# Register Mapping

The Register Mapping section discusses the PSoC<sup>®</sup> 4100S Plus 256KB PSoC 4 registers and lists all the registers in mapping tables, in address order. For Architecture details, see [PSoC 4100S and PSoC 4100S Plus: PSoC 4 Architecture Technical Reference Manual \(TRM\)](#).

Note that memory mapped I/O (MMIO) registers support only 32-bit access, unless otherwise specified in the register description.

## Register General Conventions

The register conventions specific to this section and the Register Reference chapter are listed in this table.

Convention	Description	Explanation
RW	Read/Write	These bits can be both read and written.
R	Read only	These bits can only be read. Writing has no effect on the bit value.
W	Write only	These bits can only be written. Reading the bit returns the reset value.
RW1C	Read/Write '1' to clear	These bits can be read as well as cleared by writing '1'. Writing '0' has no effect on the bit value.
RW0C	Read/Write '0' to clear	These bits can be read as well as cleared by writing '0'. Writing '1' has no effect on the bit value.
RW1S	Read/Write '1' to set	These bits can be read as well as set by writing '1'. Writing '0' has no effect on the bit value.
A	Alias	This register is an additional alias for another register. This convention is used when a physical register is mapped to multiple addresses, typically for firmware debug purposes. See the corresponding register descriptions for more details.
None / Reserved	Reserved bits	Keep these bits at the default value
'x' in a register /bit field name	Multiple instances	Multiple instances/address ranges of the same register/bit field

## 2.1.1 PERI\_DIV\_CMD

Divider command register

Bits	31	30	29	28	27	26	25	24
SW Access	RW	RW	None					
HW Access	RW1C	RW1C	None					
Name	ENABLE	DISABLE	None [29:24]					

Bits	Name	Description
31	ENABLE	<p>Clock divider enable command (mutually exclusive with DISABLE). Typically, SW sets this field to '1' to enable a divider and HW sets this field to '0' to indicate that divider enabling has completed. When a divider is enabled, its integer and fractional (if present) counters are initialized to "0". If a divider is to be re-enabled using different integer and fractional divider values, the SW should follow these steps:</p> <p>0: Disable the divider using the DIV_CMD.DISABLE field.</p> <p>1: Configure the divider's DIV_XXX_CTL register.</p> <p>2: Enable the divider using the DIV_CMD_ENABLE field.</p> <p>The SEL_DIV and SEL_TYPE fields specify which divider is to be enabled. The enabled divider may be phase aligned to either "clk_hf" (typical usage) or to ANY enabled divider.</p> <p>The PA_SEL_DIV and P_SEL_TYPE fields specify the reference divider.</p> <p>The HW sets the ENABLE field to '0' when the enabling is performed and the HW set the DIV_XXX_CTL.EN field of the divider to '1' when the enabling is performed. Note that enabling with phase alignment to a low frequency divider takes time. E.g. To align to a divider that generates a clock of "clk_hf"/n (with n being the integer divider value INT_DIV+1), up to n cycles may be required to perform alignment. Phase alignment to "clk_hf" takes affect immediately. SW can set this field to '0' during phase alignment to abort the enabling process.</p> <p>Default Value: 0</p>

### 2.1.1 PERI\_DIV\_CMD (continued)

30	DISABLE	<p>Clock divider disable command (mutually exclusive with ENABLE). SW sets this field to '1' and HW sets this field to '0'.</p> <p>The SEL_DIV and SEL_TYPE fields specify which divider is to be disabled.</p> <p>The HW sets the DISABLE field to '0' immediately and the HW sets the DIV_XXX_CTL.EN field of the divider to '0' immediately. Default Value: 0</p>
15 : 14	PA_SEL_TYPE	<p>Specifies the divider type of the divider to which phase alignment is performed for the clock enable command:</p> <p>0: 8.0 (integer) clock dividers. 1: 16.0 (integer) clock dividers. 2: 16.5 (fractional) clock dividers. 3: 24.5 (fractional) clock dividers. Default Value: 3</p>
13 : 8	PA_SEL_DIV	<p>(PA_SEL_TYPE, PA_SEL_DIV) specifies the divider to which phase alignment is performed for the clock enable command. Any enabled divider can be used as reference. This allows all dividers to be aligned with each other, even when they are enabled at different times.</p> <p>If PA_SEL_DIV is "63" and "PA_SEL_TYPE" is "3", "clk_hf" is used as reference. Default Value: 63</p>
7 : 6	SEL_TYPE	<p>Specifies the divider type of the divider on which the command is performed:</p> <p>0: 8.0 (integer) clock dividers. 1: 16.0 (integer) clock dividers. 2: 16.5 (fractional) clock dividers. 3: 24.5 (fractional) clock dividers. Default Value: 3</p>
5 : 0	SEL_DIV	<p>(SEL_TYPE, SEL_DIV) specifies the divider on which the command (DISABLE/ENABLE) is performed.</p> <p>If SEL_DIV is "63" and "SEL_TYPE" is "3" (default/reset value), no divider is specified and no clock signal(s) are generated. Default Value: 63</p>

Bits	Name	Description
7 : 6	SEL_TYPE	Specifies divider type: 0: 8.0 (integer) clock dividers. 1: 16.0 (integer) clock dividers. 2: 16.5 (fractional) clock dividers. 3: 24.5 (fractional) clock dividers. Default Value: 3
3 : 0	SEL_DIV	Specifies one of the dividers of the divider type specified by SEL_TYPE.  If SEL_DIV is "63" and "SEL_TYPE" is "3" (default/reset value), no divider is specified and no clock control signal(s) are generated.  When transitioning a clock between two out of phase dividers, spurious clock control signals may be generated for one "clk_hf" cycle during this transition. These clock control signals may cause a single clock period that is smaller than any of the two divider periods. To prevent these spurious clock signals, the clock multiplexer can be disconnected (SEL_DIV is "63" and "SEL_TYPE" is "3") for a transition time that is larger than the smaller of the two divider periods. Default Value: 15

Note: combined with fractional division, this divider type allows for a division in the range [1, 16,777,216 31/32] in 1/32 increments.</p> <p>For the generation of a divided clock, the integer division range is restricted to [2, 16,777,216 31/32].</p> <p>For the generation of a 50/50% duty cycle divided clock, the division range is restricted to [2, 16,777,216].</p> <p>Note that this field is retained. However, the counter that is used to implement the division is not and will be initialized by HW to "0" when transitioning from DeepSleep to Active power mode. Default Value: 0</p>
7 : 3	FRAC5_DIV	<p>Fractional division by (FRAC5_DIV/32). Allows for fractional divisions in the range [0, 31/32]. Note that fractional division results in clock jitter as some clock periods may be 1 "clk_hf" cycle longer than other clock periods.</p> <p>Note that this field is retained. However, the counter that is used to implement the division is not and will be initialized by HW to "0" when transitioning from DeepSleep to Active power mode. Default Value: 0</p>

### 2.1.5 PERI\_DIV\_24\_5\_CTL (continued)

0	EN	<p>Divider enabled. HW sets this field to '1' as a result of an ENABLE command. HW sets this field to '0' as a result on a DISABLE command.</p> <p>Note that this field is retained. As a result, the divider does NOT have to be re-enabled after transitioning from DeepSleep to Active power mode.</p> <p>Default Value: 0</p>

Trigger control register

Address: 0x40010600

Retention: Not Retained

Bits	7	6	5	4	3	2	1	0
SW Access	None	RW						
HW Access	None	R						
Name	None	TR_SEL [6:0]						

Bits	15	14	13	12	11	10	9	8
SW Access	None				RW			
HW Access	None				R			
Name	None [15:12]				TR_GROUP [11:8]

Name	TR_COUNT [23:16]							

Bits	31	30	29	28	27	26	25	24
SW Access	RW	RW	None					
HW Access	RW1C	R	None					
Name	TR_ACT	TR_OUT	None [29:24]					

