions and operations of the event counter.

- 20.1 Overview
- 20.2 Configuration
- 20.3 Operations in Even Counter Operation Mode
- 20.4 Setting Procedure Example
- 20.5 Frequency Measurement Range and Frequency Measurement Precision
- 20.6 Register
- 20.7 Notes on Using Event Counter

20.1 Overview

The event counter measures the frequency of an external clock whose measure period can be set. The 16-bit reload timer and 8/16-bit composite timer ch. 1 are configured to operate in event counter operation mode of the event counter.

■ Event Counter Operation Mode

In this mode, 8/16-bit composite timer ch.1 is used to generate the "H" pulse signal. The method of generating the "H" pulse signal is different for each model. For details, refer to the explanation in "20.3 Operations in Even Counter Operation Mode".

The external clock is gated by the "H" pulse signal generated by 8/16-bit composite timer ch. 1, and then input to the 16-bit reload timer as a count clock for the 16-bit reload timer. The 16-bit reload timer operates in external clock mode (reload mode). The frequency of the external clock is calculated based on the measure period set by the interrupt service subroutine of 8/16-bit composite timer ch. 1.

Note:

In the following sections of this chapter, the term "composite timer" represents "8/16-bit composite timer ch. 1" and the term "reload timer" "16-bit reload timer".

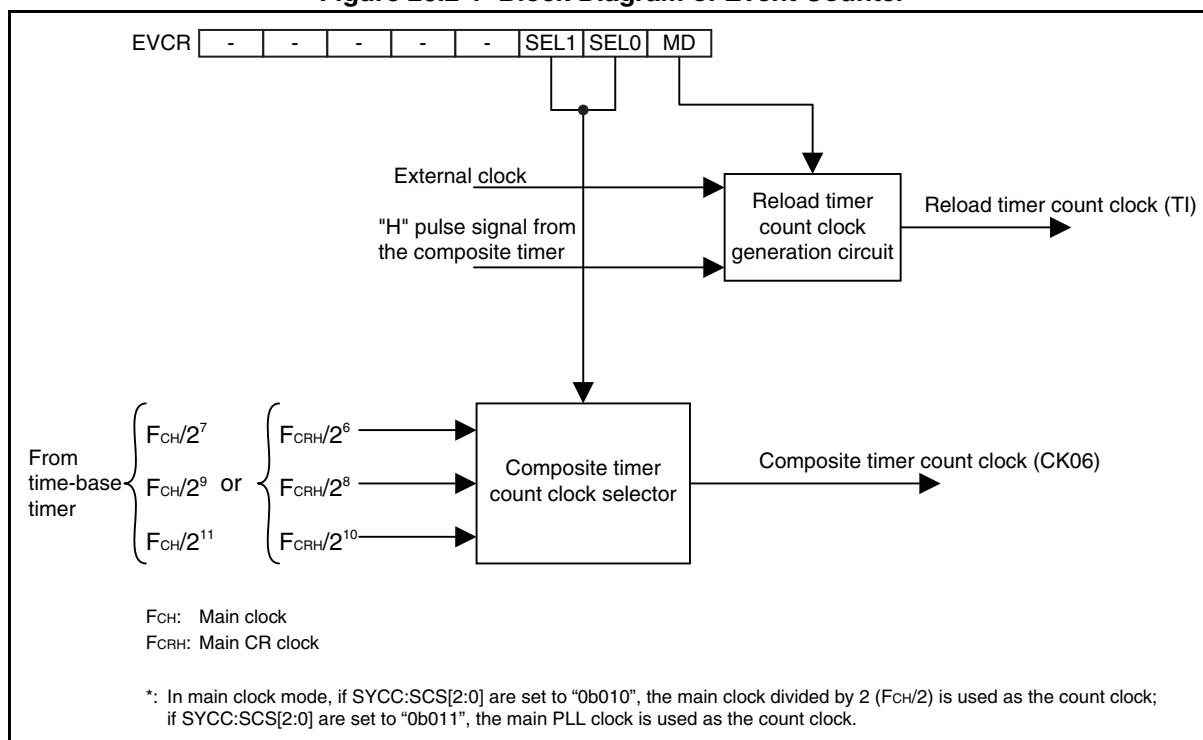

20.2 Configuration

The event counter consists of the following blocks:

- Reload timer count clock generation circuit
- Composite timer count clock (CK06) selection circuit
- Event counter control register (EVCR)

■ Block Diagram of Event Counter

Figure 20.2-1 Block Diagram of Event Counter

● Reload timer count clock generation circuit

When the MD bit of the EVCR register is set to "1", the external clock input is gated using the "H" pulse output from the composite timer, and then it is output to the reload timer as a count clock. When the MD bit is set to "0", the external clock is output directly to the reload timer as the external clock.

● Composite timer count clock (CK06) selection circuit

The event counter uses one of the following time-base timer output signals (divided machine clock signal) as the CK06 count clock according to the settings of the SEL[1:0] bits in the EVCR register:

1. $F_{CH}/2^7$ or $F_{CH}/2^9$ or $F_{CH}/2^{11}$ (Main clock mode)
2. Main PLL clock multiplied by a multiple according to the settings of the MPMC[1:0] bits in the PLLC register
3. $F_{CRH}/2^6$, $F_{CRH}/2^8$ or $F_{CRH}/2^{10}$ (Main CR clock mode)
4. Main CR PLL clock multiplied by a multiple according to the settings of the MPMC[1:0] bits in the PLLC register

- Event counter control register (EVCR)

The event counter control register enables or disables the event counter operation mode and selects a composite timer count clock source (CK06).

operation mode for the interval timer operation mode (continuous mode) or PWM timer operation mode (variable-cycle mode).

To select the interval timer operation mode (continuous mode), set the F[3:0] bit for the T10CR0 register to "0b0001." To select the PWM timer operation mode (variable-cycle mode), set this bit to "0b0100."

In addition, set the C[2:0] bit for this register to "0b110" and select the composite timer count clock source (CK06). In order to calculate the frequency of the external clock, allow a timer 00 interrupt if it is in interval timer operation mode (continuous mode), and a timer 01 interrupt if it is in PWM timer operation mode (variable-cycle mode).

When the reload timer underflows, record the underflow times and clear the underflow flag (UF) in the reload timer interrupt service subroutine. In interval timer operation mode (continuous mode), if a timer 10 interrupt occurs in the composite timer, clear the IF bit for the T10CR1 register and set the interval time when it happens the first time. When it happens the second time, clear the IF bit of the T10CR1 register, read the count value for the reload timer, and calculate the external clock frequency in the interrupt service subroutine. In PWM timer operation mode (variable-cycle mode), if a timer 11 interrupt occurs in the composite timer, clear the IF bit for the T11CR1 register, read the reload timer count value, and calculate the external clock frequency in the interrupt service subroutine.

Figure 20.3-2 shows the operations in the event counter operation mode.

Figure 20.3-2 Operations in Event Counter Operation Mode

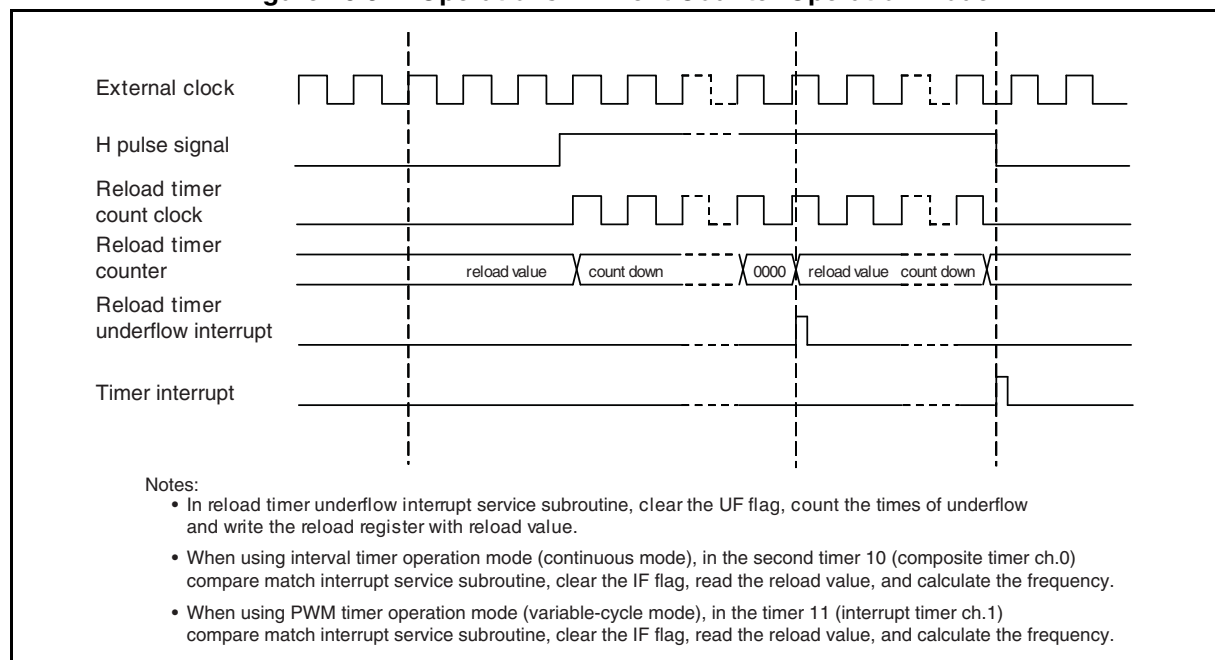

Figure 20.3-3 and Figure 20.3-4 show the equation of calculating the external clock frequency.

**Figure 20.3-3 Equation For Calculating External Clock Frequency
(When Using Interval Timer Operation Mode (Continuous Mode))**

$$\text{Frequency of external clock} = \frac{\text{Count value of reload timer}}{\text{"H" pulse width}}$$

In the above expression:
 (count value of reload timer) = Setting of TMRLRH0/TMRLRL0) × (no. of underflows) + (Setting of TMRLRHn/TMRLRLn) – (read value of TMRHn/TMRLn)

$$\text{"H" pulse width} = \frac{(\text{T10DR setting value} + 1)}{(\text{frequency of composite timer count clock source})}$$

**Figure 20.3-4 Equation For Calculating External Clock Frequency
(When Using PWM Timer Operation Mode (Variable-Cycle Mode))**

$$\text{Frequency of external clock} = \frac{\text{Count value of reload timer}}{\text{"H" pulse width of PWM signal}}$$

In the above expression:
 (count value of reload timer) = Setting of TMRLRH0/TMRLRL0) × (no. of underflows) + (Setting of TMRLRHn/TMRLRLn) – (read value of TMRHn/TMRLn)

$$\text{"H" pulse width of PWM signal} = \frac{(\text{Setting of T11DR} - \text{Setting of T10DR})}{(\text{frequency of composite timer count clock source})}$$

20.4 Setting Procedure Example

This section provides examples of procedures for setting different event counter functions.

When using interval timer operation mode (continuous mode)
(Both the MB95710L/770L Series and MB95710M/770M Series)

■ Initial Settings

1. Select an event counter mode. (EVCR:MD)
2. Select a composite timer count clock source CK06. (EVCR:SEL[1:0])
3. Set the respective interrupt levels of the reload timer and the composite timer. (ILR)
4. Set the reload value of the reload timer. (TMRLRHn/TMRLRLn)
5. Select a count clock for the reload timer. (TMCSRHn:CSL[2:0])
6. Select a reload timer operating mode. (TMCSRHn:MOD[2:0])
7. Select a reload mode. (TMCSRLn:RELD)
8. Enable the underflow interrupt (TMCSRLn:INTE)
9. Enable the counting of the reload timer. (TMCSRLn:CNT)
10. Generate a software trigger. (TMCSRLn:TRG=1)
11. Select a composite timer operating mode. (T10CR0:F[3:0])
12. Select a composite timer count clock. (T10CR0:C[2:0])
13. Set the interval time for the composite timer. (T10DR)*(L width setting)
14. Enable the interrupt of timer 10. (T10CR1:IE)
15. Start the operation of the composite timer. (T10CR1:STA)

■ Interrupt Processing in the Reload Timer

1. Clear the underflow interrupt request flag. (TMCSRLn:UF)
2. Disable the underflow interrupt. (TMCSRLn:INTE)
3. Record the number of underflows.
4. Enable the underflow interrupt. (TMCSRLn:INTE)

■ First Interrupt Process in the Composite Timer (Timer 10)

1. Clear the interrupt request flag. (T10CR1:IF)
2. Disable the interrupt. (T10CR1:IE)
3. Set the interval time for the composite timer. (T10DR)*(H width settings)
4. Enable the interrupt. (T10CR1:IE)

■ Second Interrupt Process in the Composite Timer (Timer 10)

1. Clear the interrupt request flag. (T10CR1:IF)
2. Disable the interrupt. (T10CR1:IE)
3. Read the counter value of the reload timer. (TMRHn, TMRLn)
4. Calculate the external clock frequency.
5. Set the interval time for the composite timer. (T10DR)*(L width settings)
6. Enable the interrupt. (T10CR1:IE)

Note:

In the initial settings, set the interval time to a time that is possible in the interrupt service subroutine processing for the first composite timer interrupt process.

Set the "H" pulse width in the interval time setting for the first composite timer interrupt process.

Set the interval time setting for the second composite timer interrupt process to a time for which the external clock frequency can be calculated in the interrupt service subroutine.

When measuring the frequency consecutively, replace the first composite timer interrupt process with the odd number process and the second composite timer interrupt process with the even number process.

Set the initial bit (T10CR1:SO) value for the timer output to "0". When 1 is set, the "H" pulse duration may be shortened by a maximum of one count clock interval.

When using PWM timer operation mode (variable-cycle mode)
(MB95710M/770M Series only)

■ Initial Settings

1. Select an event counter mode. (EVCR:MD)
2. Select a composite timer count clock source CK06/CK16. (EVCR:SEL[1:0])
3. Set the respective interrupt levels of the reload timer and the composite timer. (ILR)
4. Set the reload value of the reload timer. (TMRLRHn/TMRLRLn)
5. Select a count clock for the reload timer. (TMCSRHn:CSL[2:0])
6. Select a reload timer operating mode. (TMCSRHn:MOD[2:0])
7. Select a reload mode. (TMCSRLn:RELD)
8. Enable the underflow interrupt. (TMCSRLn:INTE)
9. Enable the counting of the reload timer. (TMCSRLn:CNT)
10. Generate a software trigger. (TMCSRLn:TRG = 1)
11. Select a composite timer operating mode. (T10CR0/T11CR0:F[3:0])
12. Select a composite timer count clock. (T10CR0/T11CR0:C[2:0])
13. Set the L width and cycle for the PWM timer. (T10DR/T11DR)
14. Enable the interrupt of timer 11. (T11CR1:IE)
15. Start the operation of the composite timer. (T10CR1/T11CR1:STA)

■ Interrupt Processing in Reload Timer

1. Clear the underflow interrupt request flag. (TMCSRLn:UF)
2. Disable the underflow interrupt. (TMCSRLn:INTE)
3. Record the number of underflows.
4. Enable the underflow interrupt. (TMCSRLn:INTE)

■ Interrupt Processing in Composite Timer (Timer 11)

1. Clear the interrupt request flag. (T11CR1:IF)
2. Disable the interrupt. (T11CR1:IE)
3. Read the counter value of the reload timer. (TMRHn, TMRLn)
4. Calculate the external clock frequency.
5. Enable the interrupt. (T11CR1:IE)

20.5 Frequency Measurement Range and Frequency Measurement Precision

This section describes the frequency measurement range and frequency measurement precision of the event counter.

■ Frequency Measurement Range

The maximum measurable frequency is determined by the peripheral function clock. When the frequency of the peripheral function clock is F_{PCLK} , the maximum measurable frequency is $F_{PCLK}/4$.

The minimum measurable frequency is determined by the measurement period to ensure the frequency measurement precision.

■ Frequency Measurement Precision

The frequency measurement precision is determined by the main clock frequency and the precision of the reload timer counter. The more the reload timer counter counts, the more precise the frequency to be calculated becomes.

20.6 Register

This section describes the register of the event counter.

Table 20.6-1 List of Event Counter Register

Register abbreviation	Register name	Reference
EVCR	Event counter control register	20.6.1

20.6.1 Event Counter Control Register (EVCR)

The event counter control register (EVCR) enables or disables the event counter operation mode, and selects a count clock from the CK06 clock sources of the composite timer.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	—	—	SEL1	SEL0	MD
Attribute	—	—	—	—	—	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:3] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation,

[bit2:1] SEL[1:0]: Composite timer count clock (CK06) select bits

These bits select a composite timer count clock (CK06).

The count clock is generated by the prescaler. See "3.9 Operation of Prescaler".

When both the operation of the composite timer and the counting operation of the reload timer have been enabled (T10CR1/T11CR1:STA = 1, TMCSSLn:CNT=1), the write access to the SEL[1:0] bits is prohibited.

The settings of the SEL[1:0] bits are effective even when the MD bit in the EVCR register is set to "0".

The count clock supplied from the time-base timer is used as the count clock for the composite timer. Depending on the settings of the SYCC register, the count clock from the time-base timer is generated from either main clock or main CR clock. When the count clock from the time-base timer is used as the count clock for the composite timer, resetting the time-base timer by writing "1" to the time-base timer clear bit in the time-base timer control register (TBTC:TCLR) affects the count time.

bit2:1	Details (F _{CH} : main clock, F _{CRH} : main CR clock)
Writing "00"	F _{CH} /2 ⁷ or F _{CRH} /2 ^{6*}
Writing "01"	F _{CH} /2 ⁹ or F _{CRH} /2 ^{8*}
Writing "10"	F _{CH} /2 ¹¹ or F _{CRH} /2 ^{10*}
Writing "11"	F _{CH} /2 ⁷ or F _{CRH} /2 ^{6*}

*: The clock to be used as the composite timer count clock is determined by the settings of the SYCC register. In the case of using the main clock or the main PLL clock as the composite timer count clock, the settings of PLLC:MPMC[1:0] determine whether the main clock divided by two (F_{CH}/2) or the main PLL clock is to be used as the composite timer count clock.

[bit0] MD: Event counter operation mode select bit

This bit enables or disables the event counter operation mode.

Writing "0" to this bit disables the event counter operation mode. When the event counter operation mode is disabled, the composite timer and the reload timer operate independently.

Writing "1" to this bit enables the event counter operation mode. When the event counter operation mode is enabled, the composite timer and the reload timer operate together to perform the event counter function.

When both the operation of the composite timer (T10CR1/T11CR1:STA = 1) and the counting operation of the reload timer are enabled (TMCSRLn:CNTEN = 1), the write access to the MD bit is prohibited.

bit0	Details
Writing "0"	Disables the event counter operation mode.
Writing "1"	Enables the event counter operation mode.

20.7 Notes on Using Event Counter

This section provides notes on using the event counter.

- Before switching the event counter operation mode by using the MD bit in the EVCR register, do the following operations:
 - (1) Stop the composite timer (T10CR1/T11CR1:STA = 0) and the reload timer (TMCSRLn:CNT = 0).
 - (2) Clear the interrupt flag bits in the composite timer (T10CR1/T11CR1:IF, IR) and the reload timer (TMCSRLn:UF), and the interrupt request enable bits in the composite timer (T10CR0/T11CR0:IFE, T10CR1/T11CR1:IE) and the reload timer (TMCSRLn:UF).
- Set the output time for the L level of the composite timer to a width at which the external clock frequency can be calculated in the interrupt service subroutine.
- In the MB95710L/770L Series, do not select the PWM timer operation mode (variable-cycle mode) as the "H" pulse output function of the event counter.
- If you select the interval timer mode (continuous mode) for the "H" pulse output function, set the initial bit value (T10CR1:SO) for the timer output to "0". If 1 is set, the "H" pulse duration may be shortened by a maximum of one count clock interval.

CHAPTER 21

UART/SIO

This chapter describes the functions and operations of UART/SIO.

- 21.1 Overview
- 21.2 Configuration
- 21.3 Channel
- 21.4 Pins
- 21.5 Interrupts
- 21.6 Operations and Setting Procedure Example
- 21.7 Registers

21.1 Overview

The UART/SIO is a general-purpose serial data communication interface. Serial data transfers of variable-length data can be made with a synchronous or asynchronous clock. The transfer format is NRZ. The transfer rate can be set with the dedicated baud rate generator or external clock (in clock synchronous mode).

■ Functions of UART/SIO

The UART/SIO is capable of serial data transmission/reception (serial input/output) to and from another CPU or peripheral device.

- Equipped with a full-duplex double buffer that allows 2-way full-duplex communication.
- The synchronous or asynchronous transfer mode can be selected.
- The optimum baud rate can be selected with the dedicated baud rate generator.
- The data length is variable; it can be set to 5 bit to 8 bit when no parity is used or to 6 bit to 9 bit when parity is used. (See Table 21.1-1.)
- The serial data direction (endian) can be selected.
- The data transfer format is NRZ (Non-Return-to-Zero).
- Two operation modes (operation modes 0 and 1) are available.
Operation mode 0 operates as asynchronous clock mode (UART).
Operation mode 1 operates as clock synchronous mode (SIO).

Table 21.1-1 UART/SIO Operation Modes

Operation mode	Data length		Synchronization mode	Length of stop bit
	No parity	With parity		
0	5	6	Asynchronous	1 bit or 2 bits
	6	7		
	7	8		
	8	9		
1	5	-	Synchronous	-
	6	-		
	7	-		
	8	-		

21.2 Configuration

The UART/SIO consists of the following blocks:

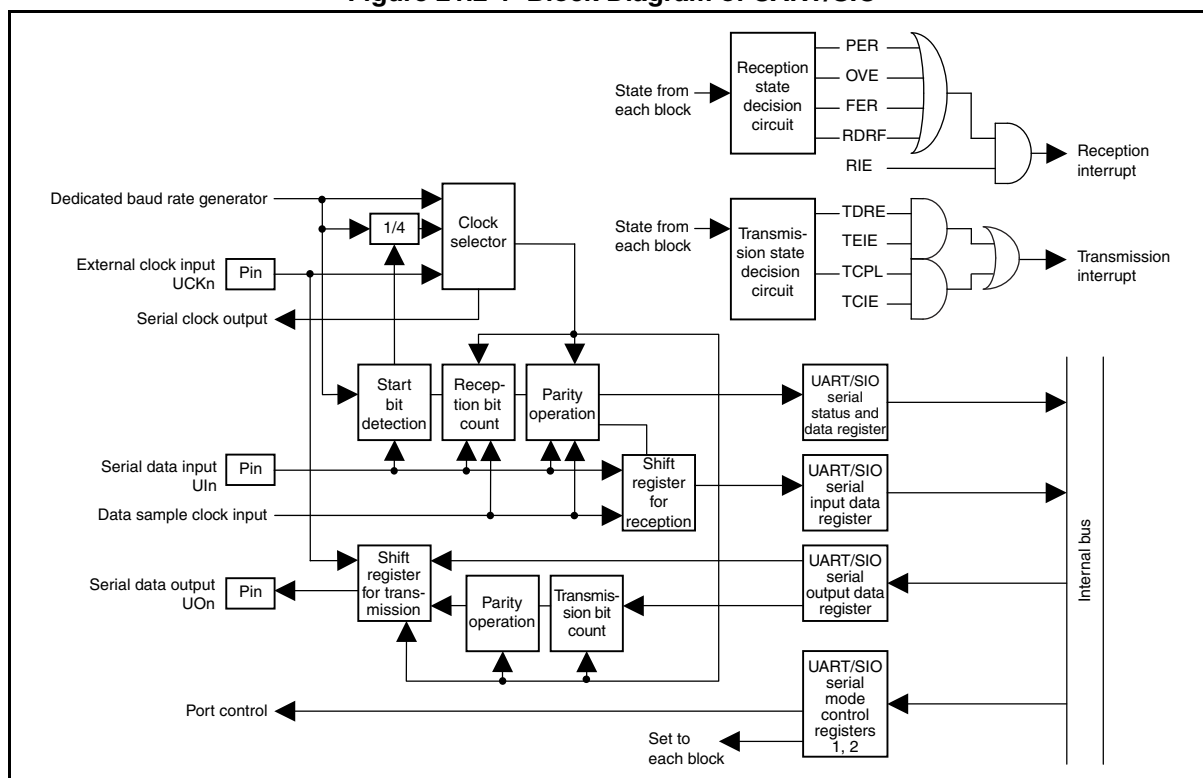

- UART/SIO serial mode control register 1 ch. n (SMC1n)
- UART/SIO serial mode control register 2 ch. n (SMC2n)
- UART/SIO serial status and data register ch. n (SSRn)
- UART/SIO serial input data register ch. n (RDRn)
- UART/SIO serial output data register ch. n (TDRn)

The number of pins and that of channels of the UART/SIO vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of UART/SIO

Figure 21.2-1 Block Diagram of UART/SIO

- UART/SIO serial mode control register 1 ch. n (SMC1n)

This register controls UART/SIO operation mode. It is used to set the serial data direction (endian), parity and its polarity, stop bit length, operation mode (synchronous/asynchronous), data length, and serial clock.

- UART/SIO serial mode control register 2 ch. n (SMC2n)

This register controls UART/SIO operation mode. It is used to enable/disable serial clock output, serial data output, transmission/reception, and interrupts and to clear the receive error flag.

- UART/SIO serial status and data register ch. n (SSRn)

This register indicates the transmission/reception status and error status of UART/SIO.

- UART/SIO serial input data register ch. n (RDRn)

This register holds the receive data. The serial input is converted and then stored in this register.

- UART/SIO serial output data register ch. n (TDRn)

This register sets the transmit data. Data written to this register is serial-converted and then output.

■ Input Clock

The UART/SIO uses the output clock (internal clock) from the dedicated baud rate generator or the input signal (external clock) from the UCKn pin as its input clock (serial clock).

21.3 Channel

This section describes the channel of UART/SIO.

■ Channel of UART/SIO

Table 21.3-1 and Table 21.3-2 show the pins and registers of UART/SIO respectively.

Table 21.3-1 Pins of UART/SIO

Pin name	Pin function
UCKn	Clock input/output
UOn	Data output
UIn	Data input

Table 21.3-2 Registers of UART/SIO

Register abbreviation	Corresponding register (Name in this manual)
SMC1n	UART/SIO serial mode control register 1 ch. n
SMC2n	UART/SIO serial mode control register 2 ch. n
SSRn	UART/SIO serial status and data register ch. n
TDRn	UART/SIO serial output data register ch. n
RDRn	UART/SIO serial input data register ch. n

21.4 Pins

This section describes the pins of the UART/SIO.

■ Pins of UART/SIO

The pins of UART/SIO are the clock input and output pin (UCKn), serial data output pin (UOn) and serial data input pin (UIn).

● UCKn

Clock input/output pin for UART/SIO.

When the clock output is enabled (SMC2n:SCKE=1), it serves as a UART/SIO clock output pin (UCKn) regardless of the value of the corresponding port direction register. At this time, do not select the external clock (set SMC1n:CKS = 0).

When it is to be used as a UART/SIO clock input pin, disable the clock output (SMC2n:SCKE = 0) and make sure that it is set as input port by the corresponding port direction register. At this time, be sure to select the external clock (set SMC1n:CKS = 0).

● UOn

Serial data output pin for UART/SIO. When the serial data output is enabled (SMC2n:TXOE = 1), it serves as a UART/SIO serial data output pin (UOn) regardless of the value of the corresponding port direction register.

● UIn

Serial data input pin for UART/SIO. When it is to be used as a UART/SIO serial data input pin, make sure that it is set as input port by the corresponding port direction register.

21.5 Interrupts

The UART/SIO has six interrupt-related bits: receive error flag bits (PER, OVE, FER), receive data register full flag bit (RDRF), transmit data register empty flag bit (TDRE), and transmission completion flag bit (TCPL).

■ Interrupts of UART/SIO

Table 21.5-1 lists the UART/SIO interrupt control bits and interrupt sources.

Table 21.5-1 UART/SIO Interrupt Control Bits and Interrupt Sources

Item	Description					
Interrupt request flag bit	SSRn:TDRE	SSRn:TCPL	SSRn:RDRF	SSRn:PER	SSRn:OVE	SSRn:FER
Interrupt request enable bit	SMC2n:TEIE	SMC2n:TCIE	SMC2n:RIE	SMC2n:RIE	SMC2n:RIE	SMC2n:RIE
Interrupt source	Transmit data register empty	Transmission completion	Receive data full	Parity error	Overrun error	Framing error

■ Transmit Interrupt

When transmit data is written to the UART/SIO serial output data register ch. n (TDRn), the data is transferred to the transmission shift register. When the next piece of data can be written, the TDRE bit is set to "1". At this time, an interrupt request to the interrupt controller occurs when transmit data register empty interrupt enable bit has been enabled (SMC2n:TEIE = 1).

The TCPL bit is set to "1" upon completion of transmission of all pieces of transmit data. At this time, an interrupt request to the interrupt controller occurs when transmission completion interrupt enable bit has been enabled (SMC2n:TCIE = 1).

■ Receive Interrupt

If the data is input successfully up to the stop bit, the RDRF bit is set to "1". If an overrun error, a parity error, or a framing error occurs, the corresponding error flag bit (PER, OVE, or FER) is set to "1".

These bits are set when a stop bit is detected. If receive interrupt enable bit has been enabled (SMC2n:RIE = 1), an interrupt request to the interrupt controller will be generated.

21.6 Operations and Setting Procedure Example

The UART/SIO has a serial communication function (operation mode 0, 1).

■ Operations of UART/SIO

● Operation mode

Two operation modes are available in the UART/SIO. Clock synchronous mode (SIO) or clock asynchronous mode (UART) can be selected (See Table 21.6-1).

Table 21.6-1 Operation Modes of UART/SIO

Operation mode	Data length		Synchronization mode	Length of stop bit
	No parity	With parity		
0	5	6	Asynchronous	1 bit or 2 bits
	6	7		
	7	8		
	8	9		
1	5	-	Synchronous	-
	6	-		
	7	-		
	8	-		

■ Setting Procedure Example

Below is an example of procedure for setting the UART/SIO.

● Initial setup

1. Set the port input. (DDR)
2. Set the interrupt level. (ILR*)
3. Set the prescaler. (PSSRn)
4. Set the baud rate. (BRSRn)
5. Select the clock. (SMC1n:CKS)
6. Set the operation mode. (SMC1n:MD)
7. Enable/disable the serial clock output. (SMC2n:SCKE)
8. Enable reception. (SMC2n:RXE = 1)
9. Enable interrupts. (SMC2n:RIE = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

● Interrupt processing

Read receive data. (RDRn)

21.6.1 Operations in Operation Mode 0

Operation mode 0 operates as clock asynchronous mode (UART).

■ Operations in UART/SIO Operation Mode 0

Clock asynchronous mode (UART) is selected when the MD bit in the UART/SIO serial mode control register 1 ch. n (SMC1n) is set to "0".

● Baud rate

The serial clock is selected by the CKS bit in the SMC1n register. Be sure to select the dedicated baud rate generator at this time.

The baud rate is equivalent to the output clock frequency of the dedicated baud rate generator, divided by four. The UART can perform communication within the range from -3% to +3% of the selected baud rate.

The baud rate generated by the dedicated baud rate generator is obtained from the equation illustrated below. (For information about the dedicated baud rate generator, see "CHAPTER 22 UART/SIO DEDICATED BAUD RATE GENERATOR".)

Figure 21.6-1 Baud Rate Calculation when Using Dedicated Baud Rate Generator

$$\text{Baud rate value} = \frac{\text{Machine clock (MCLK)}}{4 \times \begin{matrix} 1 \\ 2 \\ 4 \\ 8 \end{matrix} \times \begin{matrix} 2 \\ : \\ 255 \end{matrix}} \quad [\text{bps}]$$

Table 21.6-2 Sample Asynchronous Transfer Rates Based on Dedicated Baud Rate Generator (Machine clock = 10 MHz, 16 MHz, 16.25 MHz)

Dedicated baud rate generator setting		Internal UART division	Total division ratio (PSS × BRS × 4)	Baud rate (10 MHz / Total division ratio)	Baud rate (16 MHz / Total division ratio)	Baud rate (16.25 MHz / Total division ratio)
Prescaler select PSS[1:0]	Baud rate counter setting BRS[7:0]					
1 (Setting value: 0,0)	20	4	80	125000	200000	203125
1 (Setting value: 0,0)	22	4	88	113636	181818	184659
1 (Setting value: 0,0)	44	4	176	56818	90909	92330
1 (Setting value: 0,0)	87	4	348	28736	45977	46695
1 (Setting value: 0,0)	130	4	520	19231	30769	31250
2 (Setting value: 0,1)	130	4	1040	9615	15385	15625
4 (Setting value: 1,0)	130	4	2080	4808	7692	7813
8 (Setting value: 1,1)	130	4	4160	2404	3846	3906

The baud rate in clock asynchronous mode (UART) can be set in the following range.

Table 21.6-3 Baud Rate Setting Range in Clock Asynchronous Mode (UART)

PSS[1:0]	BRS[7:0]
0b00 to 0b11	0x02 (2) to 0xFF (255)

● Transfer data format

UART can treat data only in NRZ (Non-Return-to-Zero) format. Figure 21.6-2 shows the data format.

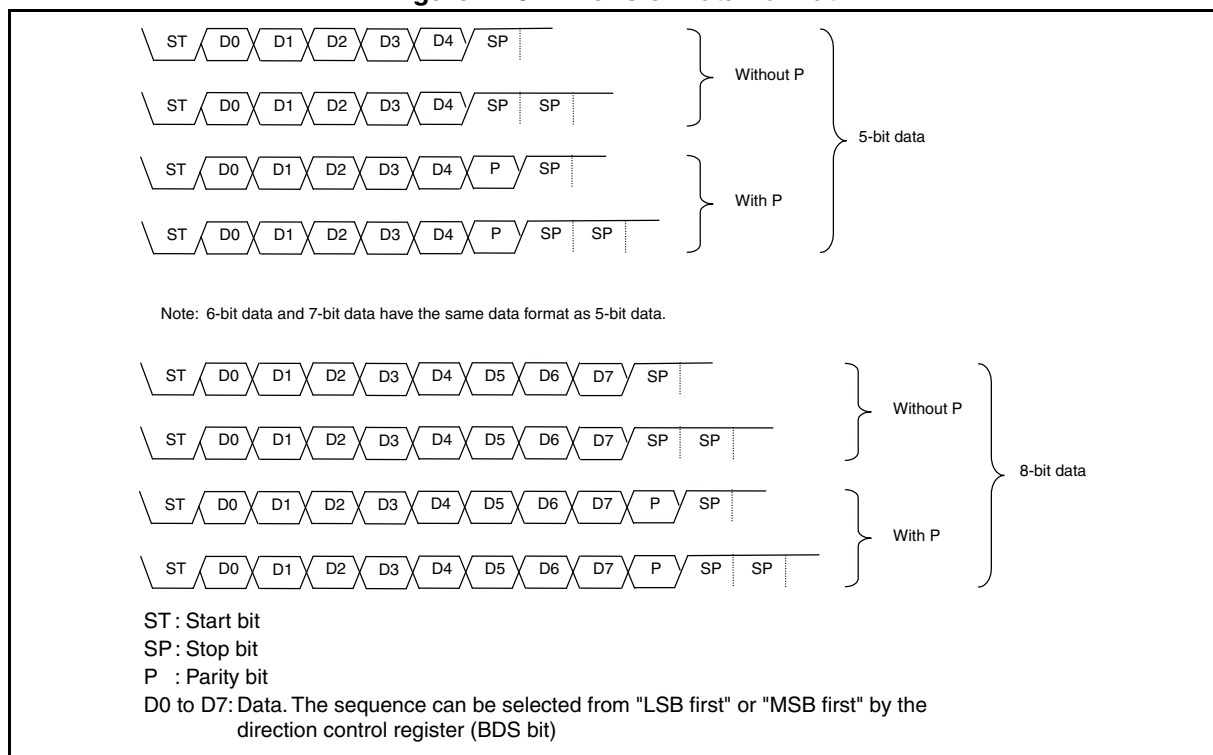

The character bit length can be selected from among 5 to 8 bits depending on the settings of SMC1n:CBL[1:0].

The stop bit length can be set to 1 or 2 bits depending on the setting of SMC1n:SBL.

The PEN bit and TDP bit in the SMC1n register can be used to enable/disable parity and to select parity polarity.

As shown in Figure 21.6-2, the transfer data always starts from the start bit ("L" level) and ends with the stop bit ("H" level) by performing the specified data bit length transfer with MSB first or LSB first ("LSB first" or "MSB first" can be selected by the BDS bit in the SMC1n register). It becomes "H" level at the idle state.

Figure 21.6-2 Transfer Data Format

● Reception in asynchronous clock mode (UART)

Use UART/SIO serial mode control register 1 ch. n (SMC1n) to select the serial data direction (endian), parity/non-parity, parity polarity, stop bit length, character bit length, and clock.

Reception remains performed as long as the reception operation enable bit (SMC2n:RXE) contains "1".

Upon detection of a start bit in receive data with the RXE bit set to "1", one frame of data is received according to the data format set in UART/SIO serial control register 1 ch. n (SMC1n).

When the reception of one frame of data has been completed, the received data is transferred to the UART/SIO serial input data register ch. n (RDRn) and the next frame of serial data can be received.

When the RDRn register stores data, the receive data register full flag bit (SSRn:RDRF) is set to "1".

A receive interrupt occurs the moment the RDRF bit is set to "1" when the receive interrupt enable bit (SMC2n:RIE) contains "1".

Received data is read from the RDRn register after each error flag (PER, OVE, FER) in the UART/SIO serial status and data register ch. n (SSRn) is checked.

When received data is read from the RDRn register, the RDRF bit is cleared to "0".

Note that modifying the SMC1n register during reception may result in unpredictable operation. If the RXE bit is set to "0" during reception, the reception is immediately disabled and initialization will be performed. The data received up to that point will not be transferred to the serial input data register.

Figure 21.6-3 Receive Operation in Asynchronous Clock Mode

● Receive error in asynchronous clock mode (UART)

If any of the following three error flags (PER, FER, OVE) has been set, receive data is not transferred to the UART/SIO serial input data register ch. n (RDRn) and the receive data register full flag bit (RDRF) is not set to "1" either.

- Parity error (PER)

The parity error bit (PER) is set to "1" if the parity bit in received serial data does not match the parity polarity bit (TDP) when the parity control bit (PEN) contains "1".

- Framing error (FER)

The framing error bit (FER) is set to "1" if "1" is not detected at the position of the first stop bit in serial data received in the set character bit length (CBL) under parity control (PEN).

Note that the stop bit is not checked if it appears at the second bit or later.

- Overrun error (OVE)

Upon completion of reception of serial data, the overrun error bit (OVE) is set to "1" if the reception of the next data is performed before the previous receive data is read.

Each flag is set at the position of the first stop bit.

Figure 21.6-4 Setting Timing for Receive Errors

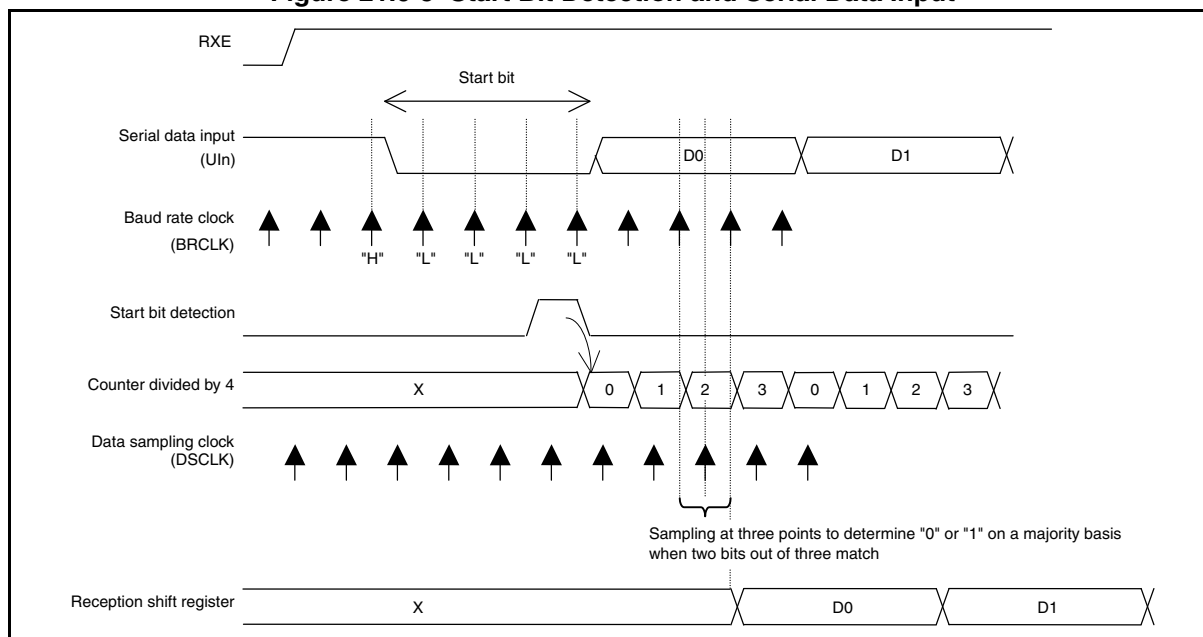

● Start bit detection and confirmation of receive data during reception

The start bit is detected by a falling of the serial input followed by a succession of three "L" levels after the serial data input is sampled according to the clock (BRCLK) signal provided by the dedicated baud rate generator with the reception operation enable bit (RXE) set to "1". When the first "H", "L", "L", "L" train is detected in a BRCLK sample, therefore, the current bit is regarded as the start bit.

The frequency-quartered circuit is activated upon detection of the start bit and serial data is input to the reception shift register at intervals of four periods of BRCLK.

When data is received, sampling is performed at three points of the baud rate clock (BRCLK) and data sampling clock (DSCLK) and received data is confirmed on a majority basis when two bits out of three match.

Figure 21.6-5 Start Bit Detection and Serial Data Input

● Transmission in asynchronous clock mode

Use UART/SIO serial mode control register 1 ch. n (SMC1n) to select the serial data direction (endian), parity/non-parity, parity polarity, stop bit length, character bit length, and clock.

Either of the following two procedures can be used to initiate the transmission process:

- Set the transmission operation enable bit (TXE) to "1", and then write transmit data to the UART/SIO serial output data register ch. n (TDRn) to start transmission.
- Write transmit data to the UART/SIO serial output data register ch. n (TDRn), and then set the transmission operation enable bit (TXE) to "1" to start transmission.

Transmit data is written to the TDRn register after it is checked that the transmit data register empty flag bit (TDRE) set to "1".

When the transmit data is written to the TDRn register, the TDRE bit is cleared to "0".

The transmit data is transferred from the TDRn register to the transmission shift register, and the TDRE bit is set to "1".

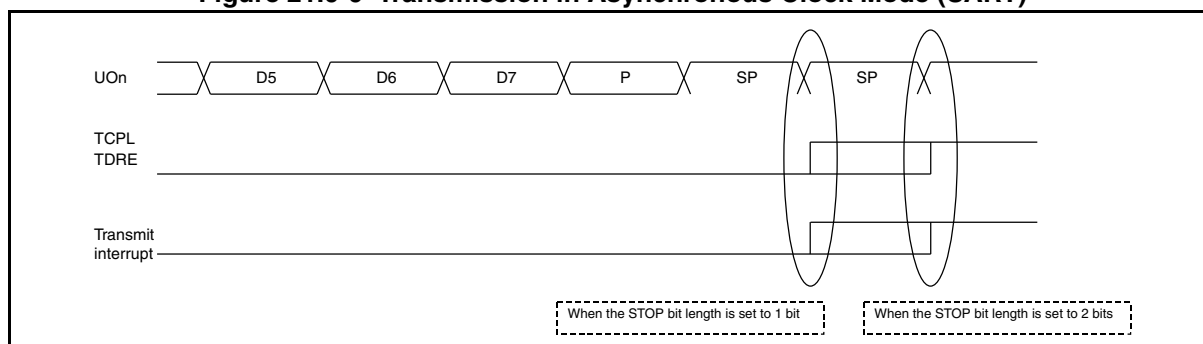

When the transmit interrupt enable bit (TIE) contains "1", a transmit interrupt occurs if the TDRE bit is set to "1". This allows the next piece of transmit data to be written to the TDRn register by interrupt handling.

To detect the completion of serial transmission by transmit interrupt, set the transmission completion interrupt enable bits as follows: TEIE = 0, TCIE = 1. Upon completion of transmission, the transmission completion flag bit (SSRn:TCPL) is set to "1" and a transmit interrupt occurs.

The TCPL bit, and the TDRE bit in consecutive data transmission are set at the position which the transmission of the last bit was completed (it varies depending on the data length, parity enable, or stop bit length setting), as shown in Figure 21.6-6.

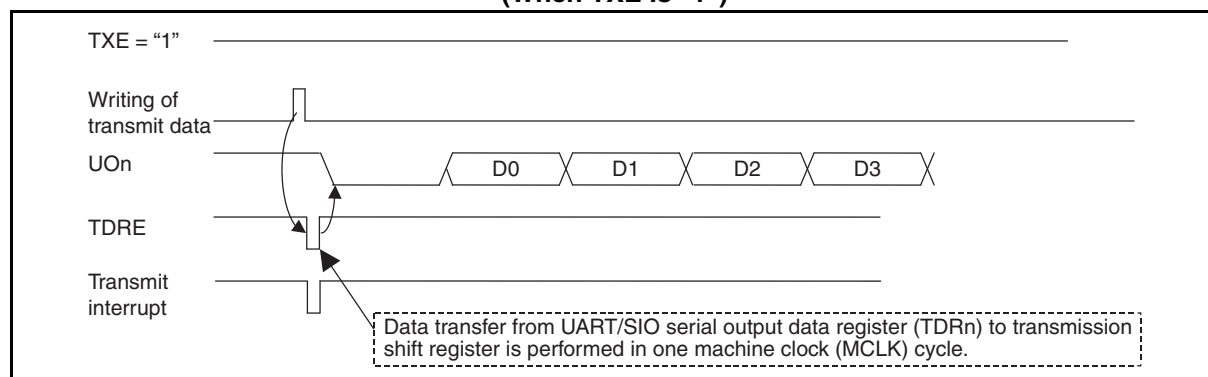

Note that modifying UART/SIO serial mode control register 1 ch. n (SMC1n) during transmission may result in unpredictable operation.

Figure 21.6-6 Transmission in Asynchronous Clock Mode (UART)

The TDRE bit is set at the point indicated in Figure 21.6-7 or Figure 21.6-8 if the preceding piece of transmit data does not exist in the transmission shift register.

**Figure 21.6-7 Setting Timing 1 for Transmit Data Register Empty Flag Bit (TDRE)
(When TXE Is "1")**

**Figure 21.6-8 Setting Timing 2 for Transmit Data Register Empty Flag Bit (TDRE)
(When TXE Is Switched from "0" to "1")**

● Concurrent transmission and reception

In asynchronous clock mode (UART), transmission and reception can be performed independently. Therefore, transmission and reception can be performed at the same time or even with transmitting and receiving frames overlapping each other in shifted phases.

21.6.2 Operations in Operation Mode 1

Operation mode 1 operates in clock synchronous mode (SIO).

■ Operations in UART/SIO Operation Mode 1

Setting the MD bit in the UART/SIO serial mode control register 1 ch. n (SMC1n) to "1" selects synchronous clock mode (SIO).

The character bit length in synchronous clock mode (SIO) is variable between 5 bits and 8 bits.

Note, however, that parity is disabled and no stop bit is used.

The serial clock is selected by the CKS bit in the SMC1n register. Select the dedicated baud rate generator or external clock. The SIO performs shift operation using the selected serial clock as a shift clock.

To input the external clock signal, set the SCKE bit to "0".

To output the dedicated baud rate generator output as a shift clock signal, set the SCKE bit to "1". The serial clock signal is obtained by dividing clock by two, which is supplied by the dedicated baud rate generator. The baud rate in the SIO mode can be set in the following range. (For more information about the dedicated baud rate generator, also see "CHAPTER 22 UART/SIO DEDICATED BAUD RATE GENERATOR".)

Table 21.6-4 Baud Rate Setting Range in Clock Synchronous Mode (SIO)

PSS[1:0]	BRS[7:0]
0b00 to 0b11	0x01(1) to 0xFF(255), 0x00(256) (The highest and lowest baud rate settings are 0x01 and 0x00, respectively.)

The baud rate applied when the external clock or dedicated baud rate generator is used is obtained from the corresponding equation illustrated below.

Figure 21.6-9 Calculating Baud Rate Based on External Clock

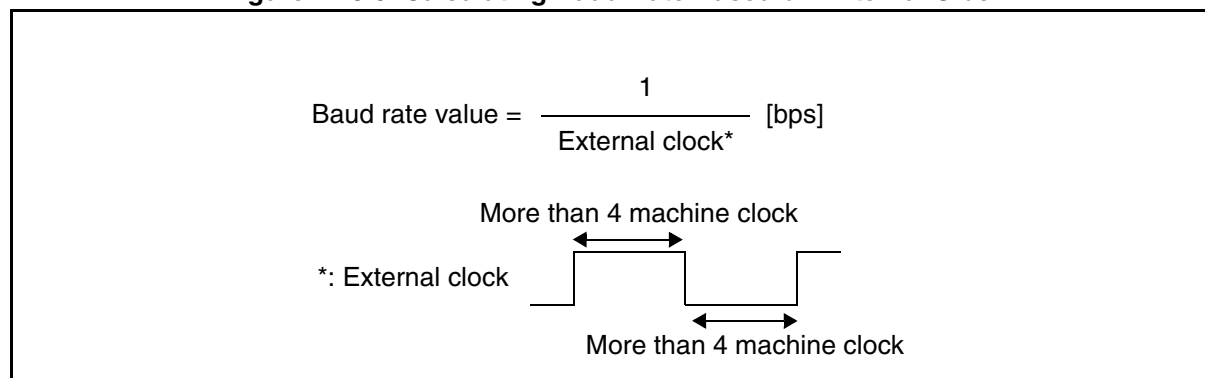

Figure 21.6-10 Baud Rate Calculation Formula for Using Dedicated Baud Rate Generator

$$\text{Baud rate value} = \frac{\text{Machine clock (MCLK)}}{2 \times \begin{matrix} 1 \\ 2 \\ 4 \\ 8 \end{matrix} \times \begin{matrix} 1 \\ : \\ 256 \end{matrix}} \quad [\text{bps}]$$

UART prescaler select register ch. n (PSSRn)
Prescaler select (PSS[1:0])

UART baud rate setting register ch. n (BRSRn)
Baud rate setting (BRS[7:0])

● Serial clock

The serial clock signal is output under control of the output for transmit data. When only reception is performed, therefore, set transmission control (TXE = 1) to write dummy transmit data to the UART/SIO serial output register. Refer to the device data sheet for the UCKn clock value.

● Reception in UART/SIO operation mode 1

For reception in operation mode 1, each register is used as shown below.

Figure 21.6-11 Registers Used for Reception in Operation Mode 1

SMC1n (UART/SIO serial mode control register 1)

⊙	⊙	⊙	⊙	⊙	⊙	⊙	⊙

⊙ : Used bit
 x : Unused bit
 1 : Set to "1"
 0 : Set to "0"

The reception depends on whether the serial clock has been set to external or internal clock.

<When external clock is enabled>

When the reception operation enable bit (RXE) contains "1", serial data is received always at the rising edge of the external clock signal.

<When internal clock is enabled>

The serial clock signal is output in accordance with transmission. Therefore, transmission must be performed even when only performing reception. The following two procedures can be used.

- Set the transmission operation enable bit (TXE) to "1", then write transmit data to the UART/SIO serial output data register to generate the serial clock signal and start reception.
- Write transmit data to the TDRn register, then set the TXE bit to "1" to generate the serial clock signal and start reception.

When 5-bit to 8-bit serial data is received by the reception shift register, the received data is transferred to the UART/SIO serial input data register ch. n (RDRn) and the next piece of serial data can be received.

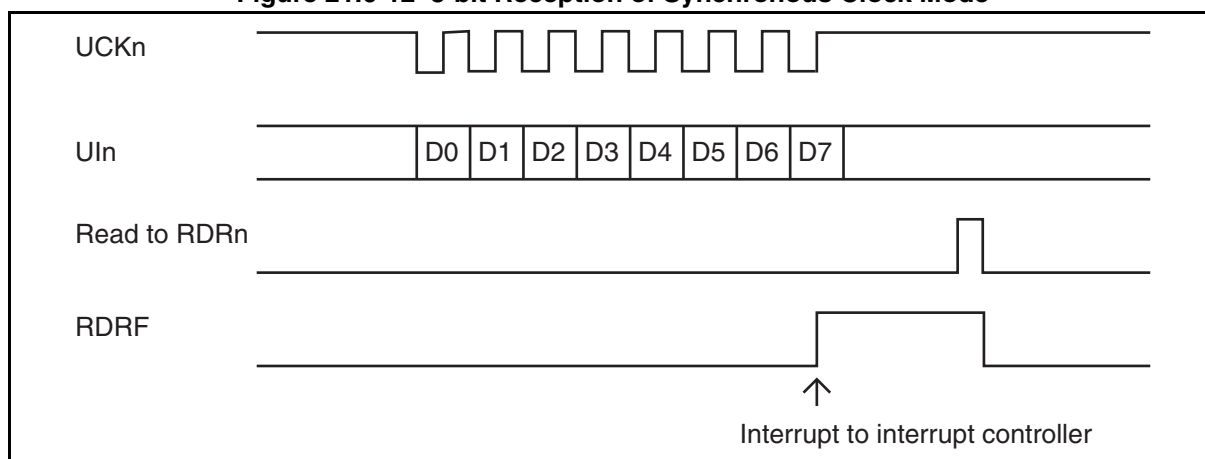

When the RDRn register stores data, the receive data register full flag bit (RDRF) is set to "1".

A receive interrupt occurs the moment the RDRF bit is set to "1" when the receive interrupt enable bit (RIE) contains "1".

To read received data, read it from the RDRn register after checking the overrun error flag bit (OVE) in the UART/SIO serial status and data register ch. n (SSRn).

When received data is read from the RDRn register, the RDRF bit is cleared to "0".

Figure 21.6-12 8-bit Reception of Synchronous Clock Mode

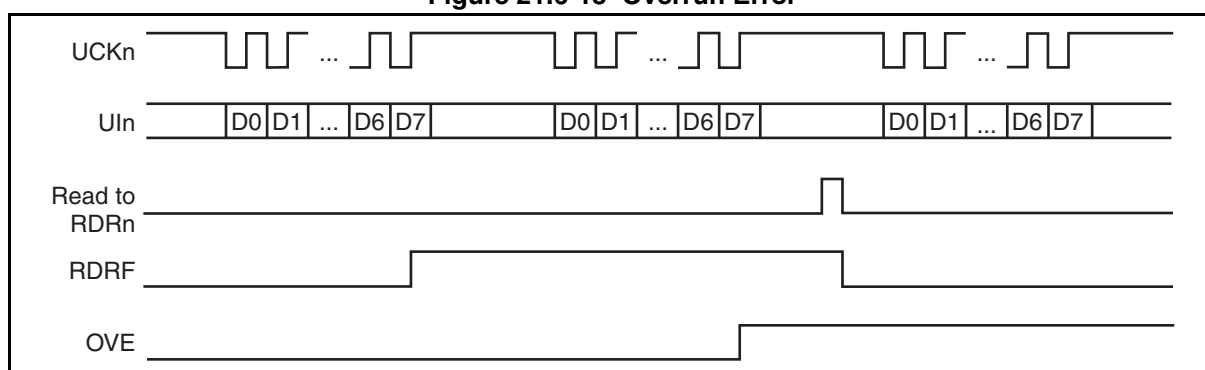

Operation when receive error occurs

When an overrun error (OVE = 1) occurs, received data is not transferred to the RDRn register.

Overrun error (OVE = 1)

Upon completion of reception for serial data, the OVE bit is set to "1" if the RDRF bit has been set to "1" by the reception for the preceding piece of data.

Figure 21.6-13 Overrun Error

● Transmission in UART/SIO operation mode 1

For transmission in operation mode 1, each register is used as shown below.

Figure 21.6-14 Registers Used for Transmission in Operation Mode 1

x	x	x	x	x	x	x	x

⊙ : Used bit
 x : Unused bit
 1 : Set to "1"
 0 : Set to "0"

The following two procedures can be used to initiate the transmission process:

- Set the transmission operation enable bit (TXE) to "1", then write transmit data to the TDRn register to start transmission.
- Write transmit data to the TDRn register, then set the TXE bit to "1" to start transmission.

Transmit data is written to the TDRn register after it is checked that the transmit data register empty flag bit (TDRE) is set to "1".

When the transmit data is written to the TDRn register, the TDRE bit is cleared to "0".

