

TLE9869QXA20

Microcontroller with LIN and H-Bridge MOSFET Driver for Automotive Applications

BC-Step

User's Manual

preliminary
Rev. 0.47, 2014-11-10

Table of Contents

1	Overview	13
1.1	Abbreviations	15
2	Block Diagram	17
3	Device Pinout and Pin Configuration	18
3.1	Device Pinout	18
3.2	Pin Configuration	19
4	Modes of Operation	22
5	Device Register Types	25
6	Power Management Unit (PMU)	26
6.1	Features	26
6.2	Introduction	26
6.2.1	Block Diagram	27
6.2.2	PMU Modes Overview	29
6.3	Power Supply Generation Unit (PGU)	34
6.3.1	Voltage Regulator 5.0V (VDDP)	35
6.3.2	Voltage Regulator 1.5V (VDDC)	36
6.3.3	External Voltage Regulator 5.0V (VDDEXT)	37
6.3.4	Register Definition	38
6.3.4.1	Power Supply Generation Register	38
6.3.4.2	VDDEXT Control Register	42
6.4	Power Control Unit	43
6.4.1	Power Control Unit - Fail Safe Scenarios	43
6.4.1.1	Power Supervision Function of PCU	43
6.4.1.2	Watchdog (WDT1) Fail Safe	44
6.4.1.3	Main Regulators Fail Safe	44
6.4.1.4	VDDEXT Failure	44
6.4.1.5	Wake-Up from Stop Mode with Reset Fail Safe	44
6.4.2	Register Definition	46
6.4.2.1	PMU System Fail Register	46
6.4.2.2	PMU Wake Fail Register	48
6.5	Wake-Up Management Unit (WMU)	49
6.5.1	Functional Description	49
6.5.2	Register Definition	50
6.5.2.1	PMU Wake-Up Configuration Register	51
6.5.2.2	PMU Wake-Up Status Register	59
6.6	Cyclic Management Unit (CMU)	63
6.6.1	Functional Description	63
6.6.2	Cyclic Sense Mode	63
6.6.2.1	Configuration of Cyclic Sense Mode	65
6.6.3	Cyclic Wake Mode	66
6.6.4	Register Definition	66
6.6.4.1	Cyclic Wake Configuration Registers (CYCMU)	67
6.7	Reset Management Unit (RMU)	71
6.7.1	Functional Description	71
6.7.2	Register Definition	76
6.7.2.1	Reset Management Unit Registers (RMU)	76
6.8	PMU Data Storage Area	79

Table of Contents

6.8.1	Functional Description	79
6.8.2	Register Definition	79
6.8.2.1	Data Storage Registers	80
7	System Control Unit - Digital Modules (SCU-DM)	84
7.1	Features	84
7.2	Introduction	84
7.2.1	Block Diagram	85
7.2.2	SCU Register Overview	87
7.2.2.1	Register Map	87
7.3	Clock Generation Unit	89
7.3.1	Low Precision Clock	89
7.3.2	High Precision Oscillator Circuit (OSC_HP)	89
7.3.2.1	External Input Clock Mode	90
7.3.2.2	External Crystal Mode	90
7.3.3	Phase-Locked Loop (PLL) Module	91
7.3.3.1	Features	91
7.3.3.2	PLL Functional Description	92
7.3.3.3	Oscillator Watchdog	96
7.3.3.4	PLL VCO Lock Detection	96
7.3.3.5	Internal Oscillator (OSC_PLL)	96
7.3.3.6	Switching PLL Parameters	97
7.3.3.7	Oscillator Watchdog Event or PLL Loss of Lock Detection	97
7.3.3.8	Oscillator Watchdog Event or Loss of Lock Recovery	98
7.3.4	Clock Control Unit	99
7.3.4.1	Clock Tree	100
7.3.4.2	Startup Control for System Clock	101
7.3.5	External Clock Output	101
7.3.6	CGU Registers	101
7.3.6.1	PLL Oscillator Register	102
7.3.6.2	PLL Registers	104
7.3.6.3	System Clock Control Registers	108
7.3.6.4	Analog Peripherals Clock Control Registers	109
7.3.6.5	External Clock Control Register	115
7.4	Reset Control	116
7.4.1	Types of Reset	116
7.4.2	Overview	116
7.4.3	Module Reset Behavior	116
7.4.4	Functional Description of Reset Types	118
7.4.4.1	Power-On / Brown-out Reset	118
7.4.4.2	Wake-up Reset	118
7.4.4.3	Hardware Reset	118
7.4.4.4	WDT1 Reset	118
7.4.4.5	WDT / Soft Reset	119
7.4.5	Reset Register Description	119
7.4.6	Bootling Scheme	120
7.5	Power Management	121
7.5.1	Overview	121
7.5.2	Functional Description	122
7.5.2.1	Slow Down Mode	122
7.5.2.2	Stop Mode	122
7.5.2.3	Sleep Mode	124

Table of Contents

7.5.3	Register Description	125
7.6	Interrupt Management	126
7.6.1	Overview	126
7.6.1.1	External Interrupts	126
7.6.1.2	Extended Interrupts	127
7.6.2	Interrupt Node Assignment	128
7.6.3	Interrupt Related Registers	129
7.6.3.1	Interrupt Event Enable Control	129
7.6.3.2	DMA Interrupt Event Enable and Select Control	133
7.6.4	Implementation of DMA Request inside the SCU	137
7.6.5	NMI Event Flags Handling	137
7.7	General Port Control	138
7.7.1	Input Pin Function Selection	138
7.7.2	Port Output Control	142
7.7.3	GPT12 T3IN/T4IN Input Pin Function Selection	149
7.8	Flexible Peripheral Management	150
7.8.1	Peripheral Management Registers	150
7.9	Module Suspend Control	152
7.10	LIN Break and Sync Byte Detection	154
7.10.1	LIN Break and Sync Byte Detection Control	154
7.10.1.1	LIN Break and Sync Byte Registers	154
7.11	Watchdog Timer	156
7.11.1	Functional Description	157
7.11.2	Register Description	159
7.12	Error Detection and Correction Control for Memories	161
7.12.1	Error Detection and Correction Control Register	161
7.12.2	Error Detection and Correction Status Register	162
7.13	Miscellaneous Control	164
7.13.1	Bit Protection Register	164
7.13.2	System Control and Status Registers	166
8	System Control Unit - Power Modules (SCU-PM)	172
8.1	Features	172
8.2	Introduction	172
8.2.1	Block Diagram	172
8.3	Clock Watchdog Unit (CWU)	173
8.3.1	Fail Safe Functionality of Clock Generation Unit (Clock Watchdog)	173
8.3.1.1	Functional Description of Clock Watchdog Module	174
8.3.2	Clock Generation Unit Register	175
8.4	Interrupt Control Unit (ICU)	180
8.4.1	Structure of PREWARN_SUP_NMI	180
8.4.2	Interrupt Control Unit Status Register	181
8.4.2.1	Interrupt Control Unit Status Overview Register	181
8.4.2.2	Interrupt Control Unit - Interrupt Enable Register	194
8.5	Power Control Unit for Power Modules (PCU_PM)	199
8.5.1	VSD-Overvoltage System Shutdown	201
8.5.2	Overtemperature System Shutdown	202
8.5.3	Power Control Unit Register	203
8.6	MISC Control	205
8.6.1	Bus Faults	205
8.6.1.1	Bus Fault Control Register	205

Table of Contents

9	ARM Cortex M3 Core	210
9.1	Features	210
9.2	Introduction	211
9.2.1	Block Diagram	211
9.3	Functional Description	212
9.3.1	Registers	212
9.3.1.1	General-Purpose Registers	212
9.3.1.2	Special-Purpose Program Status Registers (xPSR)	213
9.4	Summary of Processor Registers	214
9.5	Instruction Set Summary	257
10	DMA Controller	261
10.1	Features	261
10.2	Introduction	262
10.2.1	Block Diagram	262
10.3	Functional Description	263
10.3.1	DMA Mode Overview	263
10.3.2	DMA Arbitration Rate	264
10.3.3	Channel Control Data Structure	276
10.4	Register Definition	286
11	Address Space Organization	304
12	Memory Control Unit	309
12.1	Features	309
12.2	Introduction	309
12.2.1	Block Diagram	309
12.3	NVM Module (Flash Memory)	311
12.3.1	Definitions	312
12.3.1.1	General Definitions	312
12.3.2	Functional Description	314
12.3.2.1	Basic block functions	315
12.3.2.2	Memory Cell Array	315
12.3.2.3	SFR Accesses	316
12.3.2.4	Memory Read	316
12.3.2.5	Memory Write	317
12.3.2.6	Timing	317
12.3.2.7	Verify	317
12.3.2.8	Tearing-Safe programming	317
12.3.2.9	Disturb handling	317
12.3.2.10	ECC and EDC	317
12.3.2.11	Code and Data access through the AHB-Lite interface	318
12.3.2.12	Prefetch Unit	318
12.4	BootROM Module	318
12.4.1	BootROM addressing	318
12.4.2	BootROM firmware program structure	319
12.5	RAM Module	319
12.5.1	RAM addressing	319
12.6	Memory protection Unit (MPU)	319
13	Interrupt System	320
13.1	Features	320
13.2	Introduction	320
13.2.1	Overview	320

Table of Contents

13.3	Functional Description	322
13.3.1	Interrupt Node Assignment	322
13.3.1.1	Interrupt Node 0 and 1 - GPT12 Timer Module	322
13.3.1.2	Interrupt Node 2 - Measurement Unit	323
13.3.1.3	Interrupt Node 3 - 10 Bit ADC (ADC1)	324
13.3.1.4	Interrupt Nodes 4/5/6/7 - Capture Compare Unit (CCU6)	325
13.3.1.5	Interrupt Node 8 and 9 - SSC1/SSC2	326
13.3.1.6	Interrupt Node 10 - UART1/LIN Transceiver	327
13.3.1.7	Interrupt Node 11 - UART2	328
13.3.1.8	Interrupt Node 12 - External Interrupt 0/MON	329
13.3.1.9	Interrupt Node 13 - External Interrupt 1	329
13.3.1.10	Interrupt Node 14 - Bridge Driver	330
13.3.1.11	Interrupt Node 15 - DMA Controller	331
13.3.1.12	Non Maskable Interrupt (NMI)	332
13.3.1.13	Interrupt Flags Overview	333
13.3.2	Interrupt Structure	340
13.3.2.1	Interrupt Structure 1	340
13.3.3	Interrupt Source and Vector	340
13.3.4	Interrupt Priority	342
13.4	Interrupt Handling	343
13.5	Register Definition	344
13.5.1	Interrupt Node Enable Registers	344
13.5.2	External Interrupt Control Registers	345
13.5.3	Interrupt Flag Registers	347
13.6	Interrupt Priority Registers	363
14	Watchdog Timer (WDT1)	364
14.1	Features	364
14.2	Introduction	365
14.3	Functional Description	366
14.3.1	Modes of Operation	366
14.3.2	Normal Operation	366
14.4	Register Definition	369
15	GPIO Ports and Peripheral I/O	371
15.1	Features	371
15.2	Introduction	371
15.2.1	Port 0 and Port 1	371
15.2.2	Port 2	374
15.3	General Port Register Description	375
15.3.1	Port Data Register	376
15.3.2	Direction Register	376
15.3.3	Open Drain Control Register	377
15.3.4	Pull-Up/Pull-Down Device Register	377
15.3.4.1	Alternate Input Functions	379
15.3.5	Alternate Output Functions	379
15.3.6	Register Map	380
15.4	TLE9869QXA20 Port Module	381
15.4.1	Port 0	381
15.4.1.1	Overview	381
15.4.1.2	Port 0 Functions	382
15.4.1.3	Port 0 Register Description	384

Table of Contents

15.4.2	Port 1	387
15.4.2.1	Overview	387
15.4.2.2	Port 1 Functions	387
15.4.2.3	Port 1 Register Description	390
15.4.3	Port 2	393
15.4.3.1	Overview	393
15.4.3.2	Port 2 Functions	393
15.4.3.3	Port 2 Register Description	395
16	General Purpose Timer Units (GPT12)	397
16.1	Features	397
16.1.1	Features Block GPT1	397
16.1.2	Features Block GPT2	397
16.2	Introduction	397
16.2.1	Block Diagram GPT1	398
16.2.2	Block Diagram GPT2	399
16.3	Timer Block GPT1	400
16.3.1	GPT1 Core Timer T3 Control	401
16.3.2	GPT1 Core Timer T3 Operating Modes	403
16.3.3	GPT1 Auxiliary Timers T2/T4 Control	409
16.3.4	GPT1 Auxiliary Timers T2/T4 Operating Modes	410
16.3.5	GPT1 Clock Signal Control	418
16.3.6	Interrupt Control for GPT1 Timers	420
16.3.7	GPT1 Registers	421
16.3.7.1	GPT1 Timer Registers	421
16.3.7.2	GPT1 Timer Control Registers	422
16.3.7.3	GPT1 Timer Interrupt Control Registers	429
16.4	Timer Block GPT2	430
16.4.1	GPT2 Core Timer T6 Control	431
16.4.2	GPT2 Core Timer T6 Operating Modes	433
16.4.3	GPT2 Auxiliary Timer T5 Control	436
16.4.4	GPT2 Auxiliary Timer T5 Operating Modes	437
16.4.5	GPT2 Register CAPREL Operating Modes	441
16.4.6	GPT2 Clock Signal Control	446
16.4.7	Interrupt Control for GPT2 Timers and CAPREL	448
16.4.8	GPT2 Registers	449
16.4.8.1	GPT2 Timer Registers	449
16.4.8.2	GPT2 Timer Control Registers	450
16.4.8.3	GPT2 Timer and CAPREL Interrupt Control Registers	455
16.5	Miscellaneous GPT12 Registers	456
16.6	Register Map	459
16.7	Implementation of the GPT12 Module	460
16.7.1	Module Connections	460
17	Timer2 and Timer21	463
17.1	Features	463
17.2	Introduction	463
17.2.1	Timer2 and Timer21 Modes Overview	463
17.3	Functional Description	464
17.3.1	Auto-Reload Mode	464
17.3.1.1	Up/Down Count Disabled	464
17.3.1.2	Up/Down Count Enabled	465

Table of Contents

17.3.2	Capture Mode	467
17.3.3	Count Clock	468
17.4	Module Interfaces	469
17.4.1	Interfaces of the Timer2 and Timer21	469
17.5	Interrupt Generation	470
17.6	Register Definition	471
17.6.1	Timer 2 Registers	471
17.6.1.1	Mode Register	471
17.6.1.2	Control Register	472
17.6.1.3	Timer 2 Reload/Capture Register	474
17.6.1.4	Timer 2 Count Register	475
17.6.2	Register Map	476
18	Timer3	477
18.1	Features	477
18.2	Introduction	477
18.3	Functional Description	477
18.3.1	Timer3 Modes Overview	478
18.3.2	Mode 0	480
18.3.3	Mode 1a	481
18.3.4	Mode 1b	482
18.3.5	Mode 2	483
18.3.6	Mode 3a	484
18.3.7	Mode 3b	485
18.4	Interrupts	486
18.5	Register Definition	486
18.5.1	Timer 3 Control Registers	487
19	Capture/Compare Unit 6 (CCU6)	494
19.1	Feature Set Overview	494
19.2	Introduction	495
19.2.1	Block Diagram	496
19.3	Operating Timer T12	497
19.3.1	T12 Overview	498
19.3.2	T12 Counting Scheme	500
19.3.2.1	Clock Selection	500
19.3.2.2	Edge-Aligned / Center-Aligned Mode	501
19.3.2.3	Single-Shot Mode	503
19.3.3	T12 Compare Mode	504
19.3.3.1	Compare Channels	504
19.3.3.2	Channel State Bits	504
19.3.3.3	Hysteresis-Like Control Mode	509
19.3.4	Compare Mode Output Path	510
19.3.4.1	Dead-Time Generation	510
19.3.4.2	State Selection	512
19.3.4.3	Output Modulation and Level Selection	513
19.3.5	T12 Capture Modes	515
19.3.6	T12 Shadow Register Transfer	519
19.3.7	Timer T12 Operating Mode Selection	520
19.4	Operating Timer T13	521
19.4.1	T13 Overview	521
19.4.2	T13 Counting Scheme	523

Table of Contents

19.4.2.1	Clock Selection	523
19.4.2.2	T13 Counting	524
19.4.2.3	Single-Shot Mode	524
19.4.2.4	Synchronization to T12	525
19.4.3	T13 Compare Mode	527
19.4.4	Compare Mode Output Path	529
19.4.5	T13 Shadow Register Transfer	530
19.5	Trap Handling	532
19.6	Multi-Channel Mode	534
19.7	Hall Sensor Mode	536
19.7.1	Hall Pattern Evaluation	537
19.7.2	Hall Pattern Compare Logic	539
19.7.3	Hall Mode Flags	540
19.7.4	Hall Mode for Brushless DC-Motor Control	541
19.8	General Module Operation	543
19.8.1	Input Selection	543
19.9	Module Interfaces	543
19.9.1	Interfaces of the CCU6 Module	543
19.10	Interrupt Handling	545
19.10.1	Interrupt Structure	545
19.11	Register Definition	547
19.11.1	CCU6 Register Description	547
19.11.1.1	System Registers	548
19.11.2	Timer 12 – Related Registers	551
19.11.3	Timer 13 – Related Registers	558
19.11.4	Capture/Compare Control Registers	560
19.11.5	Global Modulation Control Registers	569
19.11.6	Multi-Channel Modulation Control Registers	574
19.11.7	Interrupt Control Registers	578
19.11.8	Register Map	589
20	UART1/UART2	590
20.1	Features	590
20.2	Introduction	590
20.2.1	Block Diagram	590
20.3	UART Modes	591
20.3.1	Mode 0, 8-Bit Shift Register, Fixed Baud Rate	591
20.3.2	Mode 1, 8-Bit UART, Variable Baud Rate	591
20.3.3	Mode 2, 9-Bit UART, Fixed Baud Rate	593
20.3.4	Mode 3, 9-Bit UART, Variable Baud Rate	593
20.4	Multiprocessor Communication	595
20.5	Baud Rate Generation	596
20.5.1	Baud-rate Generator	596
20.6	LIN Support in UART	598
20.6.1	LIN Protocol	598
20.6.2	LIN Header Transmission	599
20.6.2.1	Automatic Synchronization to the Host	599
20.6.2.2	Initialization of Break/Synch Field Detection Logic	601
20.6.2.3	Baud Rate Range Selection	601
20.6.2.4	LIN Baud Rate Detection	603
20.7	Module Interfaces	604
20.8	Interrupts	605

Table of Contents

20.9	Register Definition	605
20.9.1	UART Registers	606
20.9.1.1	UART Control Registers	606
20.9.1.2	Baud-rate Generator Control and Status Registers	607
20.9.1.3	Baud-rate Generator Timer/Reload Registers	608
20.9.2	Register Map	611
21	LIN Transceiver	612
21.1	Features	612
21.2	Introduction	612
21.2.1	Block Diagram	613
21.3	Functional Description	614
21.3.1	LIN Transceiver Modes	614
21.3.2	LIN Transceiver Status for Mode Selection	617
21.3.3	LIN Transceiver Error Handling	617
21.3.4	Slope Modes	618
21.3.5	LIN Transceiver Slope Mode Status	618
21.4	Register Definition	619
22	High-Speed Synchronous Serial Interface (SSC1/SSC2)	622
22.1	Features	622
22.2	Introduction	622
22.2.1	Block Diagram	623
22.3	Functional Description	623
22.3.1	SSC1 and SSC2 Modes Overview	623
22.3.2	Operating Mode Selection	624
22.3.3	Full-Duplex Operation	626
22.3.4	Half-Duplex Operation	628
22.3.5	Continuous Transfers	629
22.3.6	Baud Rate Generation	629
22.3.7	Error Detection Mechanisms	630
22.3.7.1	Port Control	632
22.4	Module Interfaces	633
22.4.1	Interfaces of the SSC Module	633
22.5	Interrupts	635
22.6	Register Definition	636
22.6.1	SSC1 and SSC2 Register Definition	636
22.6.2	Port Input Select Register	636
22.6.2.1	Configuration Register	636
22.6.3	Baud Rate Timer Reload Register	641
22.6.4	Transmitter Buffer Register	641
22.6.5	Receiver Buffer Register	642
22.6.6	Register Map	642
23	Measurement Unit	643
23.1	Features	643
23.2	Introduction	643
23.2.1	Block Diagram	644
23.2.2	Measurement Unit Register Overview	645
23.3	8-bit - 10 Channel ADC Core (ADC2)	645
23.3.1	8-bit ADC Channel Allocation	646
23.3.2	Transfer Characteristics of ADC2	646
23.3.3	Detailed ADC2 Measurement Channel Description	647

Table of Contents

23.3.4	8-bit - 10 Channel Control Registers	647
23.4	Monitoring Input Voltage Attenuator	648
23.4.1	Functional Description	648
23.4.2	Monitoring Input Attenuator Control Register	648
23.5	Central and PMU Regulator Temperature Sensor	651
23.5.1	Functional Description	651

1 Overview

Summary of Features

- 32 bit ARM Cortex M3 Core
 - up to 40 MHz clock frequency
 - one clock per machine cycle architecture
- On-chip memory
 - 128 kByte Flash including
 - 4 kByte EEPROM (emulated in Flash)
 - 512 Byte 100 Time Programmable Memory (100TP)
 - 6 kByte RAM
 - Boot ROM for startup firmware and Flash routines
- On-chip OSC and PLL for clock generation
 - PLL loss-of-lock detection
- MOSFET Driver including charge pump
- 9 General-purpose I/O Ports (GPIO)
- 5 analog inputs, 10-bit A/D Converter (ADC1)
- 16-bit timers - GPT12, Timer 2, Timer 21 and Timer 3
- Capture/compare unit for PWM signal generation (CCU6)
- 2 Full duplex serial interface (UART) with LIN support (for UART1 only)
- 2 Synchronous serial channel (SSC)
- On-chip debug support via 2-wire SWD
- 1 LIN 2.2 transceiver
- 1 High Voltage Monitoring Input
- Single Power Supply from 5.5 V to 27 V
- Extended power supply voltage range from 3 V to 28 V
- Low-dropout voltage regulators (LDO)
- High Speed Operational amplifier for motor current sensing via shunt
- 5 V voltage supply for external loads (e.g. hall sensor)
- Core logic supply at 1.5 V
- Programmable window watchdog (WDT1) with independent on-chip clock source
- Power saving modes
 - MCU slow-down Mode
 - Sleep Mode
 - Stop Mode
 - Cyclic wake-up Sleep Mode
- Power-on and undervoltage/brownout reset generator

VQFN-48-31

Type	Package	Marking
TLE9869QXA20	VQFN-48-31	

- Overtemperature protection
- Short circuit protection
- Loss of clock detection with fail safe mode entry for low system power consumption
- Temperature Range T_J : -40 °C up to 150 °C
- Package VQFN-48 with LTI feature
- Green package (RoHS compliant)
- AEC Qualified

1.1 Abbreviations

The following acronyms and terms are used within this document. List see in [Table 1](#).

Table 1 **Acronyms**

Acronyms	Name
AHB	Advanced High-Performance Bus
APB	Advanced Peripheral Bus
CCU6	Capture Compare Unit 6
CGU	Clock Generation Unit
CLKMU	Clock Management Unit
CMU	Cyclic Management Unit
CP	Charge Pump for MOSFET driver
CSA	Current Sense Amplifier
DPP	Data Post Processing
ECC	Error Correction Code
EEPROM	Electrically Erasable Programmable Read Only Memory
EIM	Exceptional Interrupt Measurement
FSM	Finite State Machine
GPIO	General Purpose Input Output
H-Bridge	Half Bridge
ICU	Interrupt Control Unit
IEN	Interrupt Enable
IIR	Infinite Impulse Response
LDM	Load Instruction
LDO	Low DropOut voltage regulator
LIN	Local Interconnect Network
LSB	Least Significant Bit
LTI	Lead Tip Inspection
MCU	Micro Controller Unit
MF	Measurement Functions
MSB	Most Significant Bit
MPU	Memory Protection Unit
MRST	Master Receive Slave Transmit
MTSR	Master Transmit Slave Receive
MU	Measurement Unit
NMI	Non Maskable Interrupt
NVIC	Nested Vector Interrupt Controller
NVM	Non-Volatile Memory
OTP	One Time Programmable
OSC	Oscillator

Table 1 Acronyms

Acronyms	Name
PBA	Peripheral Bridge
PC	Program Counter
PCU	Power Control Unit
PD	Pull Down

3 Device Pinout and Pin Configuration

3.1 Device Pinout

Figure 2 Device Pinout, TLE9869

3.2 Pin Configuration

After reset, all pins are configured as input (except supply and LIN pins) with one of the following settings:

- Pull-up device enabled only (PU)
- Pull-down device enabled only (PD)
- Input with both pull-up and pull-down devices disabled (I)
- Output with output stage deactivated = high impedance state (Hi-Z)

The functions and default states of the TLE9869QXA20 external pins are provided in the following table.

Type: indicates the pin type.

- I/O: Input or output
- I: Input only
- O: Output only
- P: Power supply

Not all alternate functions listed.

Table 2 Pin Definitions and Functions

Symbol	Pin Number	Type	Reset State ¹⁾	Function	
P0				Port 0 Port 0 is a 5-bit bidirectional general purpose I/O port. Alternate functions can be assigned and are listed in the Port description. Main function is listed below.	
P0.0	21	I/O	I/PU	SWD	Serial Wire Debug Clock
P0.1	23	I/O	I/PU	GPIO	General Purpose IO Alternate function mapping see Table 80
P0.2	25	I/O	I/PD	GPIO	General Purpose IO Alternate function mapping see Table 80 <i>Note: for a functional SWD connection this GPIO must be tied to zero!</i>
P0.3	24	I/O	I/PU	GPIO	General Purpose IO Alternate function mapping see Table 80
P0.4	18	I/O	I/PD	GPIO	General Purpose IOI Alternate function mapping see Table 80
P1				Port 1 Port 1 is a 5-bit bidirectional general purpose I/O port. Alternate functions can be assigned and are listed in the Port description. Main function is listed below.	
P1.0	15	I/O	I	GPIO	General Purpose IO Alternate function mapping see Table 83
P1.1	16	I/O	I	GPIO	General Purpose IO Alternate function mapping see Table 83
P1.2	17	I/O	I	GPIO	General Purpose IO Alternate function mapping see Table 83
P1.3	26	I/O	I	GPIO	General Purpose IO, used for Inrush Transistor Alternate function mapping see Table 83
P1.4	27	I/O	I	GPIO	General Purpose IO Alternate function mapping see Table 83

RESET	22	I/O	–	Reset input, not available during Sleep Mode
VBAT_SENSE	46	I	–	Battery supply voltage sense input
EP	–	–	–	Exposed Pad, connect to GND

1) Only valid for digital IOs

2) Also named VDD5V.

3) Also named VDD1V5.

4 Modes of Operation

This highly integrated circuit contains analog and digital functional blocks. For system and interface control an embedded 32 bit microcontroller is available. For internal and external power supply purposes, on-chip low drop-out regulators are existent. An internal oscillator provides a cost effective and suitable clock in particular for LIN communication. As communication interface, a LIN transceiver is available. Driver stages for a H-Bridge with external MOSFET are integrated, featuring PWM capacity, protection feature and charge pump for operation at low supply voltage. A 10-bit SAR ADC is implemented for high precision sensor measurement. A 8-bit ADC is used for diagnosis measurement.

The Micro Controller Unit (MCU) supervision and system protection including reset feature is complemented by a programmable window watchdog. A cyclic wake-up circuit, supply voltage supervision and integrated temperature sensors are available on-chip.

All relevant modules offer power saving modes in order to support terminal 30 connected automotive applications. A wake-up from the power saving mode is possible via a LIN bus message, via the monitoring input or with a programmable time period (cyclic wake-up).

The integrated circuit is available in a VQFN-48-31 package with 0.5 mm pitch, featuring LTI, and is designed to withstand the severe conditions of automotive applications.

The TLE9869QXA20 has several operation modes mainly to support low power consumption requirements.

Reset Mode

The Reset Mode is a transition mode e.g. during power-up of the device after a power-on reset, or after wake from Sleep Mode. In this mode the on-chip power supplies are enabled and all other modules are initialized. Once the core supply VDDC is stable, the Active Mode is entered. In case the watchdog timer WDT1 fails for more than four times, a fail-safe transition to the Sleep Mode is done.

Active Mode

In Active Mode all modules are activated and the TLE9869QXA20 is fully operational.

Stop Mode

The Stop Mode is one out of two major low power modes. The transition to the low power modes is done by setting the respective bits in the mode control register. In Stop Mode the embedded microcontroller is still powered allowing faster wake-up reaction times. A wake-up from this mode is possible by LIN bus activity, the high-voltage monitoring pin or the respective 5V GPIOs.

Stop Mode with Cyclic Wake-up

The Cyclic Wake-Up Mode is a special operating mode of the Stop Mode. The transition to the Cyclic Wake-Up Mode is done by first setting the respective bits in the mode control register followed by the Stop Mode command. In addition to the cyclic wake-up behavior (wake-up after a programmable time period), asynchronous wake events via the activated sources (LIN and/or MON) are available, as in normal Stop Mode.

Sleep Mode

The Sleep Mode is a low-power mode. The transition to the low-power mode is done by setting the respective bits in the MCU mode control register or in case of failure, see below. In Sleep Mode the embedded microcontroller power supply is deactivated allowing the lowest system power consumption. A wake-up from this mode is possible by LIN bus activity, the High Voltage Monitor Input pin or Cyclic Wake-up.

Sleep Mode in Case of Failure

The Sleep Mode is activated in case of 5 repeated watchdog failures or in case of supply fail (5 times). In this case MON is enabled as wake source and Cyclic Wake-up is activated with 1s wake time.

Sleep Mode with Cyclic Wake-Up

The Cyclic Wake-Up Mode is a special operating mode of the Sleep Mode. The transition to the Cyclic Wake-Up Mode is done by first setting the respective bits in the mode control register followed by the Sleep and Stop Mode command. In addition to the cyclic wake-up behavior (wake-up after a programmable time period), asynchronous wake events via the activated sources (LIN and/or MON) are available, as in normal Sleep Mode.

When using Sleep Mode with cyclic wake-up the voltage regulator is switched off and started again with the wake. A limited number of registers is buffered during sleep, and can be used by SW e.g. for counting sleep/wake cycles.

MCU Slow Down Mode

In MCU Slow Down Mode the MCU frequency is reduced for power saving during operation. LIN communication is still possible. LS MOSFET can be activated.

Wake-up Source Prioritization

All wake-up sources have the same priority. In order to handle the asynchronous nature of the wake-up sources, the first wake-up signal will initiate the wake-up sequence. Nevertheless all wake-up sources are latched in order to provide all wake-up events to the application software. The software can clear the wake-up source flags. It is ensured, that no wake-up event is lost.

As default wake-up source, the MON input is activated after power-on reset only. Additionally the device is in Cyclic Wake-Up Mode with the max. configurable dead time setting.

The following table shows the possible power mode configurations including the Stop Mode.

Modes of Operation

Table 3 Power Mode Configurations

Module/Function	Active Mode	Stop Mode	Sleep Mode	Comment
VDDEXT	ON/OFF	ON (no dynamic load)/OFF	OFF	–
Bridge Driver	ON/OFF	OFF	OFF	
LIN TRx	ON/OFF	wake-up only/ OFF	wake-up only/ OFF	–
VS sense	ON/OFF brownout detection	brownout detection	POR on VS	brownout det. done in PCU
VBAT_SENSE	ON/OFF	OFF	OFF	–
GPIO 5V (wake-up)	n.a.	disabled/static	OFF	–
GPIO 5V (active)	ON	ON	OFF	–
WDT1	ON	OFF	OFF	–
CYCLIC WAKE	n.a.	cyclic wake-up/ cyclic sense/OFF	cyclic wake-up/ OFF	–
Measurement	ON ¹⁾	OFF	OFF	–
MCU	ON/slow- down/STOP	STOP ²⁾	OFF	–
CLOCK GEN (MC)	ON	OFF	OFF	–
LP_CLK (18 MHz)	ON	OFF	OFF	WDT1
LP_CLK2 (100 kHz)	ON/OFF	ON/OFF	ON/OFF	for cyclic wake-up

1) May not be switched off due to safety reasons

2) MC PLL clock disabled, MC supply reduced to 0.9 V

Wake-up Levels and Transitions

The wake-up can be triggered by rising, falling or both signal edges for the monitor input, by LIN or by cyclic wake.

5 Device Register Types

The following register types are used within this device. List see in [Table 4](#).

Table 4 Register Types

Type	can be modified by			Description
	Hardware	Firmware	Software	
r	yes	no	no	read-only flag
rh	yes	no	no	read-only flag which is modified by hardware
rhc	yes	no	yes	read-only flag which status can be clear by a read operation
rw	no	no	yes	bit can be read or written
rwp	yes	yes	no	protected bit; read operation is always possible
rwh	yes	no	yes	bit can be written by hardware and software; hardware has priority

6 Power Management Unit (PMU)

6.1 Features

- System modes control (startup, sleep, stop and active)
- Power management (cyclic wake)
- Control of system voltage regulators with diagnosis (overload, short, over-voltage)
- Fail safe mode detection and operation in case of system errors (watchdog fail)
- Wake-up sources configuration and management (LIN, MON, GPIOs)
- System error logging

6.2 Introduction

The power management unit is responsible for generating all required voltage supplies for the embedded MCU (VDDC, VDDP) and the external supply (VDDEXT). The purpose of the power management unit is to ensure the fail safe behavior of the system IC. Therefore the power management unit controls all system modes including the corresponding transitions. Additionally, the PMU provides well defined sequences for the system mode transitions and generates hierarchical reset priorities. The reset priorities control the reset behavior of all system functionalities especially the reset behavior of the embedded MCU. All these functions are controlled by a state machine. The system master functionality of the PMU make use of an independent logic supply and system clock. Therefore the PMU has a module "Internal logic supply and system clock" which works independently of the MCU clock.

Power Management Unit (PMU)

6.2.1 Block Diagram

The following figure shows the structure of the Power Management Unit. [Table 5](#) describes the submodules more detailed.

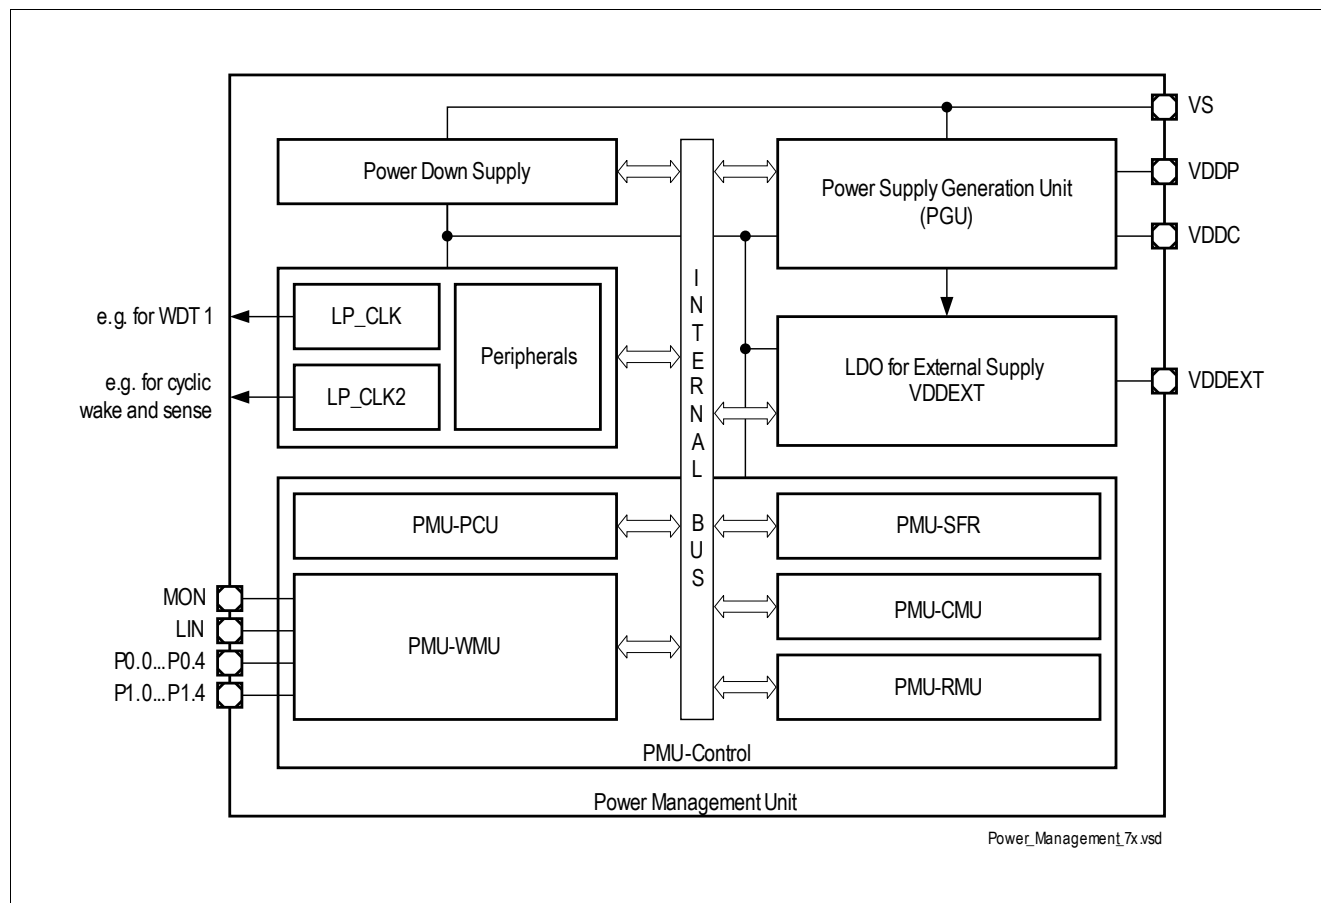

Figure 3 Power Management Unit Block Diagram

Power Management Unit (PMU)

Table 5 Description of PMU Submodules

Mod. Name	Modules	Functions
Power Down Supply	Independent Supply Voltage Generation for PMU	This supply is dedicated to the PMU to ensure an independent operation from generated power supplies (VDDP, VDDC).
LP_CLK (= 18 MHz)	<ul style="list-style-type: none"> - Clock Source for all PMU submodules - Backup Clock Source for System - Clock Source for WDT1 	<p>This ultra low power oscillator generates the clock for the PMU.</p> <p>This clock is also used as backup clock for the system in case of PLL Clock failure and as independent clock source for WDT1.</p>
LP_CLK2 (= 100 kHz)	Clock Source for PMU	This ultra low power oscillator generates the clock for the PMU in Stop Mode and in the cyclic modes.
Peripherals	Peripheral Blocks of PMU	These blocks include the analog peripherals to ensure a stable and fail safe PMU startup and operation (bandgap, bias).
Power Supply Generation Unit (PGU)	Voltage regulators for VDDP and VDDC	This block includes the voltage regulators for the pad supply (VDDP) and the core supply (VDDC).
VDDEXT	Voltage regulator for VDDEXT to supply external modules (e.g. Sensors)	This voltage regulator is a dedicated supply for external modules and can also be used for cyclic sense operations (e.g. with hall sensor).
PMU-SFR	All PMU relevant Extended Special Function Registers	This module contains all PMU relevant registers, which are needed to control and monitor the PMU.
PMU-PCU	Power Control Unit of the PMU	This block is responsible for controlling all power related actions within the PGU Module. It also contains all regulator related diagnosis like under- and overvoltage detection, over current and short circuit diagnoses.
PMU-WMU	Wake-Up Management Unit of the PMU	This block is responsible for controlling all wake-up related actions within the PMU Module.
PMU-CMU	Cyclic Management Unit of the PMU	This block is responsible for controlling all actions within cyclic mode.
PMU-RMU	Reset Management Unit of the PMU	This block generates resets triggered by the PMU like undervoltage or short circuit reset, and passes all resets to the relevant modules and their register.

6.2.2 PMU Modes Overview

The following state diagram shows the available modes of the device.

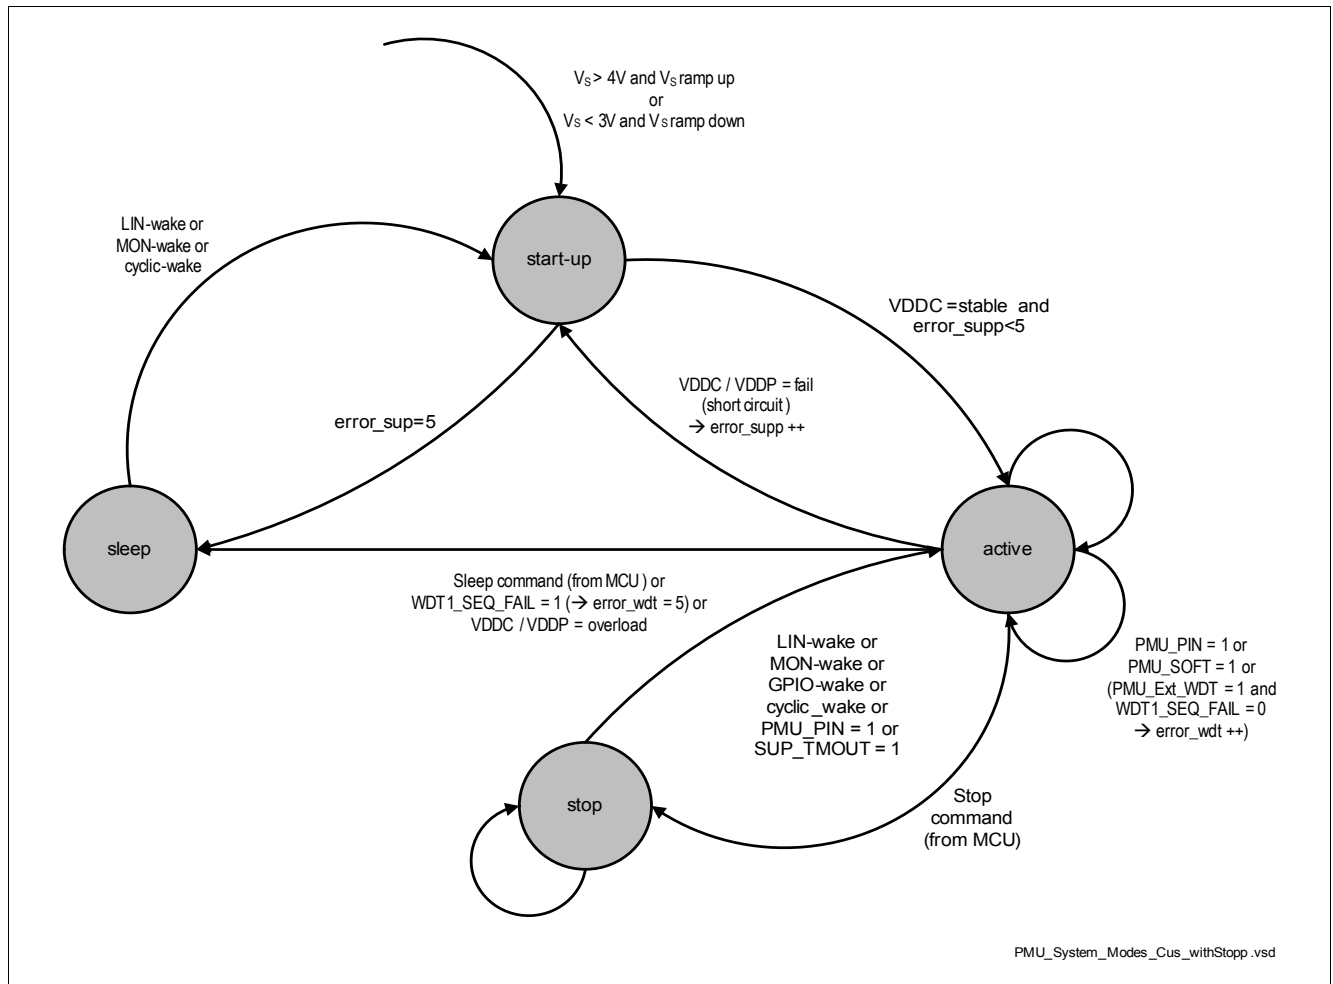

Figure 4 Power Management Unit System Modes

Active Mode

In Active Mode the Power Management Unit releases the reset of the embedded MCU and the application software takes control of the system. Now the PMU is responsible for supplying and supervising the embedded system. The supervision functionality of the PMU monitors the output voltage/current of the generated supplies and the status information of the system watchdog (WDT1).

Sleep Mode

The Sleep Mode is the power saving mode where the lowest power consumption is achieved. In this mode the PMU resets all system functionalities and switches off all voltage supplies (VDDP, VDDC, VDDEXT) which are generated in the PMU. The only submodules of the PMU which stay active are the ones responsible for controlling the wake-up procedure of the system. [Figure 5](#) shows the Sleep Mode entry procedure.

Figure 5 Sleep Mode Entry Timing

The Sleep Mode is terminated by a LIN pulse or a corresponding (rising edge / falling edge) activity at the MON input. The PMU processes the wake-up information in an independent State Machine FSM which starts the PMU internal system clock to process the startup sequences in a synchronous way. A successful startup sequence enters the startup Mode automatically. **Figure 6** illustrates the wake via LIN.

The Sleep Mode can be terminated by synchronous wake-up events too. If this is desired, the PMU must be configured by setting the corresponding SFRs. A synchronous wake-up can be configured using the Cyclic Sense. If these synchronous wake-up events are configured then the power consumption of the PMU increases in Sleep

Mode. The increased current consumption is caused by an oscillator which generates the needed time base (typically 100 kHz).

The wake-up procedure from Sleep Mode via MON pins (instead of LIN) follows the same sequence as shown in [Figure 6](#).

Figure 6 Sleep Mode LIN Wake-Up Timing

Stop Mode (also named Power Down Mode)

The objective of the Stop Mode is to provide a Low Power Mode where the data retention feature for the embedded MCU and the special function registers (SFRs). In the Stop Mode the core supply voltage VDDC goes from 1.5 V to 0.9 V with the objective to reduce leakage current as much as possible. During the Stop Mode the dynamic behavior (load jumps) of the PMU internally generated voltage supplies are limited. The corresponding limitation is given by the external buffer capacitor at the VDDC/VDDP pin. The figure below shows the Stop Mode entry sequence.

Figure 7 Stop Mode Entry Timing

Power Management Unit (PMU)

The asynchronous wake-up works using a LIN message or an event (rising edge/falling edge) at the MON input. Stop Mode terminates by an event at one of the GPIO pins. The wake-up configuration of every MON and GPIO input is stored in the corresponding SFR. The configuration for the high-voltage input (MON) are used for Stop-exit and Sleep-exit (same SFR). The Stop Mode terminates by using one of the synchronous wake-up features. The synchronous wake-up features are separated in Cyclic Sense and wake-up after time-out (Cyclic Wake). Both of these wake-up procedures work similarly to the Sleep-exit. In Cyclic Sense mode, both the MON inputs as well as the GPIOs can be evaluated and a transition will cause a termination of the Stop Mode. The sensing period for MON inputs and GPIOs is generated with the same time base (typically 100 kHz). The sensing period is set in the **CNF_CYC_SENSE**. To bias the external load of the GPIOs, the supply voltage VDDEXT may switch on for the sensing time. Only during this sensing time the PMU evaluates the corresponding GPIO. In case of a valid wake-up signal the PMU goes to Active Mode and the application software takes control over the system. If no valid wake-up information is available, then the external supply VDDEXT switches off until the configured sensing period starts again.

6.3.1 Voltage Regulator 5.0V (VDDP)

This module represents the 5 V voltage regulator, which provides the pad supply for the parallel port pins and other 5 V analog functions (e.g. LIN Transceiver).

Features

- 5 V low-drop voltage regulator
- Overcurrent monitoring and shutdown with MCU signalling (Interrupt)
- Overvoltage monitoring with MCU signalling (Interrupt)
- Undervoltage monitoring with MCU signalling (Interrupt)
- Undervoltage monitoring with reset (Undervoltage Reset, V_{DDPUV})
- Pre-Regulator for VDDC Regulator
- GPIO Supply
- Pull Down Current Source at the output for Sleep Mode only (typ. 5 mA)

The output capacitor C_{VDDP} is mandatory to ensure a proper regulator functionality.

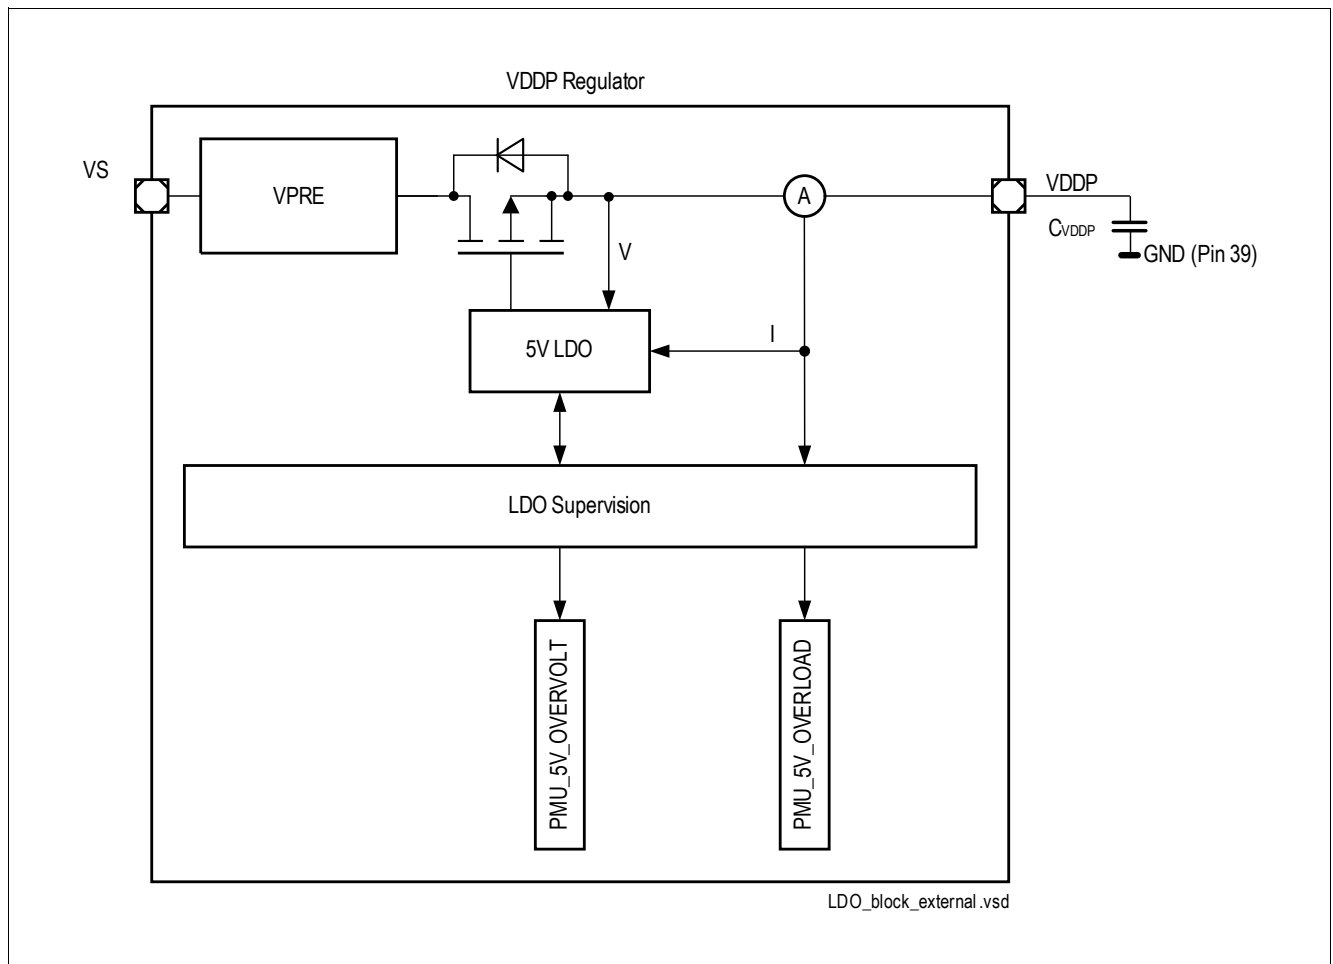

Figure 9 Module Block Diagram of VDDP Voltage Regulator

6.3.2 Voltage Regulator 1.5V (VDDC)

This module represents the 1.5 V voltage regulator, which provides the supply for the microcontroller core, digital peripherals and other chip internal analog 1.5 V functions (e.g. ADC2). To further reduce the current consumption of the MCU during Stop Mode the output voltage can be lowered to 0.9 V.

Features

- 1.5 V low-drop voltage regulator
- Overcurrent monitoring and shutdown with MCU signalling (Interrupt)
- Overvoltage monitoring with MCU signalling (Interrupt)
- Undervoltage monitoring with MCU signalling (Interrupt)
- Undervoltage monitoring with reset
- Pull Down Current Source at the output for Sleep Mode only (typ. 100 μ A)

The output capacitor C_{VDDC} is mandatory to ensure a proper regulator functionality.

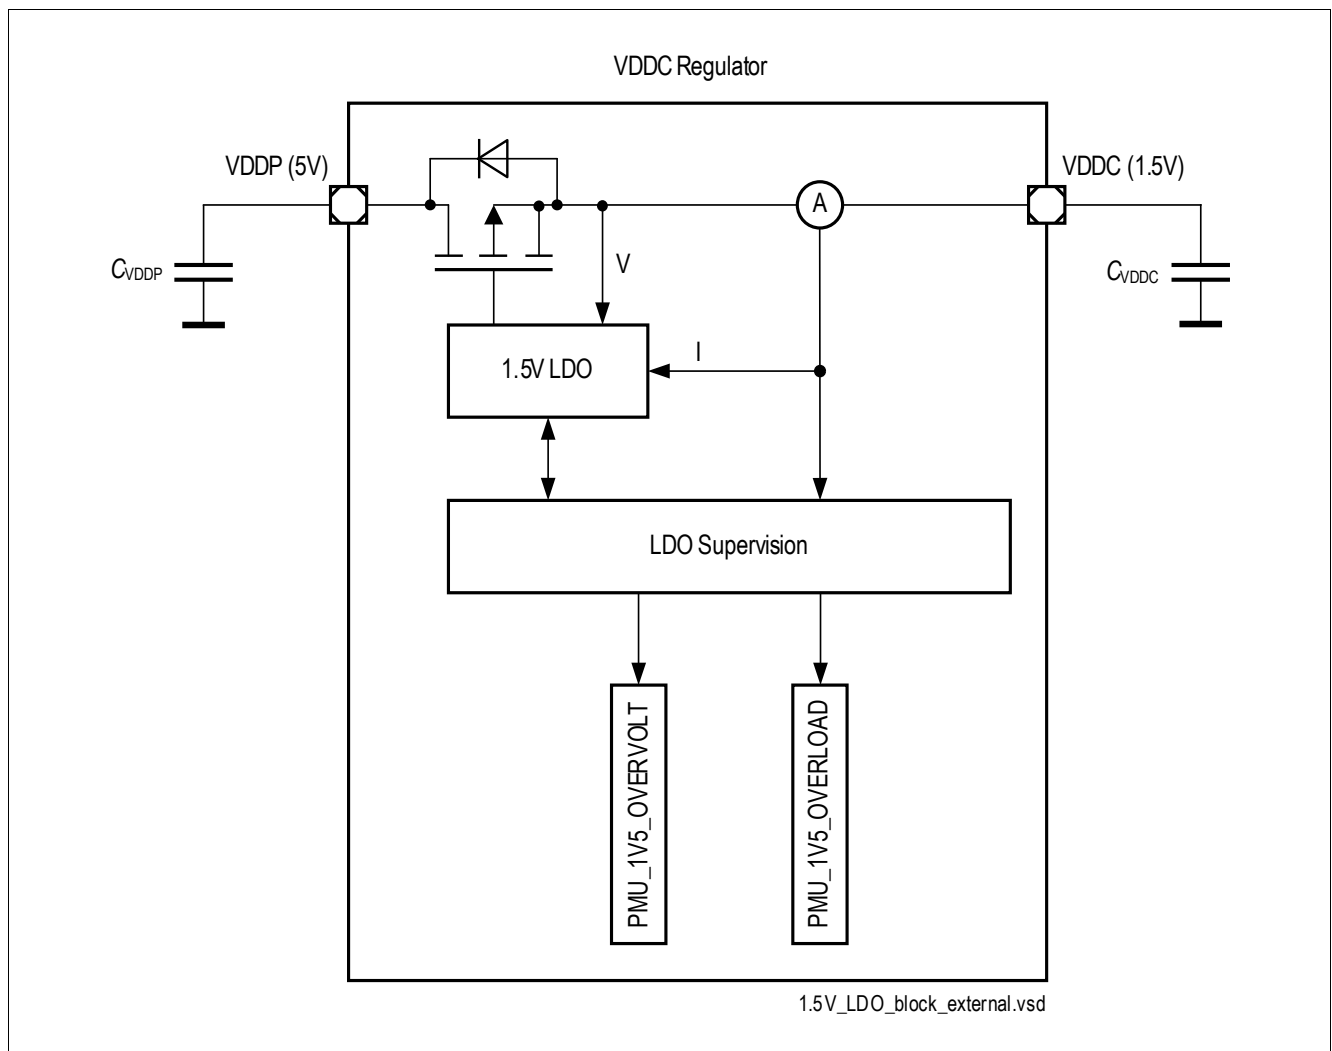

Figure 10 Module Block Diagram of VDDC Voltage Regulator

6.3.3 External Voltage Regulator 5.0V (VDDEXT)

This module represents the 5 V voltage regulator, which serves as a supply for external circuits. It can be used e.g. to supply an external sensor, LEDs or potentiometers.

Features

- Switchable +5 V, low-drop voltage regulator
- Switch-on overcurrent blanking time in order to drive small capacitive loads
- Overcurrent monitoring and shutdown with MCU signalling (Interrupt)
- Overvoltage monitoring with MCU signalling (Interrupt)
- Undervoltage monitoring with MCU signalling (Interrupt)
- Pull Down current source at the output for Sleep Mode only (typ. 100 μ A)
- Cyclic sense option together with GPIOs

The output capacitor C_{VDDEXT} is mandatory to ensure a proper regulator functionality.

6.3.4 Register Definition

Table 6 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition, Power Supply Generation Register			
PMU_SUPPLY_STS	Voltage Reg Status Register	004 _H	00xx 00xx _B
Register Definition, VDDEXT Control Register			
VDDEXT_CTRL	VDDEXT Control Register	008 _H	xxxx 0000 _B

The registers are addressed wordwise.

6.3.4.1 Power Supply Generation Register

The following register is dedicated to control the voltage regulators VDDP, VDDC. It provides an overview about the status of the two voltage supplies.

Voltage Reg Status Register

The PMU_SUPPLY_STS register shows the overvoltage and overload condition of VDDP and VDDC. To use this information as interrupt sources it must be selected explicitly in this register. The register is reset by RESET_TYPE_0.

PMU_SUPPLY_STS	Offset	Reset Value
Voltage Reg Status Register	004_H	00xx 00xx_B

7	6	5	4	3	2	1	0
Res	PMU_5V_FAIL_EN	PMU_5V_OVERLOAD	PMU_5V_OVERVOLT	Res	PMU_1V5_FAIL_EN	PMU_1V5_OVERLOAD	PMU_1V5_OVERVOLT
r	rw	r	r	r	rw	r	r

Field	Bits	Type	Description
Res	7	r	Reserved Always read as 0
PMU_5V_FAIL_EN	6	rw	Enabling of VDDP status information as interrupt source 0 _B No interrupts are generated 1 _B Interrupts are generated

Power Management Unit (PMU)

Field	Bits	Type	Description
PMU_5V_OVERLOAD	5	r	Overload at VDDP regulator <i>Note: if this flag is set and an additional filter time of 290 us (typ.) is passed the system will be put to sleep mode</i> 0 _B No overload 1 _B Overload
PMU_5V_OVERVOLT	4	r	Overvoltage at VDDP regulator 0 _B No overvoltage 1 _B Overvoltage
Res	3	r	Reserved Always read as 0
PMU_1V5_FAIL_EN	2	rw	Enabling of VDDC status information as interrupt source 0 _B No interrupts are generated 1 _B Interrupts are generated
PMU_1V5_OVERLOAD	1	r	Overload at VDDC regulator <i>Note: if this flag is set and an additional filter time of 290 us (typ.) is passed the system will be put to sleep mode</i> 0 _B No overload 1 _B Overload
PMU_1V5_OVERVOLT	0	r	Overvoltage at VDDC regulator 0 _B No overvoltage 1 _B Overvoltage

Figure 12 VDDP

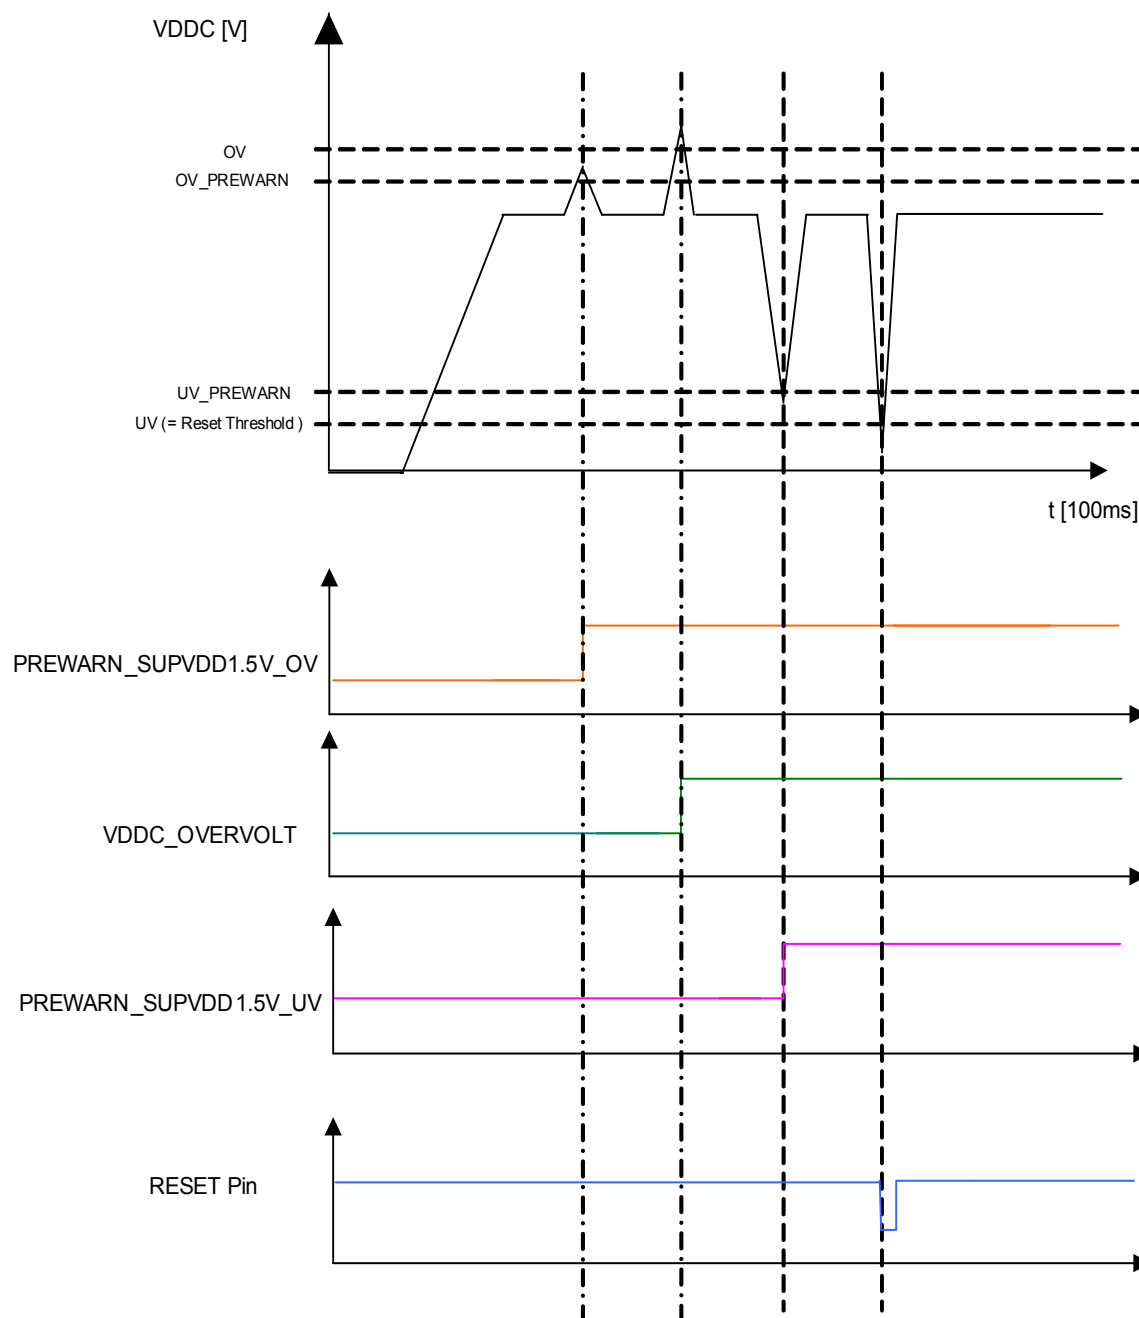

Figure 13 VDDC

6.3.4.2 VDDEXT Control Register

The VDDEXT can be fully controlled by the following SFR Register, including all diagnosis functions. There are two overvoltage-undervoltage ranges implemented (range 1 is $V_{DDEXT} \pm 250$ mV, range 2 is $V_{DDEXT} \pm 500$ mV) which serve as a supply prewarning. Both cases are indicated by the bits VDDEXT_STABLE and VDDEXT_OK.

VDDEXT Control

The register is reset by RESET_TYPE_3.

The status flag SHORT leads to a shutdown off VDDEXT. To re-enable VDDEXT the SHORT flag needs to be cleared.

VDDEXT_CTRL	Offset	Reset Value
VDDEXT Control	008 _H	xxxx 0000 _B

7	6	5	4	3	2	1	0
STABLE	OK	OVERLOAD	OVERVOLT	SHORT	FAIL_EN	RES	ENABLE
r	r	rwh	rwh	rwh	rw	r	rw

Field	Bits	Type	Description
STABLE	7	r	VDDEXT Supply works inside its specified range 1 1 _B VDDEXT Voltage inside of specified range 0 _B VDDEXT Voltage outside of specified range
OK	6	r	VDDEXT Supply works inside its specified range 2 1 _B VDDEXT in low drop mode 0 _B VDDEXT not in low drop mode
OVERLOAD	5	r	VDDEXT Supply Overload <i>Note:</i> This flag is automatically cleared, if error condition is removed. 0 _B VDDEXT not in overload condition 1 _B VDDEXT in overload condition
OVERVOLT	4	r	VDDEXT Supply Overvoltage <i>Note:</i> This flag is automatically cleared, if error condition is removed. 0 _B VDDEXT not in overvoltage condition 1 _B VDDEXT in overvoltage condition
SHORT	3	rwh	VDDEXT Supply Shorted Output <i>Note:</i> if this flag is set VDDEXT regulator is automatically switched off. To re-enable VDDEXT software must clear this flag. SHORT flag has RESET_TYPE_0. 0 _B VDDEXT no short circuit 1 _B VDDEXT short circuit

Power Management Unit (PMU)

Field	Bits	Type	Description
FAIL_EN	2	rw	Enabling of VDDEXT Supply status information as interrupt source 0 _B VDDEXT fail interrupts are disabled 1 _B VDDEXT fail Interrupts are enabled
CYC_EN	1	rw	VDDEXT Supply for Cyclic Sense Enable <i>Note: To use VDDEXT Supply for cyclic sense the bits CYC_EN AND ENABLE must be set</i> 0 _B VDDEXT for cyclic sense disable 1 _B VDDEXT for cyclic sense enable
ENABLE	0	rw	VDDEXT Supply Enable 0 _B VDDEXT Supply disabled 1 _B VDDEXT supply enabled

6.4 Power Control Unit

The Power Control Unit is the controlling instance of the system Power supply Generation Unit (PGU). It offers important fail safe features, which are described in the following subchapters.

6.4.1 Power Control Unit - Fail Safe Scenarios

The PMU handles several different failure scenarios, listed below and described in the following chapters:

- Fail safe mode (Sleep Mode) in case of power failure.
- Fail safe mode (Sleep Mode) in case of watchdog service failure.
- Fail safe mode (Sleep Mode) in case of overcurrent on voltage regulators VDDP or VDDC.
- 2 level monitoring (prewarning and reset) of voltage regulators output voltages (VDDP, VDDC, VDDEXT).
- Wake-Up from Stop Mode with cyclic sense in case of VDDEXT regulator failures.
- Wake-Up from Stop Mode in case of hardware reset on RESET pin.

6.4.1.1 Power Supervision Function of PCU

The power supervision feature of the PCU is mainly responsible for monitoring the voltage regulators VDDP and VDDC. In case of voltage regulator malfunction, the PCU restarts the voltage regulators (VDDP and VDDC). Each time this happens the error counter "error_supp" is incremented. If the counter reaches the value 5, the PCU supervision function will set the device into Sleep Mode. In this case the device can still be waked up by LIN and MON input.

After a wake-up, if the PMU can be successfully restarted and code execution will be possible, the user is able to determine the occurred failure scenario by checking the corresponding **SYS_FAIL_STS** register. In this case bit **SUPP_TMOUT** is set.

If there is a short circuit at the VDDC/VDDP voltage regulator during startup, the reset of the embedded MCU is set and the system goes to startup mode. The error counter "error_supp" is increased by one. After this the PCU itself tries to go to Active Mode again using the power-on sequence. If the short circuit still exists then the procedure is repeated. This procedure will run, as already described above, only 5 times. After reaching the value 5, the PCU sends the system into Sleep Mode.

If a successful startup after wake-up from Sleep Mode is possible, the user is able to verify the failure, by reading the **SUPP_TMOUT** flag in the **SYS_FAIL_STS** register.

6.4.1.2 Watchdog (WDT1) Fail Safe

The PCU supervises the failure information of the system watchdog (WDT1). In case the watchdog is not serviced or serviced in a wrong way (in the following denominated as “not serviced Watchdog”) the MCU is reset and the error counter “error_wdt” is increased by one. The PMU itself stays in the Active Mode and after the reset the application software takes over the system control. If the software doesn’t service the system watchdog then the described procedure starts again. After the watchdog is not serviced five times during one Active Mode period the PMU sends the embedded system to Sleep Mode. The PMU detects the transition to the Sleep Mode as safety fallback and the Sleep Mode can be terminated by two ways: first by a LIN-wake or by a rising/falling edge at a MON pin, second cyclic wake is issued after a sleep time of 1 s. The error counter is reset when the system is sent to Sleep Mode or Stop Mode by a corresponding software command.

If the system can be successfully restarted, the cause of failure can be again checked by reading the **SYS_FAIL_STS** register. The bit **WDT1_SEQ_FAIL** signals the described failure.

6.4.1.3 Main Regulators Fail Safe

If one of the voltage regulators needs to deliver too much current, a stable operation of the supply voltage is not given. In this case the overcurrent detection of VDDP and VDDC will ensure that the system will enter Sleep Mode.

If the Overcurrent condition is gone, a wake-up can be generated, then the system will startup and work properly. Afterwards the corresponding failure flags **PMU_1V5_OVL** and **PMU_5V_OVL** can be checked.

6.4.1.4 VDDEXT Failure

If VDDEXT is used in combination with the GPIOs as a supply e.g. for the switches, there are several error cases possible, which are: Overvoltage, overload and short circuit to GND. Those error cases may lead to the generation of false wake-up events or to missed wake-up events. To avoid these scenarios, errors on the VDDEXT voltage regulator would automatically revive the system from Stop Mode. The errors are signalled in the **WAKE_STS_FAIL** register.

6.4.1.5 Wake-Up from Stop Mode with Reset Fail Safe

One fail safe measure to wake-up the embedded system from the Stop-Mode can be executed by hardware reset. If there is a reset request on the reset-pin then the PMU goes to Active Mode. Simultaneously, the embedded system gets a reset which is shown by forcing the bidirectional reset-pin. The reset-pin goes high again if the PMU releases the MCU reset. This event is shown in the reset status register as a hard-reset together with a wake-up reset. In case of a fail condition at one of the voltage regulators the PMU also goes to Active Mode. After that the PMU starts the supply fail-safe procedure which is described in the Active Mode section. The described sequence can be seen in the picture below.