Bits	Name	Description
31	TR_ACT	SW sets this field to '1' by to activate (set to '1') a trigger as identified by TR_SEL and TR_OUT for TR_COUNT cycles. HW sets this field to '0' when the cycle counter is decremented to "0". Note: a TR_COUNT value of 255 is a special case and trigger activation is under direct control of the TR_ACT field (the counter is not decremented). Default Value: 0
30	TR_OUT	Specifies whether trigger activation is for a specific input or output trigger of the trigger multiplexer. Activation of a specific input trigger, will result in activation of all output triggers that have the specific input trigger selected through their TR_OUT_CTL.SEL field. Activation of a specific output trigger, will result in activation of the specified TR_SEL output trigger only. '0': TR_SEL selection and trigger activation is for an input trigger to the trigger multiplexer. '1': TR_SEL selection and trigger activation is for an output trigger from the trigger multiplexer. Default Value: 0
23 : 16	TR_COUNT	Amount of cycles a specific trigger is activated. During activation (TR_ACT is '1'), HW decrements this field to "0" using a cycle counter. During activation, SW should not modify this register field. A value of 255 is a special case: HW does NOT decrement this field to "0" and trigger activation is under direct control of TR_ACT: when TR_ACT is '1' the trigger is activated and when TR_ACT is '0' the trigger is deactivated. Default Value: 0

### 2.1.6 PERI\_TR\_CTL (continued)

11 : 8	TR_GROUP	Specifies the trigger group. Default Value: 0
6 : 0	TR_SEL	Specifies the activated trigger when TR_ACT is '1'. TR_OUT specifies whether the activated trigger is an input trigger or output trigger to the trigger multiplexer. During activation (TR_ACT is '1'), SW should not modify this register field. If the specified trigger is not present, the trigger activation has no effect. Default Value: 0

Bits	Name	Description
31	TEST_MODE	0: Normal operation mode 1: Test mode (any test mode) Setting this bit will prevent BootROM from yielding execution to Flash image. Default Value: 0
30	TEST_KEY_DFT_EN	This bit is set when a XRES test mode key is shifted in. It is the value of the test_key_dft_en signal. When this bit is set, the BootROM will not yield execution to the FLASH image (same function as setting TEST_MODE bit below). Default Value: 0
28	BLOCK_ALT_XRES	Relevant only for parts that have the alternate XRES mechanism of overloading a GPIO pin temporarily as alternate XRES during test. When set, this bit blocks the alternate XRES function, such that the pin can be used for normal I/O or for ddft/adft observation. See SAS Part-V and Part-IX for details. This register bit only resets for XRES, POR, or a detected BOD. Default Value: 0

Name	None [31:24]							

Bits	Name	Description
19 : 16	IGNORE_BITS	The number of MSB bits of the watchdog timer that are NOT checked against MATCH. This value provides control over the time-to-reset of the watchdog (which happens after 3 successive matches). Note that certain products may enforce a minimum value for this register through design time configuration. Default Value: 0
15 : 0	MATCH	Match value for Watchdog counter. Every time WDT_COUNTER reaches MATCH an interrupt is generated. Two unserved interrupts will lead to a system reset (i.e. at the third match). Default Value: 4096

SW Access	None							
HW Access	None							
Name	None [31:24]							

Bits	Name	Description
1	TEMP_HIGH	Regulator over-temp interrupt. This interrupt can occur when a short circuit exists on the vccd pin or when extreme loads are applied on IO-cells causing the die to overheat. Firmware is encouraged to shutdown all IO cells and then go to DeepSleep mode when this interrupt occurs if protection against such conditions is desired. Default Value: 0
0	WDT_MATCH	WDT Interrupt Request. This bit is set each time WDT_COUNTER==WDT_MATCH. Clearing this bit also feeds the watch dog. Missing 2 interrupts in a row will generate brown-out reset. Due to internal synchronization, it takes 2 SYSCLK cycles to update after a W1C. Default Value: 0

7 : 0	PORT_INT	Each IO port has an associated bit field in this register. The bit field reflects the IO port's interrupt line (bit field i reflects "gpio_interrupts[i]" for IO port i). The register is used when the system uses a shared/combined interrupt line "gpio_interrupt". The SW ISR reads the register to determine which IO port(s) is responsible for the shared/combined interrupt line "gpio_interrupt". Once, the IO port(s) is determined, the IO port's INTR register is read to determine the IO pad(s) in the IO port that caused the interrupt. Default Value: 0

## 7.1.1 CPUSS\_SYSREQ

SYSCALL control register

Address: 0x40100004

Retention: Retained

Bits	7	6	5	4	3	2	1	0

Name	SYSCALL_COMMAND [7:0]							

Bits	15	14	13	12	11	10	9	8

HW Access								
Name	SYSCALL_COMMAND [15:8]							

Bits	23	22	21	20	19	18	17	16
SW Access	None							
HW Access	None							
Name	None [23:16]							

Bits	31	30	29	28	27	26	25	24
SW Access	RW	R	R	RW	RW	None		
HW Access	R	A	RW	A	R	None		
Name	SY- SCALL_RE Q	HMAS- TER_0	ROM_AC- CESS_EN	PRIVI- LEGED	DIS_RE- SET_VECT _REL	None [26:24]		

Bits	Name	Description
31	SYSCALL_REQ	CPU/DAP writes a '1' to this field to request a SystemCall. The HMASTER_0 field indicates the source of the write access. Setting this field to '1' immediate results in a NMI. The SystemCall NMI interrupt handler sets this field to '0' after servicing the request. Default Value: 0
30	HMASTER_0	Indicates the source of the write access to the SYSREQ register. '0': CPU write access. '1': DAP write access. HW sets this field when the SYSREQ register is written to and SYSCALL_REQ is '0' (the last time it is set is when SW sets SYSCALL_REQ from '0' to '1'). Default Value: 0
29	ROM_ACCESS_EN	Indicates that executing from Boot ROM is enabled. HW sets this field to '1', on reset or when the SystemCall NMI vector is fetched from Boot ROM. HW sets this field to '0', when the CPU is NOT executing from either Boot or System ROM. This bit is used for debug purposes only. Default Value: 1

### 7.1.1 CPUSS\_SYSREQ (continued)

28	PRIVILEGED	Indicates whether the system is in privileged ('1') or user mode ('0'). Only CPU SW executing from ROM can set this field to '1' when ROM_ACCESS_EN is '1' (the CPU is executing a SystemCall NMI interrupt handler). Any other write to this field sets is to '0'. This field is used as the AHB-Lite hprot[1] signal to implement Cypress proprietary user/privileged modes. These modes are used to enable/disable access to specific MMIO registers and memory regions. Default Value: 1
27	DIS_RESET_VECT_REL	Disable Reset Vector fetch relocation: '0': CPU accesses to locations 0x0000:0000 - 0x0000:0007 are redirected to ROM. '1': CPU accesses to locations 0x0000:0000 - 0x0000:0007 are made to flash. Note that this field defaults to '0' on reset, ensuring actual reset vector fetches are always made to ROM. Note that this field does not affect DAP accesses. Flash DfT routines may set this bit to '1' to enable uninhibited read-back of programmed data in the first flash page. Default Value: 0
15 : 0	SYSCALL_COMMAND	Opcode of the system call being requested. Default Value: 0

Bits	Name	Description
31	PROTECTION_LOCK	Setting this field will block (ignore) any further writes to the PROTECTION_MODE field in this register. Once '1', this field cannot be cleared. Default Value: 0
30	FLASH_LOCK	Setting this bit will force SPCIF.ADDRESS.AXA to be ignored, which prevents SM Flash from being erased or overwritten. It is used to indicate the DEAD protection mode. Writes to this field are ignored when PROTECTION_LOCK is '1' Default Value: 0
3 : 0	PROTECTION_MODE	Current protection mode; this field is available as a global signal everywhere in the system. Writes to this field are ignored when PROTECTION_LOCK is '1': 0b1xxx: BOOT 0b01xx: KILL 0b001x: PROTECTED 0b0001: OPEN 0b0000: VIRGIN (also used for DEAD mode, but then FLASH_LOCK is also set) Default Value: 15

Use this setting for older, slower ROM design and frequencies in the range &lt;24, 48] MHz.</p> <p>CPUSSv2 supports two types of ROM memory: an older, slower design (operating at up to 24 MHz) and a newer, faster design (operating at up to 48 MHz). The older design requires 1 wait state for frequencies above 24 MHz. The newer design never requires wait states. All chips after Street Fighter will use the newer design. As a result, all chips after Street Fighter can always use 0 wait states.</p> <p>Default Value: 0</p>