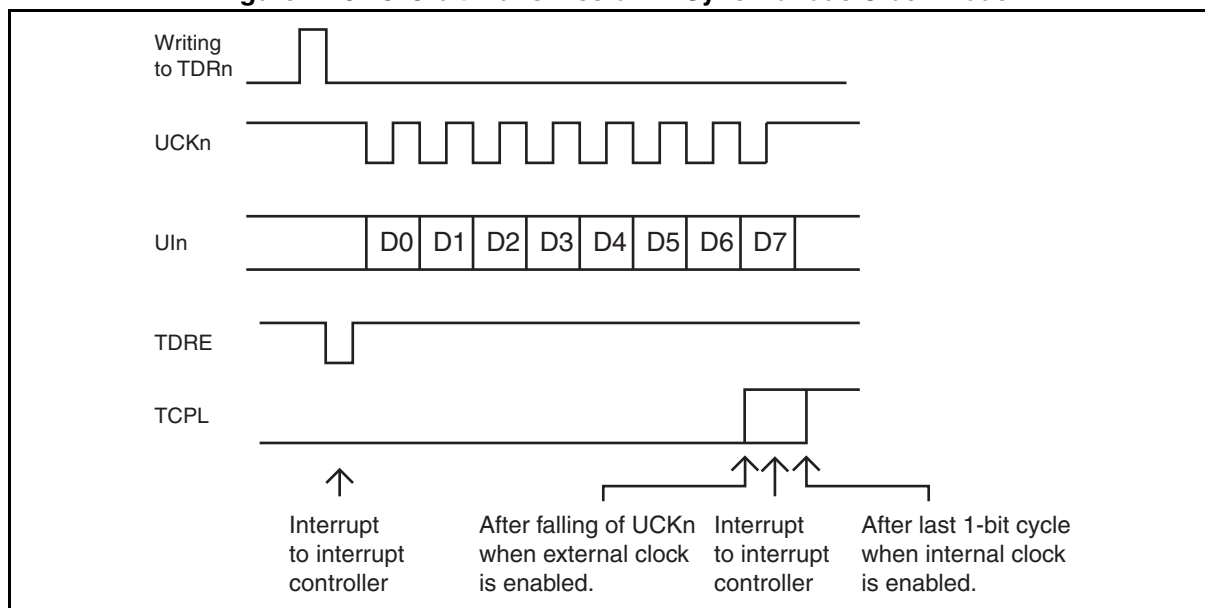

When serial transmission is started after transmit data is transferred from the TDRn register to the transmission shift register, the TDRE bit is set to "1".

When the use of the external clock signal has been set, serial data transmission starts at the fall of the first serial clock signal after the transmission process is started.

A transmission completion interrupt occurs the moment the TDRE bit is set to "1" when the transmit interrupt enable bit (TIE) contains "1". At this time, the next piece of transmit data can be written to the TDRn register. Serial transmission can be continued with the TXE bit set to "1".

To use a transmission completion interrupt to detect the completion of serial transmission, enable transmission completion interrupt output this way: TEIE = 0, TCIE = 1. Upon completion of transmission, the transmission completion flag bit (SSRn:TCPL) is set to "1" and a transmission completion interrupt occurs.

Figure 21.6-15 8-bit Transmission in Synchronous Clock Mode

● Concurrent transmission and reception

<When external clock is enabled>

Transmission and reception can be performed independently of each other. Transmission and reception can therefore be performed at the same time or even when their phases are shifted from each other and overlapping.

<When internal clock is enabled>

As the transmitting side generates a serial clock, reception is influenced.

If transmission stops during reception, the receiving side is suspended. It resumes reception when the transmitting side is restarted.

See "21.4 Pins" for operation with serial clock output and operation with serial clock input.

21.7 Registers

This section describes the registers of the UART/SIO.

Table 21.7-1 List of UART/SIO Registers

Register abbreviation	Register name	Reference
SMC1n	UART/SIO serial mode control register 1 ch. n	21.7.1
SMC2n	UART/SIO serial mode control register 2 ch. n	21.7.2
SSRn	UART/SIO serial status and data register ch. n	21.7.3
RDRn	UART/SIO serial input data register ch. n	21.7.4
TDRn	UART/SIO serial output data register ch. n	21.7.5

21.7.1 UART/SIO Serial Mode Control Register 1 ch. n (SMC1n)

The UART/SIO serial mode control register 1 ch. n (SMC1n) controls the UART/SIO operation mode. The register is used to set the serial data direction (endian), parity and its polarity, stop bit length, operation mode (synchronous/asynchronous), data length, and serial clock.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BDS	PEN	TDP	SBL	CBL1	CBL0	CKS	MD
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] BDS: Serial data direction control bit

This bit controls the serial data direction (endian).

bit7	Details
Writing "0"	Transmission or reception starts from the LSB in the UART/SIO serial input/output data register ch. n (RDRn/TDRn).
Writing "1"	Transmission or reception starts from the MSB in the UART/SIO serial input/output data register ch. n (RDRn/TDRn).

[bit6] PEN: Parity control bit

This bit enables or disables the parity in clock asynchronous mode (UART).

bit6	Details
Writing "0"	Disables the parity.
Writing "1"	Enables the parity.

[bit5] TDP: Parity polarity control bit

This bit controls the even/odd parity.

bit5	Details
Writing "0"	Selects the even parity.
Writing "1"	Selects the odd parity.

[bit4] SBL: Stop bit length control bit

This bit controls the stop bit length in clock asynchronous mode (UART).

bit4	Details
Writing "0"	1 bit
Writing "1"	2 bits

Note: The setting of this bit is only valid for transmission operation in clock asynchronous mode (UART). In a receive operation, regardless of the setting of this bit, the UART/SIO completes the receive operation when detecting a stop bit (one bit), and sets the receive data register full flag bit (SSRn:RDRF) to "1".

[bit3:2] CBL[1:0]: Character bit length control bits

These bits select the character bit length.

The setting of these bits is valid in both clock asynchronous mode (UART) and clock synchronous mode (SIO).

bit3:2	Details
Writing "00"	5 bits
Writing "01"	6 bits
Writing "10"	7 bits
Writing "11"	8 bits

[bit1] CKS: Clock select bit

This bit selects a serial clock from the external clock or the UART/SIO dedicated baud rate generator.

bit1	Details
Writing "0"	UART/SIO dedicated baud rate generator
Writing "1"	External clock

Note: Setting this bit to "1" forcibly disables the output of the UCKn pin. The external clock cannot be used in clock asynchronous mode (UART).

[bit0] MD: Operation mode select bit

This bit selects an operation mode from the clock asynchronous mode (UART) or the clock synchronous mode (SIO).

bit0	Details
Writing "0"	Clock asynchronous mode (UART)
Writing "1"	Clock synchronous mode (SIO)

Note:

During data transmission or reception, do not modify the settings of the UART/SIO serial mode control register 1 ch. n (SMC1n).

21.7.2 UART/SIO Serial Mode Control Register 2 ch. n (SMC2n)

The UART/SIO serial mode control register 2 ch. n (SMC2n) controls the UART/SIO operation mode. The register enables or disables serial clock output, serial data output, transmission/reception, and interrupts, and clears the receive error flag.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SCKE	TXOE	RERC	RXE	TXE	RIE	TCIE	TEIE
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	1	0	0	0	0	0

■ Register Functions

[bit7] SCKE: Serial clock output enable bit

This bit controls the input/output of the serial clock pin (UCKn) in clock synchronous mode (SIO).

bit7	Details
Writing "0"	Disables the serial clock, and makes the UCKn pin function as a general purpose I/O port.
Writing "1"	Enables the serial clock, and makes the UCKn pin function as a serial clock output pin.

Note: With the clock select bit (SMC1n:CKS) already set to "1", no internal clock signal is output even when this bit set to "1".

In clock asynchronous mode (UART) (SMC1n:MD = 0), when this bit is set to "0", the output from the UCKn bit will always be "H".

[bit6] TXOE: Serial data output enable bit

This bit controls the output of the serial data pin (UOn).

bit6	Details
Writing "0"	Disables serial data output, and makes the UOn pin function as a general purpose I/O port.
Writing "1"	Enables serial data output, and makes the UOn pin function as a serial data output pin.

[bit5] RERC: Receive error flag clear bit

This bit clears the receive error flags.

The read value of this bit is always "1".

bit5	Details
Writing "0"	Clears the receive error flags (PER, OVE and FER) in the SSRn register.
Writing "1"	Has no effect on operation.

[bit4] RXE: Receive operation enable bit

This bit enables or disables the reception of serial data.

If this bit is set to "0" during a receive operation, the receive operation is immediately disabled and initialized. The data received up to that point is not transferred to the UART/SIO serial input data register.

bit4	Details
Writing "0"	Disables the reception of serial data.
Writing "1"	Enables the reception of serial data.

Note: Setting this bit to "0" initializes the receive operation. It has no effect on the error flags (PER, OVE, FER, RDRF) in the SSRn register.

[bit3] TXE: Transmit operation enable bit

This bit enables or disables the transmission of serial data.

If this bit is set to "0" during a transmit operation, the transmit operation is immediately disabled and initialized. The transmission completion flag bit (SSRn:TCPL) is then be set to "1", and the transmit data register empty flag bit (SSRn:TDRE) is also be set to "1".

bit3	Details
Writing "0"	Disables the transmission of serial data.
Writing "1"	Enables the transmission of serial data.

[bit2] RIE: Receive interrupt enable bit

This bit enables or disables the receive interrupt.

With this bit set to "1" (receive interrupt enabled), a receive interrupt is generated immediately after either the receive data register full flag bit (SSRn:RDRF) or any of the receive error flag bits (SSRn:PER, OVE, FER) is set to "1".

bit2	Details
Writing "0"	Disables the receive interrupt.
Writing "1"	Enables the receive interrupt.

[bit1] TCIE: Transmission completion interrupt enable bit

This bit enables or disables the transmission completion interrupt.

With this bit set to "1" (transmission completion interrupt enabled), a transmission completion interrupt is generated immediately after the transmission completion flag bit (SSRn:TCPL) is set to "1".

bit1	Details
Writing "0"	Disables the transmission completion interrupt.
Writing "1"	Enables the transmission completion interrupt.

[bit0] TEIE: Transmit data register empty interrupt enable bit

This bit enables or disables the transmit data register empty interrupt.

With this bit set to "1" (transmit data register empty interrupt enabled), a transmit data register empty interrupt is generated immediately after the transmit data register empty flag bit (SSRn:TDRE) is set to "1".

bit0	Details
Writing "0"	Disables the transmit data register empty interrupt.
Writing "1"	Enables the transmit data register empty interrupt.

21.7.3 UART/SIO Serial Status and Data Register ch. n (SSRn)

The UART/SIO serial status and data register ch. n (SSRn) indicates the transmission/reception status and error status of the UART/SIO.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	PER	OVE	FER	RDRF	TCPL	TDRE
Attribute	—	—	R	R	R	R	R/W	R
Initial value	0	0	0	0	0	0	0	1

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] PER: Parity error flag bit

This bit detects the parity error in receive data.

This bit is set to "1" when a parity error occurs during a receive operation reception. Writing "0" to the RERC bit in the SMC2n register clears this bit.

When a parity error is detected at the same time as clearing this bit by writing "0" to the RERC bit, setting this bit to "1" is given priority.

bit5	Details
Reading "0"	Indicates that no parity error has occurred.
Reading "1"	Indicates that a parity error has occurred.

[bit4] OVE: Overrun error flag bit

This bit detects the overrun error in receive data.

This bit is set to "1" when an overrun error occurs during a receive operation reception. Writing "0" to the RERC bit in the SMC2n register clears this bit.

When an overrun error is detected at the same time as clearing this bit by writing "0" to the RERC bit, setting this bit to "1" is given priority.

bit4	Details
Reading "0"	Indicates that no overrun error has occurred.
Reading "1"	Indicates that an overrun error has occurred.

[bit3] FER: Framing error flag bit

This bit detects the framing error in receive data.

This bit is set to "1" when a framing error occurs during a receive operation reception. Writing "0" to the RERC bit in the SMC2n register clears this bit.

When a framing error is detected at the same time as clearing this bit by writing "0" to the RERC bit, setting this bit to "1" is given priority.

bit3	Details
Reading "0"	Indicates that no framing error has occurred.
Reading "1"	Indicates that a framing error has occurred.

[bit2] RDRF: Receive data register full flag bit

This bit indicates the state of the UART/SIO serial input data register ch. n (RDRn).

When receive data is loaded to the RDRn register, this bit is set to "1".

When data in the RDRn register is read, this bit is cleared to "0".

bit2	Details
Reading "0"	Indicates that there is no receive data in the RDRn register.
Reading "1"	Indicates that there is receive data in the RDRn register.

[bit1] TCPL: Transmission completion flag bit

This bit indicates the data transmission state.

When serial transmission is completed, this bit is set to "1". However, when the UART/SIO serial output data register ch. n (TDRn) contains data to be transmitted successively, this bit is not set to "1" even after one time of transmission is completed.

Writing "0" to this bit clears it.

When transmission completion setting this bit to "1" and writing "0" to this bit to clear it occur simultaneously, the former one is given priority.

Writing "1" to this bit has no effect on operation.

bit1	Details
Reading "0"	Indicates that data transmission has not been completed.
Reading "1"	Indicates that data transmission has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit0] TDRE: Transmit data register empty flag bit

This bit indicates the state of the UART/SIO serial output data register ch. n (TDRn).

When transmit data is written to the TDRn register, this bit is set to "0".

When transmit data is loaded to the shift register for the transmission and data transmission starts, this bit is set to "1".

bit0	Details
Reading "0"	Indicates that there is transmit data in the TDRn register.
Reading "1"	Indicates that there is no transmit data in the TDRn register.

21.7.4 UART/SIO Serial Input Data Register ch. n (RDRn)

The UART/SIO serial input data register ch. n (RDRn) is used for inputting (receiving) serial data.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	RD7	RD6	RD5	RD4	RD3	RD2	RD1	RD0
Attribute	R	R	R	R	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

This register stores received data. The serial data signals sent to the serial data input pin (UIn) is converted by the shift register and stored in this register.

When received data is set correctly in this register, the receive data register full flag bit (SSRn:RDRF) is set to "1". At this time, an interrupt occurs if receive interrupt requests have been enabled. If an RDRF bit check by the program or using an interruption shows that received data is stored in this register, the reading of the content for this register clears the RDRF bit to "0".

When the character bit length (SMC1n:CBL[1:0]) is set to shorter than eight bits, the excess upper bits (beyond the set bit length) are set to "0".

21.7.5 UART/SIO Serial Output Data Register ch. n (TDRn)

The UART/SIO serial output data register ch. n (TDRn) used for outputting (transmitting) serial data.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	TD7	TD6	TD5	TD4	TD3	TD2	TD1	TD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

This register holds data to be transmitted. The register accepts a write when the transmit data register empty flag bit (TDRE) is "1". An attempt to write to the bit is ignored when the bit contains "0".

When transmit data is written to the UART/SIO serial output data register ch. n (TDRn), the TDRE bit is set to "0". Upon completion of transfer of transmit data to the transmission shift register, the TDRE bit is set to "1", enabling the next transmit data to be written to the TDRn register. At this time, an interrupt occurs if transmit data register empty interrupts have been enabled. Write the next piece of transmit data when transmit data empty occurs or the TDRE bit is set to "1".

When the character bit length (SMC1n:CBL[1:0]) is set to shorter than eight bits, the excess upper bits (beyond the set bit length) are ignored.

Note:

The data in this register cannot be updated when the TDRE bit in UART/SIO serial status and data register ch.n (SSRn) is "0".

When this register is updated at writing complete the transmission data and TDRE = 0 (regardless of the setting of the TXE bit in the SMC2n register), the transmission operation is initialized by writing "0" to TXE, the TDRE bit becomes "1", and updating this register is enabled.

Moreover, when "0" is written to the TXE bit without transmission having started (when the transmit data is written to the TDRn register, and the TXE bit has not been set to "1" yet), the TCPL bit is not set to "1". In the case of modifying the transmit data, make the TDRE bit become "1" once by writing "0" to the TXE bit before modifying the transmit data.

CHAPTER 22

UART/SIO DEDICATED BAUD RATE GENERATOR

This chapter describes the functions and operations of the dedicated baud rate generator for the UART/SIO.

- 22.1 Overview
- 22.2 Channel
- 22.3 Operations
- 22.4 Registers

22.1 Overview

The UART/SIO dedicated baud rate generator generates the baud rate for the UART/SIO.

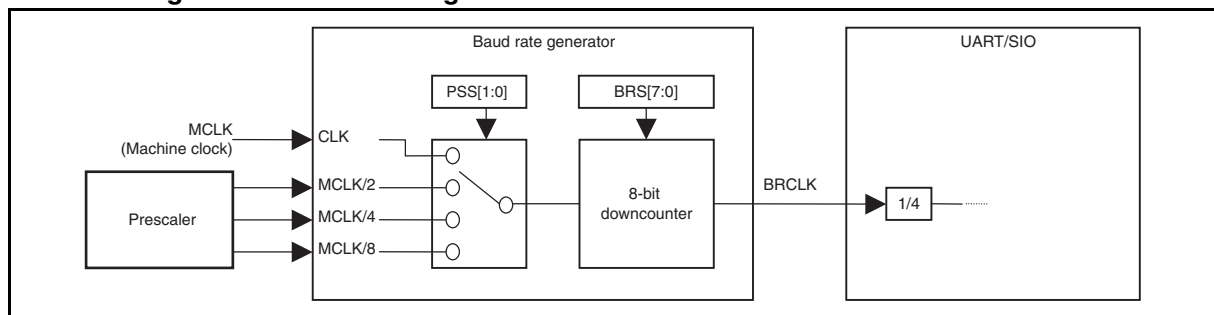

The generator consists of the UART/SIO dedicated baud rate generator prescaler select register ch. n (PSSRn) and UART/SIO dedicated baud rate generator baud rate setting register ch. n (BRSRn).

The number of pins and that of channels of the UART/SIO dedicated baud rate generator vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of UART/SIO Dedicated Baud Rate Generator

Figure 22.1-1 Block Diagram of UART/SIO Dedicated Baud Rate Generator

■ Input Clock

The UART/SIO dedicated baud rate generator uses the output clock from the prescaler or the machine clock as its input clock.

■ Output Clock

The UART/SIO dedicated baud rate generator supplies its clock to the UART/SIO.

22.2 Channel

This section describes the channel of the UART/SIO dedicated baud rate generator.

■ Channel of UART/SIO Dedicated Baud Rate Generator

Table 22.2-1 shows the registers of the UART/SIO dedicated baud rate generator.

Table 22.2-1 Registers of Dedicated Baud Rate Generator

Register abbreviation	Corresponding register (Name in this manual)
PSSRn	UART/SIO dedicated baud rate generator prescaler select register ch. n
BRSRn	UART/SIO dedicated baud rate generator baud rate setting register ch. n

22.3 Operations

The UART/SIO dedicated baud rate generator serves as the baud rate generator in clock asynchronous mode (UART).

■ Baud Rate Setting

The CKS bit in the SMC1n register of the UART/SIO is used to select the serial clock. This selects the UART/SIO dedicated baud rate generator.

In asynchronous clock mode, the shift clock that is selected by the CKS bit and divided by four is used and transfers can be performed within the range from -3% to +3%. The baud rate calculation formula for the UART/SIO dedicated baud rate generator is shown below.

Figure 22.3-1 Baud Rate Calculation Formula when UART/SIO Dedicated Baud Rate Generator Is Used

$$\text{Baud rate} = \frac{\text{Machine clock (MCLK)}}{4 \times \begin{matrix} 1 \\ 2 \\ 4 \\ 8 \end{matrix} \times \begin{matrix} 2 \\ : \\ 255 \end{matrix}} \quad [\text{bps}]$$

UART dedicated baud rate generator prescaler select register ch. n (PSSRn) Prescaler select (PSS[1:0])

UART dedicated baud rate generator baud rate setting register ch. n (BRSRn) Baud rate setting (BRS[7:0])

Table 22.3-1 Sample Asynchronous Transfer Rates by Baud Rate Generator (Machine Clock = 10MHz, 16MHz, 16.25MHz)

UART/SIO Dedicated baud rate generator setting		UART internal division	Total division ratio (PSS × BRS × 4)	Baud rate (10 MHz / Total division ratio)	Baud rate (16 MHz / Total division ratio)	Baud rate (16.25 MHz / Total division ratio)
Prescaler select PSS[1:0]	Baud rate counter setting BRS [7:0]					
1 (Setting value: 0, 0)	20	4	80	125000	200000	203125
1 (Setting value: 0, 0)	22	4	88	113636	181818	184659
1 (Setting value: 0, 0)	44	4	176	56818	90909	92330
1 (Setting value: 0, 0)	87	4	348	28736	45977	46695
1 (Setting value: 0, 0)	130	4	520	19231	30769	31250
2 (Setting value: 0, 1)	130	4	1040	9615	15385	15625
4 (Setting value: 1, 0)	130	4	2080	4808	7692	7813
8 (Setting value: 1, 1)	130	4	4160	2404	3846	3906

The baud rate can be set in UART mode within the following range.

Table 22.3-2 Baud Rate Setting Range in Clock Asynchronous Mode (UART)

PSS[1:0]	BRS[7:0]
0b00 to 0b11	0x02 (2) to 0xFF (255)

22.4 Registers

This section describes the registers of the UART/SIO dedicated baud rate generator.

Table 22.4-1 List of UART/SIO Baud Rate Generator Registers

Register abbreviation	Register name	Reference
PSSR _n	UART/SIO dedicated baud rate generator prescaler select register ch. n	22.4.1
BRSR _n	UART/SIO dedicated baud rate generator baud rate setting register ch. n	22.4.2

22.4.1 UART/SIO Dedicated Baud Rate Generator Prescaler Select Register ch. n (PSSRn)

The UART/SIO dedicated baud rate generator prescaler select register ch. n (PSSRn) controls the output of the baud rate clock and the prescaler.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	—	—	BRGE	PSS1	PSS0
Attribute	—	—	—	—	—	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:3] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit2] BRGE: Baud rate clock output enable bit

This bit enables or disables outputting the baud rate clock "BRCLK".

When "1" is written to this bit, the value of the BRS[7:0] bits in the BRSRn register is loaded to the 8-bit downcounter and BRCLK to be supplied to the UART/SIO is output.

Writing "0" to this bit stops the output of BRCLK.

bit2	Details
Writing "0"	Disables outputting the baud rate clock.
Writing "1"	Enables outputting the baud rate clock.

[bit1:0] PSS[1:0]: Prescaler select bits

These bits select a prescaler.

bit1:0	Details
Writing "00"	1
Writing "01"	1/2
Writing "10"	1/4
Writing "11"	1/8

22.4.2 UART/SIO Dedicated Baud Rate Generator Baud Rate Setting Register ch. n (BRSRn)

The UART/SIO dedicated baud rate generator baud rate setting register ch.n (BRSRn) controls the baud rate settings.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BRS7	BRS6	BRS5	BRS4	BRS3	BRS2	BRS1	BRS0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

This register sets the cycle of the 8-bit downcounter and can be used to set any baud rate clock (BRCLK). Stop the UART/SIO operation before writing a value to this register.

In clock asynchronous mode (UART), do not set BRS[7:0] to "0x00" or "0x01".

CHAPTER 23

I²C BUS INTERFACE

This chapter describes functions and operations of the I²C bus interface.

- 23.1 Overview
- 23.2 Configuration
- 23.3 Channel
- 23.4 Pins
- 23.5 Interrupts
- 23.6 Operations and Setting Procedure Example
- 23.7 Registers
- 23.8 Notes on Using I²C Bus Interface

23.1 Overview

The I²C bus interface provides the functions of transmission and reception in master and slave modes, detection of arbitration lost, detection of slave address and general call address, generation and detection of start and stop conditions, bus error detection, and MCU standby wakeup.

■ I²C Bus Interface Functions

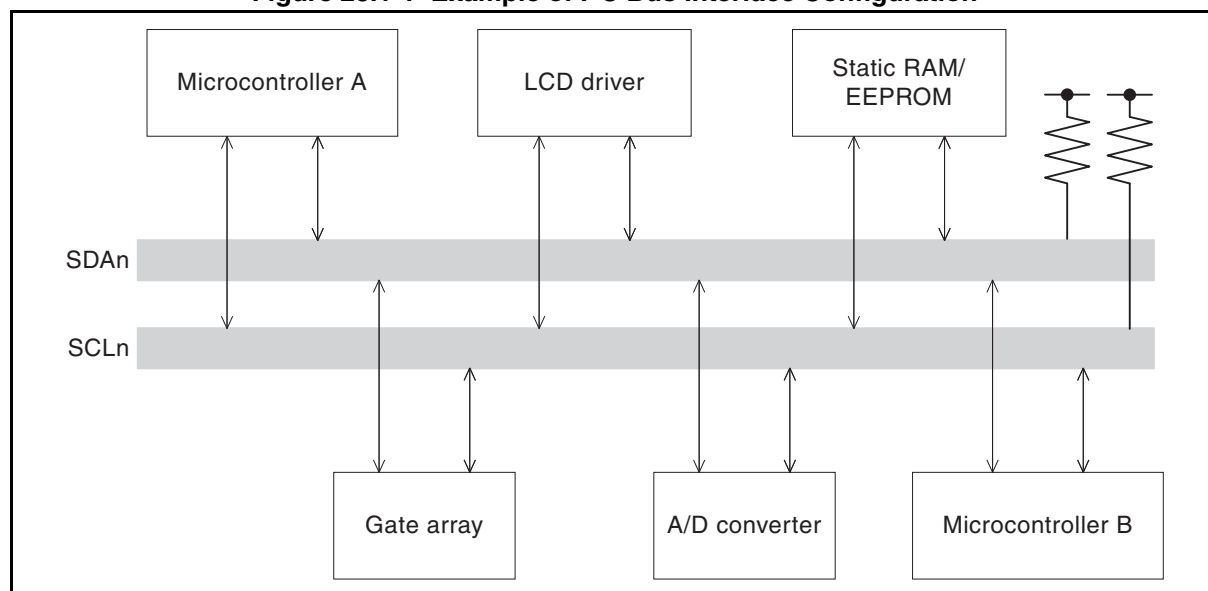

The I²C bus interface is a two-wire, bi-directional bus consisting of a serial data line (SDAn) and serial clock line (SCLn). The devices connected to the bus via these two wires can exchange data, and each device can operate as a sender or receiver in accordance with their respective functions based on the unique address assigned to each device. Furthermore, the interface establishes a master/slave relationship between devices.

The I²C bus interface can connect multiple devices provided the bus capacitance does not exceed an upper limit of 400 pF. The I²C bus interface is a true multi-master bus with collision detection and a communication control protocol that prevent loss of data even if more than one master attempts to start a data transfer at the same time.

The communication control protocol ensures that only one master is able to take control of the bus at a time, even if multiple masters attempt to take control of the bus simultaneously, without messages being lost or data being altered. Multi-master means that more than one master can attempt to take control of the bus at the same time without causing messages to be lost.

The I²C bus interface includes a function to wake up the MCU from standby mode.

Figure 23.1-1 Example of I²C Bus Interface Configuration

23.2 Configuration

The I²C bus interface consists of the following blocks:

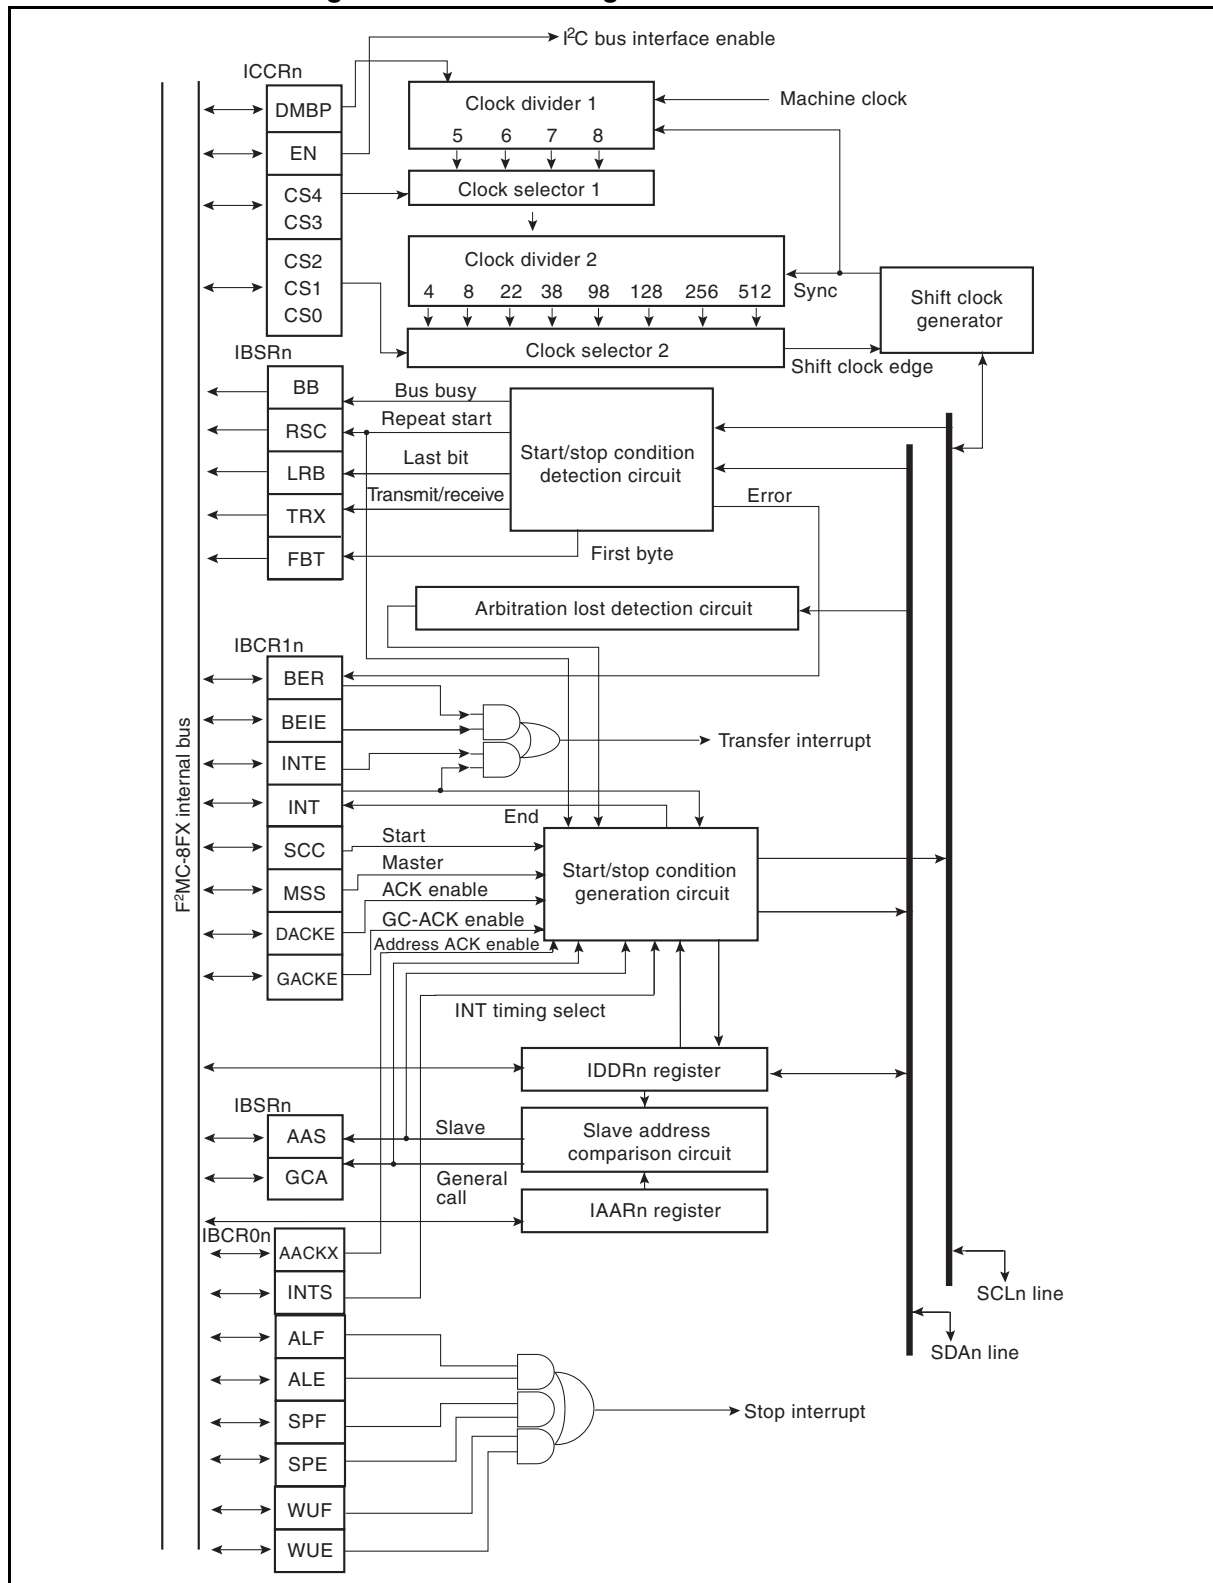

- Clock selector
 - Clock divider
 - Shift clock generator
 - Start/stop condition generation circuit
 - Start/stop condition detection circuit
 - Arbitration lost detection circuit
 - Slave address comparison circuit
 - IBSRn register
 - IBCR0n register
 - IBCR1n register
 - ICCRn register
 - IAARn register
 - IDDRn register
-

The number of pins and that of channels of the I²C bus interface vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of I²C Bus Interface

Figure 23.2-1 Block Diagram of I²C Bus Interface

- Clock selector, clock divider, and shift clock generator

This circuit uses the machine clock to generate the shift clock for the I²C bus.

- Start/stop condition generation circuit

When a start condition is transmitted with the bus idle (SCLn and SDAn at the "H" level), a master starts communications. When SCLn = "H", a start condition is generated by changing the SDAn line from "H" to "L". The master can terminate its communication by generating a stop condition. When SCLn = "H", a stop condition is generated by changing the SDAn line from "L" to "H".

- Start/stop condition detection circuit

This circuit detects a start/stop condition for data transfer.

- Arbitration lost detection circuit

This interface circuit supports multi-master systems. If two or more masters attempt to transmit at the same time, the arbitration lost condition (if logic level "1" is sent when the SDAn line goes to the "L" level) occurs. When the arbitration lost is detected, IBCR0n:ALF is set to "1" and the master changes to a slave automatically.

- Slave address comparison circuit

The slave address comparison circuit receives the slave address after the start condition to compare it with its own slave address. The address is seven-bit data followed by a data direction (R/W) bit in the eighth bit position. If the received address matches the own slave address, the comparison circuit transmits an acknowledgment.

- IBSRn register

The IBSRn register shows the status of the I²C bus interface.

- IBCR0n register and IBCR1n register

The IBCR0n register and the IBCR1n register are used to select the operating mode and to enable or disable interrupts, acknowledgment, general call acknowledgment, and the function to wake up the MCU from standby mode.

- ICCRn register

The ICCRn register is used to enable I²C bus interface operations and select the shift clock frequency.

- IAARn register

The IAARn register is used to set the slave address.

- IDDRn register

The IDDRn register holds the transmit or receive shift data or address. When transmitted, the data or address written to this register is transferred from the MSB first to the bus.

■ Input Clock

The I²C bus interface uses the machine clock as the input clock (shift clock).

23.3 Channel

This section describes the channel of the I²C bus interface.

■ Channel of I²C Bus Interface

Table 23.3-1 and Table 23.3-2 show the pins and registers on a channel of the I²C bus interface respectively.

Table 23.3-1 Pins of I²C Bus Interface

Pin name	Pin function
SDAn	I ² C bus interface I/O
SCLn	

Table 23.3-2 Registers of I²C Bus Interface

Register abbreviation	Corresponding register (Name in this manual)
IBCR0n	I ² C bus control register 0 ch. n
IBCR1n	I ² C bus control register 1 ch. n
IBSRn	I ² C bus status register ch. n
IDDRn	I ² C data register ch. n
IAARn	I ² C address register ch. n
ICCRn	I ² C clock control register ch. n

23.4 Pins

This section describes the pins of the I²C bus interface and gives their block diagram.

■ Pins of I²C Bus Interface

The pins of the I²C bus interface are SDAn and SCLn.

- SDAn pin

The SDAn pin is the data I/O pin of the I²C bus interface.

When the I²C bus interface is enabled (ICCRn:EN = 1), the SDAn pin is automatically set as a data I/O pin to function as the SDAn pin.

- SCLn pin

The SCLn pin is the serial clock I/O pin of the I²C bus interface.

When the I²C bus interface is enabled (ICCRn:EN = 1), the SCLn pin is automatically set as a shift clock I/O pin to function as the SCLn pin.

23.5 Interrupts

The I²C bus interface has a transfer interrupt and a stop interrupt which are triggered by the following events.

- **Transfer interrupt**

A transfer interrupt occurs either upon completion of data transfer or when a bus error occurs.

- **Stop interrupt**

A stop interrupt occurs upon detection of a stop condition or arbitration lost or upon access to the I²C bus interface in stop/watch mode.

■ Transfer Interrupt

Table 23.5-1 shows the transfer interrupt control bits and I²C bus interface interrupt sources.

Table 23.5-1 Transfer Interrupt Control Bits and I²C Bus Interface Interrupt Sources

Item	End of transfer	Bus error
Interrupt request flag bit	IBCR1n:INT = 1	IBCR1n:BER = 1
Interrupt request enable bit	IBCR1n:INTE = 1	IBCR1n:BEIE = 1
Interrupt source	Data transfer complete	Bus error occurred

- **Interrupt upon completion of transfer**

An interrupt request is output to the CPU upon completion of data transfer if the transfer completion interrupt request enable bit has been set to enable (IBCR1n:INTE = 1). In the interrupt service routine, write "0" to the transfer completion interrupt request flag bit (IBCR1n:INT) to clear the interrupt request. When data transfer is completed, the IBCR1n:INT bit is set to "1" regardless of the value of the IBCR1n:INTE bit.

- **Interrupt in response to a bus error**

When the following conditions are met, a bus error is deemed to have occurred, and the I²C bus interface will be stopped.

- When a stop condition is detected in master mode.
- When a start or stop condition is detected during transmission or reception of the first byte.
- When a start or stop condition is detected during transmission or reception of data (excluding the start, first data, and stop bits).

In these cases, an interrupt request is output to the CPU if the bus error interrupt request enable bit has been set to enable (IBCR1n:BEIE = 1). In the interrupt service routine, write "0" to the bus error interrupt request flag bit (IBCR1n:BER) to clear the interrupt request. When a bus error occurs, the IBCR1n:BER bit is set to "1" regardless of the value of the IBCR1n:BEIE bit.

■ Stop Interrupt

Table 23.5-2 shows the stop interrupt control bits and I²C interrupt sources (trigger events).

Table 23.5-2 Stop Interrupt Control Bits and I²C Interrupt Sources

Item	Detection of stop condition	Detection of arbitration lost	MCU wakeup from stop/watch mode
Interrupt request flag bit	IBCR0n:SPF =1	IBCR0n:ALF =1	IBCR0n:WUF =1
Interrupt request enable bit	IBCR0n:SPE =1	IBCR0n:ALE =1	IBCR0n:WUE =1
Interrupt source	Stop condition detected	Arbitration lost detected	Start condition detected

- Interrupt upon detection of a stop condition

A stop condition is considered to be valid if all of the following conditions are satisfied when the stop condition is detected.

- The bus is busy (state which the start condition is detected).
- IBCR1n:MSS = 0
- After transfer of one byte of data completes, including the acknowledgment.

In this case, an interrupt request is output to the CPU if the stop condition detection interrupt request enable bit has been set to enable (IBCR0n:SPE =1). In the interrupt service routine, write "0" to the IBCR0n:SPF bit to clear the interrupt request.

The IBCR0n:SPF bit is set to "1" when a valid stop condition occurs regardless of the value of the IBCR0n:SPE bit.

- Interrupt upon detection of arbitration lost

When arbitration lost is detected, an interrupt request is output to the CPU if the arbitration lost detection interrupt request enable bit has been set to enable (IBCR0n:ALE = 1). Either write "0" to the arbitration lost interrupt request flag bit (IBCR0n:ALF) while the bus is idle or write "0" to the IBCR1n:INT bit from the interrupt service routine while the bus is busy to clear the interrupt request.

When arbitration lost occurs, the IBCR0n:ALF bit is set to "1" regardless of the value for the IBCR0n:ALE bit.

- Interrupt for MCU wakeup from stop mode or watch mode

When a start condition is detected, an interrupt request is output to the CPU if the function to wake up the MCU from stop or watch mode has been enabled (IBCR0n:WUE = 1).

In the interrupt service routine, write "0" to the MCU standby mode wakeup interrupt request flag bit (IBCR0n:WUF) to clear the interrupt request.

23.6 Operations and Setting Procedure Example

This section describes the operations of the I²C bus interface.

■ Operations of I²C Bus Interface

- I²C bus interface

The I²C bus interface is an 8-bit serial interface synchronized with a shift clock.

- MCU standby mode wakeup function

The wakeup function wakes up the MCU upon detection of a start condition, from low power consumption mode such as stop or watch mode.

■ Setting Procedure Example

Below is an example of procedure for setting the I²C bus interface.

- Initial settings

1. Set the port for input. (DDR)
2. Set the interrupt level. (ILR*)
3. Set the slave address. (IAARn)
4. Select the clock and enable I²C operation. (ICCRn)
5. Enable bus error interrupt requests. (IBCR1n:BEIE = 1)

*: For details of the interrupt level setting register (ILR), refer to "CHAPTER 5 INTERRUPTS" in this hardware manual and "■ INTERRUPT SOURCE TABLE" in the device data sheet.

- Interrupt processing

1. Execute any process.
2. Clear the bus error interrupt request flag. (IBCR1n:BER = 0)

23.6.1 I²C Bus Interface

The I²C bus interface is an eight-bit serial interface synchronized with the shift clock.

■ I²C System

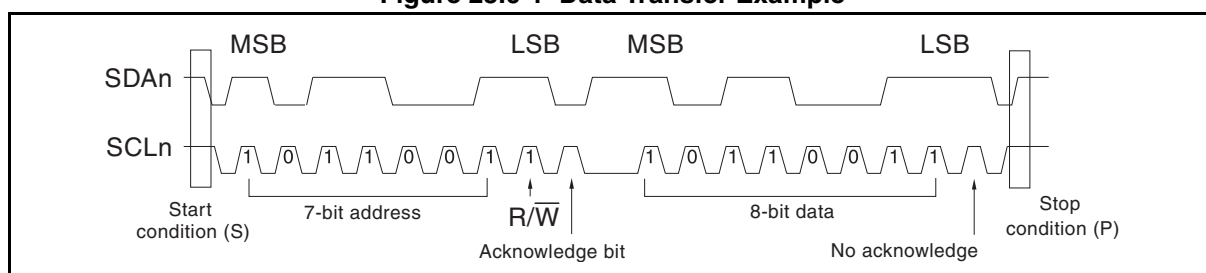

The I²C bus system uses the serial data line (SDAn) and serial clock line (SCLn) for data transfers. All the devices connected to the bus require open drain or open collector outputs which must be connected with a pull-up resistor.

Each of the devices connected to the bus has a unique address which can be set up using software. The devices always operate in a simple master/slave relationship, where the master functions as the master transmitter or master receiver. The I²C bus interface is a true multi-master bus with a collision detection function and arbitration function to prevent data from being lost if more than one master attempts to start data transfer at the same time.

■ I²C Protocol

Figure 23.6-1 shows the format required for data transfer.

Figure 23.6-1 Data Transfer Example

The slave address is transmitted after a start condition (S) is generated. This address is seven bits long followed by the data direction bit (R/\overline{W}) in the eighth bit position. Data is transmitted after the address. The data is eight bits followed by an acknowledgment.

Data can be transmitted continuously to the same slave address in consecutive units of eight bits plus acknowledgment.

Data transfer is always ended in the master stop condition (P). However, the repeated start condition (S) can be used to transmit the address which indicates a different slave without generating a stop condition.

■ Start Conditions

While the bus is idle (SCLn and SDAn are both at the logical "H" level), the master generates a start condition to start transmission. As shown in Figure 23.6-1, a start condition is triggered when the SDAn line is changed from "H" to "L" while SCLn = "H". This starts a new data transfer and commences master/slave operation.

A start condition can be generated in either of the following two ways.

- By writing "1" to the IBCR1n:MSS bit while the I²C bus is not in use (IBCR1n:MSS = 0, IBSRn:BB = 0, IBCR1n:INT = 0, and IBCR0n:ALF = 0). (Next, IBSRn:BB is set to "1" to indicate that the bus is busy.)
- By writing "1" to the IBCR1n:SCC bit during an interrupt while in master mode (IBCR1n:MSS = 1, IBSRn:BB = 1, IBCR1n:INT = 1, and IBCR0n:ALF = 0). (This generates a repeated start condition.)

Writing "1" to the IBCR1n:MSS or IBCR1n:SCC bit is ignored in any circumstances other than those mentioned above. If another system is using the bus when "1" is written to the IBCR1n:MSS bit, the IBCR0n:ALF bit is set to "1".

■ Addressing

● Slave addressing in master mode

In master mode, IBSRn:BB and IBSRn:TRX are set to "1" after the start condition is generated, and the slave address in the IDDRn register is output to the bus starting with the MSB. The address data consists of eight bits: the 7-bit slave address and the data transfer direction R/ \overline{W} bit (bit0 of IDDRn).

The acknowledgment from the slave is received after the address data is sent. SDAn goes to "L" in the ninth clock cycle and the acknowledge bit from the receiving device is received (See Figure 23.6-1). In this case, the R/ \overline{W} bit (IDDRn:bit0) is inverted logically and stored in the IBSRn:TRX bit as "1" if the SDAn level is "L".

● Addressing in slave mode

In slave mode, after the start condition is detected, IBSRn:BB is set to "1" and IBSRn:TRX is set to "0", and the data received from the master is stored in the IDDRn register. After the address data is received, the IDDRn and IAARn registers are compared. If the addresses match, IBSRn:AAS is set to "1" and an acknowledgment is sent to the master. Afterward, bit0 in the receive data (bit0 in the IDDRn register) is saved in the IBSRn:TRX bit.

■ Data Transfer

If the MCU is addressed as a slave, data can be sent or received byte by byte with the direction determined by the R/ \overline{W} bit sent by the master.

Each byte to be output on the SDAn line is fixed at eight bits. As shown in Figure 23.6-1, the receiver sends an acknowledgment to the sender by forcing the SDAn line to the stable "L" level while the acknowledge clock pulse is "H". Data is transferred at one clock pulse per bit with MSB at the head. Sending and receiving an acknowledgment is required after each byte is transferred. Therefore, nine clock pulses are required to transfer one complete data byte.

■ Acknowledgment

An acknowledgment is sent by the receiver in the ninth clock cycle for data byte transfer by the sender based on the following conditions.

An address acknowledgment is generated in the following cases.

- The received address matches the address set in IAAR_n, and the address acknowledgment is output automatically (IBCR0_n:AACKX = 0).
- A general call address (0x00) is received and the general call address acknowledgment output is enabled (IBCR1_n:GACKE = 1).

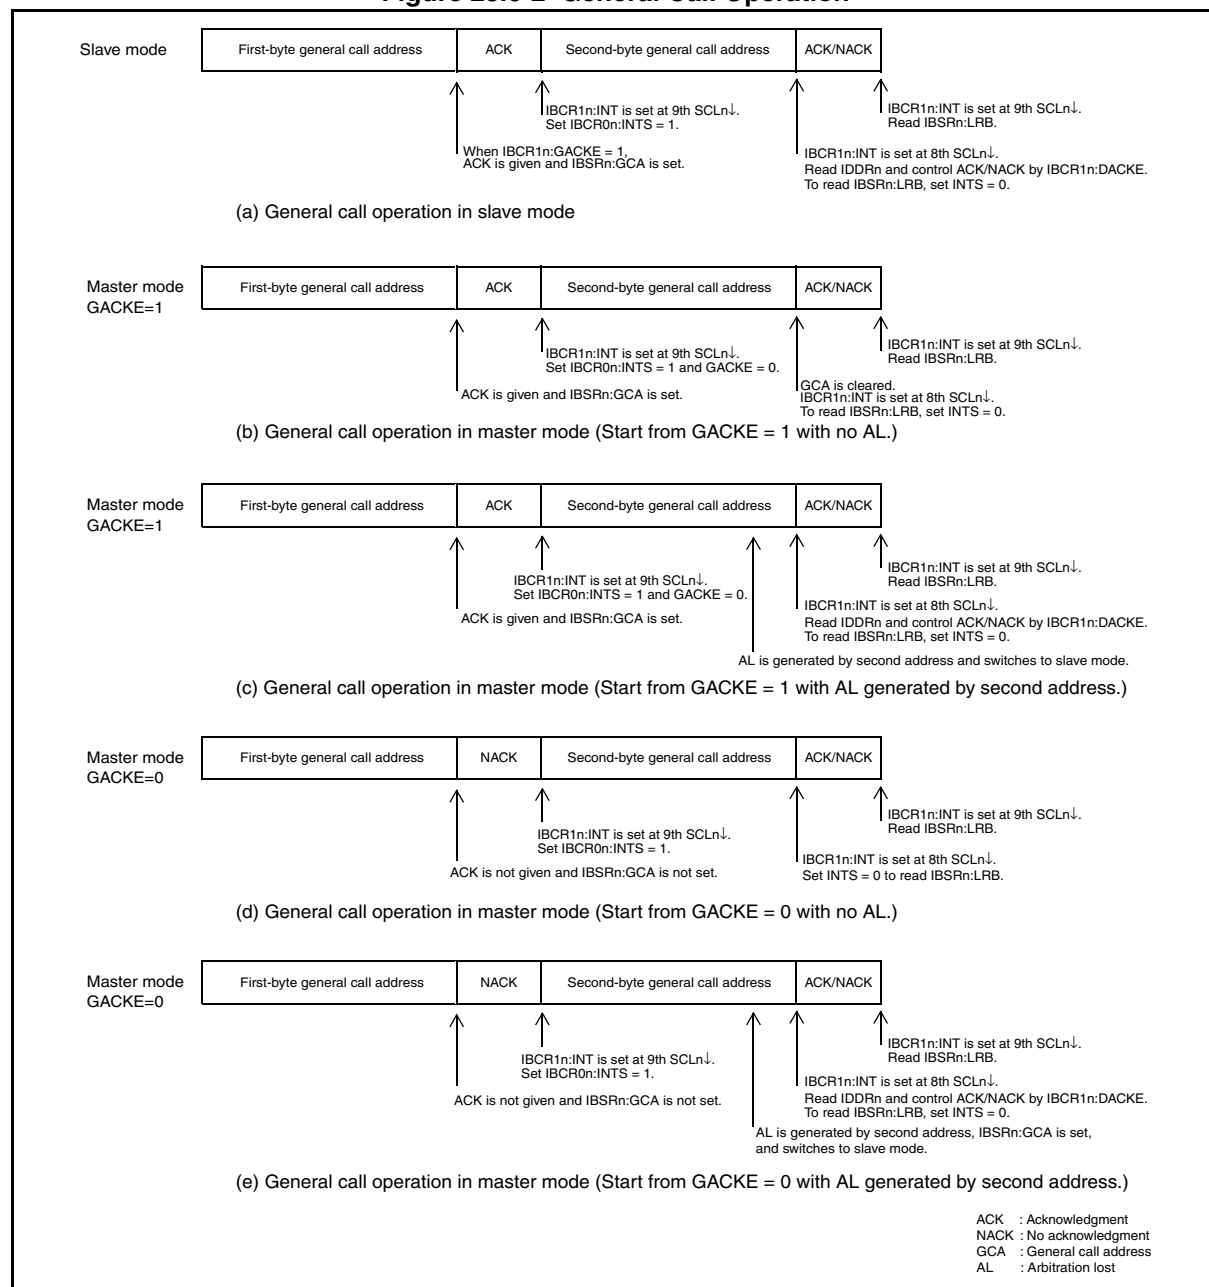

A data acknowledge bit used when data is received can be enabled or disabled by the IBCR1_n:DACKE bit. In master mode, a data acknowledgment is generated if IBCR1_n:DACKE = 1. In slave mode, a data acknowledgment is generated if an address acknowledgment has already been generated and IBCR1_n:DACKE = 1. The received acknowledgment is saved in IBSR_n:LRB in the ninth SCL_n cycle.

- If the data ACK depends on the content of received data (such as packet error checking used by the SM bus), control the data ACK by setting the data ACK enable bit (IBCR1_n:DACKE) after writing "1" to the IBCR0_n:INTS bit (for example, by a previous transfer completion interrupt) so that the latest received data can be read.
- The latest data ACK (IBSR_n:LRB) can be read after the ACK has been received (IBSR_n:LRB must be read during the transfer completion interrupt triggered by the ninth SCL_n cycle). Accordingly, if ACK is read when the IBCR0_n:INTS bit is "1", write "0" to this bit in the transfer completion interrupt triggered by the eighth SCL_n cycle so that another transfer completion interrupt will be triggered by the ninth SCL_n cycle.

General Call Address

A general call address consists of the start address byte (0x00) and the second address byte that follows. To use a general call address, set IBCR1n:GACKE=1 before the acknowledge of the first byte general call address. In addition, the acknowledgment for the second address byte can be controlled as shown below.

Figure 23.6-2 General Call Operation

If this module sends a general call address at the same time as another device, you can determine whether the module successfully seized control of the bus by checking whether arbitration lost was detected when the second address byte was transferred. If arbitration lost was detected, the module goes to slave mode and continues to receive data from the master.

■ Stop Condition

The master can release the bus and end communications by generating a stop condition. Changing the SDA_n line from "L" to "H" while SCL_n is "H" generates a stop condition. This signals to the other devices on the bus that the master has finished communications (referred to below as "bus free"). However, the master can continue to generate start conditions without generating a stop condition. This is called a repeated start condition.

Writing "0" to the IBCR1_n:MSS bit during an interrupt while in master mode (IBCR1_n:MSS = 1, IBSR_n:BB = 1, IBCR1_n:INT = 1, and IBCR0_n:ALF = 0) generates a stop condition and changes to slave mode. In any other circumstances other than those mentioned above, writing "0" to the IBCR1_n:MSS bit is ignored.

■ Arbitration

The interface circuit is a true multi-master bus able to connect multiple master devices. Arbitration occurs when another master within the system simultaneously transfers data during a master transfer.

Arbitration occurs on the SDA_n line while the SCL_n line is at the "H" level. When the send data is "1" and the data on the SDA_n line is "L" at the master, this is treated as arbitration lost. In this case, data output is halted and IBCR0_n:ALF is set to "1". If this occurs, an interrupt is generated if arbitration lost interrupts have been enabled (IBCR0_n:ALE = 1). If IBCR0_n:ALF is set to "1", the module sets IBCR1_n:MSS = 0 and IBSR_n:TRX = 0, clears TRX, and goes to slave receive mode.

If IBCR0_n:ALF is set to "1" when IBSR_n:BB = 0, IBCR0_n:ALF is cleared only by writing "0". If IBCR0_n:ALF is set to "1" when IBSR_n:BB = 1, IBCR0_n:ALF is cleared only by clearing IBCR1_n:INT to "0".

● Conditions for generating an arbitration lost interrupt when IBSR_n:BB = 0

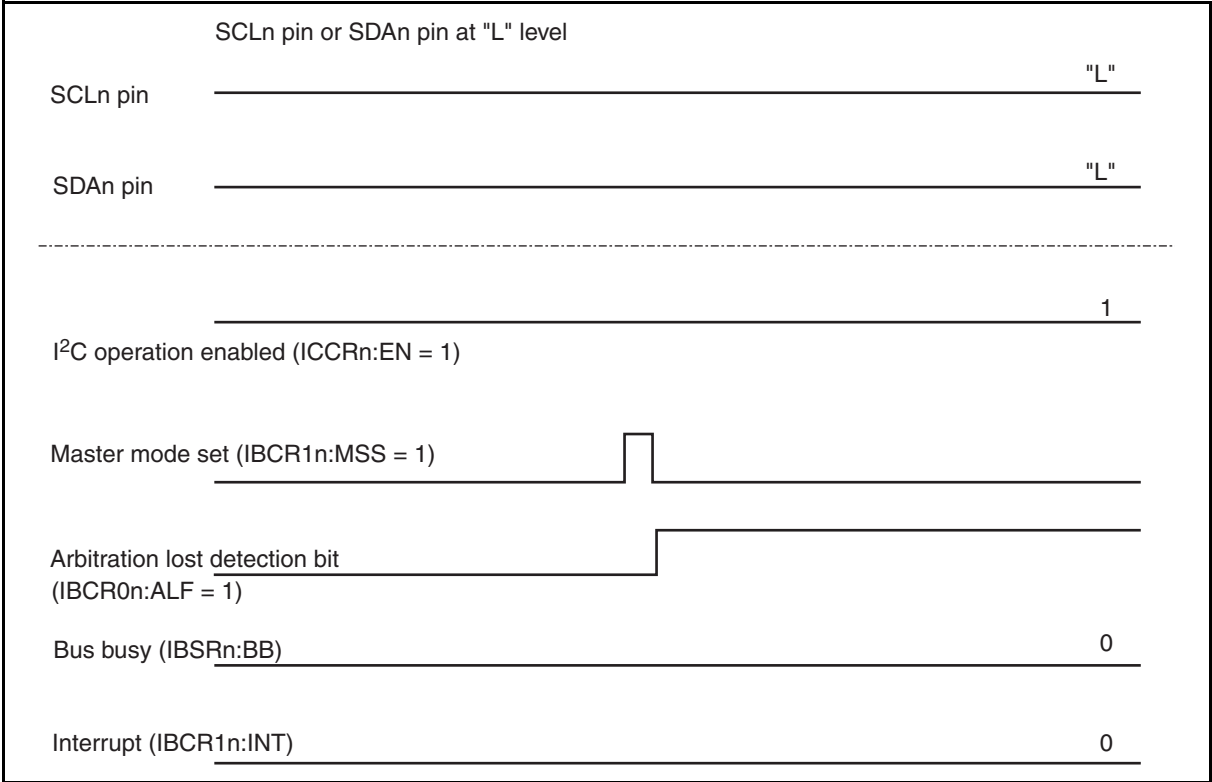

When a start condition is generated by the program (by setting the IBCR1_n:MSS bit to "1") at the timing shown in Figure 23.6-3 or Figure 23.6-4, interrupt generation (IBCR1_n:INT = 1) is prohibited by arbitration lost detection (IBCR0_n:ALF = 1).