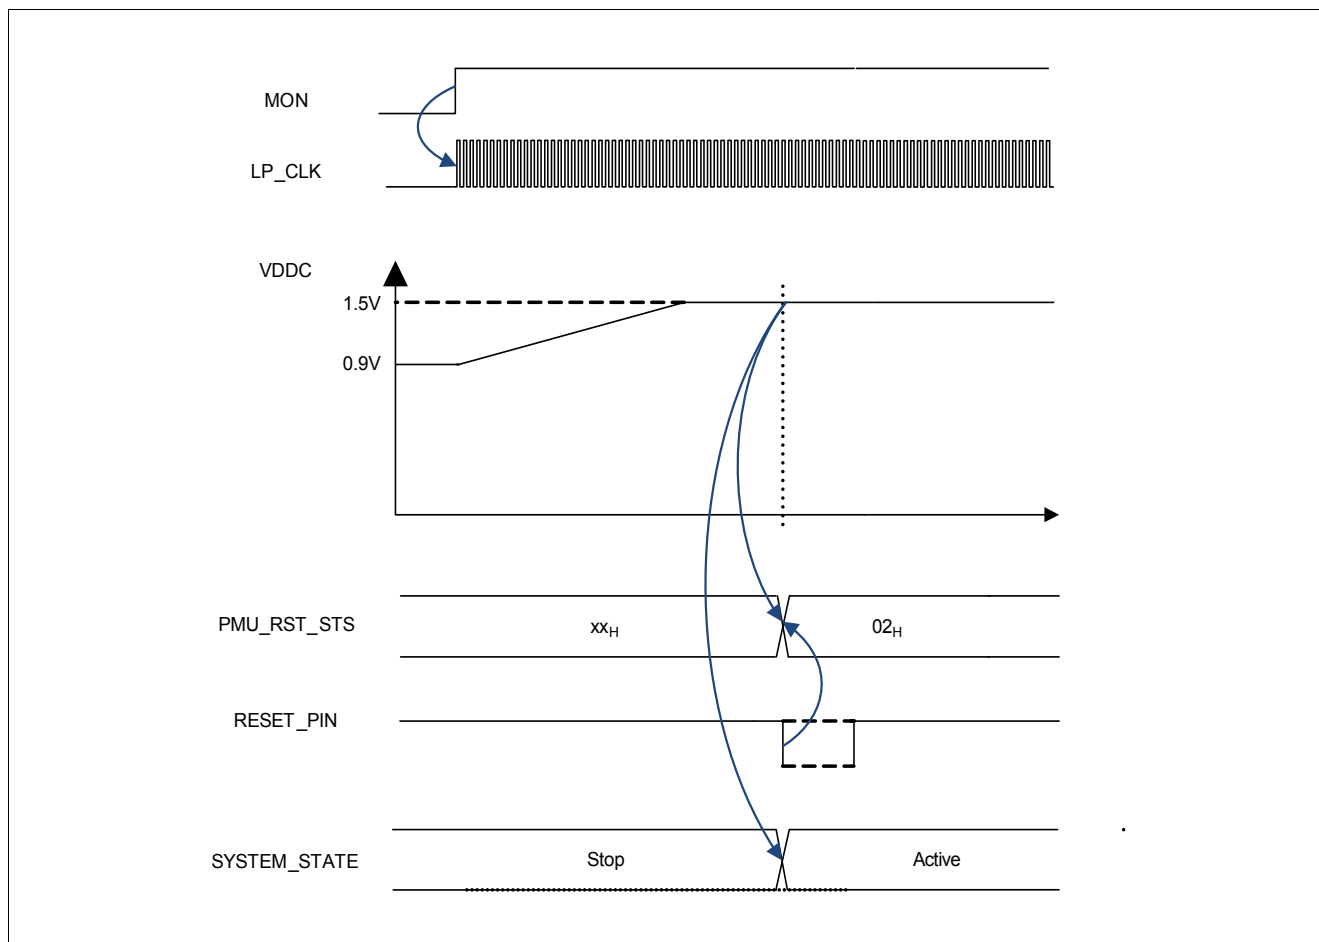

Figure 14 Stop Mode Exit Timing

6.4.2 Register Definition

Table 7 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition, PMU System Fail Register

6.5 Wake-Up Management Unit (WMU)

6.5.1 Functional Description

The Wake-Up Management Unit (WMU) is mainly responsible for handling the wake-up events on LIN, HV-Monitoring Inputs (MON), Hardware reset and all GPIOs belonging to Port 0 and Port 1. Following wake scenarios are possible:

- **Wake-Up over Port 0 and Port 1 pins:** they can be configured for rising edge triggered and falling edge triggered wake-up events. This configuration can be used to wake-up the device from normal Stop Mode and Stop Mode with cyclic sense option. To bias the GPIOs, VDDEXT as voltage source can be used. The wake-up feature from Sleep Mode in combination with GPIOs is not possible.
- **Wake-Up over Hardware reset pin:** It can be used to wake-up the device from Stop Mode. The wake-up feature from Sleep Mode is not possible.
- **Wake-Up over MON Pins:** the MON Pins can be configured for rising edge triggered and falling edge triggered wake-up events. This setup can be used to wake-up the device from Stop Mode with or without cyclic sense, but also a wake-up from Sleep Mode with or without cyclic sense is possible.
- **LIN:** is a normal wake-up source and has no configuration possibilities.
- **Wake-Up on VDDEXT fail from Stop Mode:** will be performed in case of VDDEXT failures described in Chapter [Power Control Unit - Fail Safe Scenarios](#).

Note:

1. Port 2 pins cannot invoke any wake-up.
2. None of the GPIOs is supplied during Sleep Mode, therefore wake-up is not possible through them.

Figure 15 Block Diagram of Wake-Up Management Unit in Cyclic Sense Mode with VDDEXT

6.5.2 Register Definition

These registers are for wake-up control of all wake-up capable general purpose inputs outputs

The WMU is fully controllable by the below listed SFR Registers.

Table 8 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value

6.6 Cyclic Management Unit (CMU)

6.6.1 Functional Description

The cyclic management unit is responsible for controlling the timing sequence in cyclic sense or cyclic wake operation. The unit operates with the LP_CLK2 clock.

6.6.2 Cyclic Sense Mode

To select a dedicated GPIO0.x / GPIO1.x pin for cyclic sense mode, the bit GPIO0_CYC_x / GPIO1_CYC_x need be set in the corresponding **WAKE_CONF_GPIO0_CYC** / **WAKE_CONF_GPIO1_CYC** register.

In this configuration the wake-up information of this GPIO0.x / GPIO1.x pin is only accepted during the sensing time where the VDDEXT supply (internal VDDEXT_CYC_ON gating signal) is on (see [Figure 16](#)). The sensing time where the enable signal is active, will be set in the **CNF_CYC_SENSE** and **CNF_CYC_SAMPLE_DEL-SFR**. The flags inside **CNF_CYC_SENSE** register are used to configure the dead time (T_{Dead}). The **CNF_CYC_SAMPLE_DEL** register is used to program the sample delay of the wake inputs and thus the on-time (T_{On}).

After a valid wake-up event the start-up sequence is similar to the asynchronous wake-up and the system enters the Start-up Mode automatically too. If the PMU detects a wake-up during Cyclic Sense then the enable signal of the voltage source (VDDEXT) stays active as long the application software doesn't disable this signal.

[Figure 16](#) illustrates the principle of the cyclic sense mode. Here the VDDEXT supply is used as voltage source together with a GPIO pin as a wake-up source. This can be applied to all GPIOs from Port 0 and Port 1.

Figure 16 Timing Diagram for Cyclic Sense

6.6.2.1 Configuration of Cyclic Sense Mode

The configuration of cyclic sense mode is shown in [Figure 17](#).

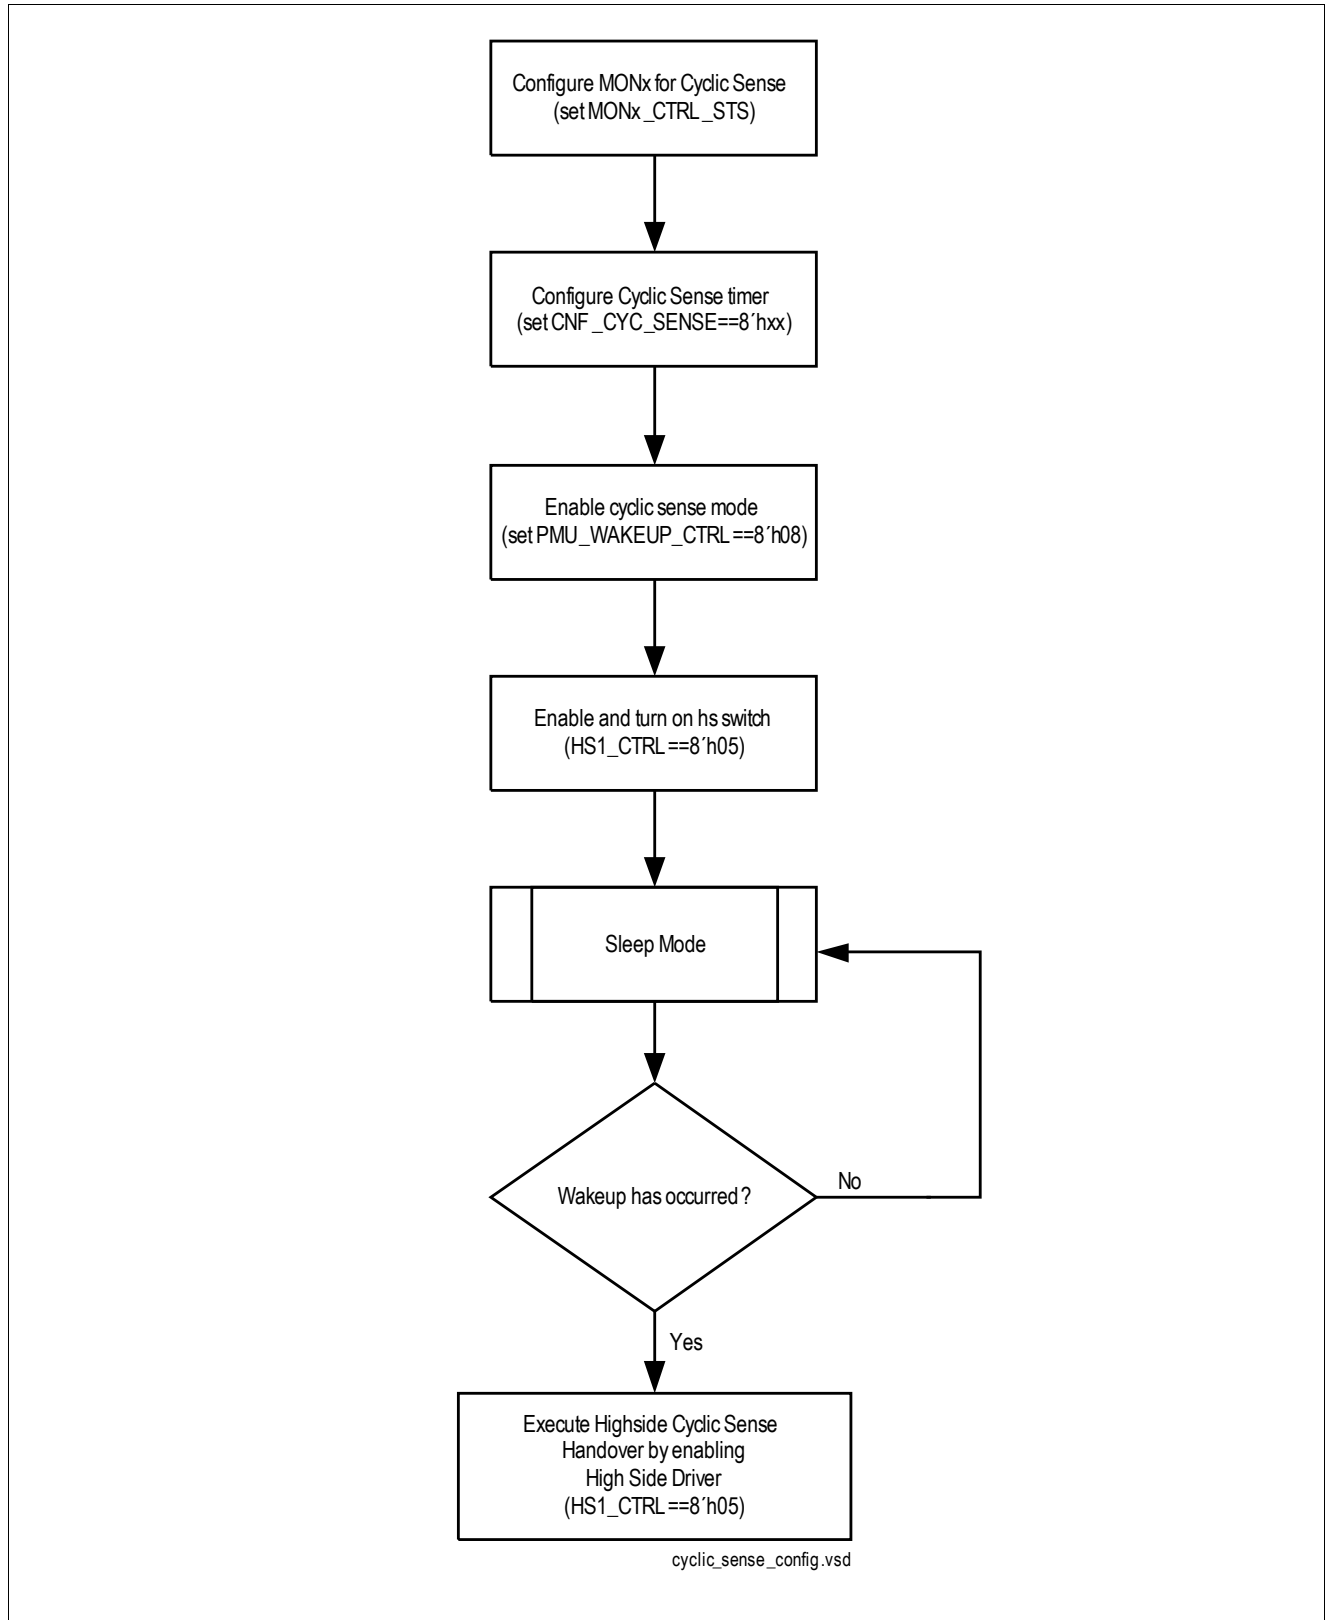

Figure 17 Configuration Flow of cyclic sense mode

6.6.3 Cyclic Wake Mode

Cyclic Wake Mode provides a synchronous wake-up after a predefined time interval in Sleep Mode or Stop Mode. Once the time interval is elapsed the PMU enters the Startup Mode and proceeds to Active Mode where the software takes over the system control. The cyclic wake interval is set in the **CNF_CYC_WAKE-XSFR**.

6.6.4 Register Definition

Dead Time in Cyclic Sense Register

The register is reset by RESET_TYPE2.

The dead time of Cyclic Sense will be configured in the CNF_CYC_SENSE register.

The following formula shows how the dead time for Cyclic Sense mode will be calculated:

$$4^{(E1E0)} \cdot (M3M2M1M0 + 1) \cdot 2ms$$

E1E0 represents the register flags CYC_SENSE_E01 and M3M2M1M0 represents the register flags CYC_SENSE_M03.

6.7 Reset Management Unit (RMU)

6.7.1 Functional Description

The Reset Management Unit (RMU) controls the reset behavior of the entire device. The master reset of the device is the power-on reset of the PMU itself. This reset is generated by the Power Down Supply and it is released when the battery voltage (V_s) reaches the minimum supply voltage for Active Mode. Then the PMU starts the sequence to power up the supply generation module which ends with the release of the MCU reset. If this status is reached then the embedded system will work in Active Mode. This scenario is signalled by the PMU_1V5DidPOR flag in the **PMU_RESET_STS1**. The figure below shows the power-on reset behavior.

Figure 18 Power-On and Startup Behavior of Reset

In case of a Sleep Mode exit a similar sequence like for battery ramp-up starts is used. If this sequence ends successfully then the PMU also releases the reset of the MCU. From the MCU point of view there is no difference to the battery ramp-up. Only inside of the RMU the identification bit **PMU_SleepEx** is set instead of the power-on identification bit. The power down sequence looks as follows:

Figure 19 Power-Down and Power Loss Sequence

In the default configuration the wake-up from Stop Mode works without reset. To wake-up with reset the corresponding **SFR** bit **WAKE_W_RST** inside the **CNF_PMU_SETTINGS** register need be configured. With this configuration the wake-up signal sets the dedicated identification bit **PMU_WAKE** which can be checked by the application software.

The third hardware related reset source is the pin-reset. The pin itself is supplied by the **VDDP** domain which is available in Active Mode and Stop Mode. Therefore the reset-pin can be used in Active Mode and Stop Mode only. Due to the bidirectional use of the pin itself the pin-reset request is gated during the execution of another reset request (e.g. soft-reset). For this purpose the pin-reset request must be stable for more than 500 ns (see

Figure 16). In case of a pin-reset request during Stop Mode the PMU goes to Active Mode and sends the wake-up signal to the MCU. At this time the reset status register also gets an update by setting bit PMU_PIN, which signals the described reset source. All other reset sources can only have an impact on the system behavior in Active Mode.

The reset request caused by a not served or wrongly served system watchdog, is also processed as a hardware related reset although this reset request is implicitly controlled by user software. The system watchdog only works in Active Mode. In this case it expects a periodic trigger (window watchdog) from the user software. If the trigger is missing then the PMU gets the signal that the watchdog was not serviced which sets the identification bit PMU_ExtWDT from WDT1. After some clock cycles of the PMU internal oscillator LP_CLK the PMU resets the MCU.

The software-reset and the reset request caused by the MCU internal watchdog are controlled explicitly by user software and can be used only in Active Mode. From the system point of view both of these reset sources have the lowest priority. The software related reset is executed within two MCU clock cycles. The system clock of the PMU works independently of the MCU clock. Due to these system conditions the PMU processes the software related resets asynchronously to its internal system clock. The software-reset is flagged by the PMU_SOFT bit. The MCU internal watchdog is signalled by the PMU_IntWDT bit. Both flags are located in the **PMU_RESET_STS2** register.

Another reset source is the PGU module. In case the main voltage regulators (VDDP and VDDC) will fail, the system will execute a system reset and enter Sleep Mode afterwards. This case is flagged by setting the indication bit SYS_FAIL.

Reset types are combinations of the above described resets. The reset of an XSFR register is depending on the corresponding reset type. Other registers (all SFRs except NMI status flags) are always reset independent of the reset type. The figure below shows this combination of resets.

	SoC power-on	Sleep-Mode	Pin-Reset	WDT_EXT	SOFT	WDT_INT	error_sup=5	error_wdt=5
RESET_TYPE_0	X							
RESET_TYPE_1	X						X	X
RESET_TYPE_2	X		X	X	X	X	X	X
RESET_TYPE_3	X	X	X	X	X	X	X	X
RESET_TYPE_4	X	X	X	X			X	X

XSFR_reset_types_customer.vsd

Figure 20 Reset Types of SFRS provided by the RMU

Out of these above listed resets mainly five reset types are derived:

- **RESET_TYPE_0** contains:
 - PMU_1V5DidPOR: this reset is issued when the power down supply detects undervoltage
- **RESET_TYPE_1** is an OR of:

- PMU_1V5DidPOR
- PMU_FAIL: this reset is issued when the VDDC or VDDP supply have a failure
- WDT_FAIL: this reset is issued when the WDT1 is not triggered consecutively 5 times properly
- **RESET_TYPE_2** is an OR of:
 - PMU_1V5DidPOR
 - PMU_PIN: this reset is issued when the RESET-Pin is pulled down
 - PMU_ExtWDT: this reset is a WDT1 related reset
 - PMU_IntWDT: this reset is an internal WDT issued reset
 - PMU_SOFT: this reset is a software related reset
 - PMU_Wake: this reset is a stop wake-up related reset
 - PMU_FAIL
 - WDT_FAIL
- **RESET_TYPE_3** is an OR of:
 - PMU_1V5DidPOR
 - PMU_PIN
 - PMU_ExtWDT
 - PMU_IntWDT
 - PMU_SOFT
 - PMU_Wake
 - PMU_SleepEx: this reset is a sleep wake-up related reset
 - PMU_FAIL
 - WDT_FAIL
- **RESET_TYPE_4** is an OR of:
 - PMU_1V5DidPOR
 - PMU_PIN
 - PMU_ExtWDT
 - PMU_Wake
 - PMU_SleepEx: this reset is a sleep wake-up related reset
 - PMU_FAIL
 - WDT_FAIL

Every register has its own reset type listed. In the Power Management Unit SFRs following reset types are used:

- RESET_TYPE_0
- RESET_TYPE_1
- RESET_TYPE_2
- RESET_TYPE_3
- RESET_TYPE_4

6.7.2 Register Definition

Table 10 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition, Reset Management Unit Registers (RMU)			
PMU_RESET_STS1	Reset Status Hard Register	010 _H	0000 0000 _H
PMU_RESET_STS2	Reset Status Soft Register	014 _H	0000 0000 _H
CNF_RST_TFB	Reset Blind Time Register	06C _H	0000 0003 _H

The registers are addressed wordwise.

6.7.2.1 Reset Management Unit Registers (RMU)

Reset Blind Time Register

The Reset Pin is a bidirectional signal. Every reset will be signaled on that pin for a few 100 ns. In order to avoid any reset deadlock situation there is a programmable reset blind time, where no hardware pin reset will be recognized. The reset blind time envelopes the phase, where the reset pin acts as an active reset output. The register is reset by RESET_TYPE_2.

CNF_RST_TFB	Offset	Reset Value
Reset Blind Time Register	06C_H	0000 0003_H

Field	Bits	Type	Description
RES	7:2	r	Reserved Always read as 0
RST_TFB	1:0	rw	Reset Pin Blind Time Selection Bits These bits select the blind time for the reset input sampling. 00 _B RST_TFB_0 0,5 µs typ. 01 _B RST_TFB_1 1 µs typ. 10 _B RST_TFB_2 5 µs typ. 11 _B RST_TFB_3 31 µs typ.

Power Management Unit (PMU)

Reset Status Hard Register

The PMU_RESET_STS1 register shows every executed reset request. The PMU writes the corresponding register bit of an executed reset. To clear the information of the PMU_RESET_STS1 register the user must overwrite the corresponding bit with a logic zero. The register is reset by RESET_TYPE_0.

1) Otherwise this flag is not set. The flag is always set in case of pin reset in Stop Mode (in combination with the flag PMU_PIN).

6.8 PMU Data Storage Area

6.8.1 Functional Description

The PMU provides the possibility for the system to store data in registers which will retain their values, when the device is set to sleep mode. In sum there are 6 x 8 Bit available.

6.8.2 Register Definition

Table 11 Register Overview

7 System Control Unit - Digital Modules (SCU-DM)

7.1 Features

- Flexible clock configuration features
- Reset management of all system resets
- System modes control for all power modes (active, power down, sleep)
- Interrupt enabling for many system peripherals
- General purpose input output control
- Debug mode control of system peripherals

7.2 Introduction

The System Control Unit (SCU) supports all central control tasks in the TLE9869QXA20. The SCU is made up of the following sub-modules:

- Clock System and Control (see [Section 7.3 on Page 89](#))
- Reset Control (see [Section 7.4 on Page 116](#))
- Power Management (see [Section 7.5 on Page 121](#))
- Interrupt Management (see [Section 7.6 on Page 126](#))
- General Port Control (see [Section 7.7 on Page 138](#))
- Flexible Peripheral Management (see [Section 7.8 on Page 150](#))
- Module Suspend Control (see [Section 7.9 on Page 152](#))
- Watchdog Timer (see [Section 7.11 on Page 156](#))
- Error Detection and Correction in Data Memory (see [Section 7.12 on Page 161](#))
- Miscellaneous Control (see [Section 7.13 on Page 164](#))

The mapping of all registers is detailed in [Section 7.2.2 on Page 87](#)

7.2.1 Block Diagram

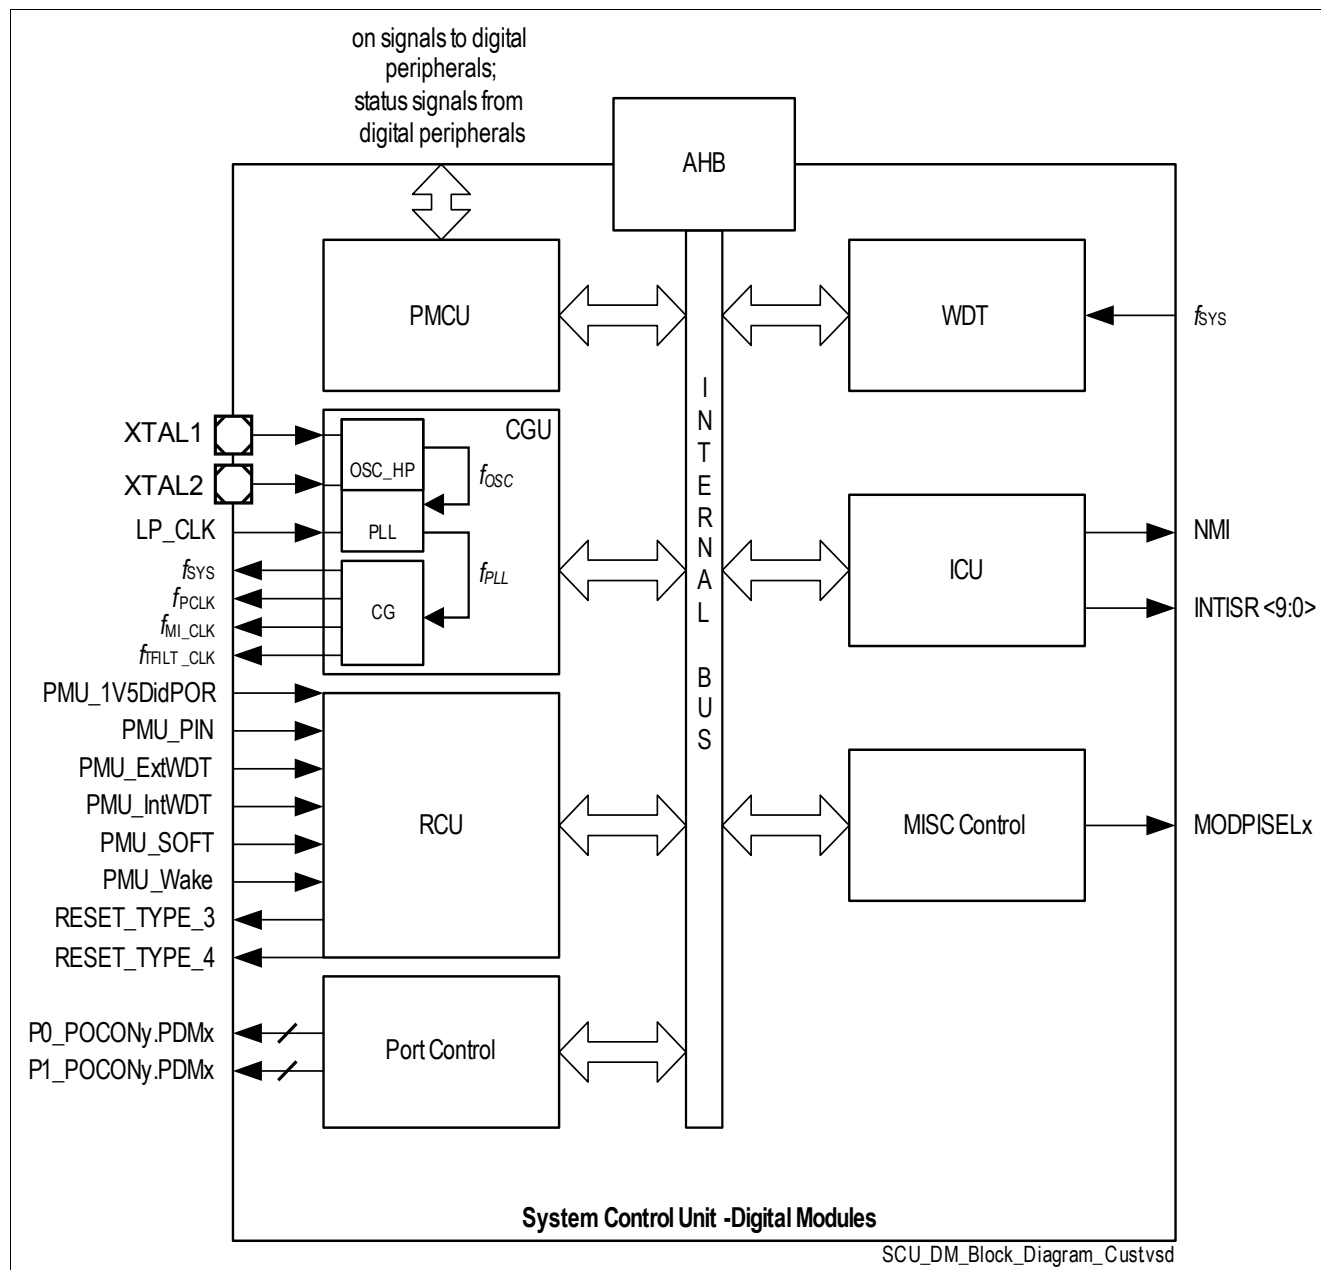

Figure 21 System Control Unit - Digital Modules Block Diagram

AMBA AHB (Advanced High-Performance Bus)

PMCU (Power Module Control Unit)

WDT (Watchdog Timer in SCU-DM)

- f_{SYS} ; System clock

CGU (Clock Generation Unit)

- f_{SYS} ; System clock
- f_{PCLK} ; Peripheral clock

- f_{MI_CLK} ; Measurement interface clock
- f_{TFILT_CLK} ; Analog module filter clock
- LP_CLK; Clock source for all PMU submodules and WDT1

ICU (Interrupt Control Unit)

- NMI (Non Maskable Interrupt)
- INTISR<9:0>; External interrupt signals

RCU (Reset Control Unit)

- PMU_1V5DidPOR; Undervoltage reset of power down supply
- PMU_PIN; Reset generated by reset pin
- PMU_ExtWDT; WDT1 reset
- PMU_IntWDT; WDT (SCU) reset
- PMU_SOFT; Software reset
- PMU_Wake; Sleep Mode/Stop Mode exit with reset
- RESET_TYPE_3; Peripheral reset (contains all resets)
- RESET_TYPE_4; Peripheral reset (without SOFT and WDT reset)

Port Control

- P0_POCONy.PDMx; driver strength control
- P1_POCONy.PDMx; driver strength control

MISC Control

- MODPISELx; Mode selection registers for UART (source section) and Timer (trigger or count selection)

7.2.2 SCU Register Overview

This chapter contains an overview of all SCU Registers.

7.2.2.1 Register Map

There are two SCU kernels in the TLE9869QXA20, namely SCU1 and SCU2. SCU1 is dedicated for LIN transmission. SCU2 is dedicated for external UART communication.

Table 13 lists the addresses of the SCU SFRs.

Table 12 shows the SCU module base addresses.

Table 12 Registers Address Space

Module	Base Address	End Address	Note
SCU	5000 5000 _H	5000 5FFF _H

7.3 Clock Generation Unit

The Clock Generation Unit (CGU) provides a flexible clock generation for TLE9869QXA20. During user program execution the frequency can be programmed for an optimal ratio between performance and power consumption. Therefore the power consumption can be adapted to the actual application state.

The CGU in the TLE9869QXA20 consists of one oscillator circuit (OSC_HP), a Phase-Locked Loop (PLL) module including an internal oscillator (OSC_PLL) and a Clock Control Unit (CCU). The CGU can convert a low-frequency input/external clock signal to a high-frequency internal clock.

The system clock f_{SYS} is generated out of the following selectable clocks:

- PLL clock output f_{PLL}
- Direct clock from oscillator OSC_HP f_{OSC}
- Low precision clock f_{LP_CLK} (HW-enabled for startup after reset and during power-down wake-up sequence)

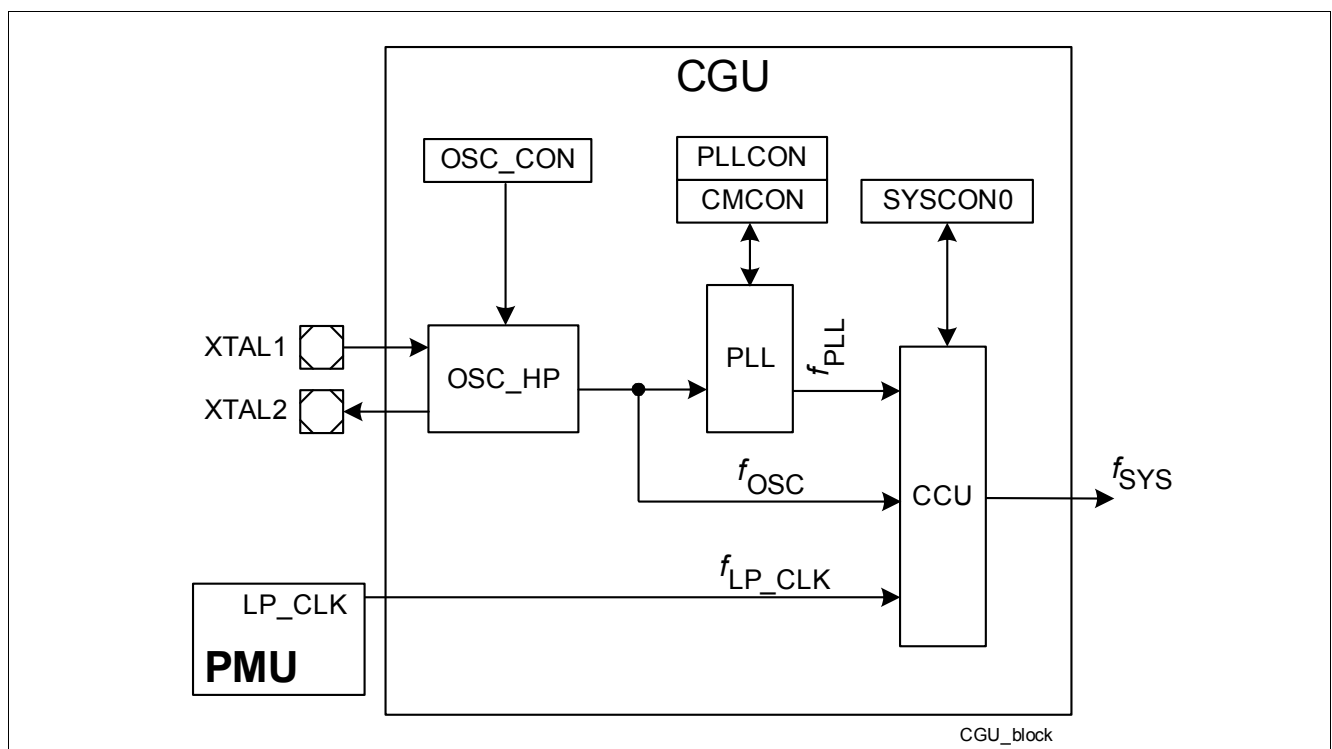

Figure 22 Clock Generation Unit Block Diagram

The following sections describe the different parts of the CGU.

7.3.1 Low Precision Clock

The clock source LP_CLK is a low-precision RC oscillator (LP-OSC) with a nominal frequency of 18 MHz that is enabled by hardware as an independent clock source for the TLE9869QXA20 startup after reset and during the power-down wake-up sequence. There is no user configuration possible on f_{LP_CLK} .

7.3.2 High Precision Oscillator Circuit (OSC_HP)

The high precision oscillator circuit, designed to work with both an external crystal oscillator or an external stable clock source, consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output.

Figure 23 shows the recommended external circuitries for both operating modes, External Crystal Mode and External Input Clock Mode.

7.3.2.1 External Input Clock Mode

When supplying the clock signal directly, not using an external crystal and bypassing the oscillator, the input frequency needs to be equal or greater than 4 MHz if the PLL VCO part is used.

When using an external clock signal it must be connected to XTAL1. XTAL2 is left open (unconnected).

7.3.2.2 External Crystal Mode

When using an external crystal, its frequency can be within the range of 4 MHz to 25 MHz. An external oscillator load circuitry must be used, connected to both pins, XTAL1 and XTAL2. It consists normally of the two load capacitances C_1 and C_2 , for some crystals a series damping resistor might be necessary. The exact values and related operating range are dependent on the crystal and have to be determined and optimized together with the crystal vendor using the negative resistance method. As starting point for the evaluation, the following load cap values may be used:

Table 14 External CAP Capacitors

Fundamental Mode Crystal Frequency (approx., MHz)	Load Caps C_1, C_2 (pF)
4	33
8	18
12	12
16	10
20	10
25	8

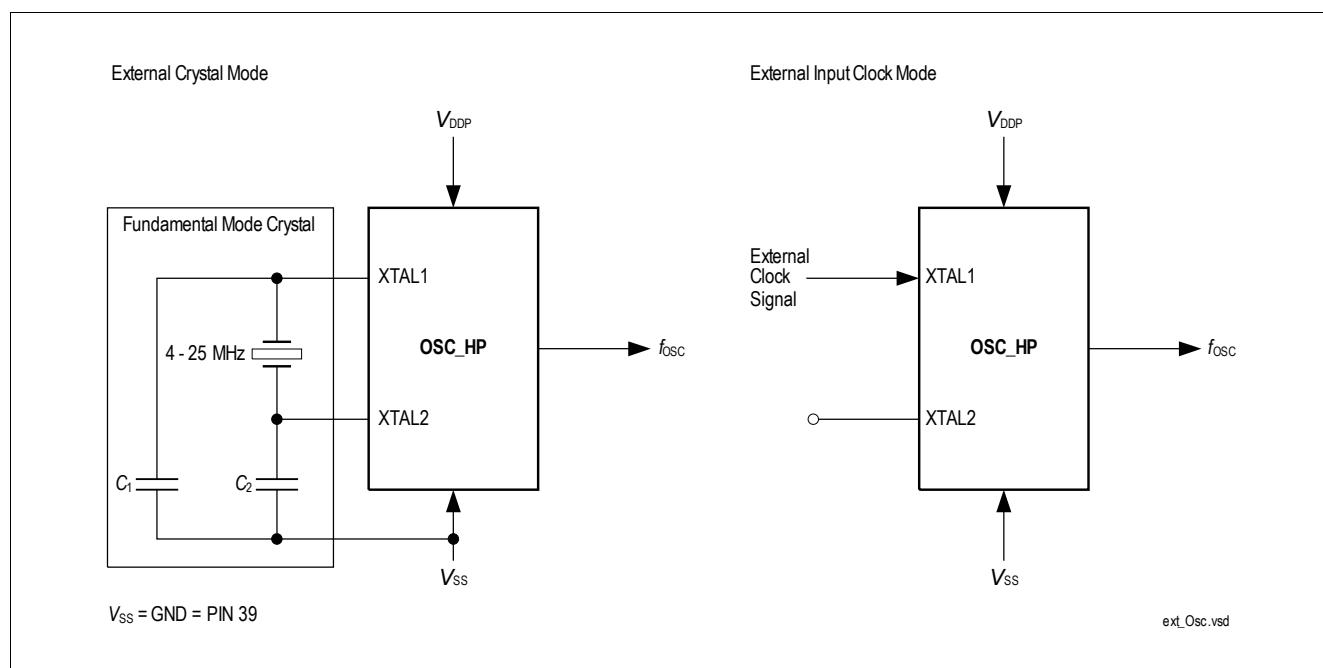

Figure 23 TLE9869QXA20 External Circuitry for the OSC_HP

7.3.3 Phase-Locked Loop (PLL) Module

This section describes the TLE9869QXA20 PLL module.

The clock f_{PLL} is generated in one of the following PLL configured modes:

- Prescaler Mode, also called VCO Bypass Mode
- Normal Mode
- Freerunning Mode

7.3.3.1 Features

Following is an overview of the PLL features/functions:

- Programmable clock generation PLL
- Loop filter
- Input frequency: $f_{OSC} = 4$ to 16 MHz
- VCO frequency: $f_{VCO} = 48$ MHz to 160 MHz (selectable by range)
- VCO lock detection
- Oscillator run detection
- Output frequency: $f_{PLL} = 46.87$ kHz to 80 MHz
- Provided: Fixed input divider **P** = 1
- Provided: 4-bit feedback divider **N**
- Provided: 2-bit output divider **K2** and 1-bit output divider **K1**
- Oscillator Watchdog
- Prescaler Mode
- Freerunning Mode
- Normal Mode
- Sleep Mode, also automatically activated during device power-save mode
- Glitchless switching between both K-Dividers
- Glitchless switching between Normal Mode and Prescaler Mode
- Internal Oscillator for oscillator watchdog
- Internal Oscillator as clock source

7.3.3.2 PLL Functional Description

The following figure shows the PLL block structure.

Figure 24 PLL Block Diagram

The reference frequency f_R can be selected to be taken either from the internal oscillator f_{INT} or from an external clock source f_{OSC} .

The PLL uses up to three dividers to manipulate the reference frequency in a configurable way. Each of the three dividers can be bypassed corresponding to the PLL operating mode (based on f_{PLL}):

- Bypassing P, N and K2 dividers; this defines the Prescaler Mode
- Bypassing K1 divider; this defines the Normal Mode
- Bypassing K1 divider and ignoring the P divider; this defines the Freerunning Mode

Table 15 shows the selectable clock source options.

Table 15 Clock Option Selection

VCOBYP	OSCDISC	Mode Selected
0	0	Normal Mode
1	x	Prescaler Mode
0	1	Freerunning Mode

Normal Mode

In Normal Mode the reference frequency f_R is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2.

The output frequency is given by:

$$f_{PLL} = \frac{N}{P \cdot K2} \cdot f_R \quad (1)$$

The Normal Mode is selected by the following settings

- PLL_CON.VCOBYP = 0
- PLL_CON.OSCDISC = 0

The Normal Mode is active when

- PLL_CON.VCOBYP = 0
- PLL_CON.OSCDISC = 0
- PLL_CON.LOCK = 1

If f_{PLL} is selected as the clock source for system frequency f_{SYS} , the user should enable PLL in normal mode as default.

Prescaler Mode (VCO Bypass Mode)

In Prescaler Mode the reference frequency f_R is only divided down by a factor K1.

The output frequency is given by

$$f_{PLL} = \frac{f_R}{K1} \quad (2)$$

The Prescaler Mode is selected by the following settings

- PLL_CON.VCOBYP = 1
- PLL_CON.OSCDISC = X

The Prescaler Mode is active when

- PLL_CON.VCOBYP = 1
- PLL_CON.OSCDISC = X
- OSC_CON.OSC2L = 0 if f_{OSC} is provided as f_R (OSC_CON.OSCSS = 01_B)

Freerunning Mode

In Freerunning Mode the base frequency output of the Voltage Controlled Oscillator (VCO) $f_{VCObase}$ is only divided down by a factor K2.

The output frequency is given by

$$f_{PLL} = \frac{f_{VCObase}}{K2} \quad (3)$$

The Freerunning Mode is enabled by the following settings/conditions

- PLL_CON.VCOBYP = 0 and PLL_CON.LOCK = 0

or

- PLL_CON.VCOBYP = 1 and OSC_CON.OSCSS = 1 and OSC_CON.OSC2L = 1

or

- PLL_CON.VCOBYP = 0 and PLL_CON.OSCDISC = 1

The Freerunning Mode is active when

- PLL_CON.VCOBYP = 0
- PLL_CON.OSCDISC = 1
- PLL_CON.LOCK = 0

General Configuration Overview

The divider values and all necessary other values can be configured via the PLL configuration registers.

In TLE9869QXA20, the P factor is fixed to 1. **Table 16** gives the valid output frequency range for the P divider dependent on f_R frequency range:

Table 16 P-Divider Factor = 1

P	f_P for $f_R =$				
	4 MHz	5 MHz	10 MHz	16 MHz	25 MHz
1	4	5	10	16	not allowed

Note: Of course the whole range in between two f_R columns in the above table is allowed. E.g. for a range $f_R = 10$ to 16, $f_P = 10$ to 16 MHz.

The P-divider output frequency f_P is fed to the Voltage Controlled Oscillator (VCO). The VCO is a part of PLL with a feedback path. A divider in the feedback path (N divider) divides the VCO frequency. The f_{VCO} range is defined by configuration of VCOSEL.

Table 17 VCO Range

VCOSEL	f_{VCOmin}	f_{VCOmax}	$f_{VCObase}^{1)}$	Unit
0	48	112	approx. max. 38	MHz
1	96	160	approx. max. 76	MHz

1) $f_{VCObase}$ is the free running operation frequency of the PLLVCO, when no input reference clock is available.

The following table shows the possible N loop division rates and gives the valid output frequency range for f_{REF} depending on N and the VCO frequency range:

Table 18 N Loop Division Rates

N	f_{DIV} for $f_{VCO} =$					
	48	72	96	112	136	160
8	6.00	9.00	12.00	14.00	not allowed ¹⁾	
9	5.33	8.00	10.66	12.44	15.11	not allowed ¹⁾
10	4.80	7.20	9.60	11.20	13.60	16.00
11	4.36	6.54	8.72	10.18	12.36	14.54
12	4.00	6.00	8.00	9.33	11.33	13.33
13	not allowed ¹⁾	5.54	7.38	8.62	10.46	12.31
14 ... 17	
18		4.00	5.33	6.22	7.55	8.88
19		not allowed ¹⁾		5.05	5.89	7.16
20 ... 23		
24			4.00	4.66	5.66	6.66
25	not allowed ¹⁾			4.48	5.44	6.40
26 ... 27			
28				4.00	4.86	5.71

1) Values in this range are only allowed in Freerunning Mode, but have no impact there.

System Control Unit - Digital Modules (SCU-DM)

Note: The whole range in between two f_{VCO} columns in the above table is allowed.

The N-divider output frequency f_{DIV} is then compared with f_{REF} in the phase detector logic, within the VCO logic. The phase detector determines the difference between the two clock signals and accordingly controls the output frequency of the VCO, f_{VCO} .

Note: Due to this operation, the VCO clock of the PLL has a frequency which is a multiple of f_{DIV} . The factor for this is controlled through the value applied to the N-divider in the feedback path. For this reason this factor is often called a multiplier, although it actually controls division.

The output frequency of the VCO, f_{VCO} , is divided by K2 to provide the final desired output frequency f_{PLL} . **Table 19** shows the output frequency range depending on the K2 divisor and the VCO frequency range:

Table 19 K2 Divisor Table

K2	f_{PLL} for $f_{VCO} =$						Duty Cycle [%]
	48	72	96	112	136	160	
2	24.0	36.0	48.0	56.0	68.0	80.0	50
3	16.0	24.0	32.0	37.3	45.3	53.3	46 - 54
4	12.0	18.0	24.0	28.0	34.0	40.0	50
5	9.6	14.4	19.2	22.4	27.2	32.0	48.5 - 51.5

Notes

1. The whole range in between two f_{VCO} columns in the above table is allowed.
2. For divider factors that cause duty cycles far off of 50%, not only the cycle time has to be checked, but also the minimum clock pulse width.

For the K1-divider the same table is valid as for the K2-divider. The only difference is that not f_{VCO} is used as reference, f_R is used instead.

Table 20 K1 Divisor Table

K1	f_{PLL} for $f_R =$			Duty Cycle [%]
	5	8	16	
1	5.0	8.0	16.0	40 - 60
2	2.5	4.0	8.0	50

For different source oscillator, the selection of $f_{PLL} = 24$ MHz or 40 MHz is shown in **Table 21**.

Table 21 System Frequency

f_{PLL} Selected	Oscillator	f_{osc}	N	P	K	Actual f_{sys}
40 MHz	On-chip	5 MHz	16	1	2	40 MHz (default)
	External	10 MHz	8	1	2	40 MHz
		8 MHz	10	1	2	40 MHz
24 MHz	On-chip	5 MHz	24	1	5	24 MHz
	External	12 MHz	8	1	4	24 MHz
		8 MHz	12	1	4	24 MHz
		6 MHz	12	1	3	24 MHz

For the TLE9869QXA20, the value of P is fixed to 1. In order to obtain the required f_{PLL} , the values of VCOSSEL, N and K can be chosen respectively by the bits VCOSSEL, NDIV and KDIV (either K2DIV or K1DIV) for different oscillator input frequency.

7.3.3.3 Oscillator Watchdog

The oscillator watchdog monitors the external incoming clock f_{OSC} . Only incoming frequencies that are too low (below 300 kHz) to enable a stable operation of the VCO circuit are detected.

As reference clock the internal oscillator (OSC_PLL) frequency f_{INT} is used and therefore the internal oscillator must be put into operation.

By setting bit OSC_CON.OSCWDTRST the detection can be restarted without a reset of the complete PLL. The detection status output is only valid after some cycles of f_{INT} .

7.3.3.4 PLL VCO Lock Detection

The PLL has a lock detection that supervises the VCO part of the PLL in order to differentiate between stable and instable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system. [Table 22](#) shows values below that the lock is not lost for different input values.

Table 22 Loss of VCO Lock Definition

Maximum Allow Changing		
$\frac{df_{DIV}}{dt}$ for $f_{REF} =$ (4)		
4 MHz	10 MHz	16 MHz
≤ 0.6 kHz/ μ s	≤ 3.7 kHz/ μ s	≤ 9.5 kHz/ μ s
20 MHz	25 MHz	40 MHz
≤ 14.9 kHz/ μ s	≤ 23.2 kHz/ μ s	≤ 59.5 kHz/ μ s

7.3.3.5 Internal Oscillator (OSC_PLL)

The PLL internal oscillator is used for two different purposes:

Operating the Oscillator Watchdog

The input frequency for the PLL direct from OSC_HP (XTAL), is supervised using the OSC_PLL as reference frequency. For more information see [Section 7.3.3.3](#).

Providing a Input Clock to the PLL

The OSC_PLL can be used as input clock for all PLL modes. This is controlled and configured via OSC_CON.OSCSS.

OSC_PLL operates at a nominal frequency of 5 MHz.

7.3.3.6 Switching PLL Parameters

The following restriction applies when changing PLL parameters via the PLL_CON register:

- Prescaler Mode (VCO bypass) may be enabled at any time, however, it has to be ensured that the maximum operating frequency of the device (see data sheet) will not be exceeded.
- Before switching NDIV, the Prescaler Mode has to be selected.
- VCOSEL and KDIV may be switched at any time, however, it has to be ensured that the maximum operating frequency of the device will not be exceeded.
- Only one parameter should be switched at one register write operation.
- Before switching the input clock source via OSC_CON.OSCSS, the Prescaler Mode has to be selected. Due to a following potential oscillator watchdog event, the PLL may switch to Freerunning Mode. The procedure to set up the PLL in normal operation follows that as stated in [Section 7.3.3.8](#).
- Before deselecting the Prescaler Mode, the RESLD bit has to be set and then the LOCK flag has to be checked. Only when the LOCK flag is set again, the Prescaler Mode may be deselected.
- Before changing VCOSEL, the Prescaler Mode must be selected.

7.3.3.7 Oscillator Watchdog Event or PLL Loss of Lock Detection

In case of detection of too low frequency of the external clock source f_{OSC} , the OSC-Too-Low flag (OSC_CON.OSC2L) is set. If enabled by NMICON.NMIOWD, a trap request to the CPU is activated correspondingly only in these two cases: 1) When PLL is in Prescaler Mode and OSCSS = 01 selecting f_{OSC} as PLL input clock source and SYSCON0.SYSCLKSEL selects PLL clock output as the system frequency, or 2) When SYSCON0.SYSCLKSEL selects f_{OSC} as the system frequency. With these 2 cases and the OSC2L condition, the OWD NMI flag FNMIOWD in NMISR is set.

Note: Do not restart the oscillator watchdog detection by setting bit OSC_CON.OSCWDTRST while PLL is in Prescaler Mode, as the detection status (OSC_CON.OSC2L) takes some time to be stable.

An oscillator watchdog event normally leads to a following PLL loss-of-lock detection.

If PLL is not the system clock source (SYSCON0.SYSCLKSEL deselects PLL or PLL is in Prescaler Mode) when the loss-of-lock is detected, only the lock flag is reset (PLL_CON.LOCK = 0). No loss-of-lock NMI is generated and no further action is taken. Otherwise if PLL is selected as clock source for system frequency and VCOBYP = 0, the PLL loss-of-lock NMI flag FNMIPLL in NMISR is set. If enabled by NMICON.NMIPLL, an NMI trap request to the CPU is activated. In addition, the lock flag is reset. Note that in the first place, the LOCK flag has to be set first before a loss-of-lock NMI request is generated. This avoids a potential PLL loss-of-lock NMI request after device power-on reset.

On an oscillator watchdog event (when PLL is in Prescaler Mode and external clock (OSC_HP) is selected as PLL clock input) or on PLL loss-of-lock detection (when PLL is in Normal Mode), the PLL will be switched to run in the Freerunning Mode on the VCO base frequency divided by K2, which is enforced by hardware until the Prescaler Mode is (re-)selected.

Due to the above, the PLL shall only run in Prescaler Mode when changing the PLL configuration or switching between PLL operation modes.

7.3.3.8 Oscillator Watchdog Event or Loss of Lock Recovery

In case of oscillator watchdog NMI, user software can first check if the PLL remains locked. If not, the clock system can be reconfigured again by executing the following sequence as the OWD NMI routine:

1. Restart the oscillator watchdog detection by setting bit OSC_CON.OSCWDTRST
2. Wait until OSC_CON.OSC2L is clear
3. When bit OSC_CON.OSC2L is cleared, then
 - a) Select the Prescaler Mode (PLL_CON.VCOBYP = 1)
 - b) Set the restart lock detection bit PLL_CON.RESLD = 1
 - c) Wait until the PLL VCO part becomes locked (PLL_CON.LOCK = 1)
 - d) When the LOCK is set again, the Prescaler Mode can be deselected (PLL_CON.VCOBYP = 0) and normal PLL operation is resumed.
4. Clear the OWD NMI flag FNMIOWD.

In the general case of PLL loss-of-lock or to re-configure the PLL settings, user software can try to configure the clock system again by executing the following sequence:

1. If input clock source is from XTAL (f_{OSC} from OSC_HP), ensure the input frequency is above threshold by checking OSC_CON.OSC2L.
2. The Prescaler Mode has to be selected (PLL_CON.VCOBYP = 1)
3. If desired, (re-)configure the PLL divider settings.
4. Set the restart lock detection bit PLL_CON.RESLD = 1
5. Wait until the PLL VCO part becomes locked (PLL_CON.LOCK = 1)
6. When the LOCK is set again, the Prescaler Mode can be deselected (PLL_CON.VCOBYP = 0) and normal PLL operation is resumed.
7. Clear the PLL loss-of-lock NMI flag FNMIPLL.

7.3.4 Clock Control Unit

The Clock Control Unit (CCU) receives the clock from the PLL f_{PLL} , or the external input clock f_{OSC} , or the low-precision input clock f_{LP_CLK} . The system frequency is derived from one of these clock sources.

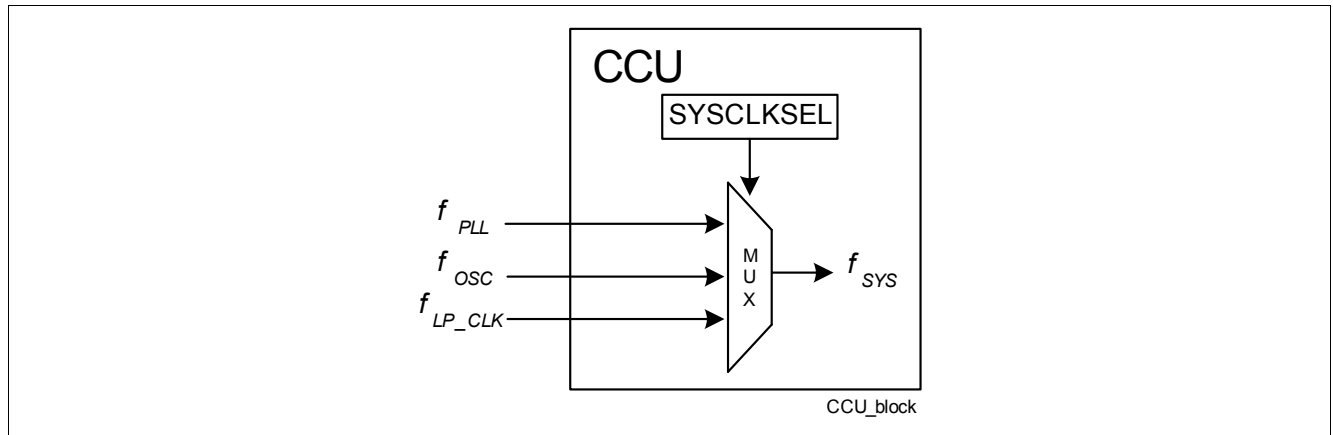

Figure 25 Clock Inputs to Clock Control Unit

The CCU generates all necessary clock signals within the microcontroller from the system clock. It consists of:

- Clock slow down circuitry
- Centralized enable/disable circuit for clock control

In normal running mode, the main module frequencies (synchronous unless otherwise stated) are as follows:

- System frequency, f_{SYS} = up to 40 MHz (measurement interface clock MI_CLK is derived from this clock)
- CPU clock (CCLK, SCLK) = up to 40 MHz (divide-down of NVM access clock)
- NVM access clock (NVMACCCLK) = up to 40 MHz
- Peripheral clock (PCLK, PCLK2, NVMCLK) = up to 40 MHz (equals CPU clock; must be same or higher)

Some peripherals are clocked by PCLK, others clocked by PCLK2 and the NVM is clocked by both NVMCLK and NVMACCCLK. During normal running mode, $PCLK = PCLK2 = NVMCLK = CCLK$. On wake-up from power-down mode, PCLK2 is restored similarly like NVMCLK, whereas PCLK is restored only after PLL is locked.

For optimized NVM access (read/write) with reduced wait state(s) and with respect to system requirements on CPU operational frequency, bit field NVMCLKFAC is provided for setting the frequency factor between the NVM access clock NVMACCCLK and the CPU clock CCLK. For details, refer to the separate NVM documentation.

For the slow down mode, the operating frequency is reduced using the slow down circuitry with clock divider setting at the bit field CLKREL. Bit field CLKREL is only effective when slow down mode is enabled via SFR bit PMCON0.SD bit. Note that the slow down setting of bit field CLKREL correspondingly reduces the NVMACCCLK clock. Slow down setting does not influence the erase and write cycles for the NVM.

7.3.4.1 Clock Tree

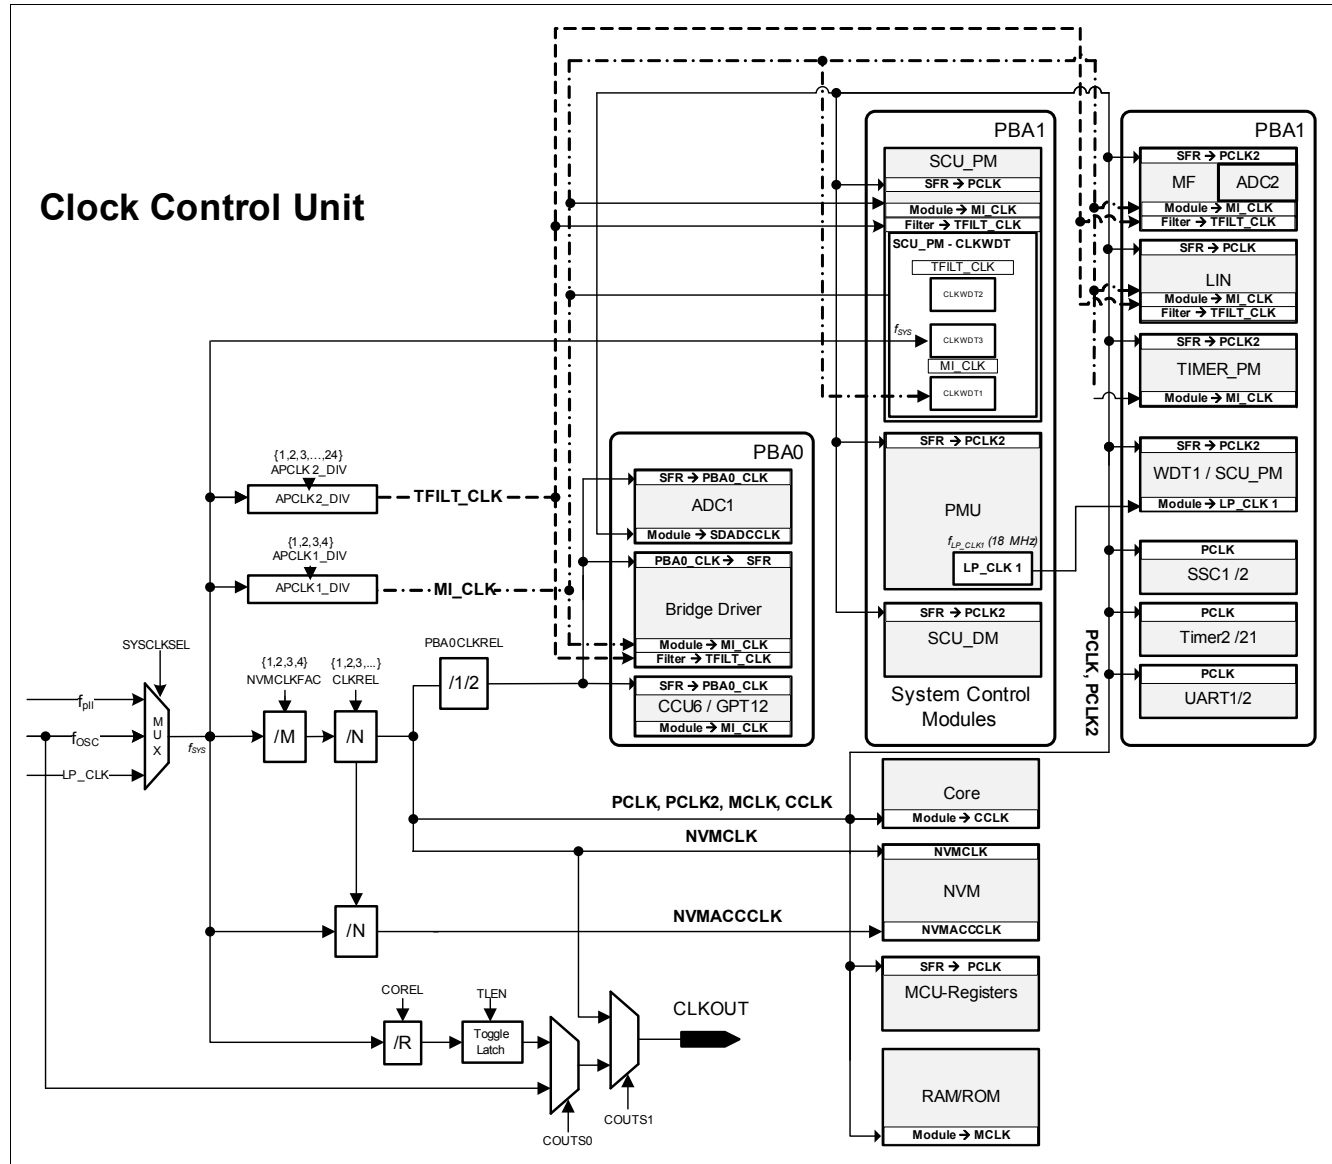

Figure 26 Clock Tree

7.3.4.2 Startup Control for System Clock

Typically when the TLE9869QXA20 starts up after reset, the LP_CLK is selected by hardware to provide the system frequency f_{SYS} . CPU runs based on this system frequency during startup operation by boot firmware (unless otherwise specified and configured by firmware). Meanwhile, the system clock input is switched to the PLL output. With user boot configuration, the PLL is configured with internal oscillator (5 MHz) as input, by default. User code can modify the default PLL configuration as required.

The exception to the above is with resets that do not reset the clock system, which are watchdog timer (WDT) reset and soft reset. With these resets, the previous user configuration of PLL and clock system is retained across the reset.

Note: In the event the PLL fails to lock during startup operation, the LP_CLK continues to provide the system clock input. The system clock input source is indicated by the register bit field SYSCON0.SYSCLKSEL.

7.3.5 External Clock Output

An external clock output is provided as CLKOUT. This output clock can be enabled/disabled via bit COCON.EN. One of three clock sources (f_{CLK} or f_{SYS}/n or f_{OSC}) can be selected for output, configured via bit fields COCON.COUTS1 and COUTS0.

If COUTS1 = 0 (independent on COUTS0), the output clock is f_{CLK} . Otherwise, if COUTS0 = 0, the output clock is from oscillator output frequency; if COUTS0 = 1, the clock output frequency is chosen by the bit field COREL which selects the n divider factor on f_{SYS} . Under this selection, the clock output frequency can further be divided by 2 using a toggle latch (TLEN = 1), the resulting output frequency has 50% duty cycle.

7.3.6 CGU Registers

The registers of the clock generation unit for PLL and oscillator control are not affected by the watchdog timer (WDT) reset and soft reset. Therefore the system clock configuration and frequency is maintained across these types of reset.

Unless otherwise stated, the reset value as stated for the following registers apply only with Power-On reset, Brown-Out reset, Hard reset, WDT1 reset or Wake-up reset.

7.3.6.1 PLL Oscillator Register

These registers control the setting and trimming of OSC_PLL, the Power Down of XTAL (OSC_HP) and the control and status monitor of oscillator watchdog.

OSC_CON

OSC Control Register

(0B0_H)

Reset Value: 10_H

7	6	5	4	3	2	1	0
OSCTRIM_8	Res	Res	XPD	OSC2L	OSCWDTRST	OSCSS

Field	Bits	Type	Description
OSCTRIM_8	7	rw	OSC_PLL Trim Configuration Bit [8] This bit field enables the trimming for the OSC_PLL. User should always set this bit with any write. This bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .
Res	6	r	Reserved This bit field is always read as zero.
Res	5	r	Reserved This bit field is always read as zero.
XPD	4	rw	XTAL (OSC_HP) Power Down Control 0 _B XTAL (OSC_HP) is not powered down. 1 _B XTAL (OSC_HP) is powered down. The XPD bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 . <i>Note: When XPD is set, switch of clock source to internal oscillator has to be done asynchronous.</i>
OSC2L	3	rh	OSC-Too-Low Condition Flag The Oscillator Watchdog monitors the f_{OSC} . 0 _B f_{OSC} is above threshold. 1 _B f_{OSC} is below threshold. On OSC-too-low detection (OSC2L: 0 → 1) and VCOBYP = 1 and OSCSS = 01, PLL switches to freerunning mode. On above condition, and when f_{OSC} is selected as the system clock source, hardware switches the system clock source to PLL (SYSCON0.SYSCLKSEL is also updated). <i>Note: OWD NMI request is activated on OSC-too-low condition only in two cases: 1) when VCOBYP = 1 and OSCSS = 01 and SYSCLKSEL selects PLL clock as system clock source; 2) when SYSCLKSEL selects f_{OSC} as system clock source.</i>

System Control Unit - Digital Modules (SCU-DM)

Field	Bits	Type	Description
OSCWDTRST	2	rwh	Oscillator Watchdog Reset Setting this bit will reset the OSC2L status flag to 1 and restart the oscillator detection. This bit will be automatically reset to 0 and thus always be read back as 0. 0 _B No effect. 1 _B Reset OSC2L flag and restart the oscillator watchdog of the PLL.
OSCSS	1:0	rw	Oscillator Source Select 00 _B PLL internal oscillator OSC_PLL (f_{INT}) is selected synchronously as f_R . 01 _B XTAL (f_{OSC} from OSC_HP) is selected synchronously as f_R . 10 _B PLL internal oscillator OSC_PLL (f_{INT}) is selected asynchronously as f_R . 11 _B PLL internal oscillator OSC_PLL (f_{INT}) is selected asynchronously as f_R . The OSCSS bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 . <i>Note: Synchronous switching of clock source to internal oscillator is not possible when XPD = 1 or no external clock is available (check bit OSC2L).</i> <i>Note: Use the 1X option only when the external clock is not available.</i>

This register OSC_CON is reset by RESET_TYPE_4.

System Control Unit - Digital Modules (SCU-DM)

Field	Bits	Type	Description
LOCK	0	r	PLL Lock Status Flag 0_B The frequency difference of f_{REF} and f_{DIV} is greater than allowed. The VCO part of the PLL can not lock on a target frequency. 1_B The frequency difference of f_{REF} and f_{DIV} is small enough to enable a stable VCO operation. Notes <ol style="list-style-type: none"> In case of a loss of VCO lock the f_{VCO} goes to the upper boundary of the selected VCO band if the reference clock input is greater as expected. In case of a loss of VCO lock the f_{VCO} goes to the lower boundary of the selected VCO band if the reference clock input is lower as expected. On loss-of-lock detection (LOCK: $1 \rightarrow 0$) and when $VCOBYP = 0$, PLL switches to freerunning mode. Loss-of-lock NMI request is activated only on loss-of-lock detection when $VCOBYP = 0$ and $SYSCON0.SYSCLOCKSEL$ selects PLL clock as system frequency.

The register PLL_CON is reset by RESET_TYPE_4.

CMCON1

7.3.6.4 Analog Peripherals Clock Control Registers

The clock frequency for the analog modules is selected via register APCLK1 and APCLK2. The APCLK1 is used as operating clock for all analog peripherals. For this reason it is important to always adapt the Analog Peripherals Clock Control Register settings to the required frequency range, if the system clock is changed.

This register APCLK2 is reset by RESET_TYPE_4.

7.3.6.5 External Clock Control Register

This register controls the setting of external clock for CLKOUT.

COCON

Clock Output Control Register

(0B4_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
EN	COUTS1	TLEN	COUTS0			COREL	
rw	rw	rw	rw			rw	

Field	Bits	Type	Description
EN	7	rw	CLKOUT Enable 0 _B No external clock signal is provided 1 _B The configured external clock signal is provided
COUTS1	6	rw	Clock Out Source Select Bit 1 0 _B f_{CLK} is selected. 1 _B Based on setting of COUTS0.
TLEN	5	rw	Toggle Latch Enable Enable this bit if 50% duty cycle is desired on CLKOUT. This bit is only applicable when both COUTS1 and COUTS0 are set to 1. 0 _B Toggle Latch is disabled. Clock output frequency is chosen by the bit field COREL. 1 _B Toggle Latch is enabled. Clock output frequency is half of the frequency that is chosen by the bit field COREL. The resulting output frequency has 50% duty cycle.
COUTS0	4	rw	Clock Out Source Select Bit 0 This bit is effective only if COUTS1 is set to 1. 0 _B Oscillator output frequency is selected. 1 _B Clock output frequency is chosen by the bit field COREL.
COREL	3:0	rw	Clock Output Divider 0000 _B f_{sys} 0001 _B $f_{sys}/2$ 0010 _B $f_{sys}/3$ 0011 _B $f_{sys}/4$ 0100 _B $f_{sys}/6$ 0101 _B $f_{sys}/8$ 0110 _B $f_{sys}/10$ 0111 _B $f_{sys}/12$ 1000 _B $f_{sys}/14$ 1001 _B $f_{sys}/16$ 1010 _B $f_{sys}/18$ 1011 _B $f_{sys}/20$ 1100 _B $f_{sys}/24$ 1101 _B $f_{sys}/32$ 1110 _B $f_{sys}/36$ 1111 _B $f_{sys}/40$

This register COCON is reset by RESET_TYPE_4.

7.4 Reset Control

This section describes the types of reset and the effects of each reset on the TLE9869QXA20.

7.4.1 Types of Reset

The following reset types are recognized by the TLE9869QXA20:

- Power-on reset
 - Requested asynchronously and released by supply voltage V_S reaching the upper threshold. Indication is a direct analysis of V_S undervoltage.
- Brown-out reset
 - Is not differentiated by system with power-on reset.
- Wake-up reset
 - Requested asynchronously by wake-up event during power save mode.
- Hardware reset
 - Requested asynchronously by event on external reset input (pin).
- WDT1 reset
 - Activated asynchronously by external WDT1 reset event.
- SCU Watchdog Timer (WDT) reset
 - Requested by WDT reset event.
- Soft reset
 - Requested synchronously by soft reset event.

7.4.2 Overview

When the TLE9869QXA20 is first powered up or with brown-out condition triggered by supply voltage input(s) going below the threshold, proper voltage thresholds must be reached before the MCU system starts operation with the release of the MCU, CPU and NVM resets. With all resets (except soft and SCU watchdog timer resets), the boot configuration is latched. The CPU starts to execute from the Boot ROM firmware with the release of MCU reset.

If the system is in power save mode, it is possible to wake-up with reset. Wake-up reset is basically equivalent to power-on reset except that it is a 'warm' reset and certain settings or configuration of the system are maintained across the reset. A wake-up via hard reset pin while in power save mode is effected as wake-up reset.

The hardware reset function via pin can be used anytime to restart the system.

The external watchdog timer (WDT1) can trigger a WDT1 reset on the system, if the timer is not refreshed before it overflows.

Likewise, the SCU watchdog timer (WDT) can trigger a watchdog timer reset on the system if the timer is not refreshed before it overflows.

Soft reset can be triggered by application software where applicable.

Note that the boot configuration is only latched with the power-on, brown-out, WDT1, wake-up and hardware resets.

7.4.3 Module Reset Behavior

Table 29 gives an overview on how the various modules or functions of the TLE9869QXA20 are affected with respect to the reset type. A "n" means that the module/function is reset to its default state. Refer to **Table 31** for effective reset as priority.