Bits	Name	Description
31	ENABLED	<p>0': IP is disabled. Non-retainable MMIO registers and logic functionality are reset (retainable MMIO registers are NOT reset):</p> <ul style="list-style-type: none"> <li>- INTR register is set to "0".</li> <li>- DW/DMA functionality is aborted.</li> <li>- DW/DMA controller input/pending triggers are de-activated.</li> <li>- DW/DMA controller output triggers are de-activated.</li> </ul> <p>Disabling the IP has the same effect as an active "rst_sys_act_n" reset in DeepSleep power mode. To prevent a loss of active (pending) DW/DMA triggers when disabling the IP or when transitioning from Active to DeepSleep power mode, the STATUS.ACTIVE and STATUS.CH_ACTIVE.CH fields can be used.</p> <p>Note that most MMIO registers are retainable, and a transition from DeepSleep to Active/Sleep power modes makes the DW/DMA controller operational, and ready to react to DW/DMA input triggers that are activated after the transition. Triggers are Active/Sleep functionality.</p> <p>'1': IP is enabled.</p> <p>Default Value: 0</p>

31 : 30	OPCODE	<p>Specifies the specific data transfer (only when the VALID bit of the descriptor's STATUS word is '1'):</p> <p>"0": A single trigger initiates a single data element transfer (DW mode). This opcode specifies a transfer of a single data element. The current descriptor is completed when the amount of transferred single data elements equals the programmed buffer size (DATA_NR+1).</p> <p>"1": A single trigger initiates a single descriptor transfer (DMA mode). This opcode specifies a transfer of DATA_NR+1 data elements as specified by the current descriptor structure. The current descriptor is completed when its data transfer is completed.</p> <p>"2": A single trigger initiates a descriptor list transfer (DMA mode). This opcode specifies a transfer of DATA_NR+1 data elements as specified by the current descriptor structure and by successive valid descriptors. The current descriptor is completed when its data transfer is completed. This OPCODE relies on FLIPPING to be set to '1', such that the CHI_CTL.PING_PONG field is flipped/inverted and the successive descriptor is used. This continues for as long as the successive descriptor is valid. Note that as the HW is using the PING/PONG descriptor, the SW can prepare the alternate PONG/PING descriptor. The interrupt mechanism is used by HW to convey to the SW that the current descriptor is completed (and can be prepared for a successive transfer).</p> <p>After completion of the opcode (and waiting for de-activation, the channel's output trigger is activated). Default Value: Undefined</p>
29	FLIPPING	<p>'1': On completion of the current descriptor structure, the current descriptor identifier CHI_CTL.PING_PONG is flipped/inverted. In DMA mode, descriptor list transfer, flipping of the current descriptor identifier can be used to construct a linked list of descriptor structures. Default Value: Undefined</p>
28	PREEMPTABLE	<p>'1': Transfer is preemptable. In DMA mode (OPCODE is "1" or "2"), multi data element transfers are constructed out of multiple single data element load (from the source location) and store (to the destination location) sequences. This field allows higher priority activated channels to preempt the current transfer in between these atomic (load, store) sequences. Preemption will NOT deactivate the current channel. As a result, after completion of a higher priority activated channel, the current channel is rescheduled. Default Value: Undefined</p>
27	SET_CAUSE	<p>'1': On completion of the current descriptor structure, the interrupt cause field of the channel is set to '1' (INTR.CH[i]). Default Value: Undefined</p>
26	INV_DESCR	<p>'1': On completion of the current descriptor structure, the VALID bit of the descriptor's STATUS word is set to '0'. Default Value: Undefined</p>

### 8.1.13 DMAC\_DESCR0\_PING\_CTL (continued)

25 : 24	WAIT_FOR_DEACT	<p>Specifies whether the data transfer engine should wait for the channel to be deactivated; i.e. the selected system trigger is not active. This field is used to synchronize the controller's data transfer(s) with the agent that generated the trigger. This field is ONLY used at the completion of an opcode. E.g., a FIFO indicates that it is empty and it needs a new data sample. The agent removes the trigger ONLY when the data sample has been written by the transfer engine AND received by the agent. Furthermore, the agent's trigger may be delayed by a few cycles before it reaches the DW/DMA controller. This field is used for level sensitive trigger, which reflect state (pulse sensitive triggers should have this field set to "0"). The wait cycles incurred by this field reduce DW/DMA controller performance.</p> <p>"0": Do not wait for de-activation (for pulse sensitive triggers).</p> <p>"1": Wait for up to 4 cycles.</p> <p>"2": Wait for up to 8 cycles.</p> <p>"3": Wait indefinitely. This option may result in DW/DMA controller lockup if the system trigger is not de-activated by the source agent.</p> <p>Default Value: Undefined</p>
23	SRC_ADDR_INCR	<p>Specifies whether the source location address is incremented by the SRC_TRANSFER_SIZE after each single data element transfer or not.</p> <p>'0': No increment, typically used for receive (RX) FIFO structures.</p> <p>'1': Increment, typically used for memory structures.</p> <p>Default Value: Undefined</p>
22	SRC_TRANSFER_SIZE	<p>Specifies the bus transfer size to the source location:</p> <p>'0': As specified by DATA_SIZE.</p> <p>'1': Word (32 bits).</p> <p>Distinguishing bus transfer size from data element size allows for source components with data elements that are smaller than their 32-bit bus interface width. E.g., an ADC source has a 32-bit bus transfer size, but only provides a 16-bit data element.</p> <p>Default Value: Undefined</p>
21	DST_ADDR_INCR	<p>Specifies whether the destination location address is incremented by the DST_TRANSFER_SIZE after each single data element transfer or not.</p> <p>'0' : No increment, typically used for transmit (TX) FIFO structures.</p> <p>'1': Increment, typically used for memory structures.</p> <p>Default Value: Undefined</p>
20	DST_TRANSFER_SIZE	<p>Specifies the bus transfer size to the destination location:</p> <p>'0': As specified by DATA_SIZE.</p> <p>'1': Word (32 bits).</p> <p>Distinguishing bus transfer size from data element size allows for destination components with data elements that are smaller than their 32-bit bus interface width. E.g., a DAC destination has a 32-bit bus transfer size, but only requires a 16-bit data element.</p> <p>Default Value: Undefined</p>

17 : 16	DATA_SIZE	<p>Specifies the data element size:</p> <p>"0": Byte (8 bits).</p> <p>"1": Halfword (16 bits).</p> <p>"2": Word (32 bits).</p> <p>DATA_SIZE, SRC_TRANSFER_SIZE and DST_TRANSFER_SIZE together determine how data elements are transferred. The following are the 9 legal settings:</p> <ul style="list-style-type: none"> <li>- DATA is 8 bit, SRC is 8 bit, DST is 8 bit</li> <li>- DATA is 8 bit, SRC is 32 bit (higher 24 bits are dropped), DST is 8 bit</li> <li>- DATA is 8 bit, SRC is 8 bit, DST is 32 bit (higher 24 bits are made "0")</li> <li>- DATA is 8 bit, SRC is 32 bit (higher 24 bits are dropped), DST is 32 bit (higher 24 bits are made "0")</li> <li>- DATA is 16 bit, SRC is 16 bit, DST is 16 bit</li> <li>- DATA is 16 bit, SRC is 32 bit (higher 16 bits are dropped), DST is 16 bit</li> <li>- DATA is 16 bit, SRC is 16 bit, DST is 32 bit (higher 16 bits are made "0")</li> <li>- DATA is 16 bit, SRC is 32 bit (higher 16 bits are dropped), DST is 32 bit (higher 16 bits are made "0")</li> <li>- DATA is 32 bit, SRC is 32 bit, DST is 32 bit</li> </ul> <p>Default Value: Undefined</p>
15 : 0	DATA_NR	<p>Number of data elements that are transferred by a single descriptor.</p> <p>In DW mode (OPCODE is "0") each trigger initiates the transfer of a single data element. This field specifies the source and/or destination buffer size in data elements: buffer size = DATA_NR+1. The buffer is typically associated to a memory structure.</p> <p>In DMA mode (OPCODE is "1" or "2") each trigger initiates the transfer of DATA_NR+1 data elements.</p> <p>Default Value: Undefined</p>

Bits	Name	Description
31	DE_CPD_LP	0': SRAM busy wait loop has not been copied. '1': Busy wait loop has been written into SRAM. Default Value: 0
23 : 22	FLASH_ROW	Page size in 64 Byte multiples (chip dependent): "0": 64 byte "1": 128 byte "2": 192 byte "3": 256 byte  The page size is used to determine the number of Bytes in a page for Flash page based operations (e.g. PGM_PAGE).  Note: the field name FLASH_ROW is misleading, as this field specifies the number of Bytes in a page, rather than the number of Bytes in a row. In a single plane flash macro architecture, a page consists of a single row. However, in a multi plane flash macro architecture, a page consists of multiple rows from different planes. Default Value: Undefined

