1 Product Description

The KP254 is a miniaturized Digital Barometric Air Pressure Sensor IC based on a capacitive principle. It is surface micromachined with a monolithic integrated signal conditioning circuit implemented in BiCMOS technology.

The sensor converts a pressure into a 10-bit digital value and sends the information via the SPI interface. In addition, a temperature sensor is integrated on chip. Based on the received SPI command, the 10-bit temperature information will be transmitted via the SPI interface.

A special reliability feature is the integrated diagnostic mode, which allows testing the sensor cells as well as the signal path. This diagnosis can be simply triggered with a SPI command.

The chip is packaged in a “green” SMD housing. The sensor has been primarily developed for measuring barometric air pressure, but can also be used in other application fields. The high accuracy, high sensitivity and reliability features of the device makes it a perfect fit for advanced automotive applications as well as in industrial and consumer applications.

1.1 Features

The following features are supported by the KP254:

- High accuracy pressure sensing (± 1.5 kPa)
- Real 10-bit pressure resolution
- Integrated temperature sensor
- Real 10-bit temperature resolution
- Self diagnosis features
- “Green” 8 pin SMD housing
- Automotive qualified

1.2 Target Applications

The KP254 is designed for use in the following target applications:

- Automotive applications
- Industrial control
- Consumer applications
- Medical applications
- Weather stations
- Altimeters

Digital Absolute Pressure Sensor

Functional Description

2.3 Block Diagram

Figure 2 shows the functional block diagram.

![Functional block diagram](image)

2.4 Transfer Function Pressure

The KP254 device is fully calibrated on delivery. The sensor has a linear transfer function between the applied pressure and the digital output signal.

![Pressure transfer function](image)
2.4.1 Pressure Transfer Function Characteristics

The following calibration is adjusted with the parameters $S_p$ and $offs_p$

$$\rho_{amb} = \frac{out_p - offs_p}{S_p}$$

<table>
<thead>
<tr>
<th>Pressure Symbol</th>
<th>Values</th>
<th>Unit</th>
<th>Output Code Symbol</th>
<th>Values</th>
<th>Unit</th>
<th>Gain and Offset Symbol</th>
<th>Value</th>
<th>Unit</th>
</tr>
</thead>
<tbody>

<td>LSB</td>
<td>$LSB_{OUT,2}$</td>
<td>1023 LSB</td>
<td></td>
<td>$offs_p$</td>
<td>-545.6</td>
<td>LSB</td>
</tr>
</tbody>
</table>

Note: The points $\rho_{IN,1}/LSB_{OUT,1}$ and $\rho_{IN,2}/LSB_{OUT,2}$ define the calibrated transfer function and not the operating range. The operating pressure range is defined by the parameter 2.8 "Ambient operating pressure range" on Page 22.

2.4.2 Accuracy

![Figure 4 Accuracy for pressure acquisition](image.png)
2.5 Transfer Function Temperature

Triggering the temperature command (see Section 2.6.1.4) the KP254 provides the ambient temperature.

**Figure 5** Temperature transfer function \(V_{DD} = 5.0\) V

### 2.5.1 Temperature Transfer Function Characteristics

The following calibration is adjusted with the parameters \(S_T\) and \(offs_T\):

\[
T_{amb} = \frac{out - offs_T}{S_T}
\]

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Values</th>
<th>Unit</th>
<th>Symbol</th>
<th>Values</th>
<th>Unit</th>

<tr>
<td>(T_{IN,2,5.0})</td>
<td>160</td>
<td>°C</td>
<td>(LSB_{OUT,2})</td>
<td>1023</td>
<td>LSB</td>
</tr>
</tbody>
</table>

1) Valid for \(V_{DD} = 5.0\) V
2) Valid for \(V_{DD} = 3.3\) V

Note: The points \(T_{IN,1}/LSB_{OUT,1}\) and \(T_{IN,2}/LSB_{OUT,2}\) define the calibrated transfer function and not the operating range. The operating temperature range is defined by the parameter 2.7 “Operating temperature” on Page 22.
2.6 Serial Interface

The communication and data transmission is based on a standard 16 bit serial peripheral interface (SPI).