System Control Unit - Digital Modules (SCU-DM)

Table 29 Effect of Reset on Modules/Functions

Module/ Function	Power-On/ Brown-Out Reset	Wake-up Reset ¹⁾	Hardware Reset ¹⁾	WDT1 Reset ¹⁾	WDT Reset	Soft Reset ²⁾
CPU Core	n	n	n	n	n	n
SCU	n except reset indication bit	n except indication bits	n except reset indication bit	n except reset indication bit	n except certain status bits ³⁾	n except certain status bits ³⁾
Peripherals	n	n	n	n	n	n
Debug System	n	n	n	n	n	n
Port Control	n	n	n	n	n	n
FW Startup Execution	Executes all INIT	Sleep: Executes all INIT	Executes most INIT	Executes most INIT	Skips not required INIT	Skips not required INIT
On-Chip Static RAM	Initialized to 0	Sleep: Initialized to 0; Stop: Not affected ⁴⁾	Not affected ⁴⁾⁵⁾	Not affected ⁴⁾⁵⁾	Not affected ⁴⁾	Not affected ⁴⁾
Memory Extension Stack RAM	Affected	Affected	Affected	Affected	Affected	Affected
NVM	n	n	n	n	n except MapRAM	n except MapRAM
Clock System incl. PLL	n	n	n	n	Not affected ⁶⁾	Not affected ⁶⁾

1) MCU sub-system: Hardware reset, WDT1 reset and wake-up reset (from Stop Mode or Sleep Mode) are generally HW-equivalent to power-on/brown-out reset, any exceptions are mainly due to power-on reset being a 'cold' start.

2) Soft Reset can be set by CPU_AIRCR. [SYSRESETREQ](#)

3) These bits include the reset requestor indication bit, the last power-on/brown-out/WDT1/wake-up reset latched boot configuration, and NMI status flags e.g. NMISR.

4) Not affected = Reset has no direct effect on RAM contents.

5) If the reset happens during a write to SRAM, the byte in the targeted write address may be corrupted.

6) All configuration including trim settings.

7.4.4 Functional Description of Reset Types

This section describes the definition and controls depending on the reset source.

7.4.4.1 Power-On / Brown-out Reset

Power-on reset is the highest level reset whereby the whole system is powered up and reset. Brown-out reset occurs when any required voltage drops below its minimum threshold.

In user mode, the system clock is switched to the PLL output at the defined frequency of the device.

7.4.4.2 Wake-up Reset

Wake-up reset occurs due to enabled event on defined functional input pins leading to reset of device while the device was in power-save mode. Wake-up reset from sleep and power-down (stop) mode is differentiated by respective indicator bits. In case of wake-up from Sleep Mode, reset is always effected.

Wake-up reset has the next highest priority after power-on/brown-out reset.

In user mode, the system clock is switched to the PLL output at the defined frequency of the device.

7.4.4.3 Hardware Reset

Hardware reset is requested asynchronously by event on external RESET (low active) input pin, and has the next highest priority after wake-up reset.

In case of hardware reset is activated while the device is in power-save mode, this is effectively a wake-up reset. Refer [Figure 14](#).

In user mode, the system clock is switched to the PLL output at the defined frequency of the device.

For details of programming the filter time of the external RESET (low active) input pin see the corresponding reset pin blind time register, RESPIN_BLIND_TIME.

7.4.4.4 WDT1 Reset

WDT1 reset occurs due to WDT1 timer overflow or when servicing in a closed window, and has the next highest priority after hardware reset.

In user mode, the system clock is switched to the PLL output at the defined frequency of the device.

7.4.4.5 WDT / Soft Reset

WDT reset occurs due to WDT timer overflow; Soft reset occurs due to software set of the soft reset request bit . These two resets are at the same priority level (same effect on system) and has the lowest priority level. With these resets, the device continues running on the previous clock system configuration.

7.4.5 Reset Register Description

RSTCON

Reset Control Register

(068_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
LOCKUP_EN							LOCKUP
rw							rw

Field	Bits	Type	Description
LOCKUP_EN	7	rw	Lockup Reset Enable Flag 0 _B Lockup is disabled. 1 _B Lockup is enabled. The LOCKUP_EN bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .
Res	6:1	r	Reserved Returns 0 if read; should be written with 0.
LOCKUP	0	rw	Lockup Flag 0 _B Lockup Status not active. 1 _B Lockup Status active. The LOCKUP bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .

This register RSTCON is reset by RESET_TYPE_3.

Note: *The Lockup reset is a reset provided by the ARM Core. The effect of the Lockup reset is the same as for a software reset.*

The registers PMU_RESET_STSx are located in PMU mapped to SFR space, see [PMU_RESET_STS1](#) and [PMU_RESET_STS2](#). The register should retain its value across all resets until power is not available. In case of power-on reset, only PMU_1V5DidPOR bit is set.

Table 30 Reset Value of Register PMU_RESET_STSx (XSFR)

Reset Source	Reset Value
Power-down Wake-up Reset	0000 0010 _B
Power-down Wake-up via Hardware Reset	0100 0010 _B
Sleep Wake-up Reset	0000 0100 _B
Soft Reset	0000 1000 _B

Table 30 Reset Value of Register PMU_RESET_STSx (XSFR) (cont'd)

Reset Source	Reset Value
WDT Reset	0001 0000 _B
WDT1 Reset	0010 0000 _B
Hardware Reset	0100 0000 _B
Power-On Reset/Brown-out Reset	1000 0000 _B

Possible Combination of Reset Sources

Table 31 lists all possible combinations of reset status bits being set in the TLE9869QXA20. A “x” means that the corresponding reset has occurred.

Table 31 Effective Reset with Combination of Reset Sources

Effective Reset	POBORS T	WKRS		HDRST	WDT1RS T	WDTRST	SWRST
		WKSL	WKST				
Power-on	x	x	x	x	x	x	x
Wake-up from sleep	—	x	—	x	x	x	—
Wake-up from stop	—	—	x	x	x	x	—
Hardware	—	—	—	x	x	x	x
WDT1	—	—	—	—	x	x	x
WDT	—	—	—	—	—	x	—
Software	—	—	—	—	—	—	x
WDT & Software	—	—	—	—	—	x	x

7.4.6 Booting Scheme

After any power-on reset, brown-out reset, hardware reset, WDT1 reset or wake-up reset, the pins TMS, P0.0, P0.2 together choose different modes. **Table 32** shows the boot selection options available in the TLE9869QXA20.

Table 32 TLE9869QXA20 Boot Options

TMS/SWD	P0.0	P0.2	MODE
0	x	x	User Mode / BSL Mode
1	1	0	Debug Mode with Serial Wire (SW) port

7.5 Power Management

This section describes the features and functionality provided for power management of the device.

7.5.1 Overview

The TLE9869QXA20 power-management system allows software to configure the various processing units so that they automatically adjust to draw the minimum necessary power for the application.

There are four power modes: Active Mode, Slow Down Mode, Stop Mode and Sleep Mode, as shown in [Figure 27](#). Sleep Mode is a special case which can only be exited with a system reset.

The operation of the system components in each of these states can be configured by software. The power modes provide flexible reduction of power consumption through a combination of techniques, including:

- Stopping the CPU clock
- Stopping the clocks of other system components individually
- Clock-speed reduction of some peripheral components
- Power-down of the entire system with fast restart capability
- Reducing or removing the power supply to power domains

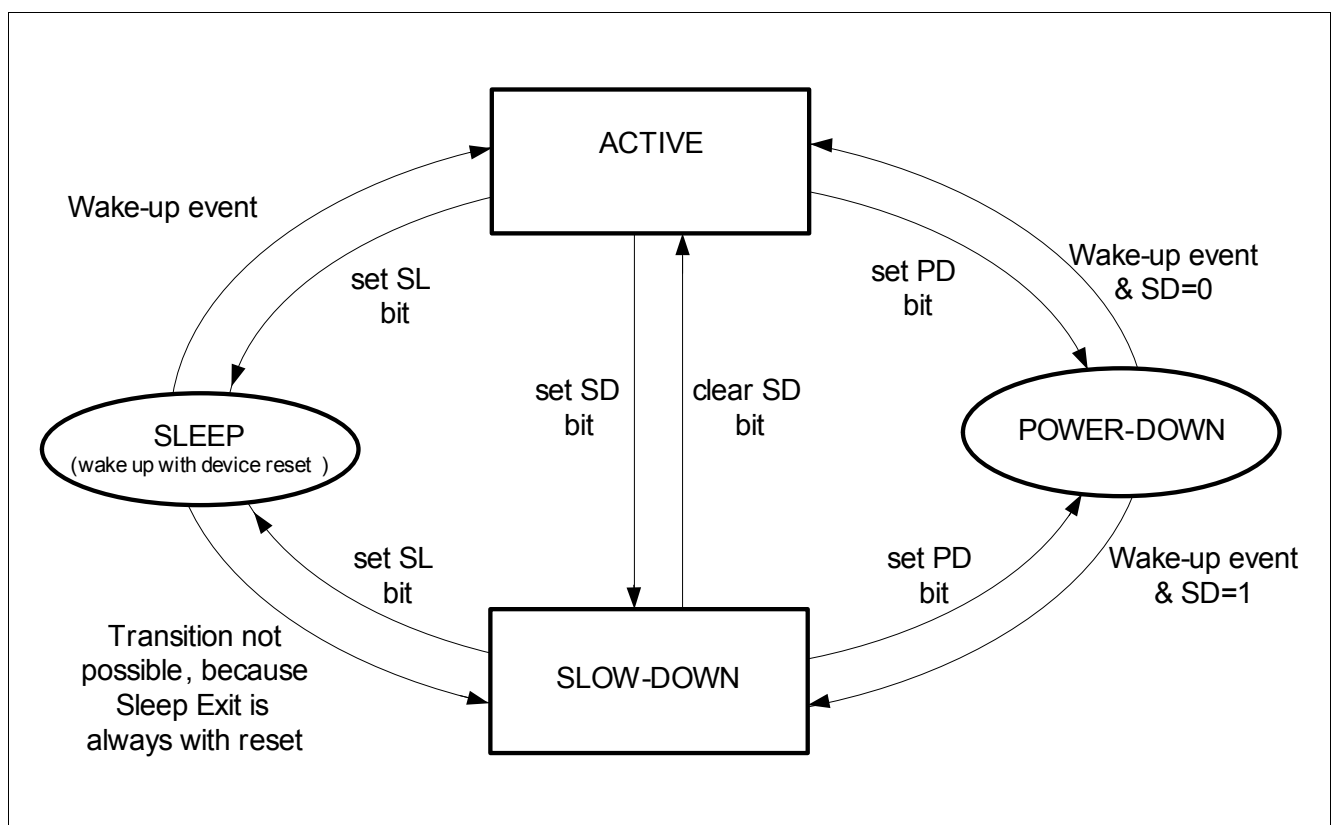

Figure 27 Transition between Various Modes of Operation (without reset)

In Slow Down Mode, the clock generation unit is instructed to reduce its clock frequency so that the clock to the system, i.e. core and peripherals, will be divided by a programmable factor.

In Stop Mode, the clock is turned off. Hence, it cannot be awakened by an interrupt or the Watchdog Timer. It will be awakened only when it receives an external wake-up signal or reset signal. The application must be prepared that the TLE9869QXA20 is served with one of these signals. A wake-up circuit is used to detect enabled wake-up signal(s) and activate the Stop Mode wake-up. During Stop Mode, this circuit remains active.

In Sleep Mode, the power supply to the whole MCU subsystem is removed. On detection of wake-up event, a system reset is generated, the MCU is reset to default configuration and then restart operation is initialized.

The priority for entry to the power-save modes starting from the highest is Sleep Mode, Stop Mode, then Slow Down Mode.

7.5.2 Functional Description

This section describes the power-save modes, their operations, and entry and exit. It also describes the respective behavior of TLE9869QXA20 system components.

7.5.2.1 Slow Down Mode

The Slow Down Mode is used to reduce the power consumption by decreasing the internal clock in the device.

The Slow Down Mode is activated by setting the bit SD in SFR **PMCON0**. The bit field **CMCON1**.CLKREL is used to select different slow down frequencies. The CPU and peripherals are clocked at this lower frequency. The Slow Down Mode is terminated by clearing bit SD.

7.5.2.2 Stop Mode

In the Stop Mode, the NVM is put into NVM shutdown mode (analog and digital parts except MapRAM shut down). The 5 V (VDDP) power supply to the analog modules ADC and PLL & internal oscillator is not removed. The MCU digital parts and the NVM MapRAM are powered by the 1.5 V (VDDC) regulator (supplying 0.9 V in this mode). All functions of the microcontroller are stopped while the contents of the NVM, on-chip RAM and the SFRs are maintained. As for the external ports, all digital pads are still powered.

In Stop Mode, the clock is turned off. Hence, the system cannot be awakened by an interrupt or the Watchdog Timer. It will be awakened only when it receives an external wake-up signal (with or without a following system reset) or with reset by asserting the hard reset pin.

Software requests Stop Mode by setting the bit **PMCON0**.PD to 1. In addition to this Flag the **WFI** or **WFE** instruction has to be executed. As soon as the controller has finished its currently executed interrupt task it will enter the Stop Mode. **Figure 28** below shows the correct sequence to enter Stop Mode:

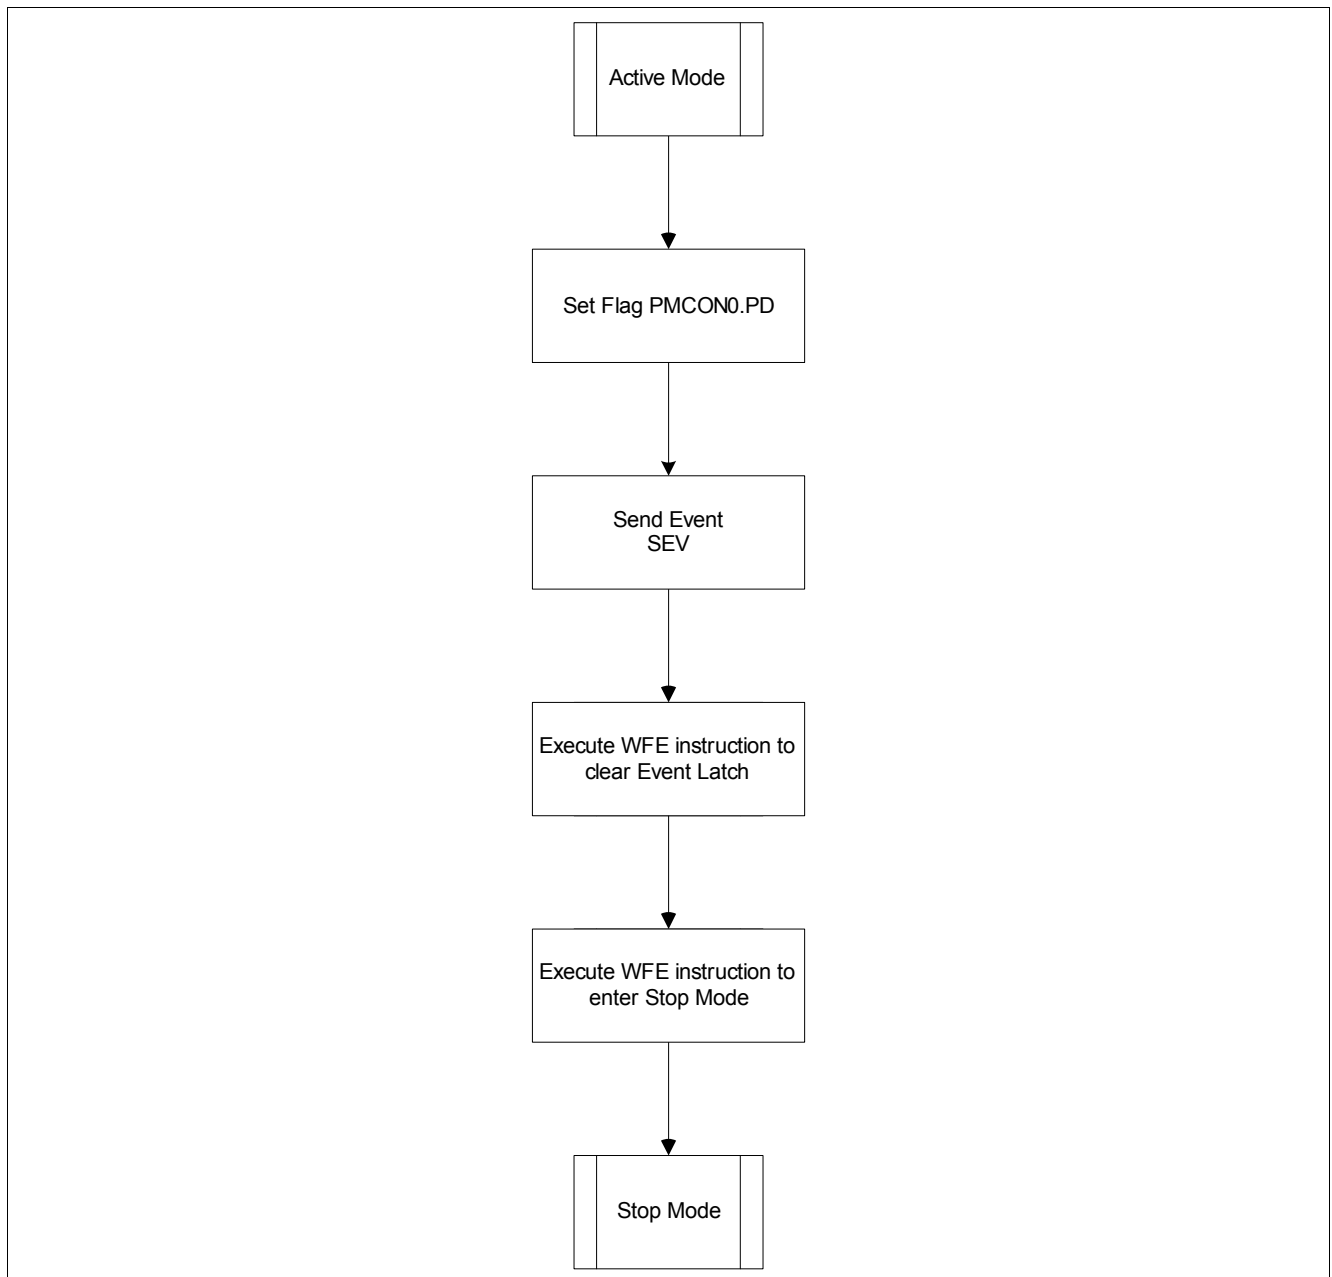

Figure 28 Stop Mode Entry Programming Sequence

Exiting Stop Mode

Stop Mode can be exited by active edge on the enabled wake-up pin(s) – or by asserting the hard reset pin.

The wake-up circuitry will perform a sequence of predefined actions such as restoring all supply voltages, restoring modules to operational mode including the oscillator and PLL. On stable clock the user configuration is restored, peripheral clock gating, CPU clock gating is removed and the CPU starts to run from the instruction following the one that sets the PD bit. It is required by the user code to insert three NOP instructions following the one that sets the PD bit.

Note: if user has selected the PLL output as system clock (typical use case), but lock status of the PLL cannot be achieved, the PLL will enter freerunning mode and software execution will be continued in PLL freerunning mode.

Usage of ARM Core low power modes for stop mode

The ARM Core provides two low power modes, which are called Sleep and Deep sleep. For system stop mode the Deep Sleep mode of the core is used. To enable the deep sleep mode the System Control Register at address E000ED10_H has to be written. Another way of entering Deep Sleep mode is to execute two dedicated mode change instructions:

- **WFI**
- **WFE**

When the controller enters stop mode via WFI instruction, it executes the lowest priority pending interrupt and after that enters sleep mode. This feature is not recommended to be used for normal operation using stop mode, because the controller would only operate interrupt triggered.

When the WFE instruction is used, the controller starts to operate triggered by an external event. If the CPU will be woken up by this external event, it stays in thread mode and continues to execute the code before it entered stop mode.

This is the recommended procedure to enter stop mode.

7.5.2.3 Sleep Mode

In the Sleep Mode, the supply to the whole MCU subsystem including the ADC, PLL and NVM is removed. The wake-up detection circuitry remains supplied. Only contents of non-volatile memory are retained. As for the external ports, only the wake-up pads are still powered. The supply to ADC pads is removed.

Sleep Mode is always exited with a system reset, which is triggered by active edge on the enabled wake-up pin(s). It is not possible to exit Sleep Mode by asserting the hard reset pin as the digital 5 V pads will not be powered.

Software requests Sleep Mode by setting the bit PMCON0.SL to 1.

Exiting Sleep Mode

Sleep Mode can only be exited with a system reset, triggered by active edge on the enabled wake-up pin(s).

7.5.3 Register Description

PMCON0

Power Mode Control Register 0

(040_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
Res	Res	Res	Res	SD	PD	SL	XTAL_ON
r	r	r	r	rw	rwh1	rwh1	rw

Field	Bits	Type	Description
Res	7:4	r	Reserved Returns 0 if read; should be written with 0.
SD	3	rw	Slow Down Mode Enable. Active High. Setting this bit will cause the chip to go into slow down mode. Reset by user. The SD bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .
PD	2	rwh1	Power Down Mode Enable. Active High. Setting this bit will cause the chip to go into a Power Down mode. Reset by wake-up circuit. The PD bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .
SL	1	rwh1	Sleep Mode Enable. Active High. Setting this bit will cause the chip to go into Sleep Mode. Reset by wake-up circuit. The SL bit is a protected bit. When the Protection Scheme is activated, this bit cannot be written directly. For more information on Protection Scheme, see Section 7.13 .
XTAL_ON	0	rw	OSC_HP Operation in Power Down Mode 0 _B OSC_HP (XTAL) will be put to Power Down Mode by hardware in power save mode. 1 _B OSC_HP (XTAL) continues to operate in Power Down Mode, if enabled by OSC_CON .XPD. This provides user the option for reduced power consumption in the Power Down Mode. It must be noted that the startup time of OSC_HP can be in the range of some milliseconds. Alternatively for fast wake-up from Power Down Mode while avoiding this power consumption, the user can selectively enable internal oscillator as clock source and disable OSC_HP before enabling Power Down Mode.

7.6 Interrupt Management

This section describes the management of interrupts by the system control unit.

7.6.1 Overview

The Interrupt Management sub-module in the SCU controls the non-core-generated interrupt requests to the core. The core has one non-maskable interrupt (NMI) node and in total 16 maskable interrupt nodes. **Figure 29** shows the block diagram of the Interrupt Management sub-module.

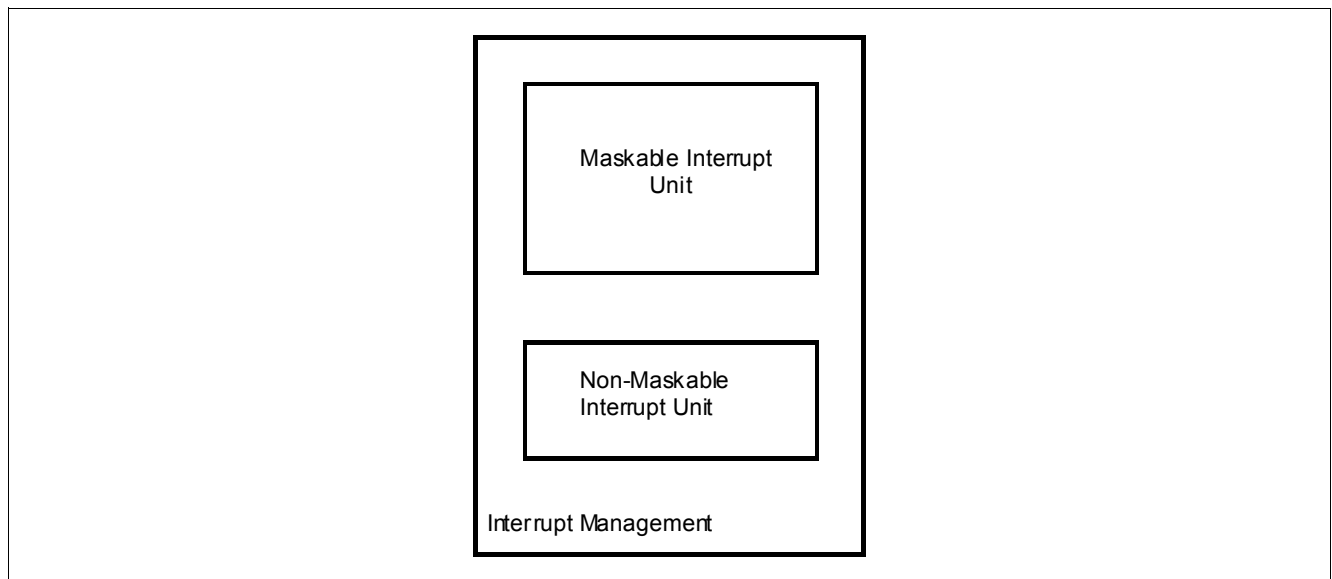

Figure 29 Interrupt Management Block Diagram

The non-maskable interrupt unit controls the NMI requests. An incoming NMI request is not maskable and in this sense, differs from the regular interrupts. In addition, an NMI request always has the highest priority to be serviced. In the TLE9869QXA20, eight different sources can generate an NMI: watchdog timer prewarning, PLL loss-of-lock, oscillator watchdog event, NVM map error, Memory ECC error, NVM operation complete, Debug Mode user IRAM event and supply prewarning. Some NMI sources can be triggered by one of several events. These NMI sources are ORed to generate an NMI interrupt directly to the core. The triggering NMI sources/events are indicated in the NMI Status Register (NMISR), and in some cases the event flags are located in the peripheral register. The NMI node source control can be configured via the NMI Control Register (NMICON).

There are generally 3 types of maskable inputs into the core: internal, external and extended interrupts. The maskable interrupt unit will generate the respective interrupt node request to the core and will maintain corresponding SCU flags and control. In general, to support all types of peripheral interrupts, an interrupt node of the core may be shared among several interrupt sources.

7.6.1.1 External Interrupts

The generation of an interrupt request from an external source by edge detection in the SCU is shown in **Figure 30**. External interrupts can be positive, negative or double edge triggered. Register EXICON0 specifies the active edge for the external interrupt.

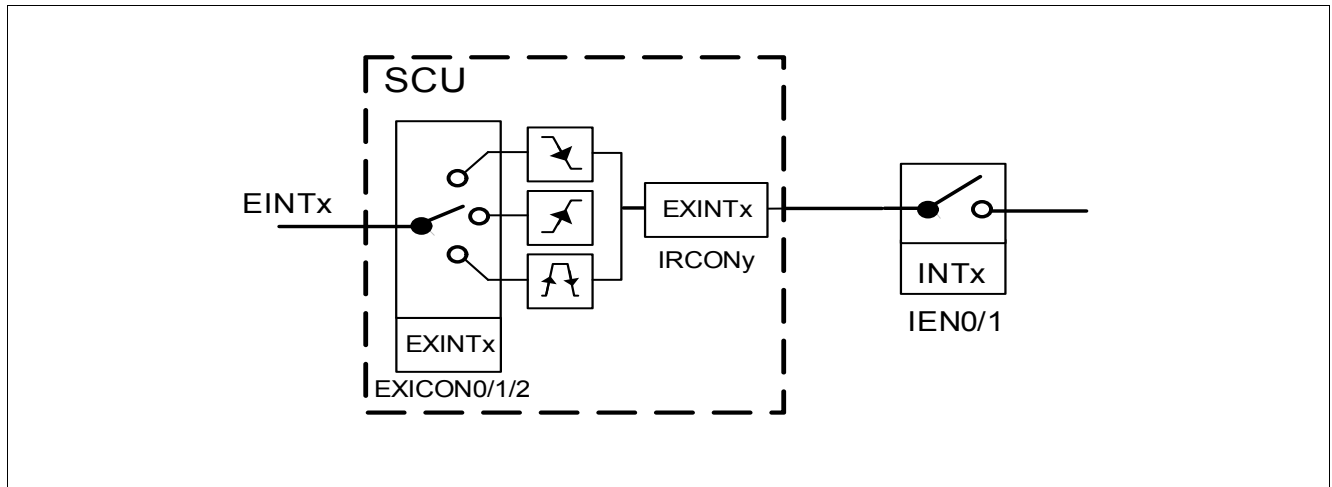

Figure 30 Interrupt Request Generation of External Interrupts

7.6.1.2 Extended Interrupts

Extended interrupts are for non-core on-chip peripherals for core-external trigger of interrupt requests to the core. There are nine such interrupts.

Interrupt signals from such on-chip peripherals are pulse triggered and active for two clock cycles. These interrupt signals belonging to the same interrupt node will be latched as one direct interrupt request to the core. IRCONx (where $x = 0-1, 3-4$) or peripheral registers hold the interrupt event flags for these extended and external interrupt events. Corresponding bits in the Interrupt Enable Registers (IEN) within the core may block or transfer these interrupt requests to the core interrupt controller. An enabled interrupt request is acknowledged when the core vectors to the interrupt routine. The software routine should clear the interrupt flags in the IRCONx registers.

As there are more peripheral interrupts than interrupt nodes supported by the core, some interrupts are multiplexed to the same interrupt node. Where possible and necessary, critical peripheral interrupts (e.g. SSC) have their own dedicated interrupt node.

7.6.2 Interrupt Node Assignment

Table 33 shows the interrupt node assignment for TLE9869QXA20.

Table 33 NMI

Interrupt Node	Vector Address	Assignment for TLE9869QXA20
NMI	0000 _H	Watchdog Timer, PLL, NVM Operation Complete, CLKWDT, Oscillator Watchdog, NVM map error, ECC error, Pre-Warn SUPP, Pre-Warn TEMP

Table 34 Interrupt Vector Table

Service Request	Node ID	Description
GPT1	0	GPT1 interrupt (T2-T4)
GPT2	1	GPT2 interrupt (T5-T6, CAPIN)
MU- ADC8/T3	2	Measurement Unit, VBG, Timer3
ADC1	3	ADC1 interrupt / VREF5V Overload / VREF5V OV/UV, 10-bit ADC
CCU0	4	CCU6 node 0 interrupt
CCU1	5	CCU6 node 1 interrupt
CCU2	6	CCU6 node 2 interrupt
CCU3	7	CCU6 node 3 interrupt
SSC1	8	SSC1 interrupt (receive, transmit, error)
SSC2	9	SSC2 interrupt (receive, transmit, error)
UART1	10	UART1 (ASC-LIN) interrupt (receive, transmit), Timer2, linsync1, LIN
UART2	11	UART2 interrupt (receive, transmit), Timer21, External interrupt (EINT2)
EXINT0	12	External interrupt (EINT0), wakeup
EXINT1	13	External interrupt (EINT1)
BDRV/CP	14	Bridge Driver / Charge Pump
DMA	15	DMA Controller

7.6.3 Interrupt Related Registers

Several interrupt related registers are located in the SCU.

7.6.3.1 Interrupt Event Enable Control

The two interrupt events of UART and three interrupt events of SSC module are of interrupt structure 1 which is described in [Chapter 13.3.2](#). As there is no enable/disable bit(s) for these interrupt events within the module, bits are defined in the SCU register MODIEN1 and MODIEN2 for this purpose.

Other Interrupt Related Registers

The following interrupt related registers are located in the SCU:

- NMICON
- NMISR
- IRCON0, IRCON1, IRCON2, IRCON3, IRCON4
- EXICON0
- MODIEN1, MODIEN2

All registers, except MODIENx, are described in the Interrupt System [Chapter 13.5](#).

7.6.3.2 DMA Interrupt Event Enable and Select Control

The integrated DMA Controller has 14 dedicated interrupt sources. They are:

DMA Interrupt Sources

- 10-bit ADC Programmed Sequencer Sequence done
- 10-bit ADC Single Sequence done
- SSC Transmit Request
- SSC Receive Request
- ADC1-CH1
- ADC1-CH2

7.6.4 Implementation of DMA Request inside the SCU

The DMA requests of SSC Transmit, SSC Receive and GPT12 have to be implemented as shown in the figure below on the example of the SSC transmit request. The Request Source of GPT12 is not multiplexed. The request has to be set by the corresponding interrupt request signal and hold until the corresponding dma_active signal goes to high. The reset of the corresponding request source flag is only done when the source is selected by the corresponding select signal:

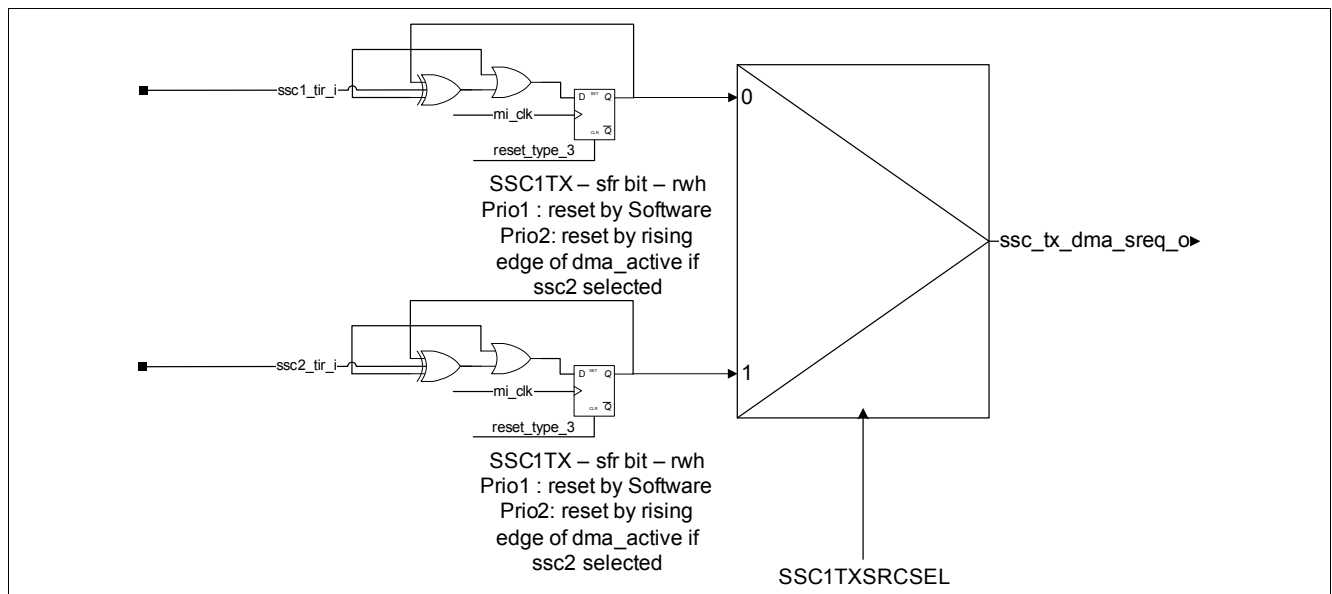

Figure 31 Implementation of DMA Request Generation and Selection by SCU

7.6.5 NMI Event Flags Handling

Each NMI event and status flag is retained across these resets: 1) WDT reset, 2) soft reset. Specifically, these include all the flags of NMISR register: FNMIWDT, FNMIPLL, FNMINVM, FNMIOCDS, FNMIOWD, FNMIMAP and indirectly, FNMI ECC and FNMISUP. In the case of watchdog resets, the requestor can be identified via the reset indicator bits WDT1RST and WDTRST. The ECC NMI is indicated by the respective event flags of SFR EDCSTAT.IRDBE, XRDBE and NVMDBE. Likewise, the supply prewarning NMI and MI_CLK WDT NMI is indicated by the respective event flags located in [Chapter 8, SCU_PM](#).

These NMI event and status flags are otherwise reset to default value with all other resets i.e. power-on, brown-out, hardware, WDT1 (except WDT1RST) and wakeup reset.

7.7 General Port Control

The SCU contains control registers for the selection of:

- alternate input functions of UART, Timers and External Interrupts ([Section 7.7.1](#))
- port output driver strength and temperature compensation ([Section 7.7.2](#))

For functional description of GPIO ports, refer to [Chapter 15](#).

7.7.1 Input Pin Function Selection

MODPISELx registers control the selection of the input pin functions. For UART, the selection of the RXD line also enables the corresponding TXD line.

7.8 Flexible Peripheral Management

The Flexible Peripheral Management sub-module provides the system designer greater control on the operational status of each individual digital peripheral. Peripherals which are not required for a particular functionality can be disabled by programming the assigned register bits which would gate off the clock inputs. This would further reduce overall power consumption of the microcontroller.

Each register bit controls one peripheral. When this bit is set, the request signal to gate the peripheral clock is activated. The peripheral will then synchronize the gating off of the clock to the peripheral.

7.9 Module Suspend Control

When the On-Chip Debug Support (Debug Mode) is in Monitor Mode (halted_o from ARM debug), timers in certain modules in TLE9869QXA20 can be suspended based on the settings of their corresponding module suspend bits in register MODSUSP. When suspended, only the timer stops counting as the counter input clock is gated off. The module is still clocked so that module registers are accessible.

7.11 Watchdog Timer

There are two watchdog timers in the system: SCU Watchdog Timer (WDT) within TLE9869QXA20, and external watchdog timer (WDT1). The description in this section refers to the SCU WDT.

The Watchdog Timer is a sub-module in the System Control Unit (SCU). The Watchdog Timer (WDT) provides a highly reliable and secure way to detect and recover from software or hardware failures. The WDT helps to abort an accidental malfunction of the TLE9869QXA20 in a user-specified time period. When enabled, the WDT will cause the TLE9869QXA20 system to be reset if the WDT is not serviced within a user-programmable time period. The CPU must service the WDT within this time interval to prevent the WDT from causing a TLE9869QXA20 system reset. Hence, routine service of the WDT confirms that the system is functioning properly.

The WDT is by default disabled.

In debug mode, the WDT is default suspended and stops counting (its debug suspend bit is default set i.e., **MODSUSP1**.WDTSUSP = 1. Therefore during debugging, there is no need to refresh the WDT. Refer to [Section 7.9](#)

Features

- 16-bit Watchdog Timer
- Programmable reload value for upper 8 bits of timer
- Programmable window boundary
- Selectable input frequency of $f_{PCLK}/2$ or $f_{PCLK}/128$

If the Window-Boundary Refresh feature of the Watchdog Timer is enabled, the period P_{WDT} between servicing the Watchdog Timer and the next overflow is shortened if WDTWINB is greater than WDTREL. See also [Figure 34](#). This period can be calculated by the same formula by replacing WDTREL with WDTWINB. In order for this feature to be useful, WDTWINB cannot be smaller than WDTREL.

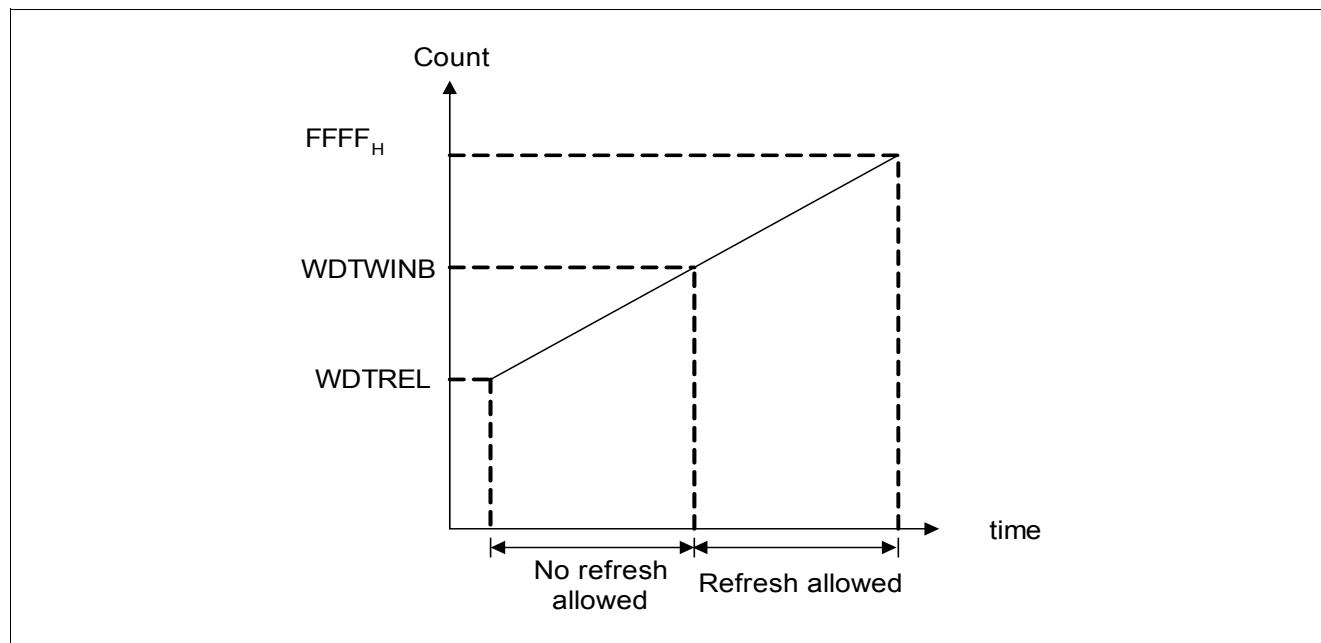

Figure 34 Watchdog Timer Timing Diagram

[Table 9](#) lists the possible ranges for the watchdog time which can be achieved using a certain module clock. Some numbers are rounded to 3 significant digits.

Table 35 Watchdog Time Ranges

Reload Value in WDTREL	Prescaler for f_{PCLK}					
	2 (WDTIN = 0)			128 (WDTIN = 1)		
	40 MHz	20 MHz	13.3 MHz	40 MHz	20 MHz	13.3 MHz
FF _H	12.8 μ s	25.6 μ s	38.4 μ s	0.82 ms	1.64 ms	2.46 ms
7F _H	1.65 ms	3.30 ms	4.95 ms	106 ms	211 ms	317 ms
00 _H	3.28 ms	6.55 ms	9.83 ms	210 ms	419 ms	629 ms

Notes

1. For safety reasons, the user is advised to rewrite WDTCON each time before the Watchdog Timer is serviced.
2. The Watchdog Timer can be suspended when Debug Mode enters Monitor Mode and has the Debug-Suspend signal activated, provided the respective suspend bit, WDTSUSP in SFR SCU_MODSUSP, is set. See [Section 7.9](#).

7.11.2 Register Description

The current count value of the Watchdog Timer is contained in the Watchdog Timer Register WDT, which is a non-bit-addressable read-only register. The operation of the Watchdog Timer is controlled by its bit-addressable Watchdog Timer Control Register WDTCON. WDTREL register specifies the reload value for the high byte of the timer. WDTWINB specifies Watchdog Window-Boundary count value.

WDTREL

Res	6	r	Reserved Returns 0 if read; should be written with 0.
Res	5	r	Reserved Returns 0 if read; should be written with 0.
RSBEC	4	w	RAM Single Bit Error Clear This bit is set by software and can be cleared only by hardware. 0 _B A single bit error on RAM is not cleared. 1 _B A single bit error on RAM is cleared.
Res	3	r	Reserved Returns 0 if read; should be written with 0.
NVMDBEC	2	w	NVM Double Bit Error Clear This bit is set by software and can be cleared only by hardware. 0 _B A double bit error on NVM is not cleared. 1 _B A double bit error on NVM is cleared.
Res	1	r	Reserved Returns 0 if read; should be written with 0.
RDBEC	0	w	RAM Double Bit Error Clear This bit is set by software and can be cleared only by hardware. 0 _B A double bit error on RAM is not cleared. 1 _B A double bit error on RAM is cleared.

7.13 Miscellaneous Control

This module consists of the Bit-Protection Scheme and general system control SFRs.

7.13.1 Bit Protection Register

The Bit-Protection Scheme disallows direct software writing of selected bits (i.e. Protected bits) by the SFR PASSWD. When the bit field MODE is 11_B, writing 10011_B to the bit field PASS opens access to writing of all protected bits and writing 10101_B to the bit field PASS closes access to writing of all protected bits. Note that access is opened for maximum 32 CCLKs if the “close access” password is not written. If “open access” password is written again before the end of 32 CCLK cycles, there will be a recount of 32 CCLK cycles.

PASSWD

Password Register

(0AC_H)

Reset Value: 07_H

7	6	5	4	3	2	1	0
PASS					PROTECT_S	MODE	
wh					rh	rw	

Field	Bits	Type	Description
PASS	7:3	wh	Password Bits The Bit-Protection Scheme only recognizes three patterns. 11000 _B Enables writing of the bit field MODE. 10011 _B Opens access to writing of all protected bits. 10101 _B Closes access to writing of all protected bits.
PROTECT_S	2	rh	Bit-Protection Signal Status Bit This bit shows the status of the protection. 0 _B Software is able to write to all protected bits. 1 _B Software is unable to write to any protected bits.
MODE	1:0	rw	Bit-Protection Scheme Control Bit 00 _B Scheme Disabled 11 _B Scheme Enabled (default) Others: Scheme Enabled These two bits cannot be written directly. To change the value between 11 _B and 00 _B , the bit field PASS must be written with 11000 _B , only then the MODE[1:0] will be registered.

The PASSWD register and the registers which contain protected bits are located in page 2 of the SCU SFR address map. The list of protected bits is shown in [Table 36](#).

System Control Unit - Digital Modules (SCU-DM)

Table 36 List of Protected Bits

7.13.2 System Control and Status Registers

The system startup status register provides information to the user about the system initialisation with the user programmable 100 TP Page at startup. This register is written by firmware.

SYS_STRTUP_STS

System Startup Status Register

(074_H)

Reset Value: 40_H

7	6	5	4	3	2	1	0
Res	Res	Res	Res	Res	PG+_CHKS_ERR	PG100TP_NU	Res
r	r	r	r	r	rwp	rwp	r

Field	Bits	Type	Description
Res	7:3	r	Reserved This bit field is always read as zero.
PG100TP_CHKS_ERR	2	rwp	100 TP Page Checksum Error Initialization of trimming parameters from NVM failed, default values out of Boot-ROM are used because of checksum error.
PG100TP_NU	1	rwp	Status of 100 TP Page No customer values written in customer 100TP Page 1.
Res	0	r	Reserved This bit field is always read as zero.

System Control Unit - Digital Modules (SCU-DM)

SYS_STARTUP_STS contains the main system control and status bits.

This register is reset by **RESET_TYPE_4**. It reflects the NVM Protection Status. It is written by firmware. In order to modify this register the PASSWD open pass phrase has to be written before.

NVM_PROT_STS
NVM Protection Status Register

(0E0_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
Res	Res	Res	Res	NVMPROTSTS			
r				rwp			

Field	Bits	Type	Description
Res	7:4	r	Reserved This bit field is always read as zero.
NVMPROTSTSL_3	3	rwp	NVM Protection Status Register Low Flags 0 _B The data in sectors of the linearly mapped area can not be read 1 _B The data in sectors of the linearly mapped area can be read
NVMPROTSTSL_2	2	rwp	NVM Protection Status Register Low Flags 0 _B The data in sectors of the non-linearly mapped area can not be read 1 _B The data in sectors of the non-linearly mapped area can be read
NVMPROTSTSL_1	1	rwp	NVM Protection Status Register Low Flags 0 _B The data in sectors of the linearly mapped area can not be changed 1 _B The data in sectors of the linearly mapped area can be changed
NVMPROTSTSL_0	0	rwp	NVM Protection Status Register Low Flags 0 _B The data in sectors of the non-linearly mapped area can not be changed 1 _B The data in sectors of the non-linearly mapped area can be changed

System Control Unit - Digital Modules (SCU-DM)

MEM_ACC_STS

Memory Access Status Register

(0E4_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
Res	RAM_PROT_ERR	ROM_ADDR_ERR	ROM_PROT_ERR	NVM_SFR_ADDR_ERR	NVM_SFR_PROT_ERR	NVM_ADDR_ERR	NVM_PROT_ERR
r				rh			

Field	Bits	Type	Description
Res	7	r	Reserved This bit field is always read as zero.
RAM_PROT_ERR	6	rh	RAM Access Protection 0 _B No Protection error 1 _B Protection error
ROM_ADDR_ERR	5	rh	ROM Address Protection 0 _B No Protection error 1 _B Protection error
ROM_PROT_ERR	4	rh	ROM Access Protection 0 _B No Protection error 1 _B Protection error
NVM_SFR_ADDR_ERR	3	rh	NVM SFR Address Protection 0 _B No Protection error 1 _B Protection error
NVM_SFR_PROT_ERR	2	rh	NVM SFR Access Protection 0 _B No Protection error 1 _B Protection error
NVM_ADDR_ERR	1	rh	NVM Address Protection 0 _B No Protection error 1 _B Protection error
NVM_PROT_ERR	0	rh	NVM Access Protection 0 _B No Protection error 1 _B Protection error

This register MEM_ACC_STS is reset by RESET_TYPE_3. It reflects the Memory Access Status of all System Memories. Software can only clear this register.

System Control Unit - Digital Modules (SCU-DM)

The Identity Register identifies the product and versioning.

ID
Identity Register
(0A8_H)
Reset Value: 8_H

7	6	5	4	3	2	1	0
PRODID					VERID		
r					r		

Field	Bits	Type	Description
PRODID	7:3	r	Product ID 10000 _B
VERID	2:0	r	Version ID Defines the stepping code of the device. 001 _B 010 _B

System Control Unit - Digital Modules (SCU-DM)

The Memory Status Register can be used in two ways. Upon the completion of the Boot ROM startup following a reset, the register stores the NVM initialization status. Subsequently, the register can be used by the user code to store the status of the NVM program and emergency program operation status.

For Boot ROM to indicate NVM initialization status upon completion of startup:

MEMSTAT

Memory Status Register

(0DC_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
SASTATUS		SECTORINFO					
rw		rw					

Field	Bits	Type	Description
SASTATUS	7:6	rw	Service Algorithm Status 00 _B Depending on SECTORINFO, there are two possible outcomes: For SECTORINFO = 00 _H , NVM initialization is successful and no SA is executed. For SECTORINFO = values other than 00 _H , SA execution is successful and only one map error is fixed. 01 _B SA execution is successful. More than one mapping error is fixed. 10 _B SA execution is not successful. Map error exists in one sector. 11 _B SA execution is not successful. At least one sector failed (this includes also the case where a sector is repaired but another sector is still failing).
SECTORINFO	5:0	rw	Sector Information 01 _H to 10 _H , which represent the different sector addresses. For values not within this range, the data will be considered invalid. Once the SA has been executed, regardless of the execution status, the last accessed sector information will be stored here.

System Control Unit - Digital Modules (SCU-DM)

For user code to indicate the NVM program and emergency program operation status:

MEMSTAT

Memory Status Register

(0DC_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
Res						EMPROP	NVMPROP
rw						rw	rw

Field	Bits	Type	Description
Res	7:2	rw	Reserved Bits Should be written with 0.
EMPROP	1	rw	Emergency Program Operation Status Bit This bit is used to store the status of the emergency program operation. 0 _B No emergency program operation is requested. 1 _B An emergency program operation is requested.
NVMPROP	0	rw	NVM Program Operation Status Bit This bit is used to store the status of the NVM program operation. 0 _B No NVM program operation is started. 1 _B An NVM program operation is started.

8 System Control Unit - Power Modules (SCU-PM)

8.1 Features

- Clock Watchdog Unit (CWU): supervision of all power modules relevant clocks with NMI signalling.
- Interrupt Control Unit (ICU): all system relevant interrupt flags and status flags.
- Power Control Unit (PCU): takes over control when device enters and exits Sleep and Stop Mode.
- External Watchdog (WDT1): independent system watchdog to monitor system activity.

8.2 Introduction

8.2.1 Block Diagram

The System Control Unit of the power modules consists of the sub-modules in the figure shown below:

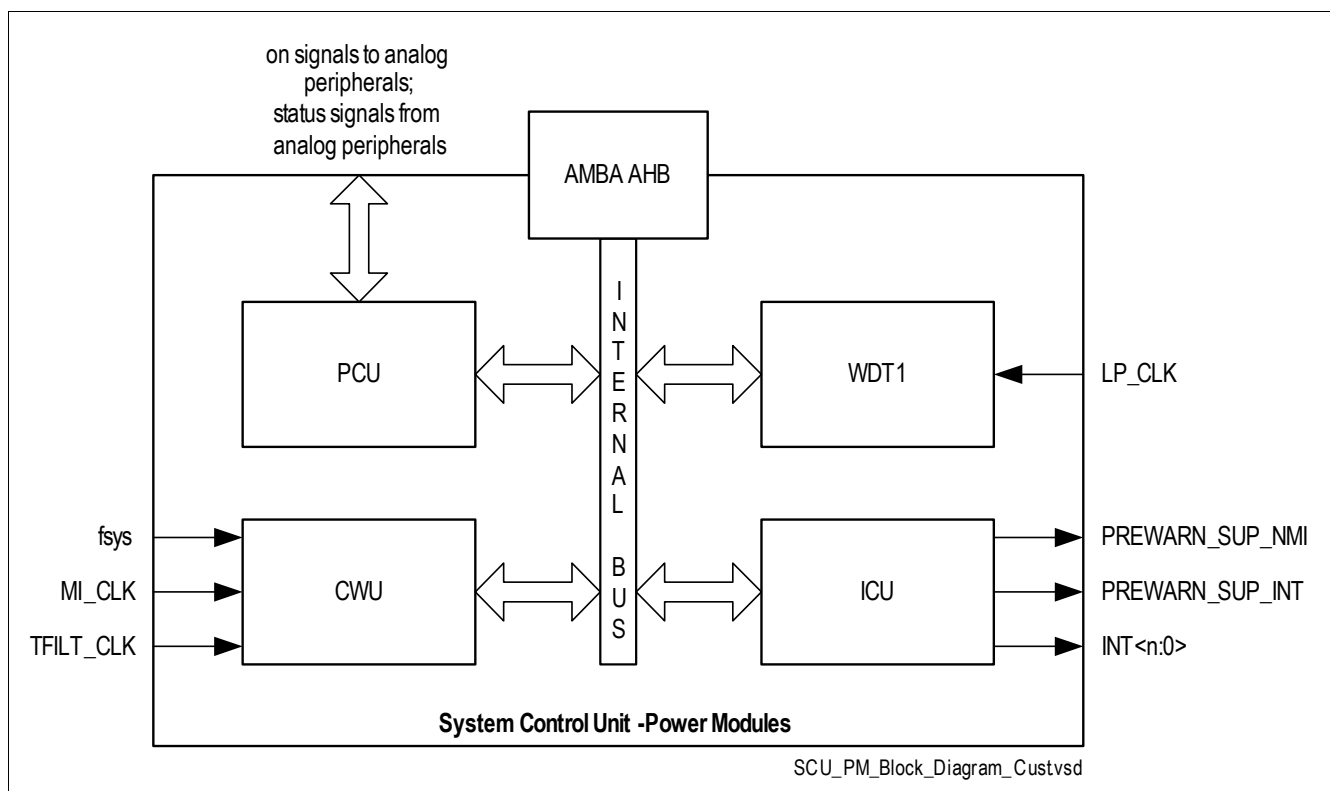

Figure 35 Block diagram of System Control Unit - Power Modules

AMBA AHB (Advanced High-Performance Bus)

CWU (Clock Watchdog Unit)

- fsys; system frequency: output of PLL
- MI_CLK; measurement interface clock (analog clock): derived out of fsys by division factors 1/2/3/4
- TFILT_CLK; clock used for digital filters: derived out of fsys by configurable division factors

WDT1 (System Watchdog)

- LP_CLK; clock source for all PMU submodules and WDT1

ICU (Interrupt Control Unit)

- PREWARN_SUP_NMI; supply prewarning NMI request
- PREWARN_SUP_INT; supply prewarning interrupt
- INT<n:0>; interrupt

8.3 Clock Watchdog Unit (CWU)

There are two clock watchdogs available. One main purpose of them, is to monitor the derived switched capacitor clocks, which are used for analog module operation. If the clocks are not in the required range, a proper functionality of those modules is not given.

The following chapter describes the functionality and the configuration possibilities of these clock watchdogs.

8.3.1 Fail Safe Functionality of Clock Generation Unit (Clock Watchdog)

The Clock Generation Unit provides also fail safe functionalities, which are related to the input clock, the generated clocks and the clock settings. Those are:

- **MI_CLK** and **TFILT_CLK** are out of Range: MI Clock settings for f_{sys} , MI_CLK and TFILT_CLK Clock settings are out of required range and as a result the analog functionalities cannot be guaranteed. This failure triggers the clock watchdog NMI. The current status can be seen in the corresponding registers APCLK1 (in SCU) for the **MI_CLK** and APCLK2 (in SCU) for the **TFILT_CLK**.
- **Loss of clock:** When there is a loss of clock in the system, there is no possibility for the software to react upon this situation, like to enter a fail safe mode or switch to another backup clock source. For this purpose there is a clock watchdog implemented in the system which monitors the f_{sys} and in case of this emergency situation, disables all critical system functions, which are:
 - Bridge Driver and Charge Pump
 - LIN

As shown in [Figure 36](#) all analog clocks are derived from **MI_CLK**. This clock structure requires to place a monitor on this clock, because f_{sys} and therefore **MI_CLK** are adjustable in a wide range (see also Chapter **System Control Unit - CGU**). As an important clock, also the TFILT_CLK is monitored by a clock watchdog. This clock watchdogs have an adjustable lower and upper limits including hysteresis. The placement of the clock watchdogs in the clock structure is sketched below:

Figure 36 Block diagram of CGU including Clock Watchdogs

8.3.1.1 Functional Description of Clock Watchdog Module

The clock watchdog module consists of a counter. This counter monitors the number of system clocks within a defined time window. The duration of the time window is defined by a clock (**LP_CLK**), which is independent from the monitored system clock (**MI_CLK**). If the required number of clock cycles is not reached within this time window an clock watchdog NMI will be issued.

In case the clock watchdog NMI will be issued, indicating that the clock is not within the required frequency range, then the user has different options to overcome this situation:

- stay on mi_clk but reconfigure PLL to re-gain the required clock frequency. This would be the most time consuming measure to avoid emergency shutdown of the above listed modules.
- switch to divider factors 2, 3 and 4 to try to come back to specified frequency range.
- switch to LP_CLK, which also can be divided by factor 2, 3 and 4. This is the fastest option which allows the user to operate with a well defined backup clock rate. After this has been done the user can start investigating the rootcause of the issued clock watchdog NMI, while operating on **LP_CLK**.

The register chapter below includes all necessary flags for setting up the analog module clock and monitoring its status during operation.

8.3.2 Clock Generation Unit Register

The analog module clock generation unit is fully controllable by the register described in this chapter.

[Table 37](#) shows the module base addresses.

Table 37 Register Address Space

Module	Base Address	End Address	Note

System Tick Calibration Register

The register is reset by RESET_TYPE_4.

STCALIB	Offset	Reset Value
System Tick Calibration Register	6C_H	0000 0000_H

Field	Bits	Type	Description
Res	31:26	r	Reserved Always read as 0
STCALIB	25:0	rw	System Tick Calibration [25]: Noref [24] Skew [23:0] Reload value to use for 10ms (100 Hz) timing STCALIB[23:0] = HCLK (in Hz) / 100 Hz - 1, e.g. 0x7A11F

8.4 Interrupt Control Unit (ICU)

The Subblock Interrupt Control Unit (ICU) of the System Control Unit - Power Modules (SCU_PM) is responsible for controlling and generating all analog peripheral relevant interrupts. Those analog interrupts are presented to the NVIC nodes 13-24 and NMI. Those are:

- **PREWARN_SUP_NMI**: combines all supply relevant interrupts to NMI.
- **Analog Module Interrupts**: combines all analog modules related interrupts.

The following two chapters describe the structure of the interrupt nodes.

8.4.1 Structure of PREWARN_SUP_NMI

This interrupt groups all system supply relevant interrupts. They can be divided into two groups:

- **voltages monitored by the Measurement Unit**. The supply voltages VS, VBAT_SENSE, VDDP and VDDC are monitored by the Measurement Unit. The Measurement Unit can be seen as an independent monitoring instance of the PMU, with independent reference voltage and supply voltage.
- **voltages monitored by measurement functions of the PMU**: The PMU itself is checking its output voltages. Here failures due to undervoltage (overload), overvoltage and overcurrent can be detected.

The following figure shows the structure of the **PREWARN_SUP**:

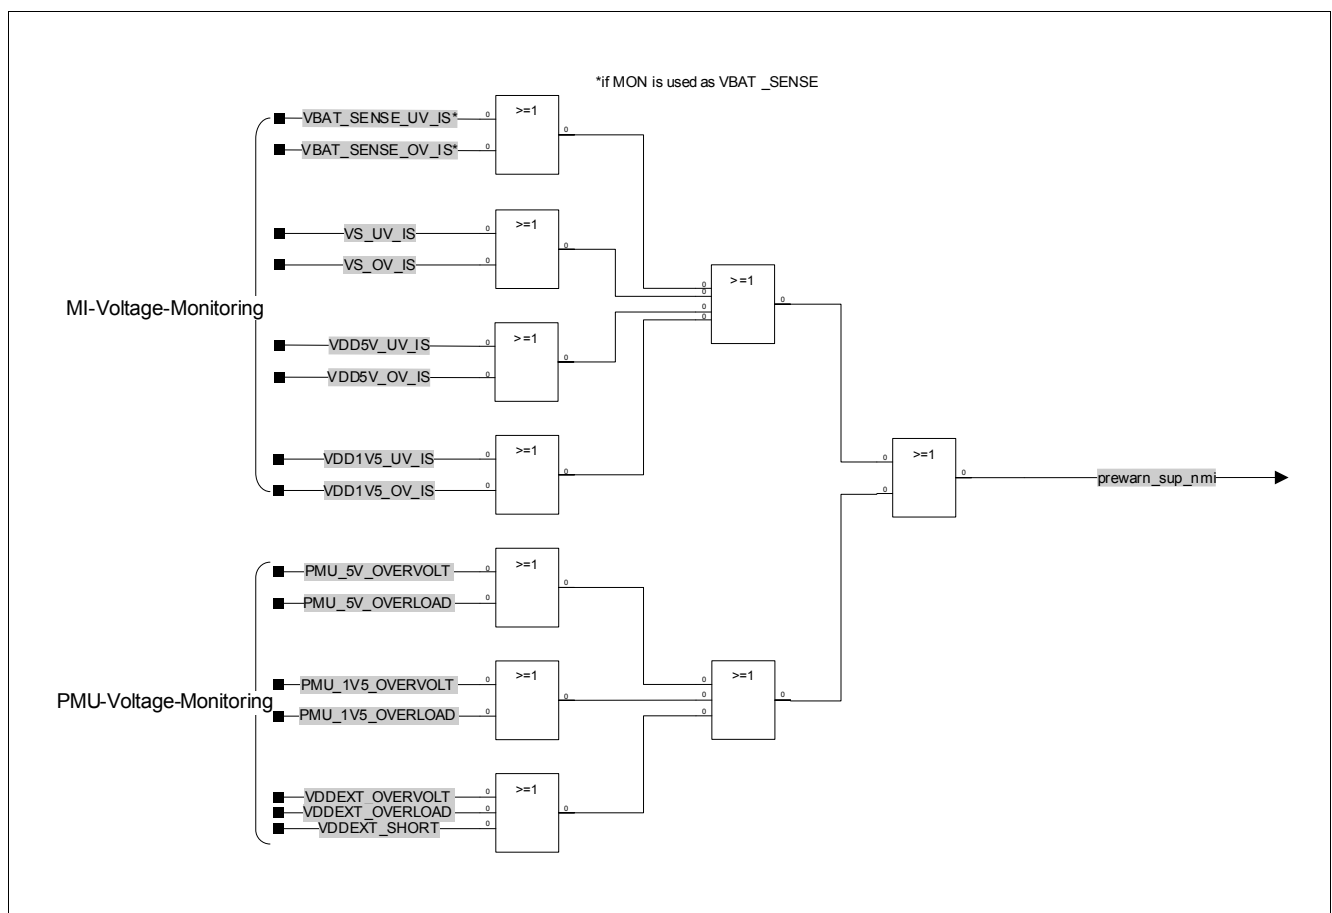

Figure 37 Structure of PREWARN_SUP

All PREWARN_SUP related flags are grouped in register **SYS_SUPPLY_IRQ_STS**. All measurement interface related flags are edge triggered. Therefore each IRQ_STS register has also an STS register where the current supply status can be monitored.

8.4.2 Interrupt Control Unit Status Register

All analog modules interrupt functionality is described in this chapter.

Table 39 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Interrupt Control Unit Status Register, Interrupt Control Unit Status Overview Register

BDRV_IRQ_CTRL	Bridge Driver Interrupt Control	5C _H	0000 0000 _H

The registers are addressed wordwise.

8.4.2.1 Interrupt Control Unit Status Overview Register

Due to the large variety of diagnosis possibilities of TLE9869QXA20, the system offers several overview registers, to help the user finding the right source of interrupt. Those registers are described in this sub-chapter.

Overview Register, Switches Interrupt Status Register and System Supply Interrupt Status Register

- **SYS_SUPPLY_IRQ_STS**: Flags for Under- and Overvoltage detection for all system relevant supplies. These Interrupts are edge triggered Interrupts.
- **SYS_IS**: Interrupts for Analog Modules.

System Control Unit - Power Modules (SCU-PM)

8.5 Power Control Unit for Power Modules (PCU_PM)

The chapter describes the implementation of the power modules state machine. This state machine is responsible for powering up and powering down the on-board power modules. It takes care about the interaction between the Measurement Unit and the modules which are evaluated by the Unit. The following modules are controlled by this statemachine:

Analog Modules controlled by Power Control Unit:

- Central Reference Voltage Generation
- Central Bias Current Generation
- 8-Bit ADC Core
- Supply Voltage Attenuators
- Monitoring Inputs Voltage Attenuators
- LIN Transceiver
- MOSFET Drivers

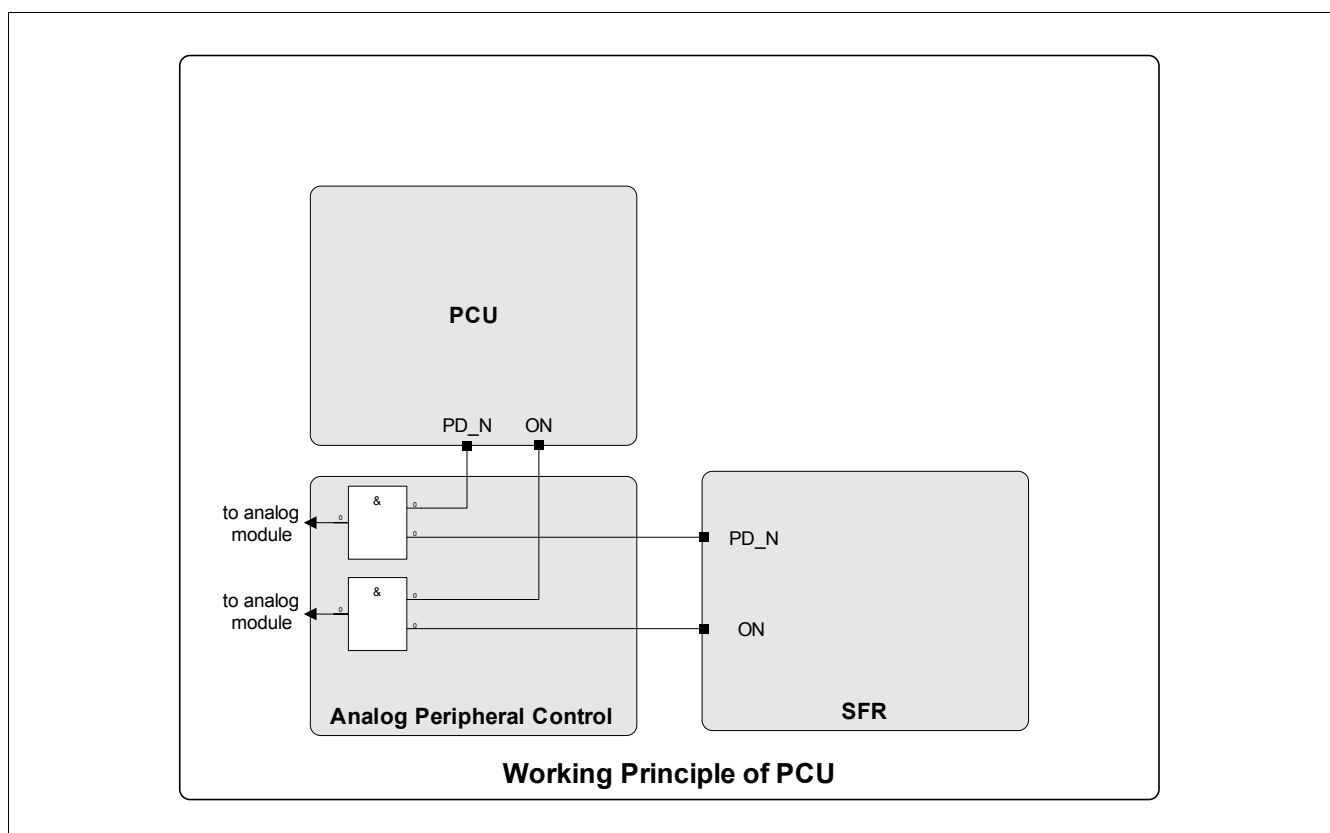

Figure 38 Function of AP_SUB_CTRL

System Control Unit - Power Modules (SCU-PM)

If the device will power up the analog modules statemachine will startup all analog modules. First of all, the reference voltage will be enabled. After that the biasing module will be enabled. If this step is completed the analog modules will be enabled step by step. After this is done the measurement interface will start-up.

When leaving Stop Mode, this sequence restores the SFR register contents with the values written before entering Stop Mode.

The Sleep and Stop Mode entry is as well controlled by this state machine. This ensures a smooth shutdown of the modules avoiding disturbances (like load jumps) on the supplies.

The power control unit also handles system failures indicated by the analog measurement interface. They are:

System failures handled by SCU_PM:

- automatic shutdown of power modules in case of VS Overvoltage
- automatic shutdown of power modules in case of System Overtemperature
- automatic shutdown of power modules in case of loss of clock
- automatic shutdown of system in case of System Overtemperature
- automatic shutdown of system in case of internal supply fail
- automatic shutdown of LIN module in case of VS Undervoltage

How to configure this actions on the above described system failures will be described in the following chapters.

8.5.1 VSD-Overvoltage System Shutdown

The PCU provides the possibility of an system shutdown in case of VSD Overvoltage. This feature can be used to reduce power dissipation in case of an increased supply voltage VSD. This feature can be enabled by bit **SYS_VSD_OV_SLM_DIS**. **This bit is low active!**. When there is an overvoltage, the system will be set in System Shutdown and all Power Modules as:

- LIN
- Bridge Driver
- Charge Pump
- Supply Voltage Attenuators

are switched off automatically. The Power Modules will be switched on when the VSD-Overvoltage condition is left again. The figure below shows the principle of the enable bit:

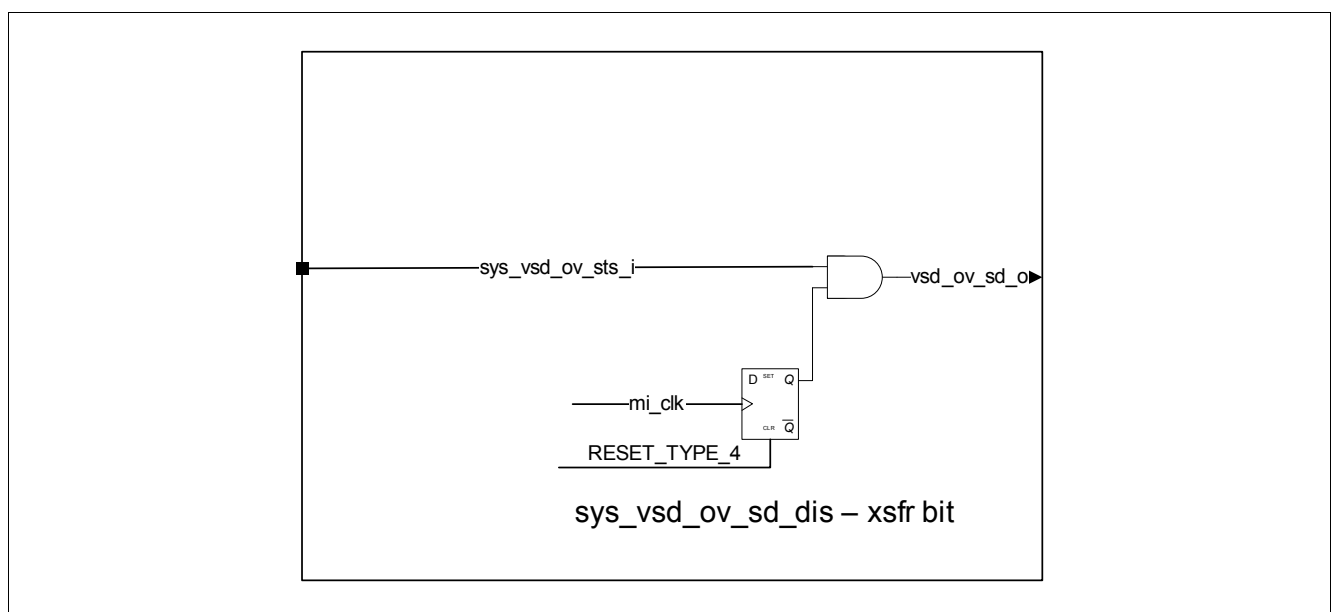

Figure 39 Implementation of Module Shutdown because of VSD Overvoltage

8.5.2 Overtemperature System Shutdown

In case of overtemperature ($T_j > 150\text{ }^{\circ}\text{C}$) the system will be set to Sleep Mode. This functionality is used to protect the system from thermal overstress. One possibility of avoiding this thermal shutdown is to stick to an emergency procedure, which helps to minimize the power dissipation in the system. This routine would require to shutdown all modules which have big contribution to power dissipation (e.g. Bridge Driver). This procedure has to be implemented in user software. Another possibility is to use the implemented hardware shutdown procedure. This procedure can be activated by the flag **SYS_OT_PS_DIS**. **This flag is low active!** When this flag is set all power dissipation contributors will be automatically shutdown.