- Conditions (1) in which no interrupt is generated due to arbitration lost

If the program triggers a start condition (by setting the IBCR1_n:MSS bit to "1") when no start condition has been detected (IBSR_n:BB = 0) and the SDA_n and SCL_n line pins are at the "L" level.

Figure 23.6-3 Timing Diagram with No Interrupt Generated with IBCR0n:ALF = 1

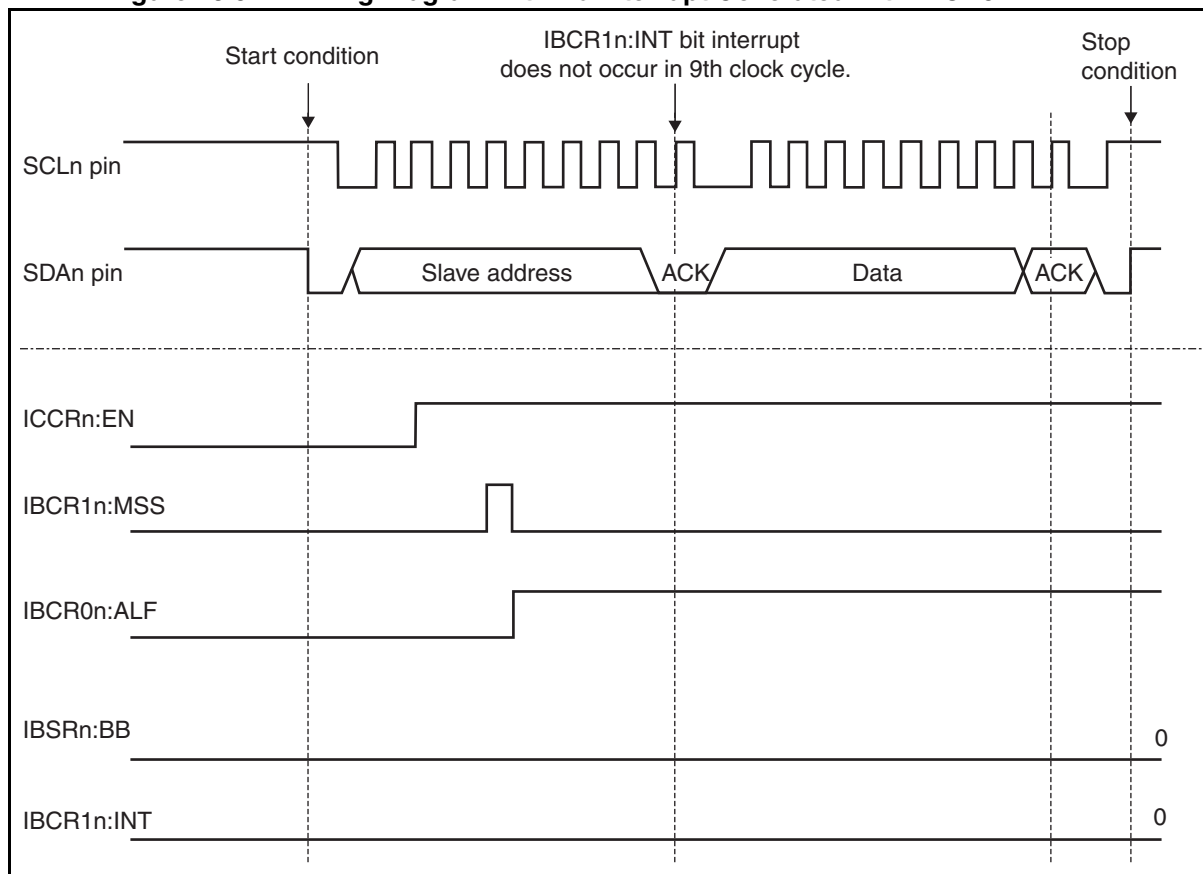

- Conditions (2) in which no interrupt is generated due to arbitration lost

If the program enables I²C bus interface operation (by setting the ICCRn:EN bit to "1") and triggers a start condition (by setting the IBCR1n:MSS bit to "1") when the I²C bus is in use by another master.

This is because, as shown in Figure 23.6-4, this I²C bus interface cannot detect the start condition (IBSRn:BB = 0) if another master starts communications on the I²C bus when the operation of this I²C bus interface has been disabled (ICCRn:EN = 0).

Figure 23.6-4 Timing Diagram with No Interrupt Generated with IBCR0n:ALF = 1

If this situation can occur, use the following procedure to set up the module from the software.

1. Trigger a start condition from the program (by setting the IBCR1n:MSS bit to "1").
2. Check the IBCR0n:ALF and IBSRn:BB bits in the arbitration lost interrupt.

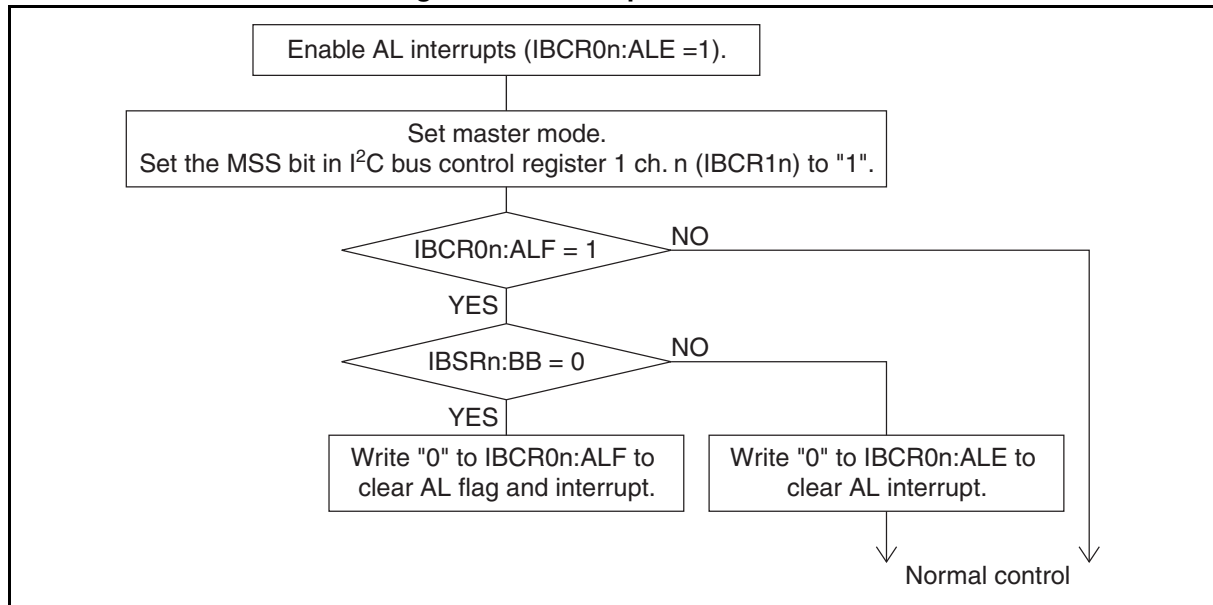

If IBCR0n:ALF = 1 and IBSRn:BB = 0, clear the IBCR0n:ALF bit to "0".

If IBCR0n:ALF = 1 and IBSRn:BB = 1, clear the IBCR0n:ALE bit to "0" and perform control as normal. (Normal control means writing "0" to the IBCR1n:INT bit in the INT interrupt to clear IBCR0n:ALF to "0".)

In other cases, perform control as normal (Normal control means writing "0" to the IBCR1n:INT bit in the INT interrupt to clear IBCR0n:ALF.)

The following sample flow chart illustrates the procedure:

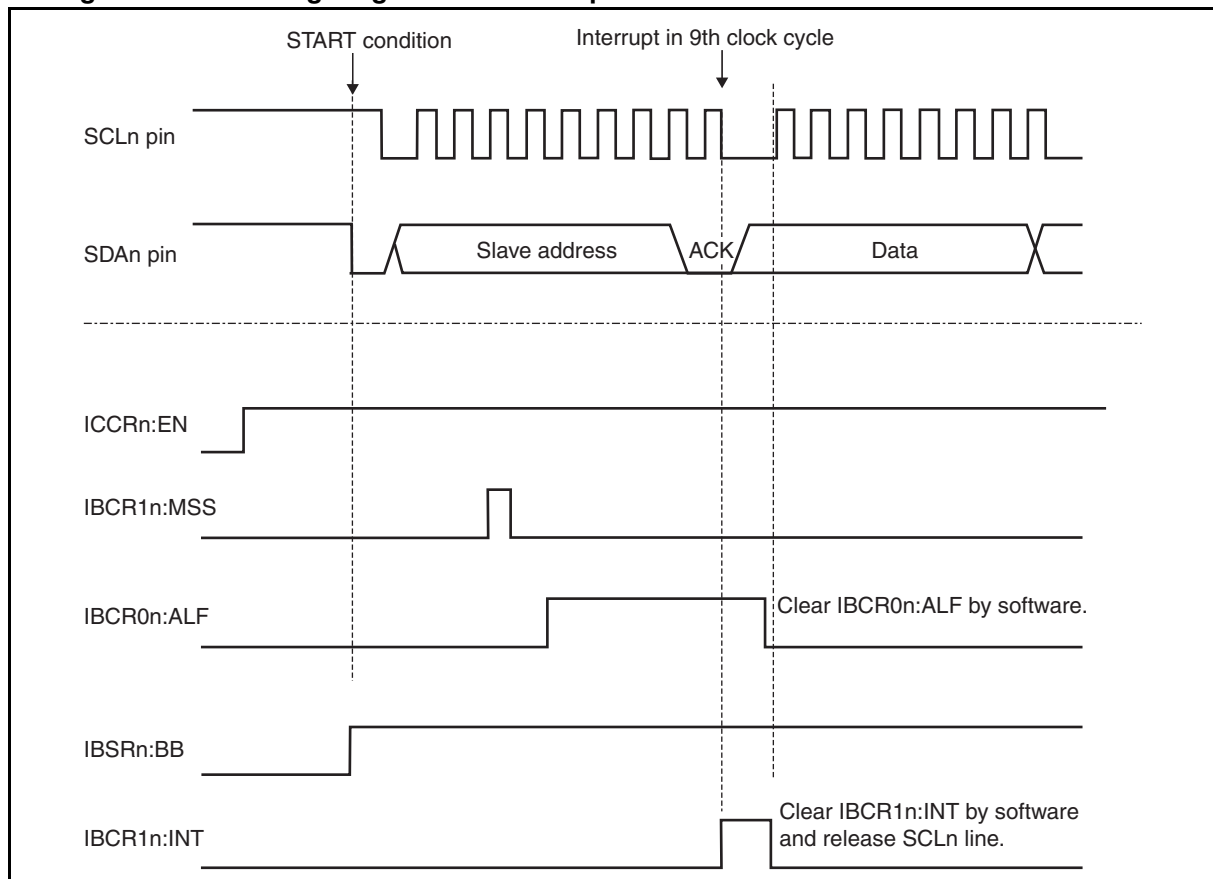

Figure 23.6-5 Sample Flow Chart 1

● Example of generating an interrupt (IBCR1n:INT = 1) with "IBCR0n:ALF = 1" detected

If a START condition is generated by the program (by setting the IBCR1n:MSS bit to "1") with the bus busy (IBSRn:BB = 1) and arbitration lost detected, a IBCR1n:INT bit interrupt occurs upon detection of "IBCR0n:ALF = 1".

Figure 23.6-6 Timing Diagram with Interrupt Generated with "IBCR0n:ALF = 1" Detected

23.6.2 Function to Wake up the MCU from Standby Mode

The wakeup function enables the I²C macro to be accessed while the MCU is in stop or watch mode.

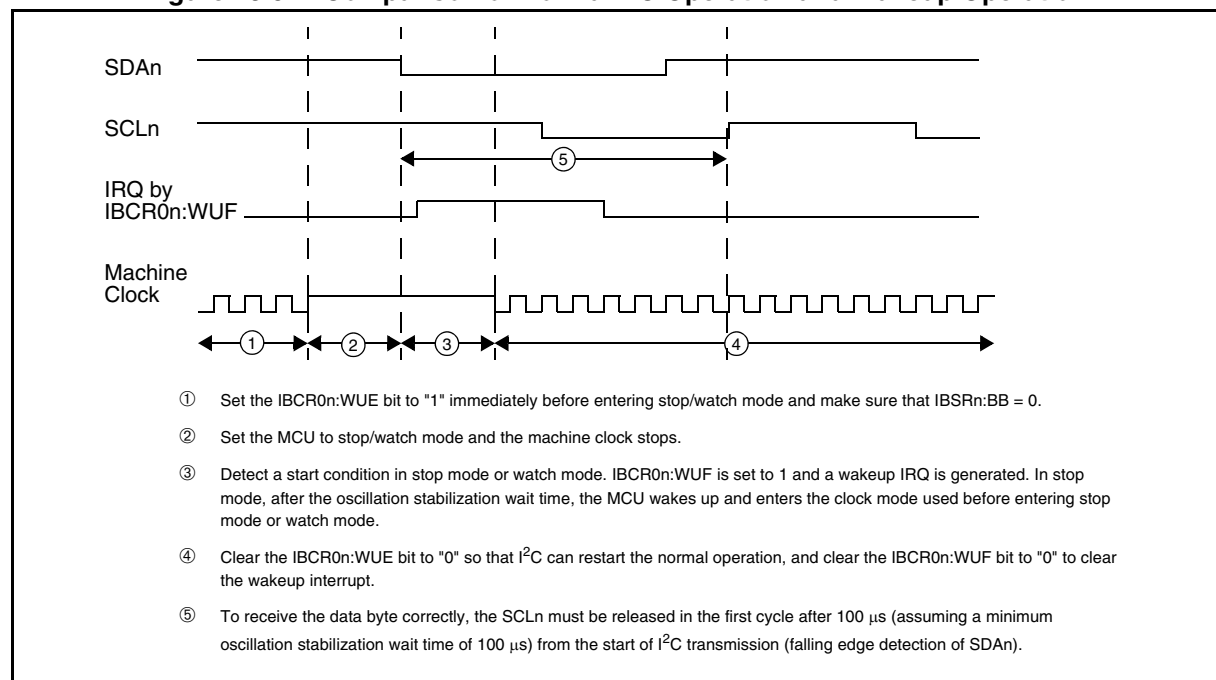

■ Function to Wake Up the MCU from Standby Mode

The I²C macro includes a function to wake up the MCU from standby mode. The function is enabled by writing "1" to the IBCR0n:WUE bit.

With the MCU in stop mode or watch mode and the IBCR0n:WUE bit set to "1", if a start condition is detected on the I²C bus, the wakeup interrupt request flag bit (IBCR0n:WUF) is set to "1" and the wakeup interrupt request is generated to wake up the MCU from stop/watch mode.

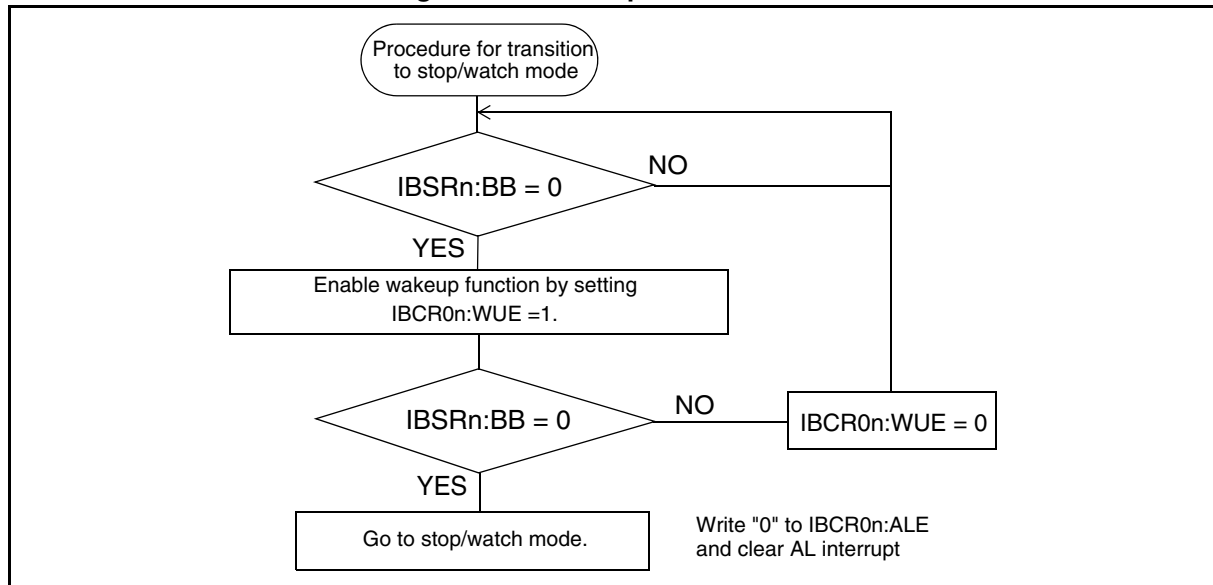

- Set IBCR0n:WUE to "1" immediately before setting the MCU to stop or watch mode. Similarly, clear IBCR0n:WUE (by writing "0") after the MCU wakes up from stop or watch mode so that I²C operation can restart as soon as possible.
- The wakeup function only applies to the MCU stop and watch modes.

Figure 23.6-7 Comparison of Normal I²C Operation and Wakeup Operation

The following sample flow chart illustrates the wakeup function.

Figure 23.6-8 Sample Flow Chart 2

23.7 Registers

This section describes the registers of the I²C bus interface.

Table 23.7-1 List of I²C Bus Interface Registers

Register abbreviation	Register name	Reference
IBCR0n	I ² C bus control register 0 ch. n	23.7.1
IBCR1n	I ² C bus control register 1 ch. n	23.7.2
IBSRn	I ² C bus status register ch. n	23.7.3
IDDRn	I ² C data register ch. n	23.7.4
IAARn	I ² C address register ch. n	23.7.5
ICCRn	I ² C clock control register ch. n	23.7.6

23.7.1 I²C Bus Control Register 0 ch. n (IBCR0n)

The I²C bus control register 0 ch. n (IBCR0n) controls the address acknowledge in the transmission of the first byte, selects the timing of the transfer completion interrupt, and enables or disables the arbitration lost interrupt, the STOP condition detection interrupt and MCU standby wakeup function.

Register Configuration

bit	7	6	5	4	3	2	1	0
Field	AACKX	INTS	ALF	ALE	SPF	SPE	WUF	WUE
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

Register Functions

[bit7] AACKX: Address acknowledge disable bit

This bit controls the address acknowledge in the transmission of the first byte.

Writing "0" to this bit causes the address acknowledge to be output automatically (The address acknowledge is returned automatically if the slave address matches).

Writing "1" to this bit prevents the address acknowledge from being output.

Modify the setting of this bit in either of the following ways:

- Write "1" to this bit in master mode.
- Clear this bit to "0" after checking that the bus busy bit (IBSRn:BB) is "0".

Notes:

- If AACKX = 1 and IBSRn:FBT = 0 when a transfer completion interrupt is generated (IBCR1n:INT = 1), no address acknowledge is output even though the I²C address matches the slave address. Clear the IBCR1n:INT bit to "0" as an interrupt is generated upon completion of transfer of each byte of address/data in the same way as during addressing.
- If AACKX = 1 and IBSRn:FBT = 1 when a transfer completion interrupt is generated (IBCR1n:INT = 1), "1" might be written to AACKX after addressing as in slave mode. Either continue normal communication after setting AACKX to "0" again or restart communication after disabling I²C operation (ICCRn:EN = 0).

bit7	Details
Writing "0"	Enable address acknowledge.
Writing "1"	Disables address acknowledge.

[bit6] INTS: Timing select bit for transfer completion flag bit at data reception

This bit selects the timing of the transfer completion interrupt (IBCR1n:INT) when data is received. Modify this bit only when IBSRn:TRX = 0 and IBSRn:FBT = 0.

Writing "0" to this bit sets the transfer completion interrupt request flag bit (IBCR1n:INT) to "1" in the ninth SCLn cycle.

Writing "1" to this bit sets the transfer completion interrupt request flag bit (IBCR1n:INT) to "1" in the eighth SCLn cycle.

Notes:

- The transfer completion interrupt request flag bit (IBCR1n:INT) is set to "1" always in the ninth SCLn cycle except during data reception (IBSRn:TRX = 1 or IBSRn:FBT = 1).
- If the data acknowledge depends on the content of the received data (such as packet error checking used by the SM bus), control the data acknowledge by setting the data acknowledge enable bit (IBCR1n:DACKE) after writing "1" to this bit (for example, using a previous transfer completion interrupt) to read latest received data.

- The latest data acknowledge (IBSRn:LRB) can be read after the acknowledge has been received (IBSRn:LRB must be read during the transfer completion interrupt in the ninth SCLn cycle.) If acknowledge is read when this bit is "1", therefore, write "0" to this bit in the transfer completion interrupt in the eighth SCLn cycle so that another transfer completion interrupt will occur in the ninth SCLn cycle.

bit6	Details
Writing "0"	Sets the INT bit to "1" in the ninth SCLn cycle.
Writing "1"	Sets the INT bit to "1" in the eighth SCLn cycle.

[bit5] ALF: Arbitration lost interrupt request flag bit

This bit detects the arbitration lost.

An arbitration lost interrupt request is generated if this bit and the IBCR0n:ALE bit are both "1".

If one of the following conditions is satisfied, this bit is set to "1".

- An arbitration lost is detected when this device is transmitting data/address as a master.
- "1" is written to the IBCR1n:MSS bit with the I²C bus being used by another system. However, when "1" is written to the MSS bit after this device returns AACK or GACK as a slave, the ALF bit is not set to "1".

If one of the following conditions is satisfied, this bit is set to "0".

- With IBSRn:BB = 0, "0" is written to the ALF bit.
- "0" is written to the IBCR1n:INT bit to clear the transmission completion flag bit.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit5	Details
Reading "0"	Indicates that no arbitration lost has been detected.
Reading "1"	Indicates that an arbitration lost has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit4] ALE: Arbitration lost interrupt enable bit

This bit enables or disables the arbitration lost interrupt.

When this bit and the ALF bit are both set to "1", an arbitration lost interrupt request is generated.

bit4	Details
Writing "0"	Disables the arbitration lost interrupt.
Writing "1"	Enables the arbitration lost interrupt.

[bit3] SPF: STOP detection interrupt request flag bit

This bit detects the STOP condition.

When this bit and the IBCR0n:SPE bit are both set to "1", a STOP detection interrupt request is generated.

With the bus busy, when a valid STOP condition is correctly detected, this bit is set to "1".

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit3	Details
Reading "0"	Indicates that no STOP condition has been detected.
Reading "1"	Indicates that a STOP condition has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit2] SPE: STOP detection interrupt enable bit

This bit enables or disables the STOP detection interrupt.

When this bit and the SPF bit are both set to "1", a STOP detection interrupt request is generated.

bit2	Details
Writing "0"	Disables the STOP detection interrupt.
Writing "1"	Enables the STOP detection interrupt.

[bit1] WUF: MCU standby mode wakeup interrupt request flag bit

This bit detects an MCU standby mode wakeup in stop mode or watch mode.

When this bit and the IBCR0n:WUE bit are both set to "1", a wakeup interrupt request is generated.

With the wakeup function enabled (WUE = 1), when a START condition is detected, the WUF bit is set to "1".

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit1	Details
Reading "0"	Indicates that no START condition has been detected.
Reading "1"	Indicates that a START condition has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit0] WUE: MCU standby mode wakeup function enable bit

This bit enables or disables the MCU standby mode wakeup function in stop mode or watch mode.

In stop mode or watch mode, when this bit is set to "1" and a START condition is generated, a wakeup interrupt request is generated to start the I²C operation.

bit0	Details
Writing "0"	Disables the MCU standby mode wakeup function in stop mode or watch mode.
Writing "1"	Enables the MCU standby mode wakeup function in stop mode or watch mode.

Notes:

- Write "1" to this bit right before the MCU enters stop mode or watch mode. To ensure that the I²C operation can restart immediately after the MCU wakes up from stop mode or watch mode, clear (write "0" to) this bit as soon as possible.
- When a wakeup interrupt request is generated, the MCU wakes up after the oscillation stabilization wait time elapses. In order to prevent data loss from occurring immediately after the MCU wakes up, after 100 μ s (assuming that the minimum oscillation stabilization wait time is 100 μ s) elapses since a wakeup caused by the start of I²C transmission (upon detection of the falling edge of SDA_n), the SCL_n must rise in the first cycle and the first bit must be received as data.
- In standby mode of the MCU, the status flags, state machine, and I²C bus output for the I²C function keep their states existing before the MCU entered standby mode. To prevent a hang-up of the entire I²C bus system, ensure that IBSRn:BB is set to "0" before making the MCU enter standby mode.
- The wakeup function does not support the transition of the MCU to stop mode or watch mode with the BB bit set to "1". When the MCU enters stop mode or watch mode with the BB bit set to "1", a bus error occurs upon detection of a START condition.
- The wakeup function is effective only when the MCU is in stop mode or watch mode.

Note:

The values of the AACKX, INTS, and WUE bits in the IBCR0n register become "0" and non-writable when the I²C operation is disabled (ICCRn:EN = 0).

23.7.2 I²C Bus Control Register 1 ch. n (IBCR1n)

The I²C bus control register 1 ch. n (IBCR1n) controls the following functions: bus error interrupt, START condition generation, master/slave mode selection, data acknowledge, general call acknowledge and transfer completion interrupt.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BER	BEIE	SCC	MSS	DACKE	GACKE	INTE	INT
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] BER: Bus error interrupt request flag bit

This bit detects the bus error.

When this bit and the BEIE bit are both set to "1", a bus error interrupt is generated.

This bit is set to "1" when an invalid START condition or an invalid STOP condition is detected.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit7	Details
Reading "0"	Indicates that no bus error has been detected.
Reading "1"	Indicates that an invalid START condition or an invalid STOP condition has been detected.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit6] BEIE: Bus error interrupt enable bit

This bit enables or disables the bus error interrupt.

When this bit and the BER bit are both set to "1", a bus error interrupt request is generated.

bit6	Details
Writing "0"	Disables the bus error interrupt.
Writing "1"	Enables the bus error interrupt.

[bit5] SCC: START condition generation bit

This bit generates a repeated START condition to restart communications in master mode.

In master mode, writing "1" to this bit generates a repeated START condition.

Writing "0" to this bit has no effect on operation.

bit5	Details
Read access	The read value is always "0".
Writing "0"	Has no effect on operation.
Writing "1"	Generates a repeated START condition in master mode.

Notes:

- Do not set this bit to "1" or the IBCR1n:MSS bit to "0" at the same time.
- With the IBCR1n:INT bit set to "0", an attempt to write "1" to the SCC bit is ignored (no START condition is generated). In addition, with the INT bit set to "1", when writing "1" to the SCC bit and writing "0" to the INT bit occur simultaneously, writing "1" to the SCC bit is given priority.

[bit4] MSS: Master/slave select bit

This bit selects an operation mode from master mode and slave mode.

Writing "1" to this bit while the I²C bus is in the idle state (IBSRn:BB = 0) selects master mode, generates a START condition, and then starts address transfer.

Writing "0" to the bit while the I²C bus is in the busy state (IBSRn:BB = 1) selects slave mode, generates a STOP condition, and then terminates data transfer.

When an arbitration lost occurs during data or address transfer in master mode, this bit is cleared to "0" and the operation mode switches to slave mode.

bit4	Details
Writing "0"	Slave mode
Writing "1"	Master mode

Notes:

- Do not set this bit to "0" or the SCC bit to "1" at the same time.
- With the INT bit set to "0", an attempt to write "0" to the MSS bit is ignored. With the INT bit set to "1", when writing "0" to the MSS bit and writing "0" to the INT bit occur simultaneously, writing "0" to the MSS bit is given priority.
- In slave mode, during transmission or reception, writing "1" to the MSS bit does not set the ALF bit to "1". Do not write "1" to the MSS bit during transmission or reception in slave mode.

[bit3] DACKE: Data acknowledge enable bit

This bit controls the data acknowledge in data reception.

Writing "0" to this bit disables data acknowledge output.

Writing "1" to this bit enables data acknowledge output. In master mode, with this bit set to "1", a data acknowledge is output in the ninth SCLn cycle during data reception. In slave mode, a data acknowledge is output in the ninth SCLn cycle only when an address acknowledgment has already been output.

bit3	Details
Writing "0"	Disables data acknowledge output.
Writing "1"	Enables data acknowledge output.

[bit2] GACKE: General call address acknowledge enable bit

This bit controls the general call address acknowledge.

Writing "0" to this bit disables general call address acknowledge output.

With this bit set to "1", in master mode or slave mode, when a general call address acknowledge (0x00) is received, a general call address acknowledge is output.

bit2	Details
Writing "0"	Disables the general call address acknowledge.
Writing "1"	Enables the general call address acknowledge.

[bit1] INTE: Transfer completion interrupt enable bit

This bit enables or disables the transfer completion interrupt.

When this bit and the IBCR1n:INT bit are both set to "1", a transfer completion interrupt request is generated.

bit1	Details
Writing "0"	Disables the transfer completion interrupt.
Writing "1"	Enables the transfer completion interrupt.

[bit0] INT: Transfer completion interrupt request flag bit

This bit detects the transfer completion.

When this bit and the INTE bit are both set to "1", a transfer completion interrupt request is generated.

If one of the following four conditions is satisfied, upon completion of transferring 1-byte address or data (the setting of the INTS bit determines whether the 1-byte address or data includes an acknowledge.), this bit is set to "1".

- In bus master mode
- The device is addressed as slave.
- The I²C bus interface has received a general call address.
- The I²C bus interface has detected an arbitration lost.
- Arbitration lost detected

If one of the following two conditions is satisfied, this bit is set to "0".

- "0" is written to this bit.
- In master mode, a repeated START condition (IBCR1n:SCC = 1) or a STOP condition (IBCR1n:MSS = 0) is generated.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

Writing "0" to clear this bit (its value becomes "0") releases the SCLn line, and the transmission of the next byte of data is then enabled.

bit0	Details
Reading "0"	Indicates that data transfer has not been completed.
Reading "1"	Indicates that 1-byte data (including an acknowledge) transfer has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

Notes:

- In the case of writing "1" to the SCC bit while this bit is "0", the setting of the SCC bit is given priority, and a START condition is generated.
- In the case of writing "0" to the MSS bit while this bit is "0", the setting of the MSS bit is given priority, and a STOP condition is generated.
- During data reception, with the IBCR0n:INTS bit already set to "1", this bit becomes "1" after 1-byte data (not including an acknowledge) transfer is completed. If the INTS bit is set to "0", this bit becomes "1" after the transmission/reception of 1-byte data/address (including an acknowledge) is completed.

Notes:

- When clearing the interrupt request flag bit (IBCR1n:BER) by writing "0" to it, do not update the interrupt request enable bit (IBCR1n:BEIE) at the same time.
- All bits in the IBCR1n register except the BER and BEIE bits are cleared to "0" either when the I²C bus interface operation is disabled (ICCRn:EN = 0).

23.7.3 I²C Bus Status Register ch. n (IBSRn)

The I²C bus status register ch. n (IBSRn) indicates the status of the I²C bus interface.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BB	RSC	—	LRB	TRX	AAS	GCA	FBT
Attribute	R	R	—	R	R	R	R	R
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] **BB: Bus busy bit**

This bit indicates the bus state.

bit7	Details
Reading "0"	Indicates that a STOP condition has been detected and the bus has entered the idle state.
Reading "1"	Indicates that a START condition has been detected and the bus has entered the busy state.

[bit6] **RSC: Repeated START condition detection bit**

This bit detects the repeated START condition.

This bit is set to "1" when a repeated START condition is detected.

If one of the following conditions is satisfied, this bit is set to "0".

- "0" is written to the IBCR1n:INT bit.
- In slave mode, the slave address does not match the address set in the IAARn register.
- In slave mode, the slave address matches the address set in the IAARn register but the IBCR0n:AACKX bit is set to "1".
- In slave mode, the device receives a general call address, but the IBCR1n:GACKE bit is set to "0".
- A STOP condition is detected.

bit6	Details
Reading "0"	Indicates that no repeated START condition has been detected.
Reading "1"	Indicates that the bus is in use and a repeated START condition has been detected.

[bit5] **Undefined bit**

The read value of this bit is always "0". Writing a value to this bit has no effect on operation.

[bit4] LRB: Acknowledge storage bit

This bit captures the value of the SDAn line in the ninth shift clock cycle during data byte transfer.

This bit is set to "1" when no acknowledge has been detected (SDAn = "H").

If one of the following conditions is satisfied, this bit is set to "0".

- An acknowledge is detected (SDAn = "L").
- A START condition or a STOP condition is detected.

bit4	Details
Reading "0"	Indicates that an acknowledge has been detected in the ninth shift clock cycle.
Reading "1"	Indicates that no acknowledge has been detected in the ninth shift clock cycle.

Note: According to the above description, this bit must be read after an acknowledge (Read the bit value at a transfer completion interrupt in the ninth SCLn cycle). Therefore, if an acknowledge is read with the IBCR0n:INTS bit set to "1", write "0" to the INTS bit at a transfer completion interrupt generated in the eighth SCLn cycle so that another transfer completion interrupt is to be generated in the ninth SCLn cycle.

[bit3] TRX: Data transfer status bit

This bit indicates the data transfer mode.

This bit is set to "1" when data transfer is executed in transmission mode.

If one of the following conditions is satisfied, this bit is set to "0".

- In receive mode, data transfer is executed.
- The device receives an NACK in slave transmit mode.

bit3	Details
Reading "0"	Indicates that the data transfer mode is receive mode.
Reading "1"	Indicates that the data transfer mode is transmit mode.

[bit2] AAS: Addressing detection bit

This bit indicates whether the MCU has undergone addressing in slave mode.

This bit is set to "1" when the MCU has undergone addressing in slave mode.

This bit is set to "0" when a START condition or a STOP condition has been detected.

bit2	Details
Reading "0"	Indicates that the MCU has not undergone addressing in slave mode.
Reading "1"	Indicates that the MCU has undergone addressing in slave mode.

[bit1] GCA: General call address detection bit

This bit detects a general call address.

If one of the following conditions is satisfied, this bit is set to "1".

- The device receives a general call address (0x00) in slave mode.
- With IBCR1n:GACKE set to "1", the device receives a general call address (0x00) in master mode.
- In master mode, an arbitration lost is detected during the transmission of the second byte of a general call address.

If one of the following conditions is satisfied, this bit is set to "0".

- A START condition or a STOP condition is detected.
- In master mode, no arbitration lost is detected during the transmission of the second byte of a general call address.

bit1	Details
Reading "0"	Indicates that the I ² C bus interface has not received a general call address (0x00) in slave mode.
Reading "1"	Indicates that the I ² C bus interface has received a general call address (0x00) in slave mode.

[bit0] FBT: First byte detection bit

This bit detects the first byte.

This bit is set to "1" when a START condition is detected.

If one of the following conditions is satisfied, this bit is set to "0".

- "0" is written to the IBCR1n:INT bit.
- In slave mode, the slave address does not match the address set in the IAARn register.
- In slave mode, the slave address matches the address set in the IAARn register, but the IBCR0n:AACKX bit is "1".
- In slave mode, the device receives a general call address, but the IBCR1n:GACKE bit is "0".
- In slave mode, a STOP condition is detected.

bit0	Details
Reading "0"	Indicates that the receive data is not the first byte in data reception.
Reading "1"	Indicates that the receive data is the first byte (address) in data reception.

23.7.4 I²C Data Register ch. n (IDDRn)

The I²C data register ch. n (IDDRn) sets the data or address to be transmitted, and holds the data or address received.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	D7	D6	D5	D4	D3	D2	D1	D0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

In transmit mode, each bit of the data or address value written to the register is shifted to the SDAn line, starting with the MSB. The write side of this register is double-buffered, where if the bus is in use (IBSRn:BB = 1), the write data is loaded to the 8-bit shift register either when the current data transfer completion interrupt is cleared (writing "0" to the IBCR1n:INT bit) or when a repeated start condition is generated (writing "1" to the IBCR1n:SCC bit). Each bit of the shift register data is output (shifted) to the SDAn line.

Note that writing to this register has no effect on the current data transfer. In slave mode, however, data is transferred to the shift register after the address is determined.

The received data or address can be read from this register at the transfer completion interrupt (IBCR1n:INT = 1). However, since the serial transfer register is directly read from when the received data or address is read, the receive data is valid only when the INT bit is "1".

23.7.5 I²C Address Register ch. n (IAARn)

The I²C address register ch. n (IAARn) register sets the slave address.
In slave mode, the I²C bus interface receives address data from the master and compares it with the value of this register.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	A6	A5	A4	A3	A2	A1	A0
Attribute	—	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] Undefined bit

The read value of this bit is always "0". Writing a value to this bit has no effect on operation.

[bit6:0] A[6:0]: Address bits

These bits set the slave address.

23.7.6 I²C Clock Control Register ch. n (ICCRn)

The I²C clock control register ch. n (ICCRn) register enables the I²C operation and selects the shift clock frequency.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	DMBP	Reserved	EN	CS4	CS3	CS2	CS1	CS0
Attribute	R/W	W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] DMBP: Divider m bypass bit

This bit is used to bypass the divider m to generate the shift clock frequency.

Writing "0" to this bit sets the value set in the CS[4:3] bits as the divider m value (m = ICCRn:CS[4:3]).

When "1" is written to this bit, the divider m is to be bypassed.

Do not write "1" to this bit when the value of divider n is "4" (ICCRn:CS[2:0] = 0b000).

bit7	Details
Writing "0"	The settings of ICCRn:CS[4:3] (clock divide m) are valid.
Writing "1"	The settings of ICCRn:CS[4:3] (clock divide m) are invalid.

[bit6] Reserved bit

Always set this bit "0".

[bit5] EN: I²C bus interface operation enable bit

This bit enables the I²C bus interface operation.

Writing "0" to this bit disables the I²C bus interface operation and clears the following bits to "0".

- AACKX, INTS, and WUE bits in the IBCR0n register
- All bits in the IBCR1n register except the BER and BEIE bits
- All bits in the IBSRn register

Writing "1" to this bit enables the I²C bus interface operation.

bit5	Details
Writing "0"	Disables the I ² C bus interface operation.
Writing "1"	Enables the I ² C bus interface operation.

[bit4:3] CS[4:3]: Clock-1 select bits (Divider m)

[bit2:0] CS[2:0]: Clock-2 select bits (Divider n)

These bits set the shift clock frequency.

The shift clock frequency (F_{sck}) is set by the following equation:

$$F_{sck} = \frac{\phi}{(m \times n + 2)}$$

φ represents the machine clock frequency (MCLK).

bit4:3	Details
Writing "00"	5
Writing "01"	6
Writing "10"	7
Writing "11"	8

bit2:0	Details
Writing "000"	4
Writing "001"	8
Writing "010"	22
Writing "011"	38
Writing "100"	98
Writing "101"	128
Writing "110"	256
Writing "111"	512

Note:

If the standby mode wakeup function is not used, disable the I²C bus interface operation before making the MCU transit to stop mode or watch mode.

23.8 Notes on Using I²C Bus Interface

This section provides notes on using the I²C bus interface.

■ Notes on Using I²C Bus Interface

- Notes on setting I²C bus interface registers
 - Enable the I²C bus interface operation (ICCRn:EN) before setting the I²C bus control registers ch. n (IBCR0n and IBCR1n).
 - Setting the master/slave select bit (IBCR1n:MSS) to "1" starts data transfer.
- Notes on setting the shift clock frequency
 - The shift clock frequency can be calculated by determining the m, n, and DMBP values using the F_{sck} equation. See "23.7.6 I²C Clock Control Register ch. n (ICCRn)" for details of the F_{sck} equation.
 - Do not write "1" to the DMBP bit in the ICCRn register if the value of n is 4 (ICCRn:CS[2:0] = 0b000).
- Notes on priority for simultaneous write operations
 - Conflict between next byte transfer and stop condition
When writing "0" to IBCR1n:MSS and clearing IBCR1n:INT occur simultaneously, the MSS bit is given priority and a STOP condition is generated.
 - Conflict between next byte transfer and start condition
When writing "1" to IBCR1n:SCC and clearing IBCR1n:INT occur simultaneously, the SCC bit is given priority and a START condition is generated.
- Notes on setting up using software
 - Do not select the repeated START condition (IBCR1n:SCC = 1) or slave mode (IBCR1n:MSS = 0) simultaneously.
 - The I²C bus interface cannot return from interrupt processing if an interrupt request enable bit is enabled (IBCR1n:BEIE = 1 or IBCR1n:INTE = 1) with the interrupt request flag bit (IBCR1n:BER or IBCR1n:INT) set to "1". Clear the BER bit or the INT bit.
 - The following bits are cleared to "0" when the I²C bus interface operation is disabled (ICCRn:EN = 0).
 - AACKX, INTS, and WUE bits in the IBCR0n register
 - All bits in the IBCR1n register except the BER bit and the BEIE bit
 - All bits in the IBSRn register
- Notes on data acknowledgment

In slave mode, a data acknowledge is generated if one of the following conditions is satisfied.

 - The received address matches the value in the address register (IAARn) and IBCR0n:AACKX is "0".
 - A general call address (0x00) is received and IBCR1n:GACKE is "1".

● Notes on selecting the transfer complete timing

- The transfer complete timing select bit (IBCR0n:INTS) is valid only during data reception (IBSRn:TRX = 0 and IBSRn:FBT = 0).
- In an operation other than data reception (IBSRn:TRX = 1 or IBSRn:FBT = 1), the transfer completion interrupt (IBCR1n:INT) is always generated in the ninth SCLn cycle.
- If the data acknowledge depends on the content of the received data (such as packet error checking used by the SM bus), control the data acknowledge by setting the data acknowledge enable bit (IBCR1n:DACE) after writing "1" to the IBCR0n:INTS bit (for example, using a previous transfer completion interrupt) to read latest received data.
- The latest data acknowledge (IBSRn:LRB) can be read after the acknowledge is received (IBSRn:LRB must be read at a transfer completion interrupt in the ninth SCLn cycle.) Therefore, if an acknowledge is read with the IBCR0n:INTS bit set to "1", write "0" to the INTS bit at a transfer completion interrupt generated in the eighth SCLn cycle so that another transfer completion interrupt is to be generated in the ninth SCLn cycle.

● Notes on using the MCU standby mode wakeup function

- Write "1" to the IBCR0n:WUE bit right before the MCU enters stop mode or watch mode. To ensure that the I²C operation can restart immediately after the MCU wakes up from stop mode or watch mode, clear (write "0" to) this bit as soon as possible.
- When a wakeup interrupt request is generated, the MCU wakes up after the oscillation stabilization wait time elapses. In order to prevent data loss from occurring immediately after the MCU wakes up, after 100 μs (assuming that the minimum oscillation stabilization wait time is 100 μs) elapses since a wakeup caused by the start of I²C transmission (upon detection of the falling edge of SDA_n), the SCL_n must rise in the first cycle and the first bit must be received as data.
- In standby mode of the MCU, the status flags, state machine, and I²C bus output for the I²C function keep their states existing before the MCU entered standby mode. To prevent a hang-up of the entire I²C bus system, ensure that IBSRn:BB is set to "0" before making the MCU enter standby mode.
- The wakeup function does not support the transition of the MCU to stop mode or watch mode with the BB bit set to "1". When the MCU enters stop mode or watch mode with the BB bit set to "1", a bus error occurs upon detection of a START condition.
- To ensure that the I²C bus interface operation correctly executes its operation, always clear IBCR0n:WUE to "0" after the MCU wakes up from stop mode or watch mode, regardless of whether the MCU has been woken up by to the I²C wakeup function or the wakeup function of another resource (such as an external interrupt).

CHAPTER 24

LCD CONTROLLER

(MB95710L SERIES)

This chapter describes the functions and operations of the LCD controller (LCDC).

- 24.1 Overview
- 24.2 Configuration
- 24.3 Pins
- 24.4 Display RAM
- 24.5 Interrupt
- 24.6 Operations
- 24.7 Registers
- 24.8 Notes on Using LCD Controller

24.1 Overview

The LCD controller has two modes: 8 COM mode and 4 COM mode.

In 8 COM mode, the LCD controller can use 36 bytes of display data memory and controls an LCD display via eight common outputs and 36 segment outputs. It also has two different bias output options for driving an LCD panel.

In 4 COM mode, the LCD controller can use 20 bytes of display data memory and controls an LCD display via four common outputs and 40 segment outputs. It also has three different bias output options for driving an LCD panel.

■ Functions of LCD Controller

The LCD controller uses its segment and common outputs to display the content of the display data memory (display RAM) directly on the LCD panel.

- It selects the 8 COM mode and the 4 COM mode through software.
- It has an LCD drive voltage divider resistor whose resistance value can be selected from 10 k Ω or 100 k Ω through software. An external divider resistor can also be used instead.
- In 8 COM mode, eight common outputs (COM0 to COM7) and 36 segment outputs (SEG00 to SEG35) are available.
- In 4 COM mode, four common outputs (COM0 to COM3) and 40 segment outputs (SEG00 to SEG39) are available.
- The display RAM size is 36 bytes (36 \times 8 bits) in 8 COM mode and 20 bytes (40 \times 4 bits) in 4 COM mode.
- It can use the main clock or the subclock as its operating clock.
- It has a blinking function, which is only available to certain pins.
- It can directly drive an LCD panel.
- In 8 COM mode, the bias can be selected from 1/3 or 1/4.
- In 4 COM mode, the duty can be selected from 1/2, 1/3 or 1/4 (governed by the bias setting).
- The interrupt is in sync with the LCD module frame frequency.

Table 24.1-1 lists the bias-duty combinations available.

Table 24.1-1 Combinations of Bias and Duty

Duty	1/2 bias	1/3 bias	1/4 bias
1/2	○	X	X
1/3	X	○	X
1/4	X	○	X
1/8, BLS8 = 0	X	○	X
1/8, BLS8 = 1	X	X	○

○ : Recommended combination

X : Prohibited combination

24.2 Configuration

The LCD controller consists of the following blocks, which are divided according to their functions into a controller section that generates the segment and common signals based on the content of the display RAM, and a driver section that drives the LCD.

Controller section

- LCDC control registers (LCDCC1 and LCDCC2)
- LCDC enable registers (LCDCE1 to LCDCE7)
- LCDC blinking setting registers (LCDCB1 and LCDCB2)
- Display RAM
- Clock selection
- Timing control

Driver section

- AC waveform generator circuit
- Common driver
- Segment driver
- Divider resistor

■ Block Diagrams of LCD Controller

Figure 24.2-1 Block Diagram of LCD Controller (8 COM Mode)

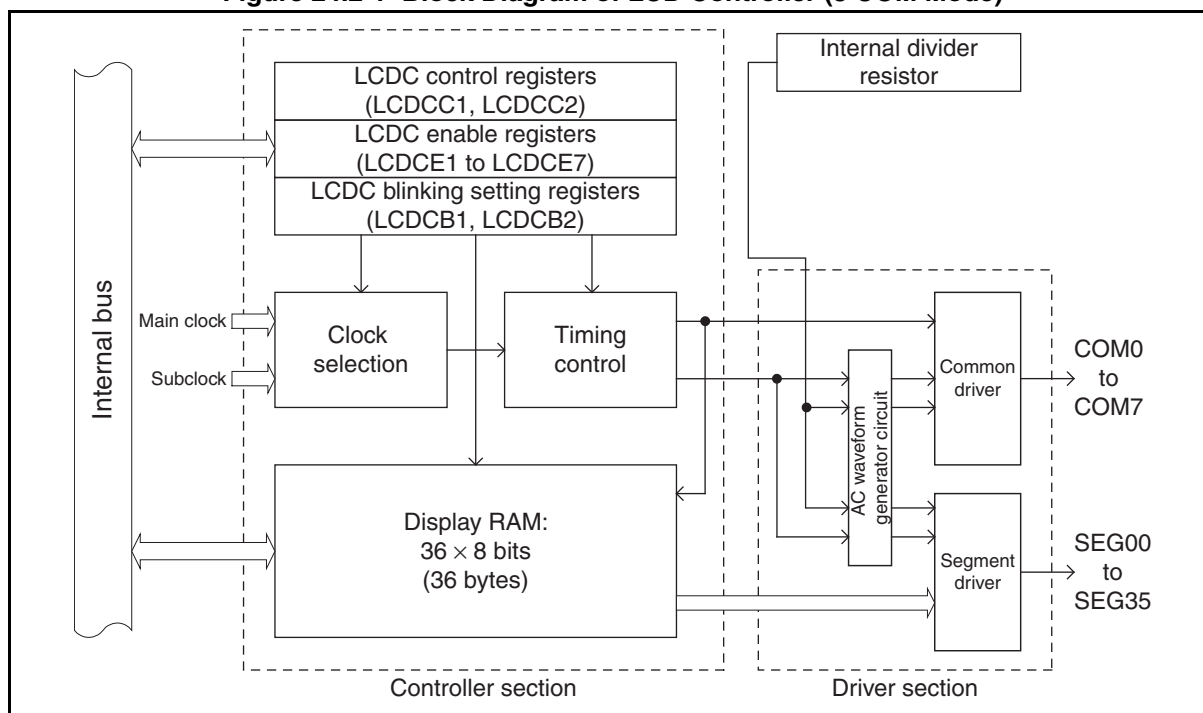

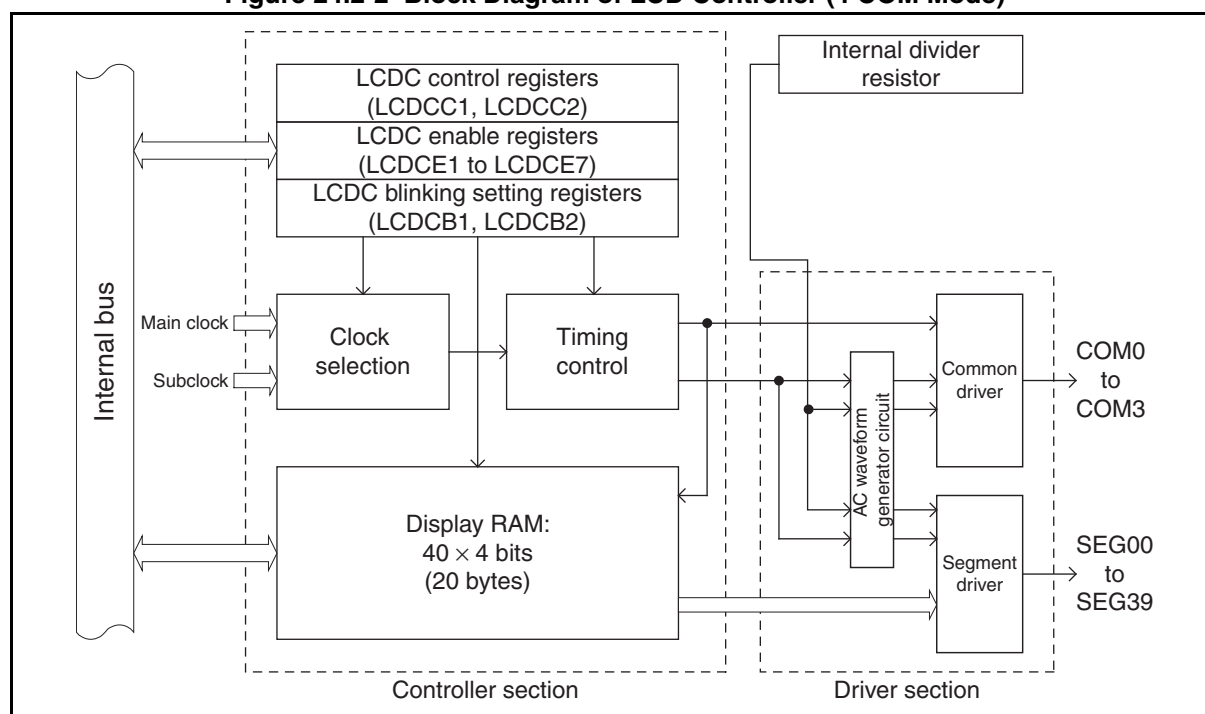

Figure 24.2-2 Block Diagram of LCD Controller (4 COM Mode)

● LCDC control register 1 (LCDCC1)

This register selects the clock for generating the frame period, the display mode, the frame period clock, and controls the LCD drive power supply.

● LCDC control register 2 (LCDCC2)

This register enables and disables interrupts, indicates interrupt status and sets the following parameters:

- Internal resistance value (10 kΩ or 100 kΩ)
- Bias to be used in 8 COM mode (1/3 or 1/4)
- Displaying data or a blank screen
- Inverted display

● LCDC enable registers 1 to 7 (LCDCE1 to LCDCE7)

These registers control port inputs, blink interval, and pins.

● LCDC blinking setting register 1 (LCDCB1), LCDC blinking setting register 2 (LCDCB2)

These registers turn on and off blinking.

● Display RAM

In 8 COM mode, 36 × 8 bits of RAM is available for generating segment output signals.

In 4 COM mode, 40 × 4 bits of RAM is available for generating segment output signals.

The content of the display RAM is read automatically in sync with the common signal selection timing and is output from segment output pins.

When the display RAM is modified, the content of the VRAM is output from segment output pins.

- Clock selection

The frame frequency is generated based on the frequency selected from eight options generated from two types of clock.

- Timing control

The COM signals and SEG signals are controlled based on the frame frequency and register settings.

- AC waveform generator circuit

The circuit generates AC waveforms for driving the LCD according to timing control signals.

- Common driver

This is the driver of the LCD common (COM) pins.

- Segment driver

This is the driver of the LCD segment (SEG) pins.

- Divider resistor

This resistor generates the LCD drive voltage. An external divider resistor can be used when an LCD drive power supply pin (V0 to V4) serves as a divider resistor connection pin.

■ LCD Controller Power Supply Voltage

The power supply voltage for the LCD driver is generated by the internal divider resistors or by connecting an external divider resistor to an LCD drive power supply pin (V0 to V4).

■ Input Clock

The LCD controller uses the clock output from the time-base timer or from the watch prescaler as the input clock (operation clock).

24.2.1 Internal Divider Resistors of LCD Controller

The internal driver resistors generate power supply voltage for the LCD driver.

■ Internal Divider Resistors

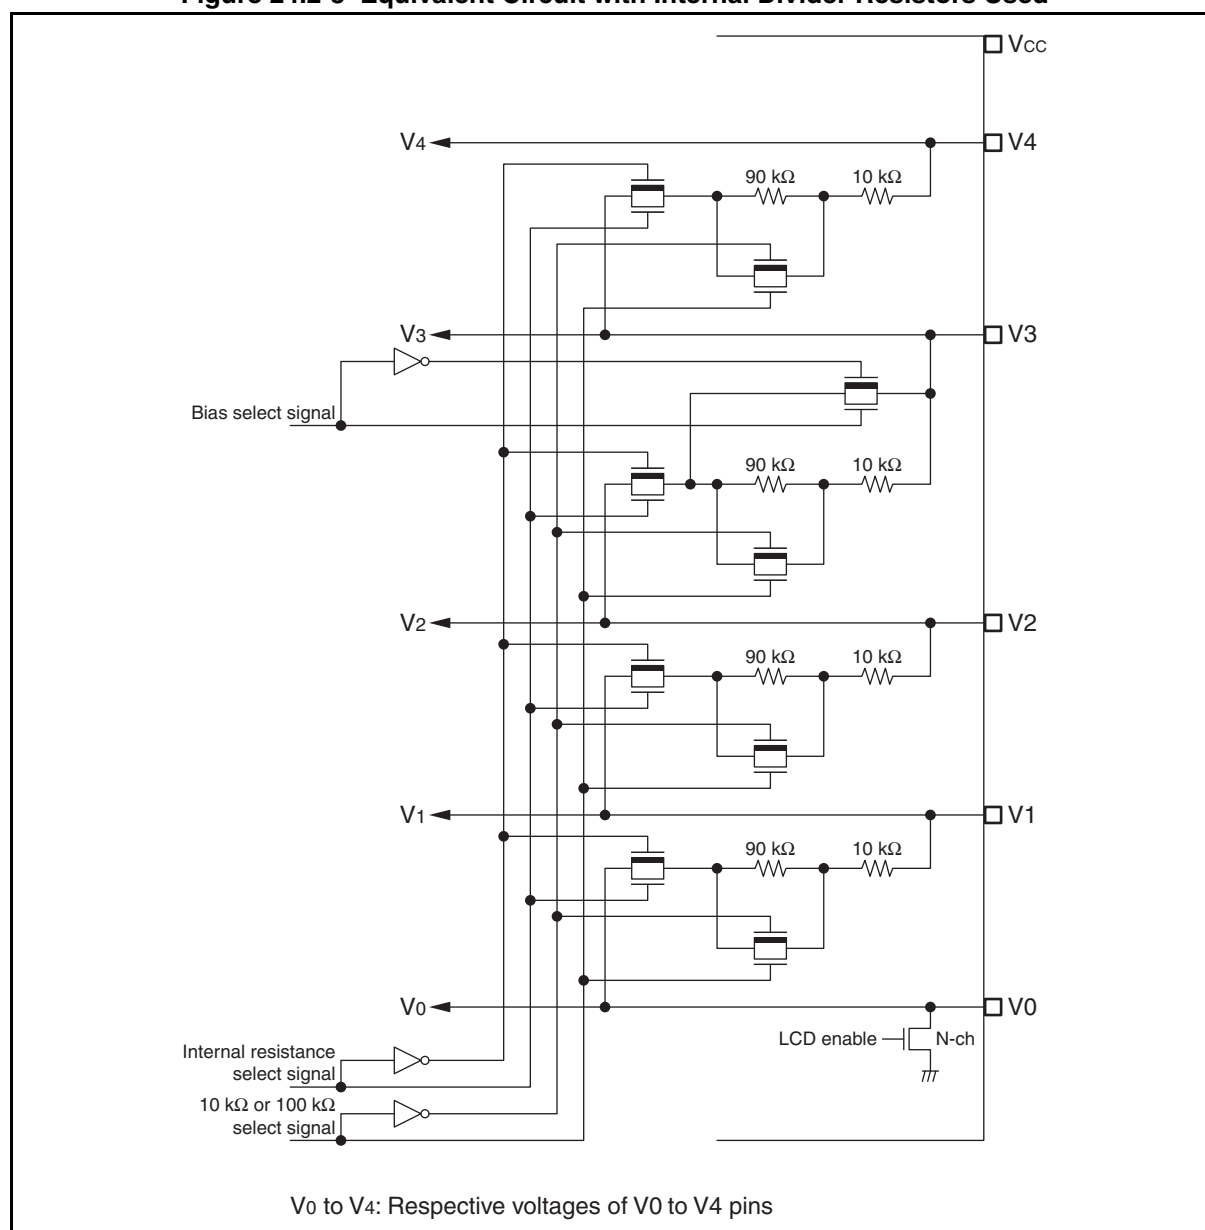

This series has internal divider resistors. In addition, an external divider resistor can be connected to an LCD drive power supply pin (V0 to V4).