#### 0x4: PWM :

Pulse width modulation (PWM) mode

#### 0x5: PWM\_DT :

PWM with deadtime insertion mode

#### 0x6: PWM\_PR :

Pseudo random pulse width modulation

21 : 20      QUADRATURE\_MODE

In QUAD mode selects quadrature encoding mode (X1/X2/X4).  
 In PWM, PWM\_DT and PWM\_PR modes, these two bits can be used to invert "dt\_line\_out" and "dt\_line\_compl\_out". Inversion is the last step in generation of "dt\_line\_out" and "dt\_line\_compl\_out"; i.e. a disabled output line "dt\_line\_out" has the value QUADRATURE\_MODE[0] and a disabled output line "dt\_line\_compl\_out" has the value QUADRATURE\_MODE[1].  
 Default Value: 0

#### 0x0: X1 :

X1 encoding (QUAD mode)

#### 0x1: X2 :

X2 encoding (QUAD mode)

#### 0x2: X4 :

X4 encoding (QUAD mode)

#### 0x1: INV\_OUT :

When bit 0 is '1', QUADRATURE\_MODE[0] inverts "dt\_line\_out" (PWM/PWM\_DT modes)

#### 0x2: INV\_COMPL\_OUT :

When bit 1 is '1', QUADRATURE\_MODE[1] inverts "dt\_line\_compl\_out" (PWM/PWM\_DT modes)

18            ONE\_SHOT

When '0', counter runs continuous. When '1', counter is turned off by hardware when a terminal count event is generated.  
 Default Value: 0

17 : 16      UP\_DOWN\_MODE

Determines counter direction.  
 Default Value: 0

#### 0x0: COUNT\_UP :

Count up (to PERIOD). An overflow event is generated when the counter reaches PERIOD. A terminal count event is generated when the counter reaches PERIOD.

## 10.1.4 TCPWM\_CNT0\_CTRL (continued)

### 0x1: COUNT\_DOWN :

Count down (to "0"). An underflow event is generated when the counter reaches "0". A terminal count event is generated when the counter reaches "0".

### 0x2: COUNT\_UPDN1 :

Count up (to PERIOD), then count down (to "0"). An overflow event is generated when the counter reaches PERIOD. An underflow event is generated when the counter reaches "0". A terminal count event is generated when the counter reaches "0".

### 0x3: COUNT\_UPDN2 :

Count up (to PERIOD), then count down (to "0"). An overflow event is generated when the counter reaches PERIOD. An underflow event is generated when the counter reaches "0". A terminal count event is generated when the counter reaches "0" AND when the counter reaches PERIOD (this counter direction can be used for PWM functionality with asymmetrical updates).

15 : 8      GENERIC

Generic 8-bit control field. In PWM\_DT mode, this field is used to determine the dead time: amount of dead time cycles in the counter clock domain. In all other modes, the lower 3 bits of this field determine pre-scaling of the selected counter clock.  
Default Value: 0

### 0x0: DIVBY1 :

Divide by 1 (other-than-PWM\_DT mode)

### 0x1: DIVBY2 :

### 0x6: DIVBY64 :

Divide by 64 (other-than-PWM\_DT mode)

### 10.1.4 TCPWM\_CNT0\_CTRL (continued)

#### 0x7: DIVBY128 :

Divide by 128 (other-than-PWM\_DT mode)

3	PWM_STOP_ON_KILL	<p>Specifies whether the counter stops on a kill events:            '0': kill event does NOT stop counter.            '1': kill event stops counter.</p> <p>This field has a function in PWM, PWM_DT and PWM_PR modes only.            Default Value: 0</p>

Bits	Name	Description
19 : 16	START_SEL	Selects one of the 16 input triggers as a start trigger. In QUAD mode, this is the second phase (phi B). Default Value: 0
15 : 12	STOP_SEL	Selects one of the 16 input triggers as a stop trigger. In PWM, PWM_DT and PWM_PR modes, this is the kill trigger. In these modes, the kill trigger is used to either temporarily block the PWM outputs (PWM_STOP_ON_KILL is '0') or stop the functionality (PWM_STOP_ON_KILL is '1'). For the PWM and PWM_DT modes, the blocking of the output signals can be asynchronous (STOP_EDGE should be NO_EDGE_DET) in which case the blocking is as long as the trigger is '1' or synchronous (STOP_EDGE should be RISING_EDGE) in which case it extends till the next terminal count event. Default Value: 0
11 : 8	RELOAD_SEL	Selects one of the 16 input triggers as a reload trigger. In QUAD mode, this is the index or revolution pulse. In this mode, it will update the counter with the value in the TCPWM_CNTn_PERIOD register. Default Value: 0
7 : 4	COUNT_SEL	Selects one of the 16 input triggers as a count trigger. In QUAD mode, this is the first phase (phi A). Default setting selects input trigger 1, which is always '1'. Default Value: 1

### 10.1.11 TCPWM\_CNT0\_TR\_CTRL0 (continued)

3 : 0	CAPTURE_SEL	Selects one of the 16 input triggers as a capture trigger. Input trigger 0 is always '0' and input trigger is always '1'. ## 12.1.1 SCB0\_CTRL (continued)

### 0x0: I2C :

Inter-Integrated Circuits (I2C) mode.

### 0x1: SPI :

Serial Peripheral Interface (SPI) mode.

### 0x2: UART :

Universal Asynchronous Receiver/Transmitter (UART) mode.

17	BLOCK	Only used in externally clocked mode. If the externally clocked logic and the internal CPU accesses to EZ memory coincide/collide, this bit determines whether the CPU access should block and result in bus wait states ('BLOCK is 1') or not ('BLOCK is 0'). If BLOCK is '0' and the accesses collide, CPU read operations return 0xffff:ffff and CPU write operations are ignored. Colliding accesses are registered as interrupt causes: INTR_TX.BLOCKED and INTR_RX.BLOCKED. Default Value: 0
16	ADDR_ACCEPT	Determines whether a received matching address is accepted in the RX FIFO ('1') or not ('0').  In I2C mode, this field is used to allow the slave to put the received slave address or general call address in the RX FIFO. Note that a received matching address is put in the RX FIFO when this bit is '1' for both I2C read and write transfers.  In multi-processor UART receiver mode, this field is used to allow the receiver to put the received address in the RX FIFO. Note: non-matching addresses are never put in the RX FIFO. Default Value: 0
11	BYTE_MODE	Determines the number of bits per FIFO data element: '0': 16-bit FIFO data elements. '1': 8-bit FIFO data elements. This mode doubles the amount of FIFO entries, but TX_CTRL.DATA_WIDTH and RX_CTRL.DATA_WIDTH are restricted to [0, 7]. Default Value: 0
10	EZ_MODE	Non EZ mode ('0') or EZ mode ('1'). In EZ mode, a meta protocol is applied to the serial interface protocol. This meta protocol adds meaning to the data frames transferred by the serial interface protocol: a data frame can represent a memory address, a write memory data element or a read memory data element. EZ mode is only used for synchronous serial interface protocols: SPI and I2C. In SPI mode, only Motorola submode (all Motorola modes: 0, 1, 2, 3) is supported and the transmitter should use continuous data frames; i.e. data frames not separated by slave deselection. This mode is only applicable to slave functionality. In EZ mode, the slave can read from and write to an addressable memory structure of 32 bytes. In EZ mode, data frames should 8-bit in size and should be transmitted and received with the Most Significant Bit (MSB) first.  In UART mode this field should be '0'. Default Value: 0

In SPI mode, only Motorola submode (all Motorola modes: 0, 1, 2, 3) is supported. ## 12.1.1 SCB0\_CTRL (continued)

3 : 0 OVS

Serial interface bit period oversampling factor expressed in SCB clock cycles. Used for SPI and UART functionality.  $OVS + 1$  SCB clock cycles constitute a single serial interface clock/bit cycle. This field is NOT used in externally clocked mode. If OVS is odd, the oversampling factor is even and the low and high phase of the interface clock period are the same. If OVS is even, the oversampling factor is odd and the low and high phase can differ by 1 SCB clock period.

In SPI master mode, the valid range is [3, 15]. At an SCB frequency of 48 MHz, the maximum SPI bit rate is 12 Mbps, assuming ideal (0 ns) IO cell and routing (chip and board) delay. The calculated maximum bit rate decreases, when realistic chip and routing delays are taken into account. The effective system bit rate is dependent on the external SPI slave that we communicate with. If the SPI output clock to SPI MISO input round trip delay is significant (multiple SPI output clock cycles), it may be necessary to increase OVS and/or to set SPI\_CTRL.LATE\_MISO\_SAMPLE to '1' to achieve the maximum possible system bit rate.