- Main power dissipation contributors are:
 - Bridge Driver and Charge Pump
 - LIN

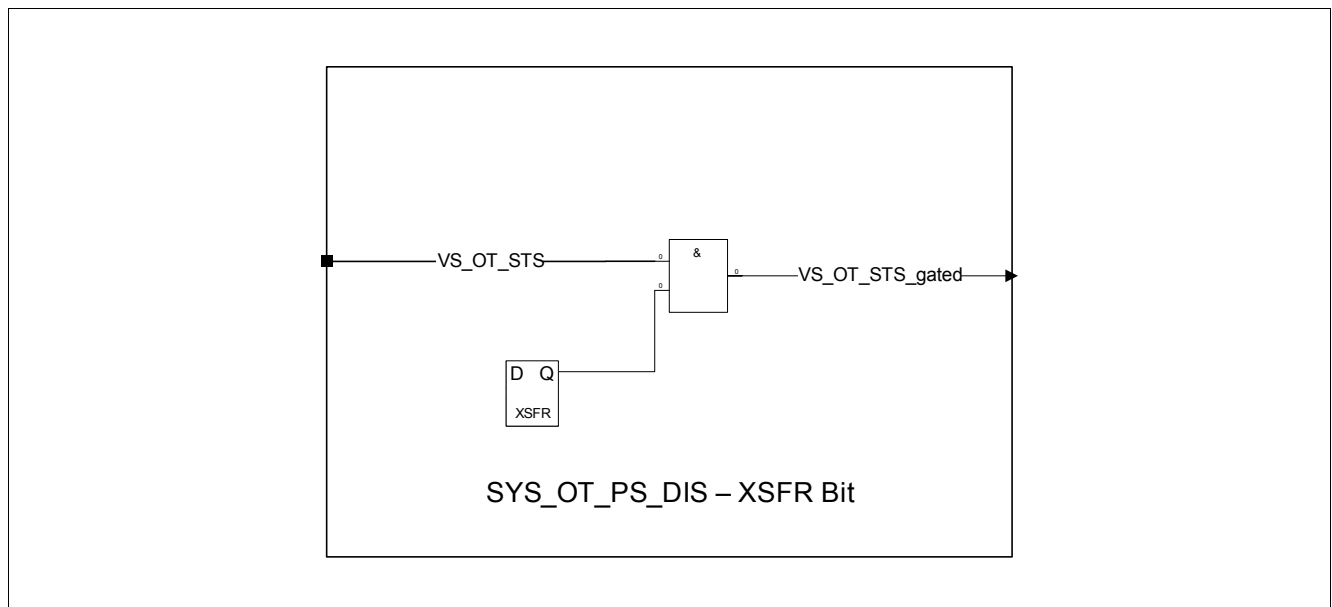

Figure 40 Implementation of Power Module Shutdown in case of System Overtemperature

As it can be seen, the bit is gating the status flag VS_OT_STS. If this bit is set, 1ms after the indication the system will be set into Sleep Mode.

8.5.3 Power Control Unit Register

The PCU is fully controllable by the below listed SFR Registers.

Table 40 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Power Control Unit Register			
PCU_CTRL_STS	Power Control Unit Control Status Register	30 _H	06E3 7EF3 _H

The registers are addressed wordwise.

Power Control Unit Register

The register is reset by RESET_TYPE_4.

8.6 MISC Control

8.6.1 Bus Faults

Due to the pipeline structure of the ARM Cortex M3 core, it is difficult to determine the fault address of a non-existing or protected memory region. For this reason, the following register allows the user to determine the address of the memory access that caused the fault. The registers model the processor's instruction pipeline.

8.6.1.1 Bus Fault Control Register

For the determining the address of a bus fault exception the following registers should be used.

Table 41 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Bus Fault Control Register			
BFSTS	Bus Fault Status Register	80 _H	0000 0000 _H
DBFA	Data Bus Fault Address Register	84 _H	xxxx xxxx _H
SBFA	System Bus Fault Address Register	88 _H	xxxx xxxx _H
BFSTS_CLR	Bus Fault Status Clear Register	8C _H	0000 0000 _H

The registers are addressed wordwise.

System Control Unit - Power Modules (SCU-PM)

BUS_FAULT_STATUS

The register is reset by RESET_TYPE_3.

The register is clocked by PCLK2 and reset by ap_all_reset_n_i.

System Control Unit - Power Modules (SCU-PM)

SYSTEM_BUS_FAULT_ADDRESS

The register is reset by RESET_TYPE_3.

The register is clocked by PCLK2 and reset by ap_all_reset_n_i.

SBFA	Offset	Reset Value
System Bus Fault Address Register	88_H	xxxx xxxx_H

Field	Bits	Type	Description
SBFA	31:0	r	Reserved Always read as 0

9 ARM Cortex M3 Core

9.1 Features

The key features of the Cortex M3 implemented are listed below.

Processor Core. A low gate count core, with low latency interrupt processing:

- A subset of the Thumb[®]-2 Instruction Set
- Banked stack pointer (SP) only
- 32-bit hardware divide instructions, SDIV and UDIV (Thumb-2 instructions)
- Handler and Thread Modes
- Thumb and debug states
- Interruptible-continued instructions LDM/STM, Push/Pop for low interrupt latency
- Automatic processor state saving and restoration for low latency Interrupt Service Routine (ISR) entry and exit
- ARM architecture v7-M Style BE8/LE support
- ARMv6 unaligned accesses

Nested Vectored Interrupt Controller (NVIC) closely integrated with the processor core to achieve low latency interrupt processing:

- External interrupts, configurable from 1 to 16
- Bits of priority (4)
- Dynamic reprioritization of interrupts
- Priority grouping. This enables selection of preemptive interrupt levels and non preemptive interrupt levels
- Support for tail-chaining and late arrival of interrupts. This enables back-to-back interrupt processing without the overhead of state saving and restoration between interrupts.
- Processor state automatically saved on interrupt entry, and restored on interrupt exit, with no instruction overhead

Bus interfaces

- Advanced High-performance Bus-Lite (AHB-Lite) interfaces: ICode, DCode, and System bus interface
- Memory access alignment
- Write buffer for buffering of write data

9.2 Introduction

The ARM Cortex-M3 processor is a leading 32-bit processor and provides a high-performance and cost-optimized platform for a broad range of applications including microcontrollers, automotive body systems and industrial control systems. Like the other Cortex family processors, the Cortex-M3 processor implements the Thumb®-2 instruction set architecture. With the optimized feature set the Cortex-M3 delivers 32-bit performance in an application space that is usually associated with 8- and 16-bit microcontrollers.

9.2.1 Block Diagram

Figure 41 shows the functional blocks of the Cortex M3.

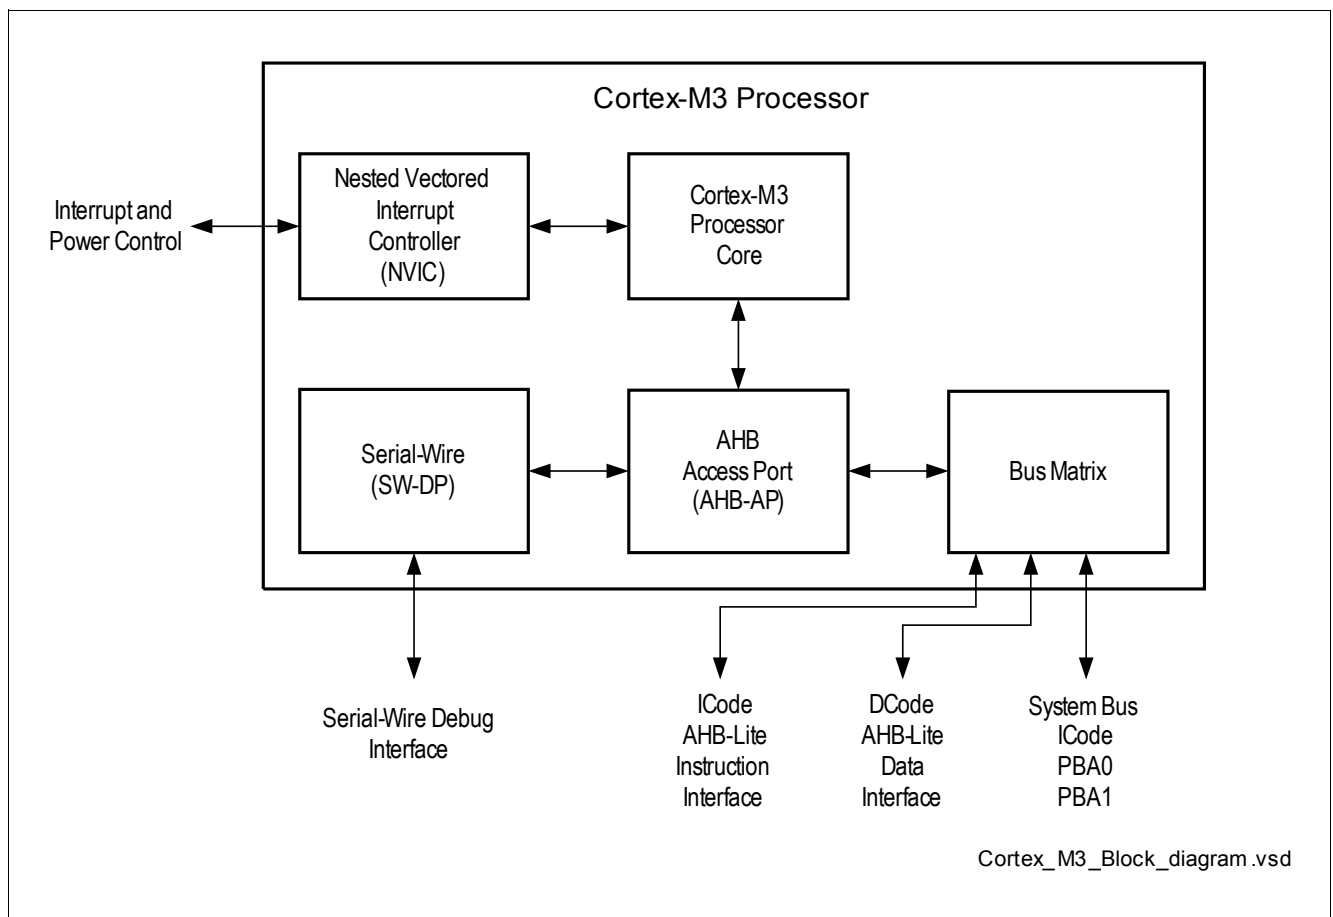

Figure 41 Cortex M3 Block Diagram

9.3 Functional Description

9.3.1 Registers

The processor has the following 32-bit registers:

- 13 general-purpose registers, R0-R12
- Stack pointer (SP), R13 alias of banked registers, SP_process and SP_main
- Link register (LR), R14
- Program counter (PC), R15
- Special-purpose program status registers (xPSR)

Figure 42 Processor Register Set

9.3.1.1 General-Purpose Registers

The general-purpose registers R0-R12 have no special architecturally-defined uses. Most instructions that can specify a general-purpose register can specify R0-R12.

Low Registers

Registers R0-R7 are accessible by all instructions that specify a general-purpose register.

High Registers

Registers R8-R12 are accessible by all 32-bit instructions that specify a general-purpose register.

Registers R8-R12 are not accessible by all 16-bit instructions.

Registers R13, R14, and R15 have the following special functions:

Stack Pointer

Register R13 is used as Stack Pointer (SP).

Link Register

Register R14 is the subroutine Link Register (LR).

Program counter

Register R15 is the Program Counter (PC).

9.3.1.2 Special-Purpose Program Status Registers (xPSR)

Processor status at the system level breaks down into three categories:

- Application PSR
- Interrupt PSR
- Execution PSR

They can be accessed as individual registers, a combination of any two from three, or a combination of all three using the Move to Register from Status (MRS) and MSR instructions.

9.4 Summary of Processor Registers

The processor has the following 32-bit registers that control functionality:

Table 42 Register Address Space for Processor Registers

Module	Base Address	End Address	Note

Interrupt Controller Type Register

ICT	Offset	Reset Value
Interrupt Controller Type	004 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:5	r	Reserved
INTLINESNUM	4:0	r	Interrupt Lines Total number of interrupt lines in groups of 32: 00000 _B 0 to 32 ¹⁾ 00001 _B 33 to 64 00010 _B 65 to 95 00011 _B 97 to 128 00100 _B 129 to 160 00101 _B 161 to 192 00110 _B 193 to 224 00111 _B 225 to 256 ¹⁾

1) The processor only supports between 1 and 240 interrupts.

SysTick Current Value Registers

SYSTICK_CUR	Offset	Reset Value
SysTick Current Value	018 _H	00XX XXXX _H

Field	Bits	Type	Description
RES	31:24	r	Reserved
CURRENT	23:0	rwc	Current Current value at the time the register is accessed. No read-modify-write protection is provided, so change with care. This register is write-clear. Writing to it with any value clears the register to 0. Clearing this register also clears the COUNTFLAG bit of the SysTick Control and Status Register.

SysTick Calibration Value Registers

SYSTICK_CAL	Offset	Reset Value
SysTick Calibration Value	01C _H	XX00 0000 XXXX XXXX XXXX XXXX XXXX XXXX _B

Field	Bits	Type	Description
NOREF	31	r	No Reference Clock 0 _B n.u. 1 _B the reference clock is not provided
SKEW	30	r	Skew 0 _B n.u. 1 _B the calibration value is not exactly 10 ms because of clock frequency. This could affect its suitability as a software real time clock.
RES	29:24	r	Reserved
TENMS	23:0	r	Tenms This value is the Reload value to use for 10ms timing. Depending on the value of SKEW, this might be exactly 10ms or might be the closest value. If this reads as 0, then the calibration value is not known. This is probably because the reference clock is an unknown input from the system or scalable dynamically.

Field	Bits	Type	Description

Int_EXINT1	13	rw	Interrupt Clear Pending for External Int 1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_EXINT0	12	rw	Interrupt Clear Pending for External Int 0 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_UART2	11	rw	Interrupt Clear Pending for UART2 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending

Field	Bits	Type	Description
Int_UART1	10	rw	Interrupt Clear Pending for UART1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_SSC2	9	rw	Interrupt Clear Pending for SSC2 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_SSC1	8	rw	Interrupt Clear Pending for SSC1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_CCU6SR3	7	rw	Interrupt Clear Pending for CCU6 SR3 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_CCU6SR2	6	rw	Interrupt Clear Pending for CCU6 SR2 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_CCU6SR1	5	rw	Interrupt Clear Pending for CCU6 SR1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_CCU6SR0	4	rw	Interrupt Clear Pending for CCU6 SR0 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_ADC1	3	rw	Interrupt Clear Pending for ADC1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_ADC2	2	rw	Interrupt Clear Pending for MU, ADC2 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending

Field	Bits	Type	Description
Int_GPT2	1	rw	Interrupt Clear Pending for GPT2 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending
Int_GPT1	0	rw	Interrupt Clear Pending for GPT1 0 _B Not Pending on reads the associated interrupt is not pending, no effect on writes 1 _B Pending on reads the associated interrupt is pending, on writes the status of the associated interrupt is changed to not pending

Field	Bits	Type	Description
Int_SSC2	9	r	Interrupt Active for SSC2 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_SSC1	8	r	Interrupt Active for SSC1 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_CCU6SR3	7	r	Interrupt Active for CCU6 SR3 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_CCU6SR2	6	r	Interrupt Active for CCU6 SR2 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_CCU6SR1	5	r	Interrupt Active for CCU6 SR1 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_CCU6SR0	4	r	Interrupt Active for CCU6 SR0 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_ADC1	3	r	Interrupt Active for ADC1 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_ADC2	2	r	Interrupt Active for MU, ADC2 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_GPT2	1	r	Interrupt Active for GPT2 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation
Int_GPT1	0	r	Interrupt Active for GPT1 0 _B DISABLE disables interrupt for read operation, no effect for write operation 1 _B ENABLE enables interrupt for read and write operation

CPU ID Base Register

CPUID	Offset	Reset Value
CPU ID Base Register	D00 _H	412F C231 _H

Field	Bits	Type	Description
IMPLEMENTER	31:24	r	Implementer Code Assigned by ARM. Read as 41 _H for a processor implemented by ARM.
VARIANT	23:20	r	Variant Number Implementation defined.
ARCHITECTURE	19:16	r	Architecture Read as F _H .
PARTNO	15:4	r	Part Number Implementation defined.
REVISION	3:0	r	Revision Number Implementation defined.

r			r	r		r							

Field	Bits	Type	Description
NMIPENDSET	31	rw	NMI PendSet On writes, makes the NMI exception active. On reads, indicates the state of the exception. <i>Note: Because NMI is higher priority than other exceptions, if the processor is not already executing the NMI handler, it enters the NMI exception handler as soon as it recognizes the write to this bit.</i> 0 _B on writes, has no effect. On reads, NMI is active. 1 _B on writes, make the NMI exception active. On reads, NMI is active.
RES	30:29	r	Reserved
PENDSVSET	28	rw	PENDSVSET On writes, sets the PendSV exception as pending. On reads, indicates the current state of the exception. <i>Note: Normally, software writes 1 to this bit to request a context switch.</i> 0 _B on writes, has no effect. On reads, PendSV is not pending. 1 _B on writes, make PendSV exception pending. On reads, PendSV is pending.
PENDSVCLR	27	w	PENDSVCLR Removes the pending status of the PendSV exception 0 _B no effect 1 _B remove pending status
PENDSTSET	26	rw	PENDSTSET On writes, sets the SysTick exception as pending. On reads, indicates the current state of the exception. 0 _B on writes, has no effect. On reads, SysTick is not pending. 1 _B on writes, make SysTick exception pending. On reads, SysTick is pending.

Field	Bits	Type	Description
PENDSTCLR	25	w	PENDSTCLR Removes the pending status of the SysTick exception. 0 _B no effect 1 _B remove pending status
RES	24	r	Reserved
ISRPREEMPT	23	r	ISRPREEMPT Indicates whether a pending exception will be serviced on exit from debug halt state. 0 _B will not service 1 _B will service a pending exception
ISRPENDING	22	r	ISRPENDING Indicates whether an external interrupt, generated by the NVIC, is pending. 0 _B no external interrupt is pending 1 _B external interrupt is pending
RES	21	r	Reserved
VECTPENDING	20:12	r	VECTPENDING The exception number for the highest priority pending exception. A value of 0 indicates that there is no pending exception. 0 _B no pending exceptions
RETTOBASE	11	r	RETTOBASE In Handler Mode, indicates whether there is an active exception other than the exception indicated by the current value of the IPSR. <i>Note: In Thread Mode the value of this bit is unknown.</i> 0 _B There is an active exception other than the exception shown by IPSR. 1 _B There is no active exception other than any exception shown by IPSR.
RES	10:9	r	Reserved
VECTACTIVE	8:0	r	VECTACTIVE The exception number of the current executing exception. A value of 0 indicates that the processor is in Thread Mode. 0 _B Thread Mode

Vector Table Offset Register

VTOR	Offset	Reset Value
Vector Table Offset Register	D08 _H	0000 0000 _H

Field	Bits	Type	Description
TBLOFF	31:7	rw	Vector Table Offset Bits[31:7] of the vector table address.
RES	6:0	r	Reserved

Application Interrupt/Reset Control Register

AIRCR	Offset	Reset Value
Application Interrupt/Reset Control Register	D0C _H	0000 0000 _H

Field	Bits	Type	Description
VECTKEY	31:16	rw	Vector Key Register writes must write 05FA _H to this field, otherwise the write is ignored. On reads, returns FA05 _H .
ENDIANNESS	15	r	Memory System Endianness This bit is static or configured by hardware input on reset. 0 _B little endian 1 _B big endian
RES	14:11	r	Reserved
PRIGROUP	10:8	rw	Priority Grouping Indicates the binary point position. This bit resets to 000 _B
RES	7:3	r	Reserved
SYSRESETREQ	2	rw	System Reset Request Writing 1 to this bit asserts a signal to the external system to request a Local reset. A Local or Power-on reset clears this bit to 0. 0 _B do not request a reset 1 _B request a reset
VECTCLRACTIVE	1	w	VECTCLRACTIVE Writing 1 to this bit clears all active state information for fixed and configurable exceptions. This includes clearing the IPSR to zero. <i>Note: The effect of writing a 1 to this bit, if the processor is not halted in Debug state, is unpredictable.</i>

Field	Bits	Type	Description
VECTRESET	0	w	<p>VECTRESET</p> <p>Writing 1 to this bit causes a local system reset. This bit self-clears.</p> <p><i>Note: The effect of writing a 1 to this bit, if the processor is not halted in Debug state, is unpredictable.</i></p> <p><i>When the processor is halted in Debug state, if a write to the register writes a 1 to both VECTRESET and SYSRESETREQ, the behavior is unpredictable.</i></p>

System Control Register

SCR	Offset	Reset Value
System Control Register	D10_H	0000 0000_H

Field	Bits	Type	Description
RES	31:5	r	Reserved
SEVONPEND	4	rw	SEVONPEND Determines whether an interrupt transition from inactive state to pending state is a wake-up event. 0 _B transitions from inactive to pending are not wake-up events 1 _B transitions from inactive to pending are wake-up events
RES	3	r	Reserved
SLEEPDEEP	2	rw	Sleep Deep Provides a qualifying hint that waking from sleep might take longer. An implementation can use this bit to select between two alternative sleep states. <i>Note: Details of the implemented sleep states, if any, and details of the use of this bit, are implementation defined.</i> <i>If the processor does not implement a deep sleep state then this bit can be RAZ/WI.</i> 0 _B selected sleep state is not deep sleep 1 _B selected sleep state is deep sleep
SLEEPONEXIT	1	rw	Sleep on Exit Determines whether, on an exit from an ISR that returns to the base level of execution priority, the processor enters a sleep state. 0 _B do not enter sleep state 1 _B enter sleep state
RES	0	r	Reserved

Configuration Control Register

CCR
Configuration Control Register

Offset
D14_H

Reset Value
0000 0200_H

Field	Bits	Type	Description
RES	31:10	r	Reserved
STKALIGN	9	rw	STKALIGN Determines whether the exception entry sequence guarantees 8-byte stack frame alignment, adjusting the SP if necessary before saving state 0 _B guaranteed SP alignment is 4-byte, no SP adjustment is performed. 1 _B 8-byte alignment guaranteed, SP adjusted if necessary.
BFHFMIGN	8	rw	BFHFMIGN Determines the effect of precise data access faults on handlers running at priority -1 or priority -2. 0 _B precise data access fault causes a lockup 1 _B handler ignores the fault
RES	7:5	r	Reserved
DIV_0_TRP	4	rw	DIV_0_TRP Controls the trap on divide by 0. 0 _B trapping disabled 1 _B trapping enabled
UNALIGN_TRP	3	rw	UNALIGN_TRP Controls the trapping of unaligned word or halfword accesses. <i>Note: Unaligned load-store multiples and word or halfword exclusive accesses always fault.</i> 0 _B trapping disabled 1 _B trapping enabled
RES	2	r	Reserved

Reset Value
0000 0000_H

Field	Bits	Type	Description
PRI_15	31:24	rw	Priority of System Handler 15, SysTick
PRI_14	23:16	rw	Priority of System Handler 14, PendSV
PRI_13	15:8	rw	Reserved for Priority of System Handler 13
PRI_12	7:0	rw	Priority of System Handler 12, DebugMonitor

Field	Bits	Type	Description
RES	9	r	Reserved
MONITORACT	8	rw	MONITORACT²⁾ 0 _B Monitor is not active 1 _B Monitor is active
SVCALLACT	7	rw	SVCALLACT²⁾ 0 _B SVCALL is not active 1 _B SVCALL is active
RES	6:4	r	Reserved
USGFAULTACT	3	rw	USGFAULTACT²⁾ 0 _B UsageFault is not active 1 _B UsageFault is active
RES	2	r	Reserved
BUSFAULTACT	1	rw	BUSFAULTACT²⁾ 0 _B BusFault is not active 1 _B BusFault is active
MEMFAULTACT	0	rw	MEMFAULTACT²⁾ 0 _B MemManage is not active 1 _B MemManage is active

1) Pending state bits are set to 1 when an exception occurs, and are cleared to 0 when the exception becomes active.

2) Active state bits are set to 1 if the associated exception is the current exception or an exception that is nested because of preemption

Configurable Fault Status Register

CFSR **Offset** **Reset Value**
Configurable Fault Status Register **D28_H** **0000 0000_H**

rw	r	rw	rw	rw	rw	rw	rw	rw	r	rw	rw	rw	r	rw	rw					

Field	Bits	Type	Description
RES	31:26	r	Reserved
DIVBYZERO	25	rw	Divide by Zero <i>Note: When SDIV or UDIV instruction is used with a divisor of 0, this fault occurs if DIV_0_TRP is enabled in the CCR.</i> 0 _B No Divide by zero error has occurred. 1 _B A divide by zero error has occurred.
UNALIGNED	24	rw	Unaligned <i>Note: Multi-word accesses always fault if not word aligned. Software can configure unaligned word and halfword accesses to fault.</i> 0 _B No unaligned access error has occurred. 1 _B A unaligned access error has occurred.
RES	23:20	r	Reserved
NOCP	19	rw	No CP 0 _B No coprocessor access error has occurred. 1 _B A coprocessor access error has occurred.
INVPC	18	rw	INVPC 0 _B No integrity check error has occurred. 1 _B A integrity check error has occurred.
INVSTATE	17	rw	INVSTATE 0 _B EPSR.T bit and EPSR.IT bits are valid for instruction execution. 1 _B Instruction executed with invalid EPSR.T or EPSR.IT field.
UNDEFINSTR	16	rw	Undefined Instruction 0 _B No Undefined Instruction Usage fault has occurred. 1 _B The processor has attempted to execute an undefined instruction. This might be an undefined instruction associated with an enabled coprocessor.

Field	Bits	Type	Description
BFARVALID	15	rw	BFAR Valid 0 _B BFAR does not have valid contents. 1 _B BFAR has valid contents.
RES	14	r	Reserved
LSPERR	13	rw	LSPERR 0 _B No bus fault occurred during FP lazy state preservation 1 _B A bus fault occurred during FP lazy state preservation
STKERR	12	rw	STKERR 0 _B No derived bus fault occurred 1 _B A derived bus fault occurred on exception entry
UNSTKERR	11	rw	UNSTKERR 0 _B No derived bus fault occurred 1 _B A derived bus fault occurred on exception return
IMPRECISERR	10	rw	IMPRECISERR 0 _B No precise data access error has occurred 1 _B An imprecise data access error has occurred.
PRECISERR	9	rw	PRECISERR 0 _B No precise data access error has occurred 1 _B An imprecise data access error has occurred, and the processor has written the faulting address to the BFAR.
IBUSERR	8	rw	IBUSERR 0 _B No bus fault on an instruction prefetch has occurred. 1 _B A bus fault on an instruction prefetch has occurred. The fault is signalled only if the instruction is issued.
MMARVALID	7	rw	MMARVALID 0 _B MMAR does not have valid contents. 1 _B MMAR has valid contents.
RES	6	r	Reserved
MLSPERR	5	rw	MLSPERR 0 _B No MemManage fault occurred during FP lazy state preservation 1 _B A MemManage fault occurred during FP lazy state preservation
MSTERR	4	rw	MSTERR 0 _B No derived MemManage fault occurred 1 _B A derived MemManage fault occurred on exception entry
MUNSTKERR	3	rw	MUNSTKERR 0 _B No derived MemManage fault occurred 1 _B A derived MemManage fault occurred on exception return
RES	2	r	Reserved
DACCVIOL	1	rw	DACCVIOL 0 _B No data access violation has occurred. 1 _B Data access violation. The MMAR shows the data address that the load or store tried to access.

Field	Bits	Type	Description
IACCVIOL	0	rw	IACCVIOL 0 _B No MPU or Execute Never (XN) default memory map access violation has occurred. 1 _B MPU or Execute Never (XN) default memory map access violation on an instruction fetch has occurred. The fault is signalled only if the instruction is issued.

Notes

1. *USAGEFAULT* contains bits 31:16 of CFSR and provides information on UsageFault exceptions
2. *BUSFAULT* contains bits 15:8 of CFSR and provides information on BusFault exceptions
3. *MemManage* contains bits 7:0 of CFSR and provides information on MemManage exceptions

Hard Fault Status Register

HFSR **Offset** **Reset Value**
Hard Fault Status Register **D2C_H** **0000 0000_H**

Field	Bits	Type	Description
DEBUGEVT	31	rw	Debug Event Indicates when a Debug event has occurred. <i>Note: The processor sets this bit to 1 only when halting debug is disabled and a Debug event occurs.</i> 0 _B No Debug event has occurred 1 _B Debug event has occurred. The Debug Fault Status Register has been updated.
FORCED	30	rw	Forced Indicates that a fault with configurable priority has been escalated to a HardFault exception, because it could not be made active, because of priority or because it was disabled. 0 _B No priority escalation has occurred 1 _B Processor has escalated a configurable priority exception to HardFault
RES	29:2	r	Reserved
VECTTBL	1	rw	VECTTBL Indicates when a fault has occurred because of a vector table read error on exception processing. 0 _B No vector table read fault has occurred 1 _B Vector table read fault has occurred
RES	0	r	Reserved

Debug Fault Status Register

DFSR
Debug Fault Status Register

Offset
D30_H

Reset Value
0000 0000_H

Field	Bits	Type	Description
RES	31:5	r	Reserved
EXTERNAL	4	rw	External Indicates a debug event generated because of the assertion of EDBGRQ . 0 _B No EDBGRQ debug event 1 _B EDBGRQ debug event
VCATCH	3	rw	Vector Catch Indicates triggering of a vector catch. The corresponding FSR shows the primary cause of exception. 0 _B No vector catch triggered 1 _B Vector catch triggered
DWTTRAP	2	rw	DWTTRAP Indicates a debug event generated by the DWT. 0 _B No current debug event generated by the DWT 1 _B At least one current debug event generated by the DWT
BKPT	1	rw	BKPT Indicates a debug event generated by BKPT instruction execution or a breakpoint match in FPB. 0 _B No current breakpoint debug event 1 _B At least one current breakpoint debug event
HALTED	0	rw	HALTED Indicates a debug event generated by either a C_HALT or C_STEP request, triggered by a write to the DHCSR, or a step request triggered by setting DEMCR.MON_STEP to 1. 0 _B No active halt request debug event 1 _B Halt request debug event active

MemManage Fault Status Register

MMFAR	Offset	Reset Value
MemManage Fault Status Register	D34 _H	XXXX XXXX _H

Field	Bits	Type	Description
ADDRESS	31:0	rw	Data Address for an MPU Fault This is the location addressed by an attempted load or store access that was faulted. The MemManage Status Register shows the cause of the fault, and whether MMFAR.ADDRESS is valid. When an unaligned access faults, the address is the actual address that faulted. Because an access might be split into multiple parts, each aligned, this address can be any offset in the range of the requested size.

Bus Fault Status Register

BFAR	Offset	Reset Value
Bus Fault Status Register	D38 _H	XXXX XXXX _H

Field	Bits	Type	Description
ADDRESS	31:0	rw	Data Address for a precise BusFault This is the location addressed by an attempted data access that was faulted. The BFSR shows the reason for the fault, and whether BFAR.ADDRESS is valid. For unaligned access faults, the address returned is the address requested by the instruction. This might not be the address that faulted.

9.5 Instruction Set Summary

This chapter provides the Instruction set. [Table 44](#) shows the instructions and their cycle counts. The cycle counts are based on a system with zero wait states.

Within the assembler syntax, depending on the operation, the <op2> field can be replaced with one of the following options:

- a simple register
- an immediate shifted register
- a register shifted register
- an immediate value

For brevity, not all load and store addressing modes are shown.

[Table 44](#) uses the following abbreviations in the cycles column:

- P for the number of cycles required for a pipeline refill.
- B for the number of cycles required to perform the barrier operation.
- N for the number of registers in the register list to be loaded or stored, including PC or LR.
- W for the number of cycles spent waiting for an appropriate event.

Table 44 Instruction Set Summary

Operation	Description	Mnemonic	Cycles (without wait states)
Move	Register	MOV Rd, <op2>	1
	16-bit immediate	MOVW Rd, #<imm>	1
	Immediate into top	MOVT Rd, #<imm>	1
	To PC	MOV PC, Rm	1 + P
Add	Add	ADD Rd, Rn, <op2>	1
	Add to PC	Add PC, PC, Rm	1 + P
	Add with carry	ADC Rd, Rn, <op2>	1
	Form address	ADR Rd, <label>	1
Subtract	Subtract	SUB Rd, Rn, <op2>	1
	Subtract with borrow	SBC Rd, Rn, <op2>	1
	Reverse	RSB Rd, Rn, <op2>	1
Multiply	Multiply	MUL Rd, Rn, Rm	1

	Wait for interrupt	WFI	1 + W
	No operation	NOP	1
Barriers	Instruction synchronization	ISB	1 + B
	Data memory	DMB	1 + B
	Data synchronization	DSB <flags>	1 + B

- 1) UMULL, SMULL, UMLAL, and SMLAL instructions use early termination depending on the size of the source values. These are interruptible, that is abandoned and restarted, with worst case latency of one cycle.
- 2) Division operations use early termination to minimize the number of cycles required based on the number of leading ones and zeros in the input operands.
- 3) Neighboring load and store single instructions can pipeline their address and data phases. This enables these instructions to complete in a single execution cycle.
- 4) Conditional branch completes in a single cycle if the branch is not taken.
- 5) An IT instruction can be folded onto a preceding 16-bit Thumb instruction, enabling execution in zero cycles.

10 DMA Controller

Figure 43 shows the Top Level Block Diagram of the TLE9869QXA20.

The Bus Matrix allows the uDMA to access the PBA0, PBA1 and RAM.

10.1 Features

The principal features of the DMA Controller are that:

- it is compatible with AHB-Lite for the DMA transfers
- it is compatible with APB for programming the registers
- it has a single AHB-Lite master for transferring data using a 32-bit address bus and 32-bit data bus
- it has a configurable number of DMA channels
- each DMA channel has dedicated handshake signals
- each DMA channel has a programmable priority level
- each priority level arbitrates using a fixed priority that is determined by the DMA channel number. The DMA also supports multiple transfer types:
 - memory-to-memory
 - memory-to-peripheral
 - peripheral-to-memory
- it supports multiple DMA cycle types
- it supports multiple DMA transfer data widths
- each DMA channel can access a primary, and alternate, channel control data structure
- all the channel control data is stored in system memory (RAM) in little-endian format
- it performs all DMA transfers using the SINGLE AHB-Lite burst type. The destination data width is equal to the source data width.
- the number of transfers in a single DMA cycle can be programmed from 1 to 1024
- the transfer address increment can be greater than the data width

10.2 Introduction

Please also refer to [Chapter 10.3, Functional Description](#).

10.2.1 Block Diagram

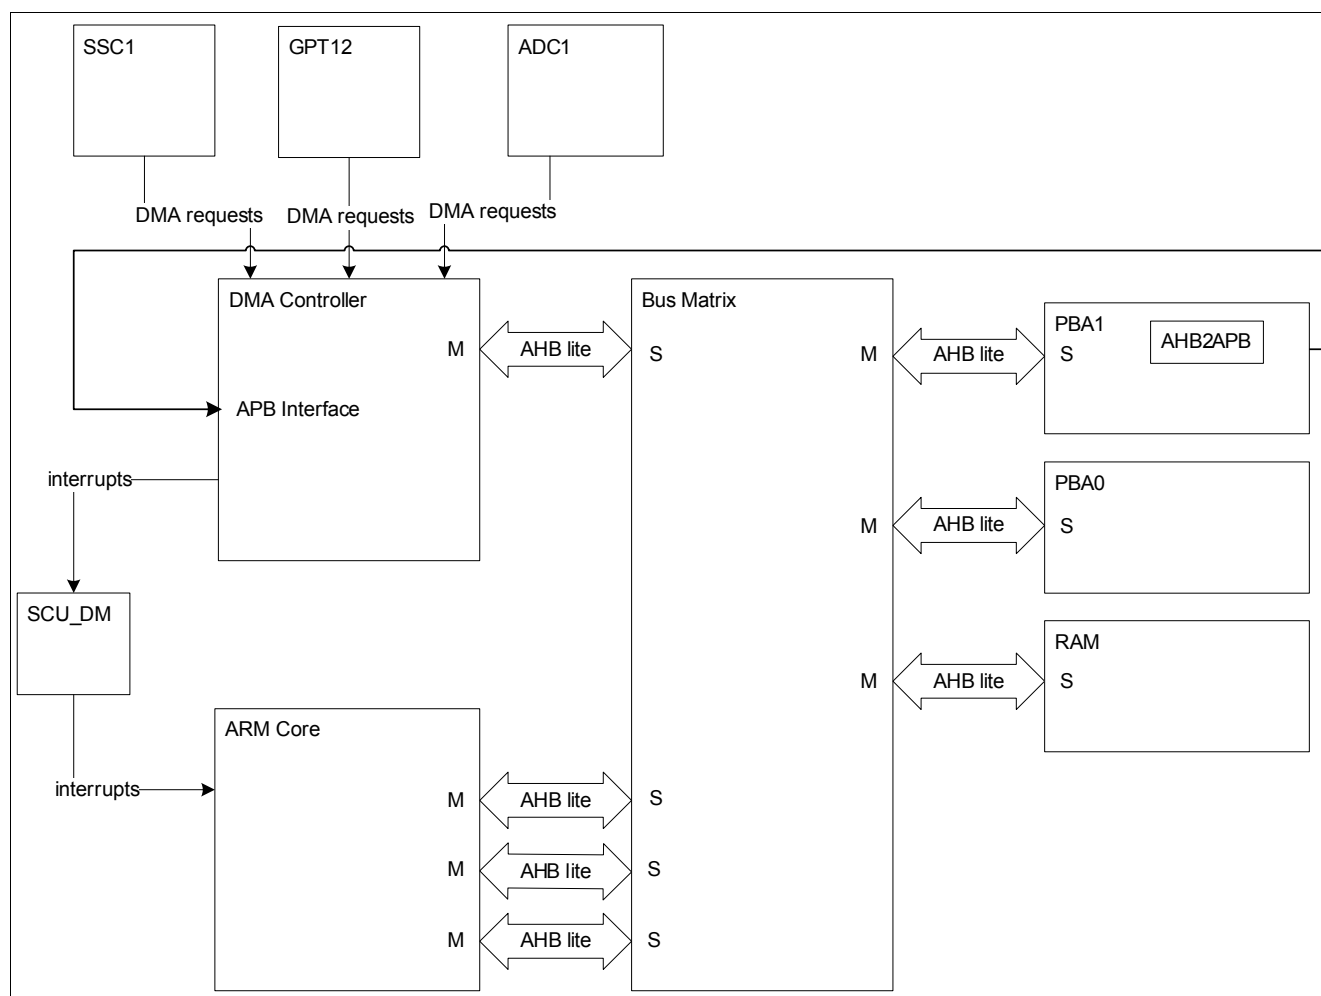

Figure 43 DMA Controller Top Level Block Diagram

10.3 Functional Description

10.3.1 DMA Mode Overview

The DMA Controller implements the following 13 hardware DMA requests:

- ADC1 complete sequence 1 done: DMA transfer is requested on completion of the ADC1 channel conversion sequence.
- ADC1 exceptional sequence 2 (ESM) done: DMA transfer is requested on completion of the ADC1 conversion sequence triggered by an exceptional measurement request.
- SSC1/2 transmit byte: DMA transfer is requested upon the completion of data transmission via SSC1/2.
- SSC1/2: receive byte: DMA transfer is requested upon the completion of data reception via SSC1/2.
- ADC1 channel 0 conversion done: DMA transfer is requested on completion of the ADC1 channel 0 conversion.
- ADC1 channel 1 conversion done: DMA transfer is requested on completion of the ADC1 channel 1 conversion.
- ADC1 channel 2 conversion done: DMA transfer is requested on completion of the ADC1 channel 2 conversion.
- ADC1 channel 3 conversion done: DMA transfer is requested on completion of the ADC1 channel 3 conversion.
- ADC1 channel 4 conversion done: DMA transfer is requested on completion of the ADC1 channel 4 conversion.
- ADC1 channel 5 conversion done: DMA transfer is requested on completion of the ADC1 channel 5 conversion.
- ADC1 channel 6 conversion done: DMA transfer is requested on completion of the ADC1 channel 6 conversion.
- ADC1 channel 7 conversion done: DMA transfer is requested on completion of the ADC1 channel 7 conversion.
- Timer3 ccu6_int: DMA transfer is requested upon a timer trigger.

Note: Channel 0 has the highest priority, when the priority setting for all channels is the same.

Burst transfers via signal transfer

Single transfers:

The DMA Controller should be programmed for single transfers, see [Table 57 “channel_cfg bit assignments” on Page 280](#),

where $R = 0$, $n = \text{number of single transfer} + 1$, $\text{transfer_type} = 1$ (basic).

For every `dma_req`, one transfer is done; if the number of transfers reaches n , `dma_done` (interrupt) is generated and the DMA channel is deactivated.

Burst transfers:

The DMA Controller should be programmed for burst transfers like this

$n = \text{number of transfers}$, $\text{transfer_type} = 2$ (auto)

Then for one dma_req, n + 1 transfers are done, dma_done (interrupt) is generated and the DMA channel is deactivated.

Timing Diagram – uDMA it takes 6 clock cycles
Normal DMA would take 2 cycles

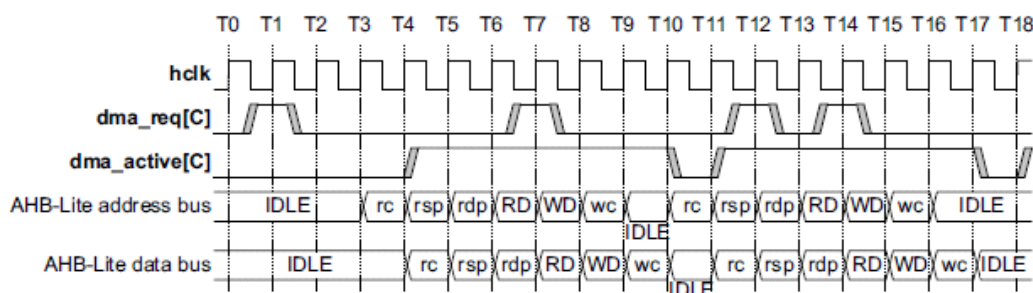

Figure 44 DMA Controller Timing Diagram

10.3.2 DMA Arbitration Rate

You can configure when the controller arbitrates during a DMA transfer. This enables you to reduce the latency to service a higher priority channel.

The controller provides four bits that configure how many AHB bus transfers occur before it rearbiterates. These bits are known as the R_power bits because the value you enter, R, is raised to the power of two and this determines the arbitration rate. For example, if R = 4 then the arbitration rate is 2^4 , that is, the controller arbitrates every 16 DMA transfers.

Table 45 lists the arbitration rates.

Table 45 AHB-Bus Transfer Arbitration Interval

R_power	Arbitrate after x DMA Transfers
0000 _B	x = 1
0001 _B	x = 2
0010 _B	x = 4
0011 _B	x = 8
0100 _B	x = 16
0101 _B	x = 32
0110 _B	x = 64
0111 _B	x = 128
1000 _B	x = 256
1001 _B	x = 512
1010-1111 _B	x = 1024

Note: Take care not to assign a low-priority channel with a large R_power because this prevents the controller from servicing high-priority requests, until it rearbiterates.

When $N > 2^R$ and is not an integer multiple of 2^R then the controller always performs sequences of 2^R transfers until $N < 2^R$ remain to be transferred. The controller performs the remaining N transfers at the end of the DMA cycle.

You store the value of the R_power bits in the channel control data structure. See [Control Data Configuration](#) on [Page 279](#) for more information about the location of the R_power bits in the data structure.

Priority

When the controller arbitrates, it determines the next channel to service by using the following information:

- The channel number
- The priority level, default or high, that is assigned to the channel.

You can configure each channel to use either the default priority level or a high priority level by setting the chnl_priority_set Register. See Channel Priority set on page 3-23.

Channel number zero has the highest priority and as the channel number increases, the priority of a channel decreases. [Table 46](#) lists the DMA channel priority levels in descending order of priority.

Table 46 DMA Channel Priority

Channel Number	Priority Level Setting	Descending Order of Channel Priority
0	High	Highest-priority DMA channel
1	High	–
2	High	–
–	High	–
–	High	–
–	High	–
12	High	–
13	High	–
0	Default	–
1	Default	–
2	Default	–
–	Default	–
–	Default	–
–	Default	–
12	Default	–
13	Default	Lowest-priority DMA channel

After a DMA transfer completes, the controller polls all the DMA channels that are available. [Figure 45 “Polling Flowchart”](#) on [Page 266](#) shows the process it uses to determine which DMA transfer to perform next.

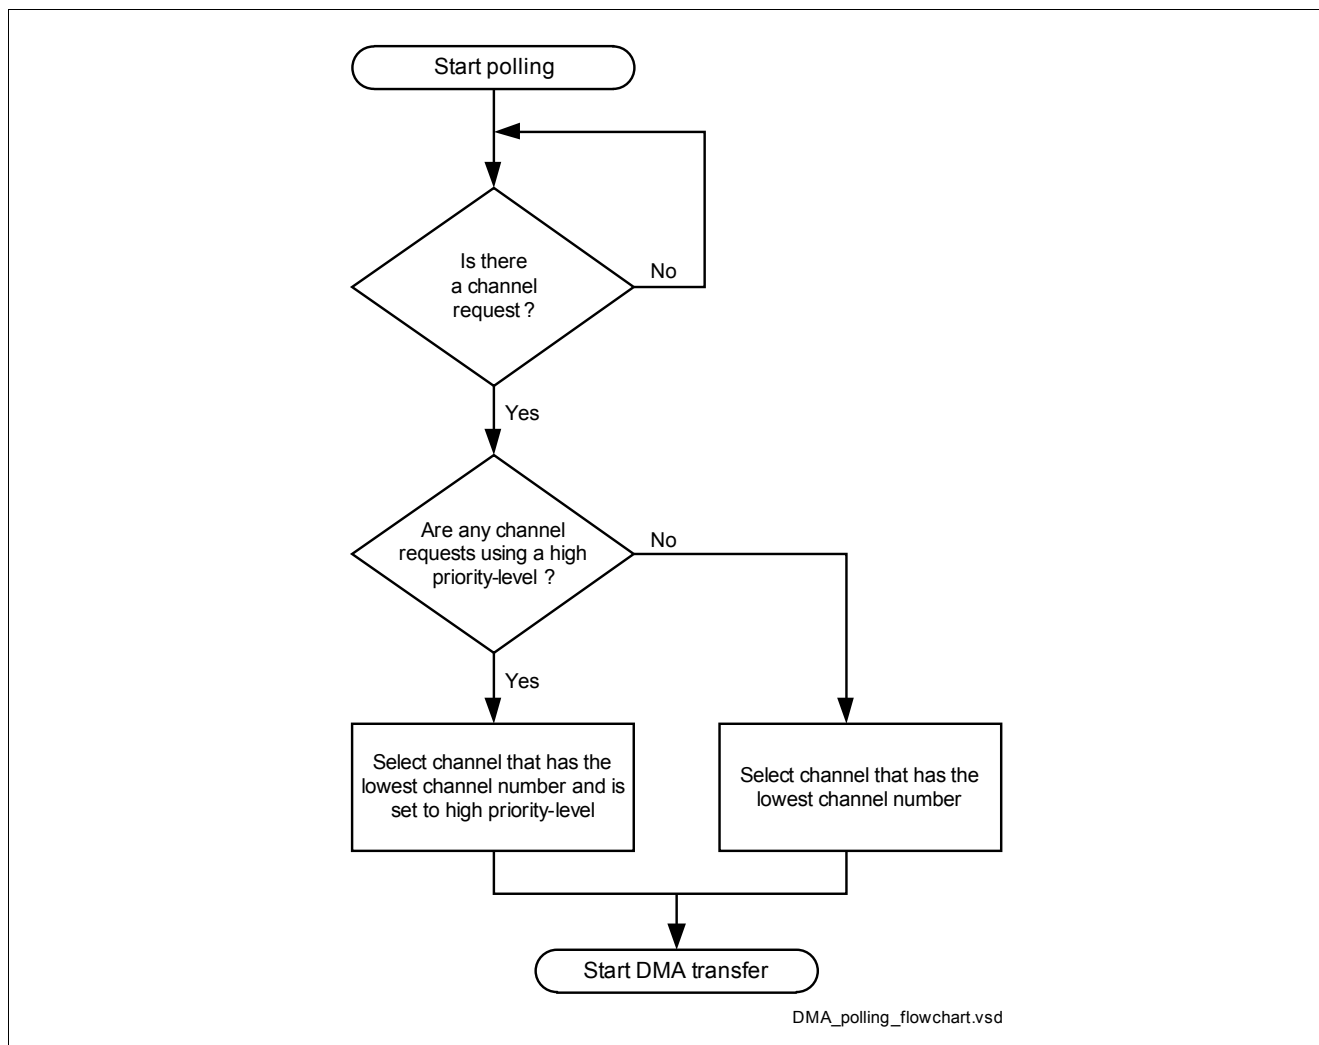

Figure 45 Polling Flowchart

DMA Cycle Types

The cycle_ctrl bits control how the controller performs a DMA cycle. You can set the cycle_ctrl bits as [Table 47](#) lists.

Table 47 DMA Cycle Types

cycle_ctrl	Description
000 _B	Channel control data structure is invalid
001 _B	Basic DMA transfer
010 _B	Auto-request
011 _B	Ping-pong
100 _B	Memory scatter-gather using the primary data structure
101 _B	Memory scatter-gather using the alternate data structure
110	Peripheral scatter-gather using the primary data structure
111	Peripheral scatter-gather using the alternate data structure

Note: The `cycle_ctrl` bits are located in the `channel_cfg` memory location that [Control Data Configuration](#) on [Page 279](#) describes.

For all cycle types, the controller arbitrates after 2^R DMA transfers. If you set a low-priority channel with a large 2^R value then it prevents all other channels from performing a DMA transfer, until the low-priority DMA transfer completes. Therefore, you must take care when setting the `R_power`, that you do not significantly increase the latency for high-priority channels.

The following sections describe the cycle types:

- **Invalid**
- **Basic**
- **Auto-Request** on [Page 267](#)
- **Ping-Pong** on [Page 267](#)
- **Memory Scatter-Gather** on [Page 269](#)
- **Peripheral Scatter-Gather** on [Page 272](#)

Invalid

After the controller completes a DMA cycle it sets the cycle type to invalid, to prevent it from repeating the same DMA cycle.

Basic

In this mode, you configure the controller to use either the primary, or alternate, data structure. After you enable the channel, and the controller receives a request then the flow for this DMA cycle is:

- The controller performs 2^R transfers. If the number of transfers remaining is zero the flow continues at step 3.
- The controller arbitrates:
 - If a higher-priority channel is requesting service then the controller services that channel.
 - If the peripheral or software signals a request to the controller then it continues at step 1.
- The controller sets `dma_done[C]` HIGH for one `hclk` cycle. This indicates to the host processor that the DMA cycle is complete.

Auto-Request

When the controller operates in this mode, it is only necessary for it to receive a single request to enable it to complete the entire DMA cycle. This enables a large data transfer to occur, without significantly increasing the latency for servicing higher priority requests, or requiring multiple requests from the processor or peripheral.

You can configure the controller to use the primary, or alternate, data structure. After you enable the channel, and the controller receives a request for this channel, then the flow for this DMA cycle is:

- The controller performs 2^R transfers for channel C. If the number of transfers remaining is zero the flow continues at step 3.
- The controller arbitrates. When channel C has the highest priority then the DMA cycle continues at step 1.
- The controller sets `dma_done[C]` HIGH for one `hclk` cycle. This indicates to the host processor that the DMA cycle is complete.

Ping-Pong

In ping-pong mode, the controller performs a DMA cycle using one of the data structures and it then performs a DMA cycle using the other data structure. The controller continues to switch from primary to alternate to primary... until it reads a data structure that is invalid, or until the host processor disables the channel.

[Figure 46 “Ping-Pong Example” on Page 268](#) shows an example of a ping-pong DMA transaction.

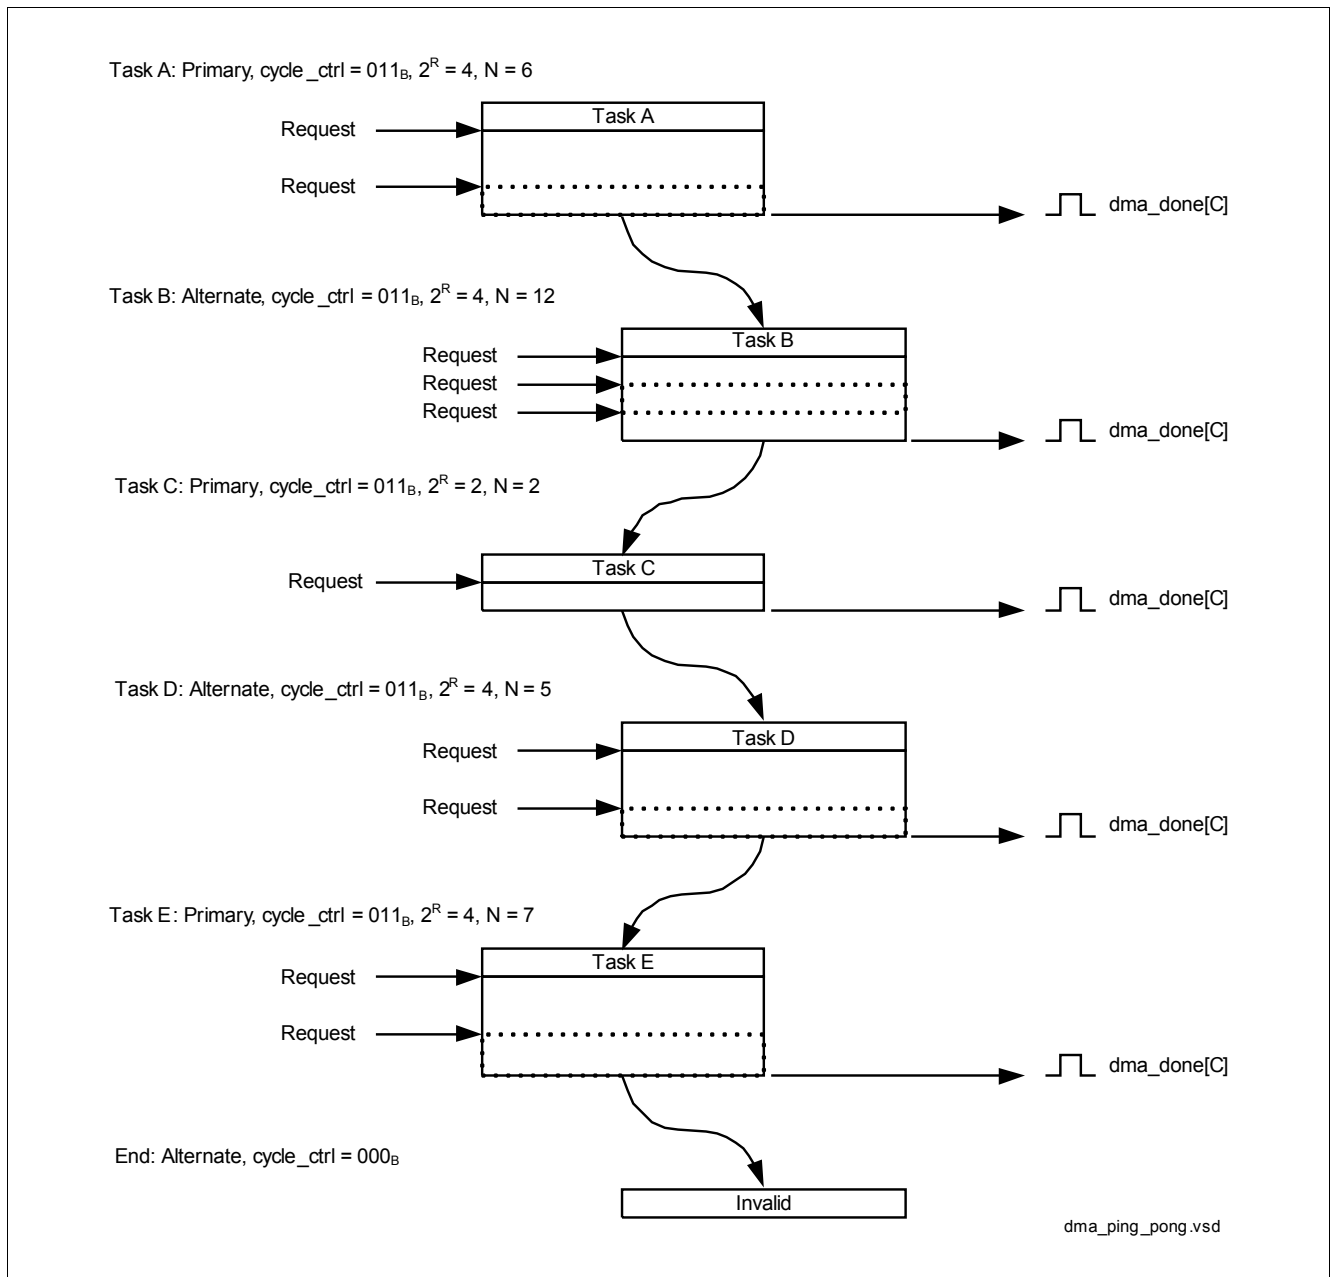

Figure 46 Ping-Pong Example

In [Figure 46 “Ping-Pong Example” on Page 268](#):

Task A

- The host processor configures the primary data structure for task A.
- The host processor configures the alternate data structure for task B. This enables the controller to immediately switch to task B after task A completes, provided that a higher priority channel does not require servicing.
- The controller receives a request and performs four DMA transfers.
- The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
- The controller performs the remaining two DMA transfers.
- The controller sets **dma_done[C]** HIGH for one **hclk** cycle and enters the arbitration process.

After task A completes, the host processor can configure the primary data structure for task C. This enables the controller to immediately switch to task C after task B completes, provided that a higher priority channel does not require servicing.

After the controller receives a new request for the channel and it has the highest priority then task B commences:

Task B

- The controller performs four DMA transfers.
- The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
- The controller performs four DMA transfers.
- The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
- The controller performs the remaining four DMA transfers.
- The controller sets **dma_done[C]** HIGH for one **hclk** cycle and enters the arbitration process.

After task B completes, the host processor can configure the alternate data structure for task D.

After the controller receives a new request for the channel and it has the highest priority then task C commences:

Task C

- The controller performs two DMA transfers.
- The controller sets **dma_done[C]** HIGH for one **hclk** cycle and enters the arbitration process.

After task C completes, the host processor can configure the primary data structure for task E. After the controller receives a new request for the channel and it has the highest priority then task D commences:

Task D

- The controller performs four DMA transfers.
- The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
- The controller performs the remaining DMA transfer.
- The controller sets **dma_done[C]** HIGH for one **hclk** cycle and enters the arbitration process.

After the controller receives a new request for the channel and it has the highest priority then task E commences:

Task E

- The controller performs four DMA transfers.
- The controller arbitrates. After the controller receives a request for this channel, the flow continues if the channel has the highest priority.
- The controller performs the remaining three DMA transfers.
- The controller sets **dma_done[C]** HIGH for one **hclk** cycle and enters the arbitration process.

If the controller receives a new request for the channel and it has the highest priority then it attempts to start the next task. However, because the host processor has not configured the alternate data structure, and on completion of task D the controller set the **cycle_ctrl** bits to 000_B, then the ping-pong DMA transaction completes.

*Note: You can also terminate the ping-pong DMA cycle in [Figure 46 “Ping-Pong Example” on Page 268](#), if you configure task E to be a basic DMA cycle by setting the **cycle_ctrl** field to 3'001_B.*

Memory Scatter-Gather

In memory scatter-gather mode the controller receives an initial request and then performs four DMA transfers using the primary data structure. After this transfer completes, it starts a DMA cycle using the alternate data structure. After this cycle completes, the controller performs another four DMA transfers using the primary data structure. The controller continues to switch from primary to alternate to primary... until either:

- The host processor configures the alternate data structure for a basic cycle.
- It reads an invalid data structure.

Note: After the controller completes the N primary transfers it invalidates the primary data structure by setting the cycle_ctrl field to 000_B.

The controller only asserts **dma_done[C]** when the scatter-gather transaction completes using a basic cycle.

In scatter-gather mode, the controller uses the primary data structure to program the alternate data structure.

Table 48 lists the fields of the channel_cfg memory location for the primary data structure, that you must program with constant values and those that can be user defined.

Table 48 channel_cfg for a Primary Data Structure, in Memory Scatter-Gather Mode

Bit	Field	Value	Description
Constant-Value Fields:			
[31:30]	dst_inc	10 _B	Configures the controller to use word increments for the address
[29:28]	dst_size	10 _B	Configures the controller to use word transfers
[27:26]	src_inc	10 _B	Configures the controller to use word increments for the address
[25:24]	src_size	10 _B	Configures the controller to use word transfers
[17:14]	R_power	0010 _B	Configures the controller to perform four DMA transfers
[3]	next_useburst	0 _B	For a memory scatter-gather DMA cycle, this bit must be set to zero
[2:0]	cycle_ctrl	100 _B	Configures the controller to perform a memory scatter-gather DMA cycle
User Defined Values:			
[23:21]	dst_prot_ctrl	–	Configures the state of HPROT when the controller writes the destination data
[20:18]	src_prot_ctrl	–	Configures the state of HPROT when the controller reads the source data
[13:4]	n_minus_1	N ¹⁾	Configures the controller to perform N DMA transfers, where N is a multiple of four

1) Because the R_power field is set to four, you must set N to be a multiple of four. The value given by N/4 is the number of times that you must configure the alternate data structure.

See **Control Data Configuration** on **Page 279** for more information.

Figure 47 “Memory Scatter-Gather Example” on Page 271 shows a memory scatter-gather example.

Initialization

- Configure primary to enable the copy A, B, C and D operations: cycle_ctrl = 100_B, 2^R = 4, N = 16
- Write the primary source data to memory, using the structure shown in the following table.

Table 49

	src_data_end_ptr	dst_data_end_ptr	channel_cfg	Unused
Data for Task A	00A000000 _H	00AE00000 _H	cycle_ctrl = 101 _B , 2 ^R = 4, N = 3	0XXXXXXXX _H
Data for Task B	00B000000 _H	00BE00000 _H	cycle_ctrl = 101 _B , 2 ^R = 2, N = 8	0XXXXXXXX _H
Data for Task C	00C000000 _H	00CE00000 _H	cycle_ctrl = 101 _B , 2 ^R = 8, N = 5	0XXXXXXXX _H
Data for Task D	00D000000 _H	00DE00000 _H	cycle_ctrl = 001 _B , 2 ^R = 4, N = 4	0XXXXXXXX _H

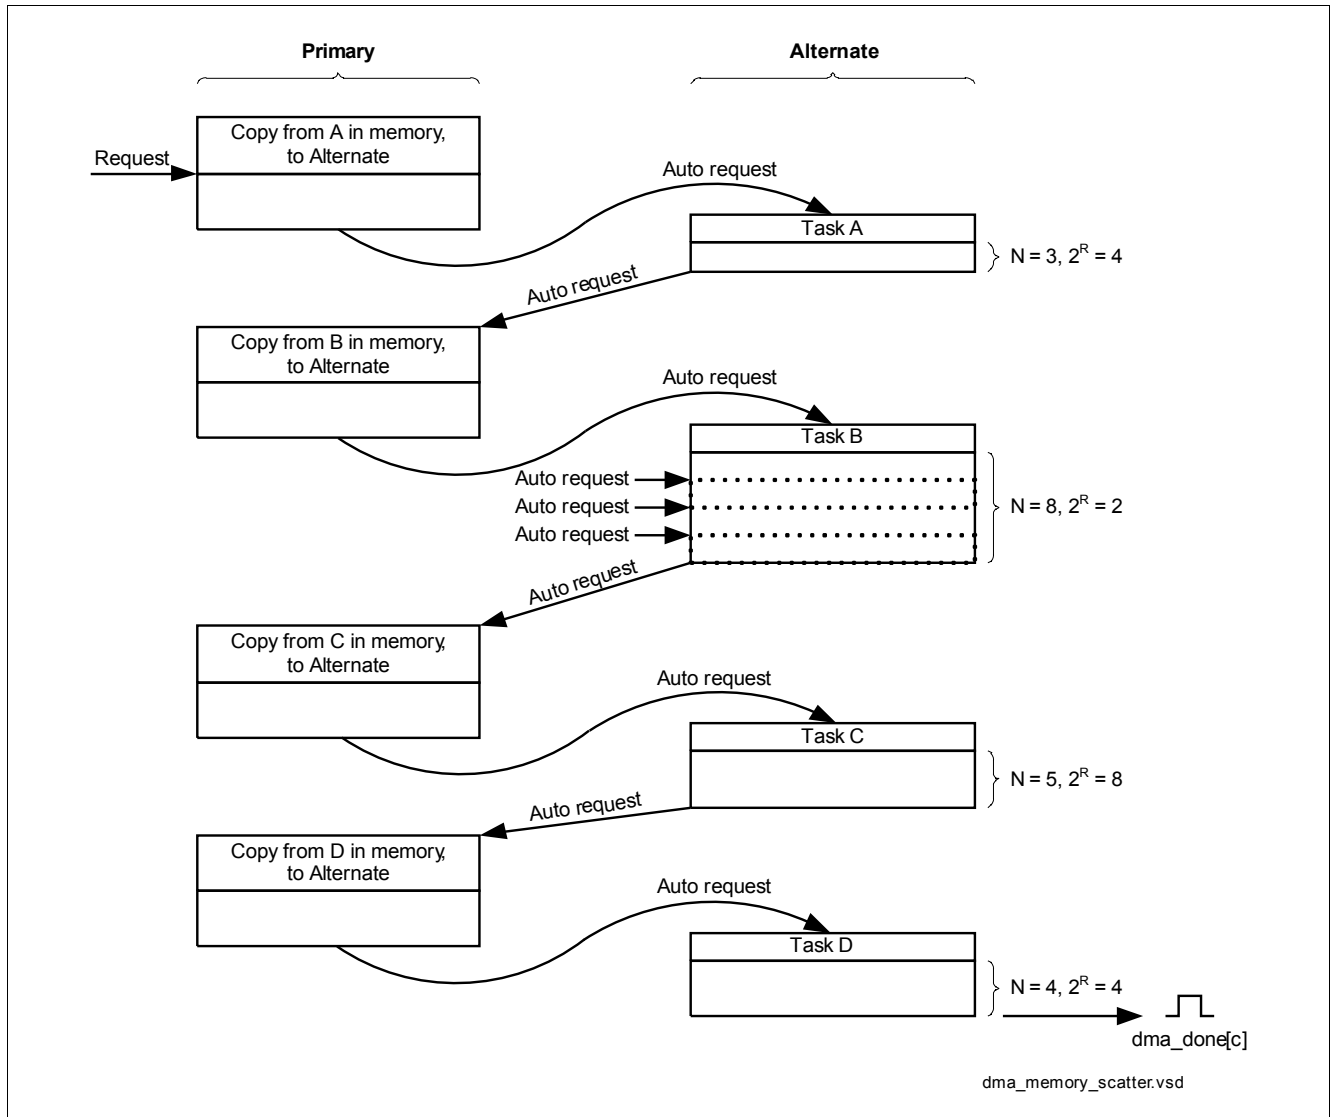

Figure 47 Memory Scatter-Gather Example

In [Figure 47 “Memory Scatter-Gather Example” on Page 271](#):

Initialization

- The host processor configures the primary data structure to operate in memory scatter-gather mode by setting `cycle_ctrl` to 100_B. Because a data structure for a single channel consists of four words then you must set 2^R to 4. In this example, there are four tasks and therefore N is set to 16.
- The host processor writes the data structure for tasks A, B, C, and D to the memory locations that the primary `src_data_end_ptr` specifies.
- The host processor enables the channel.

The memory scatter-gather transaction commences when the controller receives a request on `dma_req[]` or a manual request from the host processor. The transaction continues as follows:

Primary, copy A

- After receiving a request, the controller performs four DMA transfers. These transfers write the alternate data structure for task A.
- The controller generates an auto-request for the channel and then arbitrates.

Task A

- The controller performs task A. After it completes the task, it generates an auto-request for the channel and then arbitrates.

Primary, copy B

- The controller performs four DMA transfers. These transfers write the alternate data structure for task B.
- The controller generates an auto-request for the channel and then arbitrates.

Task B

- The controller performs task B. After it completes the task, it generates an auto-request for the channel and then arbitrates.

Primary, copy C

- The controller performs four DMA transfers. These transfers write the alternate data structure for task C.
- The controller generates an auto-request for the channel and then arbitrates.

Task C

- The controller performs task C. After it completes the task, it generates an auto-request for the channel and then arbitrates.

Primary, copy D

- The controller performs four DMA transfers. These transfers write the alternate data structure for task D.
- The controller sets the `cycle_ctrl` bits of the primary data structure to `000B`, to indicate that this data structure is now invalid.
- The controller generates an auto-request for the channel and then arbitrates.

Task D

- The controller performs task D using a basic cycle.
- The controller sets `dma_done[C]` HIGH for one `hclk` cycle and enters the arbitration process.

Peripheral Scatter-Gather

In peripheral scatter-gather mode the controller receives an initial request from a peripheral and then it performs four DMA transfers using the primary data structure. It then immediately starts a DMA cycle using the alternate data structure, without re-arbitrating or `dma_active[C]` going LOW.

Note: These are the only circumstances, where the controller does not enter the arbitration process after completing a transfer using the primary data structure.

After this cycle completes, the controller re-arbitrates and if the controller receives a request from the peripheral that has the highest priority then it performs another four DMA transfers using the primary data structure. It then immediately starts a DMA cycle using the alternate data structure, without re-arbitrating or `dma_active[C]` going LOW. The controller continues to switch from primary to alternate to primary... until either:

- The host processor configures the alternate data structure for a basic cycle.
- It reads an invalid data structure.

Note: After the controller completes the N primary transfers it invalidates the primary data structure by setting the `cycle_ctrl` field to `000B`.

The controller asserts `dma_done[C]` when the scatter-gather transaction completes using a basic cycle.

In scatter-gather mode, the controller uses the primary data structure to program the alternate data structure. [Table 50](#) lists the fields of the channel_cfg memory location for the primary data structure, that you must program with constant values and those that can be user defined.

Table 50 channel_cfg for a Primary Data Structure, in Peripheral Scatter-Gather Mode

Bit	Field	Value	Description
Constant-Value Fields:			
[31:30]	dst_inc	10 _B	Configures the controller to use word increments for the address
[29:28]	dst_size	10 _B	Configures the controller to use word transfers
[27:26]	src_inc	10 _B	Configures the controller to use word increments for the address
[25:24]	src_size	10 _B	Configures the controller to use word transfers
[17:14]	R_power	0010 _B	Configures the controller to perform four DMA transfers
[2:0]	cycle_ctrl	110 _B	Configures the controller to perform a peripheral scatter-gather DMA cycle
User Defined Values:			
[23:21]	dst_prot_ctrl	–	Configures the state of HPROT when the controller writes the destination data
[20:18]	src_prot_ctrl	–	Configures the state of HPROT when the controller reads the source data
[13:4]	n_minus_1	N ¹⁾	Configures the controller to perform N DMA transfers, where N is a multiple of four
[3]	next_useburst	–	When set to 1, the controller sets the chnl_useburst_set [C] bit to 1 after the alternate transfer completes

1) Because the R_power field is set to four, you must set N to be a multiple of four. The value given by N/4 is the number of times that you must configure the alternate data structure.

See [Control Data Configuration](#) on [Page 279](#) for more information.

[Figure 48 “Peripheral Scatter-Gather Example”](#) on [Page 274](#) shows a peripheral scatter-gather example.

Initialization

- Configure primary to enable the copy A, B, C and D operations: cycle_ctrl = 110_B, 2^R = 4, N = 16.
- Write the primary source data to memory, using the structure shown in the following table.