The internal and external divider resistors are selected by the driving power control bit in the LCDC control register (LCDCC1:VSEL). Setting the VSEL bit to "1" energizes internal divider resistors. To use only internal divider resistors without using any external divider resistor, set the VE3 bit in the LCDC enable register 1 (LCDCE1) to "1". (When the internal divider resistors are used, the V4 pin cannot be used as a general-purpose I/O port.)

With the LCD operation stopped (LCDCC1:MS[2:0] = 0b000) and the LCD controller operation in main stop mode or in watch mode disabled (LCDCC1:LCDEN = 0), the LCD controller stops immediately after the device transits to main stop or watch mode (STBC:TMD = 1).

Figure 24.2-3 shows an equivalent circuit with internal divider resistors used.

Figure 24.2-3 Equivalent Circuit with Internal Divider Resistors Used

■ Use of Internal Divider Resistors and Brightness Control

There are two types of internal divider resistor: 10 k Ω and 100 k Ω . Figure 24.2-4 shows examples of using internal divider resistors.

If sufficient brightness cannot be achieved with the internal divider resistors in use, connect a variable resistor (VR) externally (between the Vcc pin and the V4 pin) to adjust the voltage of the V4 pin. Figure 24.2-5 illustrates connecting a VR to the V4 pin to control brightness.

Figure 24.2-4 Circuits with Internal Divider Resistors

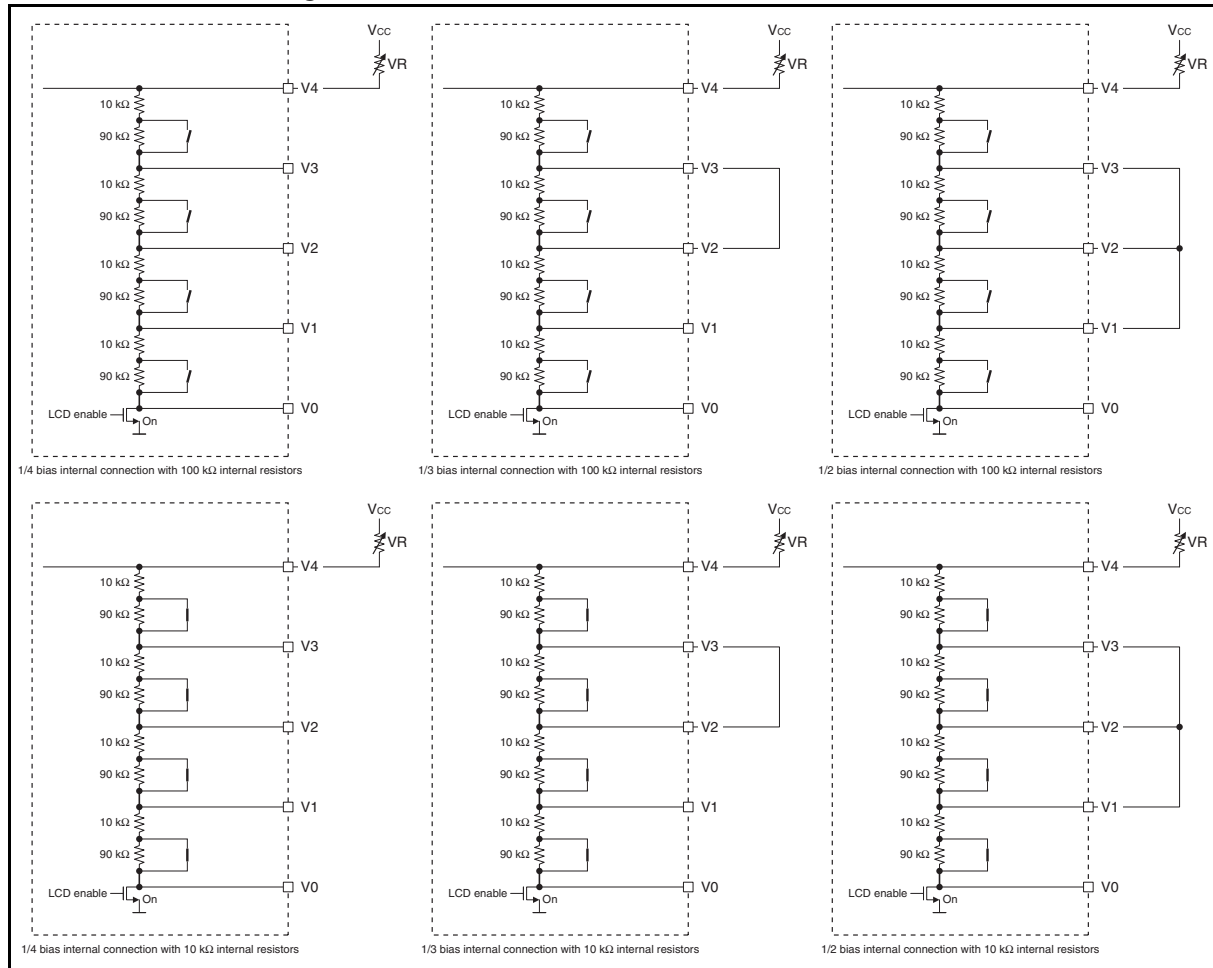

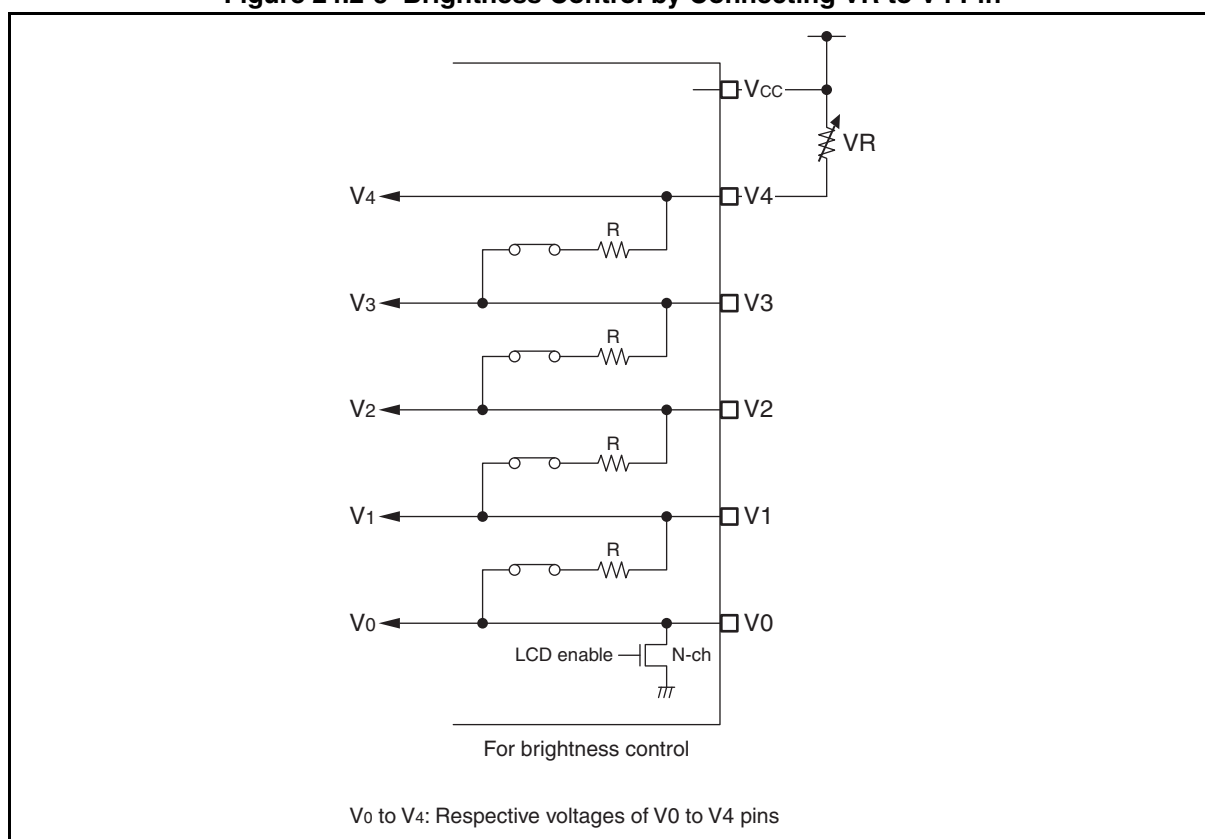

Figure 24.2-5 Brightness Control by Connecting VR to V4 Pin

24.2.2 External Divider Resistor for LCD Controller

The V0 to V4 pins of this series can be connected to external divider resistors. Connecting a variable resistor between the Vcc pin and the V4 pin can control brightness.

■ External Divider Resistor

Instead of internal divider resistors, external divider resistors can be connected to the LCD drive power supply pins (V0 to V4). Figure 24.2-6 illustrates external divider resistors connection with bias. Table 24.2-1 shows LCD drive voltages.

Figure 24.2-6 External Divider Resistors Connection

Table 24.2-1 LCD Drive Voltage Settings

	V4	V3	V2	V1	V0
1/2 bias	VLCD	X	1/2 VLCD	X	GND
1/3 bias	VLCD	2/3 VLCD	2/3 VLCD	1/3 VLCD	GND
1/4 bias	VLCD	3/4 VLCD	1/2 VLCD	1/4 VLCD	GND

VLCD : LCD operating voltage

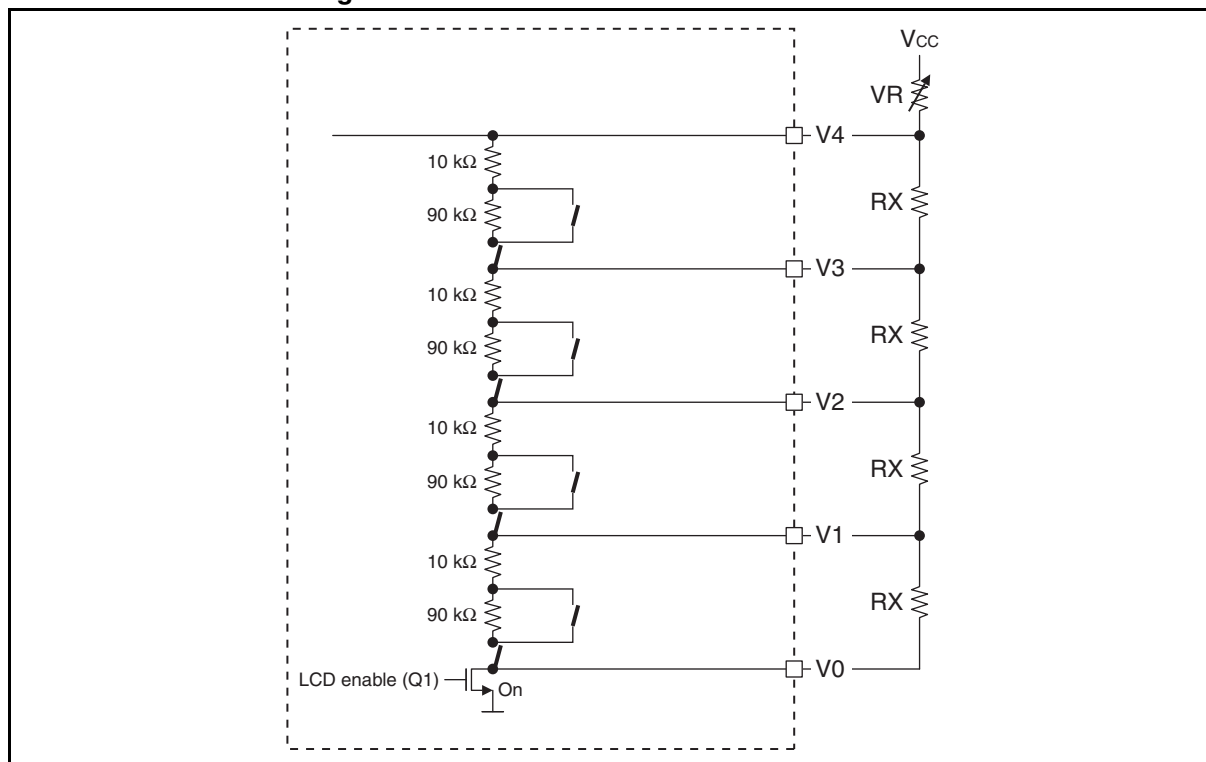

X : No external divider resistor

GND : Ground

■ Using External Divider Resistors

Since the V0 pin is connected to Vss (GND) internally via a transistor, in the case of using external divider resistors, connecting the Vss end of a divider resistor to the V0 pin cuts off current that is flowing to resistors when the LCD controller stops. illustrates the use of external divider resistors.

Figure 24.2-7 Use of External Divider Resistors

1. To connect the external divider resistors without being affected by the internal divider resistors, write "0" to the drive voltage control bit in the LCDC control register 1 (LCDCC1:VSEL) to disconnect all internal divider resistors. Write "1" to the V4 to V0 select bits in the LCDC enable register 1 (LCDCE1:VE[4:0]) to use a pin as an LCD drive power supply pin.
2. When the internal divider resistors are disconnected, writing a value other than "0b000" to the display mode select bits (MS[2:0]) in the LCDCC1 register turns on the LCDC enable transistor (Q1) and, in turn, current flows to the external divider resistors.
3. Writing "0b000" to the MS[2:0] bits turns off the LCDC enable transistor (Q1) and, in turn, no current flows to the external divider resistors.

Note:

The appropriate resistance of an external RX resistor depends on the LCD used. Use an external RX resistor whose resistance is suitable for the LCD used.

24.3 Pins

This section describes the pins of the LCD controller.

■ Pins of LCD Controller

The LCD controller has the following pins: eight common output pins (COM0 to COM7), 40 segment output pins (SEG00 to SEG39), and five LCD drive power supply pins (V0 to V4).

To use one of these pins for the LCD, set a bit corresponding to that pin in the LCDC enable registers (LCDCE1 to LCDCE7) to "1".

To use a pin for the LCD shared with a general-purpose I/O port as a general-purpose I/O port, set a bit corresponding to that pin in an LCDC enable register (LCDCE1 to LCDCE7) to "0", and then set the port input control bit in the LCDC enable register 1 (LCDCE1:PICTL) to "1".

● COM0 to COM7 pins

In 8 COM mode, COM0 to COM7 function as LCD common output pins.

In 4 COM mode, COM0 to COM3 function as LCD common output pins, and COM4 to COM7 function only as general-purpose I/O ports regardless of the settings of the LCDCE1 to LCDCE7 registers.

COM0 to COM7 can also function as general-purpose I/O ports.

● SEG00 to SEG39 pins

In 8 COM mode, SEG00 to SEG35 function as LCD segment output pins, and the default functions of SEG36 to SEG39 are general-purpose I/O ports regardless of the settings of the LCDCE1 to LCDCE7 registers.

In 4 COM mode, SEG00 to SEG39 function as LCD segment output pins.

SEG00 to SEG39 can also function as general-purpose I/O ports.

● V0 to V4 pins

V0 to V4 are power supply pins for driving the LCD.

They can also function as general-purpose I/O ports.

24.4 Display RAM

The display RAM size varies between 8 COM mode and 4 COM mode.

In 8 COM mode, the display RAM has 36×8 bits (36 bytes) of display data memory for generating segment output signals.

In 4 COM mode, the display RAM has 40×4 bits (20 bytes) of display data memory for generating segment output signals.

■ Display RAM and Output Pins

The content of the display RAM is read automatically in sync with the common signal selection timing and is output from segment output pins.

A bit containing "1" is converted into a selected voltage (displayed on the LCD); a bit containing "0" into a non-select voltage (not displayed on the LCD).

Since the LCD display operation is executed asynchronously with the CPU operation, data can be read from or written to the display RAM at any time. When a pin shared between a segment output pin and a general-purpose I/O port pin is not used as a segment output pin, the pin can be used as a general-purpose I/O port, and the display RAM corresponding to such pin can be used as normal RAM. Table 24.4-1 shows the relationship between duty setting/common outputs and the display RAM bits used.

Figure 24.4-1 and Figure 24.4-2 shows how display RAM addresses are allocated for common output pins and segment output pins in 8 COM mode and in 4 COM mode respectively.

Table 24.4-1 Relationship Between Duty Settings/Common Outputs and Display RAM Bits Used

Note:

In the RAM address column, "n" represents "0x0FBD".

24.5 Interrupt

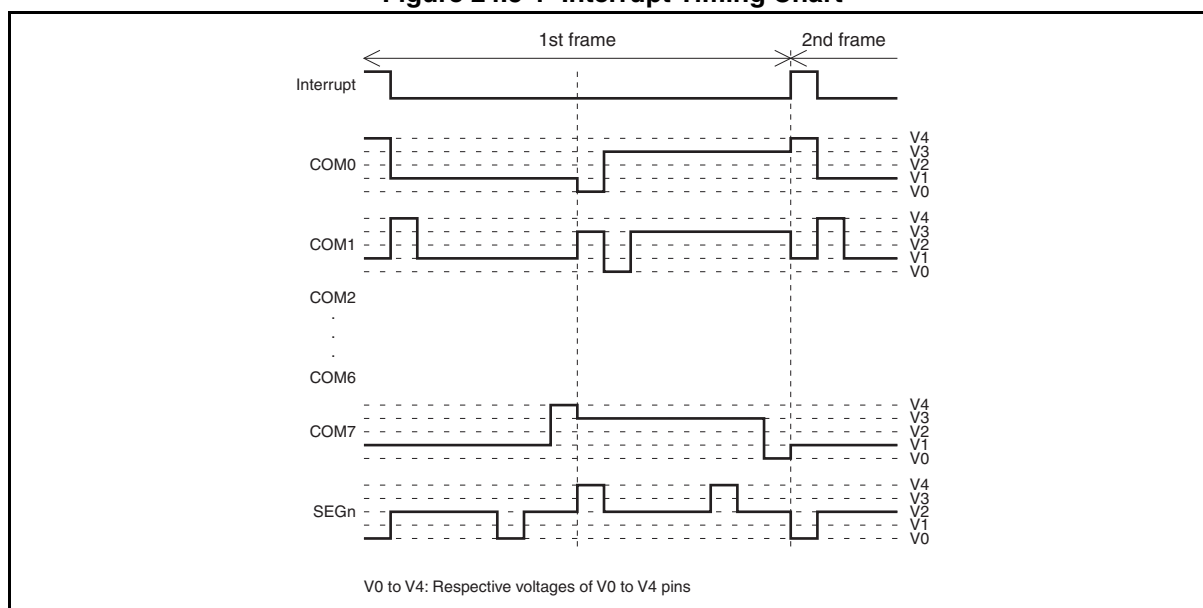

The LCD controller generates interrupts in sync with the LCD module frame frequency.

■ Interrupt during LCD Controller Operation

On completing processing a frame, the LCD controller sets the LCDC interrupt request flag bit (LCDCC2:LCDIF) to "1". If the interrupt request has already been enabled (LCDCC2:LCDIEN = 1) when the LCDIF bit is set to "1", the LCD controller makes an interrupt request to the interrupt controller. To clear an interrupt request, write "0" to the LCDIF bit during the interrupt service routine.

The LCD controller always sets the LCDIF bit to "1" on completing processing a frame, regardless of the value of the LCDIEN bit. After the LCD controller makes an interrupt request, when both the LCDIF bit and the LCDIEN bit remain "1", the CPU cannot return from the interrupt service routine. To enable the CPU to return from the interrupt service routine, always clear the LCDIF bit to "0" after the LCD controller makes an interrupt request.

Figure 24.5-1 Interrupt Timing Chart

24.6 Operations

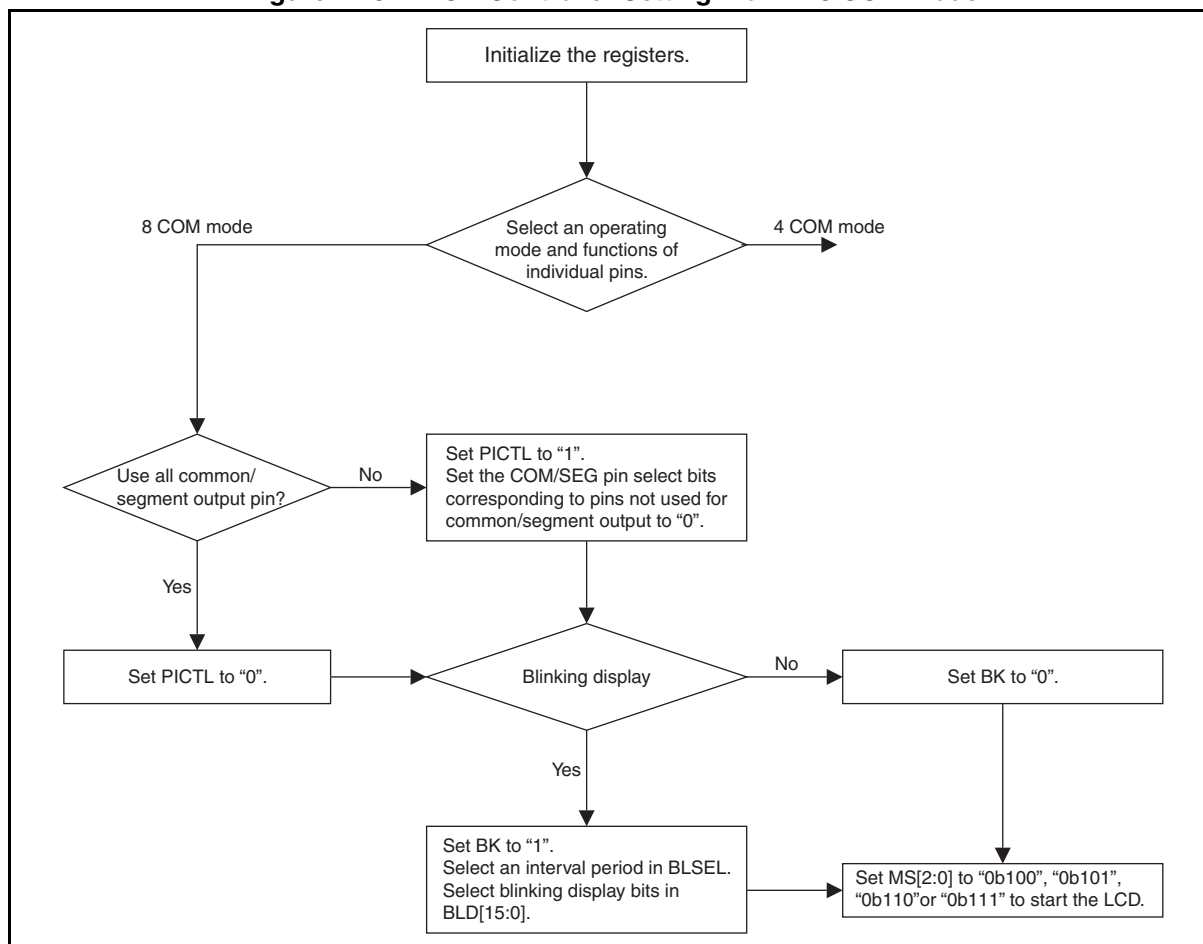

This section describes the operations of the LCD controller.

Figure 24.6-1 shows the settings required for LCD display in 8 COM mode.

Figure 24.6-2 LCD Controller Setting Flow in 8 COM Mode

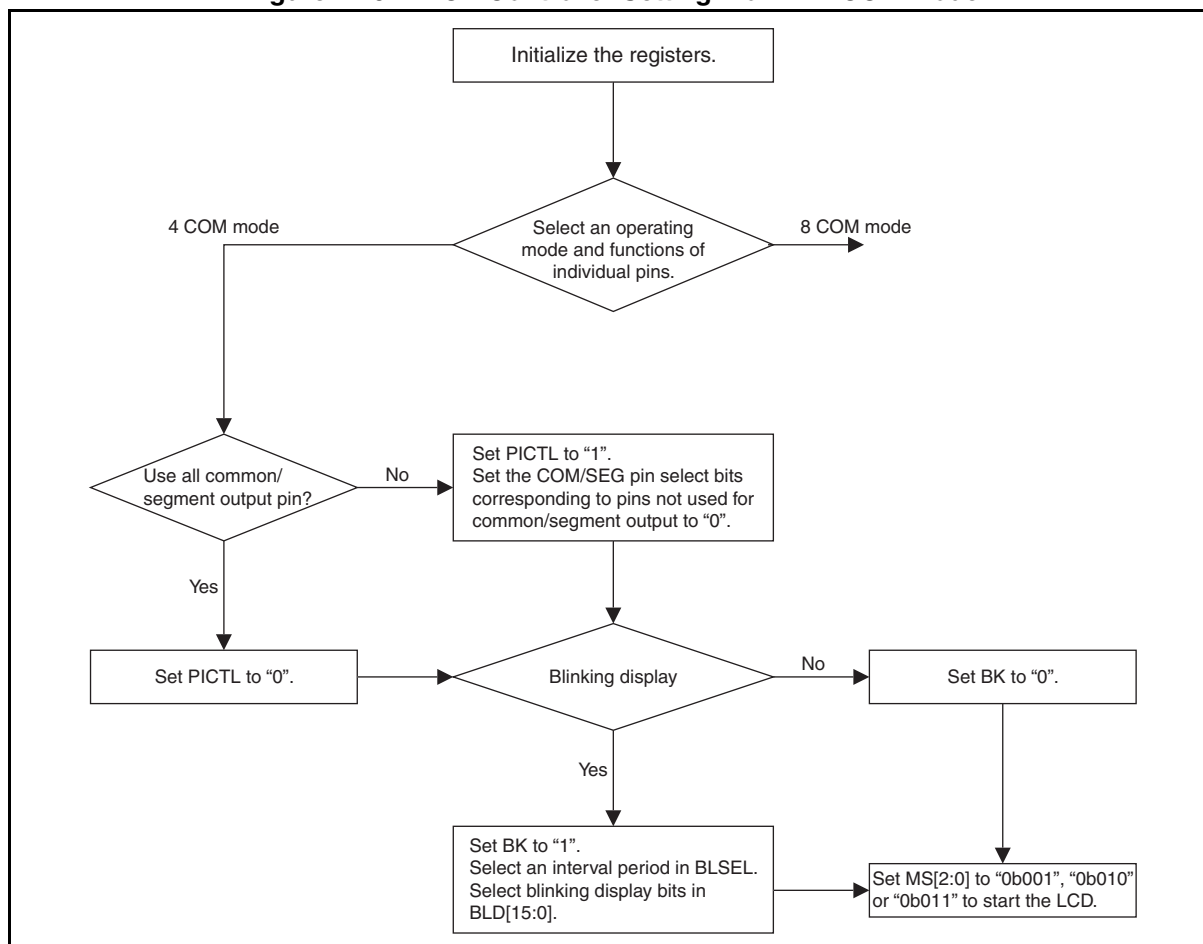

- When the selected frame period generation clock is oscillating with the settings made as shown in Figure 24.6-1, the LCD controller outputs the LCD panel drive waveform to the common output pins and segment output pins (COM0 to COM7, SEG00 to SEG35) according to the content of the display RAM and the settings of different LCDC registers.
- The LCD output pins are selected according to LCDCE1 to LCDCE7. When an LCD output pin shared with a general-purpose I/O port is not selected as a common/segment output pin, the pin is used as a general-purpose I/O port.
- The frame period generation clock can be changed even during LCD display operation. As the LCD display may flicker when the frame period generation clock is changed, always turn off the LCD display temporarily, for example, using the display blanking (LCDCC2:BK = 1) function, before changing the frame period generation clock to prevent the LCD display from flickering.
- The display drive output is a 2-frame alternating waveform selected according to bias and duty settings.
- To use the blink function, set the corresponding bits in the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2) to "1" to turn on the blinking function. The blinking interval can be selected from two options in the BLSEL bit in the LCDC enable register 1 (LCDCE1).

Figure 24.6-3 shows the settings required for LCD display in 4 COM mode.

Figure 24.6-4 LCD Controller Setting Flow in 4 COM Mode

- When the selected frame period generation clock is oscillating with the settings made as shown in Figure 24.6-3, the LCD controller outputs the LCD panel drive waveform to the common output pins and segment output pins (COM0 to COM3, SEG00 to SEG39) according to the content of the display RAM and the settings of different LCDC registers.
- The LCD output pins are selected according to LCDCE1 to LCDCE7. When an LCD output pin shared with a general-purpose I/O port is not selected as a common/segment output pin, the pin is used as a general-purpose I/O port.
- The frame period generation clock can be changed even during LCD display operation. As the LCD display may flicker when the frame period generation clock is changed, always turn off the LCD display temporarily, for example, using the display blanking (LCDC2:BK = 1) function, before changing the frame period generation clock to prevent the LCD display from flickering.
- The display drive output is a 2-frame alternating waveform selected according to bias and duty settings.
- The COM2 and COM3 pin outputs in 1/2 duty mode and the COM3 pin output in 1/3 duty mode can be used to output the non-select level waveform or as I/O ports.
- To use the blink function, set the corresponding bits in the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2) to "1" to turn on the blinking function. The blinking interval can be selected from two options in the BLSEL bit in the LCDC enable register 1 (LCDCE1).

Note:

If the selected frame period generation clock halts during LCD display operation, the AC waveform generator circuit also halts and therefore a DC voltage is applied to the liquid crystal elements. In this case, the LCD display operation must be stopped in advance. The conditions under which the main clock (time-base timer) or subclock (watch prescaler) halts depend on the selected clock mode and standby mode. The frame period is also affected if the time-base timer or watch prescaler is cleared depending on the setting of the frame period generation clock select bit (LCDCC1:CSS).

■ LCD Drive Waveform

Due to the characteristics of the LCD, DC driving of the LCD chemically changes and degrades the liquid crystal display elements. Therefore, the LCD controller driver contains an AC waveform generator circuit to drive the LCD using a 2-frame alternating waveform. There are five types of output waveform as follows:

In 8 COM mode:

- 1/3 bias, 1/8 duty output waveform
- 1/4 bias, 1/8 duty output waveform

In 4 COM mode:

- 1/2 bias, 1/2 duty output waveform
- 1/3 bias, 1/3 duty output waveform
- 1/3 bias, 1/4 duty output waveform

24.6.1 Output Waveform in LCD Controller Operation in 4 COM Mode (1/2 Bias, 1/2 Duty)

The display drive output is a multiplex drive type of 2-frame alternating waveform.

In 4 COM mode with 1/2 bias and 1/2 duty, only COM0 and COM1 are used for display; neither COM2 nor COM3 is used.

■ 4 COM Mode, 1/2 Bias, 1/2 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 24.6-5 shows the output waveform when the content of the display RAM is that shown in Table 24.6-1.

Table 24.6-1 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGN	-	-	0	0
SEG(n+1)	-	-	0	1

-: Unused

Figure 24.6-5 4 COM Mode, 1/2 Bias, 1/2 Duty Output Waveform Example

24.6.2 Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/3 Duty)

In 4 COM mode with 1/3 bias and 1/3 duty, COM0, COM1, and COM2 are used for display; COM3 is not used.

■ 4 COM Mode, 1/3 Bias, 1/3 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 24.6-6 shows the output waveform when the content of the display RAM is that shown in Table 24.6-2.

Table 24.6-2 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGn	-	1	0	0
SEG(n+1)	-	1	0	1

-: Unused

Figure 24.6-6 4 COM Mode, 1/3 Bias, 1/3 Duty Output Waveform Example

24.6.3 Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/4 Duty)

In 4 COM Mode with 1/3 bias and 1/4 duty, COM0 to COM3 are used for display.

■ 4 COM Mode, 1/3 Bias, 1/4 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 24.6-7 shows the output waveform when the content of the display RAM is that shown in Table 24.6-3.

Table 24.6-3 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGN	0	1	0	0
SEG(n+1)	0	1	0	1

Figure 24.6-7 4 COM Mode, 1/3 Bias, 1/4 Duty Output Waveform Example

24.6.4 Output Waveform in LCD Controller Operation in 8 COM Mode (1/3 Bias, 1/8 Duty)

In 8 COM Mode with 1/3 bias and 1/8 duty, COM0 to COM7 are used for display.

■ 8 COM Mode, 1/3 Bias, 1/8 Duty Output Waveform Example

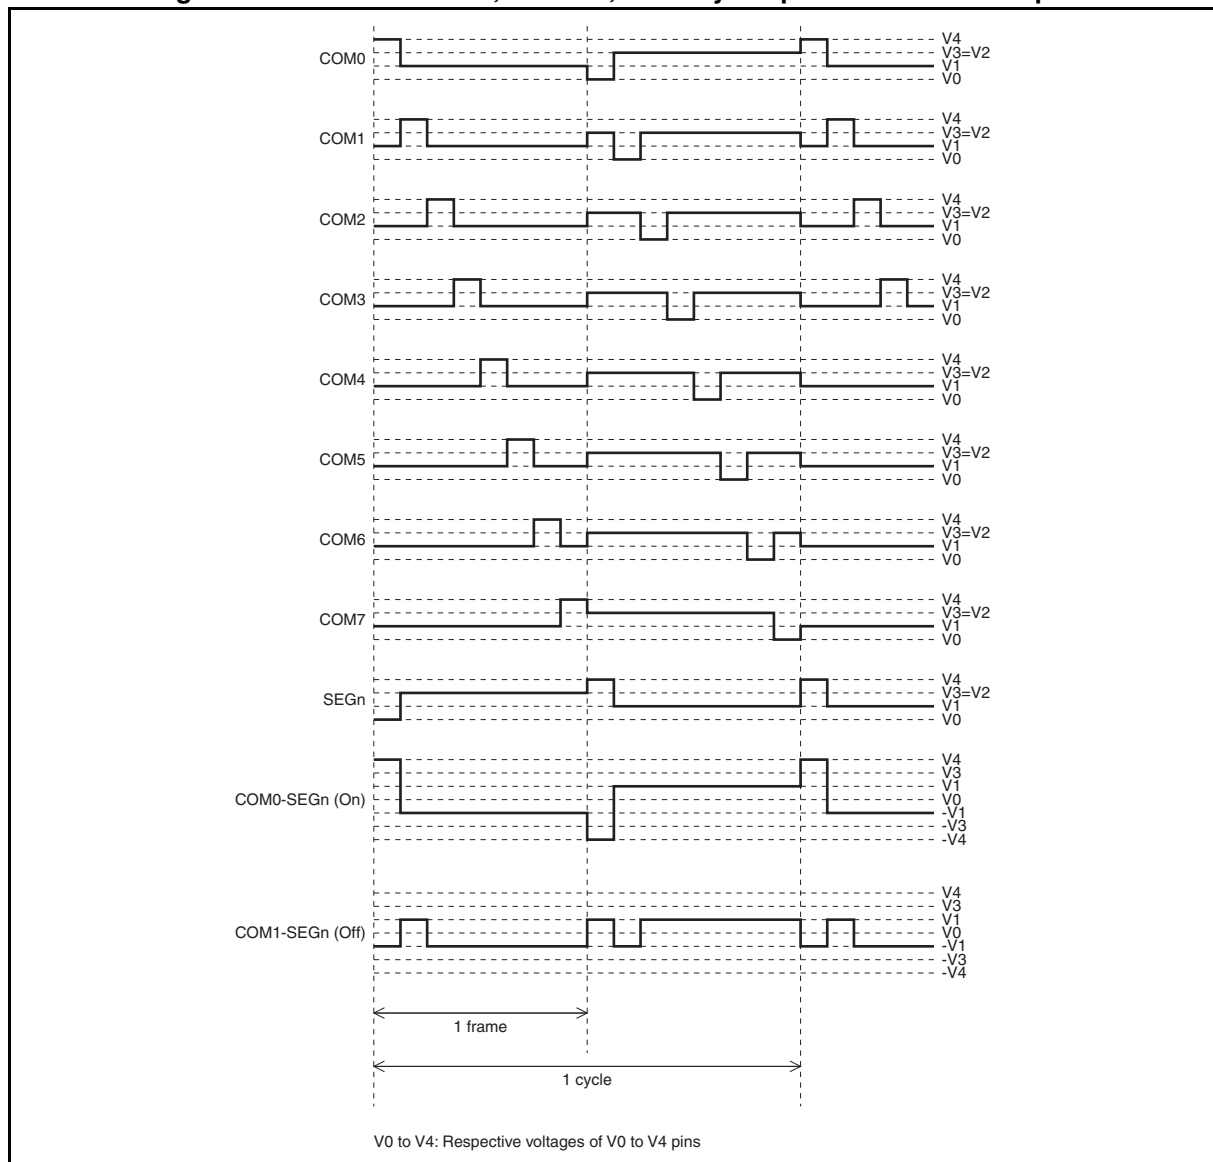

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 24.6-8 shows the output waveform when the content of the display RAM is that shown in Table 24.6-4.

Table 24.6-4 Sample Content of Display RAM

Segment	Content of Display RAM							
	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
SEGN	0	0	0	0	0	0	0	1

Figure 24.6-8 8 COM Mode, 1/3 Bias, 1/8 Duty Output Waveform Example

24.6.5 Output Waveform in LCD Controller Operation in 8 COM Mode (1/4 Bias, 1/8 Duty)

In 8 COM Mode with 1/4 bias and 1/8 duty, COM0 to COM7 are used for display.

■ 8 COM Mode, 1/4 Bias, 1/8 Duty Output Waveform Example

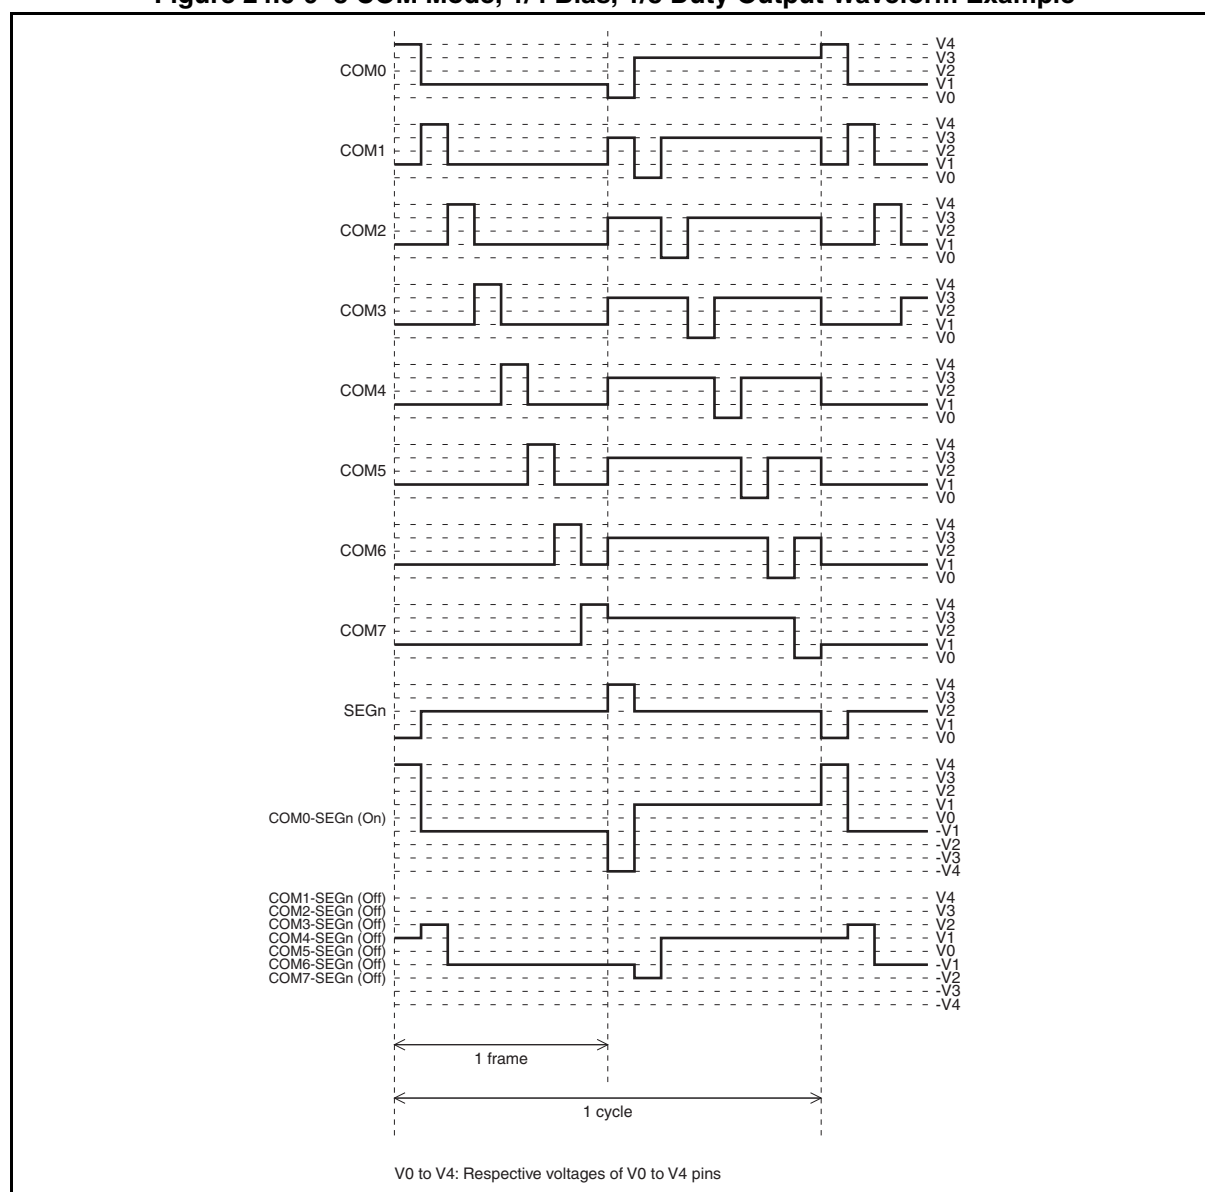

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 24.6-9 shows the output waveform when the content of the display RAM is that shown in Table 24.6-5.

Table 24.6-5 Sample Content of Display RAM

Segment	Content of Display RAM							
	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
SEGN	0	0	0	0	0	0	0	1

Figure 24.6-9 8 COM Mode, 1/4 Bias, 1/8 Duty Output Waveform Example

24.7 Registers

This section describes the registers of the LCD controller.

Table 24.7-1 List of LCD Controller Registers

Register abbreviation	Register name	Reference
LCDCC1	LCDC control register 1	24.7.1
LCDCC2	LCDC control register 2	24.7.2
LCDCE1	LCDC enable register 1	24.7.3
LCDCE2	LCDC enable register 2	24.7.4
LCDCE3	LCDC enable register 3	24.7.5
LCDCE4	LCDC enable register 4	24.7.6
LCDCE5	LCDC enable register 5	24.7.7
LCDCE6	LCDC enable register 6	24.7.8
LCDCE7	LCDC enable register 7	24.7.9
LCDCB1	LCDC blinking setting register 1	24.7.10
LCDCB2	LCDC blinking setting register 2	24.7.11

24.7.1 LCDC Control Register 1 (LCDCC1)

The LCDC control register 1 (LCDCC1) sets the clock and display mode, and controls power supply.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	CSS	LCDEN	VSEL	MS2	MS1	MS0	FP1	FP0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] CSS: Frame period generation clock select bit

This bit selects a clock for generating the frame period for the LCD display.

When this bit is "0", the LCD controller operates with the output of the time-base timer driven by the main clock. When this bit is "1", the LCD controller operates with the output of the watch prescaler driven by the subclock.

Shifting the main clock speed (using the gear function) while the time-base timer is outputting does not affect the frame period.

The LCD display may flicker when the frame period generation clock changes. To prevent the LCD display from flickering, before changing the frame period generation clock, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit7	Details
Writing "0"	Selects the main clock as the clock for generating the frame period for the LCD display.
Writing "1"	Selects the subclock as the clock for generating the frame period for the LCD display.

Note: Since the main clock stops oscillating in main stop mode and subclock mode, the LCD controller cannot operate with the output of the time-base timer in these modes.

[bit6] LCDEN: Main stop/watch mode operation enable bit

This bit controls whether the LCD controller is to continue to operate in main stop mode and watch mode.

bit6	Details
Writing "0"	Stops the LCD controller.
Writing "1"	Makes the LCD controller continue to operate even after the clock mode transits to main stop mode or watch mode.

Note: In the case of making the LCD controller continue to operate in main stop mode or watch mode, select the subclock as the clock for generating the frame period for the LCD display (CSS = 1).

[bit5] VSEL: LCD drive power control bit

This bit controls whether to energize the internal divider resistor.

bit5	Details
Writing "0"	Disconnects the internal divider resistor.
Writing "1"	Energizes the internal divider resistor.

Note: Write "0" to this bit when connecting to the external divider resistor.

[bit4:2] MS[2:0]: Display mode select bits

These bits select a display mode from 4 COM mode and 8 COM mode and also select an output waveform duty from four options.

The common output pins to be used are determined by the duty output mode selected.

When these bits are set to "0b000", the LCD controller driver stops the LCD display operation.

The LCD display may flicker when the display mode changes. To prevent the LCD display from flickering, before changing the display mode, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit4:2	Details
Writing "000"	Stops the LCD display operation.
Writing "001"	Selects 4 COM mode as the display mode and 1/2 as the output waveform duty (time division number N = 2).
Writing "010"	Selects 4 COM mode as the display mode and 1/3 as the output waveform duty (time division number N = 3).
Writing "011"	Selects 4 COM mode as the display mode and 1/4 as the output waveform duty (time division number N = 4).
Writing "100"	Selects 8 COM mode as the display mode and 1/8 as the output waveform duty (time division number N = 8).
Writing "101"	
Writing "110"	
Writing "111"	

Note: The clock (main clock or subclock) for generating the frame period for the LCD display stops as the clock mode transits to stop mode. Therefore, before the clock mode transits to stop mode, stop the LCD display operation (MS[2:0] = 0b000).

[bit1:0] FP[1:0]: Frame period select bits

These bits select an LCD display frame period.

The LCD display may flicker when the frame period changes. To prevent the LCD display from flickering, before changing the frame period, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit1:0	Details	
	Frame period generated by main clock (LCDCC1:CSS = 0) (F _{CH} : main clock, F _{CRH} : main CR clock)	Frame period generated by subclock (LCDCC1:CSS = 1) (F _{CL} : subclock, F _{CRL} : sub-CR clock)
Writing "00"	$2^{14} \times N/F_{CH}^{*1}$ $2^{13} \times N/F_{CH}^{*2}$ $2^{13} \times N/F_{CRH}$	$2^6 \times N/F_{CL}$ $2^6 \times N/F_{CRL}$
Writing "01"	$2^{15} \times N/F_{CH}^{*1}$ $2^{14} \times N/F_{CH}^{*2}$ $2^{14} \times N/F_{CRH}$	$2^7 \times N/F_{CL}$ $2^7 \times N/F_{CRL}$
Writing "10"	$2^{16} \times N/F_{CH}^{*1}$ $2^{15} \times N/F_{CH}^{*2}$ $2^{15} \times N/F_{CRH}$	$2^8 \times N/F_{CL}$ $2^8 \times N/F_{CRL}$
Writing "11"	$2^{17} \times N/F_{CH}^{*1}$ $2^{16} \times N/F_{CH}^{*2}$ $2^{16} \times N/F_{CRH}$	$2^9 \times N/F_{CL}$ $2^9 \times N/F_{CRL}$

*1: Main clock mode

*2: Main PLL clock mode

Note: Set the FP[1:0] bits according to the optimum frame period for the LCD module to be used. The frame period is affected by the source oscillation frequency.

24.7.2 LCDC Control Register 2 (LCDCC2)

The LCDC control register 2 (LCDCC2) enables or disables interrupts, indicates interrupt status and sets the following parameters:

- Internal resistance (10 k Ω or 100 k Ω)
- Bias (1/3 or 1/4) to be used in 8 COM mode
- Displaying data or a blank screen
- Inverted display

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	RSEL	BLS8	INV	BK	LCDIEN	LCDIF
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	1	0	1	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] RSEL: Internal divider resistor select bit

This bit selects a type of resistor to be used as the internal divider resistor.

bit5	Details
Writing "0"	Selects the 100 k Ω resistor.
Writing "1"	Selects the 10 k Ω resistor.

[bit4] BLS8: Bias in 8 COM mode select bit

This bit selects a type of bias to be used by software in 8 COM mode.

bit4	Details
Writing "0"	Selects 1/3 bias.
Writing "1"	Selects 1/4 bias.

Note: Although this bit can be accessed in both 8 COM mode and 4 COM mode, in 4 COM mode, writing a value to this bit has no effect on operation.

[bit3] INV: Inverted display control bit

This bit controls the inverted display on the LCD.

bit3	Details
Writing "0"	Disables the inverted display on the LCD.
Writing "1"	Enables the inverted display on the LCD.

[bit2] BK: Display blanking control bit

This bit controls display blanking of the LCD.

When display blanking is selected (BK = 1), a segment output pin outputs a non-select waveform (a waveform not meeting the display condition).

bit2	Details
Writing "0"	Makes the LCD display LCD controller display RAM data.
Writing "1"	Makes the LCD blank.

[bit1] LCDIEN: LCDC interrupt request enable bit

This bit enables or disables the generation of interrupt requests in sync with the LCD frame period.

bit1	Details
Writing "0"	Disables the generation of interrupt requests.
Writing "1"	Enables the generation of interrupt requests.

[bit0] LCDIF: LCDC interrupt request flag bit

This bit indicates whether the LCD controller has finished processing a frame.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit0	Details
Reading "0"	Indicates that the LCD controller is processing a frame.
Reading "1"	Indicates that the LCD controller has finished processing a frame.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

24.7.3 LCDC Enable Register 1 (LCDCE1)

The LCDC enable register 1 (LCDCE1) controls port input, selects a blink cycle and enables the drive power supply pins of the LCD controller.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	PICTL	BLSEL	VE4	VE3	VE2	VE1	VE0	—
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	—
Initial value	0	0	1	1	1	1	1	0

■ Register Functions

[bit7] PICTL: Port input control bit

This bit controls the general-purpose I/O ports that can also function as segment/common output pins.

Writing "0" to this bit disables the I/O function of such general-purpose I/O ports, and suppresses shoot-through current occurring while the LCD is outputting data.

Writing "1" to this bit enables the I/O function of such general-purpose I/O ports. To use a segment/common output pin shared with a general-purpose I/O port as a general-purpose I/O port, write "1" to this bit.

bit7	Details
Writing "0"	Disables the I/O function of the general-purpose I/O ports that can also function as segment/common output pins.
Writing "1"	Enables the I/O function of the general-purpose I/O ports that can also function as segment/common output pins.

Note: The input function of such general-purpose I/O ports is disabled by a reset. Therefore, to use their input function after a reset occurs, write "1" to this bit. When such general-purpose I/O ports are used as segment/common output pins, their input function is disabled regardless of the setting of this bit.

[bit6] BLSEL: Blinking interval select bit

This bit selects the blinking interval to be used when blinking is enabled.

Blinking is controlled by the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2).

A blinking interval of 1.0 s makes the LCD stay on for 0.5 s and off for 0.5 s; a blinking interval of 0.5 s makes the LCD stay on for 0.25 s and off for 0.25 s.

bit6	Details
Writing "0"	Selects 0.5 s as the blinking interval (with the subclock frequency being 32 kHz).
Writing "1"	Selects 1.0 s as the blinking interval (with the subclock frequency being 32 kHz).

[bit5] VE4: V4 function select bit

This bit selects the function of the V4 pin.

bit5	Details
Writing "0"	Makes the V4 pin function as a general-purpose I/O port.
Writing "1"	Makes the V4 pin function as an LCD drive power supply pin.

[bit4] VE3: V3 function select bit

This bit selects the function of the V3 pin.

bit4	Details
Writing "0"	Makes the V3 pin function as a general-purpose I/O port.
Writing "1"	Makes the V3 pin function as an LCD drive power supply pin.

[bit3] VE2: V2 function select bit

This bit selects the function of the V2 pin.

bit3	Details
Writing "0"	Makes the V2 pin function as a general-purpose I/O port.
Writing "1"	Makes the V2 pin function as an LCD drive power supply pin.

[bit2] VE1: V1 function select bit

This bit selects the function of the V1 pin.

bit2	Details
Writing "0"	Makes the V1 pin function as a general-purpose I/O port.
Writing "1"	Makes the V1 pin function as an LCD drive power supply pin.

[bit1] VE0: V0 function select bit

This bit selects the function of the V0 pin.

bit1	Details
Writing "0"	Makes the V0 pin function as a general-purpose I/O port.
Writing "1"	Makes the V0 pin function as an LCD drive power supply pin.

[bit0] Undefined bit

The read value is always "0". Writing a value to this bit has no effect on operation.

Note:

In the case of using the internal divider resistor, since the V4 pin cannot be used as a general-purpose I/O port, write "1" to the VE4 bit to make the V4 pin function as an LCD drive power supply pin.

24.7.4 LCDC Enable Register 2 (LCDCE2)

The LCDC enable register 2 (LCDCE2) controls the respective functions of the COM0 to COM7 pins.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] COM7: COM7 function select bit

This bit selects the function of the COM7 pin.

bit7	Details
Writing "0"	Makes the COM7 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM7 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit6] COM6: COM6 function select bit

This bit selects the function of the COM6 pin.

bit6	Details
Writing "0"	Makes the COM6 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM6 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit5] COM5: COM5 function select bit

This bit selects the function of the COM5 pin.

bit5	Details
Writing "0"	Makes the COM5 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM5 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit4] COM4: COM4 function select bit

This bit selects the function of the COM4 pin.

bit4	Details
Writing "0"	Makes the COM4 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM4 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit3] COM3: COM3 function select bit

This bit selects the function of the COM3 pin.

bit3	Details
Writing "0"	Makes the COM3 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM3 pin function as a common output pin.

[bit2] COM2: COM2 function select bit

This bit selects the function of the COM2 pin.

bit2	Details
Writing "0"	Makes the COM2 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM2 pin function as a common output pin.

[bit1] COM1: COM1 function select bit

This bit selects the function of the COM1 pin.

bit1	Details
Writing "0"	Makes the COM1 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM1 pin function as a common output pin.

[bit0] COM0: COM0 function select bit

This bit selects the function of the COM0 pin.

bit0	Details
Writing "0"	Makes the COM0 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM0 pin function as a common output pin.

24.7.5 LCDC Enable Register 3 (LCDCE3)

The LCDC enable register 3 (LCDCE3) controls the segment output pins SEG00 to SEG07.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG07	SEG06	SEG05	SEG04	SEG03	SEG02	SEG01	SEG00
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG07: SEG07 function select bit

This bit selects the function of the SEG07 pin.

bit7	Details
Writing "0"	Makes the SEG07 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG07 pin function as a segment output pin.

[bit6] SEG06: SEG06 function select bit

This bit selects the function of the SEG06 pin.

bit6	Details
Writing "0"	Makes the SEG06 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG06 pin function as a segment output pin.

[bit5] SEG05: SEG05 function select bit

This bit selects the function of the SEG05 pin.

bit5	Details
Writing "0"	Makes the SEG05 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG05 pin function as a segment output pin.

[bit4] SEG04: SEG04 function select bit

This bit selects the function of the SEG04 pin.

bit4	Details
Writing "0"	Makes the SEG04 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG04 pin function as a segment output pin.

[bit3] SEG03: SEG03 function select bit

This bit selects the function of the SEG03 pin.

bit3	Details
Writing "0"	Makes the SEG03 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG03 pin function as a segment output pin.