In SPI slave mode, the OVS field is NOT used. However, there is a frequency requirement for the SCB clock wrt. the SPI input clock (IF) on the interface to guarantee functional correct behavior. This requirement is expressed as a ratio: SCB clock/IF clock. The ratio is dependent on the setting of RX\_CTRL.MEDIAN and the external SPI master's capability to support "late MISO sample" functionality (similar to our SPI master functionality represented by SPI\_CTRL.LATE\_MISO\_SAMPLE):

- MEDIAN is '0' and external SPI master has NO "late MISO sample functionality": SCB clock/IF clock  $\geq 6$ . At a SCB frequency of 48 MHz, the maximum bit rate is 8 Mbps.
- MEDIAN is '0' and external SPI master has "late MISO sample functionality": SCB clock/IF clock  $\geq 3$ . At a SCB frequency of 48 MHz, the maximum bit rate is 16 Mbps.
- MEDIAN is '1' and external SPI master has NO "late MISO sample functionality": SCB clock/IF clock  $\geq 8$ . At a SCB frequency of 48 MHz, the maximum bit rate is 6 Mbps.
- MEDIAN is '1' and external SPI master has "late MISO sample functionality": SCB clock/IF clock  $\geq 4$ . At a SCB frequency of 48 MHz, the maximum bit rate is 12 Mbps.

As discussed earlier, the calculated maximum bit rate decreases, when realistic chip and routing delays are taken into account.

In UART standard submode (including LIN), the valid range is [7, 15]. In UART SmartCard submode, the valid range is [7, 15].

In UART TX IrDA submode this field indirectly specifies the oversampling. The oversampling determines the interface clock/bit cycle and the width of the pulse. Only normal transmission mode is supported, the pulse is roughly 3/16 of the bit period (for all bit rates). There is only one valid OVS value:

- 0: 16 times oversampling.  
 SCB clock frequency of  $16 \times 115.2$  KHz for 115.2 Kbps.  
 SCB clock frequency of  $16 \times 57.6$  KHz for 57.6 Kbps.  
 SCB clock frequency of  $16 \times 38.4$  KHz for 38.4 Kbps.  
 SCB clock frequency of  $16 \times 19.2$  KHz for 19.2 Kbps.  
 SCB clock frequency of  $16 \times 9.6$  KHz for 9.6 Kbps.  
 SCB clock frequency of  $16 \times 2.4$  KHz for 2.4 Kbps.  
 SCB clock frequency of  $16 \times 1.2$  KHz for 1.2 Kbps.  
 - all other values are not used in normal mode.

In UART RX IrDA submode (1.2, 2.4, 9.6, 19.2, 38.4, 57.6 and 115.2 Kbps) this field indirectly specifies the oversampling. The oversampling determines the interface clock/bit cycle and the width of the pulse. In normal transmission mode, this pulse is roughly 3/16 of the bit period (for all bit rates). In low power transmission mode, this pulse is potentially smaller (down to 1.62  $\mu$ s typical and 1.41  $\mu$ s minimal) than 3/16 of the bit period (for < 115.2 Kbps bitrates). Pulse widths greater or equal than two SCB clock cycles are guaranteed to be detected by the receiver. Pulse widths less than two SCB clock cycles and greater or equal than one SCB clock cycle may be detected by the receiver. Pulse widths less than one SCB clock cycle will not be detected by the receiver. RX\_CTRL.MEDIAN should be set to '1' for IrDA receiver functionality. The SCB clock (as provided by the programmable clock block) and the oversampling together determine the IrDA bitrate. Normal mode, OVS field values (with the required SCB clock frequency):

- 0: 16 times oversampling.  
 SCB clock frequency of  $16 \times 115.2$  KHz for 115.2 Kbps.  
 SCB clock frequency of  $16 \times 57.6$  KHz for 57.6 Kbps.  
 SCB clock frequency of  $16 \times 38.4$  KHz for 38.4 Kbps.  
 SCB clock frequency of  $16 \times 19.2$  KHz for 19.2 Kbps.  
 SCB clock frequency of  $16 \times 9.6$  KHz for 9.6 Kbps.  
 SCB clock frequency of  $16 \times 2.4$  KHz for 2.4 Kbps.  
 SCB clock frequency of  $16 \times 1.2$  KHz for 1.2 Kbps.  
 - all other values are not used in normal mode.

Low power mode, OVS field values (with the required SCB clock frequency):

- 0: 16 times oversampling.  
 SCB clock frequency of  $16 \times 115.2$  KHz for 115.2 Kbps.
- 1: 32 times oversampling.  
 SCB clock frequency of  $32 \times 57.6$  KHz for 57.6 Kbps.
- 2: 48 times oversampling.  
 SCB clock frequency of  $48 \times 38.4$  KHz for 38.4 Kbps.
- 3: 96 times oversampling.  
 SCB clock frequency of  $96 \times 19.2$  KHz for 19.2 Kbps.
- 4: 192 times oversampling.  
 SCB clock frequency of  $192 \times 9.6$  KHz for 9.6 Kbps.
- 5: 768 times oversampling.  
 SCB clock frequency of  $768 \times 2.4$  KHz for 2.4 Kbps.
- 6: 1536 times oversampling.  
 SCB clock frequency of  $1536 \times 1.2$  KHz for 1.2 Kbps.
- all other values are not used in low power mode.

Default Value: 15

Bits	31	30	29	28	27	26	25	24

Name	None [31:24]							

Bits	Name	Description
19 : 16	BREAK_WIDTH	<p>Break width. BREAK_WIDTH + 1 is the minimum width in bit periods of a break. During a break the transmitted/received line value is '0'. This feature is useful for standard UART submode and LIN submode ("break field" detection). Once, the break is detected, the INTR_RX.BREAK_DETECT bit is set to '1'. Note that break detection precedes baud rate detection, which is used to synchronize/refine the receiver clock to the transmitter clock. As a result, break detection operates with an unsynchronized/unrefined receiver clock. Therefore, the receiver's definition of a bit period is imprecise and the setting of this field should take this imprecision into account. The LIN standard also accounts for this imprecision: a LIN start bit followed by 8 data bits allows for up to 9 consecutive '0' bit periods during regular transmission, whereas the LIN break detection should be at least 13 consecutive '0' bit periods. This provides for a margin of 4 bit periods. Therefore, the default value of this field is set to 10, representing a minimal break field with of 10+1 = 11 bit periods; a value in between the 9 consecutive bit periods of a regular transmission and the 13 consecutive bit periods of a break field. This provides for slight imprecisions of the receiver clock wrt. the transmitter clock. There should not be a need to program this field to any value other than its default value.</p> <p>Default Value: 10</p>