Table 51

	src_data_end_ptr	dst_data_end_ptr	channel_cfg	Unused
Data for Task A	00A00000 _H	00AE00000 _H	cycle_ctrl = 111 _B , 2 ^R = 4, N = 3	0XXXXXXXX _H
Data for Task B	00B000000 _H	00BE00000 _H	cycle_ctrl = 111 _B , 2 ^R = 2, N = 8	0XXXXXXXX _H
Data for Task C	00C000000 _H	00CE00000 _H	cycle_ctrl = 111 _B , 2 ^R = 8, N = 5	0XXXXXXXX _H
Data for Task D	00D000000 _H	00DE00000 _H	cycle_ctrl = 001 _B , 2 ^R = 4, N = 4	0XXXXXXXX _H

Peripheral scatter-gather transaction:

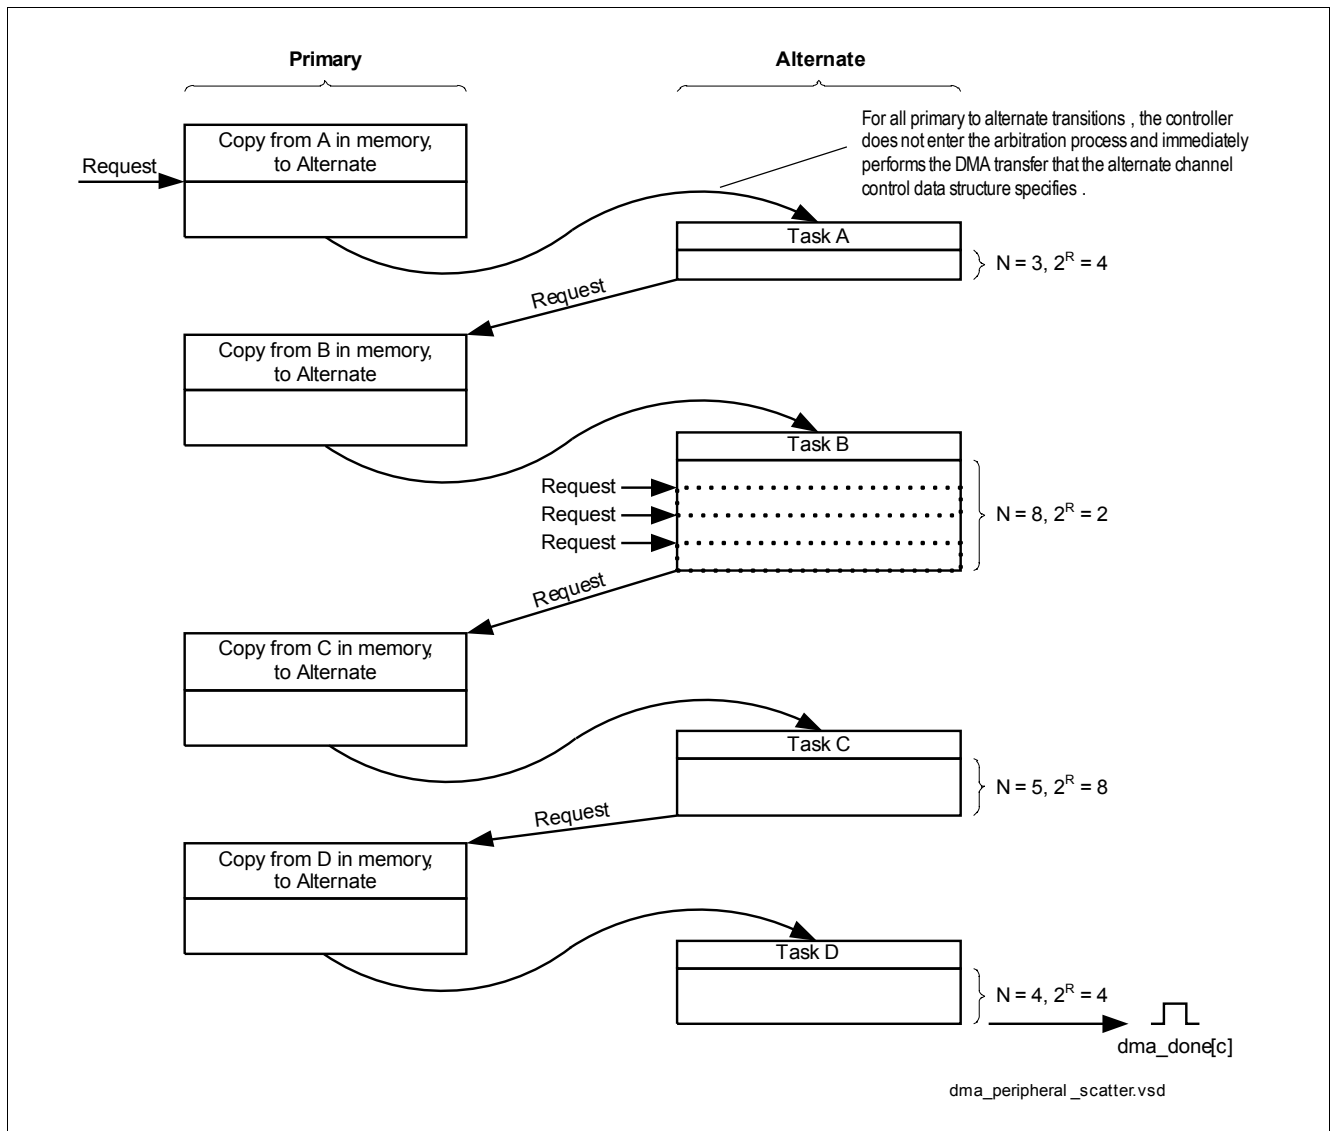

Figure 48 Peripheral Scatter-Gather Example

In [Figure 48 “Peripheral Scatter-Gather Example” on Page 274](#):

Initialization

- The host processor configures the primary data structure to operate in peripheral scatter-gather mode by setting `cycle_ctrl` to `110B`. Because a data structure for a single channel consists of four words then you must set 2^R to 4. In this example, there are four tasks and therefore N is set to 16.
- The host processor writes the data structure for tasks A, B, C, and D to the memory locations that the primary `src_data_end_ptr` specifies.
- The host processor enables the channel.

The peripheral scatter-gather transaction commences when the controller receives a request on `dma_req[]`. The transaction continues as follows:

Primary, copy A

- After receiving a request, the controller performs four DMA transfers. These transfers write the alternate data structure for task A.

Task A

- The controller performs task A.
- After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy B

- The controller performs four DMA transfers. These transfers write the alternate data structure for task B.

Task B

- The controller performs task B. To enable the controller to complete the task, the peripheral must issue a further three requests.
- After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy C

- The controller performs four DMA transfers. These transfers write the alternate data structure for task C.

Task C

- The controller performs task C.
- After the controller completes the task it enters the arbitration process.

After the peripheral issues a new request and it has the highest priority then the process continues with:

Primary, copy D

- The controller performs four DMA transfers. These transfers write the alternate data structure for task D.
- The controller sets the `cycle_ctrl` bits of the primary data structure to `000B`, to indicate that this data structure is now invalid.

Task D

- The controller performs task D using a basic cycle.
- The controller sets `dma_done[C]` HIGH for one `hclk` cycle and enters the arbitration process.

Error Signaling

If the controller detects an ERROR response on the AHB-Lite master interface, it:

- Disables the channel that corresponds to the ERROR.
- Sets `dma_err` HIGH.

After the host processor detects that `dma_err` is HIGH, it must check which channel was active when the ERROR occurred. It can do this by:

- Reading the `chnl_enable_set` Register to create a list of disabled channels.

When a channel asserts `dma_done[]` then the controller disables the channel. The program running on the host processor must always keep a record of which channels have recently asserted their `dma_done[]` outputs.

- It must compare the disabled channels list from step 1, with the record of the channels that have recently set their `dma_done[]` outputs. The channel with no record of `dma_done[C]` being set is the channel that the ERROR occurred on.

10.3.3 Channel Control Data Structure

You must provide an area of system memory to contain the channel control data structure. This system memory must:

- Provide a contiguous area of system memory that the controller and host processor can access.
- Have a base address that is an integer multiple of the total size of the channel control data structure.

Figure 49 shows the memory that the controller requires for the channel control data structure, when it uses all 14 channels and the optional alternate data structure.

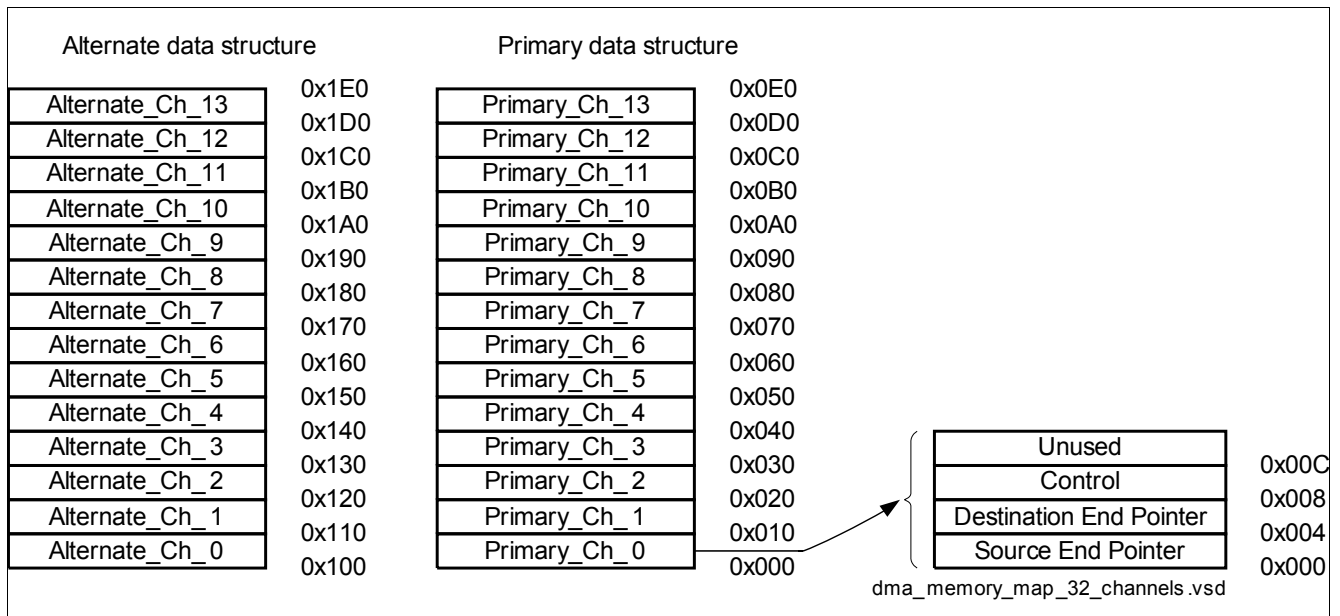

Figure 49 Memory Map for 32 Channels, Including the Alternate Data Structure

The example structure in **Figure 49** uses 1KB of system memory. In this example, the controller uses the lower 10 address bits to enable it to access all of the elements in the structure and therefore the base address must be at 0XXXXX000_H, 0XXXXX400_H, 0XXXXX800_H, or 0XXXXXC00_H. You can configure the base address for the primary data structure by writing the appropriate value in the ctrl_base_ptr Register. See Channel control data base pointer on page 3-8.

The amount of system memory you require depends on:

- The number of DMA channels you configure the controller to use.
- If you configure a DMA channel to use the alternate data structure. See Channel primary-alternate set.

Table 52 lists the address bits that the controller uses when it accesses the elements of the channel control data structure, depending on the number of channels that the controller contains.

Table 52 Address Bit Settings for the Channel Control Data Structure

Address Bits							
Number of DMA Channels Implemented	[9]	[8]	[7]	[6]	[5]	[4]	[3:0]
0-13		A	C[3]	C[2]	C[1]	C[0]	00 _H , 04 _H or 08 _H

Where:

Table 53

A	Selects one of the channel control data structures:	
	A = 0	Selects the primary data structure.
	A = 1	Selects the alternate data structure.
C[x:0]	Selects the DMA channel.	
Address[3:0]	Selects one of the control elements:	
	00 _H	Selects the source data end pointer.
	04 _H	Selects the destination data end pointer.
	08 _H	Selects the control data configuration.
	0C _H	The controller does not access this address location. If required, you can enable the host processor to use this memory location as system memory.

Note: It is not necessary for you to calculate the base address of the alternate data structure because the `alt_ctrl_base_ptr` Register provides this information. See Channel alternate control data base pointer.

Figure 49 shows an example implementation where the controller uses three DMA channels and the alternate data structure.

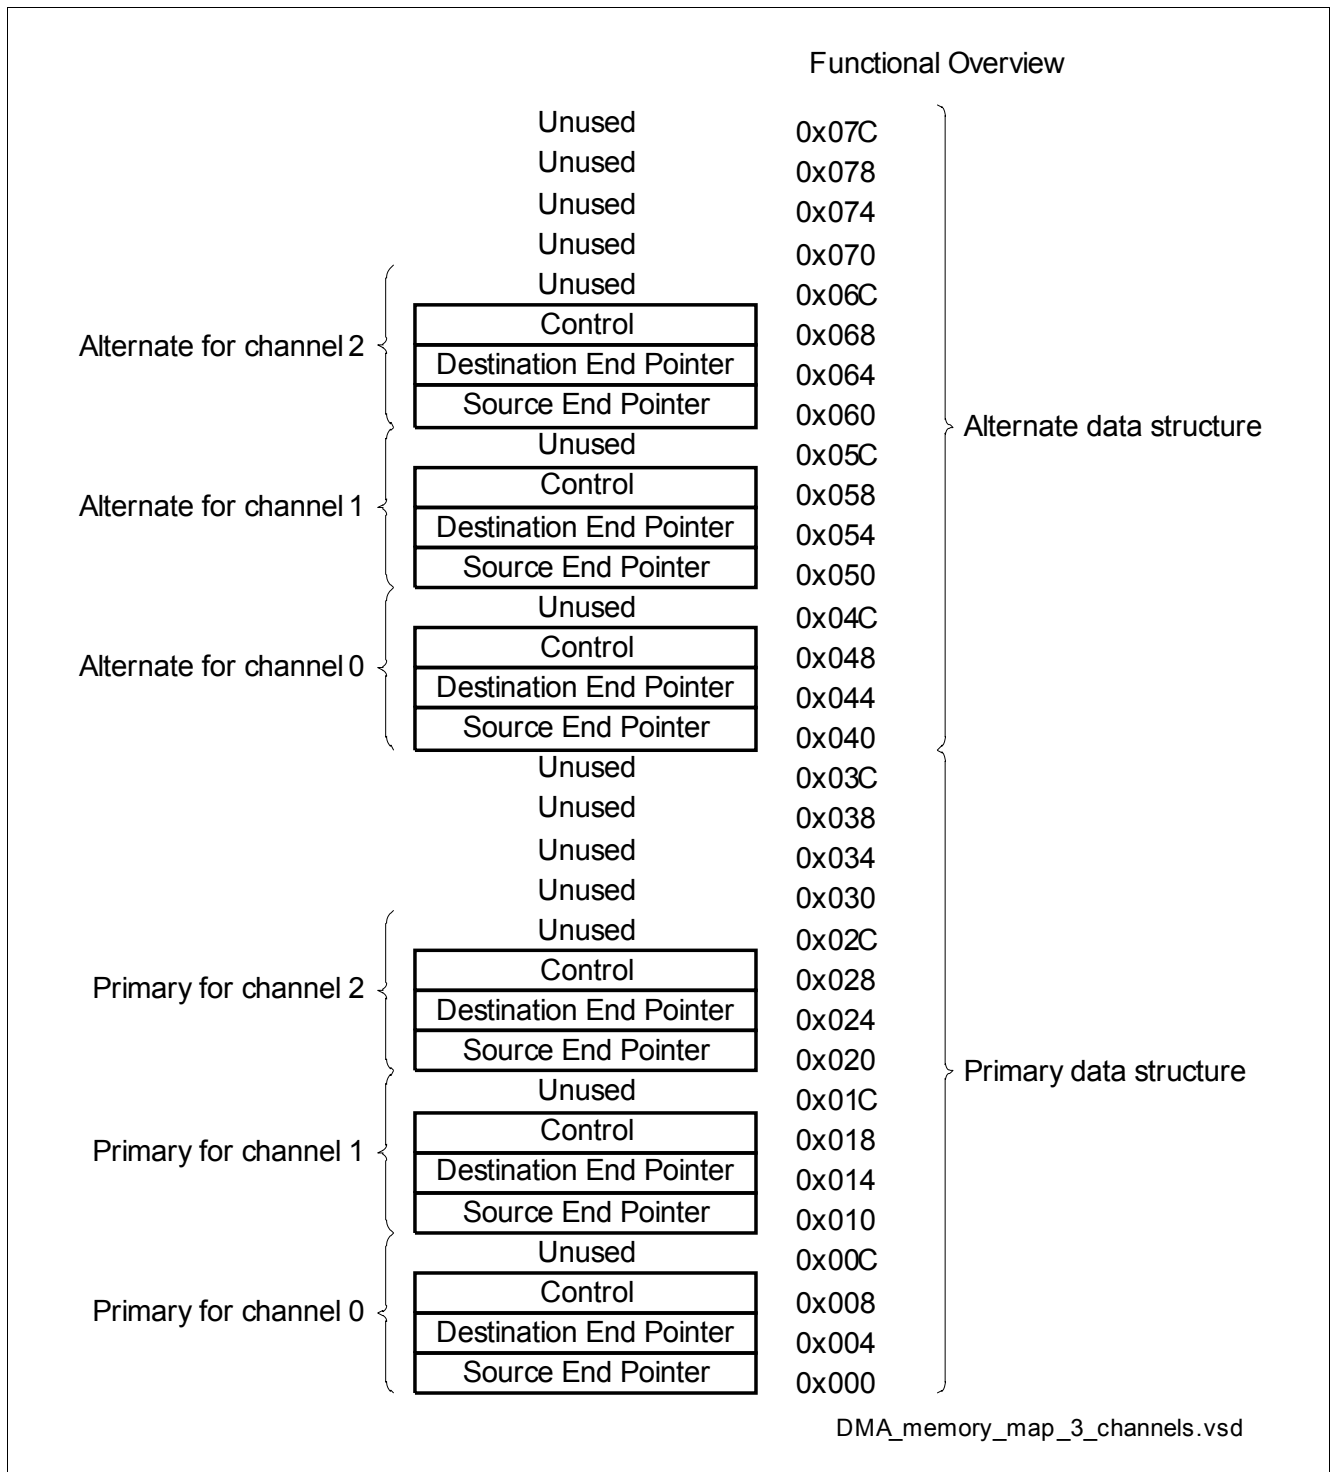

Figure 50 Memory Map for Three DMA Channels, Including the Alternate Data Structure

The example structure in [Figure 49](#) uses 128 bytes of system memory. In this example, the controller uses the lower six address bits to enable it to access all of the elements in the structure and therefore the base address must be at 0XXXXXX00_H or 0XXXXXX80_H.

[Table 54](#) lists the permitted base address values that you can assign for the primary data structure, depending on the number of channels that the controller contains.

Table 54 Permitted Base Addresses

Number of DMA Channels	Permitted Base Addresses ¹⁾ for the Primary Data Structure
0-13	0XXXXX000 _H , 0XXXXX200 _H , 0XXXXX400 _H , 0XXXXX600 _H , 0XXXXX800 _H , 0XXXXXA00 _H , 0XXXXXC00 _H , 0XXXXXE00 _H

1) Where X is a hexadecimal.

The controller uses the system memory to enable it to access two pointers and the control information that it requires for each channel. The following subsections describe these 32-bit memory locations and how the controller calculates the DMA transfer address:

- [Source Data End Pointer](#)
- [Destination Data End Pointer](#)
- [Control Data Configuration](#)
- [Address Calculation](#)

Source Data End Pointer

The src_data_end_ptr memory location contains a pointer to the end address of the source data. [Table 55](#) lists the bit assignments for this memory location.

Table 55 src_data_end_ptr bit assignments

Bit	Name	Description
[31:0]	src_data_end_ptr	Pointer to the end address of the source data

Before the controller can perform a DMA transfer, you must program this memory location with the end address of the source data. The controller reads this memory location when it starts a 2^R DMA transfer.

Note: The controller does not write to this memory location.

Destination Data End Pointer

The dst_data_end_ptr memory location contains a pointer to the end address of the destination data. [Table 56](#) lists the bit assignments for this memory location.

Table 56 dst_data_end_ptr bit assignments

Bit	Name	Description
[31:0]	dst_data_end_ptr	Pointer to the end address of the destination data

Before the controller can perform a DMA transfer, you must program this memory location with the end address of the destination data. The controller reads this memory location when it starts a 2^R DMA transfer.

Note: The controller does not write to this memory location.

Control Data Configuration

For each DMA transfer, the channel_cfg memory location provides the control information for the controller. [Figure 51](#) shows the bit assignments for this memory location.

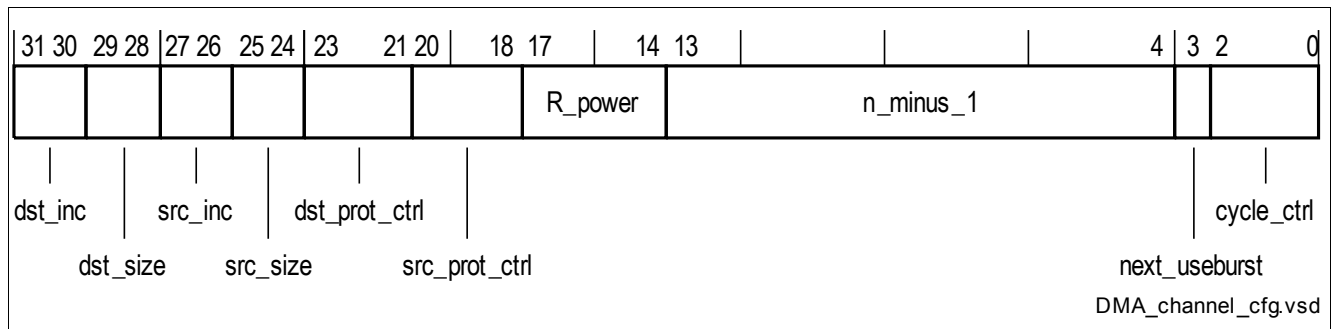

Figure 51 channel_cfg bit assignments

Table 57 lists the bit assignments for this memory location.

Table 57 channel_cfg bit assignments

Bit	Name	Description
[31:30]	dst_inc	<p>Destination address increment.</p> <p>The address increment depends on the source data width as follows:</p> <p>Source data width = byte</p> <p>00_B = byte. 01_B = halfword. 10_B = word. 11_B = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.</p> <p>Source data width = halfword</p> <p>00_B = reserved. 01_B = halfword. 10_B = word. 11_B = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.</p> <p>Source data width = word</p> <p>00_B = reserved. 01_B = reserved. 10_B = word. 11_B = no increment. Address remains set to the value that the dst_data_end_ptr memory location contains.</p>
[29:28]	dst_size	<p>Destination data size.</p> <p><i>Note: You must set dst_size to contain the same value that src_size contains.</i></p>

Table 57 channel_cfg bit assignments (cont'd)

Bit	Name	Description
[27:26]	src_inc	<p>Set the bits to control the source address increment. The address increment depends on the source data width as follows:</p> <p>Source data width = byte</p> <p>00_B = byte. 01_B = halfword. 10_B = word. 11_B = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.</p> <p>Source data width = halfword</p> <p>00_B = reserved. 01_B = halfword. 10_B = word. 11_B = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.</p> <p>Source data width = word</p> <p>00_B = reserved. 01_B = reserved. 10_B = word. 11_B = no increment. Address remains set to the value that the src_data_end_ptr memory location contains.</p>
[25:24]	src_size	<p>Set the bits to match the size of the source data:</p> <p>00_B = byte 01_B = halfword 10_B = word 11_B = reserved.</p>
[23:21]	dst_prot_ctrl	<p>Set the bits to control the state of HPROT[3:1] when the controller writes the destination data.</p> <p>Bit [23] Controls the state of HPROT[3] as follows: 0_B = HPROT[3] is LOW and the access is non-cacheable. 1_B = HPROT[3] is HIGH and the access is cacheable.</p> <p>Bit [22] Controls the state of HPROT[2] as follows: 0_B = HPROT[2] is LOW and the access is non-bufferable. 1_B = HPROT[2] is HIGH and the access is bufferable.</p> <p>Bit [21] Controls the state of HPROT[1] as follows: 0_B = HPROT[1] is LOW and the access is non-privileged. 1_B = HPROT[1] is HIGH and the access is privileged.</p>

Table 57 channel_cfg bit assignments (cont'd)

Bit	Name	Description
[20:18]	src_prot_ctrl	<p>Set the bits to control the state of HPROT[3:1] when the controller reads the source data.</p> <p>Bit [20] Controls the state of HPROT[3] as follows: 0_B = HPROT[3] is LOW and the access is non-cacheable. 1_B = HPROT[3] is HIGH and the access is cacheable.</p> <p>Bit [19] Controls the state of HPROT[2] as follows: 0 = HPROT[2] is LOW and the access is non-bufferable. 1 = HPROT[2] is HIGH and the access is bufferable.</p> <p>Bit [18] Controls the state of HPROT[1] as follows: 0_B = HPROT[1] is LOW and the access is non-privileged. 1_B = HPROT[1] is HIGH and the access is privileged.</p>
[17:14]	R_power	<p>Set these bits to control how many DMA transfers can occur before the controller rearbiterates. The possible arbitration rate settings are:</p> <p>0000_B Arbitrates after each DMA transfer. 0001_B Arbitrates after 2 DMA transfers. 0010_B Arbitrates after 4 DMA transfers. 0011_B Arbitrates after 8 DMA transfers. 0100_B Arbitrates after 16 DMA transfers. 0101_B Arbitrates after 32 DMA transfers. 0110_B Arbitrates after 64 DMA transfers. 0111_B Arbitrates after 128 DMA transfers. 1000_B Arbitrates after 256 DMA transfers. 1001_B Arbitrates after 512 DMA transfers. 1010_B-1111_B Arbitrates after 1024 DMA transfers. This means that no arbitration occurs during the DMA transfer because the maximum transfer size is 1024.</p>
[13:4]	n_minus_1	<p>Prior to the DMA cycle commencing, these bits represent the total number of DMA transfers that the DMA cycle contains. You must set these bits according to the size of DMA cycle that you require. The 10-bit value indicates the number of DMA transfers, minus one. The possible values are:</p> <p>00000000_B = 1 DMA transfer 00000001_B = 2 DMA transfers 00000010_B = 3 DMA transfers 00000011_B = 4 DMA transfers 00000100_B = 5 DMA transfers.. . 11111111_B = 1024 DMA transfers. The controller updates this field immediately prior to it entering the arbitration process. This enables the controller to store the number of outstanding DMA transfers that are necessary to complete the DMA cycle.</p>

Table 57 channel_cfg bit assignments (cont'd)

Bit	Name	Description
[3]	next_useburst	<p>Controls if the chnl_useburst_set [C] bit is set to a 1, when the controller is performing a peripheral scatter-gather and is completing a DMA cycle that uses the alternate data structure.</p> <p><i>Note: Immediately prior to completion of the DMA cycle that the alternate data structure specifies, the controller sets the chnl_useburst_set [C] bit to 0 if the number of remaining transfers is less than 2R. The setting of the next_useburst bit controls if the controller performs an additional modification of the chnl_useburst_set [C] bit.</i></p> <p>In peripheral scatter-gather DMA cycle then after the DMA cycle that uses the alternate data structure completes, either: 0 = The controller does not change the value of the chnl_useburst_set [C] bit. If the chnl_useburst_set [C] bit is 0 then for all the remaining DMA cycles in the peripheral scatter-gather transaction, the controller responds to requests on dma_req[] and dma_sreq[], when it performs a DMA cycle that uses an alternate data structure. 1 = The controller sets the chnl_useburst_set [C] bit to a 1. Therefore, for the remaining DMA cycles in the peripheral scatter-gather transaction, the controller only responds to requests on dma_req[], when it performs a DMA cycle that uses an alternate data structure.</p>
[2:0]	cycle_ctrl	<p>The operating mode of the DMA cycle. The modes are:</p> <p>000_B Stop. Indicates that the data structure is invalid.</p> <p>001_B Basic. The controller must receive a new request, prior to it entering the arbitration process, to enable the DMA cycle to complete.</p> <p>010_B Auto-request. The controller automatically inserts a request for the appropriate channel during the arbitration process. This means that the initial request is sufficient to enable the DMA cycle to complete.</p> <p>011_B Ping-pong. The controller performs a DMA cycle using one of the data structures. After the DMA cycle completes, it performs a DMA cycle using the other data structure. After the DMA cycle completes and provided that the host processor has updated the original data structure, it performs a DMA cycle using the original data structure. The controller continues to perform DMA cycles until it either reads an invalid data structure or the host processor changes the cycle_ctrl bits to 001_B or 010_B. See Ping-Pong on Page 267.</p> <p>100_B Memory scatter/gather. See Memory Scatter-Gather on Page 269. When the controller operates in memory scatter-gather mode, you must only use this value in the primary data structure.</p> <p>101_B Memory scatter/gather. See Memory Scatter-Gather on Page 269. When the controller operates in memory scatter-gather mode, you must only use this value in the alternate data structure.</p> <p>110_B Peripheral scatter/gather. See Peripheral Scatter-Gather on Page 272. When the controller operates in peripheral scatter-gather mode, you must only use this value in the primary data structure.</p> <p>111_B Peripheral scatter/gather. See Peripheral Scatter-Gather on Page 272. When the controller operates in peripheral scatter-gather mode, you must only use this value in the alternate data structure.</p>

At the start of a DMA cycle, or 2^R DMA transfer, the controller fetches the channel_cfg from system memory. After it performs 2^R, or N, transfers it stores the updated channel_cfg in system memory.

The controller does not support a `dst_size` value that is different to the `src_size` value. If it detects a mismatch in these values, it uses the `src_size` value for source and destination and when it next updates the `n_minus_1` field, it also sets the `dst_size` field to the same as the `src_size` field.

After the controller completes the `N` transfers it sets the `cycle_ctrl` field to `000B`, to indicate that the `channel_cfg` data is invalid. This prevents it from repeating the same DMA transfer.

Address Calculation

To calculate the source address of a DMA transfer, the controller performs a left shift operation on the `n_minus_1` value by a shift amount that `src_inc` specifies, and then subtracts the resulting value from the source data end pointer. Similarly, to calculate the destination address of a DMA transfer, it performs a left shift operation on the `n_minus_1` value by a shift amount that `dst_inc` specifies, and then subtracts the resulting value from the destination end pointer.

Depending on the value of `src_inc` and `dst_inc`, the source address and destination address can be calculated using the equations:

`src_inc = 00B` and `dst_inc = 00B`

- source address = `src_data_end_ptr - n_minus_1`
- destination address = `dst_data_end_ptr - n_minus_1`

`src_inc = 01B` and `dst_inc = 01B`

- source address = `src_data_end_ptr - (n_minus_1 << 1)`
- destination address = `dst_data_end_ptr - (n_minus_1 << 1)`

`src_inc = 10B` and `dst_inc = 10B`

- source address = `src_data_end_ptr - (n_minus_1 << 2)`
- destination address = `dst_data_end_ptr - (n_minus_1 << 2)`

`src_inc = 11B` and `dst_inc = 11B`

- source address = `src_data_end_ptr`
- destination address = `dst_data_end_ptr`

Table 59 lists the destination addresses for a DMA cycle of six words.

Table 58 DMA Cycle of Six Words Using a Word Increment

Initial values of <code>channel_cfg</code> , prior to the DMA cycle				
<code>src_size = 10_B</code> , <code>dst_inc = 10_B</code> , <code>n_minus_1 = 101_B</code> , <code>cycle_ctrl = 1_B</code>				
DMA Transfers	End Pointer	Count	Difference ¹⁾	Address
	02AC _H	5	014 _H	0298 _H
	02AC _H	4	010 _H	029C _H
	02AC _H	3	0C _H	02A0 _H
	02AC _H	2	08 _H	02A4 _H
	02AC _H	1	04 _H	02A8 _H
	02AC _H	0	00 _H	02AC _H

Final values of `channel_cfg`, after the DMA cycle

`src_size = 10B`, `dst_inc = 10B`, `n_minus_1 = 0B`, `cycle_ctrl = 0B`

1) This value is the result of count being shifted left by the value of `dst_inc`.

Table 59 lists the destination addresses for a DMA transfer of 12 bytes using a halfword increment.

Table 59 DMA Cycle of 12 Bytes Using a Halfword Increment

Initial values of channel_cfg, prior to the DMA cycle

src_size = 00_B, dst_inc = 01_B, n_minus_1 = 1011_B, cycle_ctrl = 1_B, R_power = 11_B

DMA Transfers	End Pointer	Count	Difference ¹⁾	Address
	05E7 _H	11	016 _H	05D1 _H
	05E7 _H	10	014 _H	05D3 _H
	05E7 _H	9	012 _H	05D5 _H
	05E7 _H	8	010 _H	05D7 _H
	05E7 _H	7	0E _H	05D9 _H
	05E7 _H	6	0C _H	05DB _H
	05E7 _H	5	0A _H	05DD _H
	05E7 _H	4	08 _H	05DF _H

Values of channel_cfg after 2^R DMA transfers

src_size = 00_B, dst_inc = 01_B, n_minus_1 = 011_B, cycle_ctrl = 1_B, R_power = 11_B

DMA Transfers	End Pointer	Count	Difference ²⁾	Address
	05E7 _H	3	06 _H	05E1 _H
	05E7 _H	2	04 _H	05E3 _H
	05E7 _H	1	02 _H	05E5 _H
	05E7 _H	0	00 _H	05E7 _H

Final values of channel_cfg, after the DMA cycle.

src_size = 00_B, dst_inc = 01_B, n_minus_1 = 0_B, cycle_ctrl = 0_B, R_power = 11_B

- 1) This value is the result of count being shifted left by the value of dst_inc.
- 2) After the controller completes the DMA cycle it invalidates the channel_cfg memory location by clearing the cycle_ctrl field.

10.4 Register Definition

Please refer to [1], Chapter 3, Programmer's Model and chapter 4, Register Description

Table 60 shows the <Module> module base address (for the configuration register).

Table 60 Register Address Space

Module	Base Address	End Address	Note
DMA	50014000 _H	50017FFF _H	

Table 61 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition,			
STATUS	DMA Status	00 _H	000D 0000 _H
CFG	DMA Configuration	04 _H	0000 0000 _H
CTRL_BASE_PTR	Channel Control Data Base Pointer	08 _H	0000 0000 _H
ALT_CTRL_BASE_PTR	Channel Alternate Control Data Base Pointer	0C _H	0000 0100 _H
WAITONREQ_STATUS	Channel Wait on Request Status	10 _H	0000 0000 _H
CHNL_SW_REQUEST	Channel Software Request	14 _H	0000 0000 _H
CHNL_USEBURST_SET	Channel Useburst Set	18 _H	0000 0000 _H
CHNL_USEBURST_CLR	Channel Useburst Clear	1C _H	0000 0000 _H

ERR_CLR	Bus Error Clear	4C _H	0000 0000 _H

The registers are addressed wordwise.

DMA Status Registers

The read-only DMA_STATUS Register returns the status of the controller. You cannot read this register when the controller is in the reset state.

STATUS	Offset	Reset Value
DMA Status	00 _H	000D 0000 _H

Field	Bits	Type	Description
RES	31:28	r	Reserved Read as 0.
RES	27:21	r	Reserved Read as 0.
CHNLS_MINUS1	20:16	r	Available Channels minus 1 Number of available DMA channels minus one 1101 _B controller configured to use 14 DMA channels
RES	15:8	r	Reserved
STATE	7:4	r	Current State of the Control State Machine State can be one of the following bit combinations (other bit combinations are undefined): 0000 _B idle 0001 _B reading channel controller data 0010 _B reading source data end pointer 0011 _B reading destination data end pointer 0100 _B reading source data 0101 _B writing destination data 0110 _B waiting for DMA request to clear 0111 _B writing channel controller data 1000 _B stalled 1001 _B done 1010 _B peripheral scatter-gather transition
RES	3:1	r	Reserved
MASTER_ENAB	0	r	Enable Status of the Controller 0 _B DISABLED controller is disabled 1 _B ENABLED controller is enabled

Channel Control Data Base Pointer Register

The CTRL_BASE_PTR register is a read/write register. You must configure this register to that base pointer points to a location in your system memory.

Note: The controller provides no internal memory for storing the channel control data.

The amount of system memory that you must assign to the controller depends on the number of DMA channels and whether you configure it to use the alternate data structure. Therefore, the base pointer address requires a variable number of bits that depend on the system implementation.

You cannot read this register when the controller is in the reset state. [Figure 52](#) shows the possible bit assignments for this register, depending on the number of DMA channels that you configure the controller to contain

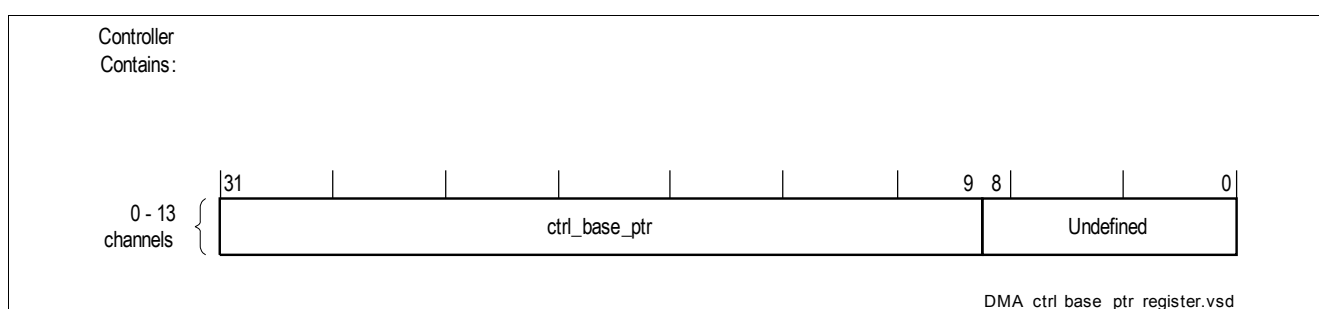

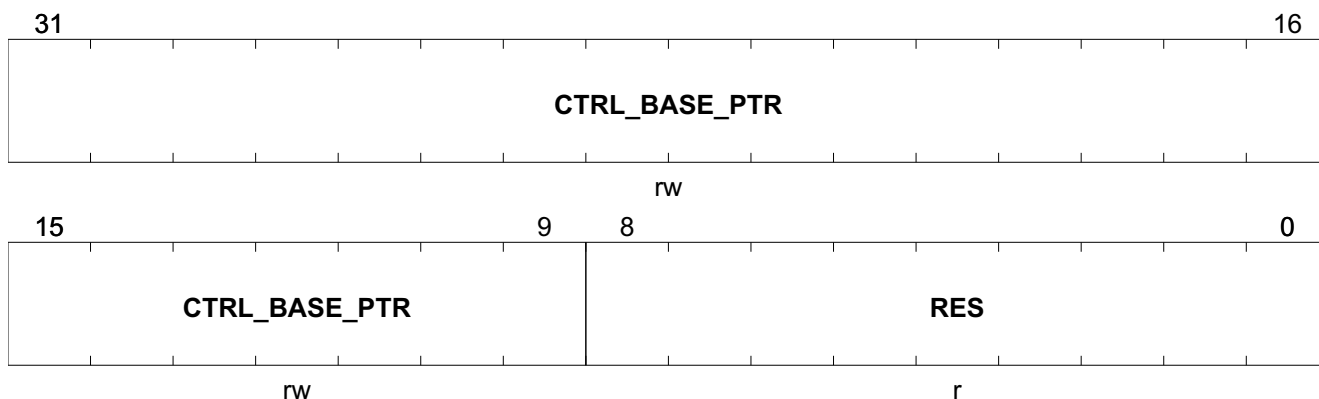

Figure 52 CTRL_BASE_PTR Register Bit Assignments

CTRL_BASE_PTR	Offset	Reset Value
Channel Control Data Base Pointer	08 _H	0000 0000 _H

Field	Bits	Type	Description
CTRL_BASE_PTR	31:9	rw	CTRL_BASE_PTR Pointer to the base address of the primary data structure. See Chapter 10.2 for information about the data structure.
RES	8:0	r	Reserved read as zero.

BITS Definition

The bit range is 31 to PL230_DMA_CHNL_BITS-5 for the field CTRL_BASE_PTR and PL230_DMA_CHNL_BITS-4 to 0 for the field res.

DMA Controller

PL230_DMA_CHNL_BITS is defined as the minimum number of bits required to represent the number of DMA channels, minus one. The values that PL230_DMA_CHNL_BITS can be assigned are

- 0, when the controller contains 1 DMA channel.
- 1, when the controller contains 2 DMA channels.
- 2, when the controller contains 3 or 4 DMA channels.
- 3, when the controller contains 5 to 8 DMA channels.
- 4, when the controller contains 9 to 16 DMA channels.
- 5, when the controller contains 17 to 32 DMA channels.

Channel Alternate Control Data Base Pointer Registers

The read-only ALT_CTRL_BASE_PTR Register returns the base address of the alternate data structure. You cannot read this register when the controller is in the reset state.

ALT_CTRL_BASE_PTR	Offset	Reset Value
Channel Alternate Control Data Base Pointer	0C _H	0000 0100 _H

Field	Bits	Type	Description
ALT_CTRL_BASE_PTR	31:0	r	Base Address of the Alternate Data Structure

Channel Wait on Request Status Register

The read-only DMA_WAITONREQ_STATUS Register returns the status of dma_waitonreq[]. You cannot read this register when the controller is in the reset state.

WAITONREQ_STATUS	Offset	Reset Value
Channel Wait on Request Status	10 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
WAITONREQ_STATUS	13:0	r	Channel Wait on Request Status Read as for each bit C (C = 13 to 0): 0 _B LOW dma_waitonreq[C] is LOW. 1 _B HIGH dma_waitonreq[C] is HIGH.

Channel Software Request Register

The write-only CHNL_SW_REQUEST Register enables you to generate a software DMA request.

CHNL_SW_REQUEST	Offset	Reset Value
Channel Software Request	14 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_SW_REQUEST	13:0	w	CHNL_SW_REQUEST Set the appropriate bit to generate a software DMA request on the corresponding DMA channel. Write as for each bit C (C = 13 to 0): <i>Note: Writing to this bit where a DMA channel is not implemented does not create a DMA request for that channel.</i> 0 _B does not create a DMA request for channel C. 1 _B creates a DMA request for channel C.

Channel Useburst Set Register

The read/write CHNL_USEBURST_SET Register disables the single request dma_sreq[] input from generating requests, and therefore only the request, dma_req[], generates requests. Reading the register returns the useburst status.

CHNL_USEBURST_SET	Offset	Reset Value
Channel Useburst Set	18_H	0000 0000_H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_USEBURST_SET	13:0	rw	CHNL_USEBURST_SET Returns the useburst status, or disables dma_sreq[C] from generating DMA requests. For each bit C (C = 13 to 0) <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">0_B</div> <div style="width: 80%;">on read: DMA channel n responds to requests that it receives on dma_req[C] or dma_sreq[C]. The controller performs 2^R, or single, bus transfers.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">1_B</div> <div style="width: 80%;">on read: DMA channel n does not respond to requests that it receives on dma_req[C] or dma_sreq[C]. The controller only responds to dma_req[C] requests and performs 2^R transfers.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">0_B</div> <div style="width: 80%;">on write: No effect. Use the CHNL_USEBURST_CLR Register to set bit [C] to 0.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">1_B</div> <div style="width: 80%;">on write: Disables dma_sreq[C] from generating DMA requests. The controller performs 2^R transfers.</div> </div>

After the penultimate 2^R transfer completes, if the number of remaining transfers, N, is less than 2^R then the controller resets the CHNL_USEBURST_SET bit to 0. This enables you to complete the remaining transfers using dma_req[] or DMA_SREQ[].

Note: If you program CHANNEL_CFG with a value of N less than 2^R then you must not set the corresponding CHNL_USEBURST_SET bit, if the peripheral does not assert dma_req[].

In peripheral scatter-gather mode, if the next_useburst bit is set in CHANNEL_CFG then the controller sets the CHNL_USEBURST_SET [n] bit to a 1, when it completes the DMA cycle that uses the alternate data structure.

Channel Useburst Clear Register

The write-only CHNL_USEBURST_CLR Register enables dma_sreq[] to generate requests.

CHNL_USEBURST_CLR	Offset	Reset Value
Channel Useburst Clear	1C _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_USEBURST_CLR	13:0	w	CHNL_USEBURST_CLR Set the appropriate bit to enable dma_sreq[] to generate requests. Write as for each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B No effect. Use the CHNL_USEBURST_SET Register to disable dma_sreq[] from generating requests. 1 _B Enables dma_sreq[C] to generate DMA requests.

Channel Request Mask Set Register

The read/write CHNL_REQ_MASK_SET Register disables a HIGH on dma_req[], or dma_sreq[], from generating a request. Reading the register returns the request mask status for dma_req[] and dma_sreq[].

CHNL_REQ_MASK_SET	Offset	Reset Value
Channel Request Mask Set	20 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_REQ_MASK_SET	13:0	rw	CHNL_REQ_MASK_SET Returns the request mask status of dma_req[] and dma_sreq[], or disables the corresponding channel from generating DMA requests. For each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B on read: External requests are enabled for channel C. 1 _B on read: External requests are disabled for channel C. 0 _B on write: No effect. Use the CHNL_REQ_MASK_CLR Register to enable DMA requests. 1 _B on write: Disables dma_req[C] and dma_sreq[C] from generating DMA requests.

Channel Request Mask Clear Register

The write-only CHNL_REQ_MASK_CLR Register enables a HIGH on dma_req[], or dma_sreq[], to generate a request.

CHNL_REQ_MASK_CLR	Offset	Reset Value
Channel Request Mask Clear	24 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_REQ_MASK_CLR	13:0	w	CHNL_REQ_MASK_CLR Set the appropriate bit to enable DMA requests for the channel corresponding to dma_req[] and dma_sreq[]. Write as for each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B No effect. Use the CHNL_REQ_MASK_SET Register to disable dma_req[] and dma_sreq[] from generating requests. 1 _B Enables dma_req[C] or dma_sreq[C] to generate DMA request.

Channel Enable Set Register

The read/write CHNL_ENABLE_SET Register enables you to enable a DMA channel. Reading the register returns the enable status of the channels.

CHNL_ENABLE_SET	Offset	Reset Value
Channel Enable Set	28 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:16	r	Reserved Always read as 0
CHNL_ENABLE_SET	13:0	rw	CHNL_ENABLE_SET Returns the enable status of the channels, or enables the corresponding channels. For each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B on read: Channel C is disabled. 1 _B on read: Channel C is enabled. 0 _B on write: No effect. Use the CHNL_ENABLE_CLR Register to disable a channel. 1 _B on write: Enables channel C.

Channel Enable Clear Register

The write-only CHNL_ENABLE_CLR Register enables you to disable a DMA channel.

CHNL_ENABLE_CLR	Offset	Reset Value
Channel Enable Clear	2C _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_ENABLE_CLR	13:0	w	CHNL_ENABLE_CLR Set the appropriate bit to disable the corresponding DMA channel. Write as for each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B No effect. Use the CHNL_ENABLE_SET Register to enable DMA channels. 1 _B Disables channel C.

Note: The controller disables a channel, by setting the appropriate bit, when either:

- it completes the DMA cycle
- it reads a channel_cfg memory location which has cycle_ctrl = 000_B
- an ERROR occurs on the AHB-Lite bus

Channel Primary-Alternate Set Register

The read/write CHNL_PRI_ALT_SET Register enables you to configure a DMA channel to use the alternate data structure. Reading the register returns the status of which data structure is in use for the corresponding DMA channel.

CHNL_PRI_ALT_SET	Offset	Reset Value
Channel Primary-Alternate Set	30 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_PRI_ALT_SET	13:0	rw	CHNL_PRI_ALT_SET Returns the channel control data structure status, or selects the alternate data structure for the corresponding DMA channel. For each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> <div> <div>0_B</div> <div>on read: DMA channel C is using the primary data structure.</div> </div> <div> <div>1_B</div> <div>on read: DMA channel C is using the alternate data structure.</div> </div> <div> <div>0_B</div> <div>on write: No effect. Use the CHNL_PRI_ALT_CLR Register to set bit [C] to 0.</div> </div> <div> <div>1_B</div> <div>on write: Selects the alternate data structure for channel C.</div> </div>

Note: The controller toggles the value of the CHNL_PRI_ALT_SET [C] bit after it completes:

- the four transfers that the primary data structure specifies for a memory scatter-gather, or peripheral scatter-gather, DMA cycle
- all the transfers that the primary data structure specifies for a ping-pong DMA cycle
- all the transfers that the alternate data structure specifies for the following DMA cycle types:
 - ping-pong
 - memory scatter-gather
 - peripheral scatter-gather

Channel Primary-Alternate Clear Register

The write-only CHNL_PRI_ALT_CLR Register enables you to configure a DMA channel to use the primary data structure.

CHNL_PRI_ALT_CLR	Offset	Reset Value
Channel Primary-Alternate Clear	34 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_PRI_ALT_CLR	13:0	w	CHNL_PRI_ALT_CLR Set the appropriate bit to select the primary data structure for the corresponding DMA channel. Write as for each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B No effect. Use the CHNL_PRI_ALT_SET Register to select the alternate data structure. 1 _B Selects the primary data structure for channel C.

Note: The controller toggles the value of the chnl_pri_alt_clr [C] bit after it completes:

- the four transfers that the primary data structure specifies for a memory scatter-gather, or peripheral scatter-gather, DMA cycle
- all the transfers that the primary data structure specifies for a ping-pong DMA cycle
- all the transfers that the alternate data structure specifies for the following DMA cycle types:
 - ping-pong
 - memory scatter-gather
 - peripheral scatter-gather

Channel Priority Set Register

The read/write CHNL_PRIORITY_SET Register enables you to configure a DMA channel to use the high priority level. Reading the register returns the status of the channel priority mask.

CHNL_PRIORITY_SET	Offset	Reset Value
Channel Priority Set	38 _H	0000 0000 _H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_PRIORITY_SET	13:0	rw	CHNL_PRIORITY_SET Returns the channel priority mask status, or sets the channel priority to high. For each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">0_B</div> <div style="width: 90%;">on read: DMA channel C is using the default priority level.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">1_B</div> <div style="width: 90%;">on read: DMA channel C is using a high priority level.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">0_B</div> <div style="width: 90%;">on write: No effect. Use the CHNL_ENABLE_CLR Register to set channel C to the default priority level.</div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 10%;">1_B</div> <div style="width: 90%;">on write: Channel C uses the high priority level.</div> </div>

Channel Priority Clear Register

The write-only CHNL_ENABLE_CLR Register enables you to configure a DMA channel to use the default priority level.

CHNL_PRIORITY_CLR
Channel Priority Clear

Offset
3C_H

Reset Value
0000 0000_H

Field	Bits	Type	Description
RES	31:14	r	Reserved Always read as 0
CHNL_PRIORITY_CLR	13:0	w	CHNL_PRIORITY_CLR Set the appropriate bit to select the default priority level for the specified DMA channel. Write as for each bit C (C = 13 to 0): <i>Note: Writing to a bit where a DMA channel is not implemented has no effect.</i> 0 _B No effect. Use the CHNL_ENABLE_SET Register to set channel C to the high priority level. 1 _B Channel C uses the default priority level.

Bus Error Clear Register

The read/write ERR_CLR Register returns the status of dma_err, and enables you to set dma_err LOW.

ERR_CLR	Offset	Reset Value
Bus Error Clear	4C_H	0000 0000_H

Field	Bits	Type	Description
RES	31:1	r	Reserved Write as zero.
ERR_CLR	0	rw	ERR_CLR Returns the status of dma_err, or sets the signal LOW. <i>Note: For test purposes, use the err_set register to set dma_err HIGH.</i> 0 _B on read: dma_err is LOW. 1 _B on read: dma_err is HIGH. 0 _B on write: No effect, status of dma_err is unchanged. 1 _B on write: Sets dma_err LOW.

Note: If you deassert dma_err at the same time as an ERROR occurs on the AHB-Lite bus, then the ERROR condition takes precedence and dma_err remains asserted.

11 Address Space Organization

The embedded Cortex M3 MCU offers the following address space organization:

Figure 53 Original Cortex M3 Memory Map

Address Space Organization

The TLE9869QXA20 manipulates operands in the following memory spaces:

- 128 kByte of Flash memory in code space
- 32 kByte Boot ROM memory in code space (used for boot code and IP storage)
- 6 kByte RAM memory in code space and data space (RAM can be read/written as program memory or external data memory)
- Special function registers (SFRs) in peripheral space

The figure below shows the detailed address alignment of TLE9869QXA20:

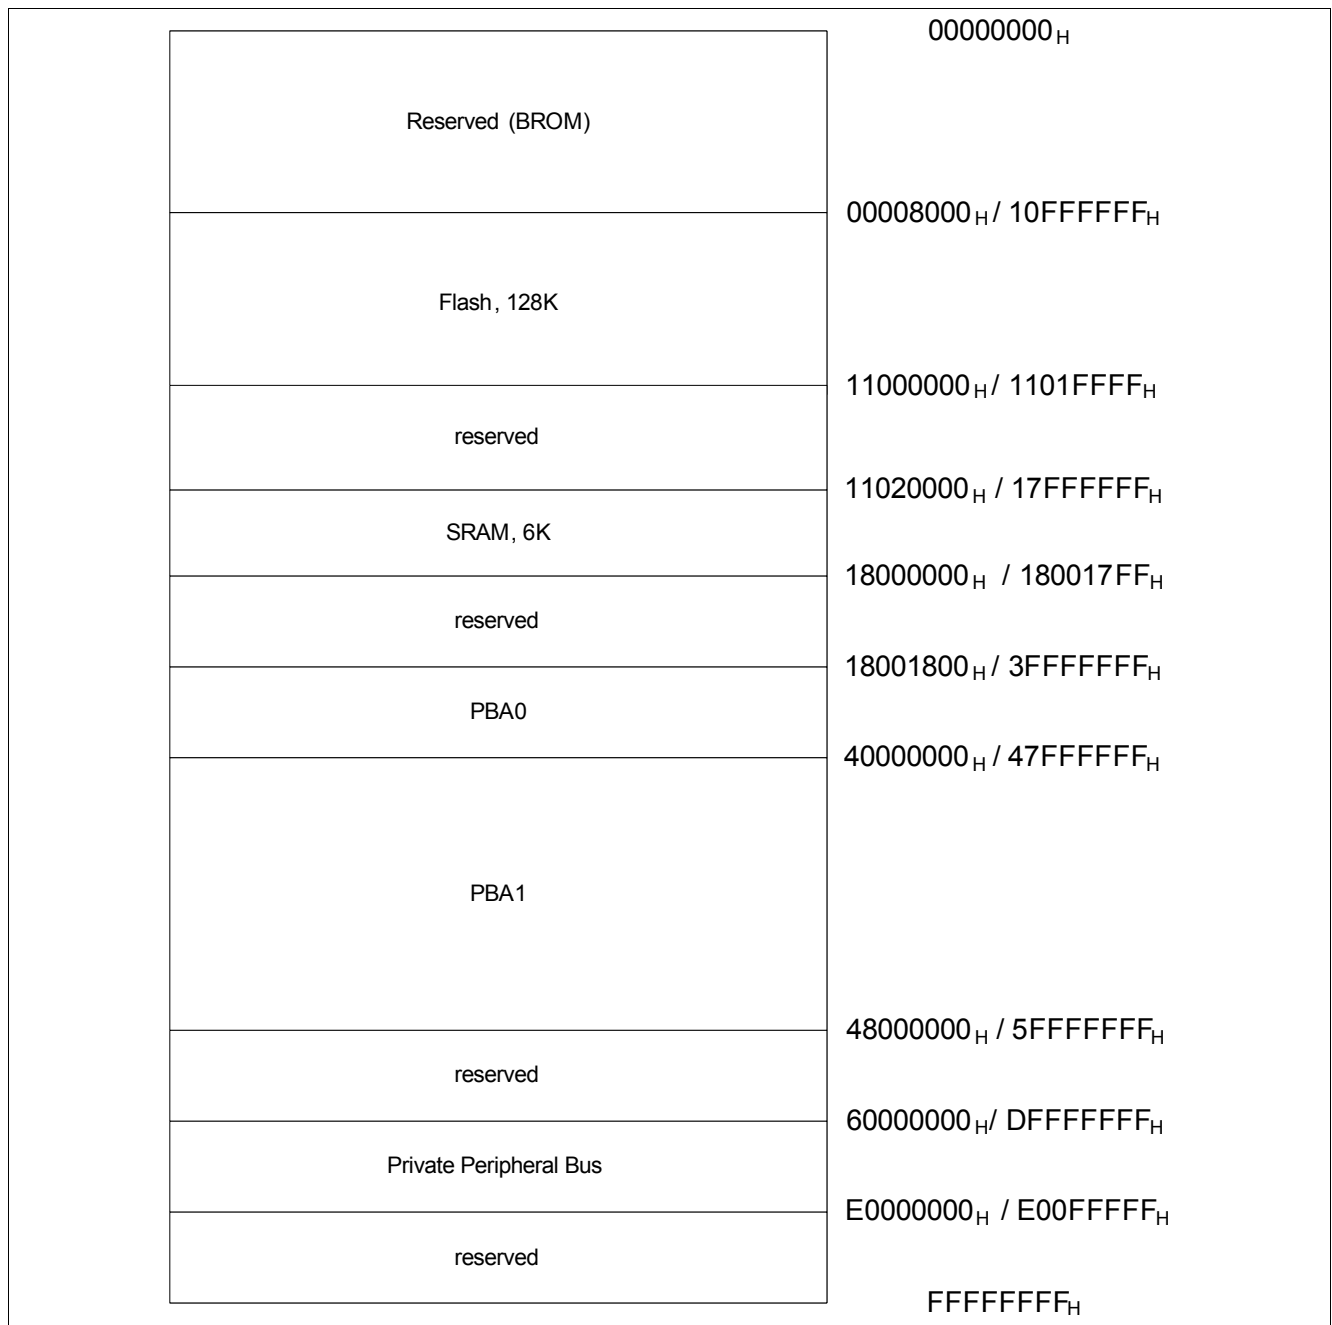

Figure 54 TLE9869QXA20 Memory Map

Each module provides, beside the physical memory implementation, standard AHB-Lite interface and Error Correction Code (ECC) logic if needed.

12 Memory Control Unit

12.1 Features

- Handling of all system memories and their interaction with CPU
- Memory protection functions for all system memories (D-Flash, P-Flash, RAM)
- Address management with access violation detection including reporting
- Linear address range for all memories (no paging)

12.2 Introduction

12.2.1 Block Diagram

The Memory Control Unit (MCU) is divided in the following sub-modules:

- NVM Memory module (embedded Flash Memory)
- RAM memory module
- BootROM memory module
- Memory protection Unit (MPU) module
- LMB (Local Memory Bus) interface logic.

A block diagram view of the MCU, together with the main interface signals, is shown in the [Figure 55](#).

Memory Control Unit

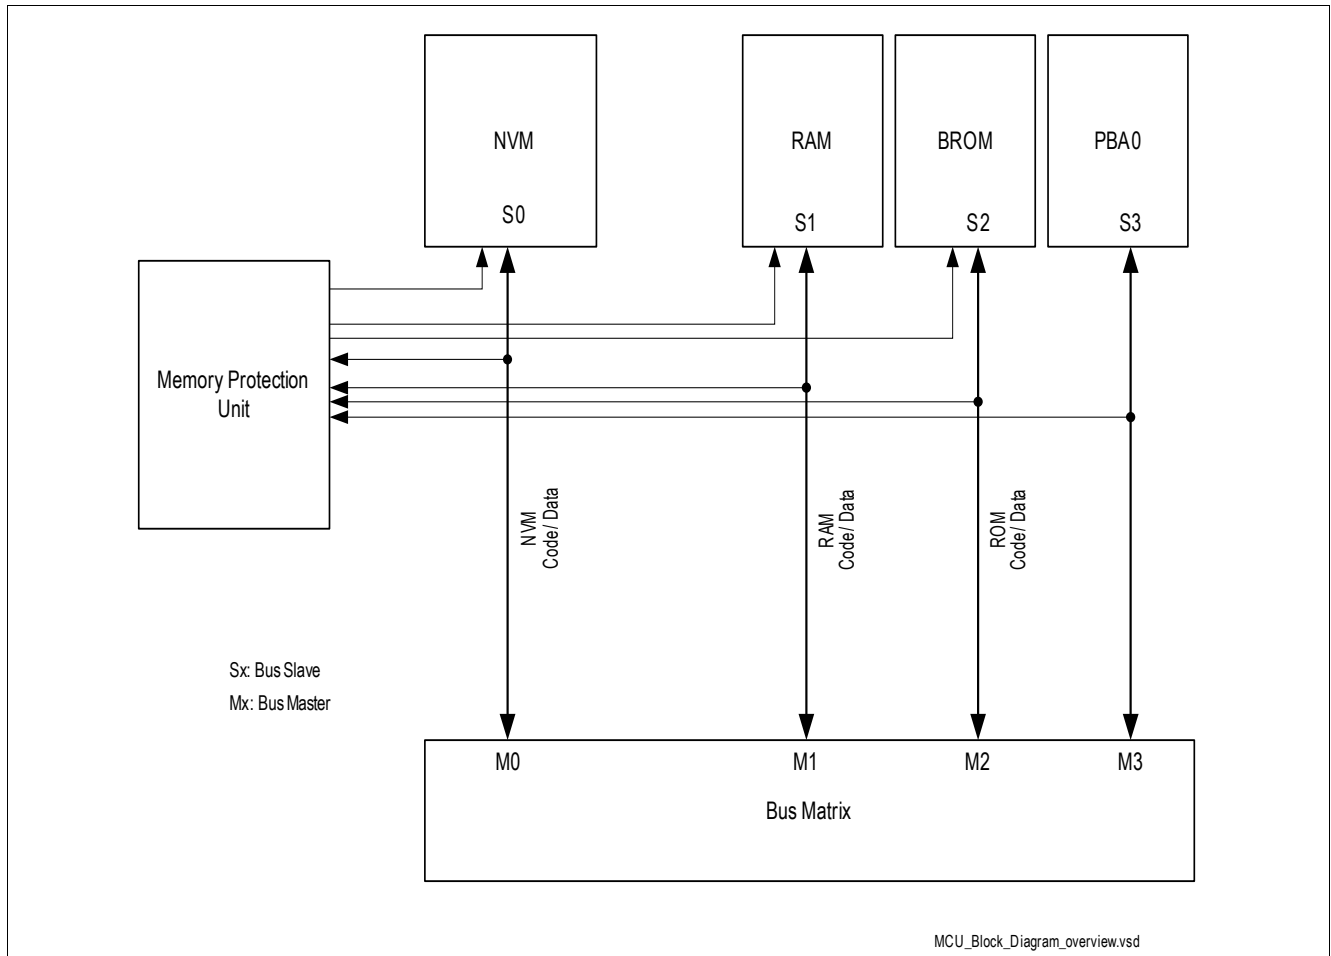

Figure 55 MCU Block View

As shown in the [Figure 55](#), the MCU interface communicates with the external world, mainly the core, via 4 AHB-Lite interfaces, Data/Code access to the NVM, BootROM and RAM plus an access to the NVM internal registers. The AMBA bus matrix block decodes the access requests coming from the masters and forwards them to the target module interface together with the required sideband signals. The AMBA bus matrix block provides all the needed interface functions between the masters and the memory peripheral. It will generate proper HSEL signals, and multiplex the response coming from the modules. In addition, the AMBA bus matrix block takes care of forwarding the transfer according to a fixed priority policy described in the AMBA chapter.

Besides the AHB-Lite and sideband signals, the MCU has access to further Core specific signals, relevant for memory protection.

12.3 NVM Module (Flash Memory)

The Flash Memory provides an embedded user-programmable non-volatile memory, allowing fast and reliable storage of user code and data.

Features

- In-System Programming via LIN (Flash Mode) and SWD
- Error Correction Code (ECC) for detection of single Bit and double Bit errors and dynamic correction of single Bit errors.
- Interrupt and signaling of double bit error by NMI
- Program width of 128 Byte (page)
- Minimum erase width of 128 Byte (page)
- Integrated hardware support for EEPROM emulation
- 8 Byte read access
- Physical read access time: 75 ns
- Code read access acceleration integrated; read buffer and automatic pre-fetch
- Page program time: 3 ms
- Page erase (128 bytes) and sector erase (4K bytes) time: 4ms

The clock for the NVM is supplied with the system frequency f_{sys} . Integrated firmware routines are provided to ease NVM, and other operations including EEPROM emulation.

The TLE9869QXA20 NVM module provides physical implementation of the memory module as well as needed complementary features and interface towards the core.

The module provides proper access to the memory through 2 AHB-Lite interfaces: 1 8-bit data interface connected to the M3 system bus for NVM internal register access, and 32-bit data interface multiplexed on M3 ICode and Dcode for code/data access.

The TLE9869QXA20 NVM module consists of the memory cell array and all the control circuits and registers needed to access the array itself. The 128 Kbyte data module is mapped in the M3 code address range 11000000H - 1101FFFFH while the dedicated SFRs are mapped in the M3 system address range 58004000H - 58007FFFH.

Access of NVM module is granted through the AMBA matrix block that forwards to the memory modules AHB-Lite interfaces the requests generated by the masters according to the defined priority policy.

12.3.1 Definitions

This section defines the nomenclature and some abbreviations. the used flash memory is a non-volatile memory (“NVM”) based on a floating gate one-transistor cell. It is called “non-volatile” because the memory content is kept when the memory power supply is shut off.

12.3.1.1 General Definitions

Logical and Physical states

Erasing

The erased state of a cell is ‘1’. Forcing an NVM cell to this state is called erasing. Erasing is possible with a granularity of a page (see below).

Writing

The written state of a cell is ‘0’. Forcing an NVM cell to this state is called writing. Each bit can be individually written.

Programming

The combination of erasing and writing is called ‘programming’. Programming often means also writing a previously erased page.

The wording ‘write’ or ‘writing’ are also used for accessing special function registers and the assembly buffer. The meaning depends therefore on the context.

The above listed processes have certain limitations:

Retention: This is the time during which the data of a flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the flash array (temperature profile) and the accesses to the flash array. With an increasing number of program/erase cycles (see endurance) the retention is lowered. Drain and gate disturbs decrease data retention as well.

Endurance: As described above, the data retention is reduced with an increasing number of program/erase cycles. A flash cell incurs one cycle whenever its page or sector is erased. This number is called “endurance”. As said for the retention, it is a statistical figure that depend on operating conditions and the use of the flash cells and on the required quality level.

Drain Disturb: Because of using a so called “one-transistor” flash cell each program access disturbs all pages of the same sector slightly. Over long these “drain disturbs” make 0 and 1 values indistinguishable and thus provoke read errors. This effect is again interrelated with the retention. A cell that incurred a high number of drain disturbs will have a lower retention. The physical sectors of the flash array are isolated from each other. So pages of a different sector do not incur a drain disturb. this effect must be therefore considered when the page erase feature is used or when re-programming an ready programmed page (implicitly causing an erase of the page before writing the new data).

Data Portions

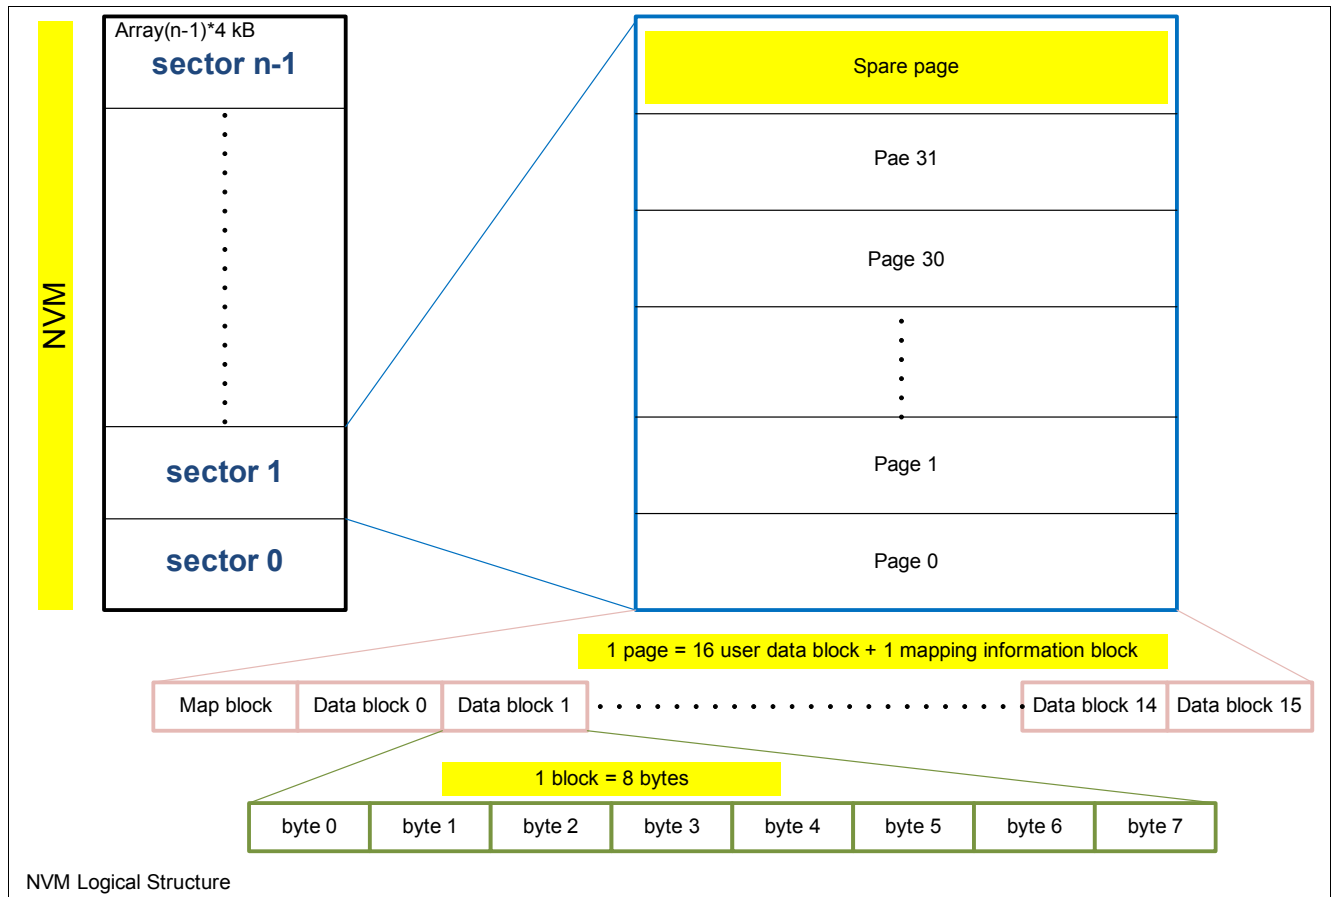

Figure 56 Logical structure of the NVM core

Doubleword

A doubleword consists of 64 bits. A doubleword represents the data size that is read from or written to the NVM core module within one access cycle.

Block

A block consists of one doubleword and its associated ECC data (64 bit data and 8 bit ECC). A block represents the smallest data portion that can be changed in the assembly buffer. Since the ECC protects 64 bits, when a byte is written to the assembly buffer automatically an NVM internal read of the complete block is triggered, the byte and the ECC are updated and the complete block is written back to the assembly buffer.

Mapblock

A map block consists of a module specific number of ECC -protected bits that hold the necessary information to map a physical page to a logical page.

Page

A page consists of 16 blocks and one map block.

Spare page

A spare page is an additional page in a sector used in each programming routine to allow tearing-safe programming.

Sector

A sector consists of 32 logical and 33 physical page.