[bit2] SEG02: SEG02 function select bit

This bit selects the function of the SEG02 pin.

bit2	Details
Writing "0"	Makes the SEG02 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG02 pin function as a segment output pin.

[bit1] SEG01: SEG01 function select bit

This bit selects the function of the SEG01 pin.

bit1	Details
Writing "0"	Makes the SEG01 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG01 pin function as a segment output pin.

[bit0] SEG00: SEG00 function select bit

This bit selects the function of the SEG00 pin.

bit0	Details
Writing "0"	Makes the SEG00 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG00 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE3 register enabled to control the segment output pins SEG00 to SEG07.

24.7.6 LCDC Enable Register 4 (LCDCE4)

The LCDC enable register 4 (LCDCE4) controls the segment output pins SEG08 to SEG15.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG15	SEG14	SEG13	SEG12	SEG11	SEG10	SEG09	SEG08
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG15: SEG15 function select bit

This bit selects the function of the SEG15 pin.

bit7	Details
Writing "0"	Makes the SEG15 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG15 pin function as a segment output pin.

[bit6] SEG14: SEG14 function select bit

This bit selects the function of the SEG14 pin.

bit6	Details
Writing "0"	Makes the SEG14 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG14 pin function as a segment output pin.

[bit5] SEG13: SEG13 function select bit

This bit selects the function of the SEG13 pin.

bit5	Details
Writing "0"	Makes the SEG13 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG13 pin function as a segment output pin.

[bit4] SEG12: SEG12 function select bit

This bit selects the function of the SEG12 pin.

bit4	Details
Writing "0"	Makes the SEG12 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG12 pin function as a segment output pin.

[bit3] SEG11: SEG11 function select bit

This bit selects the function of the SEG11 pin.

bit3	Details
Writing "0"	Makes the SEG11 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG11 pin function as a segment output pin.

[bit2] SEG10: SEG10 function select bit

This bit selects the function of the SEG10 pin.

bit2	Details
Writing "0"	Makes the SEG10 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG10 pin function as a segment output pin.

[bit1] SEG09: SEG09 function select bit

This bit selects the function of the SEG09 pin.

bit1	Details
Writing "0"	Makes the SEG09 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG09 pin function as a segment output pin.

[bit0] SEG08: SEG08 function select bit

This bit selects the function of the SEG08 pin.

bit0	Details
Writing "0"	Makes the SEG08 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG08 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE4 register enabled to control the segment output pins SEG08 to SEG15.

24.7.7 LCDC Enable Register 5 (LCDCE5)

The LCDC enable register 5 (LCDCE5) controls the segment output pins SEG16 to SEG23.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG23	SEG22	SEG21	SEG20	SEG19	SEG18	SEG17	SEG16
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG23: SEG23 function select bit

This bit selects the function of the SEG23 pin.

bit7	Details
Writing "0"	Makes the SEG23 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG23 pin function as a segment output pin.

[bit6] SEG22: SEG22 function select bit

This bit selects the function of the SEG22 pin.

bit6	Details
Writing "0"	Makes the SEG22 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG22 pin function as a segment output pin.

[bit5] SEG21: SEG21 function select bit

This bit selects the function of the SEG21 pin.

bit5	Details
Writing "0"	Makes the SEG21 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG21 pin function as a segment output pin.

[bit4] SEG20: SEG20 function select bit

This bit selects the function of the SEG20 pin.

bit4	Details
Writing "0"	Makes the SEG20 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG20 pin function as a segment output pin.

[bit3] SEG19: SEG19 function select bit

This bit selects the function of the SEG19 pin.

bit3	Details
Writing "0"	Makes the SEG19 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG19 pin function as a segment output pin.

[bit2] SEG18: SEG18 function select bit

This bit selects the function of the SEG18 pin.

bit2	Details
Writing "0"	Makes the SEG18 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG18 pin function as a segment output pin.

[bit1] SEG17: SEG17 function select bit

This bit selects the function of the SEG17 pin.

bit1	Details
Writing "0"	Makes the SEG17 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG17 pin function as a segment output pin.

[bit0] SEG16: SEG16 function select bit

This bit selects the function of the SEG16 pin.

bit0	Details
Writing "0"	Makes the SEG16 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG16 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE5 register enabled to control the segment output pins SEG16 to SEG23.

24.7.8 LCDC Enable Register 6 (LCDCE6)

The LCDC enable register 6 (LCDCE6) controls the segment output pins SEG24 to SEG31.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG31	SEG30	SEG29	SEG28	SEG27	SEG26	SEG25	SEG24
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG31: SEG31 function select bit

This bit selects the function of the SEG31 pin.

bit7	Details
Writing "0"	Makes the SEG31 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG31 pin function as a segment output pin.

[bit6] SEG30: SEG30 function select bit

This bit selects the function of the SEG30 pin.

bit6	Details
Writing "0"	Makes the SEG30 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG30 pin function as a segment output pin.

[bit5] SEG29: SEG29 function select bit

This bit selects the function of the SEG29 pin.

bit5	Details
Writing "0"	Makes the SEG29 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG29 pin function as a segment output pin.

[bit4] SEG28: SEG28 function select bit

This bit selects the function of the SEG28 pin.

bit4	Details
Writing "0"	Makes the SEG28 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG28 pin function as a segment output pin.

[bit3] SEG27: SEG27 function select bit

This bit selects the function of the SEG27 pin.

bit3	Details
Writing "0"	Makes the SEG27 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG27 pin function as a segment output pin.

[bit2] SEG26: SEG26 function select bit

This bit selects the function of the SEG26 pin.

bit2	Details
Writing "0"	Makes the SEG26 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG26 pin function as a segment output pin.

[bit1] SEG25: SEG25 function select bit

This bit selects the function of the SEG25 pin.

bit1	Details
Writing "0"	Makes the SEG25 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG25 pin function as a segment output pin.

[bit0] SEG24: SEG24 function select bit

This bit selects the function of the SEG24 pin.

bit0	Details
Writing "0"	Makes the SEG24 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG24 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE6 register enabled to control the segment output pins SEG24 to SEG31.

24.7.9 LCDC Enable Register 7 (LCDCE7)

The LCDC enable register 7 (LCDCE7) controls the segment output pins SEG32 to SEG39.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG39	SEG38	SEG37	SEG36	SEG35	SEG34	SEG33	SEG32
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG39: SEG39 function select bit

This bit selects the function of the SEG39 pin.

bit7	Details
Writing "0"	Makes the SEG39 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG39 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit6] SEG38: SEG38 function select bit

This bit selects the function of the SEG38 pin.

bit6	Details
Writing "0"	Makes the SEG38 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG38 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit5] SEG37: SEG37 function select bit

This bit selects the function of the SEG37 pin.

bit5	Details
Writing "0"	Makes the SEG37 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG37 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit4] SEG36: SEG36 function select bit

This bit selects the function of the SEG36 pin.

bit4	Details
Writing "0"	Makes the SEG36 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG36 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit3] SEG35: SEG35 function select bit

This bit selects the function of the SEG35 pin.

bit3	Details
Writing "0"	Makes the SEG35 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG35 pin function as a segment output pin.

[bit2] SEG34: SEG34 function select bit

This bit selects the function of the SEG34 pin.

bit2	Details
Writing "0"	Makes the SEG34 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG34 pin function as a segment output pin.

[bit1] SEG33: SEG33 function select bit

This bit selects the function of the SEG33 pin.

bit1	Details
Writing "0"	Makes the SEG33 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG33 pin function as a segment output pin.

[bit0] SEG32: SEG32 function select bit

This bit selects the function of the SEG32 pin.

bit0	Details
Writing "0"	Makes the SEG32 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG32 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE7 register enabled to control the segment output pins SEG32 to SEG39.

24.7.10 LCDC Blinking Setting Register 1 (LCDCB1)

The LCDC blinking setting register 1 (LCDCB1) enables or disables the blinking function.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BLD7	BLD6	BLD5	BLD4	BLD3	BLD2	BLD1	BLD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions (8 COM Mode)

[bit7] BLD7: S0C7 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM7.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM7.
Writing "1"	Enables the blinking of dots in SEG00 and COM7.

[bit6] BLD6: S0C6 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM6.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM6.
Writing "1"	Enables the blinking of dots in SEG00 and COM6.

[bit5] BLD5: S0C5 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM5.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM5.
Writing "1"	Enables the blinking of dots in SEG00 and COM5.

[bit4] BLD4: S0C4 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM4.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM4.
Writing "1"	Enables the blinking of dots in SEG00 and COM4.

[bit3] BLD3: S0C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM3.
Writing "1"	Enables the blinking of dots in SEG00 and COM3.

[bit2] BLD2: S0C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM2.
Writing "1"	Enables the blinking of dots in SEG00 and COM2.

[bit1] BLD1: S0C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM1.
Writing "1"	Enables the blinking of dots in SEG00 and COM1.

[bit0] BLD0: S0C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM0.
Writing "1"	Enables the blinking of dots in SEG00 and COM0.

■ Register Functions (4 COM Mode)

[bit7] BLD7: S1C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM3.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM3.
Writing "1"	Enables the blinking of dots in SEG01 and COM3.

[bit6] BLD6: S1C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM2.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM2.
Writing "1"	Enables the blinking of dots in SEG01 and COM2.

[bit5] BLD5: S1C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM1.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM1.
Writing "1"	Enables the blinking of dots in SEG01 and COM1.

[bit4] BLD4: S1C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM0.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM0.
Writing "1"	Enables the blinking of dots in SEG01 and COM0.

[bit3] BLD3: S0C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM3.
Writing "1"	Enables the blinking of dots in SEG00 and COM3.

[bit2] BLD2: S0C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM2.
Writing "1"	Enables the blinking of dots in SEG00 and COM2.

[bit1] BLD1: S0C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM1.
Writing "1"	Enables the blinking of dots in SEG00 and COM1.

[bit0] BLD0: S0C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM0.
Writing "1"	Enables the blinking of dots in SEG00 and COM0.

Notes:

- Select a blinking interval by using the BLSEL bit in the LCDCE1 register.
- All segments whose blinking has been enabled blink in sync.
- The setting of a blinking setting bit remains effective even when its corresponding bit in the display RAM holds "1".

24.7.11 LCDC Blinking Setting Register 2 (LCDCB2)

The LCDC blinking setting register 2 (LCDCB2) enables or disables the blinking function.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BLD15	BLD14	BLD13	BLD12	BLD11	BLD10	BLD9	BLD8
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions (8 COM Mode)

[bit7] BLD15: S1C7 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM7.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM7.
Writing "1"	Enables the blinking of dots in SEG01 and COM7.

[bit6] BLD14: S1C6 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM6.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM6.
Writing "1"	Enables the blinking of dots in SEG01 and COM6.

[bit5] BLD13: S1C5 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM5.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM5.
Writing "1"	Enables the blinking of dots in SEG01 and COM5.

[bit4] BLD12: S1C4 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM4.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM4.
Writing "1"	Enables the blinking of dots in SEG01 and COM4.

[bit3] BLD11: S1C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM3.
Writing "1"	Enables the blinking of dots in SEG01 and COM3.

[bit2] BLD10: S1C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM2.
Writing "1"	Enables the blinking of dots in SEG01 and COM2.

[bit1] BLD9: S1C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM1.
Writing "1"	Enables the blinking of dots in SEG01 and COM1.

[bit0] BLD8: S1C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM0.
Writing "1"	Enables the blinking of dots in SEG01 and COM0.

■ Register Functions (4 COM Mode)

[bit7] BLD15: S3C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM3.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM3.
Writing "1"	Enables the blinking of dots in SEG03 and COM3.

[bit6] BLD14: S3C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM2.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM2.
Writing "1"	Enables the blinking of dots in SEG03 and COM2.

[bit5] BLD13: S3C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM1.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM1.
Writing "1"	Enables the blinking of dots in SEG03 and COM1.

[bit4] BLD12: S3C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM0.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM0.
Writing "1"	Enables the blinking of dots in SEG03 and COM0.

[bit3] BLD11: S2C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM3.
Writing "1"	Enables the blinking of dots in SEG02 and COM3.

[bit2] BLD10: S2C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM2.
Writing "1"	Enables the blinking of dots in SEG02 and COM2.

[bit1] BLD9: S2C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM1.
Writing "1"	Enables the blinking of dots in SEG02 and COM1.

[bit0] BLD8: S2C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM0.
Writing "1"	Enables the blinking of dots in SEG02 and COM0.

Notes:

- Select a blinking interval by using the BLSEL bit in the LCDCE1 register.
- All segments whose blinking has been enabled blink in sync.
- The setting of a blinking setting bit remains effective even when its corresponding bit in the display RAM holds "1".

24.8 Notes on Using LCD Controller

This section provides notes on using the LCD controller.

- To use an LCD pin as a general-purpose I/O port, set a corresponding common/segment select bit in an LCDC enable register (LCDCE1 to LCDCE7) to "0", and then set the port input control bit in the LCDC enable register 1 (LCDCE1:PICTL) to "1".
- If the selected frame period generation clock halts during LCD display operation, the AC waveform generator circuit also halts and therefore a DC voltage is applied to the liquid crystal elements. In this case, the LCD display operation must be stopped in advance. The conditions under which the main clock (time-base timer) or subclock (watch prescaler) halts depend on the selected clock mode and standby mode. The frame period is also affected if the time-base timer or the watch prescaler is cleared according to the setting of the frame period generation clock select bit (LCDCC1:CSS).
- The operation of outputting display RAM data to the LCD is not in sync with the CPU accessing to the display RAM. When the interval for rewriting the display RAM is shorter than the LCD cycle, flickers may occur that are caused by different display patterns between frames.

CHAPTER 25

LCD CONTROLLER

(MB95770L SERIES)

This chapter describes the functions and operations of the LCD controller (LCDC).

- 25.1 Overview
- 25.2 Configuration
- 25.3 Pins
- 25.4 Display RAM
- 25.5 Interrupt
- 25.6 Operations
- 25.7 Registers
- 25.8 Notes on Using LCD Controller

25.1 Overview

The LCD controller has two modes: 8 COM mode and 4 COM mode.

In 8 COM mode, the LCD controller can use 28 bytes of display data memory and controls an LCD display via eight common outputs and 28 segment outputs. It also has two different bias output options for driving an LCD panel.

In 4 COM mode, the LCD controller can use 16 bytes of display data memory and controls an LCD display via four common outputs and 32 segment outputs. It also has three different bias output options for driving an LCD panel.

■ Functions of LCD Controller

The LCD controller uses its segment and common outputs to display the content of the display data memory (display RAM) directly on the LCD panel.

- It selects the 8 COM mode and the 4 COM mode through software.
- It has an LCD drive voltage divider resistor whose resistance value can be selected from 10 k Ω or 100 k Ω through software. An external divider resistor can also be used instead.
- In 8 COM mode, eight common outputs (COM0 to COM7) and 28 segment outputs (SEG00 to SEG27) are available.
- In 4 COM mode, four common outputs (COM0 to COM3) and 32 segment outputs (SEG00 to SEG31) are available.
- The display RAM size is 28 bytes (28 \times 8 bits) in 8 COM mode and 16 bytes (32 \times 4 bits) in 4 COM mode.
- It can use the main clock or the subclock as its operating clock.
- It has a blinking function, which is only available to certain pins.
- It can directly drive an LCD panel.
- In 8 COM mode, the bias can be selected from 1/3 or 1/4.
- In 4 COM mode, the duty can be selected from 1/2, 1/3 or 1/4 (governed by the bias setting).
- The interrupt is in sync with the LCD module frame frequency.

Table 25.1-1 lists the bias-duty combinations available.

Table 25.1-1 Combinations of Bias and Duty

Duty	1/2 bias	1/3 bias	1/4 bias
1/2	○	X	X
1/3	X	○	X
1/4	X	○	X
1/8, BLS8 = 0	X	○	X
1/8, BLS8 = 1	X	X	○

○ : Recommended combination

X : Prohibited combination

25.2 Configuration

The LCD controller consists of the following blocks, which are divided according to their functions into a controller section that generates the segment and common signals based on the content of the display RAM, and a driver section that drives the LCD.

Controller section

- LCDC control registers (LCDCC1 and LCDCC2)
- LCDC enable registers (LCDCE1 to LCDCE6)
- LCDC blinking setting registers (LCDCB1 and LCDCB2)
- Display RAM
- Clock selection
- Timing control

Driver section

- AC waveform generator circuit
- Common driver
- Segment driver
- Divider resistor

■ Block Diagrams of LCD Controller

Figure 25.2-1 Block Diagram of LCD Controller (8 COM Mode)

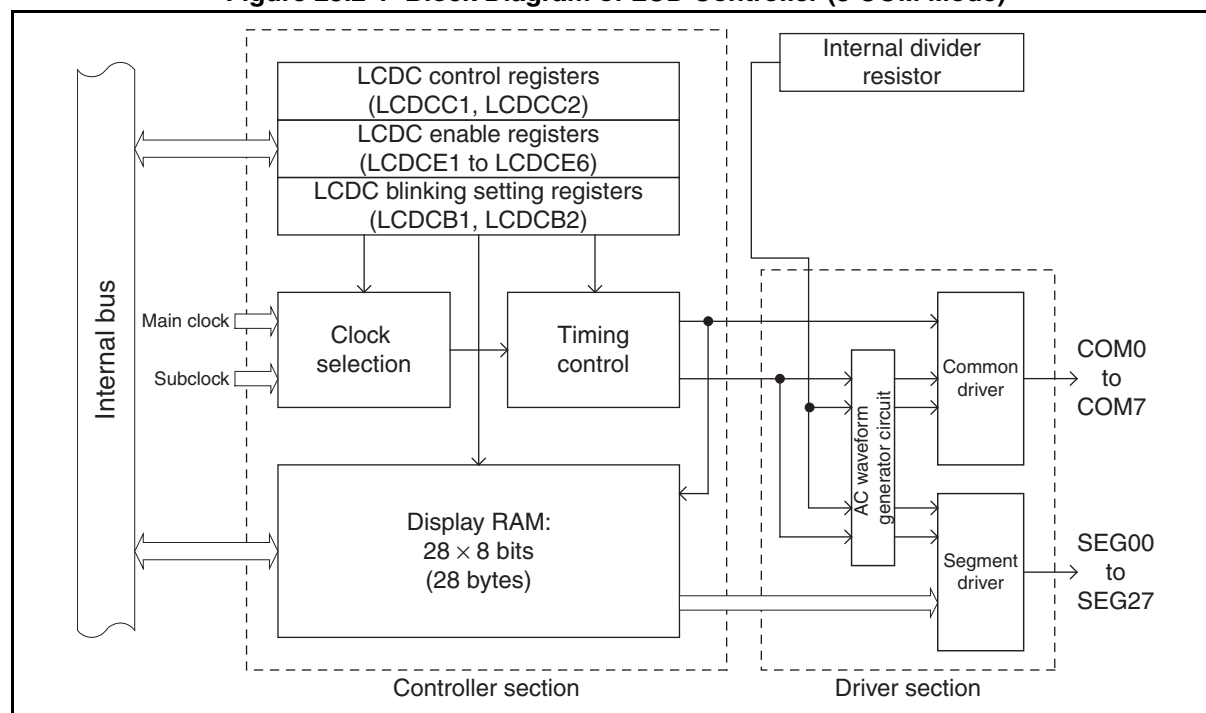

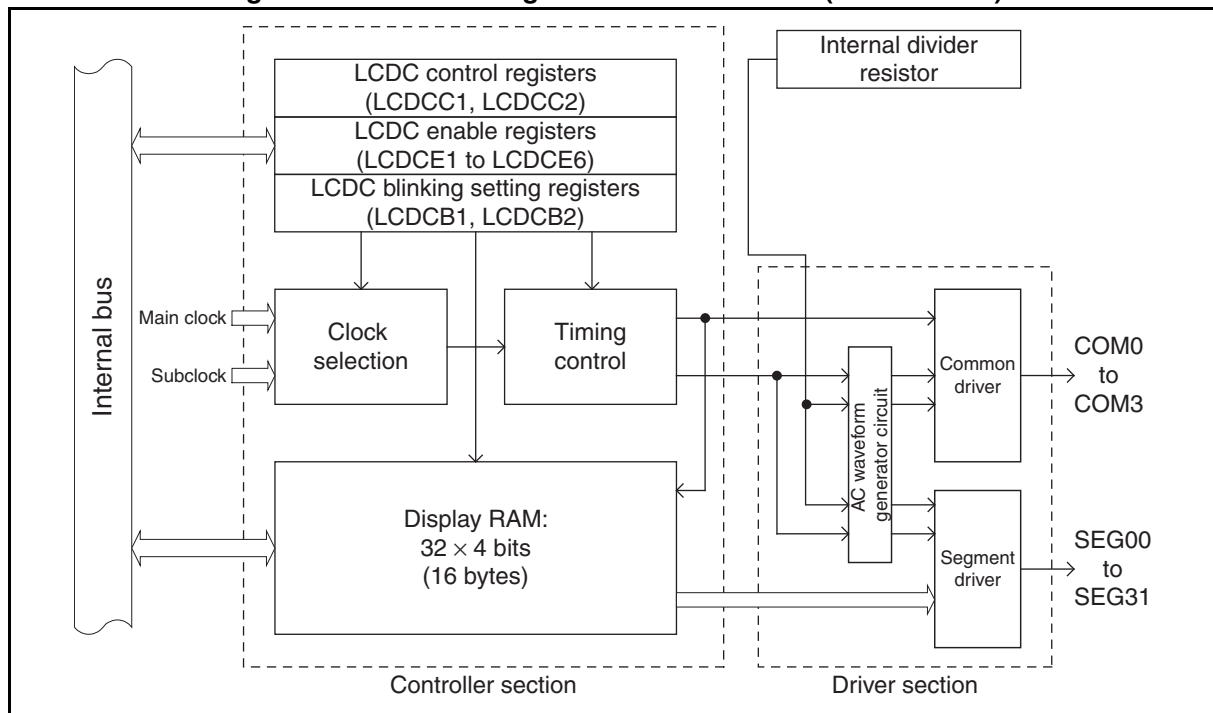

Figure 25.2-2 Block Diagram of LCD Controller (4 COM Mode)

● **LCDC control register 1 (LCDCC1)**

This register selects the clock for generating the frame period, the display mode, the frame period clock, and controls the LCD drive power supply.

● **LCDC control register 2 (LCDCC2)**

This register enables and disables interrupts, indicates interrupt status and sets the following parameters:

- Internal resistance value (10 kΩ or 100 kΩ)
- Bias to be used in 8 COM mode (1/3 or 1/4)
- Displaying data or a blank screen
- Inverted display

● **LCDC enable registers 1 to 6 (LCDCE1 to LCDCE6)**

These registers control port inputs, blink interval, and pins.

● **LCDC blinking setting register 1 (LCDCB1), LCDC blinking setting register 2 (LCDCB2)**

These registers turn on and off blinking.

● **Display RAM**

In 8 COM mode, 28 × 8 bits of RAM is available for generating segment output signals.

In 4 COM mode, 32 × 4 bits of RAM is available for generating segment output signals.

The content of the display RAM is read automatically in sync with the common signal selection timing and is output from segment output pins.

When the display RAM is modified, the content of the VRAM is output from segment output pins.

- Clock selection

The frame frequency is generated based on the frequency selected from eight options generated from two types of clock.

- Timing control

The COM signals and SEG signals are controlled based on the frame frequency and register settings.

- AC waveform generator circuit

The circuit generates AC waveforms for driving the LCD according to timing control signals.

- Common driver

This is the driver of the LCD common (COM) pins.

- Segment driver

This is the driver of the LCD segment (SEG) pins.

- Divider resistor

This resistor generates the LCD drive voltage. An external divider resistor can be used when an LCD drive power supply pin (V1 to V4) serves as a divider resistor connection pin.

■ LCD Controller Power Supply Voltage

The power supply voltage for the LCD driver is generated by the internal divider resistors or by connecting an external divider resistor to an LCD drive power supply pin (V1 to V4).

■ Input Clock

The LCD controller uses the clock output from the time-base timer or from the watch prescaler as the input clock (operation clock).

25.2.1 Internal Divider Resistors of LCD Controller

The internal driver resistors generate power supply voltage for the LCD driver.

■ Internal Divider Resistors

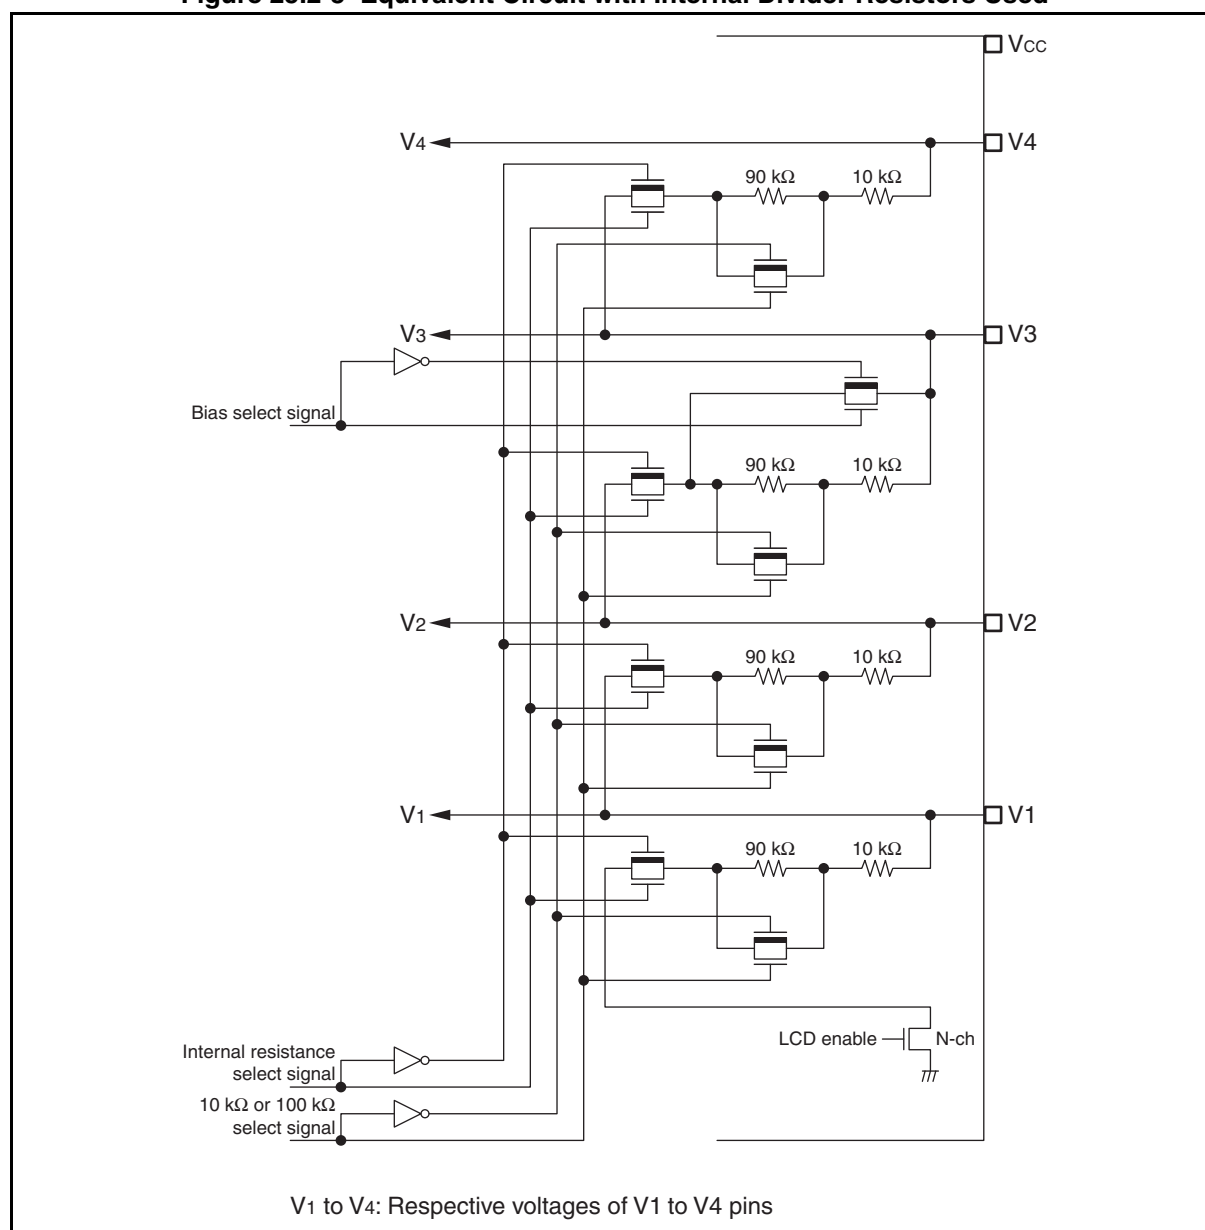

This series has internal divider resistors. In addition, an external divider resistor can be connected to an LCD drive power supply pin (V1 to V4).

The internal and external divider resistors are selected by the driving power control bit in the LCDC control register (LCDCC1:VSEL). Setting the VSEL bit to "1" energizes internal divider resistors. To use only internal divider resistors without using any external divider resistor, set the VE3 bit in the LCDC enable register 1 (LCDCE1) to "1". (When the internal divider resistors are used, the V4 pin cannot be used as a general-purpose I/O port.)

With the LCD operation stopped (LCDCC1:MS[2:0] = 0b000) and the LCD controller operation in main stop mode or in watch mode disabled (LCDCC1:LCDEN = 0), the LCD controller stops immediately after the device transits to main stop or watch mode (STBC:TMD = 1).

Figure 25.2-3 shows an equivalent circuit with internal divider resistors used.

Figure 25.2-3 Equivalent Circuit with Internal Divider Resistors Used

■ Use of Internal Divider Resistors and Brightness Control

There are two types of internal divider resistor: 10 k Ω and 100 k Ω . Figure 25.2-4 shows examples of using internal divider resistors.

If sufficient brightness cannot be achieved with the internal divider resistors in use, connect a variable resistor (VR) externally (between the Vcc pin and the V4 pin) to adjust the voltage of the V4 pin. Figure 25.2-5 illustrates connecting a VR to the V4 pin to control brightness.

Figure 25.2-4 Circuits with Internal Divider Resistors

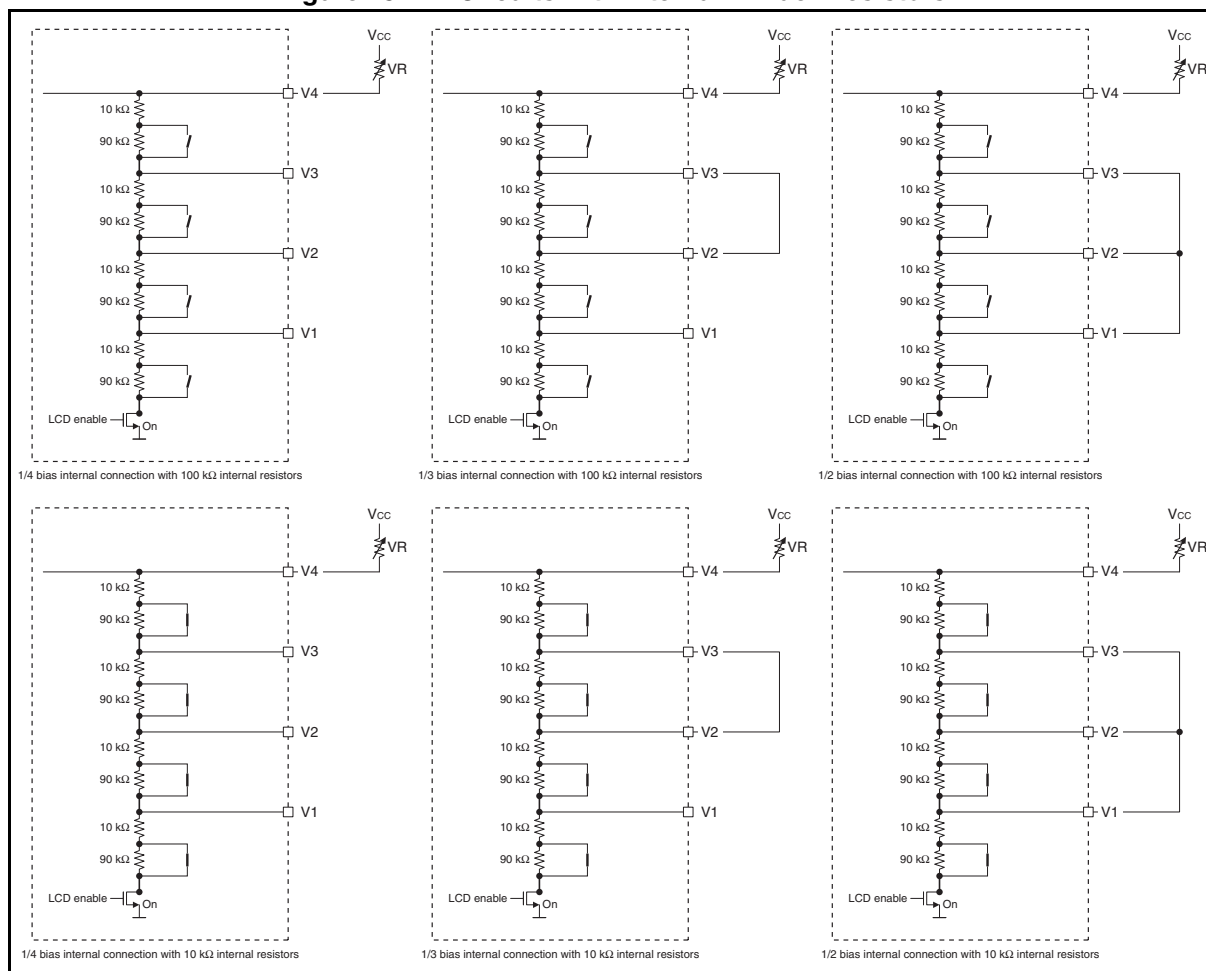

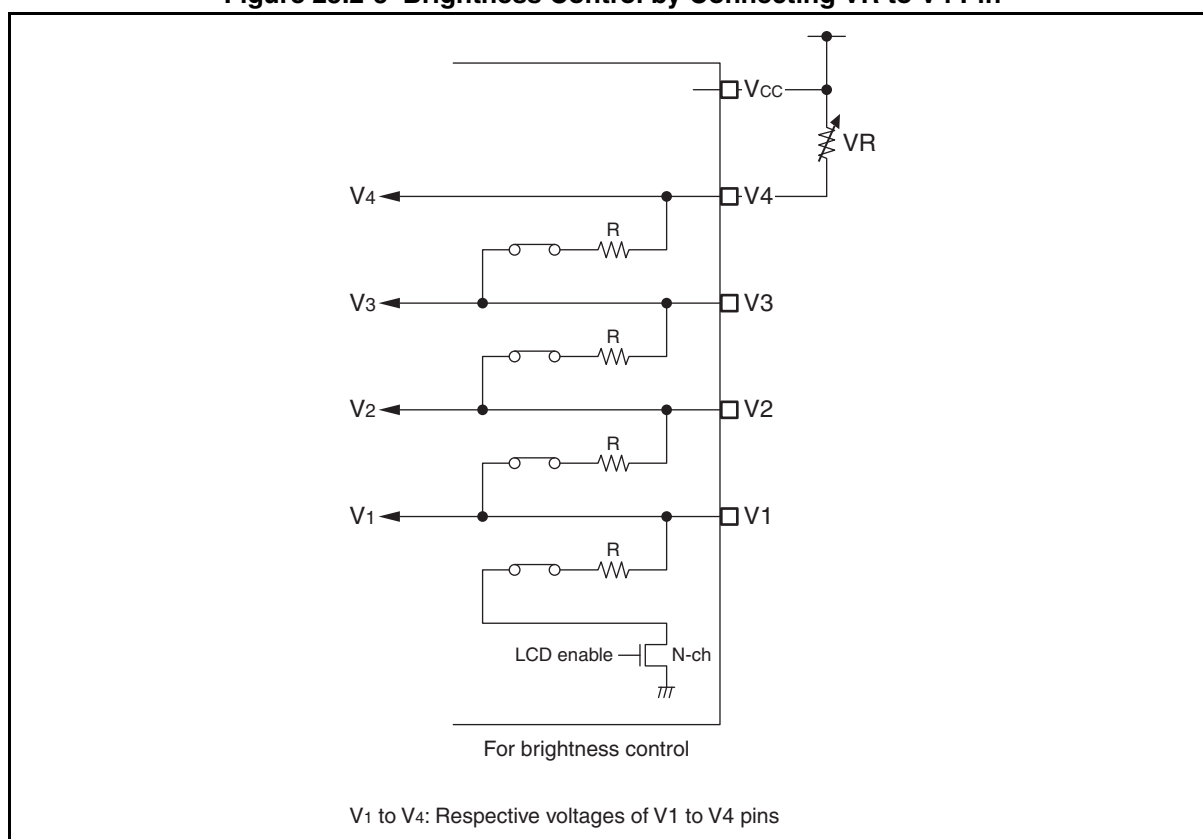

Figure 25.2-5 Brightness Control by Connecting VR to V4 Pin

25.2.2 External Divider Resistor for LCD Controller

The V1 to V4 pins of this series can be connected to external divider resistors. Connecting a variable resistor between the Vcc pin and the V4 pin can control brightness.

■ External Divider Resistor

Instead of internal divider resistors, external divider resistors can be connected to the LCD drive power supply pins (V1 to V4). Figure 25.2-6 illustrates external divider resistors connection with bias. Table 25.2-1 shows LCD drive voltages.

Figure 25.2-6 External Divider Resistors Connection

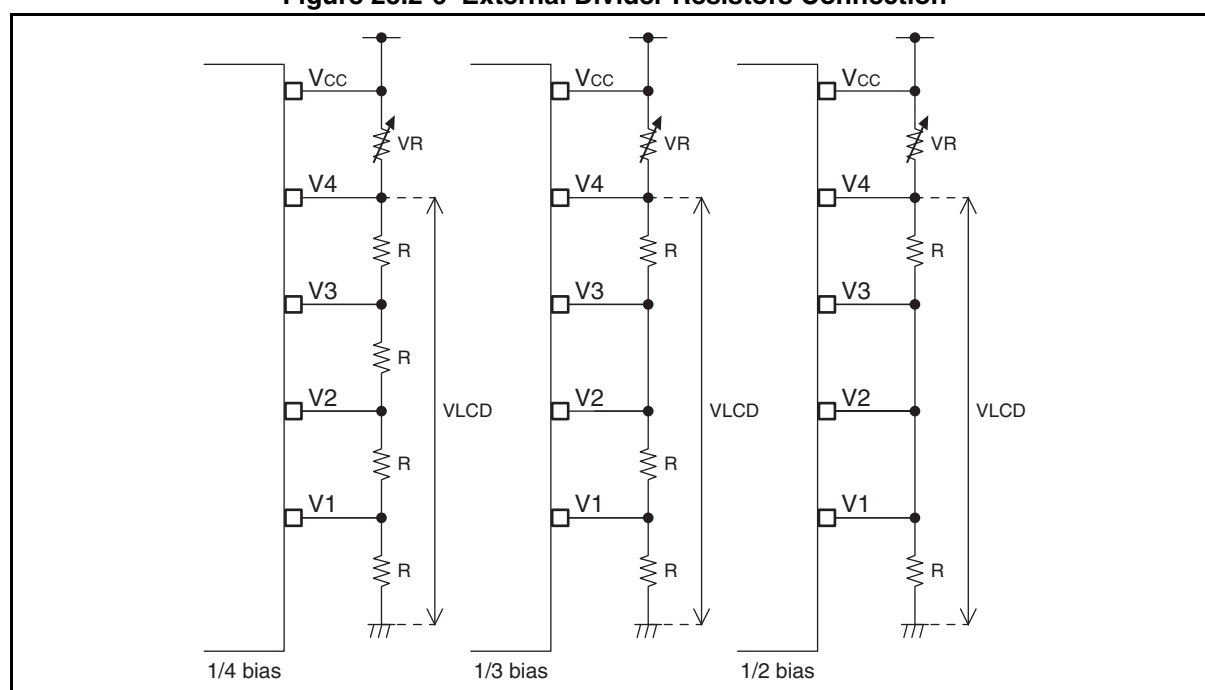

Table 25.2-1 LCD Drive Voltage Settings

	V4	V3	V2	V1
1/2 bias	VLCD	X	1/2 VLCD	X
1/3 bias	VLCD	2/3 VLCD	2/3 VLCD	1/3 VLCD
1/4 bias	VLCD	3/4 VLCD	1/2 VLCD	1/4 VLCD

VLCD : LCD operating voltage

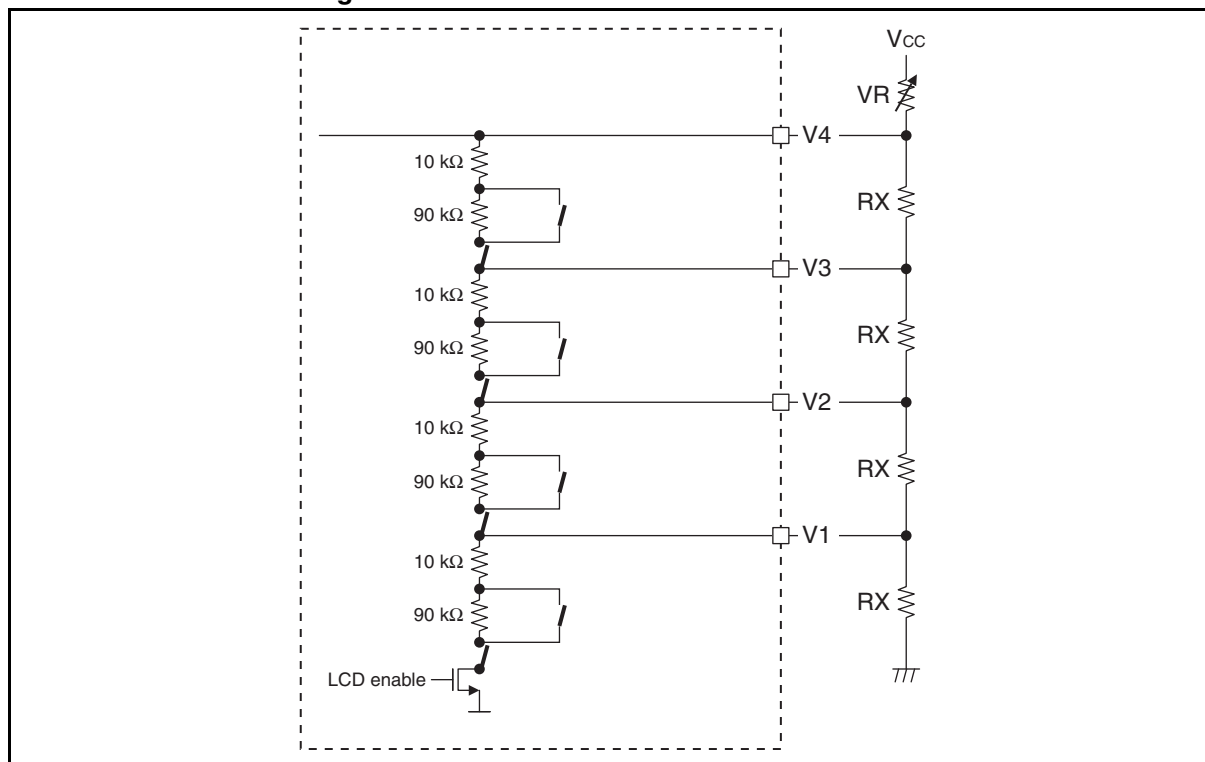

X : No external divider resistor

GND : Ground

■ Using External Divider Resistors

Since the V1 pin is connected to Vss (GND) internally via a transistor, in the case of using external divider resistors, connecting the Vss end of a divider resistor to the V1 pin cuts off current that is flowing to resistors when the LCD controller stops, illustrates the use of external divider resistors.

Figure 25.2-7 Use of External Divider Resistors

1. To connect the external divider resistors without being affected by the internal divider resistors, write "0" to the drive voltage control bit in the LCDC control register 1 (LCDCC1:VSEL) to disconnect all internal divider resistors. Write "1" to the V4 to V1 select bits in the LCDC enable register 1 (LCDCE1:VE[4:0]) to use a pin as an LCD drive power supply pin.
2. When the internal divider resistors are disconnected, writing a value other than "0b000" to the display mode select bits (MS[2:0]) in the LCDCC1 register starts the LCD controller.

Note:

The appropriate resistance of an external RX resistor depends on the LCD used. Use an external RX resistor whose resistance is suitable for the LCD used.

25.3 Pins

This section describes the pins of the LCD controller.

■ Pins of LCD Controller

The LCD controller has the following pins: eight common output pins (COM0 to COM7), 32 segment output pins (SEG00 to SEG31), and four LCD drive power supply pins (V1 to V4).

To use one of these pins for the LCD, set a bit corresponding to that pin in the LCDC enable registers (LCDCE1 to LCDCE6) to "1".

To use a pin for the LCD shared with a general-purpose I/O port as a general-purpose I/O port, set a bit corresponding to that pin in an LCDC enable register (LCDCE1 to LCDCE6) to "0", and then set the port input control bit in the LCDC enable register 1 (LCDCE1:PICTL) to "1".

● COM0 to COM7 pins

In 8 COM mode, COM0 to COM7 function as LCD common output pins.

In 4 COM mode, COM0 to COM3 function as LCD common output pins, and COM4 to COM7 function only as general-purpose I/O ports regardless of the settings of the LCDCE1 to LCDCE6 registers.

COM0 to COM7 can also function as general-purpose I/O ports.

● SEG00 to SEG31 pins

In 8 COM mode, SEG00 to SEG27 function as LCD segment output pins, and the default functions of SEG28 to SEG31 are general-purpose I/O ports regardless of the settings of the LCDCE1 to LCDCE6 registers.

In 4 COM mode, SEG00 to SEG31 function as LCD segment output pins.

SEG00 to SEG31 can also function as general-purpose I/O ports.

● V1 to V4 pins

V1 to V4 are power supply pins for driving the LCD.

They can also function as general-purpose I/O ports.

25.4 Display RAM

The display RAM size varies between 8 COM mode and 4 COM mode.

In 8 COM mode, the display RAM has 28×8 bits (28 bytes) of display data memory for generating segment output signals.

In 4 COM mode, the display RAM has 32×4 bits (16 bytes) of display data memory for generating segment output signals.

■ Display RAM and Output Pins

The content of the display RAM is read automatically in sync with the common signal selection timing and is output from segment output pins.

A bit containing "1" is converted into a selected voltage (displayed on the LCD); a bit containing "0" into a non-select voltage (not displayed on the LCD).

Since the LCD display operation is executed asynchronously with the CPU operation, data can be read from or written to the display RAM at any time. When a pin shared between a segment output pin and a general-purpose I/O port pin is not used as a segment output pin, the pin can be used as a general-purpose I/O port, and the display RAM corresponding to such pin can be used as normal RAM. Table 25.4-1 shows the relationship between duty setting/common outputs and the display RAM bits used.

Figure 25.4-1 and Figure 25.4-2 shows how display RAM addresses are allocated for common output pins and segment output pins in 8 COM mode and in 4 COM mode respectively.

Table 25.4-1 Relationship Between Duty Settings/Common Outputs and Display RAM Bits Used

25.5 Interrupt

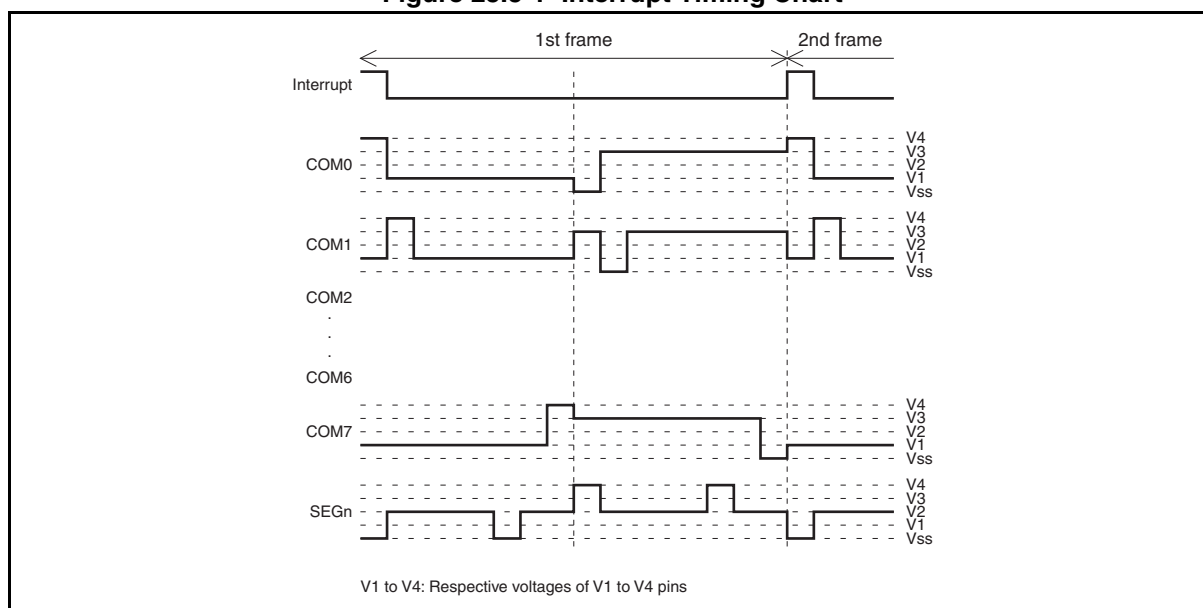

The LCD controller generates interrupts in sync with the LCD module frame frequency.

■ Interrupt during LCD Controller Operation

On completing processing a frame, the LCD controller sets the LCDC interrupt request flag bit (LCDCC2:LCDIF) to "1". If the interrupt request has already been enabled (LCDCC2:LCDIEN = 1) when the LCDIF bit is set to "1", the LCD controller makes an interrupt request to the interrupt controller. To clear an interrupt request, write "0" to the LCDIF bit during the interrupt service routine.

The LCD controller always sets the LCDIF bit to "1" on completing processing a frame, regardless of the value of the LCDIEN bit. After the LCD controller makes an interrupt request, when both the LCDIF bit and the LCDIEN bit remain "1", the CPU cannot return from the interrupt service routine. To enable the CPU to return from the interrupt service routine, always clear the LCDIF bit to "0" after the LCD controller makes an interrupt request.

Figure 25.5-1 Interrupt Timing Chart

25.6 Operations

This section describes the operations of the LCD controller.

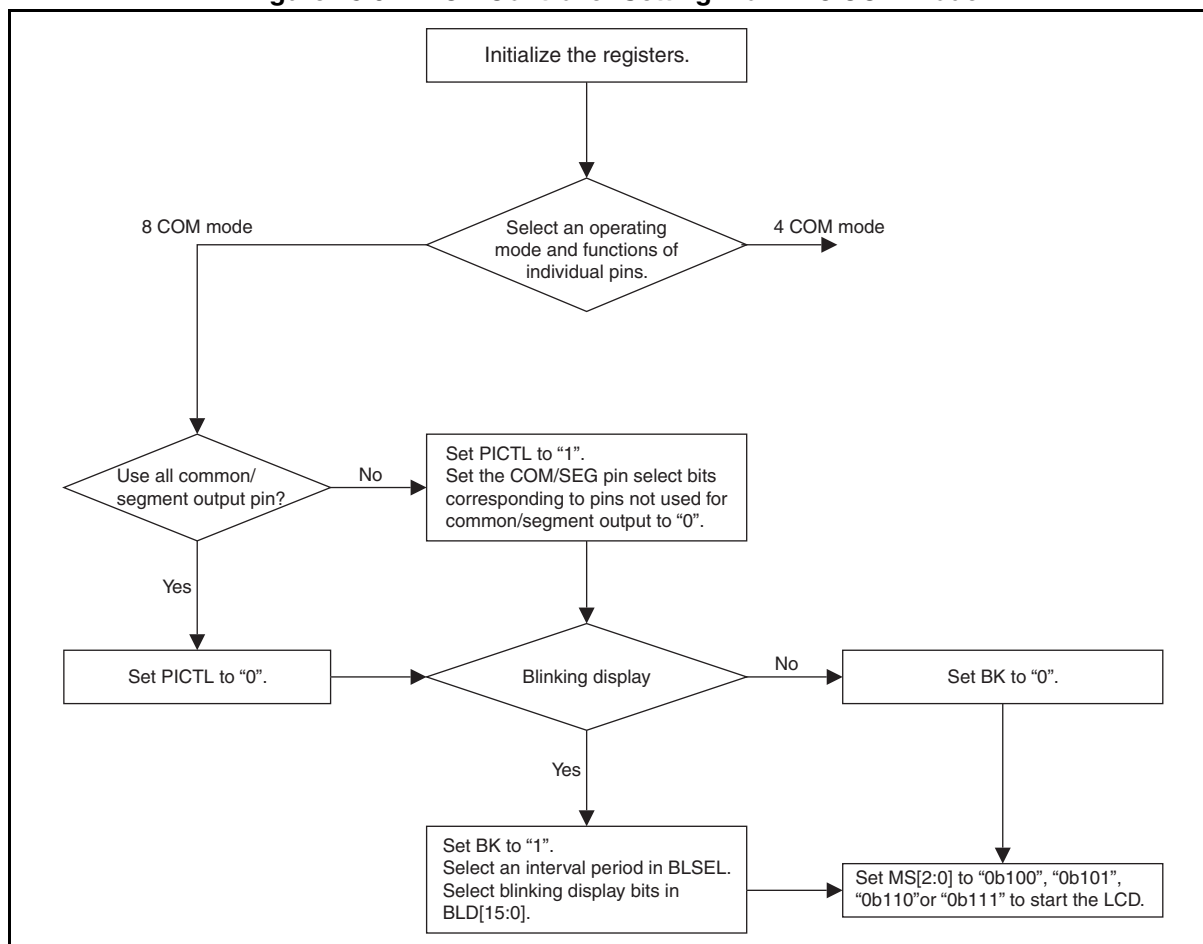

Figure 25.6-1 shows the settings required for LCD display in 8 COM mode.

Figure 25.6-2 LCD Controller Setting Flow in 8 COM Mode

- When the selected frame period generation clock is oscillating with the settings made as shown in Figure 25.6-1, the LCD controller outputs the LCD panel drive waveform to the common output pins and segment output pins (COM0 to COM7, SEG00 to SEG27) according to the content of the display RAM and the settings of different LCDC registers.
- The LCD output pins are selected according to LCDCE1 to LCDCE6. When an LCD output pin shared with a general-purpose I/O port is not selected as a common/segment output pin, the pin is used as a general-purpose I/O port.
- The frame period generation clock can be changed even during LCD display operation. As the LCD display may flicker when the frame period generation clock is changed, always turn off the LCD display temporarily, for example, using the display blanking (LCDCC2:BK = 1) function, before changing the frame period generation clock to prevent the LCD display from flickering.
- The display drive output is a 2-frame alternating waveform selected according to bias and duty settings.
- To use the blink function, set the corresponding bits in the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2) to "1" to turn on the blinking function. The blinking interval can be selected from two options in the BLSEL bit in the LCDC enable register 1 (LCDCE1).

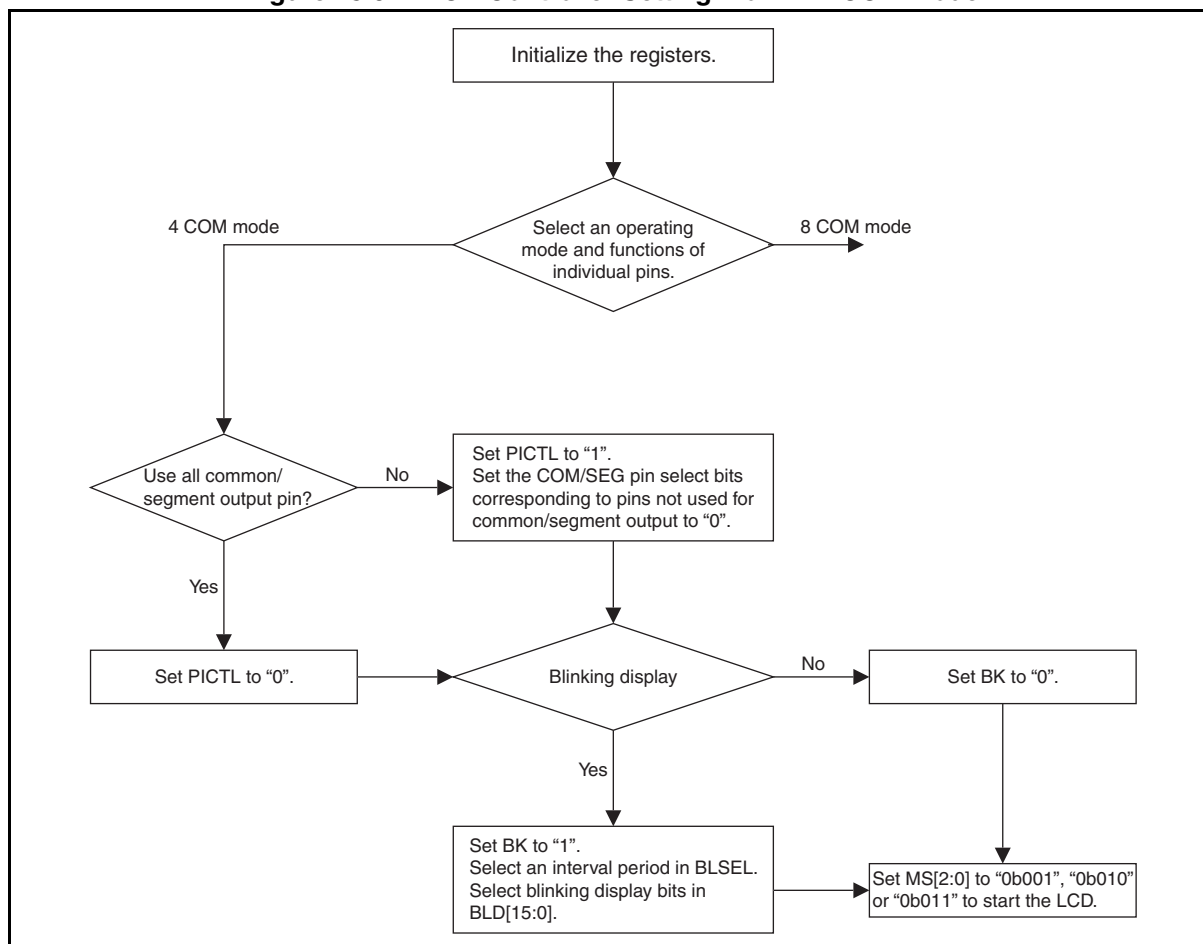

Figure 25.6-3 shows the settings required for LCD display in 4 COM mode.