![Figure 6 SPI timing](image)

2.6.1 Commands

The following Commands are defined:

- Acquire identifier
- Acquire pressure (incl. the diagnosis pressure out of range, \(E^2\)PROM check and last updated Diag1 & Diag2)\(^1\)
- Acquire temperature (incl. the diagnosis pressure out of range, \(E^2\)PROM check and last updated Diag1 & Diag2)\(^1\)
- Trigger diagnosis (triggers Diag1 and Diag2)
- Trigger test mode (entry into test mode only occurs if this is the first command received after power up, in conjunction with a high voltage level (>10V) on pin \(V_{PROG}\))

2.6.1.1 Command Behavior

The SPI command interpretation is based on following rules:

- The response to command \(N\) is the result of the previous command \((N-1)\)
- The response to the first command is the identifier
- When a command \((N)\) is sent and the processing of the previous command \((N-1)\) has not finalized, the last command \((N)\) will not interrupt the processing
- Max. one command is stacked (during processing a command a new received command is stacked; further received commands will overwrite the stack)
- If a command has finished, the sensor takes the next command from the stack; if no command is in the stack, the sensor goes into the pressure measurement mode

\(^1\) Last updated diagnosis information is only available if the Trigger diagnosis command was sent at any time before and the diagnostic reset is not active (Reset-bit C12 = '1', see Chapter 2.8.1).
**Functional Description**

- The diagnosis command triggers the Diag1 and Diag2 measurement; during this time pressure values (including out of range information) will not be updated
- Pressure and temperature values can be updated continuously based on a parallel acquisition

**2.6.1.2 Structure**

The following structure is defined for an SPI command:

![Figure 7 SPI command structure](image)

![Figure 8 SPI response structure](image)

![Figure 9 SPI response structure for identifier](image)

**2.6.1.3 Parity**

Except for the identifier response (see Section 2.6.1.6) every SPI response (including the Communication Error response, see Section 2.6.1.5) includes an odd parity (LSB, [0]). The number of bits with the value one in the 16 bit response is odd (including the parity bit).
2.6.1.4 Command Definition

**Figure 10** Acquire pressure command

```
0 0 1 X 0 0 0 0 0 0 0 0 0 0 0 0
```

**Figure 11** Acquire temperature command

```
0 1 0 X 0 0 0 0 0 0 0 0 0 0 0 0
```

**Figure 12** Trigger diagnosis command

```
1 0 0 X 0 0 0 0 0 0 0 0 0 0 0 0
```

**Figure 13** Acquire identifier command

```
1 1 1 X 0 0 0 0 0 0 0 0 0 0 0 0
```

**Figure 14** Trigger test mode command

```
0 0 0 0 1 1 0 0 0 0 0 0 0 0 0 0
```

*Note:* The Reset-bit (C12) determines how the diagnostic reset is handled. For details about the function of the Reset-bit refer to Chapter 2.8.1.

The “trigger test mode” command is only for information. The test mode is only for calibration and E²PROM programming. Both are already done during the supplier’s back-end assembly. The information should serve to avoid command for unintentional test mode operation.

*Note:* Additional safeguards are provided to prevent unintentional test mode operation. For test mode operation, the command must be the first command after power-up in combination with a high voltage level at pin \( V_{\text{PROG}} \).
2.6.1.5 Communication Error

In normal operation only the pressure, temperature, diagnosis and identifier commands are valid. Every abnormality of these commands (e.g. unused command, other value of unused bits, number of clocks not equal to 16n with n = 1, 2, 3...) will result in a communication error. The response to a detected communication error is given below.

![Figure 15 Response after a communication error](image)

2.6.1.6 Identifier Response Definition

The response to an Acquire identifier command is a fixed value as stated below. With this response, the KP254 sensor can be identified when operated in a bus system with several different parts.

![Figure 16 Identifier response definition](image)
### 2.6.2 Single Device Operation

*Figure 17* shows an example on how to connect a single device to a microcontroller. After NCS is pulled to low, the request command is sent to the sensor with the next 16 cycles of the CLK. The response of the sensor for the previous request command is returned at the same time. The SPI signal timing is shown in *Figure 18.*

---

*Figure 17  Example for single device operation*

*Figure 18  Example for single device signal timing*
2.6.3 Daisy Chain Operation

The sensors can be connected to one SPI connection in daisy chain operation to save microcontroller pins. The number of sensors connected in daisy chain operation is unlimited.

Figure 19 shows an example of a combination of daisy chain mode and parallel operation.

**Note:** Not all five sensors in this example could be addressed at once. Only one branch can be addressed at once (e.g. the KP25x_2.x branch). Finally only one NCS line can be low at the same time (NCS_S1, NCS_S2 or NCS_S3).

The responding NCS line for the addressed sensor group must be low during the complete communication. During this time the provided number of clock pulses must be the multiplication result of 16 times the number of sensors in a daisy chain (e.g. 32 clock pulses for the KP25x_2.x branch in Figure 19).

Figure 20 shows the whole signal diagram. It is important that NCS_S2.1 and NCS_S2.2 stay at the low level during the complete transmission. Therewith the sensor is able after receiving more than 16 clock pulses without a change in the NCS signal to switch automatically in daisy chain mode (in this example the first received 16 bit input data by the sensor S2.1 will be clocked to the output of sensor S2.1 with the last 16 clock pulses).
It is important that the number of clock pulses is a multiple of 16. Otherwise all commands for a daisy chain branch will be identified as invalid commands and the response of all sensors on this branch will be 01H.