12.3.2 Functional Description

The main tasks of the NVM module are reading from the memory array, writing to the assembly buffer, enabling (tearing safe) programming of a single page, provide basic in-module functionality for code protection and prefetch feature for optimized system performance. The main features are listed following:

- 128 KB memory size
- 4 KB configuration sector
- 3 ms write time per page
- 4 ms erase time per page
- Error correction and Error Detection code (ECC and EDC)
- In module memory protection logic
- Prefetch logic for optimized module performance

12.3.2.1 Basic block functions

Figure 57 shows a schematic block diagram of the NVM module

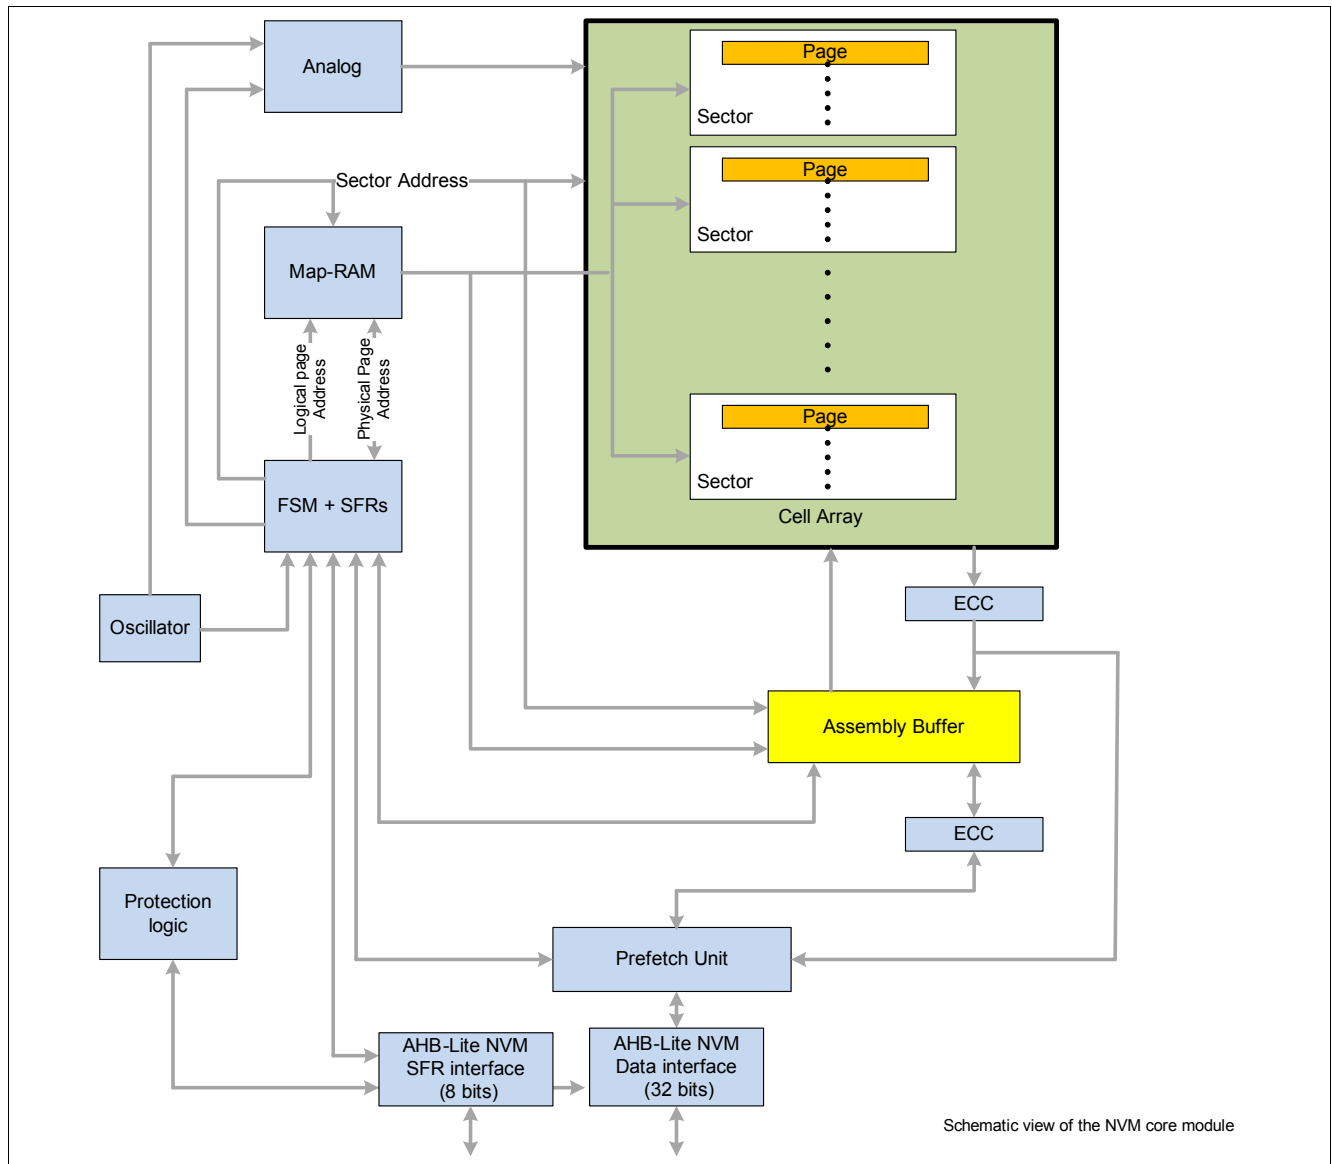

Figure 57 Schematic view of the NVM core module

12.3.2.2 Memory Cell Array

The non-volatile memory cells are organized in sectors, which consists of pages, which are structured in blocks and map block.

Page

Each page consists of 16 data blocks of 64 bits each and one map block. The map block stores the mapping information of the page in the sector. All blocks of a page are ECC-protected.

A page is the smallest granularity of data that can be changed (erased or written) within the cell array. One data block is the minimum granularity of data that can be read from the NVM module within memory read access.

Employing the integrated EEPROM emulation using the map RAM, the minimum granularity of data that can be changed in the NVM is one byte, while all other bytes in the page do not change.

Assembly Buffer

The assembly buffer is a RAM that can hold the content of one page including the mapblock.

Sector

A sector consists of 33 physical pages. 32 pages can be logically addressed during a memory access. One page is internally used as a spare page.

Map RAM

The map RAM is a static RAM that holds the mapping of a logical page addresses to physical page addresses for each sector. It is completely handled by the NVM programming related BootROM routines. The map-RAM currently is sized to support a max of 16 map-RAM mapped sectors.

FSM and SFR block

This block contains the special function registers (SFRs) of the NVM module. Beside memory reads and writes to the assembly all interactions of the BootROM software with the module take place through register accesses. The finite state machine (FSM) controls the actions (e.g. read, erase and write) of the NVM module.

Analog components

The module contains analog components to provide all the voltages necessary for erasing, writing and reading the non-volatile memory cells.

12.3.2.3 SFR Accesses

All SFRs can only be accessed through the NVM related BootROM routines, that is, the customer software cannot access the SFRs directly but has to use BootROM routines.

12.3.2.4 Memory Read

The NVM memory internally can be read with a minimum granularity of one block (64 data bits).

If the block is not within the memory address range of the NVM module, the module does not react at all and a different memory module may handle the access.

Memory read accesses are only possible while no FSM procedures (program, init, sleep or copy) is in progress. A memory read access while the FSM is busy is stalled as long as the FSM is busy and the access is carried out when the FSM is in idle mode again.

Since a read to the memory field takes a fixed time mostly independent of the system frequency, an optimized number of waitstates (3, 1 or 0) is generated for different system frequencies.

Furthermore, a module internal read buffer holds the block read last. An access to an address within this block does not trigger a new reading from the memory field but is directly served from the read buffer.

To reduce system performance penalties due to the waitstates, a special local in-module prefetch unit is implemented.

12.3.2.5 Memory Write

Data is not written to the memory array directly, but to the assembly buffer and then copied into the cell array by the write sequence.

Memory writes are handled through the BootROM software, which at first copies the existing content of a page to the assembly buffer, allows the user to modify the content of the assembly buffer and afterwards executes the programming of the data to the memory field followed by a verification step.

12.3.2.6 Timing

The target timing of the hardware sequences excluding the software overhead is shown below:

- Erase: 4.0 ms per page
- Write: 3.0 ms per page
- Program (= Erase+ Write): 7.0 ms per page

The disturb handling routine when enabled with a probability of a approximately 0.1% adds additional 7.0 ms to a page write or program operation.

12.3.2.7 Verify

The data programmed by the BootROM function is verified by the BootROM routine itself. The programmed data in the cell array is compared with the data still available in the assembly buffer. This is done using suitable hard-read levels. These hard-read levels provide a margin compared to the normal read level to ensure that the data is actually programmed with suitably distinct levels for written and erased bits.

12.3.2.8 Tearing-Safe programming

The mapping mechanism of the NVM module is used like a log-structured file system: When a page is programmed in the sector the old values are not physically overwritten, but a different physical page (spare page) is programmed in the same sector in fact. If the programming fails (e.g. because of power loss during the erase or write procedure), the old values are still present in the sector. The BootROM routines therefore can program a single page in a tearing-safe way.

When an erase or write procedure to the memory field was interrupted by a power-down, this is identified during the reconstruction of the map-RAM content after the next reset. In this case, a special routine in the BootROM (called Service Algorithm) is automatically started, identifies this tearing case of respective logical page and repairs the NVM state, ensuring that either the old or the new data (or both) are fully valid.

12.3.2.9 Disturb handling

Due to the implementation of the cell array, while writing a page into the cell array all other pages within the same sector are slightly written (disturbed) too. If some pages of a sector are changed often and other pages of the same sector only rarely, these rarely programmed pages may be disturbed too often and loose their data.

If the disturbs for a page exceed a specific value (this happens only when a different page in the same sector is programmed), the page has to be reprogrammed (refreshed). A dedicate option of the programming routines provided with the BootROM make sure that the pages are refreshed in time.

As mentioned, the refreshing of a page - when actually triggered - will double the overall programming time.

12.3.2.10 ECC and EDC

The NVM module provides all needed logic for proper error correction and detection logic. Since the block is the smallest data portion used for accessing the array in read and write, the ECC and EDC are performed at block level. Requirement is to provide a single bit ECC and 2 bits EDC per block, that is 1 bit correction over 64 data bits.

Since the ECC protects 64bits, when a byte is written to the assembly buffer automatically an NVM internal read of the complete block is triggered, the byte and the ECC are updated and the complete block is written back to the assembly buffer.

12.3.2.11 Code and Data access through the AHB-Lite interface

The system provides access to the data stored in the NVM cell array through an AHB Lite interface. Whenever the core needs to fetch instructions or read data from or write data into the NVM module, a proper AHB Lite compliant access request is forwarded by the bus matrix block into the module.

12.3.2.12 Prefetch Unit

At typical system working frequency, each NVM read access into the array takes 3 system clock cycles to move into the read buffer a complete block (containing 64 data bits). Since the on-chip micro (Cortex M3) is 32-bit microprocessor with an instruction set made of 16-bit and 32 bit opcodes, the amount of data read in 1 array access contains from a minimum of 2 to a max of 4 instructions. For this reason, in case of 32-bit instructions sequential code execution, 3 waitstates every 2 executed instructions have to be added.

In order to reduce the performance penalties due to the access time of the NVM, an internal prefetch logic is implemented. The idea is to use a prefetch unit that, assuming a sequential code execution, starts reading in a second read buffer the next 64 data bits while the system is still moving out the previously accessed data.

The idea is to have two read buffers that work interleaved: while the first read buffer is used as source of data for the AHB-Lite buffer interface, the second one is starting in parallel a new cell memory array access, assuming that data will be required in sequential order. When all the data from the first read buffer have been moved out of the memory module and the second one has completed the array access, then this last one will start providing data on the external bus while the first one will start prefetching next data from the array.

In case, a new non-sequential access request comes while both read buffers are filled with data not yet required by the core, the read buffer which was latest filled will be made available, flushing its content, to serve as soon as possible the non-sequential access request.

12.4 BootROM Module

The TLE9869QXA20 BootROM module provides physical implementation of the memory module as well as needed complementary features and interface towards the core.

The module provides proper access through a 32-bit AHB-Lite data interface multiplexed on M3 ICode and Dcode for code/data access.

The BootROM module in TLE9869QXA20 has a capacity of 24 Kbyte, organized with words of 32 bits.

The BootROM contents consists basically of three parts, used for:

- startup and boot SW
- Boot Strap Loader routines
- User routines

12.4.1 BootROM addressing

The BootROM, as visible from the memory map, is mapped starting at the address range 00000000_H - 00007FFF_H. After any reset, the device hardware-controlled start address is 00000000_H. At this location, the first instruction of the startup procedure is stored.

12.4.2 BootROM firmware program structure

The BootROM firmware provides basic functionality required to be executed after reset and routines for specific operation, such as:

- Startup routines, which is the main control firmware in the BootROM executed after every reset. This routine checks which kind of reset was issued and accordingly performs different kinds of operation to properly configure the device.
- Bootstrap loader, which provides basic functionality for code and data upload via LIN or UART into the RAM or NVM module.
- User routines, which provide functions for proper NVM operation handling and other useful ready-to-use routines designed for the customer.

For a complete description of the BootROM code, please refer to the BootROM Manual

12.5 RAM Module

The TLE9869QXA20 RAM module provides physical implementation of the memory module as well as needed complementary features and interface towards the core.

The module provides proper access through a 32-bit AHB-Lite data interface multiplexed on M3 ICode and Dcode for code/data access.

The RAM module in TLE9869QXA20 has a capacity of 6 Kbyte, organized with words of 32 bits.

The module supports 1 bit Error correction and 2 bits error detection per 32-bit word (actually requiring 7 bits parity per word). When an ECC error occurs, the corresponding status flag in the register EDCSTAT will be set. A double bit error can be configured via the interrupt enable bit in register EDCCON to trigger an exception.

12.5.1 RAM addressing

The RAM, as visible from the memory map, is mapped at the address range 1800000000H - 18000FFFFH. The module is mapped in the code area of the M3 map regions and can be used as program memory for code fetching as well as data storing.

12.6 Memory protection Unit (MPU)

The target of the memory protection scheme is to prevent unauthorized read out of critical data and user IPs from the BootROM and NVM. Two memory protection schemes are offered in the TLE9869QXA20.

The first memory protection scheme involves the blocking of all external access to the device by firmware. Firmware will block all the boot options such that it is not possible to load and execute any external code. To enable this protection scheme a valid password must be programmed via the BootROM password routine.

The second memory protection scheme is hardware based; instructions accessing memories executed from the unsafe memory address (e.g. RAM) that target the BootROM or NVM are blocked when the respective protection mode is enabled.

13 Interrupt System

13.1 Features

- Up to 16 interrupt nodes for on-chip peripherals
- Up to 8 nmi nodes for critical system events
- Maximum flexibility for all 16 interrupt nodes

13.2 Introduction

13.2.1 Overview

The TLE9869QXA20 supports 16 interrupt vectors with 16 priority levels. Fourteen of these interrupt vectors are assigned to the on-chip peripherals: GPT12, SSC, CCU6, DMA, Bridge Driver and A/D Converter are each assigned to one dedicated interrupt vector; while UART1 and Timer2 or UART2, External Interrupt 2 and Timer21 share interrupt vectors. Two vectors are dedicated for External Interrupt 0 and 1.

A non-maskable interrupt (NMI) with the highest priority is shared by the following:

- Watchdog Timer, warning before overflow
- MI_CLK Watchdog Timer overflow event
- PLL, loss of lock
- Flash, on operation complete e.g. erase.
- Oscillator watchdog detection for too low oscillation of f_{osc}
- Flash map error
- Uncorrectable ECC error on Flash and RAM
- VSUP supply prewarning when any supply voltage drops below or exceeds any threshold.
- Overtemperature prewarning when system temperature exceeds a certain limit.

Figure 58, **Figure 61**, **Figure 62**, **Figure 63** and **Figure 63** give a general overview of the interrupt sources and nodes, and their corresponding control and status flags. **Figure 69** gives the corresponding overview for the NMI sources. The table below shows the available interrupt vectors.

Table 64 Interrupt Vector Table

Service Request	Node ID	Description
GPT12	0/1	GPT interrupt (T2-T6, CAPIN)
MU- ADC8/T3	2	Measurement Unit, VBG, Timer3
ADC1	3	ADC1 interrupt / VREF5V Overload / VREF5V OV/UV, 10-bit ADC
CCU0	4	CCU6 node 0 interrupt
CCU1	5	CCU6 node 1 interrupt
CCU2	6	CCU6 node 2 interrupt
CCU3	7	CCU6 node 3 interrupt
SSC1	8	SSC1 interrupt (receive, transmit, error)
SSC2	9	SSC2 interrupt (receive, transmit, error)
UART1	10	UART1 (ASC-LIN) interrupt (receive, transmit), Timer2, linsync1, LIN
UART2	11	UART2 interrupt (receive, transmit), Timer21, External interrupt (EINT2)
EXINT0	12	External interrupt (EINT0), wakeup
EXINT1	13	External interrupt (EINT1)
BDRV/CP	14	Bridge Driver / Charge Pump
DMA	15	DMA Controller

Table 65 NMI Interrupt Table

Service Request	Node	Description
Watchdog Timer NMI	NMI	Watchdog Timer overflow
PLL NMI	NMI	PLL Loss-of-Lock
NVM Operation Complete NMI	NMI	NVM Operation Complete
Overtemperature NMI	NMI	System Overtemperature
Oscillator Watchdog NMI	NMI	Oscillator Watchdog / MI_CLK Watchdog Timer Overflow
NVM Map Error NMI	NMI	NVM Map Error
ECC Error NMI	NMI	RAM / NVM Uncorrectable ECC Error
Suppl Prewarning NMI	NMI	Supply Prewarning

1) Each CCU6 interrupt can be assigned to any of the CCU6 interrupt nodes [3:0] via CCU6 registers INPL/INPH.

13.3.2 Interrupt Structure

An interrupt event source may be generated from the on-chip peripherals or from external. Detection of interrupt events is controlled by the respective on-chip peripherals. Interrupt status flags are available for determining which interrupt event has occurred, especially useful for an interrupt node which is shared by several event sources. Each interrupt node (except NMI) has a global enable/disable bit. In most cases, additional enable bits are provided for enabling/disabling particular interrupt events (provided for NMI events). No interrupt will be requested for any occurred event that has its interrupt enable bit disabled.

There is an interrupt masking bit EA available, which is used to globally enable or disable all interrupt requests (except NMI) to the core. Resetting bit EA to 0 only masks the pending interrupt requests from the core, but does not block the capture of incoming interrupt requests.

13.3.2.1 Interrupt Structure 1

For interrupt structure 1 (see [Figure 70](#)), the interrupt event will set the interrupt status flag which doubles as a pending interrupt request to the core. An active pending interrupt request will interrupt the core only if its corresponding interrupt node is enabled. Once an interrupt node is serviced (interrupt acknowledged), its pending interrupt request (represented by the interrupt status flag) may be automatically cleared by hardware (the core).

Figure 70 Interrupt Structure 1

For the TLE9869QXA20, interrupt sources like ADC10, MU and Bridge Driver (each have a dedicated interrupt node) will have their respective interrupt status flags in the dedicated registers. These flags are not cleared by the core once their corresponding pending interrupt request is serviced. They have to be cleared by software. For the UART which has its dedicated interrupt node, interrupt status flags RI and TI in register SCON will not be cleared by the core even when its pending interrupt request is serviced. The UART interrupt status flags (and hence the pending interrupt request) can only be cleared by software.

Note: The supply prewarning NMI, prewarning overtemperature & MI_CLK WDT NMI events are of interrupt structure 1. However, only the supply prewarning NMI request source is of interrupt structure 1.

13.3.3 Interrupt Source and Vector

Each interrupt event source has an associated interrupt vector address for the interrupt node it belongs to. This vector is accessed to service the corresponding interrupt node request. The interrupt service of each interrupt node can be individually enabled or disabled via an enable bit. The assignment of the TLE9869QXA20 interrupt sources to the interrupt vector address and the corresponding interrupt node enable bits are summarized in [Table 64](#).

Interrupt System

Table 67 Interrupt Vector Address

Interrupt Node	Vector Address	Assignment for TLE9869QXA20	Enable Bit	SFR

13.3.4 Interrupt Priority

An interrupt that is currently being serviced can only be interrupted by a higher-priority interrupt, but not by another interrupt of the same or lower priority. Hence, an interrupt of the highest priority cannot be interrupted by any other interrupt request.

If two or more requests of different priority levels are received simultaneously, the request with the highest priority is serviced first. If requests of the same priority are received simultaneously, an internal polling sequence determines which request is serviced first. Thus, within each priority level, there is a second priority structure determined by the polling sequence as shown in [Table 66](#).

Table 68 Interrupt Node Table

Service Request	Node ID	Description
GPT1	0	GPT1 interrupt (T2-T4)
GPT2	1	GPT2 interrupt (T5-T6, CR)
MU- adc8/t3	2	Measurement Unit, VBG, Timer3
adc10	3	ADC10 interrupt / VREF5V Overload / VREF5V OV/UV
CCU0	4	CCU6 node 0 interrupt
CCU1	5	CCU6 node 1 interrupt
CCU2	6	CCU6 node 2 interrupt
CCU3	7	CCU6 node 3 interrupt
ssc1	8	SSC1 interrupt (receive, transmit, error)
ssc2	9	SSC2 interrupt (receive, transmit, error)
uart1	10	UART1 (ASC-LIN) interrupt (receive, transmit), Timer2, linsync1, LIN
uart2	11	UART2 interrupt (receive, transmit), Timer21, linsync2, External interrupt (EINT2)
exint0	12	External interrupt (EINT0), wakeup
exint1	13	External interrupt (EINT1)
BDRV/CP	14	Bridge Driver / Charge Pump
DMA	15	DMA Controller

The interrupt priority is configured in the corresponding NVIC control register:

Table 69

Register Short name	Register Long Name	Offset Address	Reset Value
NVIC_IPR0	Interrupt Priority	400 _H	0000 0000 _H
NVIC_IPR1	Interrupt Priority	404 _H	0000 0000 _H
NVIC_IPR2	Interrupt Priority	408 _H	0000 0000 _H
NVIC_IPR3	Interrupt Priority	40C _H	0000 0000 _H

For further description see ARM_Architecture_v7n_Reference_Manual.

13.4 Interrupt Handling

See also ARM_Architecture_v7n_Reference_Manual. The most important Interrupt Registers are listed below. This registers are dedicated to the 16 available interrupt nodes. For all nodes which are a combination of several interrupt requests, the corresponding control and status registers are located in the System Control Unit (SCU) or the System Control Unit for the Power Modules (SCU_PM).

Table 70

Register Short name	Register Long Name	Offset Address	Reset Value
NVIC_ISER0	Interrupt Set-Enable	100 _H	0000 0000 _H
NVIC_ICER0	Interrupt Clear-Enable	180 _H	0000 0000 _H
NVIC_ISPR0	Interrupt Set-Pending	200 _H	0000 0000 _H
NVIC_ICPR0	Interrupt Clear-Pending	280 _H	0000 0000 _H
NVIC_IABR0	Active Bit Register	300 _H	0000 0000 _H

13.5 Register Definition

Interrupt registers are used for interrupt node enable, external interrupt control, interrupt flags and interrupt priority setting.

Table 71 Registers Address Space Interrupt Registers

Module	Base Address	End Address	Note
SCU	50005000 _H	50005FFF _H	

13.5.1 Interrupt Node Enable Registers

Register IEN0 contains the global interrupt masking bit (EA), which can be cleared to block all pending interrupt requests at once.

The NMI interrupt vector is shared by a number of sources, each of which can be enabled or disabled individually via register NMICON.

This register IEN0 is reset by RESET_TYPE_4.

13.5.2 External Interrupt Control Registers

The external interrupts, EXT_INT[2:0], are driven into the XC8_EPOWER from the ports. External interrupts can be positive, negative or double edge triggered. Register EXICON0 specifies the active edge for the external interrupt. Among the external interrupts, external interrupt 0 and external interrupt 1 can be selected to bypass edge detection in the SCU, for direct feed-through to the core. This signal to the core can be further programmed to either low-level or negative transition activated, by the bits IT0 and IT1 in the TCON register. However for edge detection in SCU, TCON.IT0/1 must be set to falling edge triggered. An active edge event detected in SCU will generate internally two CCLK cycle low pulse for detection by core.

If the external interrupt is positive (negative) edge triggered, the external source must hold the request pin low (high) for at least one CCLK cycle, and then hold it high (low) for at least one CCLK cycle to ensure that the transition is recognized. If edge detection is bypassed for external interrupt 0 and external interrupt 1, the external source must hold the request pin "high" or "low" for at least two CCLK cycles.

External interrupts 2 share their interrupt node with other interrupt sources. Therefore in addition to the corresponding interrupt node enable, external interrupt 2 may be disabled individually, and are disabled by default after reset.

Note: Several external interrupts support alternative input pin, selected via MODPSEL register in the SCU. When switching inputs, the active edge/level trigger select and the level on the associated pins should be considered to prevent unintentional interrupt generation.

EXINT0	1:0	rw	External Interrupt 0 Trigger Select 00 _B external interrupt 0 is disabled. 01 _B Interrupt on rising edge. 10 _B Interrupt on falling edge. 11 _B Interrupt on both rising and falling edge.

13.5.3 Interrupt Flag Registers

The interrupt flags for the different interrupt sources are located in several special function registers. This section describes the interrupt flags located in system registers or external interrupts belonging to system. Other interrupt flags located in respective module registers are described in the specific module chapter.

In case of software and hardware access to a flag bit at the same time, hardware will have higher priority.

13.6 Interrupt Priority Registers

Each interrupt node can be individually programmed to one of the 16 priority levels available. The user can set them in the corresponding **NVIC_IPRx** Register (see Core Chapter).

14 Watchdog Timer (WDT1)

14.1 Features

There are two watchdog timers in the system. The Watchdog Timer (WDT) within the System Control Unit - Digital Modules (see SCU_DM) and the Watchdog Timer (WDT1) which is located within the System Control Unit - Power Modules (see SCU_PM). The Watchdog Timer WDT1 is described in this section.

In Active Mode, the WDT1 acts as a windowed watchdog timer, which provides a highly reliable and safe way to recover from software or hardware failures.

The WDT1 is always enabled in Active Mode. In Sleep Mode, Low Power Mode and SWD Mode the WDT1 is automatically disabled.

Functional Features

- Windowed Watchdog Timer with programmable timing in Active Mode
- Long open window (typ. 80ms) after power-up, reset, wake-up
- Short open window (typ. 30ms) to facilitate Flash programming
- Disabled during debugging
- Safety shutdown to Sleep Mode after 5 missed WDT1 services

14.2 Introduction

The behavior of the Watchdog Timer in Active Mode is depicted in [Figure 71](#).

Figure 71 Watchdog Timer Behavior

14.3 Functional Description

14.3.1 Modes of Operation

The mode transition from the low power modes (WDT1 off) to active (WDT1 on) automatically initializes WDT1 to start in long open window mode.

14.3.2 Normal Operation

Software has to trigger the watchdog by writing to the **WDT1_TRIG** register. By triggering the watchdog also the length of the next watchdog period is selected inherently. The next period starts immediately with the trigger.

After Reset the WDT1 is starting with a long open window. The WDT1 has to be triggered within this long open window, otherwise a reset will be generated at the end of the long open window. After this first trigger the WDT1 operates in a window watchdog mode. Triggering of a short open window during the long open window is not allowed and will also cause a WDT1 reset.

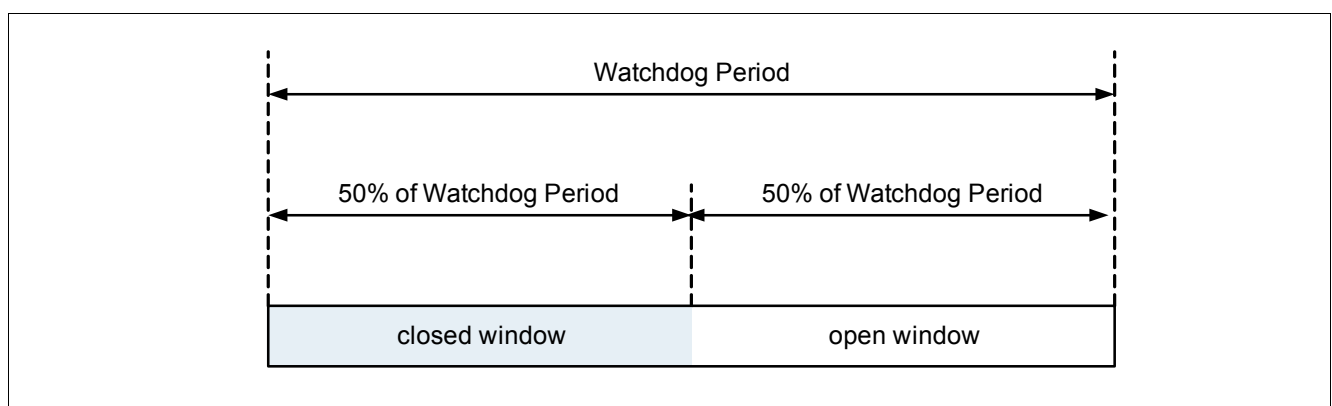

Figure 72 Windowed Watchdog

The first half of the watchdog period is the closed window and the second half is the open window. A trigger of the watchdog has to be done in the open window only. Any trigger in the closed window or failing to trigger the watchdog within the watchdog period will cause a reset. The reset will be indicated by the bit **PMU_ExtWDT** inside **PMU_RESET_STS1** register located inside PMU.

Effective open window (safe trigger point)

Due to the variations in the clock source of the WDT1 the effective usable open window, and therefore a safe trigger point, is shorter than 50% of the watchdog period as shown in **Figure 73**.

Figure 73 Effective open window

E.g. for a variation of 20% and a nominal watchdog period of T_{WD} the start of the effective open window T_{OWmin} is shifted back by 10%, and the end of the effective open window T_{OWmax} is shifted forward by 20%.

Short open window

Under certain programming conditions, e.g. NVM programming, it might be desired to interrupt the normal windowed watchdog operation. For this purpose a special trigger of a short open window (see [Figure 74](#)) allows to discard the current window period (also within the closed window) and immediately starts a short open window. The short open window has a fixed length of T_{SOW} (typ. 30 ms) independent of the settings of the WDP_SEL bits.

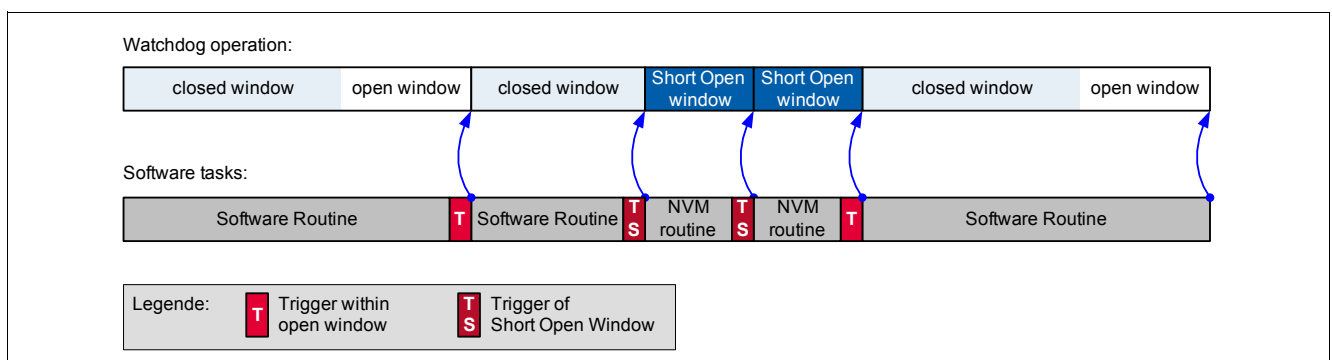

Figure 74 Short Open Window

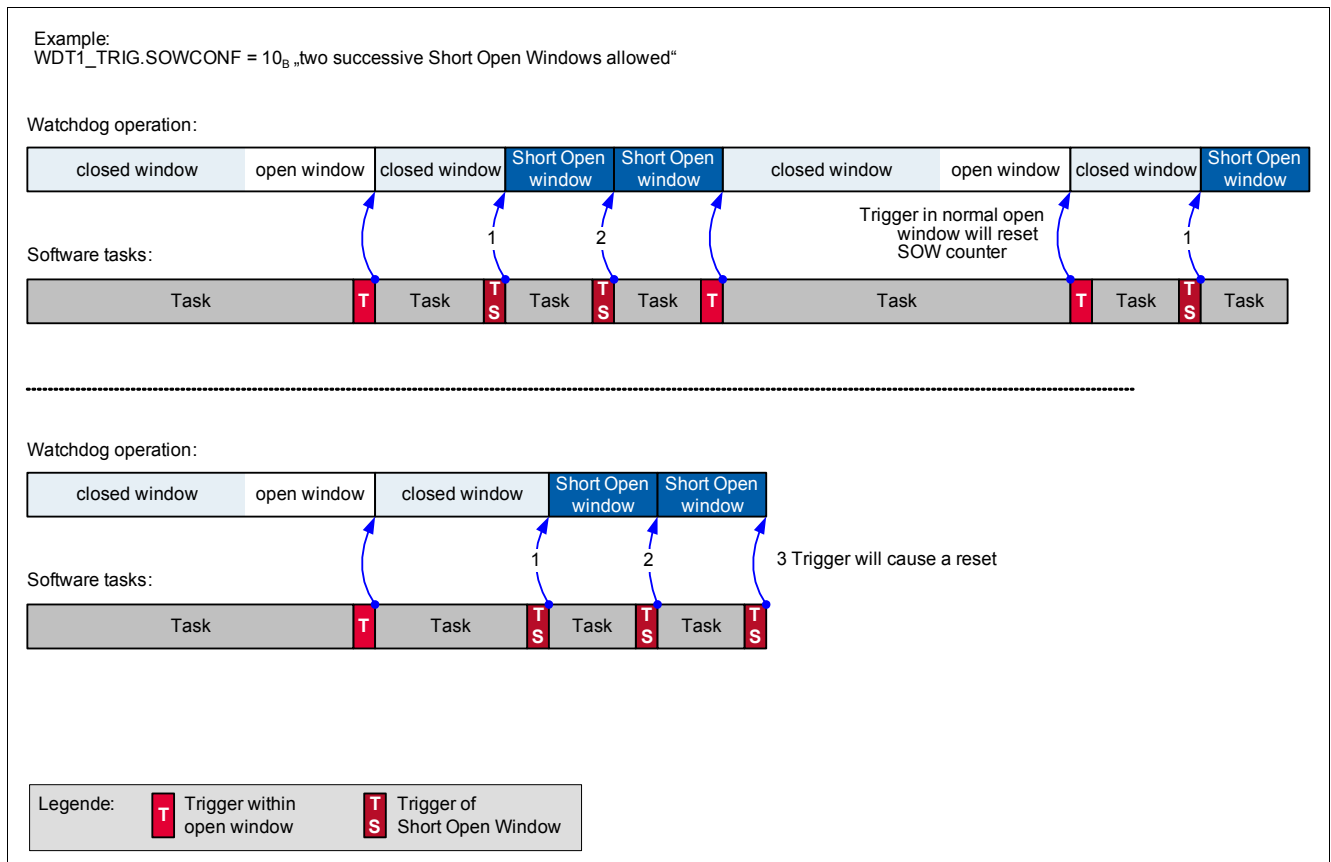

Figure 75 SOW Counter

The mechanism of inserting Short Open Windows has to be enabled/configured with the bits SOWCONF. The configuration allows to insert a maximum of three consecutive Short Open Windows. Each trigger of the Short Open Window will increase a SOW counter, if the SOW counter exceeds the maximum configured value a reset will be generated. The SOW counter value is reset to 0 by a normal trigger.

14.4 Register Definition

[Table 72](#) shows the module base addresses.

15 GPIO Ports and Peripheral I/O

This chapter describes the GPIO Ports of the TLE9869QXA20. It contains the following sections:

- Functional description of the GPIO Ports (see [Section 15.2](#))
- GPIO Port register descriptions (see [Section 15.3](#))
- TLE9869QXA20 implementation specific details and registers of the GPIO module (see [Section 15.4](#))

The TLE9869QXA20 has 15 port pins organized into three parallel ports: Port 0 (P0), Port 1 (P1) and Port 2 (P2). Each port pin has a pair of internal pull-up and pull-down devices that can be individually enabled or disabled. P0 and P1 are bidirectional and can be used as general purpose input/output (GPIO) or to perform alternate input/output functions for the on-chip peripherals. When configured as an output, the open drain mode can be selected. On Port 2 (P2) analog inputs are shared with general purpose input.

15.1 Features

Bidirectional Port Features (P0, P1)

- Configurable pin direction
- Configurable pull-up/pull-down devices
- Configurable open drain mode
- Configurable drive strength
- Transfer of data through digital inputs and outputs (general purpose I/O)
- Alternate input/output for on-chip peripherals

Analog Port Features (P2)

- Configurable pull-up/pull-down devices
- Transfer of data through digital inputs
- Alternate inputs for on-chip peripherals

15.2 Introduction

15.2.1 Port 0 and Port 1

Figure 76 shows the block diagram of an TLE9869QXA20 bidirectional port pin. Each port pin is equipped with a number of control and data bits, thus enabling very flexible usage of the pin. By defining the contents of the control register, each individual pin can be configured as an input or an output. The user can also configure each pin as an open drain pin with or without internal pull-up/pull-down device.

Each bidirectional port pin can be configured for input or output operation. Switching between input and output mode is accomplished through the register Px_DIR (x = 0 or 1), which enables or disables the output and input drivers. A port pin can only be configured as either input or output mode at any one time.

In input mode (default after reset), the output driver is switched off (high-impedance). The actual voltage level present at the port pin is translated into a logic 0 or 1 via a Schmitt-Trigger device and can be read via the register Px_DATA.

In output mode, the output driver is activated and drives the value supplied through the multiplexer to the port pin. In the output driver, each port line can be switched to open drain mode or normal mode (push-pull mode) via the register Px_OD.

The output multiplexer in front of the output driver enables the port output function to be used for different purposes. If the pin is used for general purpose output, the multiplexer is switched by software to the data register

Px_DATA. Software can set or clear the bit in Px_DATA and therefore directly influence the state of the port pin. If an on-chip peripheral uses the pin for output signals, alternate output lines (AltDataOut) can be switched via the multiplexer to the output driver circuitry. Selection of the alternate output function is defined in registers Px_ALTSEL0 and Px_ALTSEL1. When a port pin is used as an alternate function, its direction must be set accordingly in the register Px_DIR.

Each pin can also be programmed to activate an internal weak pull-up or pull-down device. Register Px_PUDSEL selects whether a pull-up or the pull-down device is activated while register Px_PUDEN enables or disables the pull device.

The port structure used in this device offers the possibility to select the output driver strength and the slew rate. These selections are independent from the output port functionality, such as open-drain, push/pull or input only. The driver strength for each pin can be adapted to the application requirements by registers Px_POCONy (y = 0, 1 or 2) in SCU.

The temperature compensation signals TC[1:0] of all output drivers are connected to all outputs and are controlled by register TCCR in SCU.

Note: For the definition of Px_POCONy and TCCR registers, refer to [Chapter 7.7.2](#) of SCU chapter.

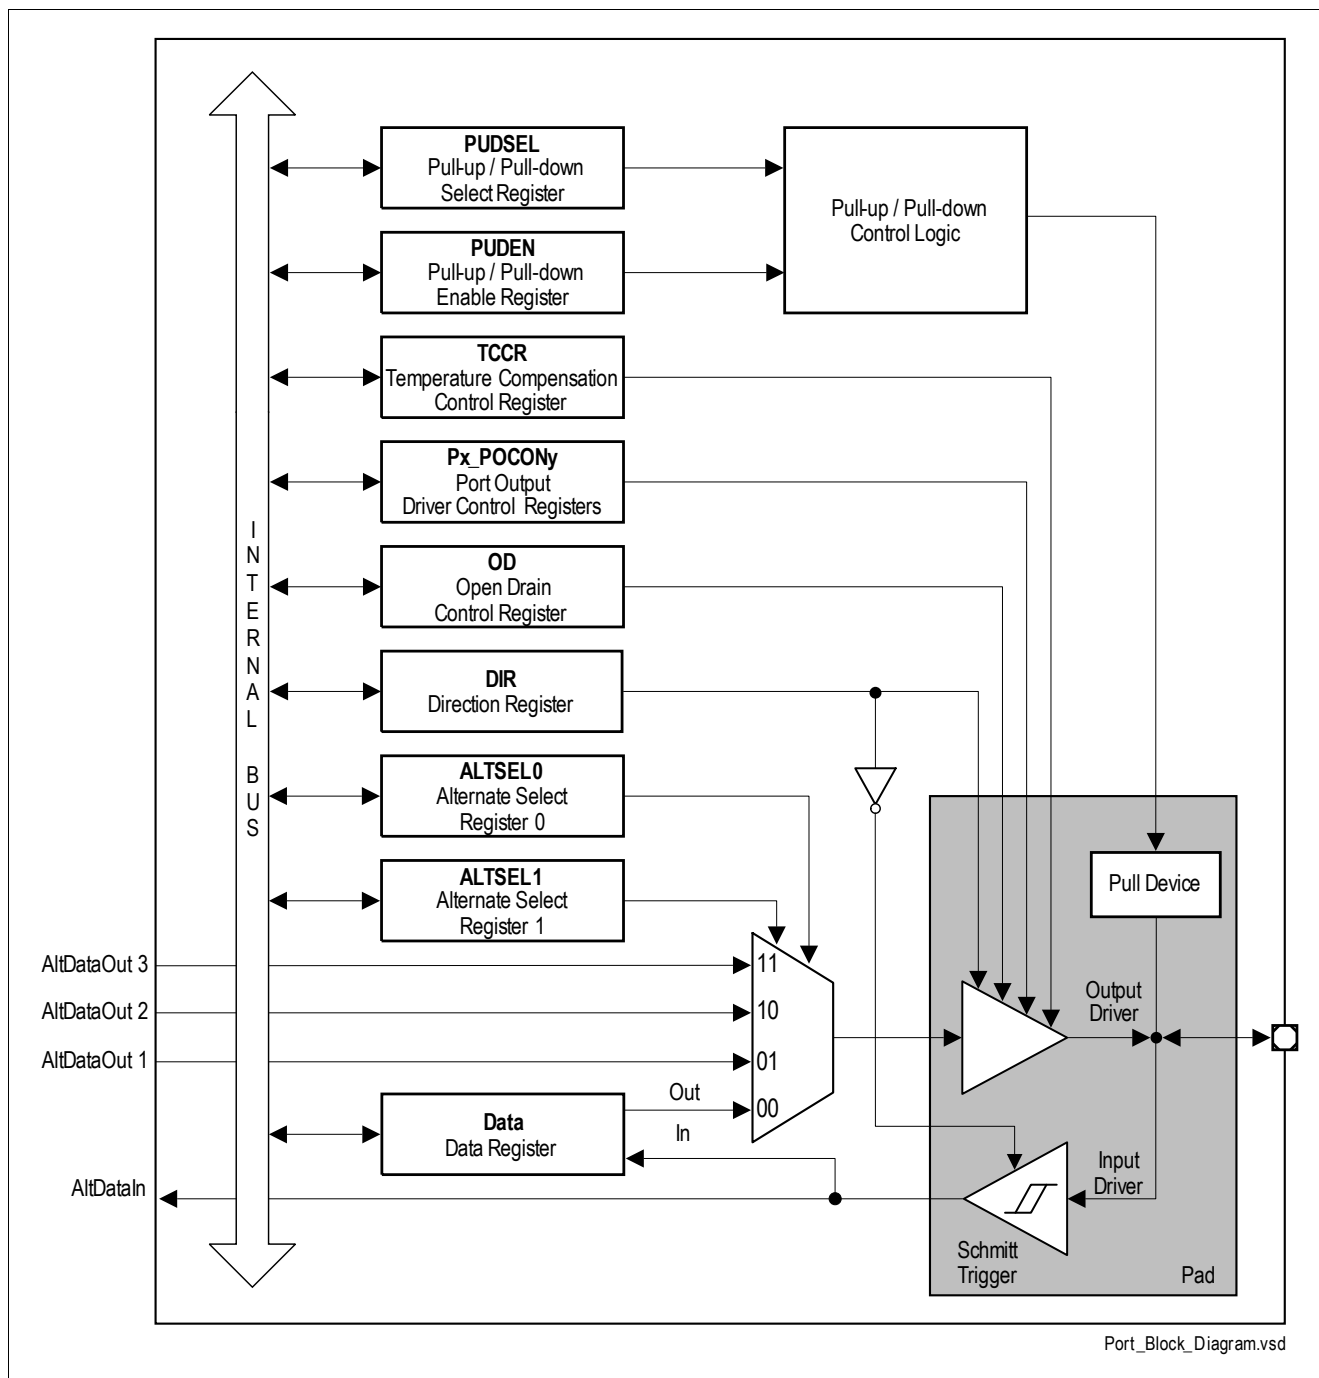

Figure 76 General Structure of Bidirectional Port (P0, P1)

15.2.2 Port 2

Figure 77 shows the structure of an input-only port pin. Each P2 pin can only function in input mode. Register P2_DIR is provided to enable or disable the input driver. When the input driver is enabled, the actual voltage level present at the port pin is translated into a logic 0 or 1 via a Schmitt-Trigger device and can be read via register P2_DATA. Each pin can also be programmed to activate an internal weak pull-up or pull-down device. Register P2_PUDSEL selects whether a pull-up or the pull-down device is activated while register P2_PUDEN enables or disables the pull device. The analog input (AnalogIn) bypasses the digital circuitry and Schmitt-Trigger device for direct feed-through to the ADC input channels.

Figure 77 General Structure of Input Port (P2)

15.3 General Port Register Description

Each port consists of 8-bit control and data registers. The registers are defined in [Figure 78](#).

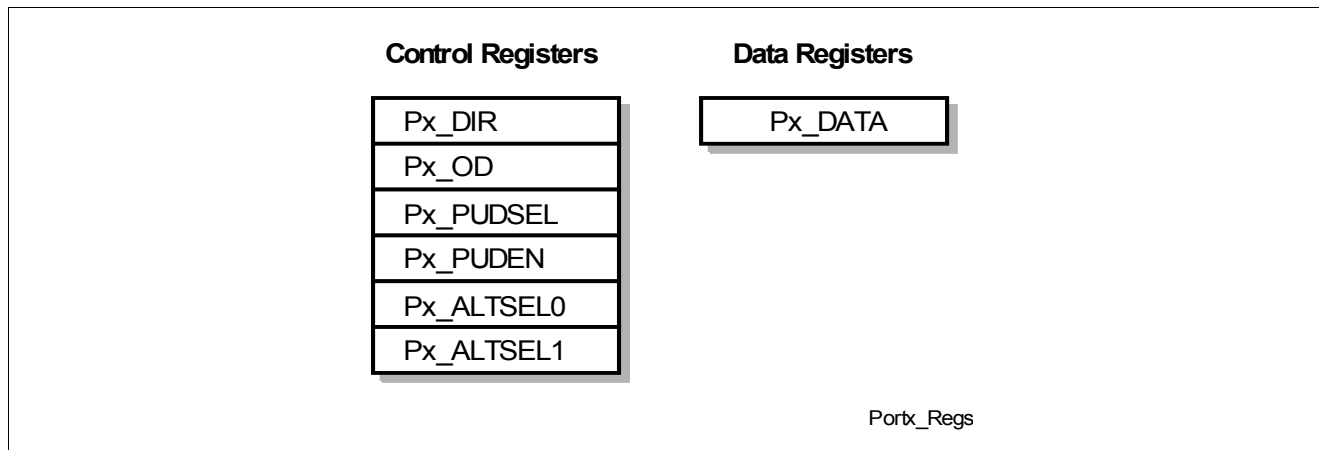

Figure 78 Port Registers

Table 74 Port Registers

Register Short Name	Register Long Name	Description
Px_DATA	Port x Data Register	376
Px_DIR	Port x Direction Register	376
Px_OD	Port x Open Drain Control Register	377
Px_PUDSEL	Port x Pull-Up/Pull-Down Select Register	377
Px_PUDEN	Port x Pull-Up/Pull-Down Enable Register	377
Px_ALTSEL0	Port x Alternate Select Register 0	379
Px_ALTSEL1	Port x Alternate Select Register 1	379

Note: Not all the registers are implemented for each port.

15.3.1 Port Data Register

If a port pin is used as general purpose output, output data is written into register Px_DATA of port x. When the port pin is used as general purpose input, the value at a port pin can be read through the register Px_DATA. The data register Px_DATA always contains a latched value of the assigned port pin.

Px_DATA

Port x Data Register

Reset Value: H

7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0
rwh	rwh	rwh	rwh	rwh	rwh	rwh	rwh

Field	Bits	Type	Description
Pn (n = 0 - 7)	n	rwh	Portx Pin n Data Value 0 Port x pin n data value = 0 1 Port x pin n data value = 1

Bit Px_DATA.n can only be written if the corresponding pin is set to output, i.e. Px_DIR.n = 1. The contents of Px_DATA.n are output on the assigned pin if the pin is assigned as GPIO pin and the direction is switched/set to output. A read operation of Px_DATA returns the register value and not the state of the Px_DATA pins.

15.3.2 Direction Register

The direction of bidirectional port pins is controlled by the respective direction register Px_DIR. For input-only port pins, register Px_DIR is used to enable or disable the input drivers.

Px_DIR

Port x Direction Register

Reset Value: H

7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0
rw	rw	rw	rw	rw	rw	rw	rw

Field	Bits	Type	Description
Pn (n = 0 - 7)	n	rw	Bidirectional: Port x Pin n Direction Control 0 Direction is set to input (default) 1 Direction is set to output or Input-only: Port x Pin n Driver Control 0 Input driver is enabled (default) 1 Input driver is disabled

15.3.3 Open Drain Control Register

Each pin in output mode can be switched to Open Drain Mode. If driven with 1, no driver will be activated and the pin output state depends on the internal pull-up/pull-down device setting; if driven with 0, the driver's pull-down transistor will be activated.

The open drain mode is controlled by the register Px_OD.

Px_OD

Port x Open Drain Control Register

Reset Value: \bar{H}

7	6	5	4	3	2	1	0
P7	P6	P5	P4	P3	P2	P1	P0

Py (y = 0 - 7)	n	rw	Port x Pin y Open Drain Mode 0 Normal Mode, output is actively driven for 0 and 1 state (default) 1 Open Drain Mode, output is actively driven only for 0 state

15.3.4 Pull-Up/Pull-Down Device Register

Internal pull-up/pull-down devices can be optionally applied to a port pin. This offers the possibility to configure the following input characteristics:

- tristate
- high-impedance with a weak pull-up device
- high-impedance with a weak pull-down device

and the following output characteristics:

- push/pull (optional pull-up/pull-down)
- open drain with internal pull-up
- open drain with external pull-up

The pull-up/pull-down device can be fixed or controlled via the registers Px_PUDSEL and Px_PUDEN. Register Px_PUDSEL selects the type of pull-up/pull-down device, while register Px_PUDEN enables or disables it. The pull-up/pull-down device can be selected pinwise.

Note: The selected pull-up/pull-down device is enabled by setting the respective bit in the Px_PUDEN register.

GPIO Ports and Peripheral I/O

15.3.4.1 Alternate Input Functions

The number of alternate functions that uses a pin for input is not limited. Each port control logic of an I/O pin provides several input paths:

- Digital input value via register
- Direct digital input value

15.3.5 Alternate Output Functions

Alternate functions are selected via an output multiplexer which can select up to four output lines. This multiplexer can be controlled by the following signals:

- Register Px_ALTSEL0
- Register Px_ALTSEL1

Selection of alternate functions is defined in registers Px_ALTSEL0 and Px_ALTSEL1.

Px_ALTSELy (y = 0, 1)

16 General Purpose Timer Units (GPT12)

16.1 Features

16.1.1 Features Block GPT1

The following list summarizes the supported features:

- $f_{\text{GPT}}/4$ maximum resolution
- 3 independent timers/counters
- Timers/counters can be concatenated
- 4 operating modes:
 - Timer Mode
 - Gated Timer Mode
 - Counter Mode
 - Incremental Interface Mode
- Reload and Capture functionality
- Shared interrupt: Node 0

16.1.2 Features Block GPT2

The following list summarizes the supported features:

- $f_{\text{GPT}}/2$ maximum resolution
- 2 independent timers/counters
- Timers/counters can be concatenated
- 3 operating modes:
 - Timer Mode
 - Gated Timer Mode
 - Counter Mode
- Extended capture/reload functions via 16-bit capture/reload register CAPREL
- Shared interrupt: Node 1

16.2 Introduction

The General Purpose Timer Unit blocks GPT1 and GPT2 have very flexible multifunctional timer structures which may be used for timing, event counting, pulse width measurement, pulse generation, frequency multiplication, and other purposes.

They incorporate five 16-bit timers that are grouped into the two timer blocks GPT1 and GPT2. Each timer in each block may operate independently in a number of different modes such as Gated timer or Counter Mode, or may be concatenated with another timer of the same block.

Each block has alternate input/output functions and specific interrupts associated with it. Input signals can be selected from several sources by register PISEL.

The GPT module is clocked with clock f_{GPT} . f_{GPT} is a clock derived from f_{SYS} .

16.2.1 Block Diagram GPT1

Block GPT1 contains three timers/counters: The core timer T3 and the two auxiliary timers T2 and T4. The maximum resolution is $f_{GPT}/4$. The auxiliary timers of GPT1 may optionally be configured as reload or capture registers for the core timer. These registers are listed in [Section 16.3.7.1](#).

Figure 82 GPT1 Block Diagram (n = 2 ... 5)

16.2.2 Block Diagram GPT2

Block GPT2 contains two timers/counters: The core timer T6 and the auxiliary timer T5. The maximum resolution is $f_{GPT}/2$. An additional Capture/Reload register (CAPREL) supports capture and reload operation with extended functionality. These registers are listed in [Section 16.4.8.1](#).

Figure 83 GPT2 Block Diagram

16.3 Timer Block GPT1

From a programmer's point of view, the GPT1 block is composed of a set of SFRs as summarized below. Those portions of port and direction registers which are used for alternate functions by the GPT1 block are shaded.

Data Registers	Control Registers	Interrupt Control	Miscellaneous
T2	T2CON	GPT12IRC	PISEL
T3	T3CON	GPT12IRCLR	ID
T4	T4CON		
	KSCCFG		
Tx	GPT1 Timer x Register	KSCCFG	Kernel State Configuration Register
TxCON	GPT1 Timer x Control Register	PISEL	Port Input Select Register
GPT12IRC	GPT12 Timer and Counter Ctrl . Status Register	ID	Module Identification Register
GPT12IRCLR	GPT12 Timer and Counter Ctrl . Status Clear Register		

mc_gpt1_registers.vsd

Figure 84 SFRs Associated with Timer Block GPT1

All three timers of block GPT1 (T2, T3, T4) can run in one of 4 basic modes: Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode. All timers can count up or down. Each timer of GPT1 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T3 is indicated by the Output Toggle Latch T3OTL, whose state may be output on the associated pin T3OUT (alternate pin function). The auxiliary timers T2 and T4 may additionally be concatenated with the core timer T3 (through T3OTL) or may be used as capture or reload registers for the core timer T3.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T2, T3, or T4, located in the non-bitaddressable SFR space (see [Section 16.3.7.1](#)). When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupts of GPT1 are controlled through the GPTM1IEN and GPTM1IRC. These registers are not part of the GPT1 block.

The input and output lines of GPT1 are connected to pins. The control registers for the port functions are located in the respective port modules.

Note: The timing requirements for external input signals can be found in [Section 16.3.5](#), [Section 16.7.1](#) summarizes the module interface signals, including pins.

16.3.1 GPT1 Core Timer T3 Control

The current contents of the core timer T3 are reflected by its count register T3. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T3 is configured and controlled via its control register T3CON.

Timer T3 Run Control

The core timer T3 can be started or stopped by software through bit T3R (Timer T3 Run Bit). This bit is relevant in all operating modes of T3. Setting bit T3R will start the timer, clearing bit T3R stops the timer.

In Gated Timer Mode, the timer will only run if T3R = 1 and the gate is active (high or low, as programmed).

Note: When bit T2RC or T4RC in timer control register T2CON or T4CON is set, bit T3R will also control (start and stop) the auxiliary timer(s) T2 and/or T4.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in [Table 91](#). The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timer T3 Output Toggle Latch

The overflow/underflow signal of timer T3 is connected to a block named 'Toggle Latch', shown in the Timer Mode diagrams. **Figure 85** illustrates the details of this block. An overflow or underflow of T3 will clock two latches: The first latch represents bit T3OTL in control register T3CON. The second latch is an internal latch toggled by T3OTL's output. Both latch outputs are connected to the input control blocks of the auxiliary timers T2 and T4. The output level of the shadow latch will match the output level of T3OTL, but is delayed by one clock cycle. When the T3OTL value changes, this will result in a temporarily different output level from T3OTL and the shadow latch, which can trigger the selected count event in T2 and/or T4.

When software writes to T3OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T3OE (overflow/underflow output enable) in register T3CON enables the state of T3OTL to be monitored via an external pin T3OUT. When T3OTL is linked to an external port pin (must be configured as output), T3OUT can be used to control external HW. If T3OE = 1, pin T3OUT outputs the state of T3OTL. If T3OE = 0, pin T3OUT outputs a high level (as long as the T3OUT alternate function is selected for the port pin).

The trigger signals can serve as an input for the counter function or as a trigger source for the reload function of the auxiliary timers T2 and T4.

As can be seen from **Figure 85**, when latch T3OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T2/T4 in this case.

Figure 85 Block Diagram of the Toggle Latch Logic of Core Timer T3 (x = 3)

16.3.2 GPT1 Core Timer T3 Operating Modes

Timer T3 can operate in one of several modes.

Timer T3 in Timer Mode

Timer mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 000_B. In Timer Mode, T3 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS1 and T3I in register T3CON. Please see [Section 16.3.5](#) for details on the input clock options.

Figure 86 Block Diagram of Core Timer T3 in Timer Mode

Timer T3 in Gated Timer Mode

Gated Timer Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 010_B or 011_B. Bit T3M.0 (T3CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see [Section 16.3.5](#)). However, the input clock to the timer in this mode is gated by the external input pin T3IN (Timer T3 External Input).

To enable this operation, the associated pin T3IN must be configured as input.

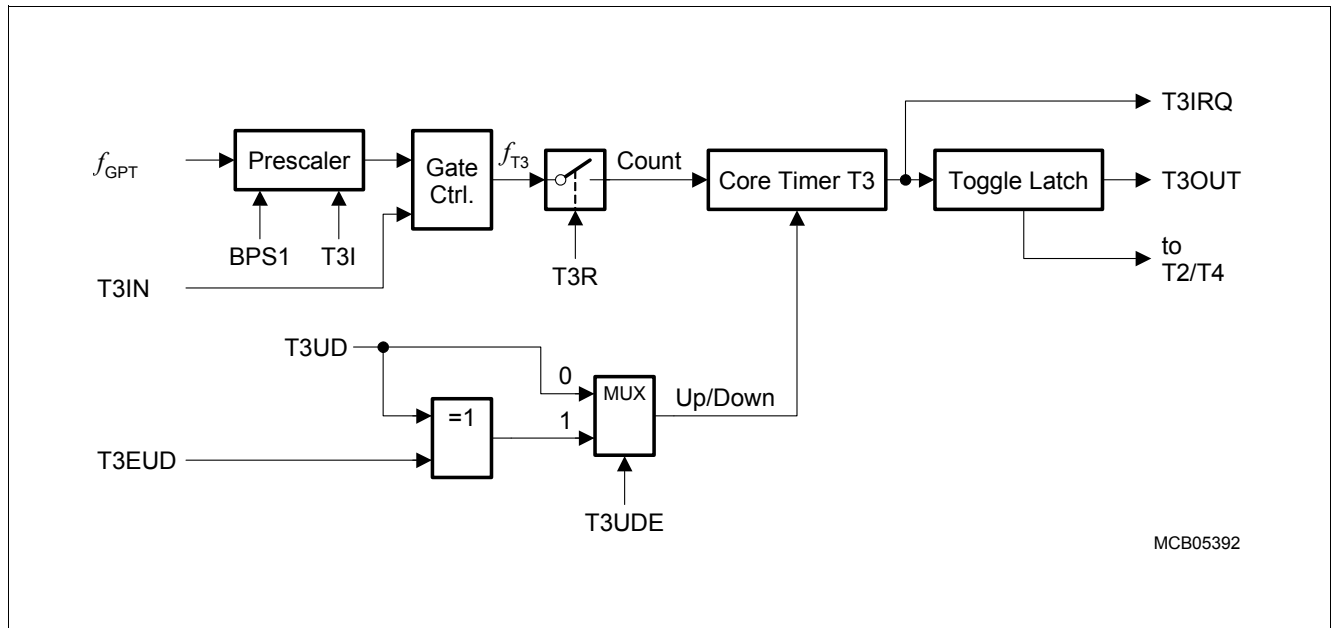

Figure 87 Block Diagram of Core Timer T3 in Gated Timer Mode

If T3M = 010_B, the timer is enabled when T3IN shows a low level. A high level at this line stops the timer. If T3M = 011_B, line T3IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T3R. The timer will only run if T3R is 1 and the gate is active. It will stop if either T3R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T3IN does not cause an interrupt request.

Timer T3 in Counter Mode

Counter Mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 001_B. In Counter Mode, timer T3 is clocked by a transition at the external input pin T3IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T3I in control register T3CON selects the triggering transition (see [Table 93](#)).

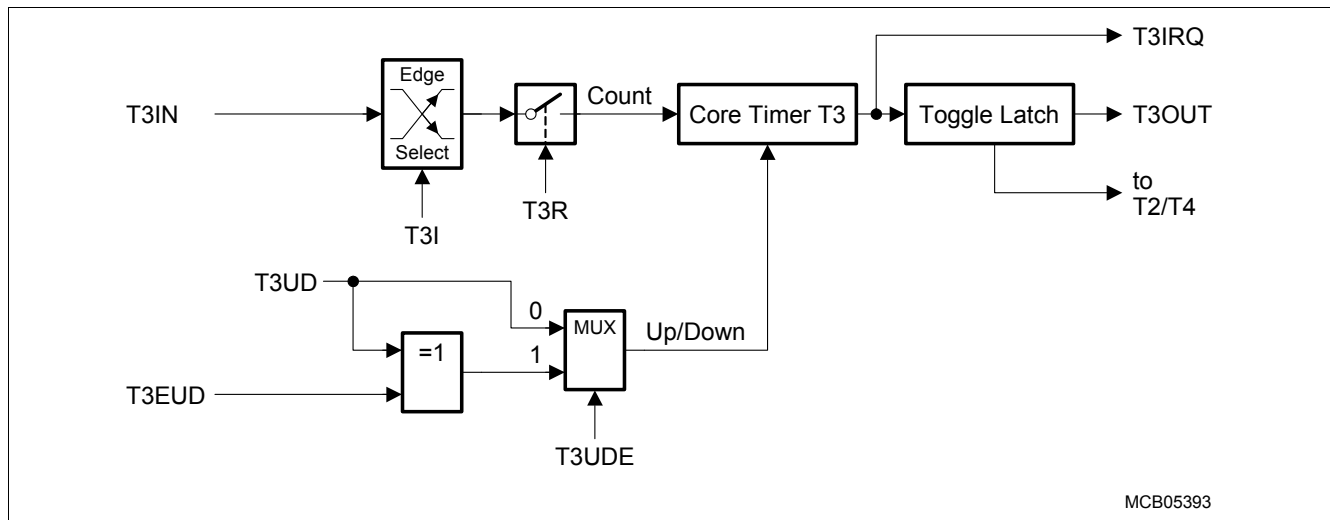

Figure 88 Block Diagram of Core Timer T3 in Counter Mode

For Counter Mode operation, pin T3IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T3IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 16.3.5](#).

Timer T3 in Incremental Interface Mode

Incremental interface mode for the core timer T3 is selected by setting bitfield T3M in register T3CON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with core timer T3 (T3IN, T3EUD) are used to interface to an incremental encoder. T3 is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

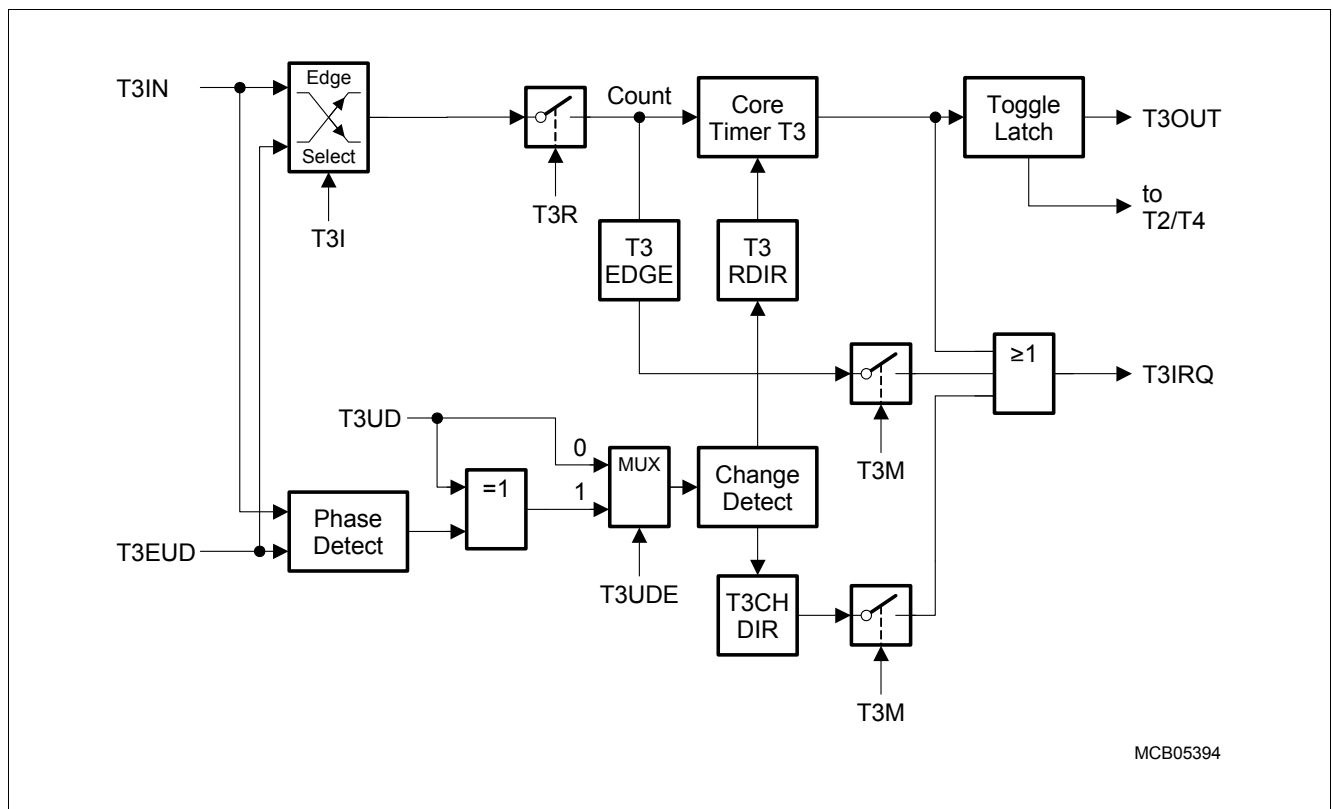

Figure 89 Block Diagram of Core Timer T3 in Incremental Interface Mode

Bitfield T3I in control register T3CON selects the triggering transitions (see [Table 95](#)). The sequence of the transitions of the two input signals is evaluated and generates count pulses as well as the direction signal. So T3 is modified automatically according to the speed and the direction of the incremental encoder and, therefore, its contents always represent the encoder's current position.

The interrupt request (T3IRQ) generation mode can be selected: In Rotation Detection Mode (T3M = 110_B), an interrupt request is generated each time the count direction of T3 changes. In Edge Detection Mode (T3M = 111_B), an interrupt request is generated each time a count edge for T3 is detected. Count direction, changes in the count direction, and count requests are monitored by status bits T3RDIR, T3CHDIR, and T3EDGE in register T3CON.

The incremental encoder can be connected directly to the TLE9869QXA20 without external interface logic. In a standard system, however, comparators will be employed to convert the encoder's differential outputs (such as A, \bar{A}) to digital signals (such as A). This greatly increases noise immunity.

Note: The third encoder output T0, which indicates the mechanical zero position, may be connected to an external interrupt input and trigger a reset of timer T3.

If input T4IN is available, T0 can be connected there and clear T3 automatically without requiring an interrupt.

Figure 90 Connection of the Encoder to the TLE9869QXA20

For incremental interface operation, the following conditions must be met:

- Bitfield T3M must be 110_B or 111_B .
- Both pins T3IN and T3EUD must be configured as input.
- Pin T4IN must be configured as input, if used for T0.
- Bit T3UDE must be 1 to enable automatic external direction control.

The maximum count frequency allowed in Incremental Interface Mode depends on the selected prescaler value. To ensure that a transition of any input signal is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 16.3.5](#).

As in Incremental Interface Mode two input signals with a 90° phase shift are evaluated, their maximum input frequency can be half the maximum count frequency.

In Incremental Interface Mode, the count direction is automatically derived from the sequence in which the input signals change, which corresponds to the rotation direction of the connected sensor. [Table 87](#) summarizes the possible combinations.

Table 87 GPT1 Core Timer T3 (Incremental Interface Mode) Count Direction

Level on Respective other Input	T3IN Input		T3EUD Input	
	Rising \uparrow	Falling \downarrow	Rising \uparrow	Falling \downarrow
High	Down	Up	Up	Down
Low	Up	Down	Down	Up

[Figure 91](#) and [Figure 92](#) give examples of T3's operation, visualizing count signal generation and direction control. They also show how input jitter is compensated, which might occur if the sensor rests near to one of its switching points.

General Purpose Timer Units (GPT12)

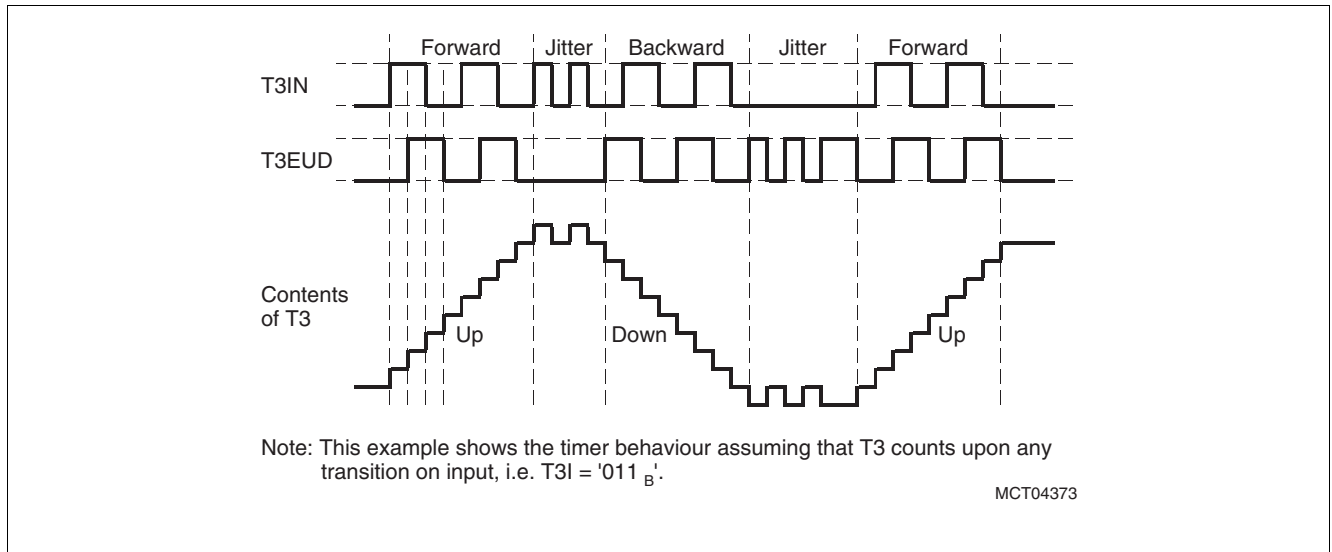

Figure 91 Evaluation of Incremental Encoder Signals, 2 Count Inputs

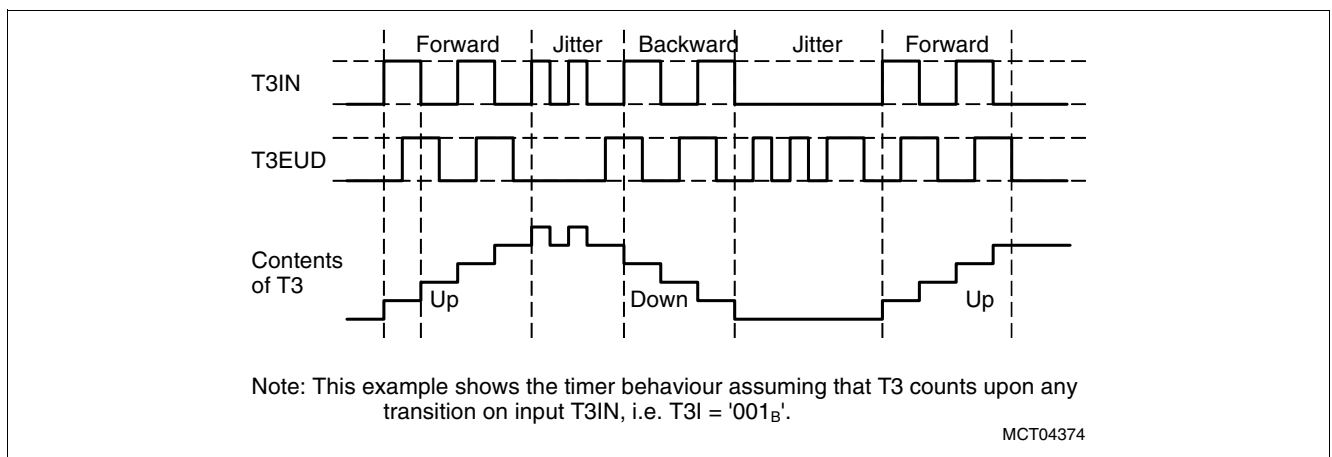

Figure 92 Evaluation of Incremental Encoder Signals, 1 Count Input

Note: Timer T3 operating in Incremental Interface Mode automatically provides information on the sensor's current position. Dynamic information (speed, acceleration, deceleration) may be obtained by measuring the incoming signal periods (see ["Combined Capture Modes" on Page 445](#)).