Figure 25.6-4 LCD Controller Setting Flow in 4 COM Mode

- When the selected frame period generation clock is oscillating with the settings made as shown in Figure 25.6-3, the LCD controller outputs the LCD panel drive waveform to the common output pins and segment output pins (COM0 to COM3, SEG00 to SEG31) according to the content of the display RAM and the settings of different LCDC registers.
- The LCD output pins are selected according to LCDCE1 to LCDCE6. When an LCD output pin shared with a general-purpose I/O port is not selected as a common/segment output pin, the pin is used as a general-purpose I/O port.
- The frame period generation clock can be changed even during LCD display operation. As the LCD display may flicker when the frame period generation clock is changed, always turn off the LCD display temporarily, for example, using the display blanking (LCDC2:BK = 1) function, before changing the frame period generation clock to prevent the LCD display from flickering.
- The display drive output is a 2-frame alternating waveform selected according to bias and duty settings.
- The COM2 and COM3 pin outputs in 1/2 duty mode and the COM3 pin output in 1/3 duty mode can be used to output the non-select level waveform or as I/O ports.
- To use the blink function, set the corresponding bits in the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2) to "1" to turn on the blinking function. The blinking interval can be selected from two options in the BLSEL bit in the LCDC enable register 1 (LCDCE1).

Note:

If the selected frame period generation clock halts during LCD display operation, the AC waveform generator circuit also halts and therefore a DC voltage is applied to the liquid crystal elements. In this case, the LCD display operation must be stopped in advance. The conditions under which the main clock (time-base timer) or subclock (watch prescaler) halts depend on the selected clock mode and standby mode. The frame period is also affected if the time-base timer or watch prescaler is cleared depending on the setting of the frame period generation clock select bit (LCDCC1:CSS).

■ LCD Drive Waveform

Due to the characteristics of the LCD, DC driving of the LCD chemically changes and degrades the liquid crystal display elements. Therefore, the LCD controller driver contains an AC waveform generator circuit to drive the LCD using a 2-frame alternating waveform. There are five types of output waveform as follows:

In 8 COM mode:

- 1/3 bias, 1/8 duty output waveform
- 1/4 bias, 1/8 duty output waveform

In 4 COM mode:

- 1/2 bias, 1/2 duty output waveform
- 1/3 bias, 1/3 duty output waveform
- 1/3 bias, 1/4 duty output waveform

25.6.1 Output Waveform in LCD Controller Operation in 4 COM Mode (1/2 Bias, 1/2 Duty)

The display drive output is a multiplex drive type of 2-frame alternating waveform.

In 4 COM mode with 1/2 bias and 1/2 duty, only COM0 and COM1 are used for display; neither COM2 nor COM3 is used.

■ 4 COM Mode, 1/2 Bias, 1/2 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 25.6-5 shows the output waveform when the content of the display RAM is that shown in Table 25.6-1.

Table 25.6-1 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGn	-	-	0	0
SEG(n+1)	-	-	0	1

-: Unused

Figure 25.6-5 4 COM Mode, 1/2 Bias, 1/2 Duty Output Waveform Example

25.6.2 Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/3 Duty)

In 4 COM mode with 1/3 bias and 1/3 duty, COM0, COM1, and COM2 are used for display; COM3 is not used.

■ 4 COM Mode, 1/3 Bias, 1/3 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 25.6-6 shows the output waveform when the content of the display RAM is that shown in Table 25.6-2.

Table 25.6-2 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGn	-	1	0	0
SEG(n+1)	-	1	0	1

-: Unused

Figure 25.6-6 4 COM Mode, 1/3 Bias, 1/3 Duty Output Waveform Example

25.6.3 Output Waveform in LCD Controller Operation in 4 COM Mode (1/3 Bias, 1/4 Duty)

In 4 COM Mode with 1/3 bias and 1/4 duty, COM0 to COM3 are used for display.

■ 4 COM Mode, 1/3 Bias, 1/4 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 25.6-7 shows the output waveform when the content of the display RAM is that shown in Table 25.6-3.

Table 25.6-3 Sample Content of Display RAM

Segment	Content of Display RAM			
	COM3	COM2	COM1	COM0
SEGN	0	1	0	0
SEG(n+1)	0	1	0	1

Figure 25.6-7 4 COM Mode, 1/3 Bias, 1/4 Duty Output Waveform Example

25.6.4 Output Waveform in LCD Controller Operation in 8 COM Mode (1/3 Bias, 1/8 Duty)

In 8 COM Mode with 1/3 bias and 1/8 duty, COM0 to COM7 are used for display.

■ 8 COM Mode, 1/3 Bias, 1/8 Duty Output Waveform Example

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 25.6-8 shows the output waveform when the content of the display RAM is that shown in Table 25.6-4.

Table 25.6-4 Sample Content of Display RAM

Segment	Content of Display RAM							
	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
SEGN	0	0	0	0	0	0	0	1

Figure 25.6-8 8 COM Mode, 1/3 Bias, 1/8 Duty Output Waveform Example

25.6.5 Output Waveform in LCD Controller Operation in 8 COM Mode (1/4 Bias, 1/8 Duty)

In 8 COM Mode with 1/4 bias and 1/8 duty, COM0 to COM7 are used for display.

■ 8 COM Mode, 1/4 Bias, 1/8 Duty Output Waveform Example

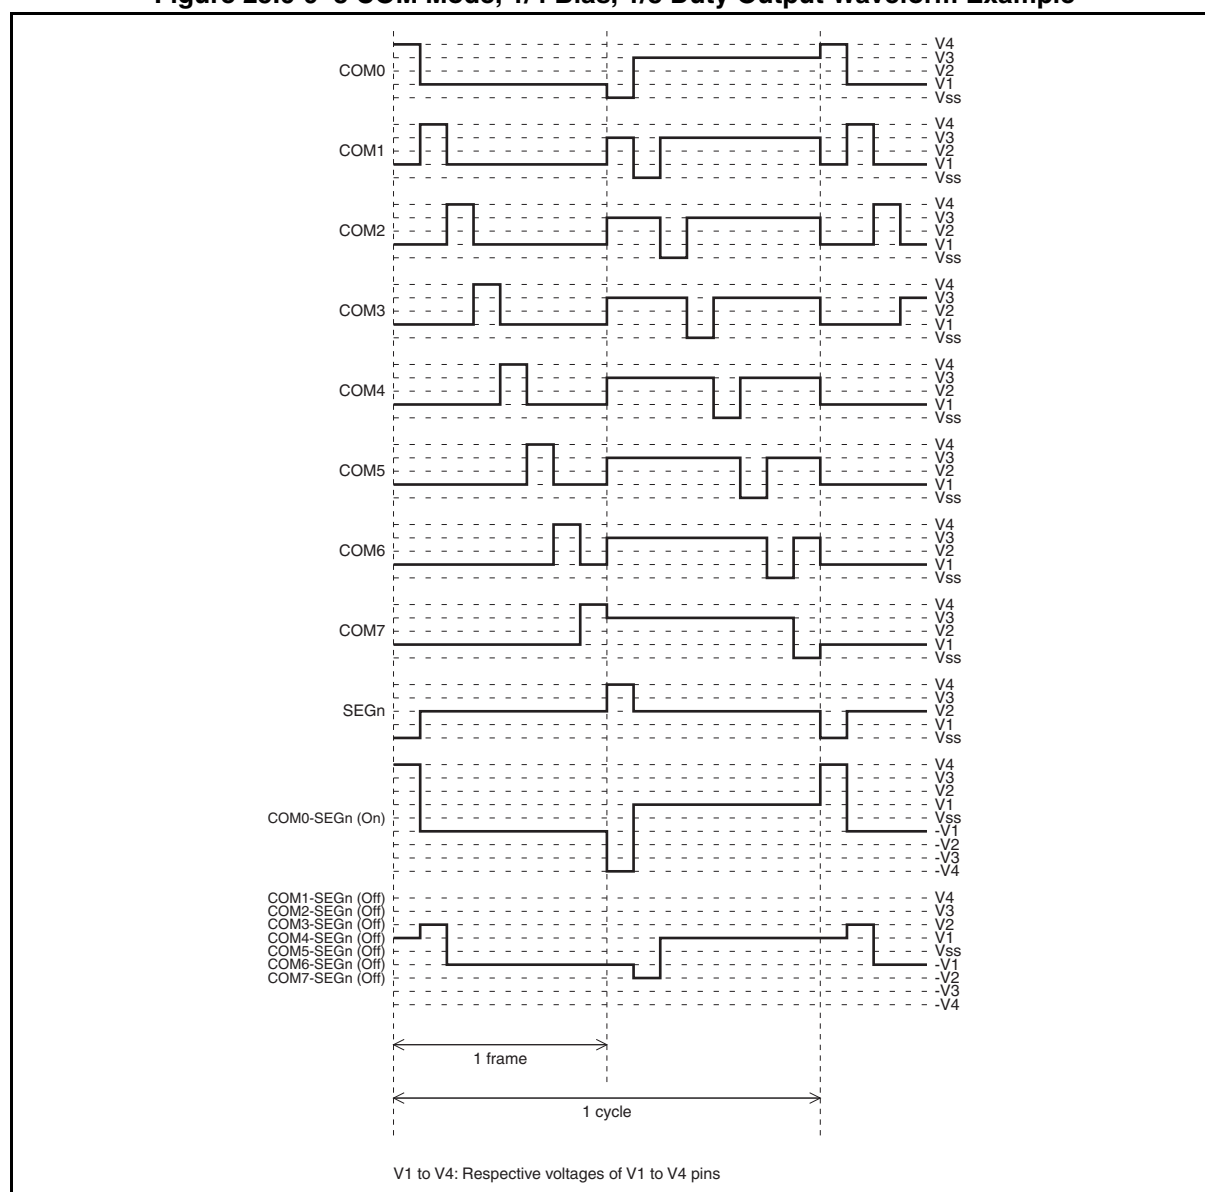

Liquid crystal elements are turned "ON" for display that have the maximum potential difference between the common and segment outputs.

Figure 25.6-9 shows the output waveform when the content of the display RAM is that shown in Table 25.6-5.

Table 25.6-5 Sample Content of Display RAM

Segment	Content of Display RAM							
	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
SEGN	0	0	0	0	0	0	0	1

Figure 25.6-9 8 COM Mode, 1/4 Bias, 1/8 Duty Output Waveform Example

25.7 Registers

This section describes the registers of the LCD controller.

Table 25.7-1 List of LCD Controller Registers

Register abbreviation	Register name	Reference
LCDCC1	LCDC control register 1	25.7.1
LCDCC2	LCDC control register 2	25.7.2
LCDCE1	LCDC enable register 1	25.7.3
LCDCE2	LCDC enable register 2	25.7.4
LCDCE3	LCDC enable register 3	25.7.5
LCDCE4	LCDC enable register 4	25.7.6
LCDCE5	LCDC enable register 5	25.7.7
LCDCE6	LCDC enable register 6	25.7.8
LCDCB1	LCDC blinking setting register 1	25.7.9
LCDCB2	LCDC blinking setting register 2	25.7.10

25.7.1 LCDC Control Register 1 (LCDCC1)

The LCDC control register 1 (LCDCC1) sets the clock and display mode, and controls power supply.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	CSS	LCDEN	VSEL	MS2	MS1	MS0	FP1	FP0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] CSS: Frame period generation clock select bit

This bit selects a clock for generating the frame period for the LCD display.

When this bit is "0", the LCD controller operates with the output of the time-base timer driven by the main clock. When this bit is "1", the LCD controller operates with the output of the watch prescaler driven by the subclock.

Shifting the main clock speed (using the gear function) while the time-base timer is outputting does not affect the frame period.

The LCD display may flicker when the frame period generation clock changes. To prevent the LCD display from flickering, before changing the frame period generation clock, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit7	Details
Writing "0"	Selects the main clock as the clock for generating the frame period for the LCD display.
Writing "1"	Selects the subclock as the clock for generating the frame period for the LCD display.

Note: Since the main clock stops oscillating in main stop mode and subclock mode, the LCD controller cannot operate with the output of the time-base timer in these modes.

[bit6] LCDEN: Main stop/watch mode operation enable bit

This bit controls whether the LCD controller is to continue to operate in main stop mode and watch mode.

bit6	Details
Writing "0"	Stops the LCD controller.
Writing "1"	Makes the LCD controller continue to operate even after the clock mode transits to main stop mode or watch mode.

Note: In the case of making the LCD controller continue to operate in main stop mode or watch mode, select the subclock as the clock for generating the frame period for the LCD display (CSS = 1).

[bit5] VSEL: LCD drive power control bit

This bit controls whether to energize the internal divider resistor.

bit5	Details
Writing "0"	Disconnects the internal divider resistor.
Writing "1"	Energizes the internal divider resistor.

Note: Write "0" to this bit when connecting to the external divider resistor.

[bit4:2] MS[2:0]: Display mode select bits

These bits select a display mode from 4 COM mode and 8 COM mode and also select an output waveform duty from four options.

The common output pins to be used are determined by the duty output mode selected.

When these bits are set to "0b000", the LCD controller driver stops the LCD display operation.

The LCD display may flicker when the display mode changes. To prevent the LCD display from flickering, before changing the display mode, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit4:2	Details
Writing "000"	Stops the LCD display operation.
Writing "001"	Selects 4 COM mode as the display mode and 1/2 as the output waveform duty (time division number N = 2).
Writing "010"	Selects 4 COM mode as the display mode and 1/3 as the output waveform duty (time division number N = 3).
Writing "011"	Selects 4 COM mode as the display mode and 1/4 as the output waveform duty (time division number N = 4).
Writing "100"	Selects 8 COM mode as the display mode and 1/8 as the output waveform duty (time division number N = 8).
Writing "101"	
Writing "110"	
Writing "111"	

Note: The clock (main clock or subclock) for generating the frame period for the LCD display stops as the clock mode transits to stop mode. Therefore, before the clock mode transits to stop mode, stop the LCD display operation (MS[2:0] = 0b000).

[bit1:0] FP[1:0]: Frame period select bits

These bits select an LCD display frame period.

The LCD display may flicker when the frame period changes. To prevent the LCD display from flickering, before changing the frame period, stop the LCD display temporarily by using blanking (LCDCC2:BK = 1).

bit1:0	Details	
	Frame period generated by main clock (LCDCC1:CSS = 0) (F _{CH} : main clock, F _{CRH} : main CR clock)	Frame period generated by subclock (LCDCC1:CSS = 1) (F _{CL} : subclock, F _{CRL} : sub-CR clock)
Writing "00"	$2^{14} \times N/F_{CH}^{*1}$ $2^{13} \times N/F_{CH}^{*2}$ $2^{13} \times N/F_{CRH}$	$2^6 \times N/F_{CL}$ $2^6 \times N/F_{CRL}$
Writing "01"	$2^{15} \times N/F_{CH}^{*1}$ $2^{14} \times N/F_{CH}^{*2}$ $2^{14} \times N/F_{CRH}$	$2^7 \times N/F_{CL}$ $2^7 \times N/F_{CRL}$
Writing "10"	$2^{16} \times N/F_{CH}^{*1}$ $2^{15} \times N/F_{CH}^{*2}$ $2^{15} \times N/F_{CRH}$	$2^8 \times N/F_{CL}$ $2^8 \times N/F_{CRL}$
Writing "11"	$2^{17} \times N/F_{CH}^{*1}$ $2^{16} \times N/F_{CH}^{*2}$ $2^{16} \times N/F_{CRH}$	$2^9 \times N/F_{CL}$ $2^9 \times N/F_{CRL}$

*1: Main clock mode

*2: Main PLL clock mode

Note: Set the FP[1:0] bits according to the optimum frame period for the LCD module to be used. The frame period is affected by the source oscillation frequency.

25.7.2 LCDC Control Register 2 (LCDCC2)

The LCDC control register 2 (LCDCC2) enables or disables interrupts, indicates interrupt status and sets the following parameters:

- Internal resistance (10 kΩ or 100 kΩ)
- Bias (1/3 or 1/4) to be used in 8 COM mode
- Displaying data or a blank screen
- Inverted display

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	RSEL	BLS8	INV	BK	LCDIEN	LCDIF
Attribute	—	—	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	1	0	1	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] RSEL: Internal divider resistor select bit

This bit selects a type of resistor to be used as the internal divider resistor.

bit5	Details
Writing "0"	Selects the 100 kΩ resistor.
Writing "1"	Selects the 10 kΩ resistor.

[bit4] BLS8: Bias in 8 COM mode select bit

This bit selects a type of bias to be used by software in 8 COM mode.

bit4	Details
Writing "0"	Selects 1/3 bias.
Writing "1"	Selects 1/4 bias.

Note: Although this bit can be accessed in both 8 COM mode and 4 COM mode, in 4 COM mode, writing a value to this bit has no effect on operation.

[bit3] INV: Inverted display control bit

This bit controls the inverted display on the LCD.

bit3	Details
Writing "0"	Disables the inverted display on the LCD.
Writing "1"	Enables the inverted display on the LCD.

[bit2] BK: Display blanking control bit

This bit controls display blanking of the LCD.

When display blanking is selected (BK = 1), a segment output pin outputs a non-select waveform (a waveform not meeting the display condition).

bit2	Details
Writing "0"	Makes the LCD display LCD controller display RAM data.
Writing "1"	Makes the LCD blank.

[bit1] LCDIEN: LCDC interrupt request enable bit

This bit enables or disables the generation of interrupt requests in sync with the LCD frame period.

bit1	Details
Writing "0"	Disables the generation of interrupt requests.
Writing "1"	Enables the generation of interrupt requests.

[bit0] LCDIF: LCDC interrupt request flag bit

This bit indicates whether the LCD controller has finished processing a frame.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit0	Details
Reading "0"	Indicates that the LCD controller is processing a frame.
Reading "1"	Indicates that the LCD controller has finished processing a frame.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

25.7.3 LCDC Enable Register 1 (LCDCE1)

The LCDC enable register 1 (LCDCE1) controls port input, selects a blink cycle and enables the drive power supply pins of the LCD controller.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	PICTL	BLSEL	VE4	VE3	VE2	VE1	—	—
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	—	—
Initial value	0	0	1	1	1	1	0	0

■ Register Functions

[bit7] PICTL: Port input control bit

This bit controls the general-purpose I/O ports that can also function as segment/common output pins.

Writing "0" to this bit disables the I/O function of such general-purpose I/O ports, and suppresses shoot-through current occurring while the LCD is outputting data.

Writing "1" to this bit enables the I/O function of such general-purpose I/O ports. To use a segment/common output pin shared with a general-purpose I/O port as a general-purpose I/O port, write "1" to this bit.

bit7	Details
Writing "0"	Disables the I/O function of the general-purpose I/O ports that can also function as segment/common output pins.
Writing "1"	Enables the I/O function of the general-purpose I/O ports that can also function as segment/common output pins.

Note: The input function of such general-purpose I/O ports is disabled by a reset. Therefore, to use their input function after a reset occurs, write "1" to this bit. When such general-purpose I/O ports are used as segment/common output pins, their input function is disabled regardless of the setting of this bit.

[bit6] BLSEL: Blinking interval select bit

This bit selects the blinking interval to be used when blinking is enabled.

Blinking is controlled by the LCDC blinking setting register 1 (LCDCB1) and the LCDC blinking setting register 2 (LCDCB2).

A blinking interval of 1.0 s makes the LCD stay on for 0.5 s and off for 0.5 s; a blinking interval of 0.5 s makes the LCD stay on for 0.25 s and off for 0.25 s.

bit6	Details
Writing "0"	Selects 0.5 s as the blinking interval (with the subclock frequency being 32 kHz).
Writing "1"	Selects 1.0 s as the blinking interval (with the subclock frequency being 32 kHz).

[bit5] VE4: V4 function select bit

This bit selects the function of the V4 pin.

bit5	Details
Writing "0"	Makes the V4 pin function as a general-purpose I/O port.
Writing "1"	Makes the V4 pin function as an LCD drive power supply pin.

[bit4] VE3: V3 function select bit

This bit selects the function of the V3 pin.

bit4	Details
Writing "0"	Makes the V3 pin function as a general-purpose I/O port.
Writing "1"	Makes the V3 pin function as an LCD drive power supply pin.

[bit3] VE2: V2 function select bit

This bit selects the function of the V2 pin.

bit3	Details
Writing "0"	Makes the V2 pin function as a general-purpose I/O port.
Writing "1"	Makes the V2 pin function as an LCD drive power supply pin.

[bit2] VE1: V1 function select bit

This bit selects the function of the V1 pin.

bit2	Details
Writing "0"	Makes the V1 pin function as a general-purpose I/O port.
Writing "1"	Makes the V1 pin function as an LCD drive power supply pin.

[bit1:0] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

Note:

In the case of using the internal divider resistor, since the V4 pin cannot be used as a general-purpose I/O port, write "1" to the VE4 bit to make the V4 pin function as an LCD drive power supply pin.

25.7.4 LCDC Enable Register 2 (LCDCE2)

The LCDC enable register 2 (LCDCE2) controls the respective functions of the COM0 to COM7 pins.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] COM7: COM7 function select bit

This bit selects the function of the COM7 pin.

bit7	Details
Writing "0"	Makes the COM7 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM7 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit6] COM6: COM6 function select bit

This bit selects the function of the COM6 pin.

bit6	Details
Writing "0"	Makes the COM6 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM6 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit5] COM5: COM5 function select bit

This bit selects the function of the COM5 pin.

bit5	Details
Writing "0"	Makes the COM5 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM5 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit4] COM4: COM4 function select bit

This bit selects the function of the COM4 pin.

bit4	Details
Writing "0"	Makes the COM4 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM4 pin function as a common output pin.

Note: In 4 COM mode, writing a value to this bit has no effect on operation.

[bit3] COM3: COM3 function select bit

This bit selects the function of the COM3 pin.

bit3	Details
Writing "0"	Makes the COM3 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM3 pin function as a common output pin.

[bit2] COM2: COM2 function select bit

This bit selects the function of the COM2 pin.

bit2	Details
Writing "0"	Makes the COM2 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM2 pin function as a common output pin.

[bit1] COM1: COM1 function select bit

This bit selects the function of the COM1 pin.

bit1	Details
Writing "0"	Makes the COM1 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM1 pin function as a common output pin.

[bit0] COM0: COM0 function select bit

This bit selects the function of the COM0 pin.

bit0	Details
Writing "0"	Makes the COM0 pin function as a general-purpose I/O port.
Writing "1"	Makes the COM0 pin function as a common output pin.

25.7.5 LCDC Enable Register 3 (LCDCE3)

The LCDC enable register 3 (LCDCE3) controls the segment output pins SEG00 to SEG07.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG07	SEG06	SEG05	SEG04	SEG03	SEG02	SEG01	SEG00
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG07: SEG07 function select bit

This bit selects the function of the SEG07 pin.

bit7	Details
Writing "0"	Makes the SEG07 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG07 pin function as a segment output pin.

[bit6] SEG06: SEG06 function select bit

This bit selects the function of the SEG06 pin.

bit6	Details
Writing "0"	Makes the SEG06 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG06 pin function as a segment output pin.

[bit5] SEG05: SEG05 function select bit

This bit selects the function of the SEG05 pin.

bit5	Details
Writing "0"	Makes the SEG05 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG05 pin function as a segment output pin.

[bit4] SEG04: SEG04 function select bit

This bit selects the function of the SEG04 pin.

bit4	Details
Writing "0"	Makes the SEG04 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG04 pin function as a segment output pin.

[bit3] SEG03: SEG03 function select bit

This bit selects the function of the SEG03 pin.

bit3	Details
Writing "0"	Makes the SEG03 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG03 pin function as a segment output pin.

[bit2] SEG02: SEG02 function select bit

This bit selects the function of the SEG02 pin.

bit2	Details
Writing "0"	Makes the SEG02 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG02 pin function as a segment output pin.

[bit1] SEG01: SEG01 function select bit

This bit selects the function of the SEG01 pin.

bit1	Details
Writing "0"	Makes the SEG01 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG01 pin function as a segment output pin.

[bit0] SEG00: SEG00 function select bit

This bit selects the function of the SEG00 pin.

bit0	Details
Writing "0"	Makes the SEG00 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG00 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE3 register enabled to control the segment output pins SEG00 to SEG07.

25.7.6 LCDC Enable Register 4 (LCDCE4)

The LCDC enable register 4 (LCDCE4) controls the segment output pins SEG08 to SEG15.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG15	SEG14	SEG13	SEG12	SEG11	SEG10	SEG09	SEG08
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG15: SEG15 function select bit

This bit selects the function of the SEG15 pin.

bit7	Details
Writing "0"	Makes the SEG15 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG15 pin function as a segment output pin.

[bit6] SEG14: SEG14 function select bit

This bit selects the function of the SEG14 pin.

bit6	Details
Writing "0"	Makes the SEG14 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG14 pin function as a segment output pin.

[bit5] SEG13: SEG13 function select bit

This bit selects the function of the SEG13 pin.

bit5	Details
Writing "0"	Makes the SEG13 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG13 pin function as a segment output pin.

[bit4] SEG12: SEG12 function select bit

This bit selects the function of the SEG12 pin.

bit4	Details
Writing "0"	Makes the SEG12 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG12 pin function as a segment output pin.

[bit3] SEG11: SEG11 function select bit

This bit selects the function of the SEG11 pin.

bit3	Details
Writing "0"	Makes the SEG11 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG11 pin function as a segment output pin.

[bit2] SEG10: SEG10 function select bit

This bit selects the function of the SEG10 pin.

bit2	Details
Writing "0"	Makes the SEG10 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG10 pin function as a segment output pin.

[bit1] SEG09: SEG09 function select bit

This bit selects the function of the SEG09 pin.

bit1	Details
Writing "0"	Makes the SEG09 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG09 pin function as a segment output pin.

[bit0] SEG08: SEG08 function select bit

This bit selects the function of the SEG08 pin.

bit0	Details
Writing "0"	Makes the SEG08 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG08 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE4 register enabled to control the segment output pins SEG08 to SEG15.

25.7.7 LCDC Enable Register 5 (LCDCE5)

The LCDC enable register 5 (LCDCE5) controls the segment output pins SEG16 to SEG23.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG23	SEG22	SEG21	SEG20	SEG19	SEG18	SEG17	SEG16
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG23: SEG23 function select bit

This bit selects the function of the SEG23 pin.

bit7	Details
Writing "0"	Makes the SEG23 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG23 pin function as a segment output pin.

[bit6] SEG22: SEG22 function select bit

This bit selects the function of the SEG22 pin.

bit6	Details
Writing "0"	Makes the SEG22 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG22 pin function as a segment output pin.

[bit5] SEG21: SEG21 function select bit

This bit selects the function of the SEG21 pin.

bit5	Details
Writing "0"	Makes the SEG21 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG21 pin function as a segment output pin.

[bit4] SEG20: SEG20 function select bit

This bit selects the function of the SEG20 pin.

bit4	Details
Writing "0"	Makes the SEG20 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG20 pin function as a segment output pin.

[bit3] SEG19: SEG19 function select bit

This bit selects the function of the SEG19 pin.

bit3	Details
Writing "0"	Makes the SEG19 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG19 pin function as a segment output pin.

[bit2] SEG18: SEG18 function select bit

This bit selects the function of the SEG18 pin.

bit2	Details
Writing "0"	Makes the SEG18 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG18 pin function as a segment output pin.

[bit1] SEG17: SEG17 function select bit

This bit selects the function of the SEG17 pin.

bit1	Details
Writing "0"	Makes the SEG17 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG17 pin function as a segment output pin.

[bit0] SEG16: SEG16 function select bit

This bit selects the function of the SEG16 pin.

bit0	Details
Writing "0"	Makes the SEG16 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG16 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE5 register enabled to control the segment output pins SEG16 to SEG23.

25.7.8 LCDC Enable Register 6 (LCDCE6)

The LCDC enable register 6 (LCDCE6) controls the segment output pins SEG24 to SEG31.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	SEG31	SEG30	SEG29	SEG28	SEG27	SEG26	SEG25	SEG24
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] SEG31: SEG31 function select bit

This bit selects the function of the SEG31 pin.

bit7	Details
Writing "0"	Makes the SEG31 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG31 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit6] SEG30: SEG30 function select bit

This bit selects the function of the SEG30 pin.

bit6	Details
Writing "0"	Makes the SEG30 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG30 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit5] SEG29: SEG29 function select bit

This bit selects the function of the SEG29 pin.

bit5	Details
Writing "0"	Makes the SEG29 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG29 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit4] SEG28: SEG28 function select bit

This bit selects the function of the SEG28 pin.

bit4	Details
Writing "0"	Makes the SEG28 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG28 pin function as a segment output pin.

Note: In 8 COM mode, writing a value to this bit has no effect on operation.

[bit3] SEG27: SEG27 function select bit

This bit selects the function of the SEG27 pin.

bit3	Details
Writing "0"	Makes the SEG27 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG27 pin function as a segment output pin.

[bit2] SEG26: SEG26 function select bit

This bit selects the function of the SEG26 pin.

bit2	Details
Writing "0"	Makes the SEG26 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG26 pin function as a segment output pin.

[bit1] SEG25: SEG25 function select bit

This bit selects the function of the SEG25 pin.

bit1	Details
Writing "0"	Makes the SEG25 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG25 pin function as a segment output pin.

[bit0] SEG24: SEG24 function select bit

This bit selects the function of the SEG24 pin.

bit0	Details
Writing "0"	Makes the SEG24 pin function as a general-purpose I/O port.
Writing "1"	Makes the SEG24 pin function as a segment output pin.

Note:

Only when the PICTL bit in the LCDCE1 register is set to "1" is the LCDCE6 register enabled to control the segment output pins SEG24 to SEG31.

25.7.9 LCDC Blinking Setting Register 1 (LCDCB1)

The LCDC blinking setting register 1 (LCDCB1) enables or disables the blinking function.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BLD7	BLD6	BLD5	BLD4	BLD3	BLD2	BLD1	BLD0
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions (8 COM Mode)

[bit7] BLD7: S0C7 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM7.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM7.
Writing "1"	Enables the blinking of dots in SEG00 and COM7.

[bit6] BLD6: S0C6 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM6.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM6.
Writing "1"	Enables the blinking of dots in SEG00 and COM6.

[bit5] BLD5: S0C5 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM5.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM5.
Writing "1"	Enables the blinking of dots in SEG00 and COM5.

[bit4] BLD4: S0C4 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM4.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM4.
Writing "1"	Enables the blinking of dots in SEG00 and COM4.

[bit3] BLD3: S0C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM3.
Writing "1"	Enables the blinking of dots in SEG00 and COM3.

[bit2] BLD2: S0C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM2.
Writing "1"	Enables the blinking of dots in SEG00 and COM2.

[bit1] BLD1: S0C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM1.
Writing "1"	Enables the blinking of dots in SEG00 and COM1.

[bit0] BLD0: S0C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM0.
Writing "1"	Enables the blinking of dots in SEG00 and COM0.

■ Register Functions (4 COM Mode)

[bit7] BLD7: S1C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM3.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM3.
Writing "1"	Enables the blinking of dots in SEG01 and COM3.

[bit6] BLD6: S1C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM2.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM2.
Writing "1"	Enables the blinking of dots in SEG01 and COM2.

[bit5] BLD5: S1C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM1.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM1.
Writing "1"	Enables the blinking of dots in SEG01 and COM1.

[bit4] BLD4: S1C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM0.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM0.
Writing "1"	Enables the blinking of dots in SEG01 and COM0.

[bit3] BLD3: S0C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM3.
Writing "1"	Enables the blinking of dots in SEG00 and COM3.

[bit2] BLD2: S0C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM2.
Writing "1"	Enables the blinking of dots in SEG00 and COM2.

[bit1] BLD1: S0C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM1.
Writing "1"	Enables the blinking of dots in SEG00 and COM1.

[bit0] BLD0: S0C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG00 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG00 and COM0.
Writing "1"	Enables the blinking of dots in SEG00 and COM0.

Notes:

- Select a blinking interval by using the BLSEL bit in the LCDCE1 register.
- All segments whose blinking has been enabled blink in sync.
- The setting of a blinking setting bit remains effective even when its corresponding bit in the display RAM holds "1".

25.7.10 LCDC Blinking Setting Register 2 (LCDCB2)

The LCDC blinking setting register 2 (LCDCB2) enables or disables the blinking function.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	BLD15	BLD14	BLD13	BLD12	BLD11	BLD10	BLD9	BLD8
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions (8 COM Mode)

[bit7] BLD15: S1C7 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM7.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM7.
Writing "1"	Enables the blinking of dots in SEG01 and COM7.

[bit6] BLD14: S1C6 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM6.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM6.
Writing "1"	Enables the blinking of dots in SEG01 and COM6.

[bit5] BLD13: S1C5 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM5.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM5.
Writing "1"	Enables the blinking of dots in SEG01 and COM5.

[bit4] BLD12: S1C4 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM4.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM4.
Writing "1"	Enables the blinking of dots in SEG01 and COM4.

[bit3] BLD11: S1C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM3.
Writing "1"	Enables the blinking of dots in SEG01 and COM3.

[bit2] BLD10: S1C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM2.
Writing "1"	Enables the blinking of dots in SEG01 and COM2.

[bit1] BLD9: S1C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM1.
Writing "1"	Enables the blinking of dots in SEG01 and COM1.

[bit0] BLD8: S1C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG01 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG01 and COM0.
Writing "1"	Enables the blinking of dots in SEG01 and COM0.

■ Register Functions (4 COM Mode)

[bit7] BLD15: S3C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM3.

bit7	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM3.
Writing "1"	Enables the blinking of dots in SEG03 and COM3.

[bit6] BLD14: S3C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM2.

bit6	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM2.
Writing "1"	Enables the blinking of dots in SEG03 and COM2.

[bit5] BLD13: S3C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM1.

bit5	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM1.
Writing "1"	Enables the blinking of dots in SEG03 and COM1.

[bit4] BLD12: S3C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG03 and COM0.

bit4	Details
Writing "0"	Disables the blinking of dots in SEG03 and COM0.
Writing "1"	Enables the blinking of dots in SEG03 and COM0.

[bit3] BLD11: S2C3 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM3.

bit3	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM3.
Writing "1"	Enables the blinking of dots in SEG02 and COM3.

[bit2] BLD10: S2C2 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM2.

bit2	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM2.
Writing "1"	Enables the blinking of dots in SEG02 and COM2.

[bit1] BLD9: S2C1 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM1.

bit1	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM1.
Writing "1"	Enables the blinking of dots in SEG02 and COM1.

[bit0] BLD8: S2C0 blinking setting bit

This bit enables or disables the blinking of dots in SEG02 and COM0.

bit0	Details
Writing "0"	Disables the blinking of dots in SEG02 and COM0.
Writing "1"	Enables the blinking of dots in SEG02 and COM0.

Notes:

- Select a blinking interval by using the BLSEL bit in the LCDCE1 register.
- All segments whose blinking has been enabled blink in sync.
- The setting of a blinking setting bit remains effective even when its corresponding bit in the display RAM holds "1".

25.8 Notes on Using LCD Controller

This section provides notes on using the LCD controller.

- To use an LCD pin as a general-purpose I/O port, set a corresponding common/segment select bit in an LCDC enable register (LCDCE1 to LCDCE6) to "0", and then set the port input control bit in the LCDC enable register 1 (LCDCE1:PICTL) to "1".
- If the selected frame period generation clock halts during LCD display operation, the AC waveform generator circuit also halts and therefore a DC voltage is applied to the liquid crystal elements. In this case, the LCD display operation must be stopped in advance. The conditions under which the main clock (time-base timer) or subclock (watch prescaler) halts depend on the selected clock mode and standby mode. The frame period is also affected if the time-base timer or the watch prescaler is cleared according to the setting of the frame period generation clock select bit (LCDCC1:CSS).
- The operation of outputting display RAM data to the LCD is not in sync with the CPU accessing to the display RAM. When the interval for rewriting the display RAM is shorter than the LCD cycle, flickers may occur that are caused by different display patterns between frames.

CHAPTER 26

EXAMPLE OF SERIAL PROGRAMMING CONNECTION

This chapter describes the example of serial programming connection.

- 26.1 Basic Configuration of Serial Programming Connection
- 26.2 Example of Serial Programming Connection

26.1 Basic Configuration of Serial Programming Connection

The MB95710L/770L Series supports Flash memory serial on-board programming. This section describes the configuration.

■ Basic Configuration of Serial Programming Connection

The BGM adaptor MB2146-07-E or MB2146-08-E, manufactured by Spansion Inc., is used for serial onboard programming.

Figure 26.1-1 shows the basic configuration of serial programming connection.

Figure 26.1-1 Basic Configuration of Serial Programming Connection

Table 26.1-1 Pins Used for Standard Serial Onboard Programming

Pin	Function	Details
V _{CC}	Power supply voltage supply pin	The programming voltage (1.8 V to 5.5 V) is supplied from the user system.
V _{SS}	GND pin	It is shared with the GND of the Flash microcontroller programmer.
C	Decoupling capacitor connection	Connect it to a decoupling capacitor and then to the ground.
$\overline{\text{RST}}$	Reset	The $\overline{\text{RST}}$ pin is pulled up to V _{CC} .
DBG	1-line UART setting serial programming mode	The DBG pin provides 1-line UART communication with the programmer. The serial programming mode is set if voltage is supplied to the DBG pin and the V _{CC} pin at specific timings. (For the timings, see Figure 26.2-1.)

● UART clock

The UART clock is supplied from the main CR clock.

26.2 Example of Serial Programming Connection

The MCU enters the PGM mode at the following timing.

■ MCU Transiting to PGM Mode

The MCU enters the PGM mode at the following timing.

The serial programmer controls the DBG pin according to V_{CC} input.

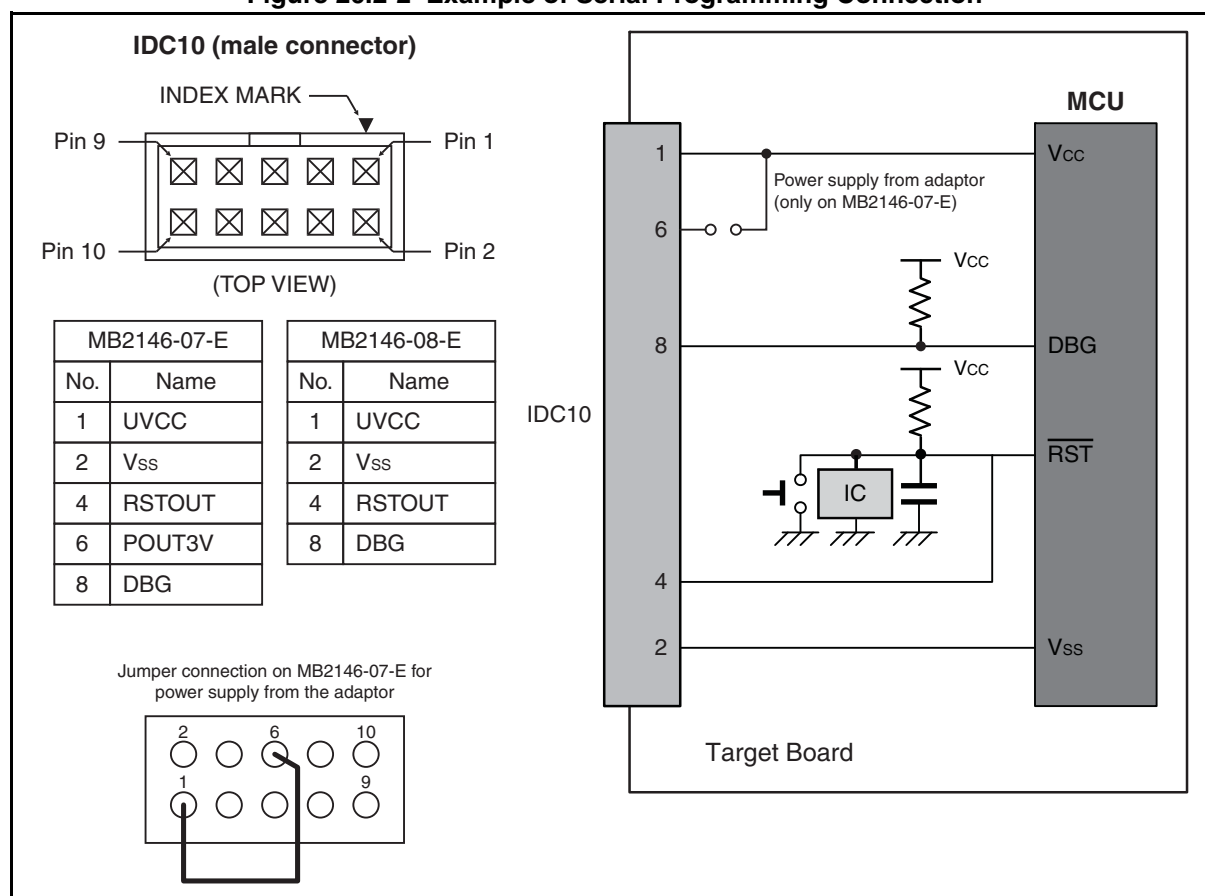

Figure 26.2-1 Timing Diagram

■ Example of Serial Programming Connection

Figure 26.2-2 shows an example of connection for serial programming.

Figure 26.2-2 Example of Serial Programming Connection

Since the pull-up resistor that can be used depends on the tool used and the interconnection length, refer to the tool document when selecting a pull-up resistor.

In the case of using MB2146-07-E of Spansion Inc., it is recommended to use a pull-up resistor of approximately 2 kΩ to 10 kΩ.

CHAPTER 27

DUAL OPERATION FLASH MEMORY

This chapter describes the function and operations of the 160/288/480 Kbit Dual operation Flash memory.

- 27.1 Overview
- 27.2 Sector/Bank Configuration
- 27.3 Invoking Flash Memory Automatic Algorithm
- 27.4 Checking Automatic Algorithm Execution Status
- 27.5 Programming/Erasing Flash Memory
- 27.6 Operations
- 27.7 Flash Security
- 27.8 Registers
- 27.9 Notes on Using Dual Operation Flash Memory

27.1 Overview

The dual operation Flash memory is located at 0x1000 to 0x1FFF and at 0xC000 to 0xFFFF for 160 Kbit Flash memory, at 0x1000 to 0x1FFF and at 0x8000 to 0xFFFF for 288 Kbit Flash memory, or at 0x1000 to 0xFFFF for 480 Kbit Flash memory on the CPU memory map.

The dual operation Flash memory consists of an upper bank and a lower bank*. Unlike conventional Flash products, programming/erasing data to/from one bank and reading data from another bank can be executed simultaneously.

*: MB95F718E/F718L/F778E/F778L:

upper bank: 32 Kbyte \times 1 + 24 Kbyte \times 1; lower bank: 2 Kbyte \times 2

MB95F716E/F716L/F776E/F776L:

upper bank: 32 Kbyte \times 1; lower bank: 2 Kbyte \times 2

MB95F714E/F714L/F774E/F774L:

upper bank: 16 Kbyte \times 1; lower bank: 2 Kbyte \times 2

■ Overview of Dual Operation Flash Memory

The following methods can be used to write data into and erase data from the Flash memory:

- Programming/erasing using a dedicated serial programmer
- Programming/erasing by program execution

Since data can be written into and erased from the Dual operation Flash memory by instructions from the CPU via the Flash memory interface circuit, program code and data can be efficiently updated with the device mounted on a circuit board. The minimum sector size of the dual operation Flash is 2 Kbyte, which is a sector configuration facilitating the management of the program/data area.

Data can be updated by executing a program in RAM or by executing a program in the Flash memory in dual operation. The erase/program operation and the read operation can be executed in different banks (upper bank/lower bank) simultaneously.

The dual operation Flash can use the following combinations:

Upper bank	Lower bank
Read	
Read	Program/sector erase
Program/sector erase	Read
Chip erase	
Sector erase (erase suspend)	Program
Program	Sector erase (erase suspend)

■ Features of Dual Operation Flash Memory

- Sector configuration
 - 20 Kbyte (16 Kbyte + 2 Kbyte × 2)
 - 36 Kbyte (32 Kbyte + 2 Kbyte × 2)
 - 60 Kbyte (32 Kbyte + 24 Kbyte + 2 Kbyte × 2)
- Two-bank configuration, enabling simultaneous execution of a program/erase operation and a read operation
- Automatic algorithm (Embedded Algorithm)
- Erase-suspend/erase-resume functions integrated
- Detecting the completion of programming/erasing using the data polling flag or the toggle bit
- Detecting the completion of programming/erasing by CPU interrupts
- Capable of erasing data in specific sectors (any combination of sectors)
- Compatible with JEDEC standard commands
- Number of program/erase cycles (minimum): 100000
- Flash read cycle time (minimum): 1 machine cycle

■ Programming and Erasing Flash Memory

- Programming data to and reading data from the same bank of the Flash memory cannot be executed simultaneously.
- To program data to or erase data from a bank in the Flash memory, copy the program for programming/erasing either to another bank or to the RAM first, and then execute the program.
- The dual operation Flash memory enables programming in the Flash memory and controlling programming by using interrupts. In addition, it is not necessary to download a program to RAM in order to program data to a bank, thereby reducing the time of program download and eliminating the need to protecting RAM data against power interruption.

27.2 Sector/Bank Configuration

This section shows the sector/bank configuration of the Flash memory.

■ Sector/Bank Configuration of Dual Operation Flash Memory

Figure 27.2-1 shows the sector configuration of the Dual operation Flash memory. The upper and lower addresses of each sector are shown in the figure.

● Bank configuration

The lower bank of the Flash memory is SA0 and SA1 and the upper bank SA2 and SA3.

Figure 27.2-1 Sector/Bank Configuration of Dual Operation Flash Memory

Flash memory (20 Kbyte)		Flash memory (36 Kbyte)		Flash memory (60 Kbyte)		CPU address
SA0: 2 Kbyte	Lower bank	SA0: 2 Kbyte	Lower bank	SA0: 2 Kbyte	Lower bank	0x1000
SA1: 2 Kbyte		SA1: 2 Kbyte		SA1: 2 Kbyte		0x17FF
-		-		SA2: 24 Kbyte		0x1800
						0x1FFF
						0x2000
						0x7FFF
SA3: 16 Kbyte	Upper bank	SA3: 32 Kbyte	Upper bank	SA3: 32 Kbyte	Upper bank	0x8000
						0xBFFF
						0xC000
						0xFFFF

27.3 Invoking Flash Memory Automatic Algorithm

There are four commands that invoke the Flash memory automatic algorithm: read/reset, program, chip erase, and sector erase. The sector erase command is capable of suspending and resuming sector erase.

■ Command Sequence Table

Table 27.3-1 lists commands used in programming/erasing Flash memory.

Table 27.3-1 Command Sequence

Command sequence	Bus write cycle	1st bus write cycle		2nd bus write cycle		3rd bus write cycle		4th bus write cycle		5th bus write cycle		6th bus write cycle	
		Address	Data	Address	Data	Address	Data	Address	Data	Address	Data	Address	Data
Read/reset	1	0xUXXX	0xF0	-	-	-	-	-	-	-	-	-	-
Program	4	0xUAAA	0xAA	0xU554	0x55	0xUAAA	0xA0	PA	PD	-	-	-	-
Chip erase	6	0xUAAA	0xAA	0xU554	0x55	0xUAAA	0x80	0xUAAA	0xAA	0xU554	0x55	0xUAAA	0x10
Sector erase	6	0xUAAA	0xAA	0xU554	0x55	0xUAAA	0x80	0xUAAA	0xAA	0xU554	0x55	SA	0x30
Unlock bypass entry	3	0xUAAA	0xAA	0xU554	0x55	0xUAAA	0x20	-	-	-	-	-	-
Unlock bypass program	2	0xUXXX	0xA0	PA	PD	-	-	-	-	-	-	-	-
Unlock bypass reset	2	0xUXXX	0x90	0xUXXX	any	-	-	-	-	-	-	-	-
Sector erase suspend		Programming data "0xB0" to the address "0xUXXX" suspends erasing during sector erase.											
Sector erase resume		Programming data "0x30" to the address "0xUXXX" resumes suspended sector erase.											
Erase sector add		Programming data "0x30" to the SA adds a new sector to be erased.											

PA : Program address

SA : Sector address (Specify any address in a sector.)

PD : Program data

U : The upper four bits represent an address in a sector to which data can be programmed.

X : Any address value

any : Any program data

Notes:

- Addresses in Table 27.3-1 are values on the CPU memory map. All addresses and data are in hexadecimal notation. However, "X" is an arbitrary value.
 - "U" in an address in Table 27.3-1 is not arbitrary, but represents the upper four bits (bit15 to bit12) of an address.
 - The chip erase command is accepted only when programming data into all sectors has been enabled. The chip erase command is ignored if the bit for any sector in the flash memory sector write control register 0 (SWRE0) has been set to "0" (to disable programming data to that sector).
-

■ Note on Issuing Commands

Enable programming data into a required sector before issuing the first command in the command sequence table.

27.4 Checking Automatic Algorithm Execution Status

Since the Flash memory uses the automatic algorithm to execute the program/erase flow, its internal operating status can be checked through the hardware sequence flags.

■ Hardware Sequence Flags

● Overview of hardware sequence flags

The hardware sequence flag consists of the following 5-bit output:

- Data polling flag (DQ7)
- Toggle bit flag (DQ6)
- Execution timeout flag (DQ5)
- Sector erase timer flag (DQ3)
- Toggle bit2 flag (DQ2)

The hardware sequence flags can tell whether a program command, a chip erase command or a sector erase command has been terminated, whether an erase code can be written and whether an erase sector or a non-erase sector is being read.

The value of a hardware sequence flag can be checked by a read access to the address of a target sector in the Flash memory after a command sequence is set. Note that a hardware sequence flag is output only to the bank from which a command has been issued.

Table 27.4-1 shows the bit allocation of the hardware sequence flags.

Table 27.4-1 Bit Allocation of Hardware Sequence Flag

Bit no.	7	6	5	4	3	2	1	0
Hardware sequence flag	DQ7	DQ6	DQ5	-	DQ3	DQ2	-	-

- To decide whether a program command, a chip erase command or a sector erase command is being executed or has been terminated, check the respective hardware sequence flags or the flash memory program/erase status bit in the flash memory status register (FSR:RDY). After programming/erasing is terminated, the Flash memory returns to the read/reset state.
- When creating a program/erase program, read data after confirming the termination of programming/erasing using the DQ2, DQ3, DQ5, DQ6 and DQ7 flags.
- The hardware sequence flags can also be used to check whether the second sector erase code write and those to be executed afterward are valid or not.

● Description of hardware sequence flags

Table 27.4-2 lists the functions of the hardware sequence flags.

Table 27.4-2 List of Hardware Sequence Flag Functions

State		DQ7	DQ6	DQ5	DQ3	DQ2
State transition during normal operation	Programming → Programming completed (when program address has been specified)	$\overline{\text{DQ7}} \rightarrow \text{DATA: 7}$	Toggle → DATA: 6	0 → DATA: 5	0 → DATA: 3	0 → DATA: 2
	Chip/sector erase → Erase completed	0 → 1	Toggle → 1	0 → 1	1	Toggle → 1
	Sector erase wait → Erase started	0	Toggle	0	0 → 1	Toggle
	Erasing → sector erase suspended (Sector being erased)	0	Toggle → 0	0	1	Toggle
	Sector erase suspended → Erasing resumed (Sector being erased)	0	0 → Toggle	0	1	Toggle
	Sector erase being suspended (Sector not being erased)	DATA: 7	DATA: 6	DATA: 5	DATA: 3	DATA: 2
Abnormal operation	Programming	$\overline{\text{DQ7}}$	Toggle	1	0	0
	Chip/sector erase	0	Toggle	1	1	Toggle

27.4.1 Data Polling Flag (DQ7)

The data polling flag (DQ7) is a hardware sequence flag indicating that the automatic algorithm is being executing or has been completed using the data polling function.

■ Data Polling Flag (DQ7)

Table 27.4-3 and Table 27.4-4 show the state transition of the data polling flag during normal operation and the one during abnormal operation respectively.

Table 27.4-3 State Transition of Data Polling Flag (During Normal Operation)

Operating state	Programming → Programming completed	Chip/sector erase → Erasing completed	Sector erase wait → Erasing started	Sector erase → Sector erase suspended (Sector being erased)	Sector erase suspended → Erasing resumed (Sector being erased)	Sector erase being suspended (Sector not being erased)
DQ7	$\overline{DQ7} \rightarrow \text{DATA: } 7$	$0 \rightarrow 1$	0	0	0	DATA: 7

Table 27.4-4 State Transition of Data Polling Flag (During Abnormal Operation)

Operating state	Programming	Chip/sector erase
DQ7	$\overline{DQ7}$	0

● At programming

When read access takes place during execution of the automatic write algorithm, the Flash memory outputs the inverted value of bit7 in the last data written to DQ7.

If read access takes place on completion of the automatic write algorithm, the Flash memory outputs bit7 of the value read from the read-accessed address to DQ7.

● At chip/sector erase

When read access is made to the sector currently being erased during execution of the chip/sector erase algorithm, bit7 of Flash memory outputs "0". Bit7 of Flash memory outputs "1" upon completion of chip/sector erase.

● At sector erase suspension

- When read access takes place with a sector erase operation suspended, the Flash memory outputs "0" to DQ7 if the read address is the sector being erased. If not, the Flash memory outputs bit7 (DATA:7) of the value read from the read address to DQ7.
- Referring the data polling flag (DQ7) together with the toggle bit flag (DQ6) permits a decision on whether Flash memory is in the sector erase suspended state or which sector is being erased.

Note:

Once the automatic algorithm has been started, read access to the specified address is ignored. Data reading is allowed after the data polling flag (DQ7) is set to "1". Data reading after the end of the automatic algorithm should be performed following read access made to confirm the completion of data polling.

27.4.2 Toggle Bit Flag (DQ6)

The toggle bit flag (DQ6) is a hardware sequence flag using the toggle bit function to indicate whether the automatic algorithm is being executed or has terminated.

■ Toggle Bit Flag (DQ6)

Table 27.4-5 and Table 27.4-6 show the state transition of the toggle bit flag during normal operation and the one during abnormal operation respectively.

Table 27.4-5 State Transition of Toggle Bit Flag (During Normal Operation)

Operating state	Programming → Programming completed	Chip/sector erase → Erasing completed	Sector erase wait → Erasing started	Sector erase → Sector erase suspended (Sector being erased)	Sector erase suspended → Erasing resumed (Sector being erased)	Sector erase being suspended (Sector not being erased)
DQ6	Toggle → DATA: 6	Toggle → 1	Toggle	Toggle → 0	0 → Toggle	DATA: 6

Table 27.4-6 State Transition of Toggle Bit Flag (During Abnormal Operation)

Operating state	Programming	Chip/sector erase
DQ6	Toggle	Toggle

● At programming and chip/sector erase

- When read accesses are made continuously while the automatic write algorithm or the automatic chip/sector erase algorithm is being executed, the Flash memory toggles the output between "1" and "0" at each read access.
- When read accesses are made continuously after the automatic write algorithm or the chip/sector erase algorithm terminates, the Flash memory outputs bit6 (DATA:6) of the value read from the read address at each read access.

● At sector erase suspension

When a read access is made with a sector erase operation suspended, the Flash memory outputs "0" if the read address is the sector being erased. Otherwise, the Flash memory outputs bit6 (DATA: 6) of the value read from the read address.

Note:

When using dual-operation Flash memory (Flash memory write control program is executed on the Flash memory), the toggle bit flag (DQ6) cannot be used to check the operating state of programming/erasing. See the notes in "27.9 Notes on Using Dual Operation Flash Memory" when writing a program.
The note above does not apply if the Flash memory write control program is executed on the RAM.

27.4.3 Execution Timeout Flag (DQ5)

The execution timeout flag (DQ5) is a hardware sequence flag indicating that the execution time of the automatic algorithm exceeds a specified time (required for programming/erasing) in the Flash memory.

■ Execution Timeout Flag (DQ5)

Table 27.4-7 and Table 27.4-8 show the state transition of the execution timeout flag during normal operation and the one during abnormal operation respectively.