### 12.1.7 SCB0\_UART\_RX\_CTRL (continued)

13	SKIP_START	<p>Only applicable in standard UART submode. When '1', the receiver skips start bit detection for the first received data frame. Instead, it synchronizes on the first received data frame bit, which should be a '1'. This functionality is intended for wake up from DeepSleep when receiving a data frame. The transition from idle ('1') to START ('0') on the RX line is used to wake up the CPU. The transition detection (and the associated wake up functionality) is performed by the GPIO2 IP. The woken up CPU will enable the SCB's UART receiver functionality. Once enabled, it is assumed that the START bit is ongoing (the CPU wakeup and SCB enable time should be less than the START bit period). The SCB will synchronize to a '0' to '1' transition, which indicates the first data frame bit is received (first data frame bit should be '1'). After synchronization to the first data frame bit, the SCB will resume normal UART functionality: subsequent data frames will be synchronized on the receipt of a START bit.</p> <p>Default Value: 0</p>
12	LIN_MODE	<p>Only applicable in standard UART submode. When '1', the receiver performs break detection and baud rate detection on the incoming data. First, break detection counts the amount of bit periods that have a line value of '0'. BREAK_WIDTH specifies the minum required amount of bit periods. Successful break detection sets the INTR_RX.BREAK_DETECT interrupt cause to '1'. Second, baud rate detection counts the amount of peripheral clock periods that are use to receive the synchronization byte (0x55; least significant bit first). The count is available through UART_RX_STATUS.BR_COUNTER. Successful baud rate detection sets the INTR_RX.BAUD_DETECT interrupt cause to '1' (BR_COUNTER is reliable). This functionality is used to synchronize/refine the receiver clock to the transmitter clock. The receiver software can use the BR_COUNTER value to set the right IP clock (from the programmable clock IP) to guarantee successful receipt of the first LIN data frame (Protected Identifier Field) after the synchronization byte.</p> <p>Default Value: 0</p>
10	MP_MODE	<p>Multi-processor mode. When '1', multi-processor mode is enabled. In this mode, RX_CTRL.DATA_WIDTH should indicate a 9-bit data frame. In multi-processor mode, the 9th received bit of a data frame separates addresses (bit is '1') from data (bit is '0'). A received address is matched with RX_MATCH.DATA and RX_MATCH.MASK. In the case of a match, subsequent received data are sent to the RX FIFO. In the case of NO match, subsequent received data are dropped.</p> <p>Default Value: 0</p>
9	DROP_ON_FRAME_ERROR	<p>Behaviour when an error is detected in a start or stop period.</p> <p>When '0', received data is sent to the RX FIFO.</p> <p>When '1', received data is dropped and lost.</p> <p>Default Value: 0</p>
8	DROP_ON_PARITY_ERROR	<p>Behaviour when a parity check fails.</p> <p>When '0', received data is sent to the RX FIFO.</p> <p>When '1', received data is dropped and lost.</p> <p>Only applicable in standard UART and SmartCard submodes (negatively acknowledged SmartCard data frames may be dropped with this field).</p> <p>Default Value: 0</p>
6	POLARITY	<p>Inverts incoming RX line signal. Inversion is after local loopback. This functionality is intended for IrDA receiver functionality.</p> <p>Default Value: 0</p>
5	PARITY_ENABLED	<p>Parity checking enabled ('1') or not ('0'). Only applicable in standard UART submode. In SmartCard submode, parity checking is always enabled through hardware. In IrDA submode, parity checking is always disabled through hardware.</p> <p>Default Value: 0</p>
4	PARITY	<p>Parity bit. When '0', the receiver expects an even parity. When '1', the receiver expects an odd parity. Only applicable in standard UART and SmartCard submodes.</p> <p>Default Value: 0</p>

### 12.1.7 SCB0\_UART\_RX\_CTRL (continued)

2 : 0	STOP_BITS	<p>Stop bits. STOP_BITS + 1 is the duration of the stop period in terms of halve bit periods. Valid range is [1, 7]; i.e. a stop period should last at least one bit period. If STOP_BITS is '1', stop bits error detection is NOT performed. If STOP_BITS is in [2, 7], stop bits error detection is performed and the associated interrupt cause INTR_RX.FRAME_ERROR is set to '1' if an error is detected. In other words, the receiver supports data frames with a 1 bit period stop bit sequence, but requires at least 1.5 bit period stop bit sequences to detect errors. This limitation is due to possible transmitter and receiver clock skew that prevents the design from doing reliable stop bit detection for short (1 bit bit period) stop bit sequences. Note that in case of a stop bits error, the successive data frames may get lost as the receiver needs to resynchronize its start bit detection. The amount of lost data frames depends on both the amount of stop bits, the idle ('1') time between data frames and the data frame value.</p> <p>Default Value: 2</p>

Bits	Name	Description
23 : 16	BASE_EZ_ADDR	I2C slave base EZ address. Address as provided by an I2C write transfer. This field is only reliable in internally clocked mode. In externally clocked mode the field may be unreliable, as clock domain synchronization is not performed in the design. Default Value: Undefined
15 : 8	CURR_EZ_ADDR	I2C slave current EZ address. Current address pointer. This field is only reliable in internally clocked mode. In externally clocked mode the field may be unreliable (during an ongoing transfer when I2C_EC_BUSY is '1'), as clock domain synchronization is not performed in the design. Default Value: Undefined
5	M_READ	I2C master read transfer ('1') or I2C master write transfer ('0'). When the I2C master is inactive/ idle or transmitting START, REPEATED START, STOP or an address, this field is '0'. Default Value: 0
4	S_READ	I2C slave read transfer ('1') or I2C slave write transfer ('0'). When the I2C slave is inactive/idle or receiving START, REPEATED START, STOP or an address, this field is '0'. Default Value: 0

### 12.1.11 SCB0\_I2C\_STATUS (continued)

1	I2C_EC_BUSY	Indicates whether the externally clocked logic is potentially accessing the EZ memory and/or updating BASE_EZ_ADDR or CURR_EZ_ADDR (this is only possible in EZ mode). This bit can be used by SW to determine whether BASE_EZ_ADDR and CURR_EZ_ADDR are reliable. Default Value: Undefined
0	BUS_BUSY	<p>I2C bus is busy. The bus is considered busy ('1'), from the time a START is detected or from the time the SCL line is '0'. The bus is considered idle ('0'), from the time a STOP is detected. If SCB block is disabled, BUS_BUSY is '0'. After enabling the block, it takes time for the BUS_BUSY to detect a busy bus. This time is the maximum high time of the SCL line. For a 100 kHz interface frequency, this maximum high time may last roughly 5 us (half a bit period).</p> <p>For single master systems, BUS_BUSY does not have to be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START (no bus collisions).</p> <p>For multi-master systems, BUS_BUSY can be used to detect an idle bus before a master starts a transfer using I2C_M_CMD.M_START_ON_IDLE (to prevent bus collisions). Default Value: 0</p>

4	M_STOP	When '1', attempt to transmit a STOP. When this action is performed, the hardware sets this field to '0'. I2C_M_CMD.M_START has a higher priority than this command: in situations where both a STOP and a REPEATED START could be transmitted, M_START takes precedence over M_STOP. Default Value: 0
3	M_NACK	When '1', attempt to transmit a negative acknowledgement (NACK). When this action is performed, the hardware sets this field to '0'. Default Value: 0
2	M_ACK	When '1', attempt to transmit an acknowledgement (ACK). When this action is performed, the hardware sets this field to '0'. Default Value: 0

### 12.1.12 SCB0\_I2C\_M\_CMD (continued)

1	M_START_ON_IDLE	<p>When '1', transmit a START as soon as the bus is idle (I2C_STATUS.BUS_BUSY is '0', note that BUSY has a default value of '0'). For bus idle detection the hardware relies on STOP detection. As a result, bus idle detection is only functional after at least one I2C bus transfer has been detected on the bus (default/reset value of BUSY is '0'). A START is only transmitted when the master state machine is in the default state. When this action is performed, the hardware sets this field to '0'.</p> <p>Default Value: 0</p>
0	M_START	<p>When '1', transmit a START or REPEATED START. Whether a START or REPEATED START is transmitted depends on the state of the master state machine. A START is only transmitted when the master state machine is in the default state. A REPEATED START is transmitted when the master state machine is not in the default state, but is working on an ongoing transaction. The REPEATED START can only be transmitted after a NACK or ACK has been received for a transmitted data element or after a NACK has been transmitted for a received data element. When this action is performed, the hardware sets this field to '0'.</p> <p>Default Value: 0</p>

10	UART_ARB_LOST	UART lost arbitration: the value driven on the TX line is not the same as the value observed on the RX line. This condition event is usefull when transmitter and receiver share a TX/RX line. This is the case in LIN or SmartCard modes. Set to '1', when event is detected. Write with '1' to clear bit. Default Value: 0
9	UART_DONE	UART transmitter done event. This happens when the IP is done transferring all data in the TX FIFO; i.e. EMPTY is '1'. Set to '1', when event is detected. Write with '1' to clear bit. Default Value: 0
8	UART_NACK	UART transmitter received a negative acknowledgement in SmartCard mode. Set to '1', when event is detected. Write with '1' to clear bit. Default Value: 0

Bits	Name	Description
11	BREAK_DETECT	Break detection is successful: the line is '0' for UART_RX_CTRL.BREAK_WIDTH + 1 bit period. Can occur at any time to address unanticipated break fields; i.e. "break-in-data" is supported. This feature is supported for the UART standard and LIN submodes. For the UART standard submodes, ongoing receipt of data frames is NOT affected; i.e. Firmware is expected to take the proper action. For the LIN submode, possible ongoing receipt of a data frame is stopped and the (partially) received data frame is dropped and baud rate detection is started. Set to '1', when event is detected. Write with '1' to clear bit. Default Value: 0
10	BAUD_DETECT	LIN baudrate detection is completed. The receiver software uses the UART_RX_STATUS.BR_COUNTER value to set the right IP clock (from the programmable clock IP) to guarantee successful receipt of the first LIN data frame (Protected Identifier Field) after the synchronization byte. Set to '1', when event is detected. Write with '1' to clear bit. Default Value: 0