16.3.3 GPT1 Auxiliary Timers T2/T4 Control

Auxiliary timers T2 and T4 have exactly the same functionality. They can be configured for Timer Mode, Gated Timer Mode, Counter Mode, or Incremental Interface Mode with the same options for the timer frequencies and the count signal as the core timer T3. In addition to these 4 counting modes, the auxiliary timers can be concatenated with the core timer, or they may be used as reload or capture registers in conjunction with the core timer. The start/stop function of the auxiliary timers can be remotely controlled by the T3 run control bit. Several timers may thus be controlled synchronously.

The current contents of an auxiliary timer are reflected by its count register T2 or T4, respectively. These registers can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timers T2 and T4 are determined by their control registers T2CON and T4CON, which are organized identically. Note that functions which are present in all 3 timers of block GPT1 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timers have no output toggle latch and no alternate output function.

Timer T2/T4 Run Control

Each of the auxiliary timers T2 and T4 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T2R or T4R). In this case it is required that the respective control bit TxRC = 0.
- Through the core timer's run bit (T3R). In this case the respective remote control bit must be set (TxRC = 1).

The selected run bit is relevant in all operating modes of T2/T4. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T3R will start/stop timer T3 and the selected auxiliary timer(s) synchronously.

Count Direction Control

The count direction of the GPT1 timers (core timer and auxiliary timers) is controlled in the same way, either by software or by the external input pin TxEUD. Please refer to the description in [Table 91](#).

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timers T2 and T4 in Counter Mode

Counter Mode for an auxiliary timer Tx is selected by setting bitfield TxM in register TxCON to 001_B. In Counter Mode, an auxiliary timer can be clocked either by a transition at its external input line TxIN, or by a transition of timer T3's toggle latch T3OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield TxI in control register TxCON selects the triggering transition (see [Table 94](#)).

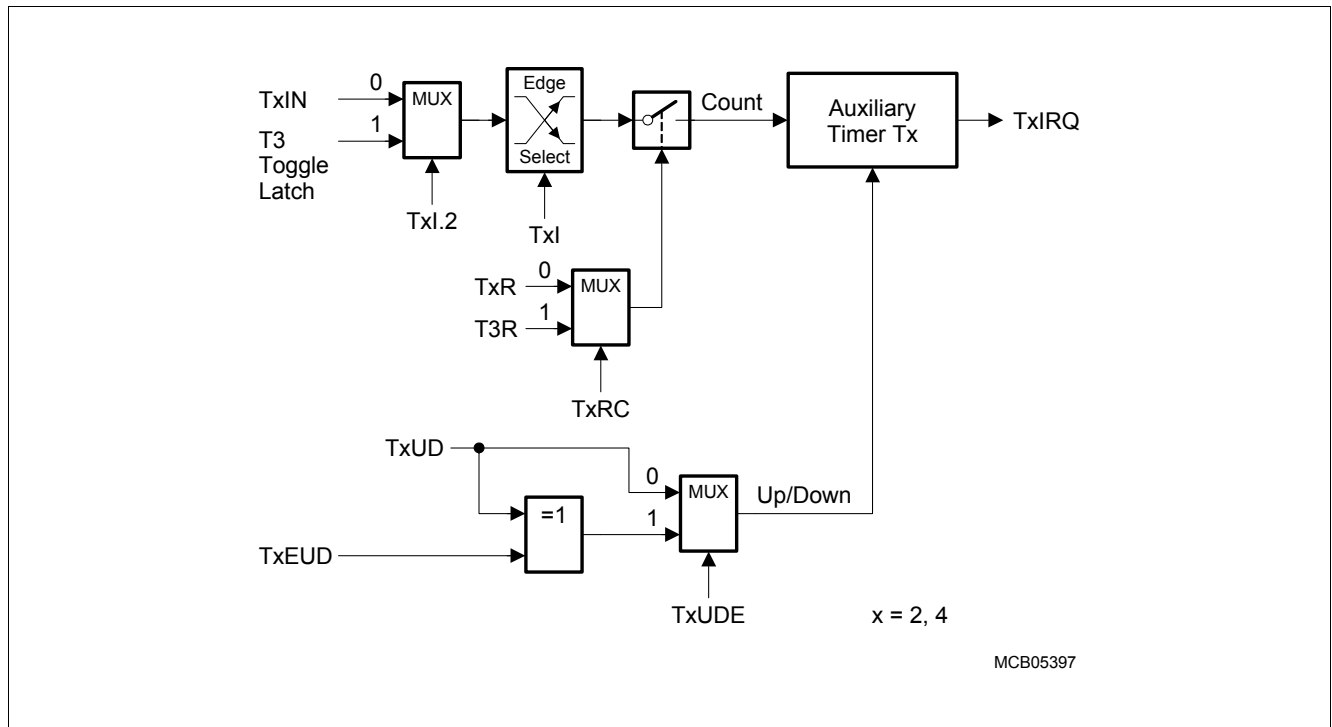

Figure 95 Block Diagram of an Auxiliary Timer in Counter Mode

Note: Only state transitions of T3OTL which are caused by the overflows/underflows of T3 will trigger the counter function of T2/T4. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

For counter operation, pin TxIN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 16.3.5](#).

Timer Concatenation

Using the toggle bit T3OTL as a clock source for an auxiliary timer in Counter Mode concatenates the core timer T3 with the respective auxiliary timer. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T3OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T3OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T3. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T3OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T3. This configuration forms a 33-bit timer (16-bit core timer + T3OTL + 16-bit auxiliary timer).
As long as bit T3OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

T3, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

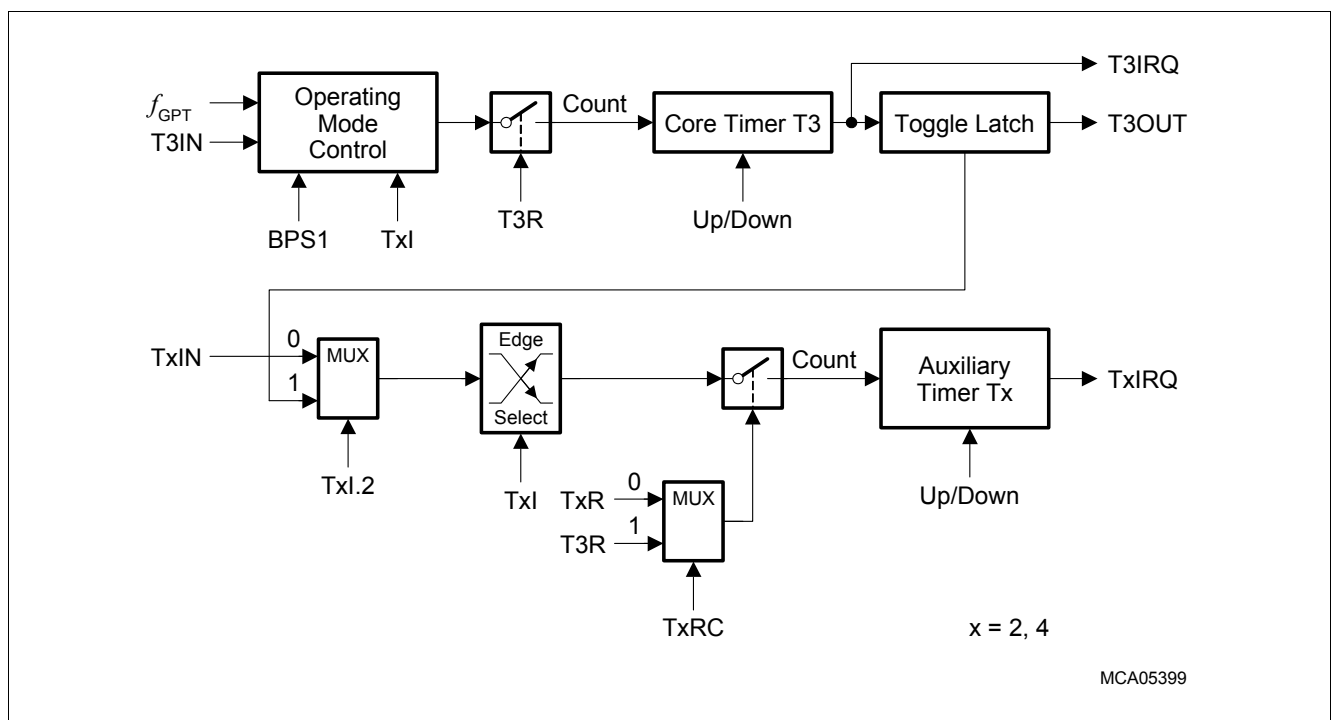

Figure 96 Concatenation of Core Timer T3 and an Auxiliary Timer

Timers T2 and T4 in Capture Mode

Capture mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 101_B. In capture mode, the contents of the core timer T3 are latched into an auxiliary timer register in response to a signal transition at the respective auxiliary timer's external input pin TxIN. The capture trigger signal can be a positive, a negative, or both a positive and a negative transition.

The two least significant bits of bitfield TxI select the active transition (see [Table 94](#)). Bit 2 of TxI is irrelevant for capture mode and must be cleared (TxI.2 = 0).

Note: When programmed for capture mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

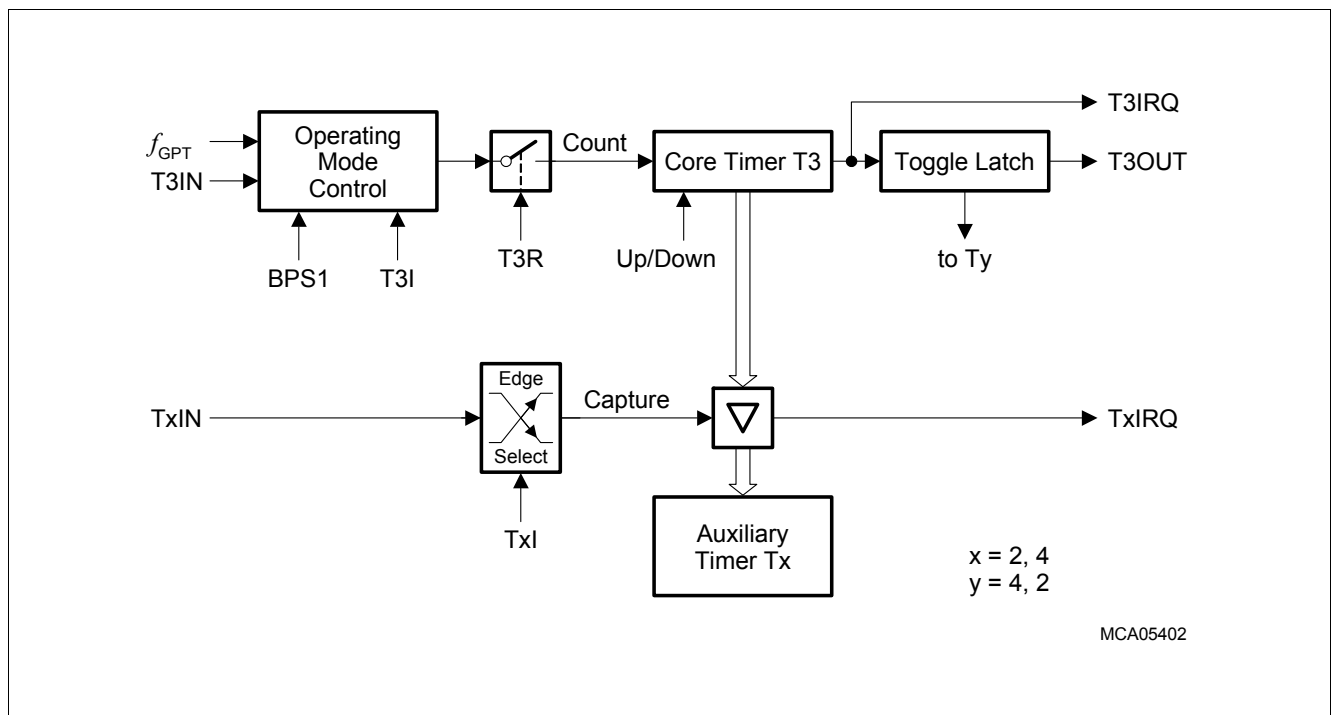

Figure 97 GPT1 Auxiliary Timer in Capture Mode

Upon a trigger (selected transition) at the corresponding input pin TxIN the contents of the core timer are loaded into the auxiliary timer register and the associated interrupt request flag TxIR will be set.

For capture mode operation, the respective timer input pin TxIN must be configured as input. To ensure that a transition of the capture input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 16.3.5](#).

Timers T2 and T4 in Incremental Interface Mode

Incremental interface mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 110_B or 111_B. In Incremental Interface Mode, the two inputs associated with an auxiliary timer Tx (TxIN, TxEUD) are used to interface to an incremental encoder. Tx is clocked by each transition on one or both of the external input pins to provide 2-fold or 4-fold resolution of the encoder input.

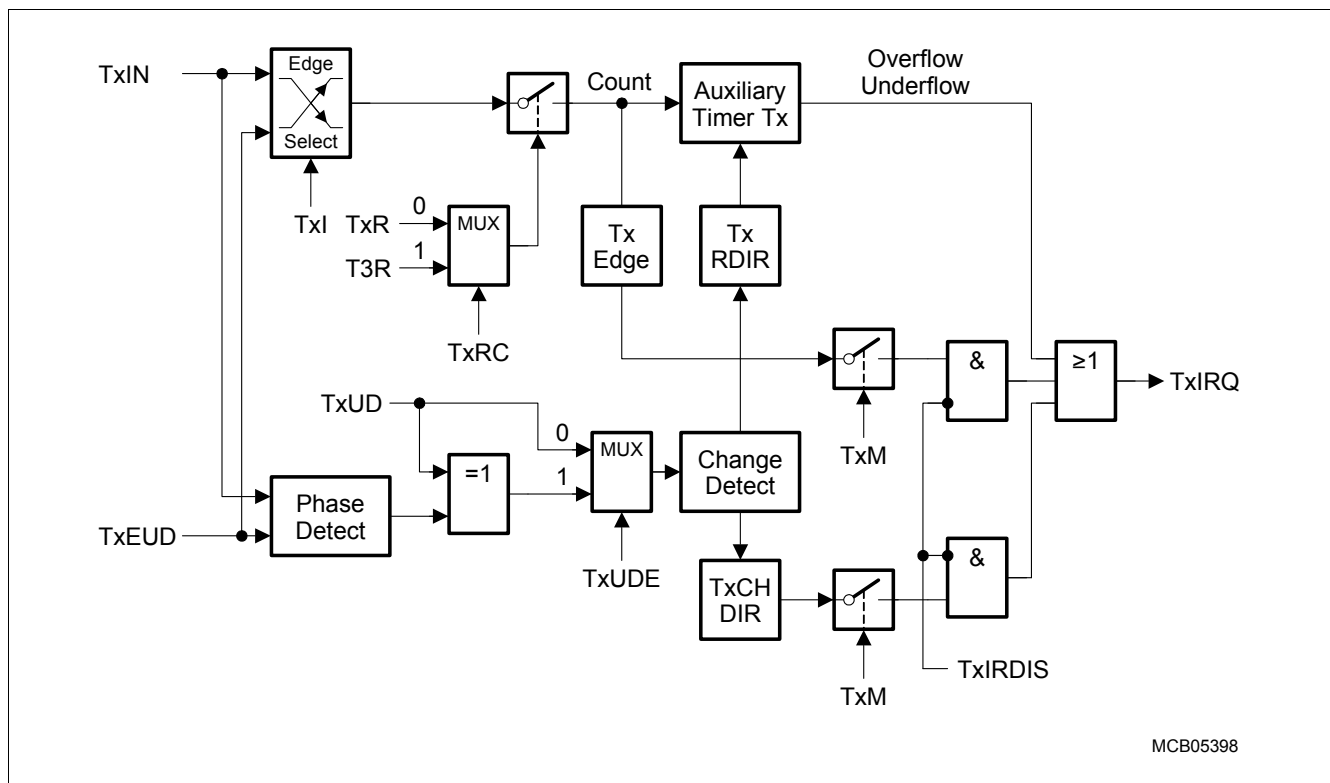

Figure 98 Block Diagram of an Auxiliary Timer in Incremental Interface Mode

The operation of the auxiliary timers T2 and T4 in Incremental Interface Mode and the interrupt generation are the same as described for the core timer T3. The descriptions, figures and tables apply accordingly.

Note: Timers T2 and T4 operating in Incremental Interface Mode automatically provide information on the sensor's current position. For dynamic information (speed, acceleration, deceleration) see ["Combined Capture Modes" on Page 445](#).

Timers T2 and T4 in Reload Mode

Reload Mode for an auxiliary timer Tx is selected by setting bitfield TxM in the respective register TxCON to 100_B. In reload mode, the core timer T3 is reloaded with the contents of an auxiliary timer register, triggered by one of two different signals. The trigger signal is selected the same way as the clock source for Counter Mode (see [Table 94](#)), i.e. a transition of the auxiliary timer's input TxIN or the toggle latch T3OTL may trigger the reload.

Note: When programmed for reload mode, the respective auxiliary timer (T2 or T4) stops independently of its run flag T2R or T4R.

The timer input pin TxIN must be configured as input if it shall trigger a reload operation.

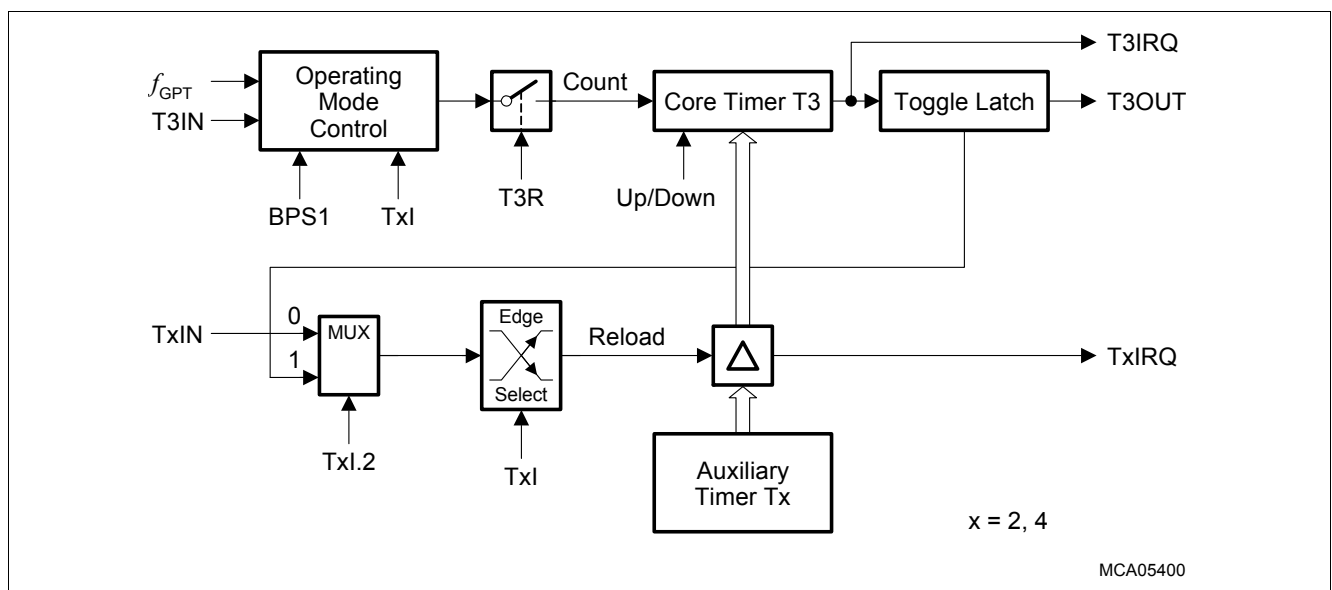

Figure 99 GPT1 Auxiliary Timer in Reload Mode

Upon a trigger signal, T3 is loaded with the contents of the respective timer register (T2 or T4) and the respective interrupt request flag (T2IR or T4IR) is set.

Note: When a T3OTL transition is selected for the trigger signal, the interrupt request flag T3IR will also be set upon a trigger, indicating T3's overflow or underflow. Modifications of T3OTL via software will NOT trigger the counter function of T2/T4.

To ensure that a transition of the reload input signal applied to TxIN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 16.3.5](#).

The reload mode triggered by the T3 toggle latch can be used in a number of different configurations. The following functions can be performed, depending on the selected active transition:

- If both a positive and a negative transition of T3OTL are selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer each time it overflows or underflows. This is the standard reload mode (reload on overflow/underflow).
- If either a positive or a negative transition of T3OTL is selected to trigger a reload, the core timer will be reloaded with the contents of the auxiliary timer on every second overflow or underflow.
- Using this "single-transition" mode for both auxiliary timers allows to perform very flexible Pulse Width Modulation (PWM). One of the auxiliary timers is programmed to reload the core timer on a positive transition of T3OTL, the other is programmed for a reload on a negative transition of T3OTL. With this combination the core timer is alternately reloaded from the two auxiliary timers.

[Figure 100](#) shows an example for the generation of a PWM signal using the "single-transition" reload mechanism. T2 defines the high time of the PWM signal (reloaded on positive transitions) and T4 defines the low time of the PWM signal (reloaded on negative transitions). The PWM signal can be output on pin T3OUT if T3OE = 1. With this method, the high and low time of the PWM signal can be varied in a wide range.

16.3.5 GPT1 Clock Signal Control

All actions within the timer block GPT1 are triggered by transitions of its basic clock. This basic clock is derived from the system clock by a basic block prescaler, controlled by bitfield BPS1 in register T3CON (see [Figure 82](#)). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT1's basic clock via a programmable prescaler, is used for (gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 88 Basic Clock Selection for Block GPT1

Block Prescaler ¹⁾	BPS1 = 01 _B	BPS1 = 00 _B ²⁾	BPS1 = 11 _B	BPS1 = 10 _B
Prescaling Factor for GPT1: F(BPS1)	F(BPS1) = 4	F(BPS1) = 8	F(BPS1) = 16	F(BPS1) = 32
Maximum External Count Frequency	$f_{\text{GPT}}/8$	$f_{\text{GPT}}/16$	$f_{\text{GPT}}/32$	$f_{\text{GPT}}/64$
Input Signal Stable Time	$4 \times t_{\text{GPT}}$	$8 \times t_{\text{GPT}}$	$16 \times t_{\text{GPT}}$	$32 \times t_{\text{GPT}}$

1) Please note the non-linear encoding of bitfield BPS1.

2) Default after reset.

Note: When initializing the GPT1 block, and the block prescaler BPS1 in register T3CON needs to be set to a value different from its reset value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, incremental interface, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur.

In this case (e.g. when changing BPS1 during operation of the GPT1 block), disable related interrupts before modification of BPS1, and afterwards clear the corresponding service request flags and re-initialize those registers (T2, T3, T4) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT1 timer is derived from the GPT1 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{\text{Tx}} = \frac{f_{\text{GPT}}}{F(\text{BPS1}) \times 2^{\langle \text{TxI} \rangle}} \quad r_{\text{Tx}}[\mu\text{s}] = \frac{F(\text{BPS1}) \times 2^{\langle \text{TxI} \rangle}}{f_{\text{GPT}}[\text{MHz}]} \quad (6)$$

The effective count frequency depends on the common module clock prescaler factor F(BPS1) as well as on the individual input prescaler factor $2^{\langle \text{TxI} \rangle}$. [Table 92](#) summarizes the resulting overall divider factors for a GPT1 timer that result from these cascaded prescalers.

[Table 89](#) lists GPT1 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor and the module clock f_{GPT} . Note that some numbers may be rounded.

General Purpose Timer Units (GPT12)

Table 89 GPT1 Timer Parameters

Module Clock $f_{GPT} = 10 \text{ MHz}$			Overall Prescaler Factor	Module Clock $f_{GPT} = 40 \text{ MHz}$		
Frequency	Resolution	Period		Frequency	Resolution	Period
2.5 MHz	400 ns	26.21 ms	4	10.0 MHz	100 ns	6.55 ms
1.25 MHz	800 ns	52.43 ms	8	5.0 MHz	200 ns	13.11 ms
625.0 kHz	1.6 μs	104.9 ms	16	2.5 MHz	400 ns	26.21 ms
312.5 kHz	3.2 μs	209.7 ms	32	1.25 MHz	800 ns	52.43 ms
156.25 kHz	6.4 μs	419.4 ms	64	625.0 kHz	1.6 μs	104.9 ms
78.125 kHz	12.8 μs	838.9 ms	128	312.5 kHz	3.2 μs	209.7 ms
39.06 kHz	25.6 μs	1.678 s	256	156.25 kHz	6.4 μs	419.4 ms
19.53 kHz	51.2 μs	3.355 s	512	78.125 kHz	12.8 μs	838.9 ms
9.77 kHz	102.4 μs	6.711 s	1024	39.06 kHz	25.6 μs	1.678 s
4.88 kHz	204.8 μs	13.42 s	2048	19.53 kHz	51.2 μs	3.355 s
2.44 kHz	409.6 μs	26.84 s	4096	9.77 kHz	102.4 μs	6.711 s

External Count Clock Input

The external input signals of the GPT1 block are sampled with the GPT1 basic clock (see [Figure 82](#)). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

[Table 90](#) summarizes the resulting requirements for external GPT1 input signals.

Table 90 GPT1 External Input Signal Limits

GPT1 Basic Clock = 10 MHz		Input Frequ. Factor	GPT1 Divider BPS1	Input Phase Duration	GPT1 Basic Clock = 40 MHz	
Max. Input Frequency	Min. Level Hold Time				Max. Input Frequency	Min. Level Hold Time
1.25 MHz	400 ns	$f_{GPT}/8$	01 _B	$4 \times t_{GPT}$	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	00 _B	$8 \times t_{GPT}$	2.5 MHz	200 ns
312.5 kHz	1.6 μs	$f_{GPT}/32$	11 _B	$16 \times t_{GPT}$	1.25 MHz	400 ns
156.25 kHz	3.2 μs	$f_{GPT}/64$	10 _B	$32 \times t_{GPT}$	625.0 kHz	800 ns

These limitations are valid for all external input signals to GPT1, including the external count signals in Counter Mode and Incremental Interface Mode, the gate input signals in Gated Timer Mode, and the external direction signals.

16.3.6 Interrupt Control for GPT1 Timers

When a timer overflows from $FFFF_H$ to 0000_H (when counting up), or when it underflows from 0000_H to $FFFF_H$ (when counting down), its interrupt request flag in register GPT12E_T2, GPT12E_T3, or GPT12E_T4 will be set. This will cause an interrupt to the respective timer interrupt vector, if the respective interrupt enable bit is set.

In **Reload Mode**, upon a trigger signal, T3 is loaded with the contents of the respective timer (T2 or T4) and the respective interrupt request flag in register GPT12E_T2 or GPT12E_T4 is set.

In **Incremental Interface Mode**, the interrupt request generation can be selected as follows:

- In Rotation Detection Mode ($T3M = 110_B$), an interrupt request is generated each time the count direction of T3 changes.
- In Edge Detection Mode ($T3M = 111_B$), an interrupt request is generated each time a count edge for T3 is detected.

In **Capture Mode**, upon a trigger (selected transition) at the corresponding input pin the content of the core timer T3 are loaded into the auxiliary timer register Tx and the associated interrupt request flag in register GPT12E_T2 or GPT12E_T4 will be set.

16.3.7 GPT1 Registers

16.3.7.1 GPT1 Timer Registers

T2

Timer T2 Count Register

(20_H)

Reset Value: 0000_H

Field	Bits	Typ	Description
T2	[15:0]	rwh	Timer T2 Current Value Contains the current value of the timer T2

T3

Timer T3 Count Register

16.3.7.3 GPT1 Timer Interrupt Control Registers

The Interrupt Control and Status register are located in the SCU.

16.4 Timer Block GPT2

From a programmer's point of view, the GPT2 block is represented by a set of SFRs as summarized below. Those portions of port and direction registers which are used for alternate functions by the GPT2 block are shaded.

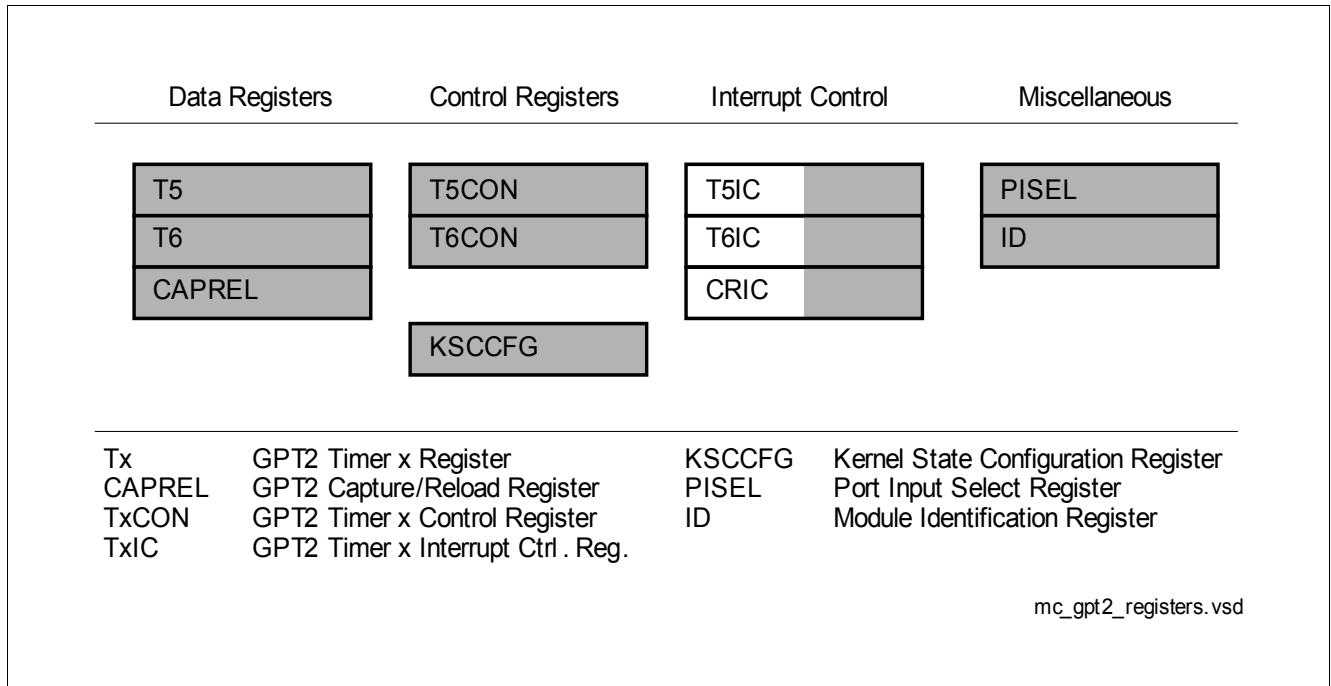

Figure 101 SFRs Associated with Timer Block GPT2

Both timers of block GPT2 (T5, T6) can run in one of 3 basic modes: Timer Mode, Gated Timer Mode, or Counter Mode. All timers can count up or down. Each timer of GPT2 is controlled by a separate control register TxCON.

Each timer has an input pin TxIN (alternate pin function) associated with it, which serves as the gate control in Gated Timer Mode, or as the count input in Counter Mode. The count direction (up/down) may be programmed via software or may be dynamically altered by a signal at the External Up/Down control input TxEUD (alternate pin function). An overflow/underflow of core timer T6 is indicated by the Output Toggle Latch T6OTL, whose state may be output on the associated pin T6OUT (alternate pin function). The auxiliary timer T5 may additionally be concatenated with core timer T6 (through T6OTL).

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by the input pin CAPIN, or by GPT1 timer's T3 input lines T3IN and T3EUD. The reload function is triggered by an overflow or underflow of timer T6. Overflows/underflows of timer T6 may also clock the timers of the CAPCOM units.

The current contents of each timer can be read or modified by the CPU by accessing the corresponding timer count registers T5 or T6, located in the SFR space (see [Section 16.4.8.1](#)). When any of the timer registers is written to by the CPU in the state immediately preceding a timer increment, decrement, reload, or capture operation, the CPU write operation has priority in order to guarantee correct results.

The interrupts of GPT2 are controlled through the GPTM1IEN and GPTM1IRC. These registers are not part of the GPT2 block.

The input and output lines of GPT2 are connected to pins. The control registers for the port functions are located in the respective port modules.

Note: The timing requirements for external input signals can be found in [Section 16.4.6](#), [Section 16.7.1](#) summarizes the module interface signals, including pins.

16.4.1 GPT2 Core Timer T6 Control

The current contents of the core timer T6 are reflected by its count register T6. This register can also be written to by the CPU, for example, to set the initial start value.

The core timer T6 is configured and controlled via its control register T6CON.

Timer T6 Run Control

The core timer T6 can be started or stopped by software through bit T6R (timer T6 run bit). This bit is relevant in all operating modes of T6. Setting bit T6R will start the timer, clearing bit T6R stops the timer.

In Gated Timer Mode, the timer will only run if T6R = 1 and the gate is active (high or low, as programmed).

Note: When bit T5RC in timer control register T5CON is set, bit T6R will also control (start and stop) the Auxiliary Timer T5.

Count Direction Control

The count direction of the GPT2 timers (core timer and auxiliary timer) can be controlled either by software or by the external input pin TxEUD (Timer Tx External Up/Down Control Input). These options are selected by bits TxUD and TxUDE in the respective control register TxCON. When the up/down control is provided by software (bit TxUDE = 0), the count direction can be altered by setting or clearing bit TxUD. When bit TxUDE = 1, pin TxEUD is selected to be the controlling source of the count direction. However, bit TxUD can still be used to reverse the actual count direction, as shown in [Table 100](#). The count direction can be changed regardless of whether or not the timer is running.

Note: When pin TxEUD is used as external count direction control input, it must be configured as input.

Timer T6 Output Toggle Latch

The overflow/underflow signal of timer T6 is connected to a block named 'Toggle Latch', shown in the Timer Mode diagrams. **Figure 102** illustrates the details of this block. An overflow or underflow of T6 will clock two latches: The first latch represents bit T6OTL in control register T6CON. The second latch is an internal latch toggled by T6OTL's output. Both latch outputs are connected to the input control block of the auxiliary timer T5. The output level of the shadow latch will match the output level of T6OTL, but is delayed by one clock cycle. When the T6OTL value changes, this will result in a temporarily different output level from T6OTL and the shadow latch, which can trigger the selected count event in T5.

When software writes to T6OTL, both latches are set or cleared simultaneously. In this case, both signals to the auxiliary timers carry the same level and no edge will be detected. Bit T6OE (overflow/underflow output enable) in register T6CON enables the state of T6OTL to be monitored via an external pin T6OUT. When T6OTL is linked to an external port pin (must be configured as output), T6OUT can be used to control external HW. If T6OE = 1, pin T6OUT outputs the state of T6OTL. If T6OE = 0, pin T6OUT outputs a high level (while it selects the timer output signal).

As can be seen from **Figure 102**, when latch T6OTL is modified by software to determine the state of the output line, also the internal shadow latch is set or cleared accordingly. Therefore, no trigger condition is detected by T5 in this case.

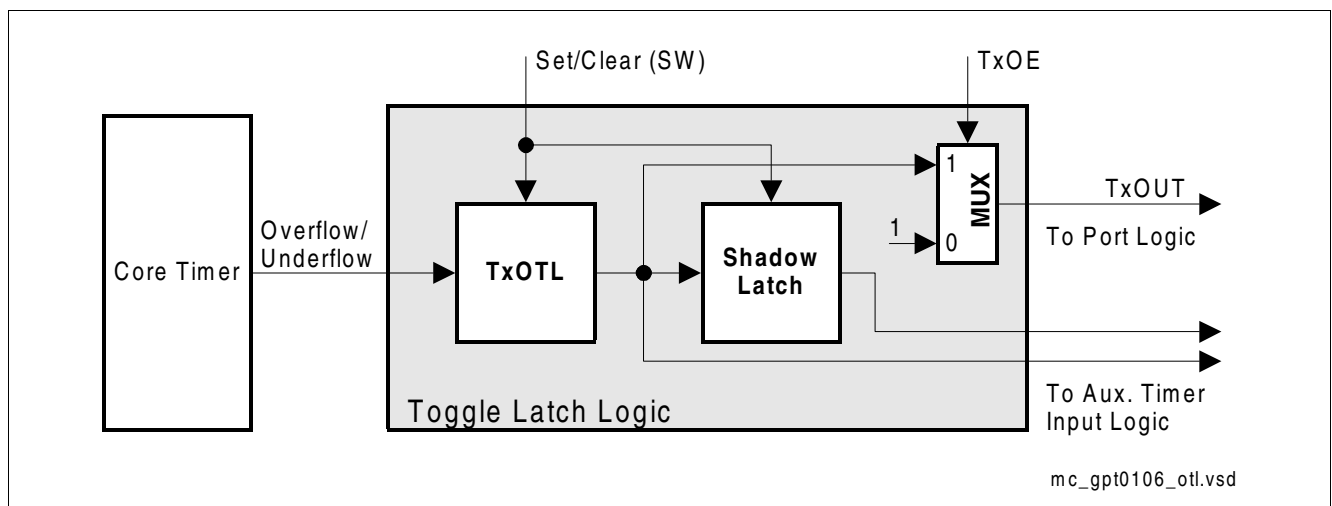

Figure 102 Block Diagram of the Toggle Latch Logic of Core Timer T6 (x = 6)

Note: T6 is also used to clock the timers in the CAPCOM units. For this purpose, there is a direct internal connection between the T6 overflow/underflow line and the CAPCOM timers (signal T6OUF).

16.4.2 GPT2 Core Timer T6 Operating Modes

Timer T6 can operate in one of several modes.

Timer T6 in Timer Mode

Timer mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 000_B. In this mode, T6 is clocked with the module's input clock f_{GPT} divided by two programmable prescalers controlled by bitfields BPS2 and T6I in register T6CON. Please see [Section 16.4.6](#) for details on the input clock options.

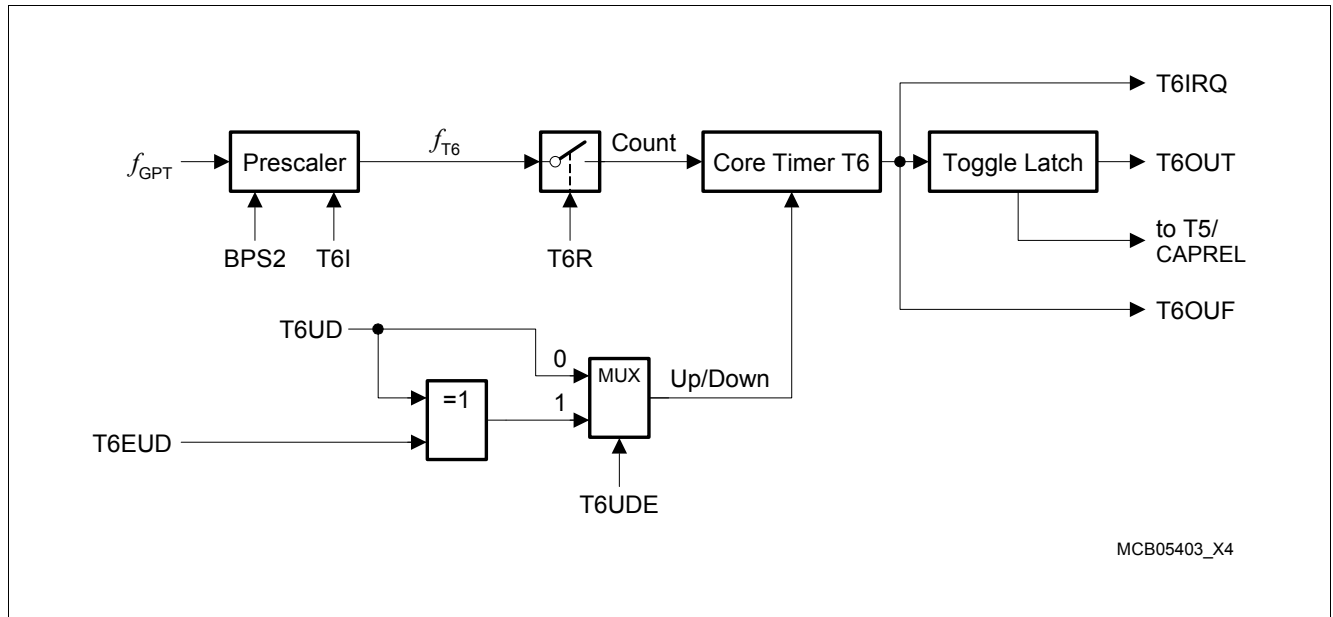

Figure 103 Block Diagram of Core Timer T6 in Timer Mode

Timer T6 in Gated Timer Mode

Gated Timer Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 010_B or 011_B. Bit T6M.0 (T6CON.3) selects the active level of the gate input. The same options for the input frequency are available in Gated Timer Mode as in Timer Mode (see [Section 16.4.6](#)). However, the input clock to the timer in this mode is gated by the external input pin T6IN (Timer T6 External Input).

To enable this operation, the associated pin T6IN must be configured as input.

Figure 104 Block Diagram of Core Timer T6 in Gated Timer Mode

If T6M = 010_B, the timer is enabled when T6IN shows a low level. A high level at this line stops the timer. If T6M = 011_B, line T6IN must have a high level in order to enable the timer. Additionally, the timer can be turned on or off by software using bit T6R. The timer will only run if T6R is 1 and the gate is active. It will stop if either T6R is 0 or the gate is inactive.

Note: A transition of the gate signal at pin T6IN does not cause an interrupt request.

Timer T6 in Counter Mode

Counter Mode for the core timer T6 is selected by setting bitfield T6M in register T6CON to 001_B. In Counter Mode, timer T6 is clocked by a transition at the external input pin T6IN. The event causing an increment or decrement of the timer can be a positive, a negative, or both a positive and a negative transition at this line. Bitfield T6I in control register T6CON selects the triggering transition (see [Table 102](#)).

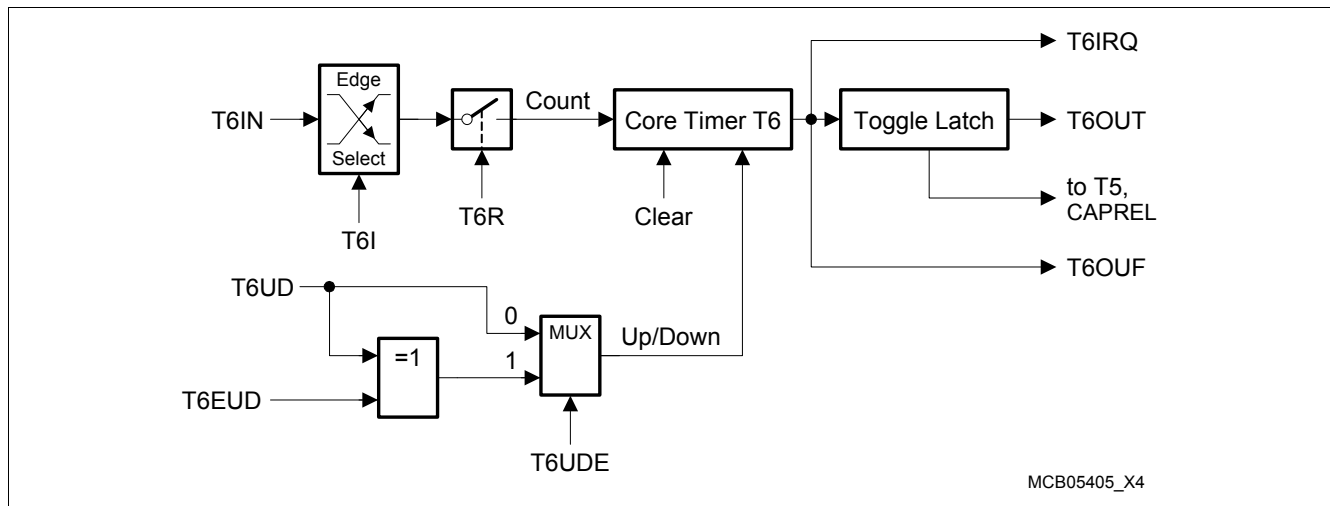

Figure 105 Block Diagram of Core Timer T6 in Counter Mode

For Counter Mode operation, pin T6IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T6IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 16.4.6](#).

16.4.3 GPT2 Auxiliary Timer T5 Control

Auxiliary timer T5 can be configured for Timer Mode, Gated Timer Mode, or Counter Mode with the same options for the timer frequencies and the count signal as the core timer T6. In addition to these 3 counting modes, the auxiliary timer can be concatenated with the core timer. The contents of T5 may be captured to register CAPREL upon an external or an internal trigger. The start/stop function of the auxiliary timers can be remotely controlled by the T6 run control bit. Several timers may thus be controlled synchronously.

The current contents of the auxiliary timer are reflected by its count register T5. This register can also be written to by the CPU, for example, to set the initial start value.

The individual configurations for timer T5 are determined by its control register T5CON. Some bits in this register also control the function of the CAPREL register. Note that functions which are present in all timers of block GPT2 are controlled in the same bit positions and in the same manner in each of the specific control registers.

Note: The auxiliary timer has no output toggle latch and no alternate output function.

Timer T5 Run Control

The auxiliary timer T5 can be started or stopped by software in two different ways:

- Through the associated timer run bit (T5R). In this case it is required that the respective control bit T5RC = 0.
- Through the core timer's run bit (T6R). In this case the respective remote control bit must be set (T5RC = 1).

The selected run bit is relevant in all operating modes of T5. Setting the bit will start the timer, clearing the bit stops the timer.

In Gated Timer Mode, the timer will only run if the selected run bit is set and the gate is active (high or low, as programmed).

Note: If remote control is selected T6R will start/stop timer T6 and the auxiliary timer T5 synchronously.

16.4.4 GPT2 Auxiliary Timer T5 Operating Modes

The operation of the auxiliary timer in the basic operating modes is almost identical with the core timer's operation, with very few exceptions. Additionally, some combined operating modes can be selected.

Timer T5 in Timer Mode

Timer Mode for the auxiliary timer T5 is selected by setting its bitfield T5M in register T5CON to 000_B .

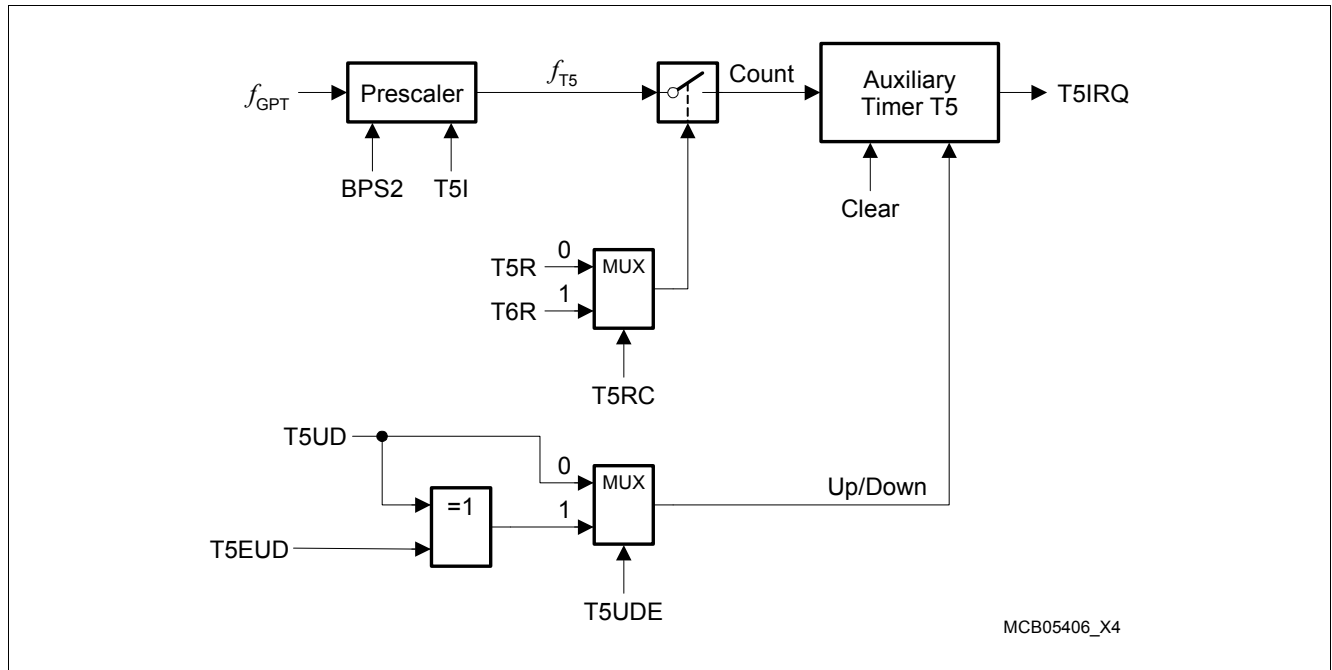

Figure 106 Block Diagram of Auxiliary Timer T5 in Timer Mode

Timer T5 in Gated Timer Mode

Gated Timer Mode for the auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 010_B or 011_B. Bit T5M.0 (T5CON.3) selects the active level of the gate input.

Note: A transition of the gate signal at line T5IN does not cause an interrupt request.

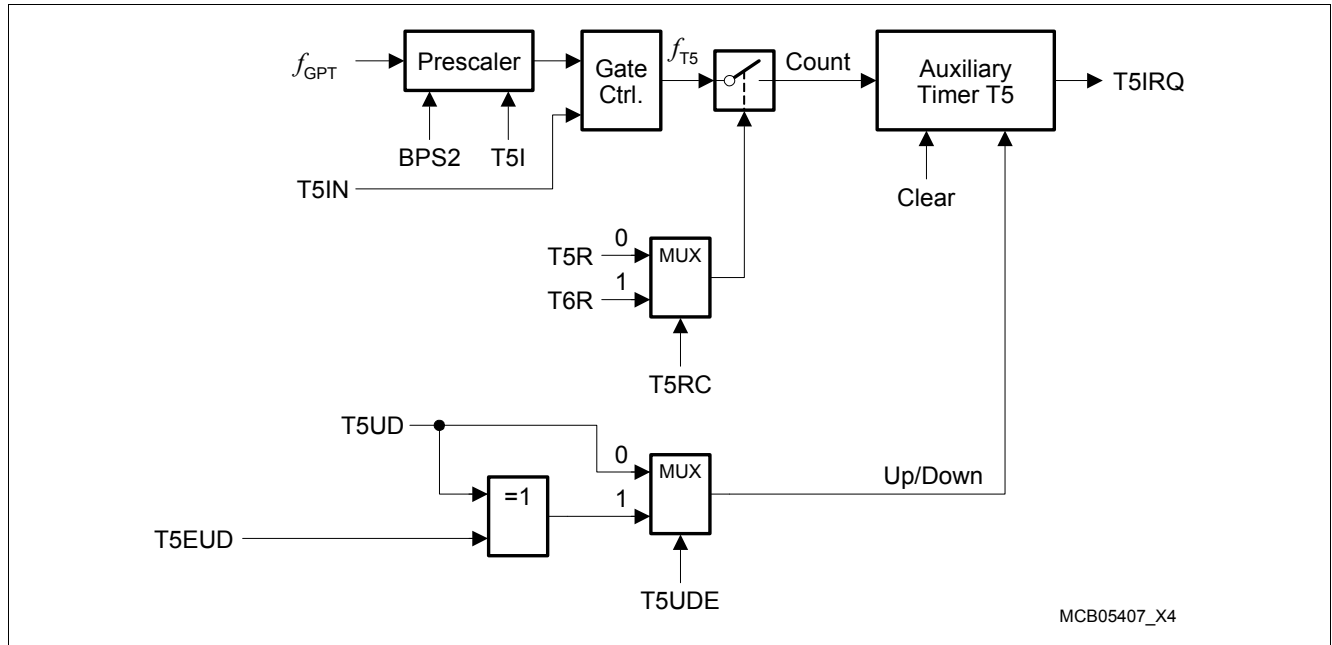

Figure 107 Block Diagram of Auxiliary Timer T5 in Gated Timer Mode

Note: There is no output toggle latch for T5.

Start/stop of the auxiliary timer can be controlled locally or remotely.

Timer T5 in Counter Mode

Counter Mode for auxiliary timer T5 is selected by setting bitfield T5M in register T5CON to 001_B. In Counter Mode, the auxiliary timer can be clocked either by a transition at its external input line T5IN, or by a transition of timer T6's toggle latch T6OTL. The event causing an increment or decrement of a timer can be a positive, a negative, or both a positive and a negative transition at either the respective input pin or at the toggle latch. Bitfield T5I in control register T5CON selects the triggering transition (see [Table 103](#)).

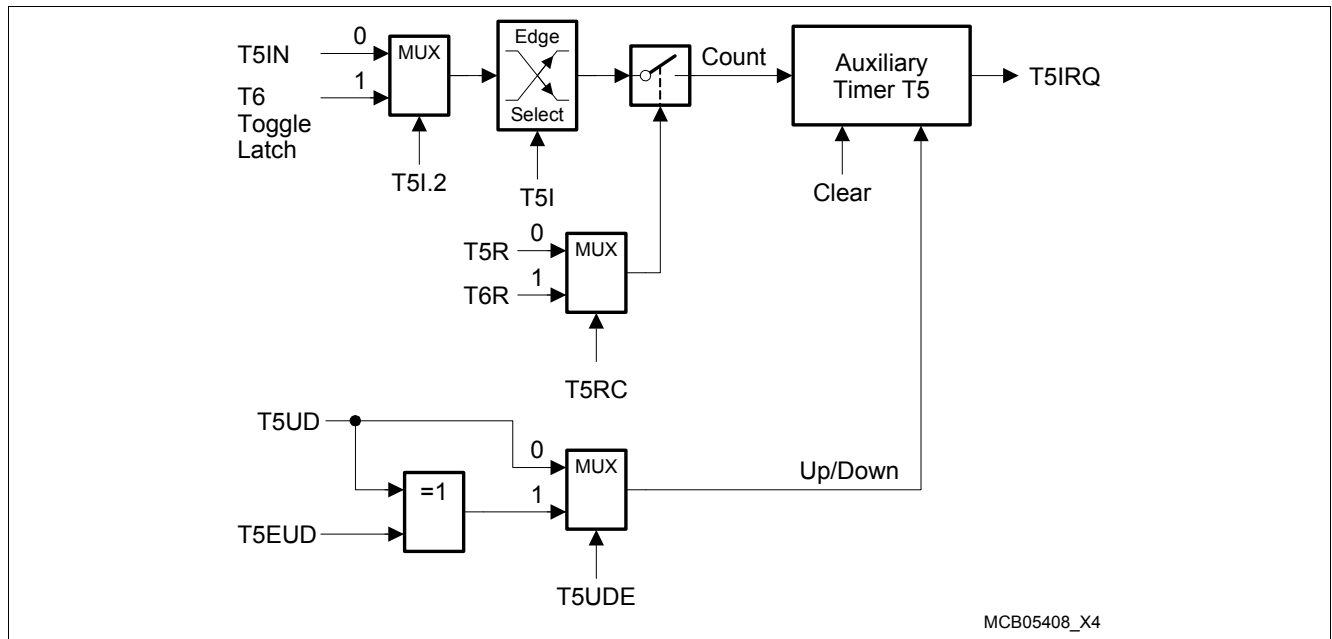

Figure 108 Block Diagram of Auxiliary Timer T5 in Counter Mode

Note: Only state transitions of T6OTL which are caused by the overflows/underflows of T6 will trigger the counter function of T5. Modifications of T6OTL via software will NOT trigger the counter function of T5.

For counter operation, pin T5IN must be configured as input. The maximum input frequency allowed in Counter Mode depends on the selected prescaler value. To ensure that a transition of the count input signal applied to T5IN is recognized correctly, its level must be held high or low for a minimum number of module clock cycles before it changes. This information can be found in [Section 16.4.6](#).

Timer Concatenation

Using the toggle bit T6OTL as a clock source for the auxiliary timer in Counter Mode concatenates the core timer T6 with the auxiliary timer T5. This concatenation forms either a 32-bit or a 33-bit timer/counter, depending on which transition of T6OTL is selected to clock the auxiliary timer.

- **32-bit Timer/Counter:** If both a positive and a negative transition of T6OTL are used to clock the auxiliary timer, this timer is clocked on every overflow/underflow of the core timer T6. Thus, the two timers form a 32-bit timer.
- **33-bit Timer/Counter:** If either a positive or a negative transition of T6OTL is selected to clock the auxiliary timer, this timer is clocked on every second overflow/underflow of the core timer T6. This configuration forms a 33-bit timer (16-bit core timer + T6OTL + 16-bit auxiliary timer).
As long as bit T6OTL is not modified by software, it represents the state of the internal toggle latch, and can be regarded as part of the 33-bit timer.

The count directions of the two concatenated timers are not required to be the same. This offers a wide variety of different configurations.

General Purpose Timer Units (GPT12)

T6, which represents the low-order part of the concatenated timer, can operate in Timer Mode, Gated Timer Mode or Counter Mode in this case.

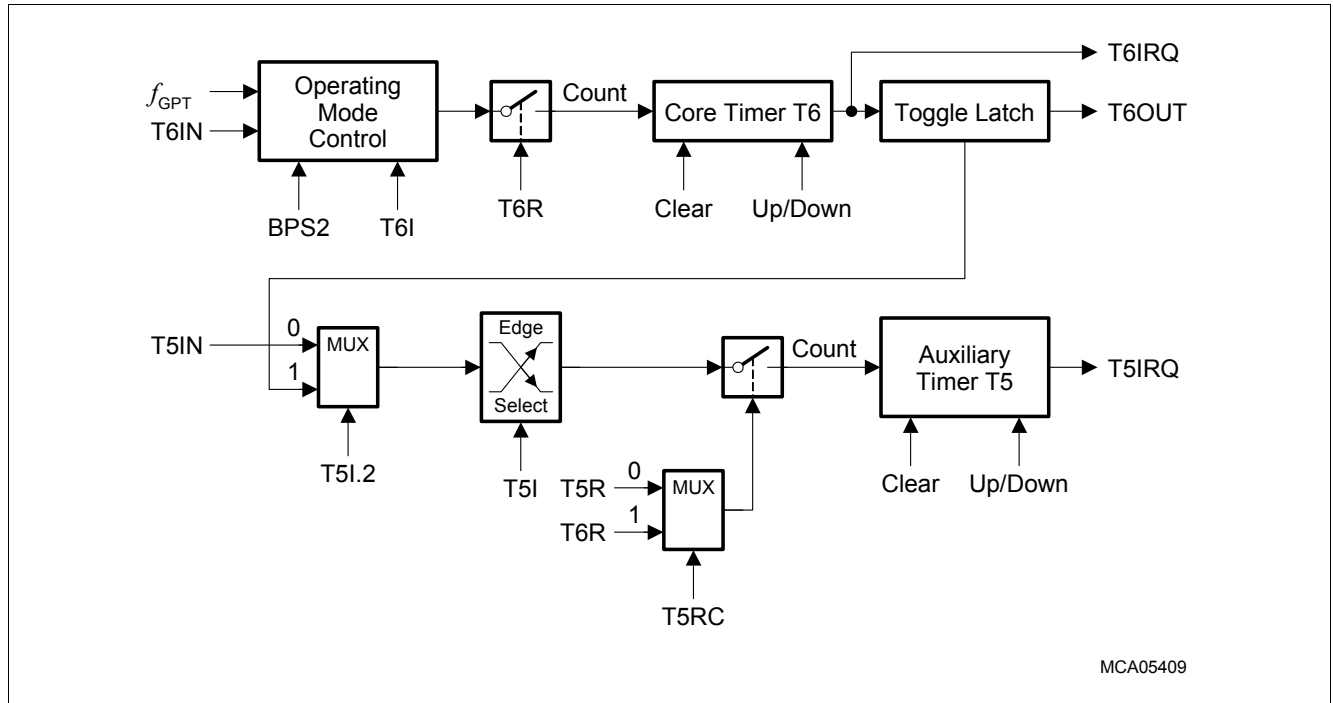

Figure 109 Concatenation of Core Timer T6 and Auxiliary Timer T5

16.4.5 GPT2 Register CAPREL Operating Modes

The Capture/Reload register CAPREL can be used to capture the contents of timer T5, or to reload timer T6. A special mode facilitates the use of register CAPREL for both functions at the same time. This mode allows frequency multiplication. The capture function is triggered by CAPIN, by T3IN and T3EUD, or by read GPT1 timers. The reload function is triggered by an overflow or underflow of timer T6.

In addition to the capture function, the capture trigger signal can also be used to clear the contents of timers T5 and T6 individually.

The functions of register CAPREL are controlled via several bit(field)s in the timer control registers T5CON and T6CON.

Capture/Reload Register CAPREL in Capture Mode

Capture mode for register CAPREL is selected by setting bit T5SC in control register T5CON (set bitfield CI in register T5CON to a non-zero value to select a trigger signal). In capture mode, the contents of the auxiliary timer T5 are latched into register CAPREL in response to a signal transition at the selected external input pin(s). Bit CT3 selects the external input line CAPIN or the input lines T3IN and/or T3EUD of GPT1 timer T3 as the source for a capture trigger. Either a positive, a negative, or both a positive and a negative transition at line CAPIN can be selected to trigger the capture function, or transitions on input T3IN or input T3EUD or both inputs, T3IN and T3EUD. The active edge is controlled by bitfield CI in register T5CON. [Table 96](#) summarizes these options.

Table 96 CAPREL Register Input Edge Selection

CT3	CI	Triggering Signal/Edge for Capture Mode
X	00 _B	None. Capture Mode is disabled.
0	01 _B	Positive transition (rising edge) on CAPIN. ¹⁾
0	10 _B	Negative transition (falling edge) on CAPIN.
0	11 _B	Any transition (rising or falling edge) on CAPIN.
1	01 _B	Any transition (rising or falling edge) on T3IN.
1	10 _B	Any transition (rising or falling edge) on T3EUD.
1	11 _B	Any transition (rising or falling edge) on T3IN or T3EUD.

1) Rising edge must be selected if capturing is triggered by the internal GPT1 read signals (see register PISEL and [“Combined Capture Modes” on Page 445](#)).

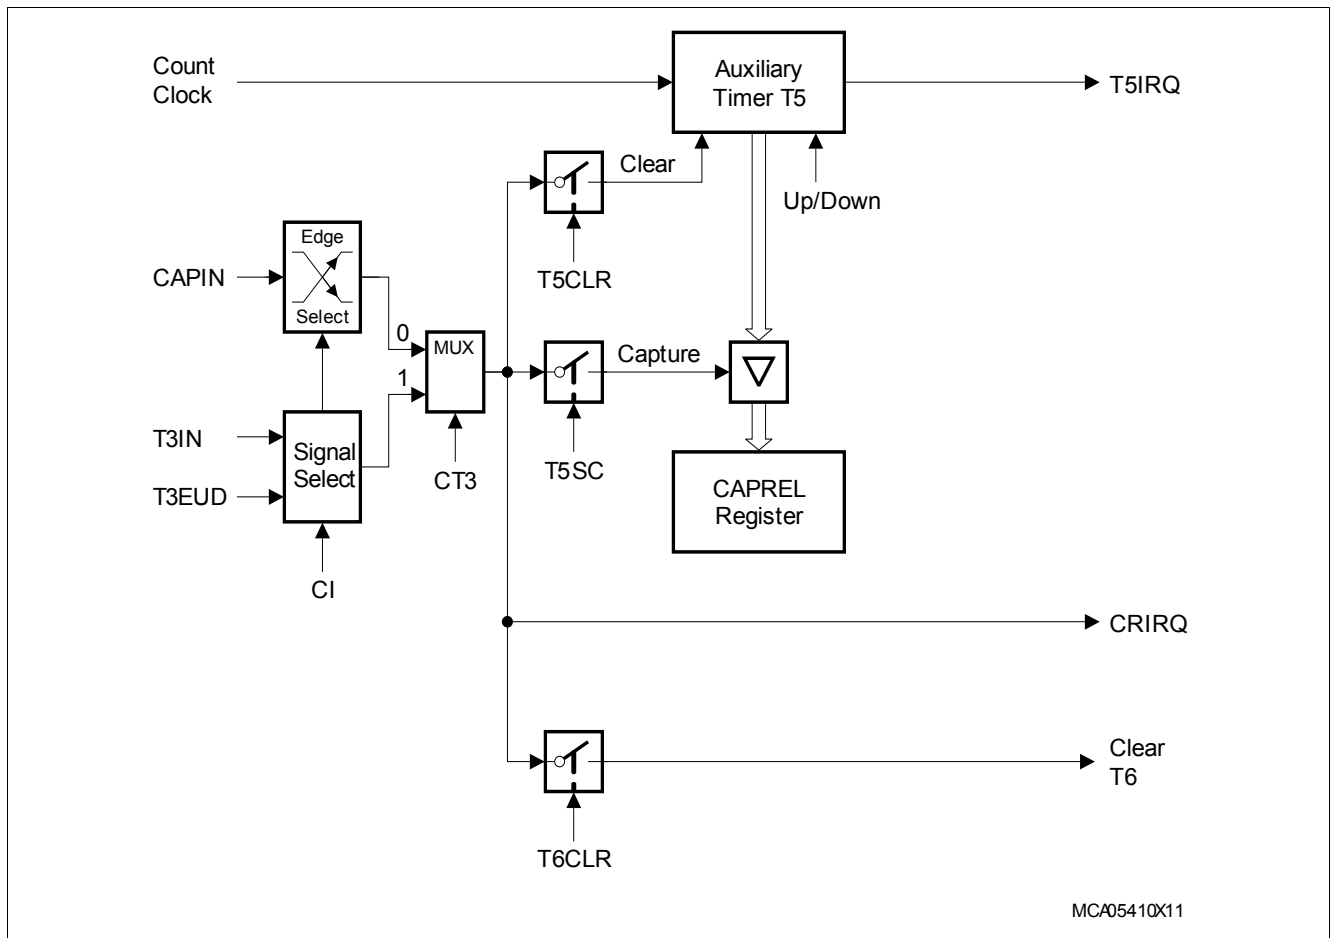

Figure 110 Capture/Reload Register CAPREL in Capture Mode

When a selected trigger is detected, the contents of the auxiliary timer T5 are latched into register CAPREL and the interrupt request line CRIRQ is activated. The same event can optionally clear timer T5 and/or timer T6. This option is enabled by bit T5CLR in register T5CON and bit T6CLR in register T6CON, respectively. If TxCLR = 0 the contents of timer Tx is not affected by a capture. If TxCLR = 1 timer Tx is cleared after the current timer T5 value has been latched into register CAPREL.

Note: Bit T5SC only controls whether or not a capture is performed. If T5SC is cleared the external input pin(s) can still be used to clear timer T5 and/or T6, or as external interrupt input(s). This interrupt is controlled by the CAPREL interrupt control register GPTM1IEN and GPTM1IRC.

When capture triggers T3IN or T3EUD are enabled (CT3 = 1), register CAPREL captures the contents of T5 upon transitions of the selected input(s). These values can be used to measure T3's input signals. This is useful, for example, when T3 operates in Incremental Interface Mode, in order to derive dynamic information (speed, acceleration) from the input signals.

For capture mode operation, the selected pins CAPIN, T3IN, or T3EUD must be configured as input. To ensure that a transition of a trigger input signal applied to one of these inputs is recognized correctly, its level must be held high or low for a minimum number of module clock cycles, detailed in [Section 16.4.6](#).

Capture/Reload Register CAPREL in Reload Mode

Reload mode for register CAPREL is selected by setting bit T6SR in control register T6CON. In reload mode, the core timer T6 is reloaded with the contents of register CAPREL, triggered by an overflow or underflow of T6. This will not activate the interrupt request line CRIRQ associated with the CAPREL register. However, interrupt request line T6IRQ will be activated, indicating the overflow/underflow of T6.

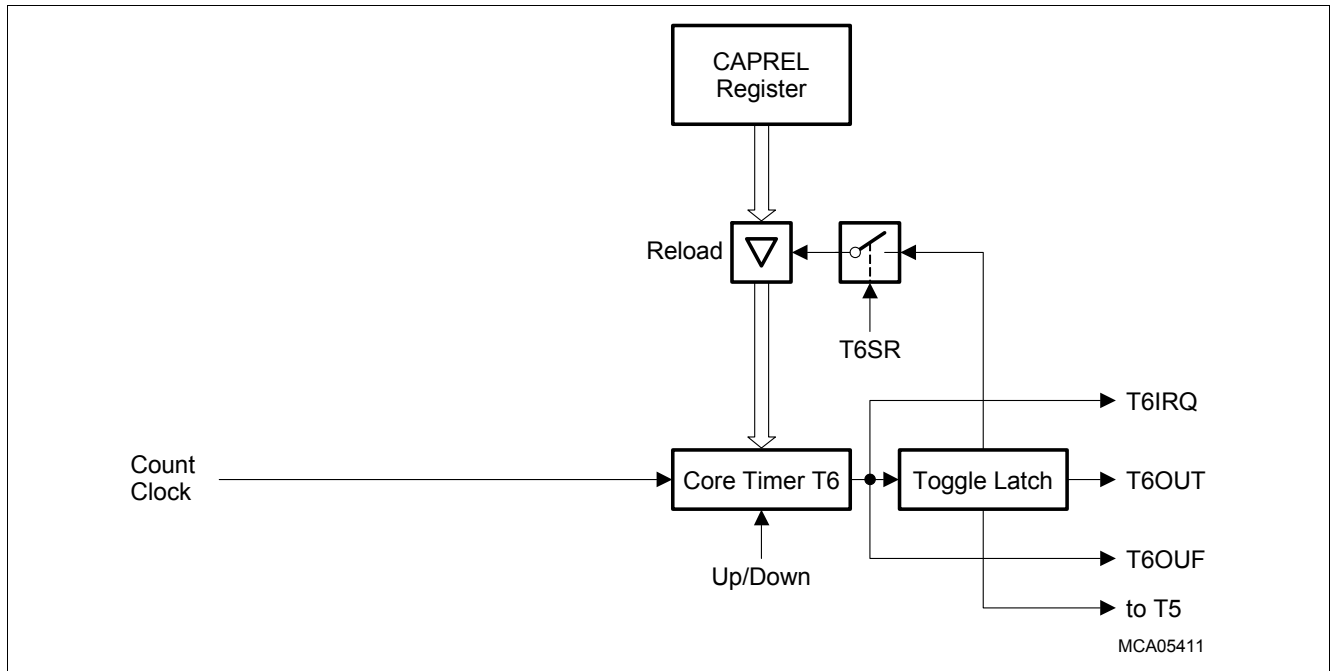

Figure 111 Capture/Reload Register CAPREL in Reload Mode

Note: The underflow signal of Timer T6 can furthermore be used to clock one or more of the timers of the CAPCOM units, which gives the user the possibility to set compare events based on a finer resolution than that of the external events. This connection is accomplished via signal T6OUF.

Capture Correction

A certain deviation of the output frequency is generated by the fact that timer T5 will count actual time units (e.g. T5 running at 1 MHz will count up to the value $64_H/100_D$ for a 10 kHz input signal), while T6OTL will only toggle upon an underflow of T6 (i.e. the transition from 0000_H to $FFFF_H$). In the above mentioned example, T6 would count down from 64_H , so the underflow would occur after 101 timing ticks of T6. The actual output frequency then is 79.2 kHz, instead of the expected 80 kHz.

This deviation can be compensated for by using T6 overflows. In this case, T5 counts down and T6 counts up. Upon a signal transition on pin CAPIN, the count value in T5 is captured into CAPREL and T5 is cleared to 0000_H . In its next clock cycle, T5 underflows to $FFFF_H$, and continues to count down with the following clocks. T6 is reloaded from CAPREL upon an overflow, and continues to count up with its following clock cycles (8 times faster in the above example). In this case, T5 and T6 count the same number of steps with their respective internal count frequency.

In the above example, T5 running at 1 MHz will count down to the value $FF9C_H/-100_D$ for a 10 kHz input signal applied at CAPIN, while T6 counts up from $FF9C_H$ through $FFFF_H$ to 0000_H . So the overflow occurs after 100 timing ticks of T6, and the actual output frequency at T6OUT then is the expected 80 kHz.

However, in this case CAPREL does not directly contain the time between two CAPIN events, but rather its 2's complement. Software will have to convert this value, if it is required for the operation.

Combined Capture Modes

For incremental interface applications in particular, several timer features can be combined to obtain dynamic information such as speed, acceleration, or deceleration. The current position itself can be obtained directly from the timer register (T2, T3, T4).

The time information to determine the dynamic parameters is generated by capturing the contents of the free-running timer T5 into register CAPREL. Two trigger sources for this event can be selected:

- Capture trigger on sensor signal transitions
- Capture trigger on position read operations

Capturing on sensor signal transitions is available for timer T3 inputs. This mode is selected by setting bit CT3 and selecting the intended signal(s) via bitfield CI in register T5CON. CAPREL then indicates the time between two selected transitions (measured in T5 counts).

Capturing on position read operations is available for timers T2, T3, and T4. This mode is selected by clearing bit CT3 and selecting the rising edge via bitfield CI in register T5CON. Bitfield ISCAPIN in register PISEL then selects either a read access from T3 or a read access from any of T2 or T3 or T4. CAPREL then indicates the time between two read accesses.

These operating modes directly support the measurement of position and rotational speed. Acceleration and deceleration can then be determined by evaluating subsequent speed measurements.