Table 27.4-7 State Transition of Execution Timeout Flag (During Normal Operation)

Operating state	Programming → Programming completed	Chip/sector erase → Erasing completed	Sector erase wait → Erasing started	Sector erase → Sector erase suspended (Sector being erased)	Sector erase suspended → Erasing resumed (Sector being erased)	Sector erase being suspended (Sector not being erased)
DQ5	0 → DATA: 5	0 → 1	0	0	0	DATA: 5

Table 27.4-8 State Transition of Execution Timeout Flag (During Abnormal Operation)

Operating state	Programming	Chip/sector erase
DQ5	1	1

● At programming and chip/sector erase

When a read access is made with the automatic write algorithm or the automatic chip/sector erase algorithm invoked, the flag outputs "0" when the algorithm execution time is within the specified time (required for programming/erasing) or "1" when it exceeds that time.

The execution timeout flag (DQ5) can be used to check whether programming/erasing has succeeded or failed regardless of whether the automatic algorithm has been running or terminated. When the execution timeout flag (DQ5) outputs "1", it can be judged that programming fails if flash memory program/erase status bit (RDY) in the flash memory status register (FSR) is "0".

If an attempt is made to write "1" to a Flash memory address holding "0", for example, the Flash memory is locked, the time limit is exceeded and the execution timeout flag (DQ5) outputs "1". The state in which the execution timeout flag (DQ5) outputs "1" means that the Flash memory has not been used correctly; it does not mean that the Flash memory is defective. When this state occurs, execute the reset command.

27.4.4 Sector Erase Timer Flag (DQ3)

The sector erase timer flag (DQ3) is a hardware sequence flag indicating whether the Flash memory is waiting for sector erase after the sector erase command has started.

■ Sector Erase Timer Flag (DQ3)

Table 27.4-9 and Table 27.4-10 show the state transition of the sector erase timer flag during normal operation and the one during abnormal operation respectively.

Table 27.4-9 State Transition of Sector Erase Timer Flag (During Normal Operation)

Operating state	Programming → Programming completed	Chip/sector erase → Erasing completed	Sector erase wait → Erasing started	Sector erase → Sector erase suspended (Sector being erased)	Sector erase suspended → Erasing resumed (Sector being erased)	Sector erase being suspended (Sector not being erased)
DQ3	0 → DATA: 3	1	0 → 1	1	1	DATA: 3

Table 27.4-10 State Transition of Sector Erase Timer Flag (During Abnormal Operation)

Operating state	Programming	Chip/sector erase
DQ3	0	1

● At sector erase

- When a read access is made after the sector erase command has started, the sector erase timer flag (DQ3) outputs "0" within the sector erase wait time. The flag outputs "1" if the sector erase wait time has elapsed.
- When the data polling function or the toggle bit function indicates that the erase algorithm is being executed (DQ7 = 0, DQ6: toggle output), the Flash memory executes sector erase. If the command subsequently set is not a sector erase suspend command, it is ignored until sector erase is terminated.
- If the sector erase timer flag (DQ3) is "0", the Flash memory can accept the sector erase command. Before writing the sector erase command to the Flash memory, make sure that the sector erase timer flag (DQ3) is "0". If the flag is "1", the Flash memory may not accept suspending the sector erase command.

● At sector erase suspension

When a read access is made with the sector erase operation suspended, the Flash memory outputs "1" if the read address of that read access is the address of a sector being erased. If the read address is not the address of a sector being erased, the Flash memory outputs bit3 (DATA: 3) of the value read from the read address.

27.4.5 Toggle Bit2 Flag (DQ2)

The toggle bit2 flag (DQ2) is a hardware sequence flag using the toggle bit function to indicate whether a read address is an erase target sector in the sector erase suspend state and whether output data is toggled.

■ Toggle Bit2 Flag (DQ2)

Table 27.4-11 and Table 27.4-12 show the state transition of the toggle bit2 flag during normal operation and the one during abnormal operation respectively.

Table 27.4-11 State Transition of Toggle Bit2 Flag (During Normal Operation)

Operating state	Programming → Programming completed	Chip/sector erase → Erasing completed	Sector erase wait → Erasing started	Sector erase → Sector erase suspended (Sector being erased)	Sector erase suspended → Erasing resumed (Sector being erased)	Sector erase being suspended (Sector not being erased)
DQ2	0 → DATA: 2	Toggle → 1	Toggle	Toggle	Toggle	DATA: 2

Table 27.4-12 State Transition of Toggle Bit2 Flag (During Abnormal Operation)

Operating state	Programming	Chip/sector erase
DQ2	0	Toggle

● At chip/sector erase

- When read accesses are continuously made to a sector to be erased while the automatic chip/sector erase algorithm is being executed, the Flash memory toggles the output between "1" and "0" at each read access.
- When read accesses are continuously made to a sector not to be erased while the automatic chip/sector erase algorithm is being executed, the Flash memory outputs bit2 (DATA: 2) of the value read from a read address of each read access.

● At sector erase suspension

- With a sector erase operation suspended, when read accesses are continuously made to a sector to be erased, the Flash memory toggles the output between "1" and "0" whenever a read access is made.
- With a sector erase operation suspended, when read accesses are continuously made to a sector not to be erased, the Flash memory outputs bit2 (DATA: 2) of the read value of a read address whenever a read access is made.

27.5 Programming/Erasing Flash Memory

This section describes the respective procedures for reading/resetting the Flash memory, programming, chip-erasing, sector-erasing, sector erase suspending and sector erase resuming by entering respective commands to invoke the automatic algorithm.

■ Details of Programming/Erasing Flash Memory

The automatic algorithm can be invoked by programming the read/reset, program, chip erase, sector erase, sector-erase suspend, and sector erase resume command sequence to the Flash memory from the CPU. Always write the commands of a command sequence continuously from the CPU to the Flash memory. The termination of the automatic algorithm can be checked by the data polling function. After the automatic algorithm terminates normally, the Flash memory returns to the read/reset state.

The operations are explained in the following order:

- Enter the read/reset state
- Program data
- Erase all data (chip erase)
- Erase arbitrary data (sector erase)
- Suspend sector erase
- Resume sector erase
- Unlock bypass program

27.5.1 Placing Flash Memory in Read/Reset State

This section explains the procedure for entering the read/reset command to place the Flash memory in read/reset state.

■ Placing Flash Memory in Read/Reset State

- To place the Flash memory in the read/reset state, send read/reset commands in the command sequence table from the CPU to the Flash memory.
- Since the read/reset state is the initial state of the Flash memory, the Flash memory always enters this state after power-on or the normal termination of a command. The read/reset state is also regarded as the command input wait state.
- In the read/reset state, data in the Flash memory can be read by a read access to the Flash memory.
- In the case of a read access to the Flash memory, no read/reset commands are required. If a command does not terminate normally, use a read/reset command to initialize the automatic algorithm.

27.5.2 Programming Data to Flash Memory

This section explains the procedure for entering the program command to program data to the Flash memory.

■ Programming Data to Flash Memory

- To invoke the automatic algorithm for programming data to the Flash memory, send program commands in the command sequence table consecutively from the CPU to the Flash memory.
- When data is programmed to a target address in the fourth cycle, the automatic algorithm is invoked and starts automatic programming.

● Addressing method

Programming can be performed in any order of addresses and across a sector boundary. The size of data that can be written by a single program command is one byte only.

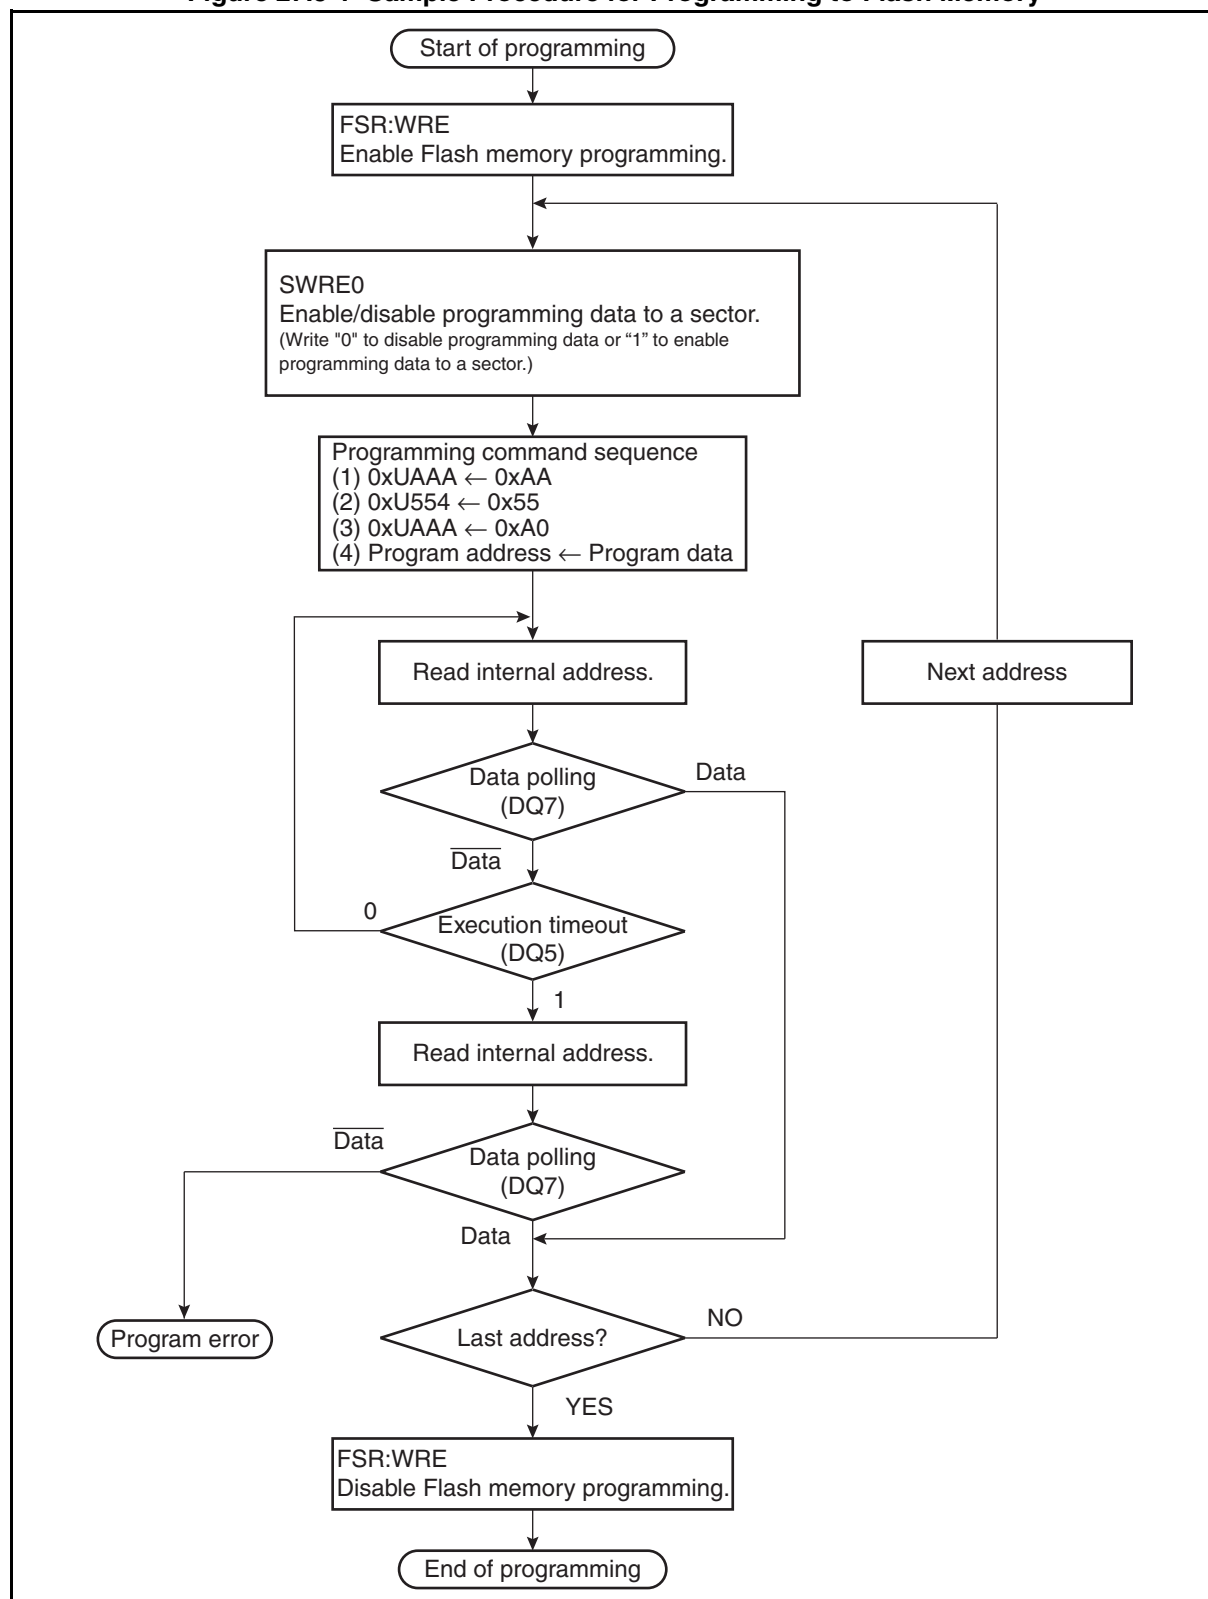

● Note on programming data

- Bit data cannot be returned from "0" to "1" by programming. When "1" is written to bit data that is currently "0", the data polling function (DQ7) or toggle operation (DQ6) is not terminated, it is determined that Flash memory component is defective, and the execution timeout flag (DQ5) indicates that an error has occurred because the execution time of the automatic algorithm exceeds the programming time specified.
When data is read in the read/reset state, the bit data remains "0". To make the bit data return from "0" to "1", erase the Flash memory.
- All commands are ignored during programming.
- During programming, if a hardware reset occurs, the integrity of data being written to the current address is not guaranteed. Start programming the data from the chip erase command or the sector erase command again.

■ Flash Memory Programming Procedure

- Figure 27.5-1 gives an example of the procedure for programming data to the Flash memory. The hardware sequence flag can be used to check the operating state of the automatic algorithm in the Flash memory. The data polling flag (DQ7) is used for checking the end of programming data into Flash memory in this example.
- Data for flag checking is read from the address to which data has been last written.
- Since the data polling flag (DQ7) and the execution timeout flag (DQ5) are changed simultaneously, check the data polling flag (DQ7) even when the execution timeout flag (DQ5) is "1".
- Similarly, since the toggle bit flag (DQ6) stops toggling at the same time as the execution timeout flag (DQ5) changes to "1", check DQ6 after DQ5 changes to "1".

Figure 27.5-1 Sample Procedure for Programming to Flash Memory

27.5.3 Erasing All Data from Flash Memory (Chip Erase)

This section explains the procedure for issuing the chip erase command to erase all data in the Flash memory.

■ Erasing Data from Flash Memory (Chip Erase)

- To erase all data from the Flash memory, send the chip erase command mentioned in the command sequence table continuously from the CPU to the Flash memory.
- The chip erase command is executed in six bus operations. Chip erasing starts at the point when the sixth cycle of programming commands is complete.
- In chip erase, the user does not need to program data to the Flash memory before starting erasing data. While the automatic erase algorithm is running, it automatically writes "0" to all cells in the Flash memory before erasing data.

■ Note on Chip Erase

- The chip erase command is accepted only when programming data to all sectors has been enabled. The chip erase command is ignored even if only one bit for a sector in the flash memory sector write control register 0 (SWRE0) has been set to "0" (to disable programming data to that sector).
- During chip erase, if a hardware reset occurs, the integrity of data in the Flash memory is not guaranteed.

27.5.4 Erasing Specific Data from Flash Memory (Sector Erase)

This section explains the procedure for entering the sector erase command to erase a specific sector in the Flash memory. Sector-by-sector erase is enabled and multiple sectors can also be specified simultaneously.

■ Erasing Specific Data from Flash Memory (Sector Erase)

To erase data from a specific sector in the Flash memory, send the sector erase command mentioned in the command sequence table continuously from the CPU to the Flash memory.

● Specifying a sector

- The sector erase command is executed in six bus operations. A minimum of 35 μ s sector erase wait time starts as an address in the sector to be erased is specified as the address for the sixth cycle and the sector erase code (0x30) is written as data.
- To erase data from multiple sectors, write the erase code (0x30) to an address in sector to be erased after programming the sector erase code to the address of the first sector to be erased as explained above.

● Note on specifying multiple sectors

- Sector erase starts as a minimum of 35 μ s sector erase wait time elapses after the last sector erase code has been written.
- To erase data from multiple sectors simultaneously, input the addresses of sectors to be erased and the erase code (in the sixth cycle of the command sequence) within 35 μ s. If the erase code is input after 35 μ s elapses, it will not be accepted due to the end of the sector erase wait time.
- The sector erase timer flag (DQ3) can be used to check whether it is valid to write sector erase codes continuously.
- Specify the address of a sector to be erased as the address at which the sector erase timer flag (DQ3) is read.

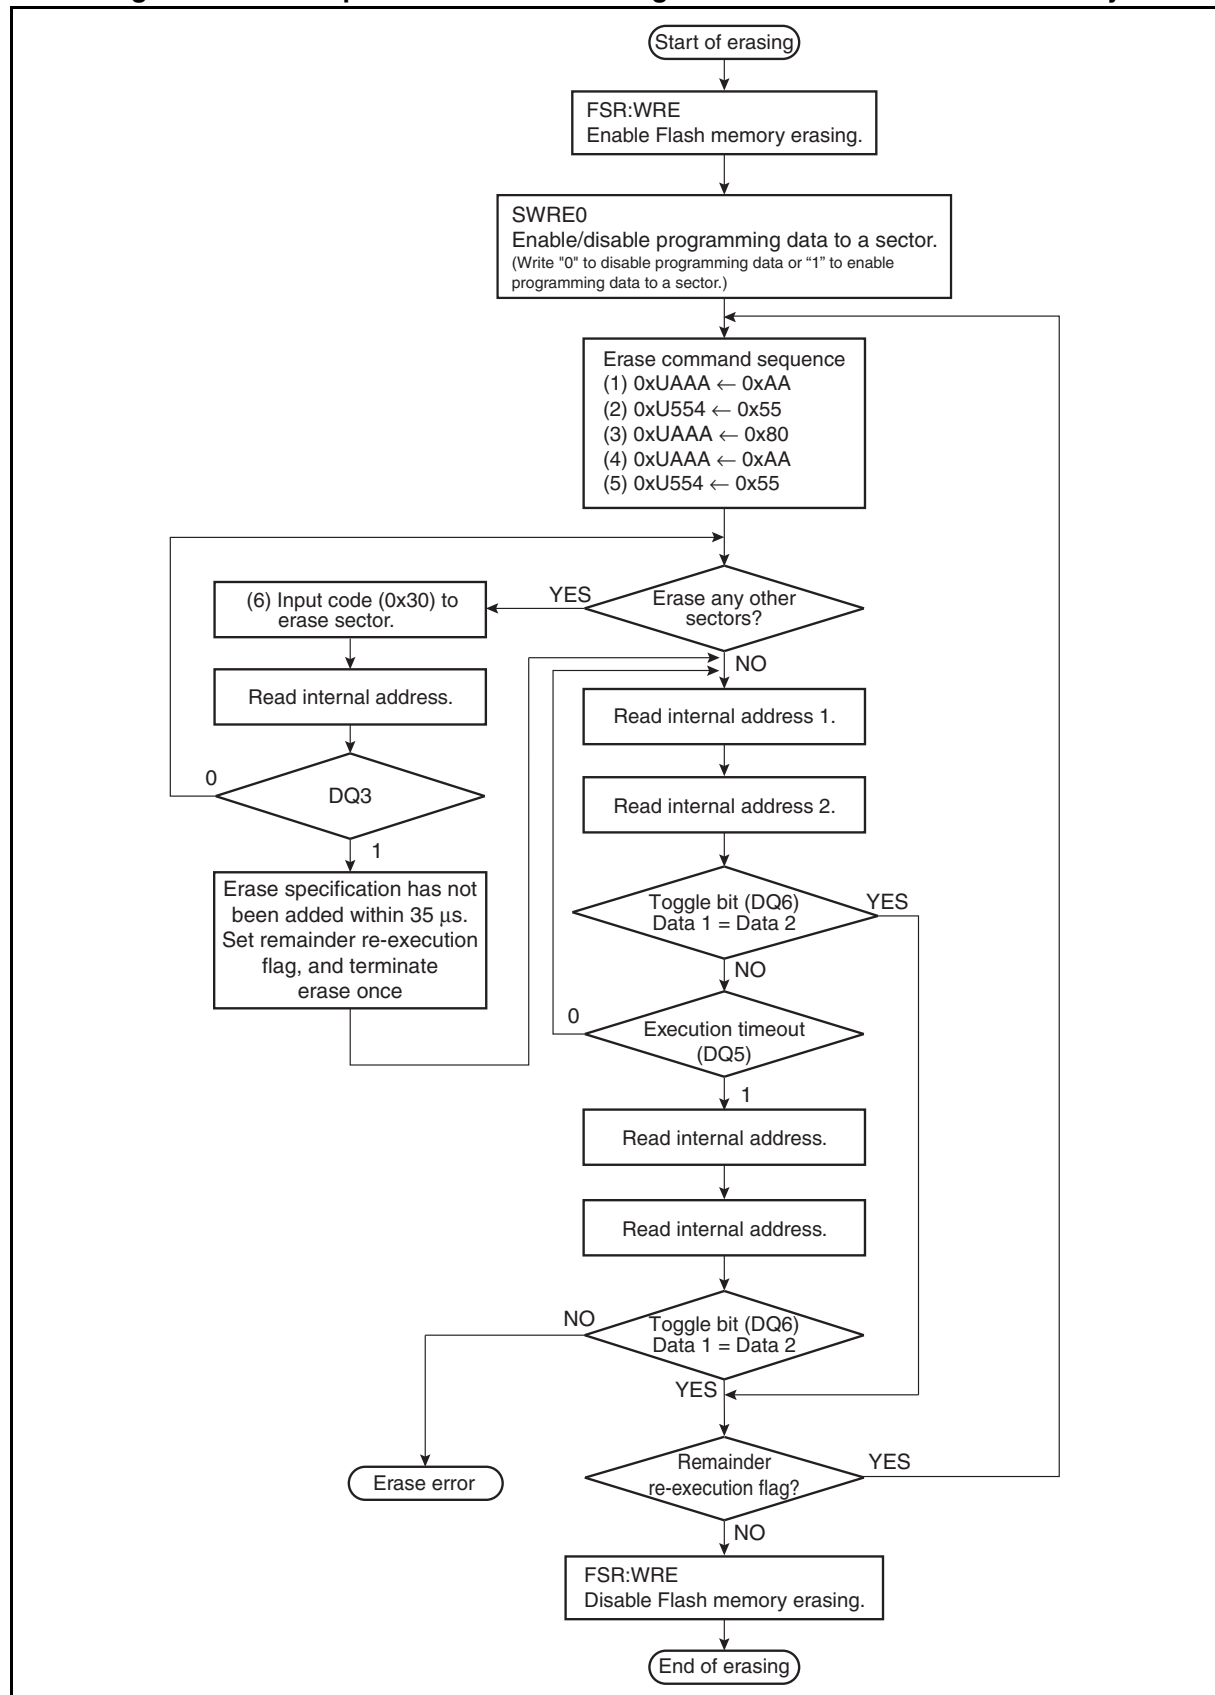

■ Flash Memory Sector Erase Procedure

- Hardware sequence flags can be used to check the state of the automatic algorithm in the Flash memory. Figure 27.5-2 gives an example of the Flash memory sector erase procedure. In this example, the toggle bit flag (DQ6) is used to check the end of sector erase.
- The toggle bit flag (DQ6) stops toggling the output at the same time as the execution timeout flag (DQ5) changes to "1". Check the toggle bit flag (DQ6) even when the execution timeout flag (DQ5) is "1".
- Since the data polling flag (DQ7) and the execution timeout flag (DQ5) are changed simultaneously, check the data polling flag (DQ7).

■ Note on Erasing Data from Sectors

If a hardware reset occurs while data is being erased, the integrity of data in the Flash memory is not guaranteed. Therefore, run the sector erase procedure again after a hardware reset occurs.

Figure 27.5-2 Sample Procedure for Erasing Data from Sectors in Flash Memory

27.5.5 Suspending Sector Erase from Flash Memory

This section explains the procedure for entering the sector erase suspend command to suspend sector erase from the Flash memory. Data can be read from sectors not being erased.

■ Suspending Sector Erase from Flash Memory

- To suspend the Flash memory sector erase, send the sector erase suspend command mentioned in the command sequence table from the CPU to the Flash memory.
- The sector erase suspend command suspends the current sector erase operation, allowing data to be read from sectors that are not being erased.
- The sector erase suspend command is only enabled during the sector erase period including the erase wait time; it is ignored in chip erasing or programming.
- The sector erase suspend command is executed when the sector erase suspend code (0xB0) is written. Specify an address in the sector selected to be erased. If an attempt is made to execute the sector erase suspend command again when sector erase has been suspended, the new sector erase suspend command input is ignored.
- When a sector erase suspend command is input during the sector erase wait time, the sector erase wait time ends immediately, the sector erase operation is stopped, and the Flash memory enters the erase stop state.
- When a sector erase suspend command is input during sector erase after the sector erase wait time, the erase suspend state occurs after a maximum of 35 μ s has elapsed since the issue of the sector erase suspend command.

Note:

To suspend sector erase by issuing a sector erase suspend command, issue the command after 35 μ s + 2 MCLK (machine clock) or longer has elapsed since the issue of a sector erase command or a sector erase resume command.

To suspend sector erase command again after resuming sector erase by issuing a sector erase resume command, issue the command after 2 ms or longer has elapsed since the issue of the sector erase resume command.

27.5.6 Resuming Sector Erase of Flash Memory

This section explains the procedure for entering the sector erase resume command to resume suspended erasing of a sector in the Flash memory.

■ Resuming Sector Erase of Flash Memory

- To resume suspended sector erase, send the sector erase resume command mentioned in the command sequence table from the CPU to the Flash memory.
- The sector erase resume command resumes a sector erase operation suspended by the sector erase suspend command. The sector erase resume command is executed by writing erase resume code (0x30). Specify an address in the sector selected to be erased.
- A sector erase resume command input during sector erase is ignored.

27.5.7 Unlock Bypass Program

This sections explains details of the unlock bypass state.

■ Transiting from Normal Command State to Unlock Bypass State

If an unlock bypass program command is input in the normal command state, the Flash memory will transit to the unlock bypass state. In this state, a program command can be executed if the command is input within two cycles as mentioned in Table 27.3-1.

■ Returning from Unlock Bypass State to Normal Command State

If an unlock bypass reset command is input in the unlock bypass state, the Flash memory will return to the normal command state from the unlock bypass state. In addition, executing a hardware reset in the unlock bypass state will also make Flash memory return to the normal command state.

27.6 Operations

Pay attention in particular to the following points when using dual operation Flash memory:

- Interrupt generated when upper banks are updated
- Procedure of setting the sector swap enable bit in the flash memory status register (FSR:SSEN)

■ Interrupt Generated When Upper Banks Are Updated

The dual operation Flash memory consists of two banks. Like conventional Flash products, however, it cannot be erased/programmed and read at the same time in banks on the same side.

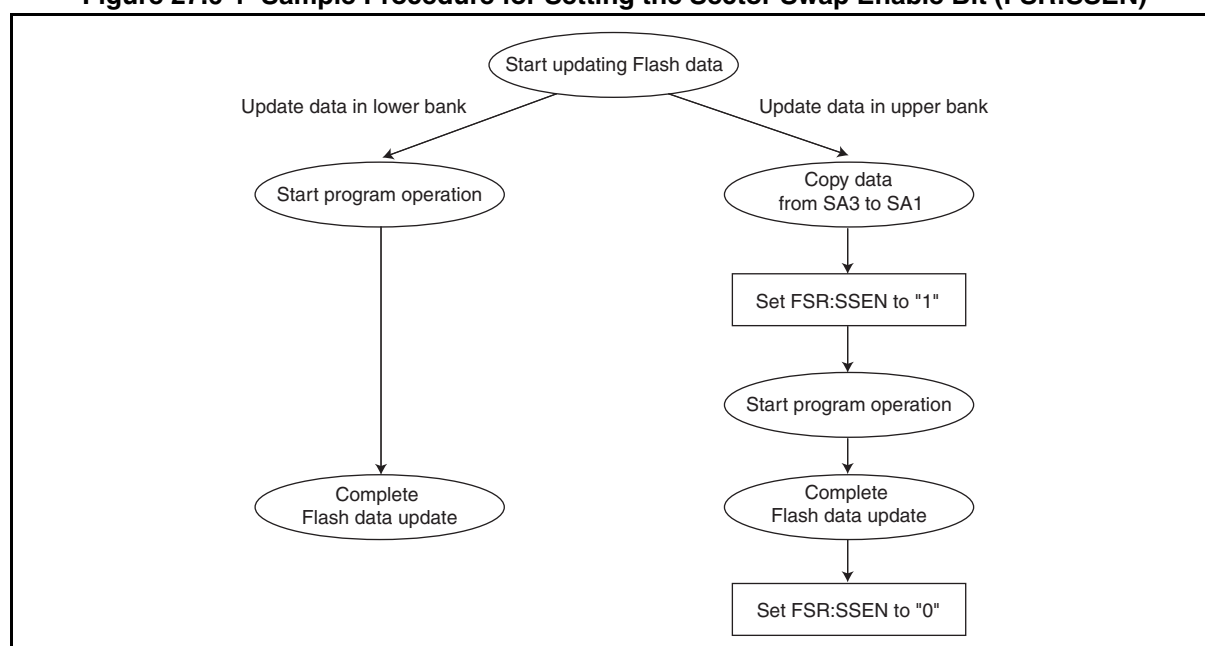

As SA3 contains an interrupt vector, an interrupt vector from the CPU cannot be read normally when an interrupt occurs during programming data to an upper bank. Before an upper bank can be updated, the sector swap enable bit must be set to "1" (FSR:SSEN = 1). When an interrupt occurs, therefore, SA1 is accessed to read interrupt vector data. The same data must be copied to SA1 and SA3 before the sector swap enable bit (FSR:SSEN) is set.

■ Procedure for Setting Sector Swap Enable Bit (FSR:SSEN)

Figure 27.6-1 shows a sample procedure of setting the sector swap enable bit (FSR:SSEN).

To modify data in the upper bank, it is necessary to set FSR:SSEN to "1". While data is being written to the Flash memory, modifying the setting of FSR:SSEN is prohibited. The setting of FSR:SSEN can only be modified before the start of programming data to the Flash memory or after the completion of programming data to the Flash memory. In addition, control the Flash memory interrupts while setting FSR:SSEN as follows: before setting FSR:SSEN, disable the Flash memory interrupts; after setting FSR:SSEN, enable the interrupts.

Figure 27.6-1 Sample Procedure for Setting the Sector Swap Enable Bit (FSR:SSEN)

■ Operation during Programming/Erasing

It is prohibited to program data to the Flash memory within an interrupt routine when an interrupt occurs during Flash memory programming/erasing.

When two or more program/erase routines exist, wait for one program/erase routine to finish before executing another program/erase routine.

While data is being written to or erased from the Flash memory, state transition in the current mode (clock mode or standby mode) is prohibited. Ensure that programming data to or erasing data from the Flash memory ends before state transition occurs.

27.7 Flash Security

The Flash security controller function prevents contents of the Flash memory from being read by external pins.

■ Flash Security

Writing protection code "0x01" to the Flash memory address (0xFFFC) restricts access to the Flash memory, disabling any read/write access to the Flash memory from any external pin. Once the protection of the Flash memory is enabled, the function cannot be unlocked until a chip erase command operation is executed.

It is advisable to write the protection code at the end of Flash programming to avoid enabling unnecessary protection during writing.

Once Flash security is enabled, a chip erase operation must be executed before data can be written to the Flash memory again.

27.8 Registers

This section describes the registers for the dual operation Flash memory.

Table 27.8-1 List of Dual Operation Flash Memory Registers

Register abbreviation	Register name	Reference
FSR2	Flash memory status register 2	27.8.1
FSR	Flash memory status register	27.8.2
SWRE0	Flash memory sector write control register 0	27.8.3
FSR3	Flash memory status register 3	27.8.4
FSR4	Flash memory status register 4	27.8.5

27.8.1 Flash Memory Status Register 2 (FSR2)

This section describes the Flash memory status register 2 (FSR2).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	PEIEN	PGMEND	PTIEN	PGMTO	EEIEN	ERSEND	ETIEN	ERSTO
Attribute	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] PEIEN: PGMEND interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the completion of Flash memory programming.

bit7	Details
Writing "0"	Disables the interrupt request upon completion of Flash memory programming (FSR2:PGMEND = 1).
Writing "1"	Enables the interrupt request upon completion of Flash memory programming (FSR2:PGMEND = 1).

[bit6] PGMEND: PGMEND interrupt request flag bit

This bit indicates the completion of Flash memory programming.

The PGMEND bit is set to "1" upon completion of the Flash memory automatic algorithm.

An interrupt request is generated when the PGMEND bit is set to "1", provided that generating an interrupt request upon completion of Flash memory programming has been enabled (FSR2:PEIEN = 1).

When the PGMEND bit is set to "0" after Flash memory programming is completed, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

When Flash memory programming fails (FSR3:HANG = 1), the PGMEND bit is cleared to "0".

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit6	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory programming is in progress.
Reading "1"	Indicates that Flash memory programming has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit5] PTIEN: PGMTO interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the failure of Flash memory programming.

bit5	Details
Writing "0"	Disables the interrupt request upon failure of Flash memory programming (FSR2:PGMTO = 1).
Writing "1"	Enables the interrupt request upon failure of Flash memory programming (FSR2:PGMTO = 1).

[bit4] PGMTO: PGMTO interrupt request flag bit

This bit indicates that Flash memory programming has failed.

When Flash memory programming fails, the PGMTO bit is set to "1" upon completion of the Flash memory automatic algorithm. Afterward, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

An interrupt request is generated when the PGMTO bit is set to "1", provided that generating an interrupt request upon failure of Flash memory programming has been enabled (FSR2:PTIEN = 1).

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit4	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory programming is in progress.
Reading "1"	Indicates that Flash memory programming has failed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit3] EEIEN: ERSEND interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the completion of Flash memory sector erase.

bit3	Details
Writing "0"	Disables the interrupt request upon completion of Flash memory sector erase (FSR2:ERSEND = 1).
Writing "1"	Enables the interrupt request upon completion of Flash memory sector erase (FSR2:ERSEND = 1).

[bit2] ERSEND: ERSEND interrupt request flag bit

This bit indicates the completion of Flash memory sector erase.

The ERSEND bit is set to "1" upon completion of the Flash memory automatic algorithm.

An interrupt request is generated when the ERSEND bit is set to "1", provided that generating an interrupt request upon completion of Flash memory sector erase has been enabled (FSR2:EEIEN = 1).

When the ERSEND bit is set to "0" after Flash memory sector erase is completed, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

When Flash memory sector erase fails (FSR3:HANG = 1), the ERSEND bit is cleared to "0".

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit2	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory sector erase is in progress.
Reading "1"	Indicates that Flash memory sector erase has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit1] ETIEN: ERSTO interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the failure of Flash memory sector erase.

bit1	Details
Writing "0"	Disables the interrupt request upon failure of Flash memory sector erase (FSR2:ERSTO = 1).
Writing "1"	Enables the interrupt request upon failure of Flash memory sector erase (FSR2:ERSTO = 1).

[bit0] ERSTO: ERSTO interrupt request flag bit

This bit indicates that Flash memory sector erase has failed.

When Flash memory sector erase fails, the ERSTO bit is set to "1" upon completion of the Flash memory automatic algorithm. Afterward, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

An interrupt request is generated when the ERSTO bit is set to "1", provided that generating an interrupt request upon failure of Flash memory sector erase has been enabled (FSR2:ETIEN = 1).

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit0	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory sector erase is in progress.
Reading "1"	Indicates that Flash memory sector erase has failed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

27.8.2 Flash Memory Status Register (FSR)

This section describes the Flash memory status register (FSR).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	RDYIRQ	RDY	Reserved	IRQEN	WRE	SSEN
Attribute	—	—	R/W	R	W	R/W	R/W	R/W
Initial value	0	0	0	X	0	0	0	0

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] RDYIRQ: Flash memory operation flag bit

This bit indicates the operating state of the Flash memory.

After the Flash memory programming/erasing is completed, the RDYIRQ bit is set to "1" at the point when the automatic algorithm of the Flash memory ends.

With the interrupt triggered by the completion of Flash memory programming/erasing having been enabled (FSR:IRQEN = 1), if the RDYIRQ bit is set to "1", an interrupt request occurs.

After Flash memory programming/erasing is completed, if the RDYIRQ bit has already been set to "0", further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit5	Details
Reading "0"	Indicates that Flash memory programming/erasing is in progress.
Reading "1"	Indicates that Flash memory programming/erasing has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit4] RDY: Flash memory program/erase status bit

This bit indicates the program/erase status of the Flash memory.

When the RDY bit is "0", programming data into and erasing data from the Flash memory are disabled.

The read/reset command/sector erase suspend command can still be accepted when the RDY bit is "0". When programming or erasing ends, the RDY bit is set to "1".

After a program/erase command is issued, there is a delay of two machine clock (MCLK) cycles before the RDY bit becomes "0". After the issue of a program/erase command, wait for those two machine clock cycles to elapse (e.g. inserting NOP twice) before reading this bit.

bit4	Details
Reading "0"	Indicates that data is being programmed/erased. (Programming/erasing next data is disabled.)
Reading "1"	Indicates that data has been programmed/erased. (Programming/erasing next data is enabled.)

[bit3] Reserved bit

Always set this bit to "0".

[bit2] IRQEN: Flash memory program/erase interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the completion of Flash memory programming/erasing.

bit2	Details
Writing "0"	Disables generating an interrupt upon completion of Flash memory programming/erasing.
Writing "1"	Enables generating an interrupt upon completion of Flash memory programming/erasing.

[bit1] WRE: Flash memory program/erase enable bit

This bit enables or disables the programming/erasing of data into/from the Flash memory area.

Set the WRE bit before invoking a Flash memory program/erase command.

Writing "0" to this bit disables generating program/erase signals even when a program/erase command is input.

Writing "1" to this bit enables programming/erasing Flash memory data after a program/erase command is input.

When not programming data into or erasing data from the Flash memory, set the WRE bit to "0" in order to prevent data from being accidentally written into or erased from the Flash memory.

To program data to the Flash memory, set FSR:WRE to "1" to enable programming data to the Flash memory, and set the flash memory sector write control register 0 (SWRE0) according to the Flash memory sector into which data is to be written. When Flash memory programming is disabled (FSR:WRE = 0), no write access to a sector in the Flash memory can be executed even though it has been enabled by setting a bit corresponding to that sector in the Flash memory sector write control register 0 (SWRE0) to "1".

bit1	Details
Writing "0"	Disables Flash memory area programming/erasing.
Writing "1"	Enables Flash memory area programming/erasing.

[bit0] SSEN: Sector swap enable bit

This bit is used to swap part of SA3 in the upper bank, at which interrupt vectors are kept, for SA1 in the lower bank.

bit0	Details
Writing "0"	Maps SA1 to 0x1800-0x1FFF, and the 2 Kbyte address area of SA3 to 0xF800-0xFFFF.
Writing "1"	Maps the 2 Kbyte address area of SA3 to 0x1800-0x1FFF, and SA1 to 0xF800-0xFFFF.

Figure 27.8-1 Access Sector Map by FSR:SSEN Value

27.8.3 Flash Memory Sector Write Control Register 0 (SWRE0)

The flash memory sector write control register 0 (SWRE0) is installed in the Flash memory interface and used to set the function of protecting the Flash memory against spurious writes.

The flash memory sector write control register 0 (SWRE0) has bits for enabling/disabling programming data into individual sectors (SA0 to SA3). The initial value of each bit is "0", meaning programming data is disabled. Writing "1" to a bit in SWRE0 enables programming data into the sector corresponding to that bit. Writing "0" to a bit in SWRE0 prevents data from being accidentally written into the sector corresponding to that bit. When "0" is written to a bit in SWRE0, even though "1" is written to that bit afterward, data cannot be programmed into the sector corresponding to that bit. To re-program the data, execute a reset operation.

Only write data to SWRE0 by the byte. Setting the bits in SWRE0 using the bit manipulation instruction is prohibited.

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	Reserved	Reserved	Reserved	Reserved	SA3E	SA2E	SA1E	SA0E
Attribute	W	W	W	W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:4] Reserved bits

Always set these bits to "0".

[bit3:0] SA3E, SA2E, SA1E, SA0E: Programming function setup bits

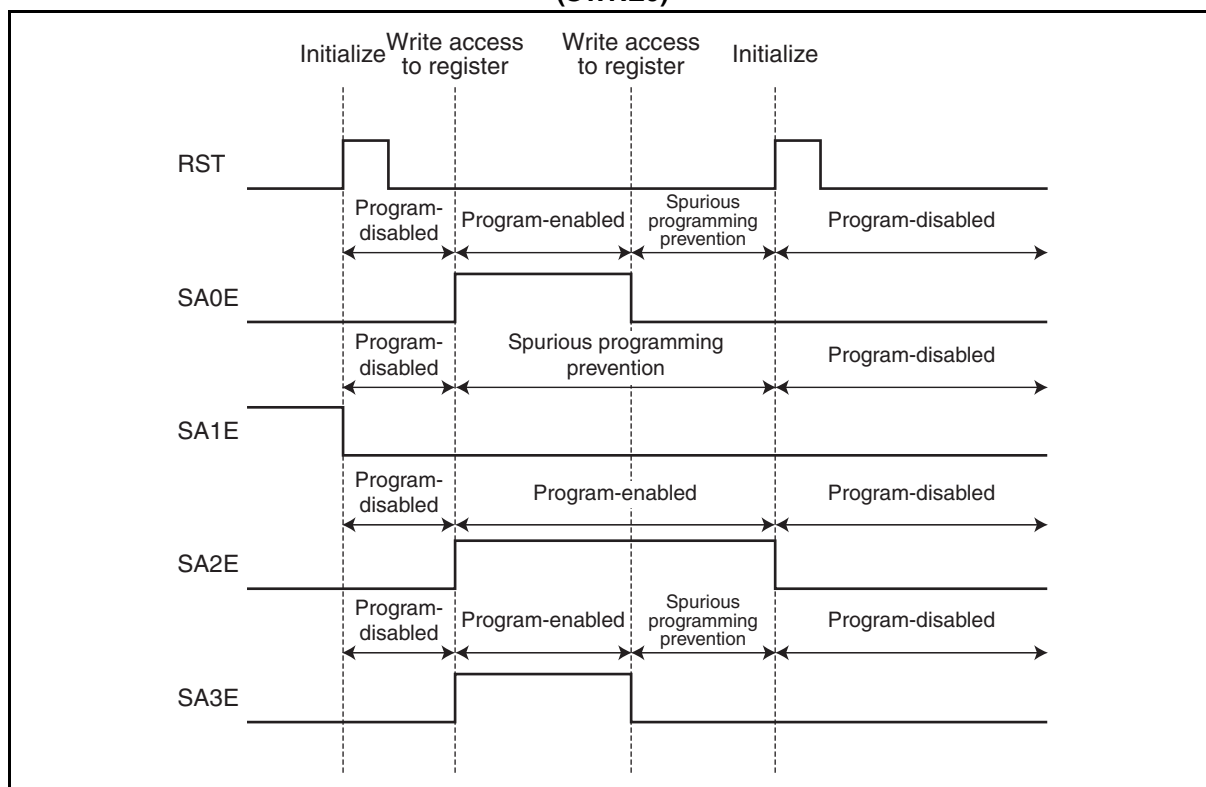

These bits are used to set the function of preventing data from being accidentally written into a sector of the Flash memory. Writing "1" to a bit in SWRE0 enables programming data into the sector corresponding to that bit. Writing "0" to a bit in SWRE0 prevents data from being accidentally written into the sector corresponding to that bit. In addition, a reset initializes that bit to "0" (programming disabled).

Table of programming function setup bits and their corresponding Flash memory sectors	
Bit name	Corresponding sector in Flash memory
SA3E	SA3
SA2E	SA2
SA1E	SA1
SA0E	SA0

Settings of SAxE (x = 0, 1, 2 or 3) and their respective programming functions:

- Program-disabled (SAxE = 0)
With "0" not written to the SAxE bit in the flash memory sector write control register 0 (SWRE0), programming data to a sector can be enabled by setting the SAxE bit corresponding to that sector to "1". (This is the state after a reset).
- Program-enabled (SAxE = 1)
Data can be written to a sector corresponding to the SAxE bit.
- Spurious programming prevention (SAxE = 0)
With "0" written to the SAxE bit in the flash memory sector write control register 0 (SWRE0), programming data to a sector cannot be enabled even though the SAxE bit corresponding to that sector is set to "1".

Figure 27.8-2 Examples of Flash Memory Program-disabled, Program-enabled, and Spurious Programming Prevention States Depending on Flash Memory Sector Write Control Register 0 (SWRE0)

■ Note on Setting SWRE0 Register

To program data to or erase data from SA0 (0x1000 to 0x17FF) or SA1 (0x1800 to 0x1FFF) of the Flash memory when FSR:SEN is "0", set both SA0E and SA1E in the SWRE0 register to "1" first.

To program data to or erase data when FSR:SEN is "1", set SA0E, SA1E, SA2E and SA3E in the SWRE0 register to "1" first.

For details of the sector map of the Flash memory, see Figure 27.2-1 and Figure 27.8-1.

27.8.4 Flash Memory Status Register 3 (FSR3)

This section describes the flash memory status register 3 (FSR3).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	CERS	ESPS	SERS	PGMS	HANG
Attribute	—	—	—	R	R	R	R	R
Initial value	0	0	0	X	X	X	X	X

■ Register Functions

[bit7:5] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit4] CERS: Flash memory chip erase status bit

This bit indicates the chip erase status of the Flash memory.

bit4	Details
Reading "0"	Indicates that Flash memory chip erase has been completed.
Reading "1"	Indicates that Flash memory chip erase is in progress.

[bit3] ESPS: Flash memory sector erase suspend status bit

This bit indicates the sector erase suspend of the Flash memory.

bit3	Details
Reading "0"	Indicates that Flash memory sector erase suspend has been completed.
Reading "1"	Indicates that Flash memory sector erase suspend is in progress.

[bit2] SERS: Flash memory sector erase status bit

This bit indicates the sector erase status of the Flash memory.

bit2	Details
Reading "0"	Indicates that Flash memory sector erase has been completed.
Reading "1"	Indicates that Flash memory sector erase is in progress.

[bit1] PGMS: Flash memory program status bit

This bit indicates the program status of the Flash memory.

The PGMS bit will never be asserted under the condition that the machine clock (MCLK) cycle is longer than 1 μ s. Use this bit with the machine clock (MCLK) cycle shorter than 1 μ s.

bit1	Details
Reading "0"	Indicates that Flash memory program has been completed.
Reading "1"	Indicates that Flash memory program is in progress.

[bit0] HANG: Flash memory hang up status bit

This bit indicates whether the Flash memory has malfunctioned or not.

bit0	Details
Reading "0"	Indicates that no malfunction of command input has occurred so far.
Reading "1"	Indicates that a malfunction of command input has occurred.

27.8.5 Flash Memory Status Register 4 (FSR4)

This section describes of the flash memory status register 4 (FSR4).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	CEREND	CTIEN	CERTO	—	—	—	—
Attribute	—	R/W	R/W	R/W	—	—	—	—
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7] Undefined bit

The read value of this bit is always "0". Writing a value to this bit has no effect on operation.

[bit6] CEREND: Flash memory chip erase completion status bit

This bit indicates the completion of Flash memory chip erase.

The CEREND bit is set to "1" upon completion of the Flash memory automatic algorithm.

When the CEREND bit is set to "0" after Flash memory chip erase is completed, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

When Flash memory chip erase fails (FSR3:HANG = 1), this bit is cleared to "0".

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit6	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory chip erase is in progress.
Reading "1"	Indicates that Flash memory chip erase has been completed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit5] CTIEN: CERTO interrupt enable bit

This bit enables or disables the generation of interrupt requests triggered by the failure of Flash memory chip erase.

bit5	Details
Writing "0"	Disables the interrupt request upon failure of Flash memory chip erase (FSR4:CERTO = 1).
Writing "1"	Enables the interrupt request upon failure of Flash memory chip erase (FSR4:CERTO = 1).

[bit4] CERTO: CERTO interrupt request flag bit

This bit indicates that Flash memory chip erase has failed.

When Flash memory chip erase fails, the CERTO bit is set to "1" upon completion of the Flash memory automatic algorithm.

An interrupt request is generated when the CERTO bit is set to "1", provided that generating an interrupt request upon failure of Flash memory chip erase has been enabled (FSR4:CTIEN = 1).

When the CERTO bit is set to "1" after Flash memory chip erase is completed, further Flash memory programming/erasing is disabled. Writing a reset command can make the Flash memory return to the normal command state.

Writing "0" to this bit clears it.

Writing "1" to this bit has no effect on operation.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit4	Details
Reading "0"	Indicates that the device is in the command input wait state or Flash memory chip erase is in progress.
Reading "1"	Indicates that Flash memory chip erase has failed.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

[bit3:0] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

■ Examples of Status of Flash Memory Status Register 2, Flash Memory Status Register 3, Flash Memory Status Register 4 and RDY Bit (FSR:RDY)

Figure 27.8-3 FSR2:PGMEND during Flash Memory Programming

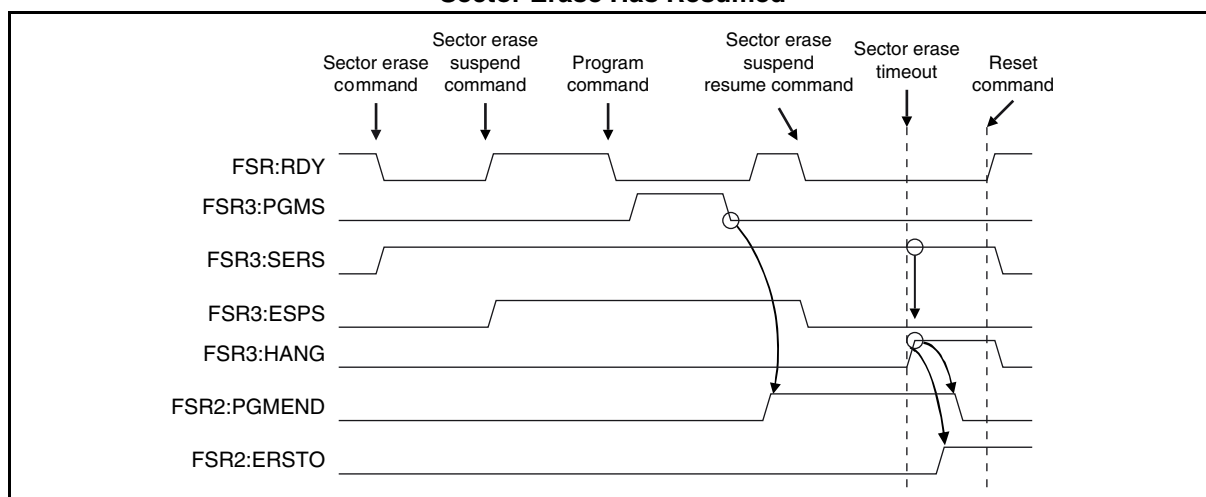

Figure 27.8-11 FSR4:CERTO when Chip Erase Failed

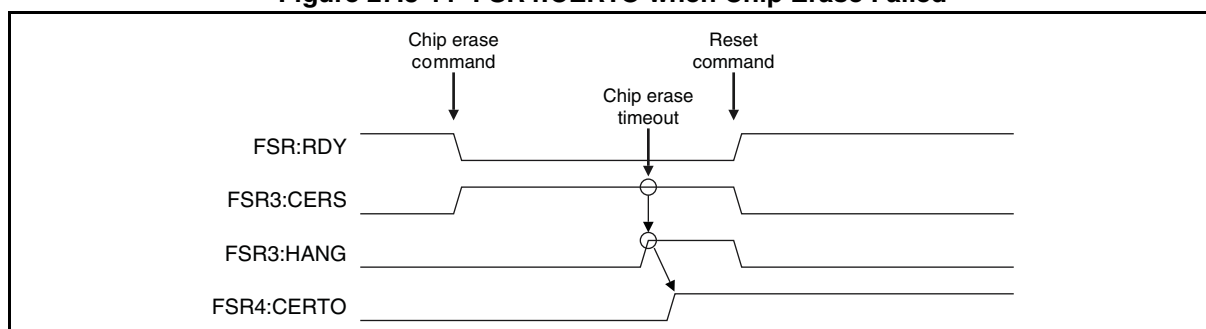

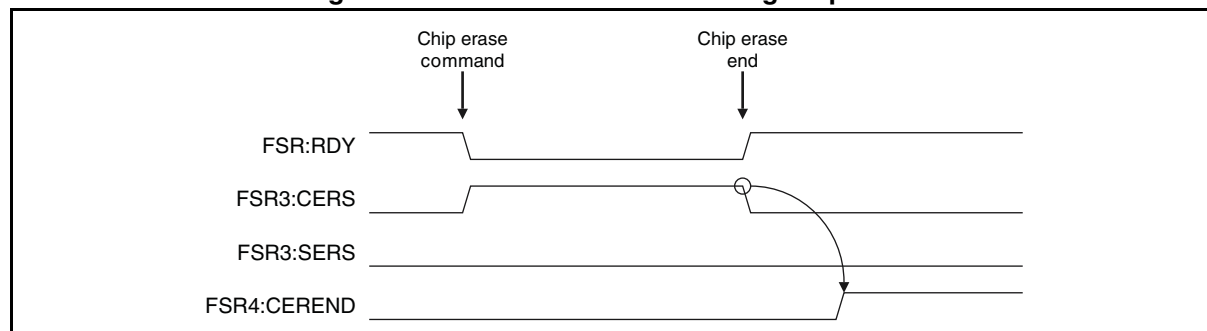

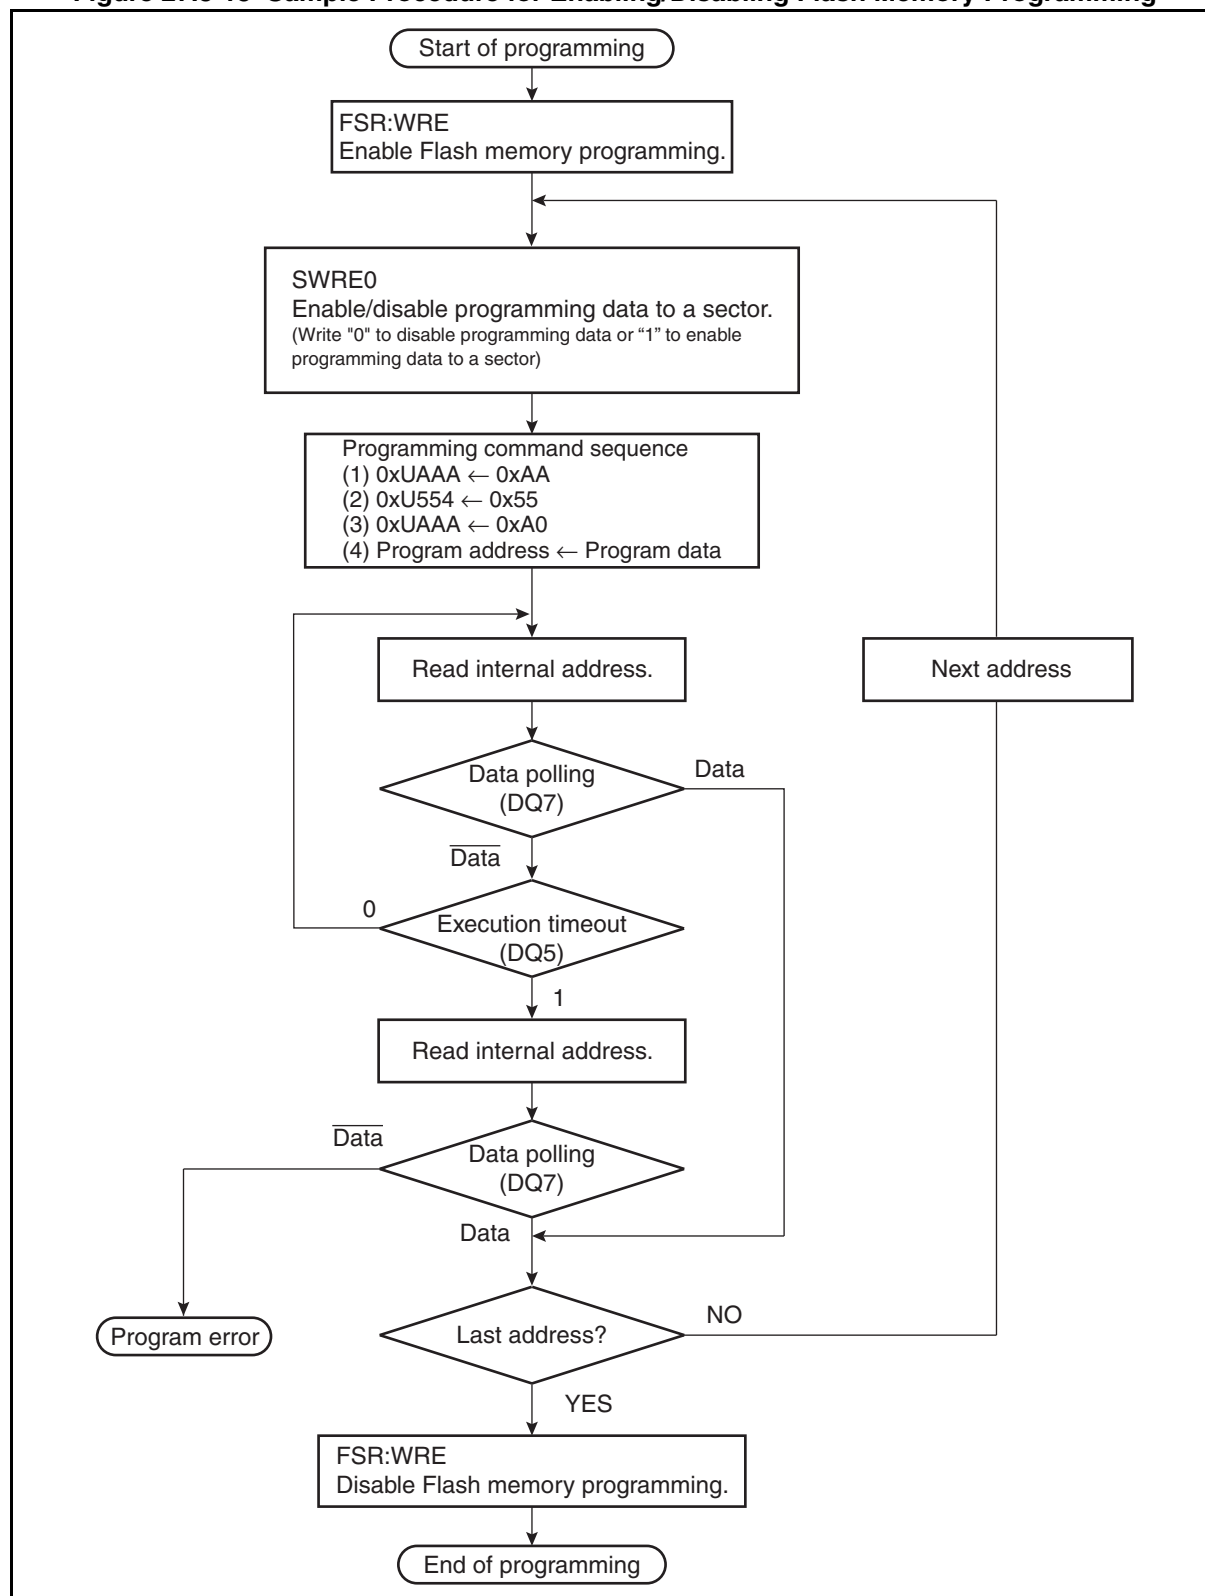

Figure 27.8-12 FSR4:CEREND during Chip Erase

Flash Memory Sector Write Control Register 0 (SWRE0) Setup Flow Chart

Set the FSR:WRE bit to "1" to enable Flash memory programming, then enable or disable programming data into a sector by setting the corresponding bit in the SWRE0 register to "1" or "0" respectively.