### 12.1.45 SCB0\_INTR\_RX (continued)

9	PARITY_ERROR	<p>Parity error in received data frame. Set to '1', when event is detected. Write with '1' to clear bit. If UART_RX_CTL.DROP_ON_PARITY_ERROR is '1', the received frame is dropped. If UART_RX_CTL.DROP_ON_PARITY_ERROR is '0', the received frame is send to the RX FIFO. In SmartCard submode, negatively acknowledged data frames generate a parity error. Note that Firmware can only identify the erroneous data frame in the RX FIFO if it is fast enough to read the data frame before the hardware writes a next data frame into the RX FIFO.</p> <p>Default Value: 0</p>
8	FRAME_ERROR	<p>Frame error in received data frame. Set to '1', when event is detected. Write with '1' to clear bit. This can be either a start or stop bit(s) error:</p> <p>Start bit error: after the detection of the beginning of a start bit period (RX line changes from '1' to '0'), the middle of the start bit period is sampled erroneously (RX line is '1'). Note: a start bit error is detected BEFORE a data frame is received.</p> <p>Stop bit error: the RX line is sampled as '0', but a '1' was expected. Note: a stop bit error may result in failure to receive successive data frame(s). Note: a stop bit error is detected AFTER a data frame is received.</p> <p>A stop bit error is detected after a data frame is received, and the UART_RX_CTL.DROP_ON_FRAME_ERROR field specifies whether the received frame is dropped or send to the RX FIFO. If UART_RX_CTL.DROP_ON_FRAME_ERROR is '1', the received data frame is dropped. If UART_RX_CTL.DROP_ON_FRAME_ERROR is '0', the received data frame is send to the RX FIFO. Note that Firmware can only identify the erroneous data frame in the RX FIFO if it is fast enough to read the data frame before the hardware writes a next data frame into the RX FIFO; i.e. the RX FIFO does not have error flags to tag erroneous data frames.</p> <p>Default Value: 0</p>
7	BLOCKED	<p>SW cannot get access to the EZ memory (EZ_DATA accesses), due to an externally clocked EZ access. This may happen when STATUS.EC_BUSY is '1'.</p> <p>Default Value: 0</p>
6	UNDERFLOW	<p>Attempt to read from an empty RX FIFO.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>
5	OVERFLOW	<p>Attempt to write to a full RX FIFO. Note: in I2C mode, the OVERFLOW is set when a data frame is received and the RX FIFO is full, independent of whether it is ACK'd or NACK'd.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>
3	FULL	<p>RX FIFO is full. Note that received data frames are lost when the RX FIFO is full. Dependent on CTRL.BYTE_MODE: (FF_DATA_NR = EZ_DATA_NR/2)</p> <p>BYTE_MODE is '0': # entries == FF_DATA_NR/2.</p> <p>BYTE_MODE is '1': # entries == FF_DATA_NR.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>
2	NOT_EMPTY	<p>RX FIFO is not empty.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>
0	TRIGGER	<p>More entries in the RX FIFO than the value specified by TRIGGER_LEVEL in SCB_RX_FIFO_CTL.</p> <p>Only used in FIFO mode.</p> <p>Default Value: 0</p>

Bits	Name	Description
5 : 4	LOCK_DELAY	<p>Selects the number of PLL phase frequency detector cycles that the phase error must be in range before declaring lock. (PFD clock cycle = Clock Reference Period/REFERENCE_DIV) Default Value: 1</p> <p><b>0x0: PFD_CLK_16 :</b></p> <p>16 PFD clock cycles</p> <p><b>0x1: PFD_CLK_32 :</b></p> <p>32 PFD clock cycles</p> <p><b>0x2: PFD_CLK_48 :</b></p> <p>48 PFD clock cycles</p>

### 15.1.21 EXCO\_PLL\_TRIM (continued)

		<b>0x3: PFD_CLK_64 :</b>  64 PFD clock cycles
3 : 2	LOCK_WINDOW	This register determines how much phase error is tolerated before declaring the PLL unlocked (lock_out goes low). Phase error is a measure of the phase difference between the PLL feedforward path (CLK_REF PERIOD/REFERENCE_DIV[1:0]) and feedback path (CLK_VCO/FEEDBACK_DIV[1:0]). The average phase error when locked is zero, but accumulated jitter - particularly on CLK_REF - leads to the need for a relatively large allowed phase error window. Default Value: 0  <b>0x0: DELAY_25NS :</b>  Delay 25 ns  <b>0x1: DELAY_50NS :</b>  Delay 50 ns  <b>0x2: DELAY_75NS :</b>  Delay 75 ns  <b>0x3: DELAY_100NS :</b>  Delay 100 ns
1 : 0	VCO_GAIN	Programmable VCO frequency characteristic at high freq - set to <10> Default Value: 2

HW Access	None				R	R	R	R
Name	None [23:20]				DSI_SYNC_TRIGGER	DSI_TRIGGER_LEVEL	DSI_TRIGGER_EN	CONTINUOUS

  

Bits	31	30	29	28	27	26	25	24
SW Access	RW	None						
HW Access	R	None						
Name	EOS_DSI_OUT_EN	None [30:24]						

Bits	Name	Description
31	EOS_DSI_OUT_EN	Enable to output EOS_INTR. When enabled each time EOS_INTR is set by the hardware also a trigger plus is send on the tr_sar_out signal. Default Value: 0
19	DSI_SYNC_TRIGGER	- 0: bypass clock domain synchronisation of the trigger signal. - 1: synchronize the trigger signal to the SAR clock domain, if needed an edge detect is done in the peripheral clock domain. Default Value: 1
18	DSI_TRIGGER_LEVEL	- 0: trigger signal is a pulse input, a positive edge detected on the trigger signal triggers a new scan. - 1: trigger signal is a level input, as long as the trigger signal remains high the SAR will do continuous scans. Default Value: 0

### 17.1.2 SAR0\_SAMPLE\_CTRL (continued)

17	DSI_TRIGGER_EN	- 0: firmware trigger only: disable hardware trigger. - 1: enable hardware trigger (e.g. from TCPWM, GPIO or UDB). Default Value: 0
16	CONTINUOUS	- 0: Wait for next FW_TRIGGER (one shot) or hardware trigger (e.g. from TPWM for periodic triggering) before scanning enabled channels. - 1: Continuously scan enabled channels, ignore triggers. Default Value: 0
7	AVG_SHIFT	Averaging shifting: after averaging the result is shifted right to fit in the sample resolution. For averaging the sample resolution is the highest resolution allowed by rounding. Default Value: 0
6 : 4	AVG_CNT	Averaging Count for channels that have over sampling enabled (AVG_EN). A channel will be sampled back to back $(1 \leq (AVG\_CNT+1)) = [2..256]$ times before the result is stored and the next enabled channel is sampled (1st order accumulate and dump filter). If shifting is not enabled (AVG_SHIFT=0) then the result is forced to shift right so that it fits in 16 bits, so right shift is done by $\max(0, AVG\_CNT-3)$ . Default Value: 0
3	DIFFERENTIAL_SIGNED	Output data from a differential conversion as a signed value Default Value: 1  <b>0x0: UNSIGNED :</b>  result data is unsigned (zero extended if needed)  <b>0x1: SIGNED :</b>  Default: result data is signed (sign extended if needed)
2	SINGLE_ENDED_SIGNED	Output data from a single ended conversion as a signed value Default Value: 0  <b>0x0: UNSIGNED :</b>  Default: result data is unsigned (zero extended if needed)  <b>0x1: SIGNED :</b>  result data is signed (sign extended if needed)
1	LEFT_ALIGN	Left align data in data[15:0], default data is right aligned in data[11:0], with sign extension to 16 bits if the channel is differential. Default Value: 0
0	SUB_RESOLUTION	Conversion resolution for channels that have sub-resolution enabled (RESOLUTION=1) (otherwise resolution is 12-bit). Default Value: 0  <b>0x0: 8B :</b>  8-bit.  <b>0x1: 10B :</b>  10-bit.