2.7 Start-up Behavior
During the start-up phase ($t_{start-up}$), there is no response on any commands.

2.8 Diagnosis
The sensor is able to detect automatically the following malfunctions:
- Pressure out of range
- Signal path check (Diag1)
- Sensor cell check (Diag2)
- $E^2$PROM check

If a malfunction is detected, the responding diagnosis code is sent with the next response.

*Note: The Diag1 and Diag2 test can only be triggered by a separate SPI command.*

If more than one test fails, only that diagnosis code with the highest priority will be sent.
KP254
Digital Absolute Pressure Sensor

Functional Description

2.8.1 Diagnostic Reset

The Reset-bit (C12) of a SPI command allows using different reset strategies:

- C12 = ‘0’: All detected failures will be reset (with the exception of FEC error
- C12 = ‘1’: A detected failure will not be reset

Reset of FEC error is not possible. Once FEC error is detected and transmitted it remains until supply reset.

2.8.1.1 Reset-bit C12 = ‘0’

A detected failure is only transmitted by the responding diagnosis code as long as the failure is present. The diagnosis code will be reset after once transmitted. Only if the failure is detected again, the diagnosis code will be transmitted again with the next response.

Table 4 Diagnosis codes

<table>
<thead>
<tr>
<th>Failure</th>
<th>Priority</th>
<th>Diagnosis Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>E2PROM: FEC error</td>
<td>1</td>
<td>010000</td>

</tr>
<tr>
<td>Pressure out of range: Low</td>
<td>5</td>
<td>000011</td>
</tr>
<tr>
<td>No error</td>
<td>0</td>
<td>010100</td>
</tr>
</tbody>
</table>

\(^1\) Note: This diagnosis code is not valid until a self diagnosis is triggered by sending the Trigger diagnosis command.

Figure 21 Example for reset strategy Reset-bit C12 = ‘0’

2.8.1.2 Reset-bit C12 = ‘1’

Once a failure is detected the responding diagnosis code will be transmitted as long as:

- A failure with a higher priority is not detected
- The sensor is not reset (power down)
- Independent of the presence of the failure
2.8.2 Pressure out of Range
The measured pressure is internally checked. If the pressure value falls below the lower limit or exceeds the higher limit the responding diagnosis code will be set. The limits are defined in Table 10 “Transfer function” on Page 25

2.8.3 Diag1
The Diag1 test checks the functionality of the signal path. Therefore the inputs of the sigma delta ADC are shorted. Afterwards, the system response is compared with the expected range (~ 50% of full scale range). If the system response is out of range, the diagnosis code is set.

2.8.4 Diag2
The Diag2 test checks the functionality of the pressure sensor cells. Therefore a malfunction (e.g. broken membrane) can be detected. The KP254 pressure sensing element is made of 2 measuring cells and 2 reference cells. In the normal mode these four cells are connected in a Wheatstone bridge configuration. In the Diag2 mode, the connection of the cells is modified as shown in Figure 24.
2.8.5 \textbf{E}^2\text{PROM Check}

During the initialization phase, and after receiving a SPI command, the content of the E\(^2\)PROM cells is copied into the corresponding E\(^2\)PROM registers. Thereby, a parity check is done based on the parity row and column. A one bit error is corrected by the forward error correction. Any additional bit error results in an FECerror. In that case the diagnosis code 1 will be transmitted with the next response.
3 Specification

3.1 Application Circuit Example

</tr>
</tbody>
</table>

1) The use of a blocking capacitor with a nominal value of 100nF is mandatory; any drift or tolerances in capacity of standard capacitors are already considered. To avoid any measurement inaccuracy the supply blocking capacitor has to be placed as close as possible to the VDD pin, at least the distance must be less than 10 mm.

2) The minimum capacity including any variations or drift over lifetime must not undershoot this value.

</tbody>
</table>

Attention: Stresses above the max. values listed in Table 6 “Absolute maximum ratings” may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability. Maximum ratings are absolute ratings; exceeding only one of these values may cause irreversible damage to the integrated circuit.
### 3.3 Operating Range

The following operating conditions must not be exceeded in order to ensure correct operation of the device. All parameters specified in the following sections refer to these operating conditions, unless noted otherwise.

#### Table 7 Operating range

4 Package Information

For passivation the sensor is covered with a transparent gel.

4.1 PG-DSOF-8-16 Outline

Figure 26 Package outline
Green Product (RoHS compliant)
To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).

4.2 Identification Code
The identification code is provided in a machine readable format. The date and sales code are provided in human readable format.

![Identification code diagram]

The identification code for the KP254 is on the same side of the package as pin 8 (GND).
5 Revision History

KP254 Digital Absolute Pressure Sensor

Revision History: 2015-07-29, Revision 1.1