Figure 27.8-13 Sample Procedure for Enabling/Disabling Flash Memory Programming

■ Note on Setting (FSR:WRE)

To program data to the Flash memory, set the WRE bit to "1" to enable Flash memory programming and then set the bit in the SWRE0 register corresponding to a sector to which data is to be written. When Flash memory programming is disabled by setting the WRE bit to "0", no write access to a sector in the Flash memory can be executed even though it has been enabled by setting a bit corresponding to that sector in the SWRE0 register to "1".

27.9 Notes on Using Dual Operation Flash Memory

This section provides notes on using the dual operation Flash memory.

■ Restriction on Using Toggle Bit Flag (DQ6)

When using the dual-operation Flash memory (The Flash memory write control program is executed on the Flash memory), the toggle bit flag (DQ6) cannot be used to check the operating state of the Flash memory during programming or erasing. Therefore, use the data polling flag (DQ7) to check the internal operating state of the Flash memory after programming data to the Flash memory or erasing data from the Flash memory as shown in the examples in Figure 27.5-1 and Figure 27.5-2.

The restriction above does not apply if the Flash memory write control program is executed on the RAM.

CHAPTER 28

NON-VOLATILE REGISTER (NVR) INTERFACE

This chapter describes the functions and operations of the NVR interface.

- 28.1 Overview
- 28.2 Configuration
- 28.3 Registers
- 28.4 Notes on Main CR Clock Trimming
- 28.5 Notes on Using NVR Interface

28.1 Overview

The NVR (Non-Volatile Register) area is a reserved area in the Flash that stores system information and option settings. After a reset, data in the NVR Flash area will be fetched and stored in registers in the NVR I/O area. In the MB95710L/770L Series, the NVR interface is used to store the following data:

- Coarse trimming value for main CR Clock (5 bits)
- Fine trimming value for main CR Clock (5 bits)
- Watchdog timer selection ID (16 bits)
- Temperature dependent adjustment value for main CR clock (5 bits)

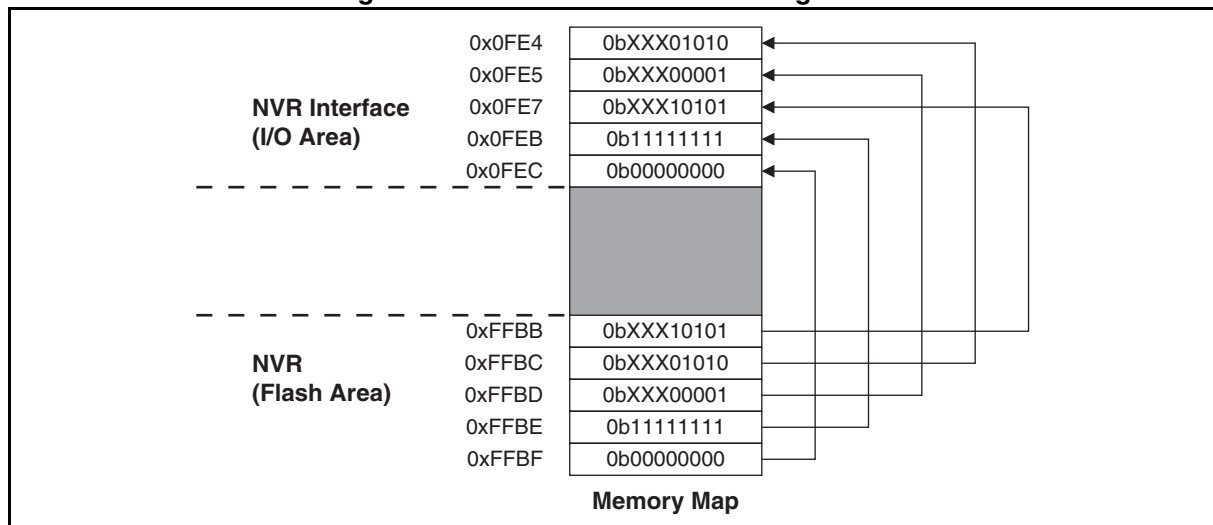

■ Functions of NVR Interface

Functions of the NVR interface are as follows:

1. The NVR interface retrieves all data from the NVR Flash area and stores it in the registers in the NVR I/O area after a reset. See Figure 28.1-1 and Figure 28.2-1.
2. The NVR interface enables the user to know the value of the initial CR trimming setting.
3. The NVR interface enables the user to select the hardware watchdog timer or software watchdog timer by modifying the 16-bit watchdog timer selection ID. The watchdog timer selection ID cannot be modified while the CPU is running.

Figure 28.1-1 shows the retrieval of NVR during a reset.

Figure 28.1-1 Retrieval of NVR during Reset

28.3 Registers

This section lists the registers of the NVR interface.

Table 28.3-1 List of NVR Interface Registers

Register abbreviation	Register name	Reference
CRTH	Main CR clock trimming register (upper)	28.3.1
CRTL	Main CR clock trimming register (lower)	28.3.2
CRTDA	Main CR clock temperature dependent adjustment register	28.3.3
WDTH	Watchdog timer selection ID register (upper)	28.3.4
WDTL	Watchdog timer selection ID register (lower)	28.3.4

28.3.1 Main CR Clock Trimming Register (Upper) (CRTH)

This section describes the main CR clock trimming register (upper) (CRTH).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	CRTH4	CRTH3	CRTH2	CRTH1	CRTH0
Attribute	—	—	—	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	X	X	X	X	X

■ Register Functions

[bit7:5] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit4:0] CRTH[4:0]: Main CR clock coarse trimming bits

The settings of these bits are loaded from the Flash address 0xFFBC (bit4:0) after a reset. Their initial values are determined by the pre-loaded values in the NVR Flash area.

Coarse trimming modifies the main CR clock frequency with a bigger step. Increasing the coarse trimming value decreases the main CR clock frequency.

bit4:0	Details
Writing "00000"	Highest main CR clock frequency
:	:
Writing "11111"	Lowest main CR clock frequency

See "28.4 Notes on Main CR Clock Trimming" and "28.5 Notes on Using NVR Interface" for details of main CR clock trimming and notes on changing the main CR clock values respectively.

28.3.2 Main CR Clock Trimming Register (Lower) (CRTL)

This section describes the main CR clock trimming register (lower) (CRTL).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	CRTL4	CRTL3	CRTL2	CRTL1	CRTL0
Attribute	—	—	—	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	X	X	X	X	X

■ Register Functions

[bit7:5] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit4:0] CRTL[4:0]: Main CR clock fine trimming bits

The settings of these bits are loaded from the Flash address 0xFFBD (bit4:0) after a reset. Their initial values are determined by the pre-loaded values in the NVR Flash area.

Fine trimming modifies the main CR clock frequency with a smaller step. Increasing the fine trimming value decreases the main CR clock frequency.

bit4:0	Details
Writing "00000"	Highest main CR clock frequency
:	:
Writing "11111"	Lowest main CR clock frequency

See "28.4 Notes on Main CR Clock Trimming" and "28.5 Notes on Using NVR Interface" for details of main CR clock trimming and notes on changing the main CR clock values respectively.

28.3.3 Main CR Clock Temperature Dependent Adjustment Register (CRTDA)

This section describes the main CR clock temperature dependent adjustment register (CRTDA).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	CRTDA4	CRTDA3	CRTDA2	CRTDA1	CRTDA0
Attribute	—	—	—	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	X	X	X	X	X

■ Register Functions

[bit7:5] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit4:0] CRTDA[4:0]: Main CR clock temperature dependent adjustment bits

These bits are loaded from the Flash address 0xFFBB (bit4:0) after a reset. Their initial values are determined by the pre-load values in the NVR Flash area.

Temperature dependent adjustment maintains the accuracy of the main CR output frequency within a temperature range. It works in combination with the coarse trimming settings in the CRTH register and the fine trimming settings in the CRTL register. In addition, increasing the value of the CRTDA register decreases the main the main CR clock frequency

bit4:0	Details
Writing "00000"	Highest main CR clock frequency
:	:
Writing "11111"	Lowest main CR clock frequency

See "28.4 Notes on Main CR Clock Trimming" and "28.5 Notes on Using NVR Interface" for details of main CR clock trimming and notes on changing the main CR clock values respectively.

28.3.4 Watchdog Timer Selection ID Register (Upper/Lower) (WDTH/WDTL)

This section describes the watchdog timer selection ID register (upper/lower) (WDTH/WDTL).

■ Register Configuration

WDTH								
bit	7	6	5	4	3	2	1	0
Field	WDTH7	WDTH6	WDTH5	WDTH4	WDTH3	WDTH2	WDTH1	WDTH0
Attribute	R	R	R	R	R	R	R	R
Initial value	X	X	X	X	X	X	X	X

WDTL								
bit	7	6	5	4	3	2	1	0
Field	WDTL7	WDTL6	WDTL5	WDTL4	WDTL3	WDTL2	WDTL1	WDTL0
Attribute	R	R	R	R	R	R	R	R
Initial value	X	X	X	X	X	X	X	X

■ Functions of WDTH Register

[bit7:0] WDTH[7:0]: Watchdog timer selection ID (upper) bits

These bits are loaded from the Flash address 0xFFBE (bit7:0) after a reset. The initial values are determined by the pre-loaded values in the NVR Flash area.

These bits cannot be modified while the CPU is running.

See Table 28.3-2 for watchdog timer selection.

See "28.5 Notes on Using NVR Interface" for notes on writing NVR values.

■ Functions of WDTL Register

[bit7:0] WDTL[7:0]: Watchdog timer selection ID (lower) bits

These bits are loaded from the Flash address 0xFFBF (bit7:0) after a reset. The initial values are determined by the pre-loaded values in the NVR Flash area.

These bits cannot be modified while the CPU is running.

See Table 28.3-2 for watchdog timer selection.

See "28.5 Notes on Using NVR Interface" for notes on writing NVR values.

Table 28.3-2 Watchdog Timer Selection ID

WDTH[7:0], WDTL[7:0]	Function
0xA596	The hardware watchdog timer is disabled; the software watchdog timer is enabled.
0xA597	The hardware watchdog timer is enabled; the software watchdog timer is disabled. The hardware watchdog timer can be stopped in all standby modes (stop mode, sleep mode, time-base timer mode and watch mode).
Other than the above	The hardware watchdog timer is enabled; the software watchdog timer is disabled. The hardware watchdog timer keeps operating in all standby modes (stop mode, sleep mode, time-base timer mode and watch mode).

28.4 Notes on Main CR Clock Trimming

This section provides notes on main CR clock trimming.

After a hardware reset, the 10-bit main CR clock trimming value and the 5-bit temperature dependent adjustment value will be loaded from the NVR Flash area to registers in the NVR I/O area.

Table 28.4-1 shows the step size of main CR clock trimming.

Table 28.4-1 Step Size of Main CR Clock Trimming

Function	Coarse trimming value CRTH[4:0]	Fine trimming value CRTL[4:0]
To achieve the minimum frequency	0b11111	0b11111
To achieve the maximum frequency	0b00000	0b00000
Step Size	220 kHz to 300 kHz	14 kHz to 20 kHz

The relationship between main CR clock frequency and trimming step size is shown in the diagram below.

**Figure 28.4-1 Relationship between Main CR Clock Frequency and Trimming Step Size
(with CRTDA[4:0] = 0b10000)**

28.5 Notes on Using NVR Interface

This section provides notes on using the NVR interface.

■ Note on Changing Main CR Frequency

Please note that the NVR interface does not program a modified value to the NVR Flash area. To modify the CRTH, CRTL and CRTDA registers, program their new values to the NVR Flash with the Flash writer.

■ Note on Flash Erase and Trimming Value

1. A Flash erase operation will erase all NVR data.

The Flash writer carries out the following procedure to keep original system settings.

- (1) Make a backup of data in CRTH:CRTH[4:0], CRTL:CRTL[4:0] and CRTDA:CRTDA[4:0].
- (2) Erase the Flash.
- (3) Restore all data in CRTH:CRTH[4:0], CRTL:CRTL[4:0] and CRTDA:CRTDA[4:0] to the NVR Flash area.

If there is new data in CRTH:CRTH[4:0], CRTL:CRTL[4:0] and CRTDA:CRTDA[4:0], the Flash writer will program the new data to the NVR Flash area.

2. The trimming value has been preset before this device is shipped. If the preset trimming value is modified after the device has been shipped, Spansion does not warrant proper operation of the device with respect to use based on the modified trimming value.
3. If the Flash operation is performed by the user program code, restore the original trimming data to the NVR Flash area by the user program code. Otherwise, the trimming value, which has been preset before this device is shipped, is erased by the Flash erase operation.

CHAPTER 29

COMPARATOR

This chapter describes the functions and operations of the comparator.

- 29.1 Overview
- 29.2 Configuration
- 29.3 Pins
- 29.4 Interrupt
- 29.5 Operations and Setting Procedure Example
- 29.6 Register

29.1 Overview

The comparator monitors two analog input voltages and automatically generates an interrupt upon detection of a change in the edge of comparator output.

■ Function of Comparator

The function of the comparator is to monitor two analog input voltages and compare them. Using the voltage of the non-inverting analog input (positive input) or an external voltage as a reference voltage, the comparator outputs "H" if the voltage of the inverting analog input voltage (negative input) is lower than the reference voltage; otherwise, it outputs "L". In addition, upon detection of a rising edge or falling edge of the comparator output, the comparator outputs a corresponding interrupt.

29.2 Configuration

The comparator module consists of the following blocks:

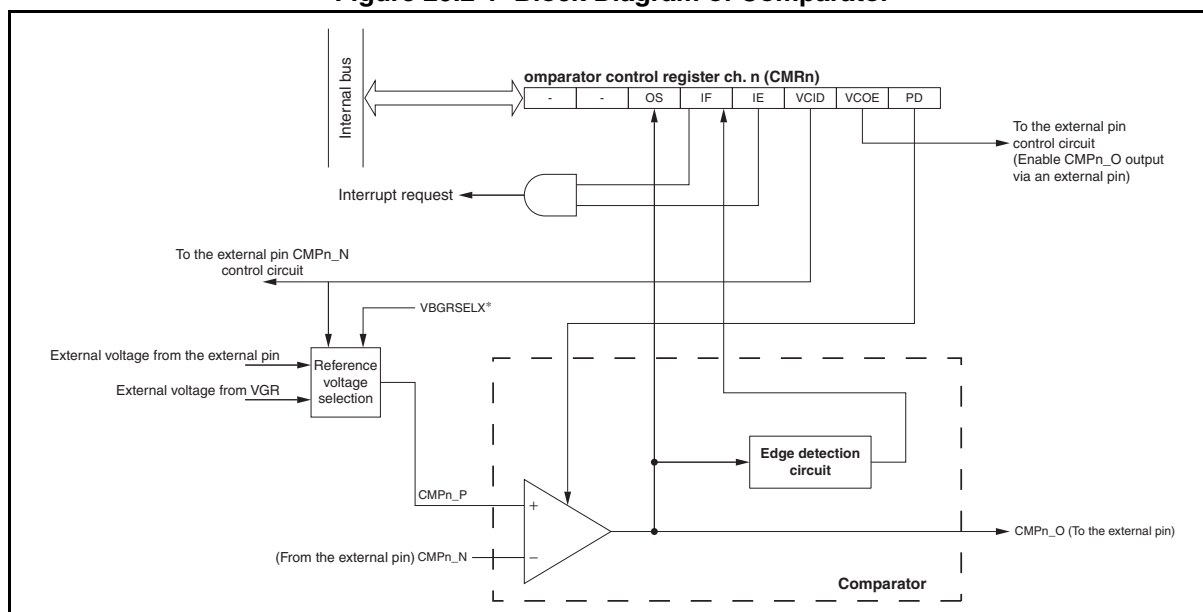

- Comparator
- Edge detection circuit
- Comparator control register ch. n (CMRn)

The number of pins and that of channels of the comparator vary among products. For details, refer to the device data sheet.

In this chapter, "n" in a pin name and a register abbreviation represents the channel number. For details of pin names, register names and register abbreviations of a product, refer to the device data sheet.

■ Block Diagram of Comparator

Figure 29.2-1 Block Diagram of Comparator

*: See "30.2.2 System Configuration Register 2 (SYSC2)" for details of the VBGRSELX bit and of selecting the internal reference voltage and external reference voltage.

● Comparator

The comparator monitors the voltages of two external analog inputs and compares them. Using the voltage of the non-inverting analog input (positive input) or an external voltage as a reference voltage, the comparator outputs "H" if the voltage of the inverting analog input (negative input) is higher than the reference voltage; otherwise, it outputs "L".

● Edge detection circuit

Except in stop mode, watch mode or time-base timer mode, upon detection of a rising edge or falling edge of comparator output, the edge detection circuit automatically raises the interrupt flag (CMRn:IF).

● Comparator control register ch. n (CMRn)

This register has the following functions:

- To power up or power down the comparator (CMRn:PD)
- To enable or disable comparator output (CMRn:VCOE)
- To enable or disable comparator analog input (CMRn:VCID)

Except in stop mode, watch mode or time-base timer mode, if the interrupt request enable bit (IE) in the CMRn register has been set to "1", upon detection of a rising edge or falling edge of comparator output, the comparator generates an interrupt request, and the output edge detection interrupt flag bit (IF) in the CMRn register is automatically set to "1" at the same time.

The output status of a comparator can be read through the output status bit (OS) in the CMRn register.

29.3 Pins

This section describes the pins of the comparator.

■ Pins of Comparator

Table 29.3-1 shows details of the pins of the comparator.

Table 29.3-1 Pins of Comparator

Pin name	Pin function
CMPn_P	Comparator non-inverting analog input (positive input)
CMPn_N	Comparator inverting analog input (negative input)
CMPn_O	Comparator digital output

29.4 Interrupt

The comparator generates an interrupt called output edge detection interrupt. An interrupt request number and an interrupt vector are assigned to the interrupt.

■ Output Edge Detection Interrupt

Table 29.4-1 shows details of the output edge detection interrupt.

Table 29.4-1 Details of Output Edge Detection Interrupt

Item	Details
Interrupt generating condition	An output rising edge or output falling edge occurs.
Interrupt flag	CMRn:IF
Interrupt enable bit	CMRn:IE

Note:

In stop mode, watch mode or time-base timer mode, the edge detection circuit stops operating, and the IF bit in the comparator control register ch. n (CMRn) is not to be updated even if the comparator has been turned on.

29.5 Operations and Setting Procedure Example

The comparator can be activated by the software according to the setting of the PD bit in the CMRn register.

■ Software Activation of Comparator

To activate the comparator with the software, do the settings shown in Figure 29.5-1.

Figure 29.5-1 Settings for Activating Comparator

	bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
CMRn	—	—	OS	IF	IE	VCID	VCOE	PD
	x	x	○	○	0	1	0	0
○ : Bit to be used								
x : Unused bit								
0 : Set to "0"								
1 : Set to "1"								

After the comparator is activated as shown above, it has to wait for the stabilization time to elapse before starting to operate. For details of the stabilization time of the comparator, refer to the device data sheet.

Note:

Before activating the comparator, set the IE bit in the CMRn register to "0" in advance in order to avoid any unexpected interrupt generated due to the comparator being unstable at its startup.

■ Setting Procedure Example

Below is an example of procedure for setting the comparator:

● Initial settings

1. Disable the comparator interrupt request. (CMRn:IE = 0)
2. Activate the comparator according to the settings shown in Figure 29.5-1.
3. Wait until the comparator stabilizes.
4. Clear the interrupt flag bit. (CMRn:IF = 0)
5. Enable the comparator interrupt request, and enable the comparator output if necessary. (CMRn:IE = 1, CMRn:VCOE = 1)

29.6 Register

This section describes the register of the comparator.

Table 29.6-1 List of Comparator Register

Register abbreviation	Register name	Reference
CMRn	Comparator control register ch. n	29.6.1

29.6.1 Comparator Control Register ch. n (CMRn)

The comparator control register ch. n (CMRn) has the following functions:

- To power up or power down the comparator (CMRn:PD)
- To enable or disable comparator output (CMRn:VCOE)
- To enable and disable comparator analog input (CMRn:VCID)

Except in stop mode, watch mode or time-base timer mode, if CMRn:IE has been set to "1", upon detection of a rising edge or falling edge of comparator output, the comparator generates an interrupt request and the interrupt flag bit (CMRn:IF) is automatically set to "1" at the same time.

The output status of the comparator can be read through the OS bit in the comparator control register ch. n (CMRn).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	OS	IF	IE	VCID	VCOE	PD
Attribute	—	—	R	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	0	0	0	0	0	1

■ Register Functions

[bit7:6] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit5] OS: Output status bit

This bit indicates the output status of the comparator.

bit5	Details
Reading "0"	Indicates that the comparator outputs "L".
Reading "1"	Indicates that the comparator outputs "H".

Note: This bit is not updated in stop mode, watch mode or time-base timer mode. When the PD bit is set to "1" (to power down the comparator), the OS bit becomes "0".

[bit4] IF: Output edge detection interrupt flag bit

This bit detects the output rising edge and the output falling edge of the comparator.

With the comparator in operation, this bit is set to "1" if an output rising edge or an output falling edge occurs.

When read by the read-modify-write (RMW) type of instruction, this bit always returns "1".

bit4	Details
Reading "0"	Indicates that no output rising edge/falling edge has occurred.
Reading "1"	Indicates that an output rising edge/falling edge has occurred.
Writing "0"	Clears this bit.
Writing "1"	Has no effect on operation.

Note: This bit is not updated in stop mode, watch mode or time-base timer mode.

[bit3] IE: Interrupt request enable bit

This bit enables or disables the interrupt request of the comparator.

Writing "0" to this bit disables the interrupt request of the comparator.

Writing "1" to this bit enables the interrupt request of the comparator. With the interrupt request enabled, the comparator generates an interrupt request when detecting an output rising edge or an output falling edge.

bit3	Details
Writing "0"	Disables the interrupt request of the comparator.
Writing "1"	Enables the interrupt request of the comparator.

[bit2] VCID: Comparator analog input disable bit

This bit enables or disables comparator analog input.

bit2	Details
Writing "0"	Enables comparator analog input.
Writing "1"	Disables comparator analog input.

[bit1] VCOE: Comparator output enable bit

This bit enables or disables comparator output.

bit1	Details
Writing "0"	Disables comparator output. The output pin of the comparator is used as general-purpose I/O port.
Writing "1"	Enables comparator output.

[bit0] PD: Comparator power down control bit

This bit powers up or down the comparator.

bit0	Details
Writing "0"	Powers up the comparator.
Writing "1"	Powers down the comparator.

CHAPTER 30

SYSTEM CONFIGURATION CONTROLLER

This chapter describes the functions and operations of the system configuration controller (called the "controller" in this chapter).

30.1 Overview

30.2 Registers

30.3 Notes on Using Controller

30.1 Overview

The controller consists of the system configuration register (SYSC) and the system configuration register 2 (SYSC2). The SYSC register configures the clock and reset system. The SYSC2 register selects the external clock to be multiplied by the PLL, and the reference voltage of the comparator.

■ Functions of SYSC

- Selecting the general purpose I/O port/reset function for the PF2/ $\overline{\text{RST}}$ pin
- Enabling/disabling reset output for the $\overline{\text{RST}}$ pin
- Selecting the general purpose I/O port/oscillation function for the PF0/X0 pin and that for the PF1/X1 pin
- Selecting the general purpose I/O port/oscillation function for the PG1/X0A pin and that for the PG2/X1A pin
- Selecting the external clock input function for the PF0/X0 pin and that for the PF1/X1 pin
- Selecting the external clock input function for the PG1/X0A pin and that for the PG2/X1A pin

■ Functions of SYSC2

- Selecting the external clock to be multiplied by the PLL
- Selecting the reference voltage of the comparator

30.2 Registers

This section describes the registers of the controller.

Table 30.2-1 List of Controller Registers

Register abbreviation	Register name	Reference
SYSC	System configuration register	30.2.1
SYSC2	System configuration register 2	30.2.2

30.2.1 System Configuration Register (SYSC)

This section describes the system configuration register (SYSC).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	Reserved	Reserved	PGSEL1	PGSEL0	PFSEL1	PFSEL0	RSTOE	RSTEN
Attribute	W	W	R/W	R/W	R/W	R/W	R/W	R/W
Initial value	0	0	1	1	1	1	1	1

■ Register Functions

[bit7:6] Reserved bits

Always set these bits to "0".

[bit5:4] PGSEL[1:0]: PG1 and PG2 function select bits

These bits select the function of the PG1 and PG2 pins.

Writing "00" to these bits makes the PG1 and PG2 pins function as subclock oscillation pins. Write "00" to these bits when using a crystal oscillator or a ceramic oscillator. The subclock oscillation is enabled or disabled by the subclock oscillation enable bit (SYCC2:SOSCE).

Writing "10" to these bits makes the PG1 pin function as a subclock external input pin and the PG2 pin as a general-purpose I/O port. Write "10" to these bits when using an external subclock. The subclock is enabled or disabled by the subclock oscillation enable bit (SYCC2:SOSCE).

Writing "01" or "11" to these bits makes the PG1 and PG2 pins function as general-purpose I/O ports.

bit5:4	Details
Writing "00"	Makes the PG1 and PG2 pins function as subclock oscillation pins.
Writing "01"	Makes the PG1 and PG2 pins function as general-purpose I/O ports.
Writing "10"	Makes the PG1 pin function as a subclock external input pin and the PG2 pin as a general-purpose I/O port.
Writing "11"	Makes the PG1 and PG2 pins function as general-purpose I/O ports.

[bit3:2] PFSEL[1:0]: PF0 and PF1 function select bits

These bits select the function of the PF0 and PF1 pins.

Writing "00" to these bits makes the PF0 and PF1 pins function as main clock oscillation pins. Write "00" to these bits when using a crystal oscillator or a ceramic oscillator. The main clock oscillation is enabled or disabled by the main clock oscillation enable bit (SYCC2:MOSCE).

Writing "10" to these bits makes the PF0 pin function as a main clock external input pin and the PF1 pin as a general-purpose I/O port. Write "10" to these bits when using an external main clock. The main clock is enabled or disabled by the main clock oscillation enable bit (SYCC2:MOSCE).

Writing "01" or "11" to these bits makes the PF0 and PF1 pins function as general-purpose I/O ports.

bit3:2	Details
Writing "00"	Makes the PF0 and PF1 pins function as main clock oscillation pins.
Writing "01"	Makes the PF0 and PF1 pins function as general-purpose I/O ports.
Writing "10"	Makes the PF0 pin function as a main clock external input pin and the PF1 pin as a general-purpose I/O port.
Writing "11"	Makes the PF0 and PF1 pins function as general-purpose I/O ports.

[bit1] RSTOE: Reset output enable/disable bit

This bit enables or disables the reset output function of the PF2/ $\overline{\text{RST}}$ pin with the reset input function enabled. When the reset input function is disabled (SYSC:RSTEN = 0), the reset output function is disabled regardless of the setting of this bit.

See the PF2 function select bit (SYSC:RSTEN) for details of selecting the reset input function.

bit1	Details
Writing "0"	Disables the reset output function of the PF2/ $\overline{\text{RST}}$ pin.
Writing "1"	Enables the reset output function of the PF2/ $\overline{\text{RST}}$ pin.

[bit0] RSTEN: PF2 function select bit

This bit enables or disables the reset input function of the PF2/ $\overline{\text{RST}}$ pin. The reset input function is always enabled on MB95F714L/F716L/F718L/F774L/F776L/F778L regardless of the setting of this bit.

Writing "0" to this bit disables the reset input function of the PF2/ $\overline{\text{RST}}$ pin and enables the general-purpose I/O port function.

Writing "1" to this bit enables the reset input function of the PF2/ $\overline{\text{RST}}$ pin and disables the general-purpose I/O port function.

Set bit2 in the PDRF register to "1" before modifying this bit.

bit0	Details
Writing "0"	Selects the general-purpose I/O port function of the PF2/ $\overline{\text{RST}}$ pin.
Writing "1"	Selects the reset output function of the PF2/ $\overline{\text{RST}}$ pin.

Note:

To keep the reset input/output function after the reset, SYSC:RSTEN and SYSC:RSTOE are initialized to "1" after the power is switched on. They are not initialized by any other type of reset.

When the reset input/output functions have to be used in a system, it is strongly recommended that SYSC:RSTEN be initialized to "1" in the initialize program routine after a reset for stable operation. With the reset input/output functions having been enabled, all types of reset, including the watchdog reset, can be used.

30.2.2 System Configuration Register 2 (SYSC2)

This section describes the system configuration register 2 (SYSC2).

■ Register Configuration

bit	7	6	5	4	3	2	1	0
Field	—	—	—	—	—	Reserved	PLLSEL	VBGRSELX
Attribute	—	—	—	—	—	W	R/W	R/W
Initial value	0	0	0	0	0	0	0	0

■ Register Functions

[bit7:3] Undefined bits

Their read values are always "0". Writing values to these bits has no effect on operation.

[bit2] Reserved bit

Always set this bit to "0".

[bit1] PLLSEL: PLL target select bit

Set this bit according to the external clock frequency when using the PLL to multiply the main clock by two (PLL:MPMC[1:0] = 00).

The setting of this bit is effective only when the PLL multiplication rate is two. When the PLL multiplication rate is 2.5, 3 or 4, the setting of this bit has no effect on operation.

When using the main CR PLL clock, always write "0" to this bit.

When the setting of this bit does not match the frequency of the external clock, the accuracy of the operating frequency cannot be guaranteed.

bit1	Details
Writing "0"	Selects an external clock whose frequency is 5 MHz or below to be multiplied by two.
Writing "1"	Selects an external clock whose frequency is higher than 5 MHz to be multiplied by two.

[bit0] VBGRSELX: Comparator reference voltage select bit

This bit selects the reference voltage of the comparator.

bit0	Details
Writing "0"	Selects the internal voltage (bandgap reference voltage) as the reference voltage of the comparator. For details of the bandgap reference voltage, refer to the data sheet of the MB95710L/770L Series.
Writing "1"	Selects the external voltage from the CMP0_P pin as the reference voltage of the comparator.

30.3 Notes on Using Controller

This section provides notes on using the controller.

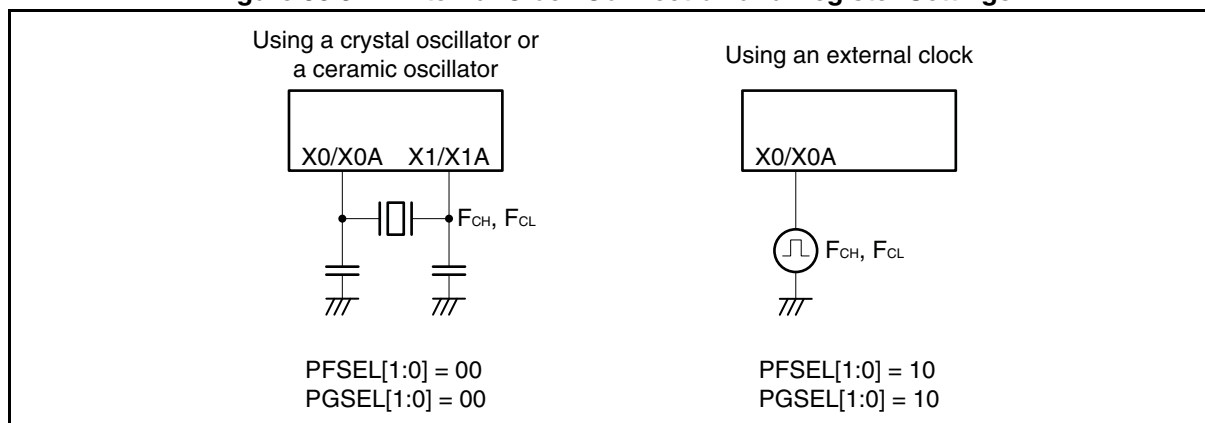

■ Method for Setting PFSEL[1:0] and PGSEL[1:0]

When connecting the X0 and X1 pins to a crystal oscillator or a ceramic oscillator, write "00" to the PFSEL[1:0] bits. In the case of writing a value other than "00" to the PFSEL[1:0] bits, no clock oscillates, and the device does not transit to main clock mode. When connecting the X0A and X1A pins to a crystal oscillator or a ceramic oscillator, write "00" to the PGSEL[1:0] bits. In the case of writing a value other than "00" to the PGSEL[1:0] bits, no clock oscillates, and the device does not transit to subclock mode.

When connecting the X0 pin to an external clock, write "10" to the PFSEL[1:0] bits. In the case of writing a value other than "10" to the PFSEL[1:0] bits, no external clock is supplied to the device, and the device does not transit to main clock mode. When connecting the X0A pin to an external clock, write "10" to the PGSEL[1:0] bits. In the case of writing a value other than "10" to the PGSEL[1:0] bits, no external clock is supplied to the device, and the device does not transit to subclock mode.

In addition, before setting the PFSEL[1:0] bits and the PGSEL[1:0] bits, ensure that the main clock and the subclock have stopped respectively.

Figure 30.3-1 External Clock Connection and Register Settings

■ Subclock Oscillation Stabilization Wait Time

The MB95710L/770L Series has a low current consumption subclock oscillation cell to reduce the current consumption of subclock oscillation. Since only a small amount of current is used to make the cell oscillate, the cell oscillation may not be stable at its beginning.

In the case of using a crystal oscillator or a ceramic oscillator as the subclock, set the subclock oscillation stabilization wait time to 7.75 ms or above (WATR:SWT[3:0] = 0b1000 or above, subclock (F_{CL}) = 32.768 kHz).

In the case of using an external clock as the subclock, since the low current consumption subclock oscillation cell is not used, the subclock oscillation stabilization wait time can be set to any value.

■ Notes on Changing Value of VBGRSELX

It is recommended to access the SYSC2 register through the RAM or use a source clock whose frequency is 4 MHz or less when changing the value of the VBGRSELX bit in the SYSC2 register. In addition, since the main CR clock becomes unstable immediately after the value of the VBGRSELX bit has been changed, it is recommended not to perform communications with any peripheral function such as the UART/SIO when using the main CR clock or the main CR PLL clock as a source clock.

APPENDIX

This section provides an overview of instructions.

APPENDIX A Instruction Overview

APPENDIX B Major Changes

APPENDIX A Instruction Overview

This section explains the instructions used in F²MC-8FX.

■ Instruction Overview of F²MC-8FX

In the F²MC-8FX, there are 140 kinds of one byte instructions (256 bytes on the map), and the instruction code is composed of the instruction and the operand following it.

Figure A-1 shows the correspondence of the instruction code and the instruction map.

Figure A-1 Instruction Code and Instruction Map

- The instruction is classified into following four types; forwarding system, operation system, branch system and others.
- There are various methods of addressing, and ten kinds of addressing can be selected by the selection and the operand specification of the instruction.
- This provides with the bit operation instruction, and can execute the read-modify-write (RMW) type of instruction.
- There is an instruction that directs special operation.

Code: CM26-00118-1EA

■ Meanings of Signs in Instruction Codes

Table A-1 shows the meanings of signs used in explaining instruction codes in APPENDIX A.

Table A-1 Meanings of Signs in Instruction Codes

Sign	Meanings
dir	Direct address (8-bit length)
off	Offset (8-bit length)
ext	Extended address (16-bit length)
#vct	Vector table number (3-bit length)
#d8	Immediate data (8-bit length)
#d16	Immediate data (16-bit length)
dir:b	Bit direct address (8-bit length: 3-bit length)
rel	Branch relative address (8-bit length)
@	Register indirect (Example: @A, @IX, @EP)
A	Accumulator (Whether 8- bit length or 16- bit length is decided by the instruction used.)
AH	Upper 8-bit of accumulator (8-bit length)
AL	Lower 8-bit of accumulator (8-bit length)
T	Temporary accumulator (Whether 8- bit length or 16- bit length is decided by the instruction used.)
TH	Upper 8-bit of temporary accumulator (8-bit length)
TL	Lower 8-bit of temporary accumulator (8-bit length)
IX	Index register (16-bit length)
EP	Extra pointer (16-bit length)
PC	Program counter (16-bit length)
SP	Stack pointer (16-bit length)
PS	Program status (16-bit length)
dr	Either of accumulator or index register (16-bit length)
CCR	Condition code register (8-bit length)
RP	Register bank pointer (5-bit length)
DP	Direct bank pointer (3-bit length)
Ri	General-purpose register (8-bit length, i = 0 to 7)
x	This shows that x is immediate data. (Whether 8- bit length or 16- bit length is decided by the instruction used.)
(x)	This shows that contents of x are objects of the access. (Whether 8- bit length or 16- bit length is decided by the instruction used.)
((x))	This shows that the address that contents of x show is an object of the access. (Whether 8- bit length or 16- bit length is decided by the instruction used.)

■ Meanings of Items in Instruction Table

Table A-2 Meanings of Items in Instruction Table

Item	Meaning
MNEMONIC	It shows the assembly description of the instruction.
~	It shows the number of cycles of the instruction. One instruction cycle is a machine cycle. Note: The number of cycles of the instruction can be delayed by 1 cycle by the immediately preceding instruction. Moreover, the number of cycles of the instruction might be extended in the access to the I/O area.
#	It shows the number of bytes for the instruction.
Operation	It shows the operations for the instruction.
TL, TH, AH	They show the change (auto forwarding from A to T) in the content when each TL, TH, and AH instruction is executed. The sign in the column indicates the followings respectively. <ul style="list-style-type: none"> • -: No change • dH: upper 8 bits of the data described in operation. • AL and AH: the contents become those of the immediately preceding instruction's AL and AH. • 00: Become 00
N, Z, V, C	They show the instruction into which the corresponding flag is changed respectively. The sign in the column shows the followings respectively. <ul style="list-style-type: none"> • -: No change • +: Change • R: Become "0" • S: Become "1"
OP CODE	It shows the code of the instruction. When a pertinent instruction occupies two or more codes, it follows the following description rules. [Example] 48 to 4F: This shows 48, 49....4F.

A.1 Addressing

F²MC-8FX has the following ten types of addressing:

- Direct addressing
- Extended addressing
- Bit direct addressing
- Index addressing
- Pointer addressing
- General-purpose register addressing
- Immediate addressing
- Vector addressing
- Relative addressing
- Inherent addressing

■ Explanation of Addressing

● Direct addressing

This is used when accessing the direct area of "0x0000" to "0x047F" with addressing indicated "dir" in instruction table. In this addressing, when the operand address is "0x00" to "0x7F", it is accessed into "0x0000" to "0x007F". Moreover, when the operand address is "0x80" to "0xFF", the access can be mapped in "0x0080" to "0x047F" by setting of direct bank pointer DP. Figure A.1-1 shows an example.

Figure A.1-1 Example of Direct Addressing

● Extended addressing

This is used when the area of the entire 64 Kbyte is accessed by addressing shown "ext" in the instruction table. In this addressing, the first operand specifies one high rank byte of the address and the second operand specifies one subordinate position byte of the address.

Figure A.1-2 shows an example.

Figure A.1-2 Example of Extended Addressing

● Bit direct addressing

This is used when accessing the direct area of "0x0000" to "0x047F" in bit unit with addressing indicated "dir:b" in instruction table. In this addressing, when the operand address is "0x00" to "0x7F", it is accessed into "0x0000" to "0x007F". Moreover, when the operand address is "0x80" to "0xFF", the access can be mapped in "0x0080" to "0x047F" by setting of direct bank pointer DP. The position of the bit in the specified address is specified by the values of the instruction code of three subordinate position bits.

Figure A.1-3 shows an example.

Figure A.1-3 Example of Bit Direct Addressing

● Index addressing

This is used when the area of the entire 64 Kbyte is accessed by addressing shown "@IX+off" in the instruction table. In this addressing, the content of the first operand is sign extended and added to IX (index register) to the resulting address. Figure A.1-4 shows an example.

Figure A.1-4 Example of Index Addressing

● Pointer addressing

This is used when the area of the entire 64 Kbyte is accessed by addressing shown "@EP" in the instruction table. In this addressing, the content of EP (extra pointer) is assumed to be an address. Figure A.1-5 shows an example.

Figure A.1-5 Example of Pointer Addressing

● General-purpose register addressing

This is used when accessing the register bank in general-purpose register area with the addressing shown "Ri" in instruction table. In this addressing, fix one high rank byte of the address to "01" and create one subordinate position byte from the contents of RP (register bank pointer) and three subordinate bits of the operation code to access to this address. Figure A.1-6 shows an example.

Figure A.1-6 Example of General-purpose Register Addressing

● Immediate addressing

This is used when immediate data is needed in addressing shown "#d8" in the instruction table. In this addressing, the operand becomes immediate data as it is. The specification of byte/word depends on the operation code. Figure A.1-7 shows an example.

Figure A.1-7 Example of Immediate Addressing

● Vector addressing

This is used when branching to the subroutine address registered in the table with the addressing shown "#vct" in the instruction table. In this addressing, information on "#vct" is contained in the operation code, and the address of the table is created using the combinations shown in Table A.1-1.

Table A.1-1 Vector Table Address Corresponding to "#vct"

#vct	Vector table address (jump destination high-ranking address: subordinate address)
0	0xFFC0 : 0xFFC1
1	0xFFC2 : 0xFFC3
2	0xFFC4 : 0xFFC5
3	0xFFC6 : 0xFFC7
4	0xFFC8 : 0xFFC9
5	0xFFCA : 0xFFCB
6	0xFFCC : 0xFFCD
7	0xFFCE : 0xFFCF

Figure A.1-8 shows an example.

Figure A.1-8 Example of Vector Addressing

● Relative addressing

This is used when branching to the area in 128 bytes before and behind PC (program counter) with the addressing shown "rel" in the instruction table. In this addressing, add the content of the operand to PC with the sign and store the result in PC. Figure A.1-9 shows an example.

Figure A.1-9 Example of Relative Addressing

In this example, by jumping to the address where the operation code of BNE is stored, it results in an infinite loop.

● Inherent addressing

This is used when doing the operation decided by the operation code with the addressing that does not have the operand in the instruction table. In this addressing, the operation depends on each instruction. Figure A.1-10 shows an example.

Figure A.1-10 Example of Inherent Addressing

A.2 Special Instruction

This section explains special instructions other than the addressings.

■ Special Instruction

● JMP @A

This instruction is to branch the content of A (accumulator) to PC (program counter) as an address. N pieces of the jump destination is arranged on the table, and one of the contents is selected and transferred to A. N branch processing can be done by executing this instruction.

Figure A.2-1 shows a summary of the instruction.

Figure A.2-1 JMP @A

● MOVW A, PC

This instruction works as the opposite of "JMP @A". That is, it stores the content of PC to A. When you have executed this instruction in the main routine and set it to call a specific subroutine, you can make sure that the content of A is the specified value in the subroutine. Also, you can identify that the branch is not from the part that cannot be expected, and use it for the reckless driving judgment.

Figure A.2-2 shows a summary of the instruction.

Figure A.2-2 MOVW A, PC

When this instruction is executed, the content of A reaches the same value as the address where the following instruction is stored, rather than the address where operation code of this instruction is stored. Therefore, in Figure A.2-2, the value "0x1234" stored in A corresponds to the address where the following operation code of "MOVW A, PC" is stored.

● MULU A

This instruction performs an unsigned multiplication of AL (lower 8-bit of the accumulator) and TL (lower 8-bit of the temporary accumulator), and stores the 16-bit result in A. The contents of T (temporary accumulator) do not change. The contents of AH (higher 8-bit of the accumulator) and TH (higher 8-bit of the temporary accumulator) before execution of the instruction are not used for the operation. Note that since the instruction does not change the flags, a branch may occur depending on the multiplication result.

Figure A.2-3 shows a summary of the instruction.

Figure A.2-3 MULU A

● DIVU A

This instruction divides the 16-bit value in T by the unsigned 16-bit value in A, and stores the 16-bit result and the 16-bit remainder in A and T, respectively. When the value in A before execution of instruction is "0", the Z flag becomes "1" to indicate zero-division is executed. Note that since the instruction does not change other flags, a branch may occur depending on the division result.

Figure A.2-4 shows a summary of the instruction.

Figure A.2-4 DIVU A

● XCHW A, PC

This instruction swaps the contents of A and PC, resulting in a branch to the address contained in A before execution of the instruction. After the instruction is executed, A becomes the address that follows the address where the operation code of "XCHW A, PC" is stored. This instruction is effective especially when it is used in the main routine to specify a table for use in a subroutine.

Figure A.2-5 shows a summary of the instruction.

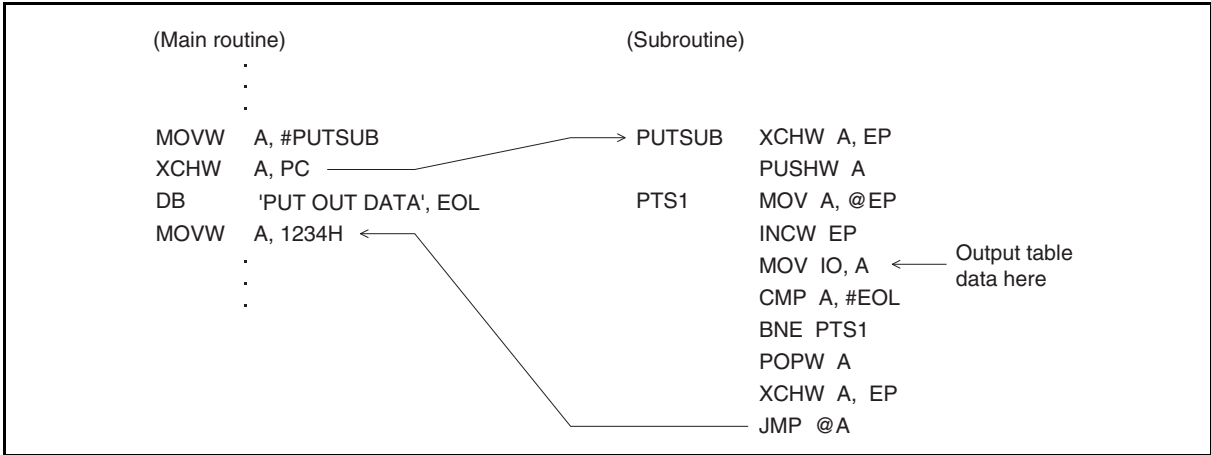

Figure A.2-5 XCHW A, PC

When this instruction is executed, the content of A reaches the same value as the address where the following instruction is stored, rather than the address where operation code of this instruction is stored. Therefore, in Figure A.2-5, the value "0x1235" stored in A corresponds to the address where the following operation code of "XCHW A, PC" is stored. This is why "0x1235" is stored instead of "0x1234".

Figure A.2-6 shows an assembler language example.

Figure A.2-6 Example of Using "XCHW A, PC"

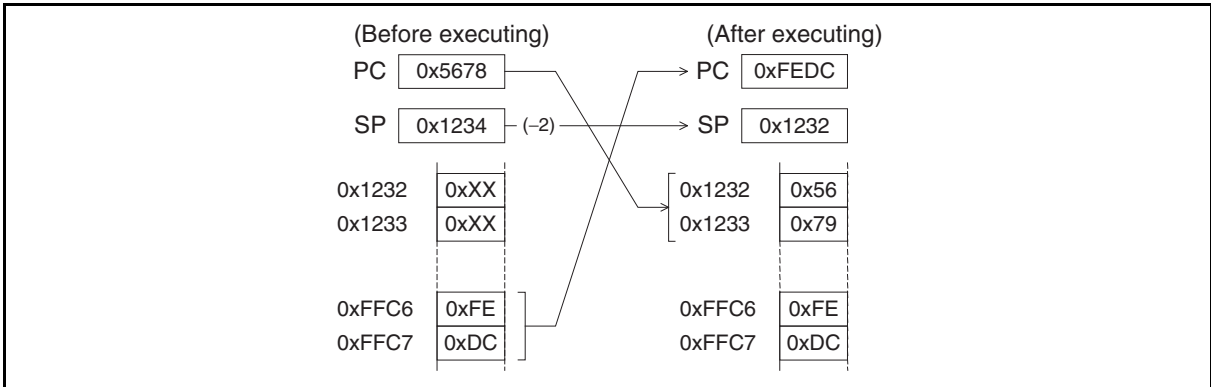

● CALLV #vct

This instruction is used to branch to a subroutine address stored in the vector table. The instruction saves the return address (contents of PC) in the location at the address contained in SP (stack pointer), and uses vector addressing to cause a branch to the address stored in the vector table. Because `CALLV #vct` is a 1-byte instruction, the use of this instruction for frequently used subroutines can reduce the entire program size.

Figure A.2-7 shows a summary of the instruction.

Figure A.2-7 Example of Executing CALLV #3

After the `CALLV #vct` instruction is executed, the contents of PC saved on the stack area are the address of the operation code of the next instruction, rather than the address of the operation code of `CALLV #vct`. Accordingly, Figure A.2-7 shows that the value saved in the stack (0x1232 and 0x1233) is 0x5679, which is the address of the operation code of the instruction that follows "CALLV vct" (return address).

Table A.2-1 Vector Table

Vector use (call instruction)	Vector table address	
	Upper	Lower
CALLV #7	0xFFCE	0xFFCF
CALLV #6	0xFFCC	0xFFCD
CALLV #5	0xFFCA	0xFFCB
CALLV #4	0xFFC8	0xFFC9
CALLV #3	0xFFC6	0xFFC7
CALLV #2	0xFFC4	0xFFC5
CALLV #1	0xFFC2	0xFFC3
CALLV #0	0xFFC0	0xFFC1

A.3 Bit Manipulation Instructions (SETB, CLRB)

Some peripheral function registers include bits that are read differently than usual by a bit manipulation instruction.

■ Read-modify-write Operation

By using these bit manipulation instructions, you can set only the specified bit in a register or RAM location to "1" (SETB) or clear to "0" (CLRB). However, as the CPU operates data in 8-bit units, the actual operation (read-modify-write operation) involves a sequence of steps: 8-bit data is read, the specified bit is changed, and the data is written back to the location at the original address.

Table A.3-1 shows bus operation for bit manipulation instructions.

Table A.3-1 Bus Operation for Bit Manipulation Instructions

CODE	MNEMONIC	~	Cycle	Address bus	Data bus	RD	WR	RMW
A0 to A7	CLRB dir:b	4	1	N+2	Next instruction	1	0	1
			2	dir address	Data	1	0	1

■ Read Destination on the Execution of Bit Manipulation Instructions

For some I/O ports and the interrupt request flag bits, the read destination differs between a normal read operation and a read-modify-write operation.

● I/O ports (during a bit manipulation)

From some I/O ports, an I/O pin value is read during a normal read operation, while a port data register value is read during a bit manipulation. This prevents the other port data register bits from being changed accidentally, regardless of the I/O directions and states of the pins.

● Interrupt request flag bits (during a bit manipulation)

An interrupt request flag bit functions as a flag bit indicating whether an interrupt request exists during a normal read operation, however, "1" is always read from this bit during a bit manipulation. This prevents the flag from being cleared accidentally by writing the value "0" to the interrupt request flag bit when manipulating another bit.

A.4 F²MC-8FX Instructions

Table A.4-1 to Table A.4-4 show the instructions used by F²MC-8FX.

■ Transfer Instructions

Table A.4-1 Transfer Instructions

APPENDIX B Major Changes

Page	Section	Change Results
Revision 1.0		
-	-	Initial release
Revision 2.0		
17	CHAPTER 3 CLOCK CONTROLLER 3.1 Overview of Clock Controller ■ Block Diagram of Clock Controller Figure 3.1-1	Corrected the connection between the PLL clock oscillator circuit and the PLLC control register (PLLC).
61	CHAPTER 4 RESET 4.1 Reset Operation ■ Reset Sources ● Low-voltage detection reset (optional)	Added the following statement. However, the LVD control register (LVDC) of the low-voltage detection circuit is not reset by the low-voltage detection reset.
228	CHAPTER 15 8/12-BIT A/D CONVERTER 15.8 Notes on Using 8/12-bit A/D Converter ■ Notes on Using 8/12-bit A/D Converter ● 8/12-bit A/D converter analog input sequences	Corrected the name of the analog input pin. AN → ANn

Page	Section	Change Results
366	CHAPTER 23 I ² C BUS INTERFACE 23.3 Channel ■ Channel of I ² C Bus Interface Table 23.3-2	Corrected the register name of the IBCR0n register. I ² C bus control register 0 → I ² C bus control register 0 ch. n
		Corrected the register name of the IBCR1n register. I ² C bus control register 1 → I ² C bus control register 1 ch. n
		Corrected the register name of the IBSRn register. I ² C bus status register → I ² C bus status register ch. n
		Corrected the register name of the IDDRn register. I ² C data register → I ² C data register ch. n
		Corrected the register name of the IAARn register. I ² C address register → I ² C address register ch. n
		Corrected the register name of the ICCRn register. I ² C clock control register → I ² C clock control register ch. n
410	CHAPTER 24 LCD CONTROLLER (MB95710L SERIES) 24.4 Display RAM ■ Display RAM and Output Pins	Corrected the definition of "n" in "Note". 0x0FCD → 0x0FBD
466	CHAPTER 25 LCD CONTROLLER (MB95770L SERIES) 25.4 Display RAM ■ Display RAM and Output Pins	Corrected the definition of "n" in "Note". 0x0FCD → 0x0FBD
510	CHAPTER 26 EXAMPLE OF SERIAL PROGRAMMING CONNECTION 26.2 Example of Serial Programming Connection ■ Example of Serial Programming Connection	Added statements related to the use of the pull-up resistor.

The products described in this document are designed, developed and manufactured as contemplated for general use, including without limitation, ordinary industrial use, general office use, personal use, and household use, but are not designed, developed and manufactured as contemplated (1) for any use that includes fatal risks or dangers that, unless extremely high safety is secured, could have a serious effect to the public, and could lead directly to death, personal injury, severe physical damage or other loss (i.e., nuclear reaction control in nuclear facility, aircraft flight control, air traffic control, mass transport control, medical life support system, missile launch control in weapon system), or (2) for any use where chance of failure is intolerable (i.e., submersible repeater and artificial satellite). Please note that Spansion will not be liable to you and/or any third party for any claims or damages arising in connection with above-mentioned uses of the products. Any semiconductor devices have an inherent chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions. If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the US Export Administration Regulations or the applicable laws of any other country, the prior authorization by the respective government entity will be required for export of those products.