Bits	31	30	29	28	27	26	25	24
SW Access	None							
HW Access	None							
Name	None [31:24]							

Bits	Name	Description
7	INJ_COLLISION_INTR	Injection Collision Interrupt: hardware sets this interrupt when the injection trigger signal is asserted (INJ_START_EN==1 && INJ_TAILGATING==0) while the SAR is BUSY. Raising this interrupt is delayed to when the sampling of the injection channel has been completed, i.e. not when the preceeding scan with which this trigger collided is completed. When this interrupt is set it implies that the injection channel was sampled later than was intended. Write with '1' to clear bit. Default Value: 0
6	INJ_RANGE_INTR	Injection Range detect Interrupt: hardware sets this interrupt if the injection conversion result (after averaging) met the condition specified by the SAR_RANGE registers. Write with '1' to clear bit. Default Value: 0
5	INJ_SATURATE_INTR	Injection Saturation Interrupt: hardware sets this interrupt if an injection conversion result (before averaging) is either 0x000 or 0xFFFF (for 12-bit resolution), this is an indication that the ADC likely saturated. Write with '1' to clear bit. Default Value: 0

### 17.1.16 SAR0\_INTR (continued)

4	INJ_EOC_INTR	Injection End of Conversion Interrupt: hardware sets this interrupt after completing the conversion for the injection channel (irrespective of if tailgating was used). Write with '1' to clear bit. Default Value: 0
3	DSI_COLLISION_INTR	This interrupt is set when a hardware trigger signal is asserted while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the hardware trigger has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with '1' to clear bit. Default Value: 0
2	FW_COLLISION_INTR	Firmware Collision Interrupt: hardware sets this interrupt when FW_TRIGGER is asserted while the SAR is BUSY. Raising this interrupt is delayed to when the scan caused by the FW_TRIGGER has been completed, i.e. not when the preceding scan with which this trigger collided is completed. When this interrupt is set it implies that the channels were sampled later than was intended (jitter). Write with '1' to clear bit. Default Value: 0
1	OVERFLOW_INTR	Overflow Interrupt: hardware sets this interrupt when it sets a new EOS_INTR while that bit was not yet cleared by the firmware. Write with '1' to clear bit. Default Value: 0
0	EOS_INTR	End Of Scan Interrupt: hardware sets this interrupt after completing a scan of all the enabled channels. Write with '1' to clear bit. Default Value: 0

Name	IN-J_START_EN	INJ_TAILGATING	None [29:24]					

Bits	Name	Description
31	INJ_START_EN	Set by firmware to enable the injection channel. If INJ_TAILGATING is not set this bit also functions as trigger for this channel. Cleared by hardware after this channel has been sampled (i.e. this channel is always one shot even if CONTINUOUS is set). Also cleared if the SAR is disabled. Default Value: 0
30	INJ_TAILGATING	Injection channel tailgating. - 0: no tailgating for this channel, SAR is immediately triggered when the INJ_START_EN bit is set if the SAR is not busy. If the SAR is busy, the INJ channel addressed pin is sampled at the end of the current scan. - 1: injection channel tailgating. The addressed pin is sampled after the next trigger and after all enabled channels have been scanned. Default Value: 0
13 : 12	INJ_SAMPLE_TIME_SEL	Injection sample time select: select which of the 4 global sample times to use for this channel Default Value: 0

### 17.1.29 SAR0\_INJ\_CHAN\_CONFIG (continued)

10	INJ_AVG_EN	Averaging enable for this channel. If set the AVG_CNT and AVG_SHIFT settings are used for sampling the addressed pin(s) Default Value: 0
9	INJ_RESOLUTION	Resolution for this channel. Default Value: 0  <b>0x0: 12B :</b>  12-bit resolution is used for this channel.  <b>0x1: SUBRES :</b>  The resolution specified by SUB_RESOLUTION in the SAR_SAMPLE_CTRL register is used for this channel.
8	INJ_DIFFERENTIAL_EN	Differential enable for this channel. - 0: The voltage on the addressed pin is measured (Single-ended) and the resulting value is stored in the corresponding data register. - 1: The differential voltage on the addressed pin pair is measured and the resulting value is stored in the corresponding data register. (INJ_PIN_ADDR[0] is ignored). Default Value: 0
6 : 4	INJ_PORT_ADDR	Address of the port that contains the pin to be sampled by this channel. Default Value: 0  <b>0x0: SARMUX :</b>  SARMUX pins.  <b>0x1: CTB0 :</b>  CTB0  <b>0x2: CTB1 :</b>  CTB1  <b>0x3: CTB2 :</b>  Reserved  <b>0x4: CTB3 :</b>  Reserved  <b>0x6: AROUTE_VIRT :</b>  Reserved  <b>0x7: SARMUX_VIRT :</b>  SARMUX virtual port

### 17.1.29 SAR0\_INJ\_CHAN\_CONFIG (continued)

2 : 0	INJ_PIN_ADDR	Address of the pin to be sampled by this injection channel. If differential is enabled then PIN_ADDR[0] is ignored and considered to be 0, i.e. PIN_ADDR points to the even pin of a pin pair. Default Value: 0

### 18.1.4 PASS0\_DSAB\_DSAB\_CTRL (continued)

11 : 8 SEL\_OUT

This field (along with REF\_SWAP\_EN and ENABLED) provides bitwise selection of the current sources that drive the DSAB ZTC and PTAT outputs. The available current sources are a function of the type of SRSS. The SRSS current sources are disabled in chip DeepSleep mode which is indicated by ( ) entries in the truth table. CTB(m) factory trim has SRSS-ZTC and either SRSS-PTAT (SRSSv2) or DSAB\_PTAT (SRSS-LITE) enabled. If different settings are used, then a periodic re-trim of CTB(m) offset should be performed.

Truth Table with SRSSv2 (backwards compatible with PSoC4A family)

ENABLED	SEL_OUT	REF_SWAP_EN	"Chip Power Mode"	ZTC Output	PTAT Output
0	X	X	Active	SRSS-ZTC	SRSS-PTAT
0	X	X	DeepSleep	(SRSS-ZTC)	(SRSS-PTAT)
1	0	0	Active	SRSS-ZTC	SRSS-PTAT
1	0	0	DeepSleep	(SRSS-ZTC)	(SRSS-PTAT)
1	0	1	Active	SRSS-PTAT	SRSS-ZTC

1	1	1	Active	SRSS-PTAT	DSAB-PTAT
1	1	1	DeepSleep	(SRSS-PTAT)	DSAB-PTAT

Truth Table with SRSS-LITE

ENABLED	SEL_OUT	REF_SWAP_EN	"Chip Power Mode"	ZTC Output	PTAT Output
0	X	X	Active	SRSS-ZTC	DSAB-PTAT
0	X	X	DeepSleep	(SRSS-ZTC)	--

1	1	0	DeepSleep	DSAB-PTAT	--
1	1	1	Active	--	DSAB-PTAT
1	1	1	DeepSleep	--	DSAB-PTAT

Default Value: 0

5 : 0 CURRENT\_SEL

DSAB DAC control field

Nominal DSAB Output Current = CURRENT\_SEL \* 0.075 uA

In products with SRSS-LITE, this setting impacts the CTB(m) offset. A value of 0x20 is used during factory trim and is required to maintain low offsets across temperature variation. If a different setting is used then a periodic re-trim of CTB(m) offset should be performed.  
 Default Value: 0

'1': counter has counted to "0".</p> <p>COUNTFLAG is set to '1' by a count transition from "1" to "0".            COUNTFLAG is cleared to '0' by a read of this register, and by any write to the SYST_CVR register.            Default Value: 0</p>

### 19.1.19 CM0P\_SYST\_CSR (continued)

2	CLKSOURCE	<p>Indicates the SysTick counter clock source:</p> <p>'0': SysTick uses the low frequency clock "clk_lf". For this mode to function, "clk_lf" should be less than half the frequency of "clk_sys". Note that "clk_lf" is generated by a low accuracy ILO (Internal Low power Oscillator), with a target frequency of 32.768 kHz (frequency can be as low as 15 KHz and as high as 60 kHz).</p> <p>'1': SysTick uses the system/processor clock "clk_sys".</p> <p>In PSoC4A-BLE (and later products), SysTick counter functionality on the low frequency clock is provided. in SF, TSG6M products, this functionality is not provided. For these products, this field should be set to '1', such that SysTick uses the system clock "clk_sys".</p> <p>Default Value: 0</p>
1	TICKINT	<p>Indicates whether counting to "0" causes the status of the SysTick exception to change to pending:</p> <p>'0': count to "0" does not affect the SysTick exception status.</p> <p>'1': count to "0" changes the SysTick exception status to pending.</p> <p>Changing the value of the counter to "0" by writing zero to the SYST_CVR register to "0" never changes the status of the SysTick exception.</p> <p>Default Value: 0</p>
0	ENABLE	<p>Indicates the enabled status of the SysTick counter:</p> <p>'0': counter is disabled.</p> <p>'1': counter is operating.</p> <p>Default Value: 0</p>