16.4.6 GPT2 Clock Signal Control

All actions within the timer block GPT2 are triggered by transitions of its basic clock. This basic clock is derived from the module clock f_{GPT} by a basic block prescaler, controlled by bitfield BPS2 in register T6CON (see [Figure 83](#)). The count clock can be generated in two different ways:

- **Internal count clock**, derived from GPT2's basic clock via a programmable prescaler, is used for (gated) Timer Mode.
- **External count clock**, derived from the timer's input pin(s), is used for Counter Mode.

For both ways, the basic clock determines the maximum count frequency and the timer's resolution:

Table 97 Basic Clock Selection for Block GPT2

Block Prescaler ¹⁾	BPS2 = 01 _B	BPS2 = 00 _B ²⁾	BPS2 = 11 _B	BPS2 = 10 _B
Prescaling Factor for GPT2: F(BPS2)	F(BPS2) = 2	F(BPS2) = 4	F(BPS2) = 8	F(BPS2) = 16
Maximum External Count Frequency	$f_{\text{GPT}}/4$	$f_{\text{GPT}}/8$	$f_{\text{GPT}}/16$	$f_{\text{GPT}}/32$
Input Signal Stable Time	$2 \times t_{\text{GPT}}$	$4 \times t_{\text{GPT}}$	$8 \times t_{\text{GPT}}$	$16 \times t_{\text{GPT}}$

1) Please note the non-linear encoding of bitfield BPS2.

2) Default after reset.

Note: When initializing the GPT2 block, and the block prescaler BPS2 in T6CON needs to be set to a value different from its reset value (00_B), it must be initialized first before any mode involving external trigger signals is configured. These modes include counter, capture, and reload mode. Otherwise, unintended count/capture/reload events may occur.

In this case (e.g. when changing BPS2 during operation of the GPT2 block), disable related interrupts before modification of BPS2, and afterwards clear the corresponding service request flags and re-initialize those registers (T5, T6, CAPREL) that might be affected by a count/capture/reload event.

Internal Count Clock Generation

In Timer Mode and Gated Timer Mode, the count clock for each GPT2 timer is derived from the GPT2 basic clock by a programmable prescaler, controlled by bitfield TxI in the respective timer's control register TxCON.

The count frequency f_{Tx} for a timer Tx and its resolution r_{Tx} are scaled linearly with lower clock frequencies, as can be seen from the following formula:

$$f_{\text{Tx}} = \frac{f_{\text{GPT}}}{F(\text{BPS2}) \times 2^{\langle \text{TxI} \rangle}} \quad r_{\text{Tx}}[\mu\text{s}] = \frac{F(\text{BPS2}) \times 2^{\langle \text{TxI} \rangle}}{f_{\text{GPT}}[\text{MHz}]} \quad (7)$$

The effective count frequency depends on the common module clock prescaler factor F(BPS2) as well as on the individual input prescaler factor $2^{\langle \text{TxI} \rangle}$. [Table 101](#) summarizes the resulting overall divider factors for a GPT2 timer that result from these cascaded prescalers.

[Table 98](#) lists GPT2 timer's parameters (such as count frequency, resolution, and period) resulting from the selected overall prescaler factor and the module clock f_{GPT} . Note that some numbers may be rounded.

General Purpose Timer Units (GPT12)

Table 98 GPT2 Timer Parameters

System Clock = 10 MHz			Overall Divider Factor	System Clock = 40 MHz		
Frequency	Resolution	Period		Frequency	Resolution	Period
5.0 MHz	200 ns	13.11 ms	2	20.0 MHz	50 ns	3.28 ms
2.5 MHz	400 ns	26.21 ms	4	10.0 MHz	100 ns	6.55 ms
1.25 MHz	800 ns	52.43 ms	8	5.0 MHz	200 ns	13.11 ms
625.0 kHz	1.6 μ s	104.9 ms	16	2.5 MHz	400 ns	26.21 ms
312.5 kHz	3.2 μ s	209.7 ms	32	1.25 MHz	800 ns	52.43 ms
156.25 kHz	6.4 μ s	419.4 ms	64	625.0 kHz	1.6 μ s	104.9 ms
78.125 kHz	12.8 μ s	838.9 ms	128	312.5 kHz	3.2 μ s	209.7 ms
39.06 kHz	25.6 μ s	1.678 s	256	156.25 kHz	6.4 μ s	419.4 ms
19.53 kHz	51.2 μ s	3.355 s	512	78.125 kHz	12.8 μ s	838.9 ms
9.77 kHz	102.4 μ s	6.711 s	1024	39.06 kHz	25.6 μ s	1.678 s
4.88 kHz	204.8 μ s	13.42 s	2048	19.53 kHz	51.2 μ s	3.355 s

External Count Clock Input

The external input signals of the GPT2 block are sampled with the GPT2 basic clock (see [Figure 83](#)). To ensure that a signal is recognized correctly, its current level (high or low) must be held active for at least one complete sampling period, before changing. A signal transition is recognized if two subsequent samples of the input signal represent different levels. Therefore, a minimum of two basic clock periods are required for the sampling of an external input signal. Thus, the maximum frequency of an input signal must not be higher than half the basic clock.

[Table 99](#) summarizes the resulting requirements for external GPT2 input signals.

Table 99 GPT2 External Input Signal Limits

GPT2 Basic Clock = 10 MHz		Input Freq. Factor	GPT2 Divider BPS2	Input Phase Duration	GPT2 Basic Clock = 40 MHz	
Max. Input Frequency	Min. Level Hold Time				Max. Input Frequency	Min. Level Hold Time
2.5 MHz	200 ns	$f_{GPT}/4$	01 _B	$2 \times t_{GPT}$	10.0 MHz	50 ns
1.25 MHz	400 ns	$f_{GPT}/8$	00 _B	$4 \times t_{GPT}$	5.0 MHz	100 ns
625.0 kHz	800 ns	$f_{GPT}/16$	11 _B	$8 \times t_{GPT}$	2.5 MHz	200 ns
312.5 kHz	1.6 μ s	$f_{GPT}/32$	10 _B	$16 \times t_{GPT}$	1.25 MHz	400 ns

These limitations are valid for all external input signals to GPT2, including the external count signals in Counter Mode and the gate input signals in Gated Timer Mode.

16.4.7 Interrupt Control for GPT2 Timers and CAPREL

When a timer overflows from $FFFF_H$ to 0000_H (when counting up), or when it underflows from 0000_H to $FFFF_H$ (when counting down), its interrupt request flag in register GPT2_T5 or GPT2_T6I will be set. This will cause an interrupt to the respective timer interrupt vector, if the respective interrupt enable bit is set.

Whenever a transition according to the selection in bit field CI is detected at pin CAPIN, interrupt request flag in register GPT12_CR is set. Setting any request flag will cause an interrupt to the respective timer or CAPREL interrupt vector, if the respective interrupt enable bit is set.

There is an interrupt control register for each of the two timers (T5, T6) and for the CAPREL register. All interrupt control registers have the same structure described in section Interrupt Control.

16.4.8 GPT2 Registers

16.4.8.1 GPT2 Timer Registers

T5

Timer 5 Count Register

(2C_H)

Reset Value: 0000_H

16.7 Implementation of the GPT12 Module

This chapter describes the implementation of the GPT12 module in the TLE9869QXA20 device.

16.7.1 Module Connections

Besides the described intra-module connections, the timer unit blocks GPT1 and GPT2 are connected to their environment in two basic ways:

- **Internal connections** interface the timers with on-chip resources such as clock generation unit, interrupt controller, or other timers.

The GPT module is clocked with the TLE9869QXA20 system clock, so $f_{\text{GPT}} = f_{\text{SYS}}$.

- **External connections** interface the timers with external resources via port pins.

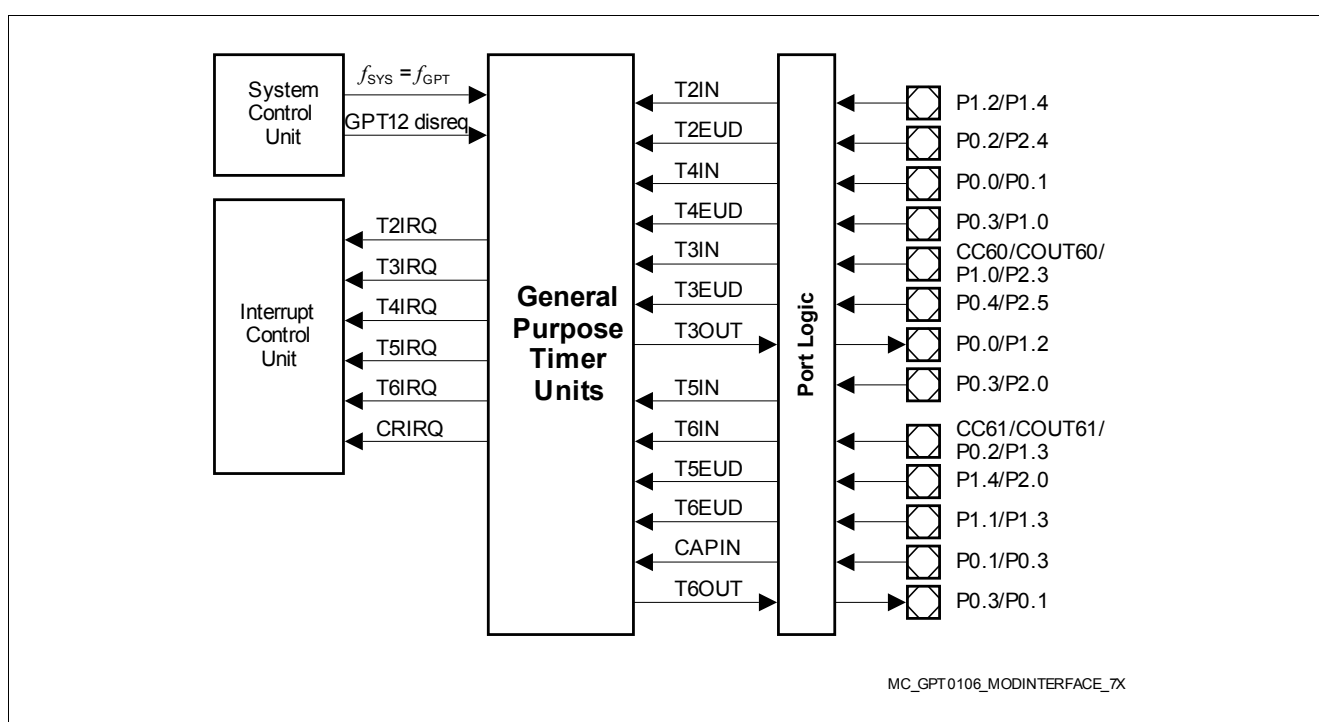

Figure 113 GPT Module Interfaces

Note: The GPT12E output signal 'T6OFL' is connected to the CAPCOM2 input 'TOUF' and to the GSC.

The following table [Table 106](#) (GPT12) shows the digital connections of the GPT12 module with other modules or pins in the TLE9869QXA20 device.

Table 106 GPT12 Digital Connections in TLE9869QXA20

Signal	from/to Module	I/O to GPT	Can be used to/as

CAPIND	read trigger from T2 or T3 or T4	I	
CRIRQ	ICU/SCU	O	interrupt request from capture control

Port Control

Port pins to be used for timer input signals must be switched to input (bitfield PC in the respective port control register must be 0xxx_B) and must be selected via register PISEL.

Port pins to be used for timer output signals must be switched to output and the alternate timer output signal must be selected (bitfield PC in the respective port control register must be 1xxx_B).

Note: For a description of the port control registers, please refer to chapter "Parallel Ports".

Interrupts

The GPT12 has six interrupt request lines.

Interrupt nodes to be used for timer interrupt requests must be enabled and programmed to a specific interrupt level.

Debug Details

While the module GPT is disabled, its registers can still be read. While disabled the following registers can be written: PISEL, T5CON.

17 Timer2 and Timer21

This chapter describes the Timer2 and Timer21. Each timer is a 16-bit timer which additionally can function as a counter. Each Timer 2 module also provides a single channel 16-bit capture.

17.1 Features

- 16-bit auto-reload mode
 - selectable up or down counting
- One channel 16-bit capture mode

17.2 Introduction

The timer modules are general purpose 16-bit timer. Timer 2 can function as a timer or counter in each of its modes. As a timer, it counts with an input clock of PCLK/12 (if prescaler is disabled). As a counter, Timer 2 counts 1-to-0 transitions on pin T2. In the counter mode, the maximum resolution for the count is PCLK/24 (if prescaler is disabled).

Note: "Timer 2" is generally referred in the following description which is applicable to each of the Timer2 and Timer21.

17.2.1 Timer2 and Timer21 Modes Overview

Table 107 Timer2 and Timer21 Modes

Mode	Description
Auto-reload	Up/Down Count Disabled <ul style="list-style-type: none"> • Count up only • Start counting from 16-bit reload value, overflow at FFFF_H • Reload event configurable for trigger by overflow condition only, or by negative/positive edge at input pin T2EX as well • Programmable reload value in register RC2 • Interrupt is generated with reload events.

Table 107 Timer2 and Timer21 Modes (cont'd)

Mode	Description
Auto-reload	Up/Down Count Enabled <ul style="list-style-type: none"> Count up or down, direction determined by level at input pin T2EX No interrupt is generated Count up <ul style="list-style-type: none"> Start counting from 16-bit reload value, overflow at FFFF_H Reload event triggered by overflow condition Programmable reload value in register RC2 Count down <ul style="list-style-type: none"> Start counting from FFFF_H, underflow at value defined in register RC2 Reload event triggered by underflow condition Reload value fixed at FFFF_H
Channel capture	<ul style="list-style-type: none"> Count up only Start counting from 0000_H, overflow at FFFF_H Reload event triggered by overflow condition Reload value fixed at 0000_H Capture event triggered by falling/rising edge at pin T2EX Captured timer value stored in register RC2 Interrupt is generate with reload or capture event

Timer 2 can be started by using TR2 bit by hardware or software. Timer 2 can be started by setting TR2 bit by software. If bit T2RHEN is set, Timer 2 can be started by hardware. Bit T2REGS defines the event on pin T2EX: falling edge or rising edge, that can set the run bit TR2 by hardware. Timer 2 can only be stopped by resetting TR2 bit by software.

17.3 Functional Description

17.3.1 Auto-Reload Mode

The auto-reload mode is selected when the bit CP_RL2 in register **T2CON** is zero. In the auto-reload mode, Timer 2 counts to an overflow value and then reloads its register contents with a 16-bit start value for a fresh counting sequence. The overflow condition is indicated by setting bit TF2 in the **T2CON** register. This will then generate an interrupt request to the core. The overflow flag TF2 must be cleared by software.

The auto-reload mode is further classified into two categories depending upon the DCEN control bit.

17.3.1.1 Up/Down Count Disabled

If DCEN = 0, the up-down count selection is disabled. The timer, therefore, functions as a pure up counter/timer only. The operational block diagram is shown in **Figure 114**.

In this mode, if EXEN2 = 0, the timer starts to count up to a maximum of FFFF_H, once TR2 is set. Upon overflow, bit TF2 is set and the timer register is reloaded with the 16-bit reload value of the RC2 register. This reload value is chosen by software, prior to the occurrence of an overflow condition. A fresh count sequence is started and the timer counts up from this reload value as in the previous count sequence.

If EXEN2 = 1, the timer counts up to a maximum of FFFF_H once TR2 is set. A 16-bit reload of the timer registers from register RC2 is triggered either by an overflow condition or by a negative/positive edge (chosen by T2MOD.EDGESEL) at input pin T2EX. If an overflow caused the reload, the overflow flag TF2 is set. If a negative/positive transition at pin T2EX caused the reload, bit EXF2 is set. In either case, an interrupt is generated

to the core and the timer proceeds to its next count sequence. The EXF2 flag, similar to the TF2, must be cleared by software.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The reload will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

Note: In counter mode, if the reload via T2EX and the count clock T2 are detected simultaneously, the reload takes precedence over the count. The counter increments its value with the following T2 count clock.

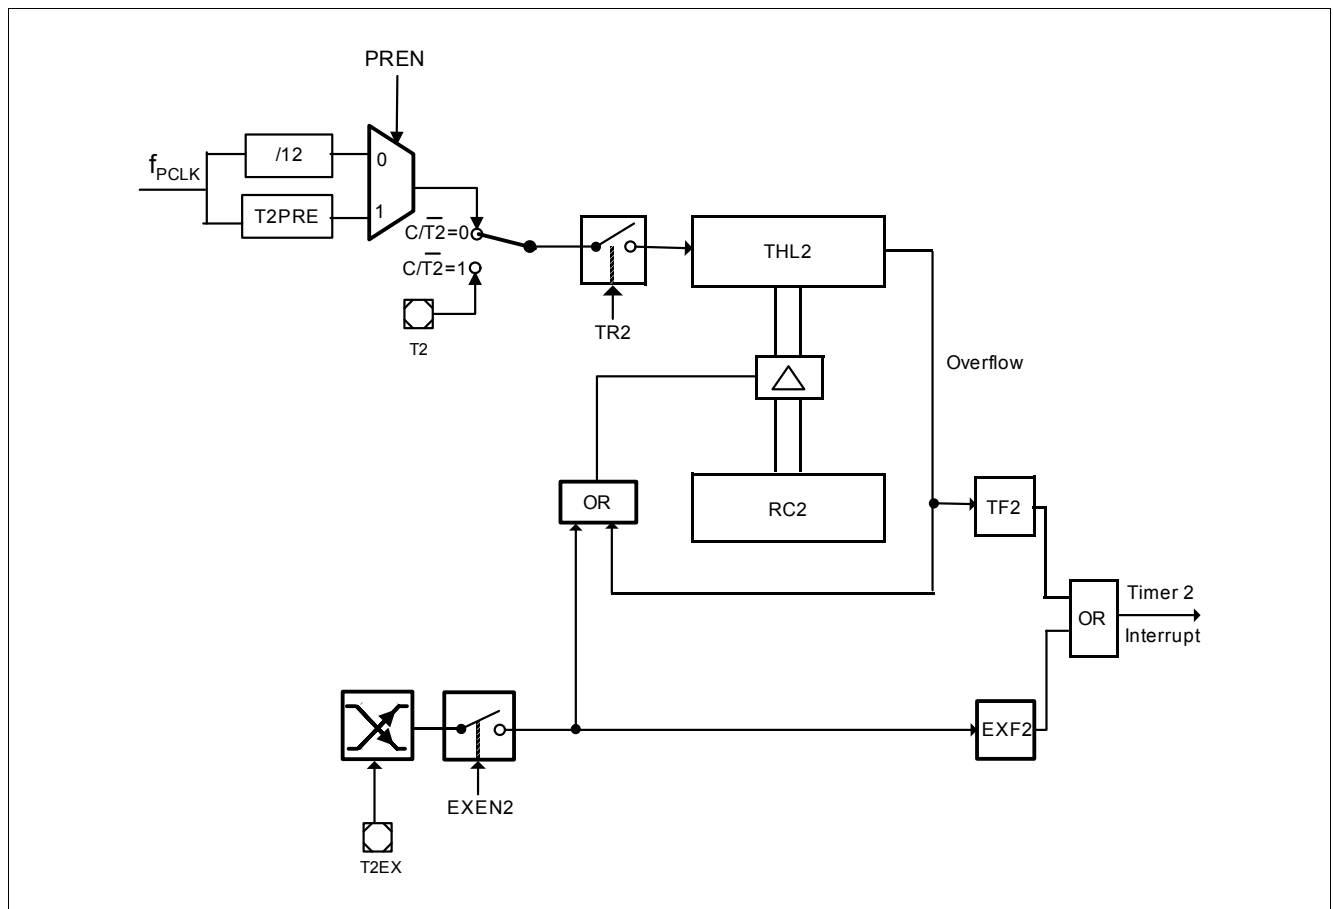

Figure 114 Auto-Reload Mode (DCEN = 0)

17.3.1.2 Up/Down Count Enabled

If DCEN = 1, the up-down count selection is enabled. The direction of count is determined by the level at input pin T2EX. The operational block diagram is shown in [Figure 115](#).

A logic 1 at pin T2EX sets the Timer 2 to up counting mode. The timer, therefore, counts up to a maximum of FFFF_H. Upon overflow, bit TF2 is set and the timer register is reloaded with a 16-bit reload value of the RC2 register. A fresh count sequence is started and the timer counts up from this reload value as in the previous count sequence. This reload value is chosen by software, prior to the occurrence of an overflow condition.

A logic 0 at pin T2EX sets the Timer 2 to down counting mode. The timer counts down and underflows when the THL2 value reaches the value stored at register RC2. The underflow condition sets the TF2 flag and causes FFFF_H to be reloaded into the THL2 register. A fresh down counting sequence is started and the timer counts down as in the previous counting sequence.

Timer2 and Timer21

If bit T2RHEN is set, Timer 2 can only be started either by rising edge (T2REGS = 1) at pin T2EX and then do the up counting, or be started by falling edge (T2REGS = 0) at pin T2EX and then do the down counting.

In this mode, bit EXF2 toggles whenever an overflow or an underflow condition is detected. This flag, however, does not generate an interrupt request.

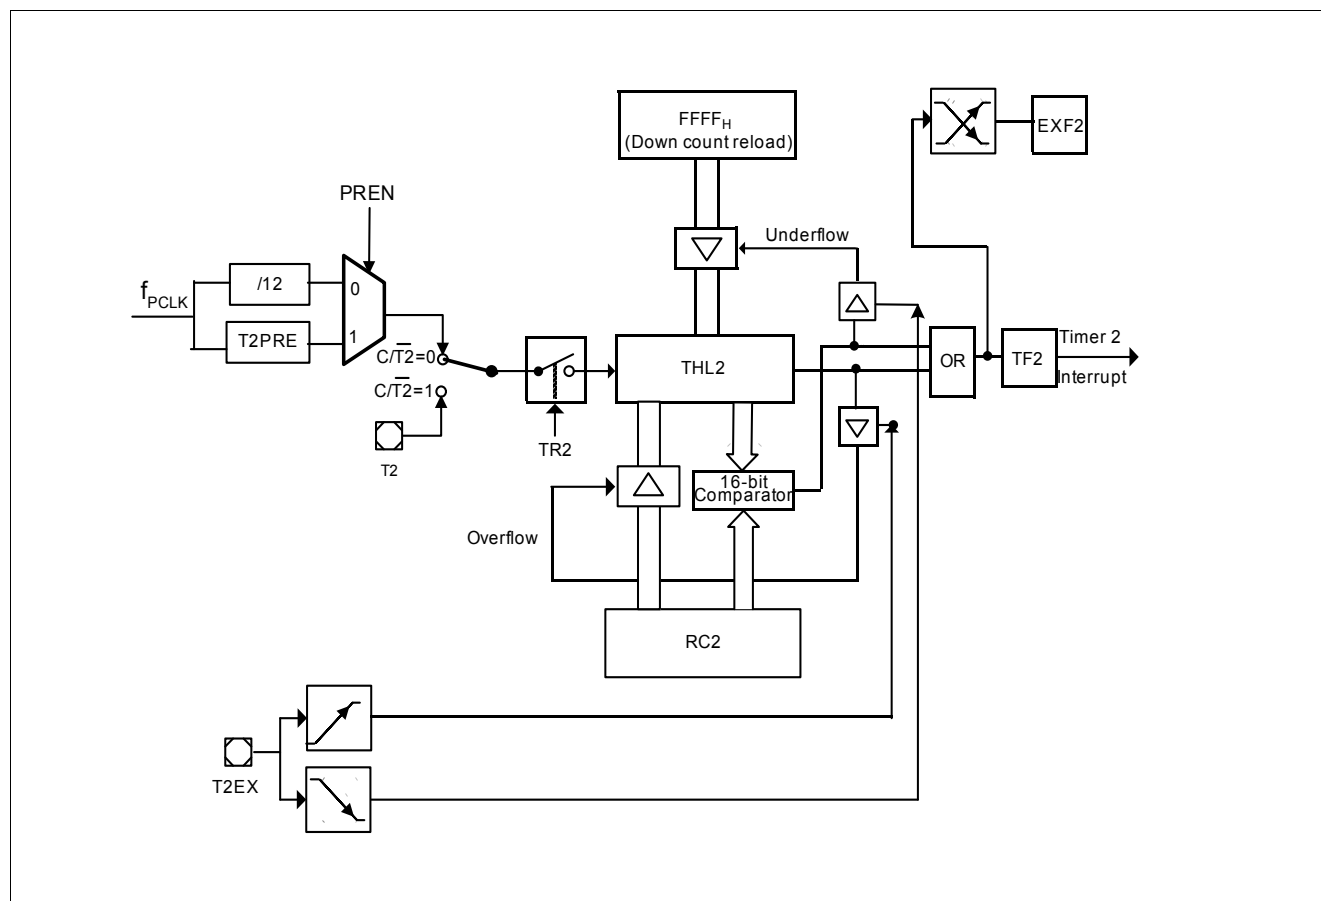

Figure 115 Auto-Reload Mode (DCEN = 1)

17.3.2 Capture Mode

In order to enter the 16-bit capture mode, bits CP_RL2 and EXEN2 in register **T2CON** must be set. In this mode, the down count function must remain disabled. The timer functions as a 16-bit timer or counter and always counts up to FFFF_H and overflows. Upon an overflow condition, bit TF2 is set and the timer reloads its registers with 0000_H. The setting of TF2 generates an interrupt request to the core.

Additionally, with a falling/rising edge on pin T2EX (chosen by T2MOD.EDGESEL) the contents of the timer register (THL2) are captured into the RC2 register. The external input is sampled in every PCLK cycle. When a sampled input shows a low (high) level in one PCLK cycle and a high (low) in the next PCLK cycle, a transition is recognized. If the capture signal is detected while the counter is being incremented, the counter is first incremented before the capture operation is performed. This ensures that the latest value of the timer register is always captured.

If bit T2RHEN is set, Timer 2 is started by first falling edge/rising edge at pin T2EX, which is defined by bit T2REGS. If bit EXEN2 is set, bit EXF2 is also set at the same point when Timer2 is started with the same falling edge/rising edge at pin T2EX, which is defined by bit EDGESEL. The capture will happen with the following negative/positive transitions at pin T2EX, which is defined by bit EDGESEL.

When the capture operation is completed, bit EXF2 is set and can be used to generate an interrupt request. **Figure 116** describes the capture function of Timer 2.

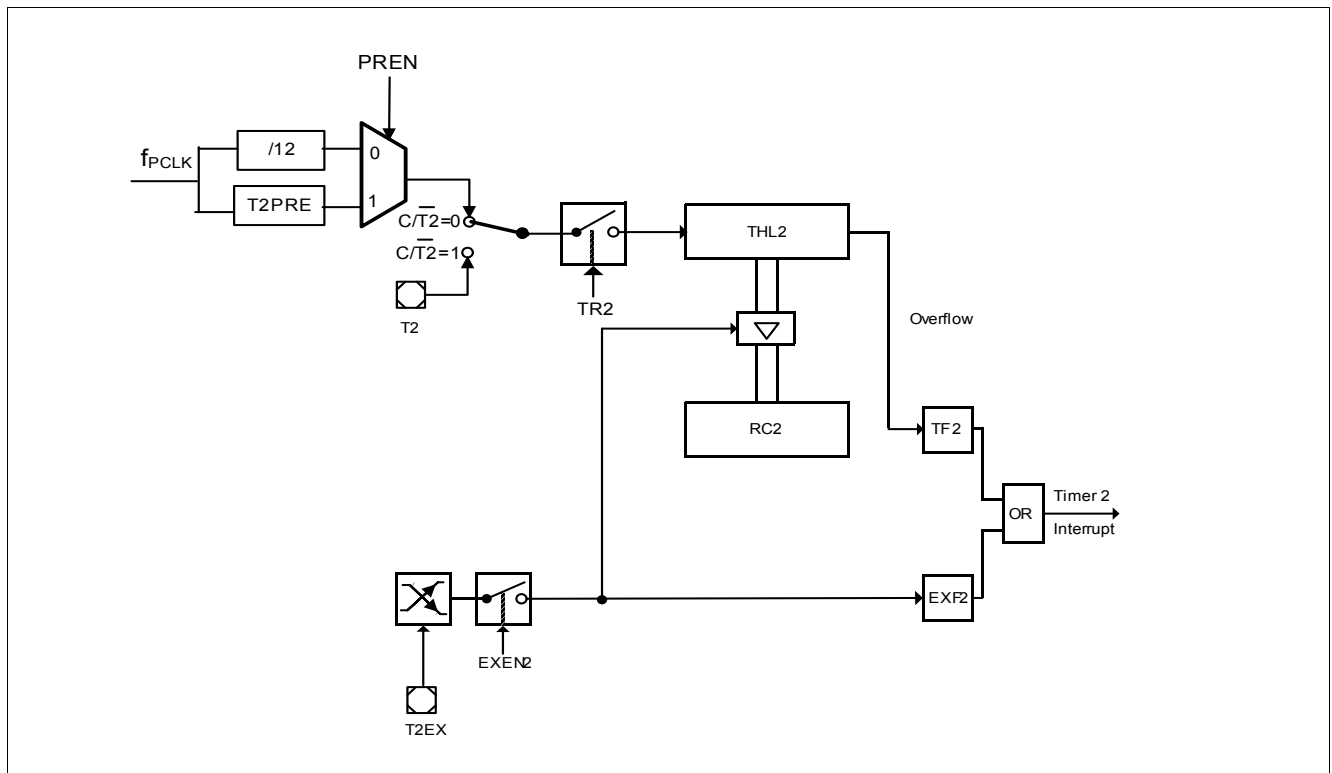

Figure 116 Capture Mode

17.3.3 Count Clock

The count clock for the auto-reload mode is chosen by the bit C_T2 in register **T2CON**. If C_T2 = 0, a count clock of PCLK/12 (if prescaler is disabled) is used for the count operation.

If C_T2 = 1, Timer 2 behaves as a counter that counts 1-to-0 transitions of input pin T2. The counter samples pin T2 over 2 PCLK cycles. If a 1 was detected during the first clock and a 0 was detected in the following clock, then the counter increments by one. Therefore, the input levels should be stable for at least 1 clock.

If bit T2RHEN is set, Timer 2 can be started by the falling edge/rising edge on pin T2EX, which is defined by bit T2REGS.

Note: If pin T2 is not connected, counting clock function on pin T2 cannot be used.

17.4 Module Interfaces

This section describes:

- the TLE9869QXA20 module related interfaces such as port connections and interrupt control
- all TLE9869QXA20 module related registers with their addresses

17.4.1 Interfaces of the Timer2 and Timer21

Overviews of the Timer2 and Timer21 kernel I/O interfaces and interrupt signals are shown in [Figure 117](#) and [Figure 118](#).

Timer2 and Timer21 can be suspended when Debug Mode enters Monitor Mode and has the Debug Suspend signal activated, provided the timer suspend bits, T2SUSP and T21SUSP (in SCU SFR MODSUSP) are set. Refer to SCU chapter.

The interrupt request of the Timer2 and Timer21 is not connected directly to the CPU's Interrupt Controller, but via the System Control Unit (SCU). The General Purpose IO (GPIO) Port provides the interface from the Timer2 and Timer21 to the external world.

The external trigger and counter inputs of the two Timer 2 modules can be selected from several different sources. This selection is performed by the SCU via the corresponding input control and select bits in SFR MODPISEL1 and MODPISEL2.

In the TLE9869QXA20, Timer2 and Timer21 allow additionally to trigger ADC1 conversions through the t2(1)_adc_trigger signals. These trigger signals are generated while the timer is working in timer mode (C_T2 = 0).

Figure 117 Timer 2 Module I/O Interface

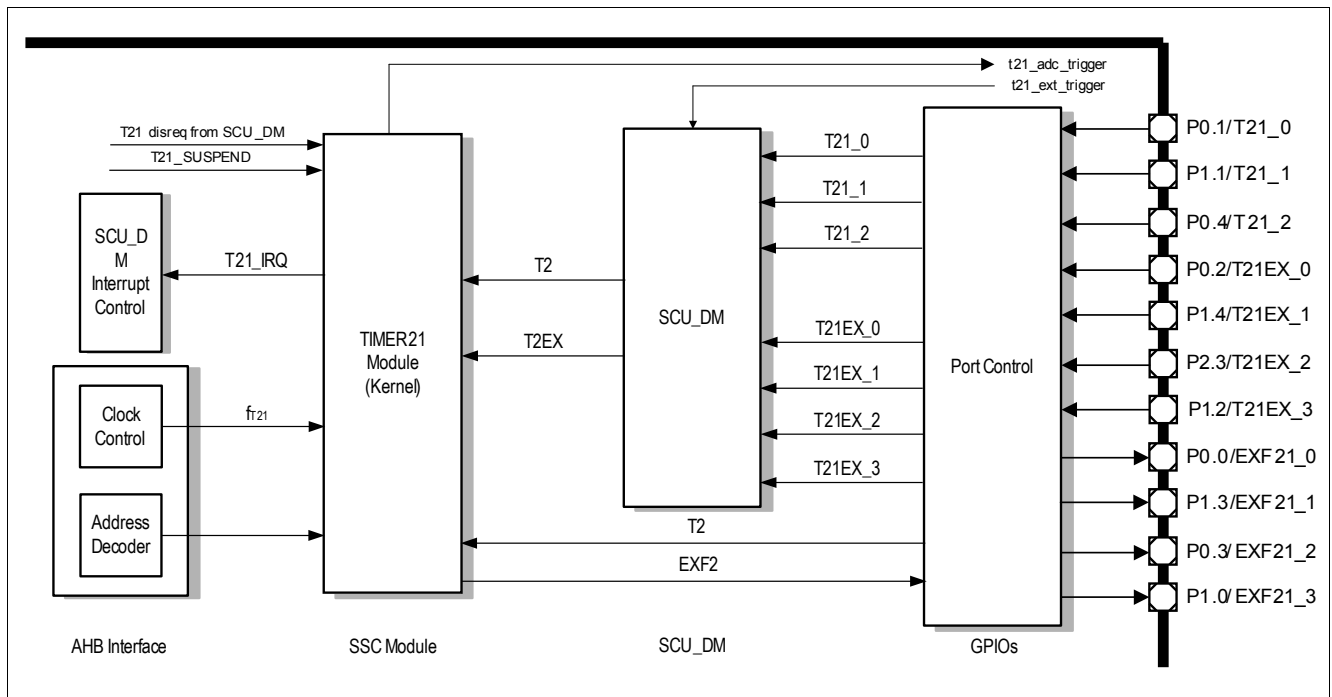

Figure 118 Timer 21 Module I/O Interface

17.5 Interrupt Generation

When an interrupt event happened, the corresponding interrupt flag bit EXF2/TF2 is set; an interrupt for the interrupt event EXF2/TF2 will be generated.

*Note: When the timer/counter is stopped and while the module remains enabled, it is possible for an external event at T2EX to generate an interrupt. For this to occur, bit EXEN2 in SFR **T2CON** must be set. In this case, a dummy reload or capture happens depending on the CP_RL2 bit selection. The resulting interrupt could therefore be used in the product as an external falling/rising edge triggered interrupt.*

17.6 Register Definition

17.6.1 Timer 2 Registers

All Timer2 and Timer21 register names described in the following sections will be referenced in other chapters with the module name prefix "T2_" and "T21_", respectively.

17.6.1.1 Mode Register

The T2MOD is used to configure Timer 2 for various modes of operation.

T2MOD

Timer 2 Mode Register

(04_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0
T2REGS	T2RHEN	EDGESEL	PREN		T2PRE		DCEN
rw	rw	rw	rw		rw		rw

Field	Bits	Type	Description
DCEN	0	rw	Up/Down Counter Enable 0 _B Up/Down Counter function is disabled 1 _B Up/Down Counter function is enabled and controlled by pin T2EX (Up = 1, Down = 0)
T2PRE	3:1	rw	Timer 2 Prescaler Bit Selects the input clock for Timer 2 which is derived from the peripheral clock. 000 _B $f_{T2} = f_{PCLK}$ 001 _B $f_{T2} = f_{PCLK} / 2$ 010 _B $f_{T2} = f_{PCLK} / 4$ 011 _B $f_{T2} = f_{PCLK} / 8$ 100 _B $f_{T2} = f_{PCLK} / 16$ 101 _B $f_{T2} = f_{PCLK} / 32$ 110 _B $f_{T2} = f_{PCLK} / 64$ 111 _B $f_{T2} = f_{PCLK} / 128$
PREN	4	rw	Prescaler Enable 0 _B Prescaler is disabled and the 2 or 12 divider takes effect. 1 _B Prescaler is enabled (see T2PRE bit) and the 2 or 12 divider is bypassed.
EDGESEL	5	rw	Edge Select in Capture Mode/Reload Mode 0 _B The falling edge at Pin T2EX is selected. 1 _B The rising edge at Pin T2EX is selected.
T2RHEN	6	rw	Timer 2 External Start Enable 0 _B Timer 2 External Start is disabled. 1 _B Timer 2 External Start is enabled.
T2REGS	7	rw	Edge Select for Timer 2 External Start 0 _B The falling edge at Pin T2EX is selected. 1 _B The rising edge at Pin T2EX is selected.

17.6.1.2 Control Register

Control register is used to control the operating modes and interrupt of Timer 2.

T2CON

Timer 2 Control Register

(00_H)

Reset Value: 00_H

7	6	5	4	3	2	1	0

Res	7:2	r	Reserved Returns 0 if read; should be written with 0.

17.6.1.3 Timer 2 Reload/Capture Register

The RC2 register is used for a 16-bit reload of the timer count upon overflow or a capture of current timer count depending on the mode selected.

RC2L

Timer 2 Reload/Capture Register, Low Byte

(08_H)

Reset Value: 00_H

Field	Bits	Type	Description
RC2	[7:0]	rw	Reload/Capture Value <i>Note:</i> Reload/Capture Value can be set by software (highest priority) and is updated by hardware during capture mode. These contents are loaded into the timer register upon an overflow condition, if CP_RL2 = 0. If CP_RL2 = 1, this register is loaded with the current timer count upon a negative/positive transition at pin T2EX when EXEN2 = 1.

RC2H

Timer 2 Reload/Capture Register, High Byte

(0C_H)

Reset Value: 00_H

Field	Bits	Type	Description
RC2	[7:0]	rw	Reload/Capture Value <i>Note:</i> Reload/Capture Value can be set by software (highest priority) and is updated by hardware during capture mode. These contents are loaded into the timer register upon an overflow condition, if CP_RL2 = 0. If CP_RL2 = 1, this register is loaded with the current timer count upon a negative/positive transition at pin T2EX when EXEN2 = 1.

17.6.1.4 Timer 2 Count Register

The T2L/T2H register holds the current 16-bit value of the Timer 2 count.

T2L

Timer 2, Low Byte

(10_H)

Reset Value: 00_H

Field	Bits	Type	Description
T2L	[7:0]	rwh	Timer 2 Value These bits indicate the current timer value T2[7:0]. <i>Note:</i> Timer 2 can be updated of software (highest priority) and is updated by hardware if T2R is set

T2H

Timer 2, High Byte

(14_H)

Reset Value: 00_H

Field	Bits	Type	Description
T2H	[7:0]	rw	Timer 2 Value These bits indicate the current timer value T2[15:8]. <i>Note:</i> Timer 2 can be updated of software (highest priority) and is updated by hardware if T2R is set

17.6.2 Register Map

There are two kernels in the TLE9869QXA20, namely Timer2 and Timer21. [Table 108](#) shows the Timer2 and Timer21 module base addresses.

[Table 109](#) lists the addresses of the Timer2 and Timer21 SFRs.

Table 108 Registers Address Space

Module	Base Address	End Address	Note
TIMER2	48004000 _H	48004FFF _H	
TIMER21	48005000 _H	48005FFF _H

18 Timer3

18.1 Features

- 16-bit-upcounting Timer/Counter
- Counting frequency up to f_{sys}
- Selectable clock prescaler
- 6 modes of operation
- Interrupt upon overflow
- Interrupt on compare

18.2 Introduction

The possible applications for the timer include measuring the time interval between events, counting events and generating a signal at regular intervals.

Timer3 can function as timer or counter. When functioning as a timer, Timer3 is incremented in periods based on the MI_CLK or LP_CLK clock. When functioning as a counter, Timer3 is incremented in response to a 1-to-0 transition (falling edge) at its respective input. Timer3 can be configured in four different operating modes to use in a variety of applications, see [Table 110](#).

Various modes of operation are suitable for numerous tasks, like:

- simple time measurement between two events
- triggering of the measuring unit upon PWM/CCU6 unit
- detection precise measurement of the 100kHz LP_CLK2

18.3 Functional Description

Six modes of operation are provided to fulfill various tasks using this timer. In every mode the clocking source can be selected between MI_CLK and LP_CLK. A prescaler provides in addition capability to divide the selected clock source by 2, 4 or 8. The clocking source and the prescaler can be set in the register [APCLK_CTRL2.T3CLK_DIV](#) (SCU). The timer counts upwards, starting with the value in the timer count registers, until the maximum count value which depends on the selected mode of operation. The Timer 3 provides two individual interrupts upon counter overflow, one for the counter register low byte and one for the counter register high byte. The run control of the Timer3 is controlled by software by setting the bits TR3L/TR3H in the register [CTRL](#). Some modes of operation are providing in addition to the software a run control triggered by various hardware sources coming from other modules within the device. Furthermore the Timer 3 provides a 16-bit compare register, [CMP](#). The compare register can be used by some operation modes to issue an overflow interrupt upon matching of the timer counter register to the compare register. The entire Timer 3 module will be enabled by resetting bit T3_DIS in the register [PMCON2](#).

Timer Overflow

When a timer overflow occurs, the timer overflow flag, [T3L_OVF_STS](#) or [T3H_OVF_STS](#), is set, and an interrupt may be raised if the interrupt enable control bit, in the System Control Unit-Power Management is set. The overflow flag has to be cleared when the interrupt service routine is entered.

*Note: When Timer3 operates in Mode 3, the Timer3 control bit **TR3L** is reserved for TL3 and **TR3H** is reserved for TH3. For details see in [Section 18.3.6](#).*

18.3.1 Timer3 Modes Overview

The Timer 3 provides six modes of operation, which are described in the following chapters. The six modes of operations are divided into four main modes. Some of the four main modes are further separated into sub-modes. The bit field T3M in the register **MODE_CONF** selects one out of the four main modes. The bit field T3_SUBM in the register **MODE_CONF** selects a sub-mode of the selected main mode, if applicable. The following table provides an overview of the timer modes together with the reasonable configuration options in **Table 110**.

When the bit **T3_PD_N** is set the timer is reset and the module clock gating is active (valid for all main operating modes).

Table 110 Timer3 Modes

Mode	Sub-Mode	Operation
0	No Sub-Mode	13-bit Timer The timer is essentially an 8-bit counter with a divide-by-32 prescaler.
1	a	16-bit Timer The timer registers, TL3 and TH3, are concatenated to form a 16-bit counter.
1	b	16-bit Timer triggered by an event The timer registers, TL3 and TH3, are concatenated to form a 16-bit counter, which is triggered by an event to enable a single shot measurement on a preset channel with the measurement unit.
2	No Sub-Mode	8-bit Timer with Auto-reload The timer register TL3 is reloaded with a user-defined 8-bit value in TH3 upon overflow.
3	a	Timer3 operates as Two 8-bit Timers The timer registers, TL3 and TH3, operate as two separate 8-bit counters.
3	b	Timer3 operates as Two 8-bit Timers for clock measurement The timer registers, TL3 and TH3, operate as two separate 8-bit counters. In this mode the LP_CLK2 Low Power Clock can be measured. TL3 acts as an edge counter for the clock edges and TH3 as a counter which counts the time between the edges.

The modes are determined in **MODE_CONF**.

Compare	Compare	0	0	1	1	0	1

18.3.2 Mode 0

Mode 0 implements a 13-bit-timer/counter compatible to the 8048 microcontroller. **HI** holds the upper 8 bits of the 13-bit timer value. **LO** holds the lower 5 bits of the 13-bit timer value. The bits **LO** [7:5] are not defined and should not be used in this mode of operation. An overflow will be generated by the transition of the timer value from 0x1FFF to 0x0000.

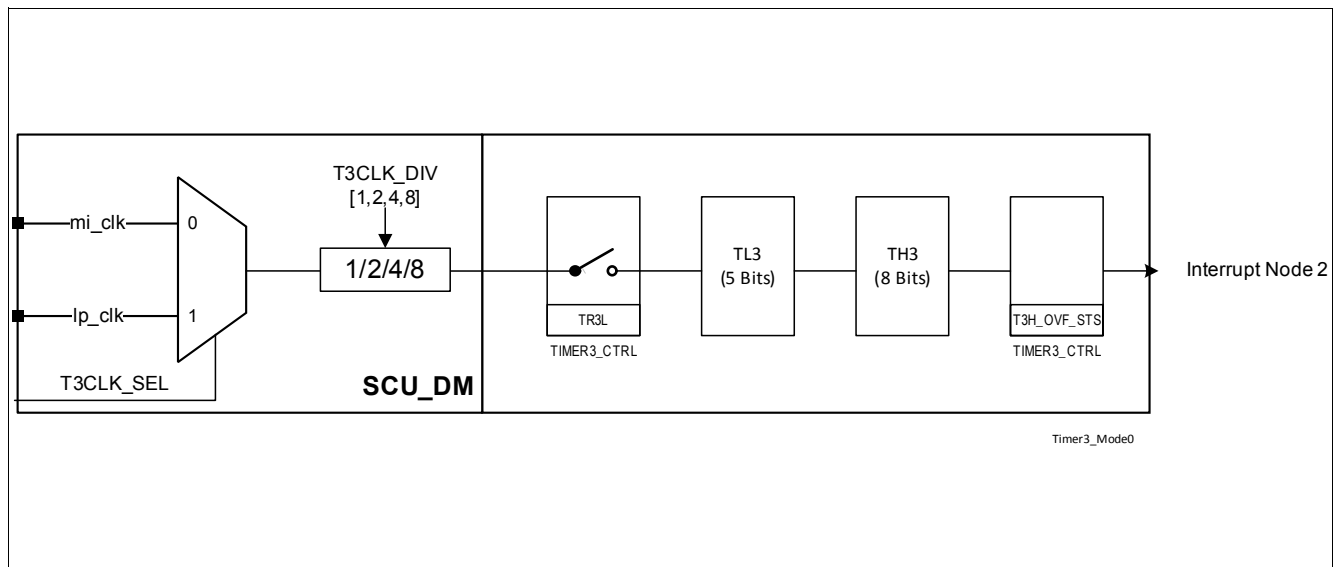

Figure 119 Timer3, Mode 0: 13-Bit Timer

18.3.3 Mode 1a

Mode 1a implements a 16-bit-timer/counter. TIMER3_HI holds the upper 8 bits while TIMER3_LO holds the lower 8 bits of the 16-bit timer value. An overflow will be generated by the transition of the timer value from 0xFFFF to 0x0000.

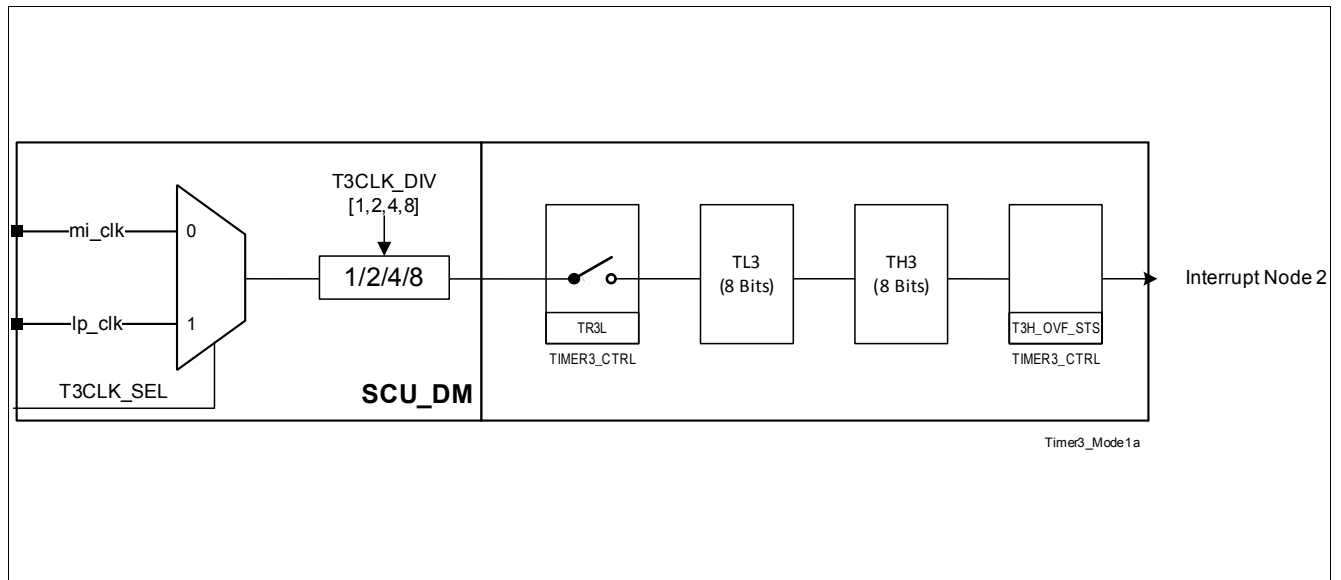

Figure 120 Timer3, Mode 1a: 16-Bit Timer

18.3.4 Mode 1b

Mode 1b is intended to delay certain actions based on a PWM trigger source. The timer operates as a 16-bit-timer. The timer starts counting upwards upon trigger by the selected trigger source. The trigger source has to be selected in the register **T3_TRIGG_CTRL**, bits T3_TRIGG_INP_SEL. To enable a repetitive operation a reset of the timer counter can be defined on the rising edge, falling edge or on both edges of the selected trigger source. The desired selection can be taken in the register **T3_TRIGG_CTRL**, bits T3_RES_CONF. An interrupt will be issued upon overflow, or if the compare value is reached. The compare value may be defined in the registers **CMP**. In this mode the preload of the timer count registers **TIMER3_HI** and **TIMER3_LO** has no effect, the counting always starts with 0x0000 until the set compare value.

This mode can be used to trigger the measurement unit with a desired delay based on a PWM edge to perform measurements synchronous to the selected PWM source. The working principle of this mode is shown in **Figure 1**.

Note: If **TIMER3_CMP_LO** and **TIMER3_CMP_HI** specify a delay that is greater than the pulse width of the PWM signal, the **ccu6_int** is not issued .

Note: The **TIMER3_CMP** value is stored internally (shadowed) on the trigger edge. This means, if the **TIMER3_CMP** value changes during a current PWM period, the change takes effect with the next PWM period.

Note: trigger select **T12_PM** and **T12_ZM** (in **T3_TRIGG_INP_SEL**) shall be only operated with rising edge **T3_RES_CONF**.

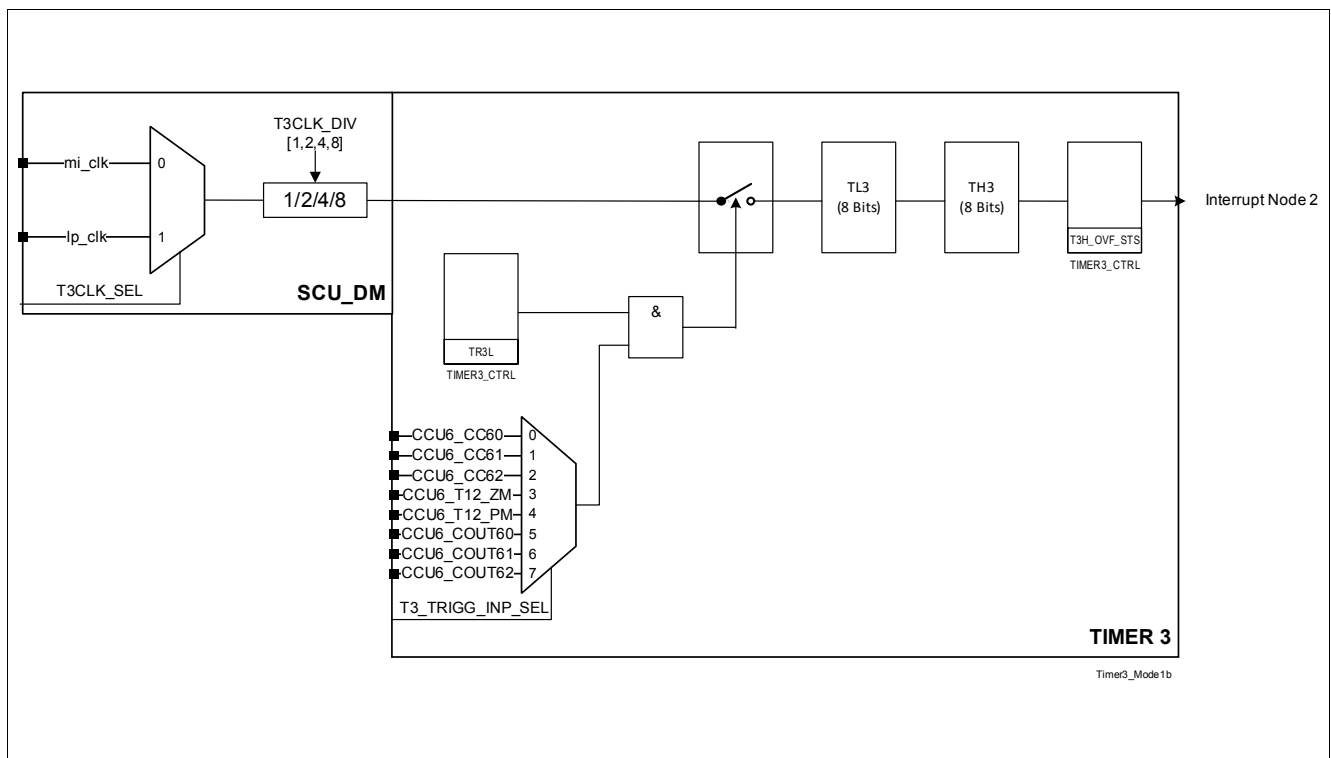

Figure 121 Timer3, Mode 1b: 16-Bit Timer triggered by an event

18.3.5 Mode 2

In Mode 2 the timer operates as a 8-bit-timer with reload. The register `TIMER3_LOW` is the timer value count register, while the register `TIMER3_HIGH` holds the reload value. Upon an overflow of the `TIMER3_LOW` register from 0xFF to 0x00 an interrupt gets issued. Simultaneously the `TIMER3_LOW` register gets loaded with the value in the `TIMER3_HIGH` register. The working principle is shown in [Figure 122](#).

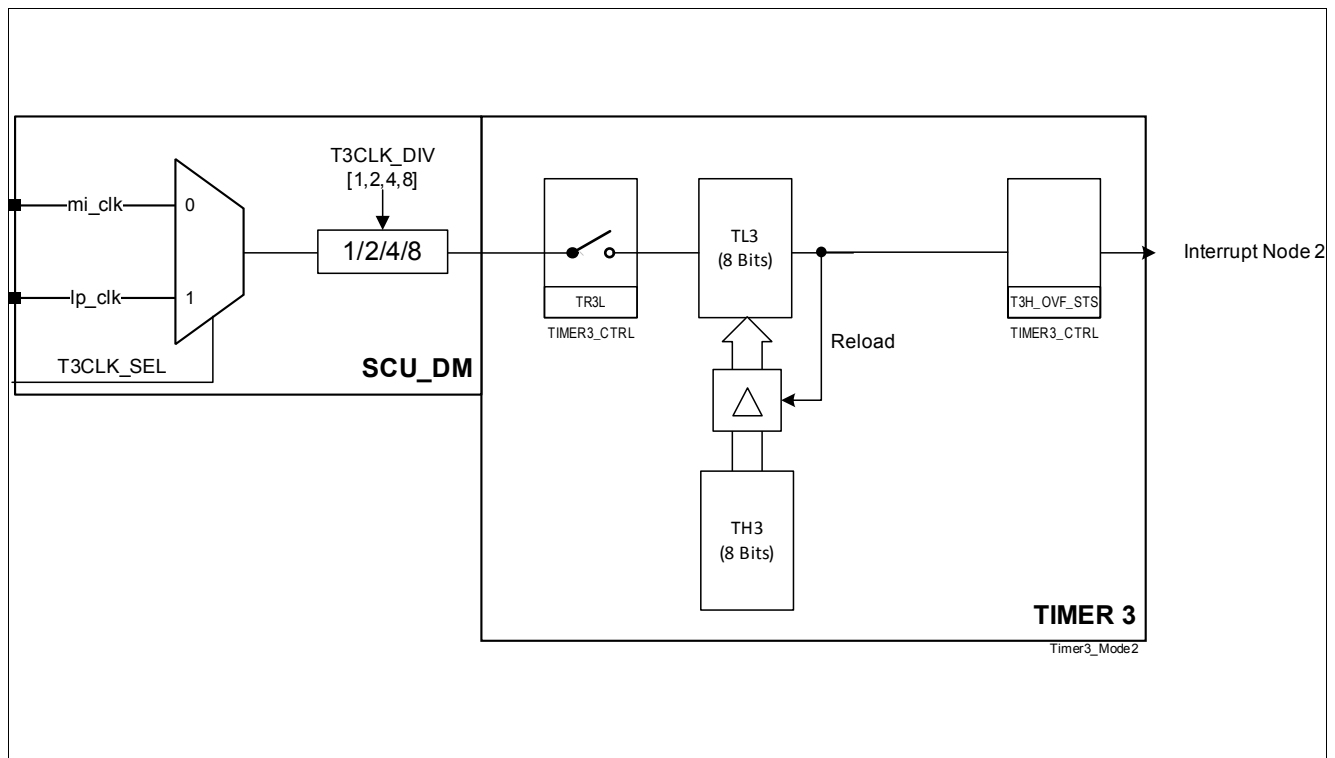

Figure 122 Timer 3, Mode 2: 8-Bit Timer with Auto-Reload

18.3.6 Mode 3a

In Mode 3a, the two Timer 3 registers, TL3 and TH3, function as two separate 8-bit counters.

The 8-bit counter, TL3, uses the Timer 3 control bits TR3 and T3L_OVF_STS, while the other 8-bit counter, TH3, is locked into a timer function (counting machine cycles). Furthermore, TH3 sets the Timer 3 flag bit T3H_OVF_STS, upon overflow and generates an interrupt if is set.

Mode 3a is provided for applications requiring an extra 8-bit timer.

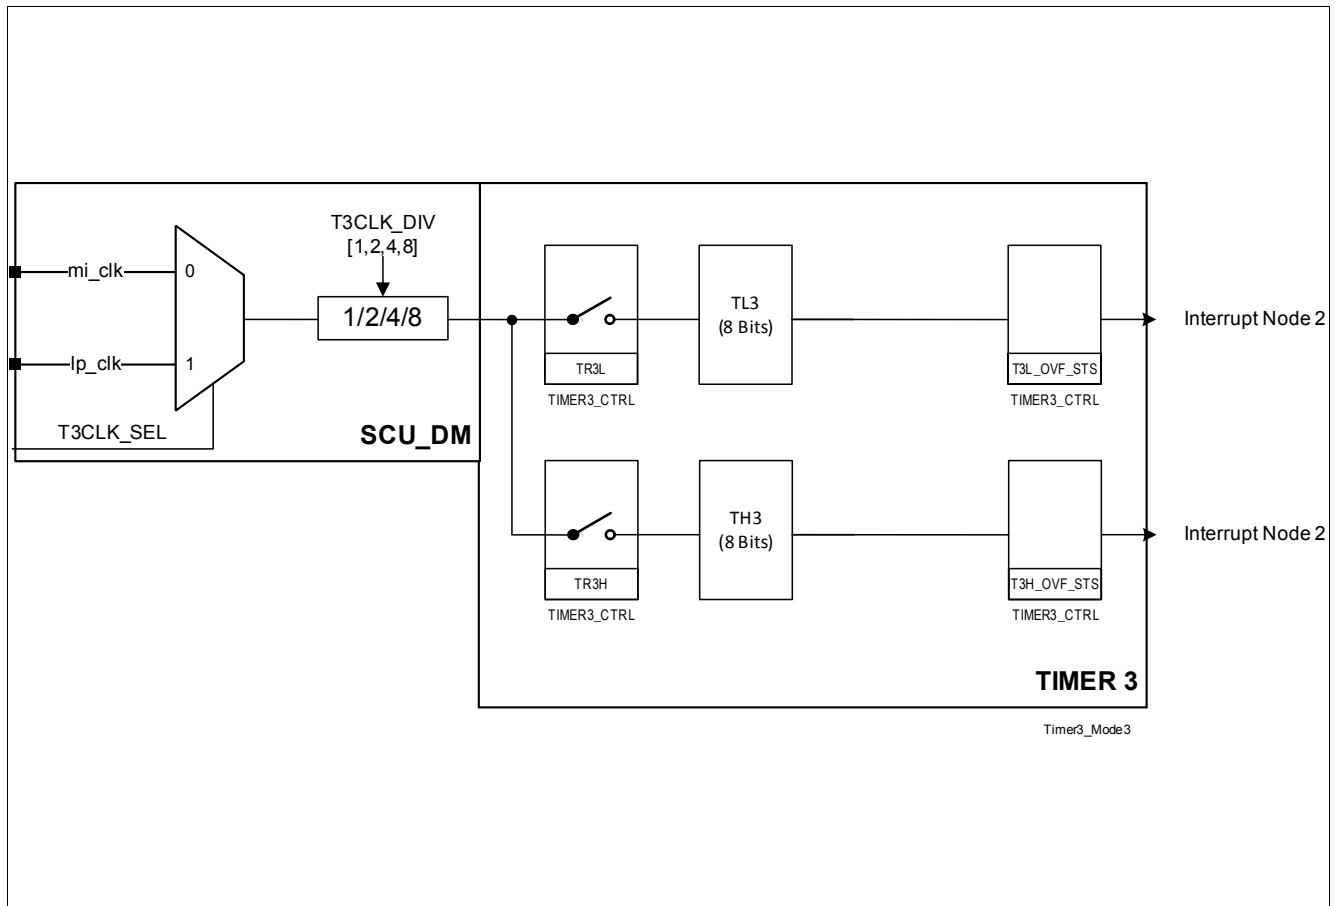

Figure 123 Timer 3, Mode 3a: Two 8-Bit Timers

18.3.7 Mode 3b

The Mode 3b is used to measure the period of the LP_CLK2. The Timer 3 is split up into an 8-bit counter (TIMER3_LO) and an 8-bit timer (TIMER3_HI). The TIMER3_LO counts falling edges of the LP_CLK2, no trigger source selection is required. The TIMER3_CMP_LO defines how many falling edges shall be counted. The TIMER3_HI runs with the selected clocking source and starts counting with the next falling edge on LP_CLK2. Once TIMER3_LO has counted the desired number of edges of the LP_CLK2, by hitting the TIMER3_CMP_LO value an interrupt will be issued and TIMER3_HI stops.

The recommended sequence in order to obtain correct results in the following:

disable the LP_CLK2 in CNF_CYC_SENSE.7

configure mode 3b

start the timer3 with the RUN bit

enable the LP_CLK2 in CNF_CYC_SENSE.7

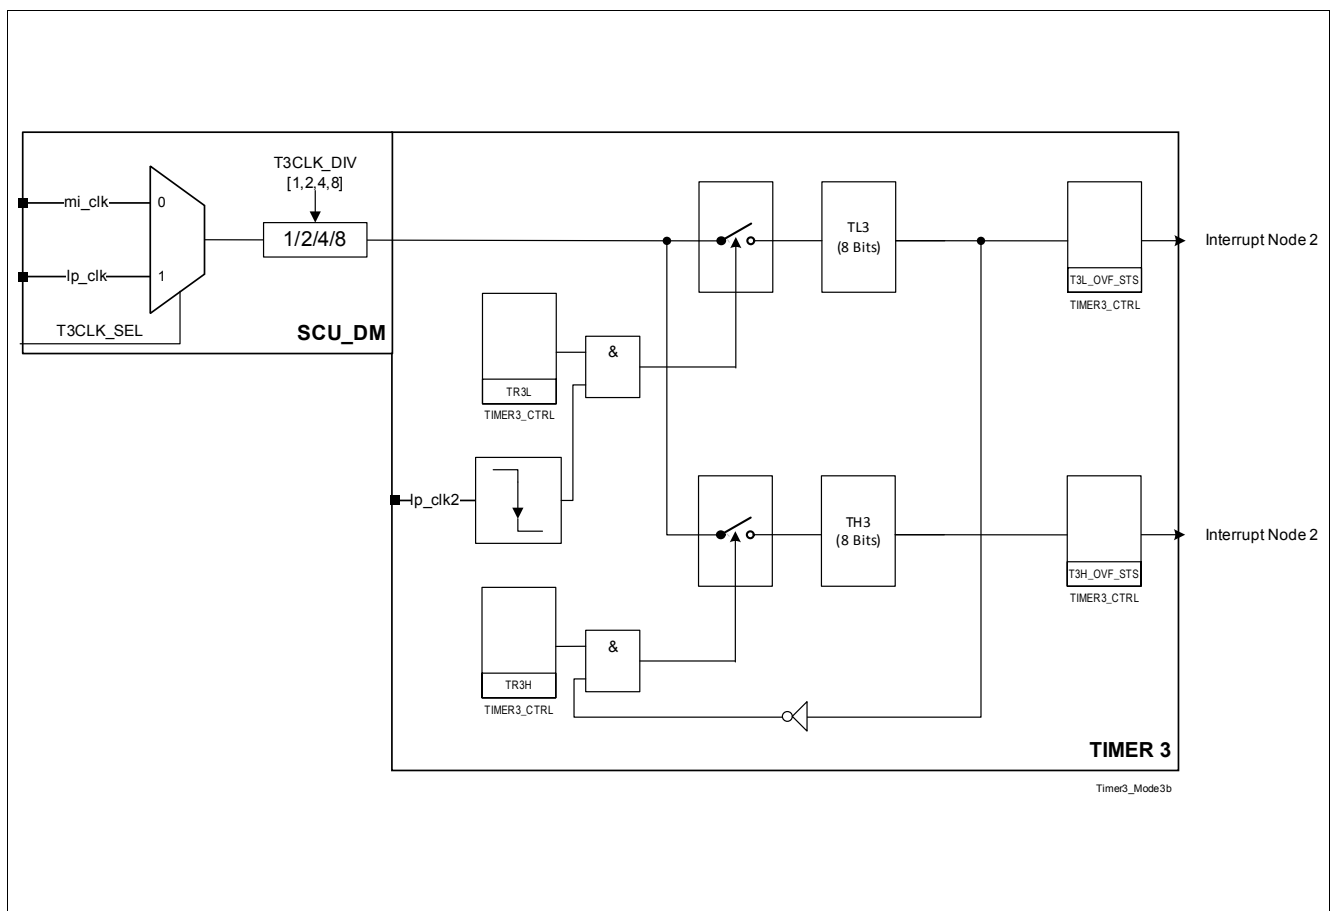

Figure 124 Timer 3, Mode 3b: Two 8-Bit Timers for clock measurement

18.4 Interrupts

Figure 125 shows the interrupt generation of Timer3.

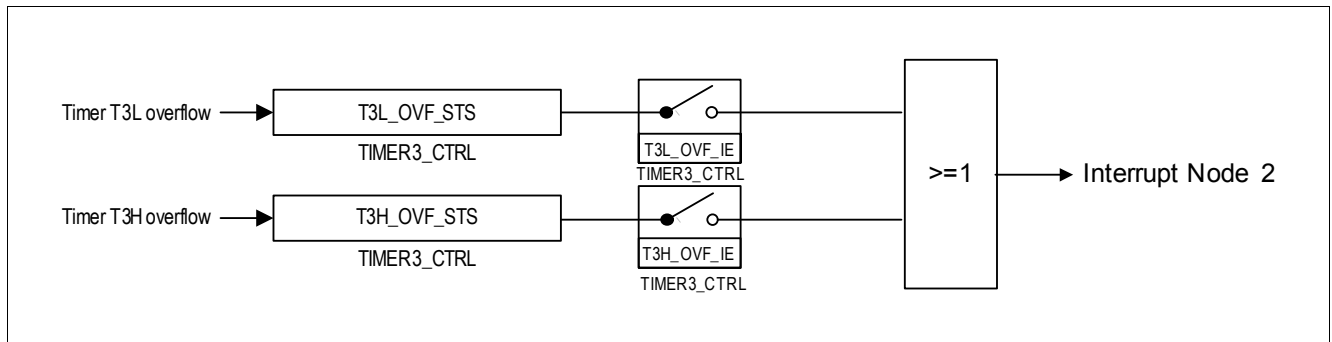

Figure 125 Timer3 Interrupt Generation

The module generates two interrupts. One is assigned to the overflow of lower 8 bit timer, while the other interrupt signals the overflow of the higher 8 bit counter.

18.5 Register Definition

A total of six **SFR** Registers control the operation of Timer 3. TL3/TH3 are the low and high timer registers. **CTRL** and **MODE_CONF** are the mode selection register.

The addresses of the kernel SFRs are listed in Table 113.

Table 112 shows the module base addresses.

Table 112 Register Address Space

Module	Base Address	End Address	Note
TIMER3	4800 6000 _H	4800 6020 _H	

Table 113 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition, Timer 3 Control Registers			
T3_TRIGG_CTRL	Timer 3 Trigger Control Register	00 _H	0000 0000 _H
CMP	Timer 3 Compare Value	04 _H	0000 0000 _H
CNT	Timer 3	08 _H	0000 0000 _H
CTRL	Timer 3 Control Register	0C _H	0000 0001 _H
MODE_CONF	Timer 3 Mode Configuration Register	10 _H	0000 0001 _H
ISRCLR	Timer 3 Interrupt Status Clear Register	14 _H	0000 0000 _H

The registers are addressed wordwise.

18.5.1 Timer 3 Control Registers

After each write access the AHB bus is stalled for at least 2 (timer3_clk) and 3 (hclk) cycles.

Timer 3 Trigger Control Register

The register is reset by RESET_TYPE_3.

T3_TRIGG_CTRL	Offset	Reset Value
Timer 3 Trigger Control Register	00 _H	0000 0000 _H

Field	Bits	Type	Description
Res	31:8	r	Reserved Always read as 0

19 Capture/Compare Unit 6 (CCU6)

The CCU6 is a high-resolution 16-bit capture and compare unit with application specific modes, mainly for AC drive control. Special operating modes support the control of brushless DC-motors using Hall sensors or Back-EMF detection. Furthermore, block commutation and control mechanisms for multi-phase machines are supported.

It also supports inputs to start several timers synchronously, an important feature in devices with several CCU6 modules.

This chapter is structured as follows:

- Functional description of the CCU6 kernel (see [Section 19.2](#))
 - Introduction (see [Section 19.2](#))
 - Operating T12 (see [Section 19.3](#))
 - Operating T13 (see [Section 19.4](#))
 - Trap handling (see [Section 19.5](#))
 - Multi-Channel mode (see [Section 19.6](#))
 - Hall sensor mode (see [Section 19.7](#))
 - Interrupt handling (see [Section 19.10](#))
 - General module operation (see [Section 19.8](#))
- CCU6 kernel registers description (see [Section 19.11.1](#))
- TLE9869QXA20 implementation specific details (see [Section 19.9](#))

19.1 Feature Set Overview

This section gives an overview over the different building blocks and their main features.

Timer 12 Block Features

- Three capture/compare channels, each channel can be used either as capture or as compare channel
- Generation of a three-phase PWM supported (six outputs, individual signals for high-side and low-side switches)
- 16-bit resolution, maximum count frequency = peripheral clock
- Dead-time control for each channel to avoid short-circuits in the power stage
- Concurrent update of T12 registers
- Center-aligned and edge-aligned PWM can be generated
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events
- Multiple interrupt request sources
- Hysteresis-like control mode

Timer 13 Block Features

- One independent compare channel with one output
- 16-bit resolution, maximum count frequency = peripheral clock
- Concurrent update of T13 registers
- Can be synchronized to T12
- Interrupt generation at period-match and compare-match
- Single-shot mode supported
- Start can be controlled by external events
- Capability of counting external events

Additional Specific Functions

- Block commutation for brushless DC-drives implemented
- Position detection via hall-sensor pattern
- Noise filter supported for position input signals
- Automatic rotational speed measurement and commutation control for block commutation
- Integrated error handling
- Fast emergency stop without CPU load via external signal ($\overline{\text{CTRAP}}$)
- Control modes for multi-channel AC-drives
- Output levels can be selected and adapted to the power stage

19.2 Introduction

The CCU6 unit is made up of a Timer T12 block with three capture/compare channels and a Timer T13 block with one compare channel. The T12 channels can independently generate PWM signals or accept capture triggers, or they can jointly generate control signal patterns to drive DC-motors or inverters.

A rich set of status bits, synchronized updating of parameter values via shadow registers, and flexible generation of interrupt request signals provide means for efficient software-control.

Note: The capture/compare module itself is named CCU6 (capture/compare unit 6). A capture/compare channel inside this module is named CC6x.

The Timer T12 can work in capture and/or compare mode for its three channels. The modes can also be combined (e.g. a channel works in compare mode, whereas another channel works in capture mode). The Timer T13 can work in compare mode only. The multi-channel control unit generates output patterns which can be modulated by T12 and/or T13. The modulation sources can be selected and combined for the signal modulation.

19.2.1 Block Diagram

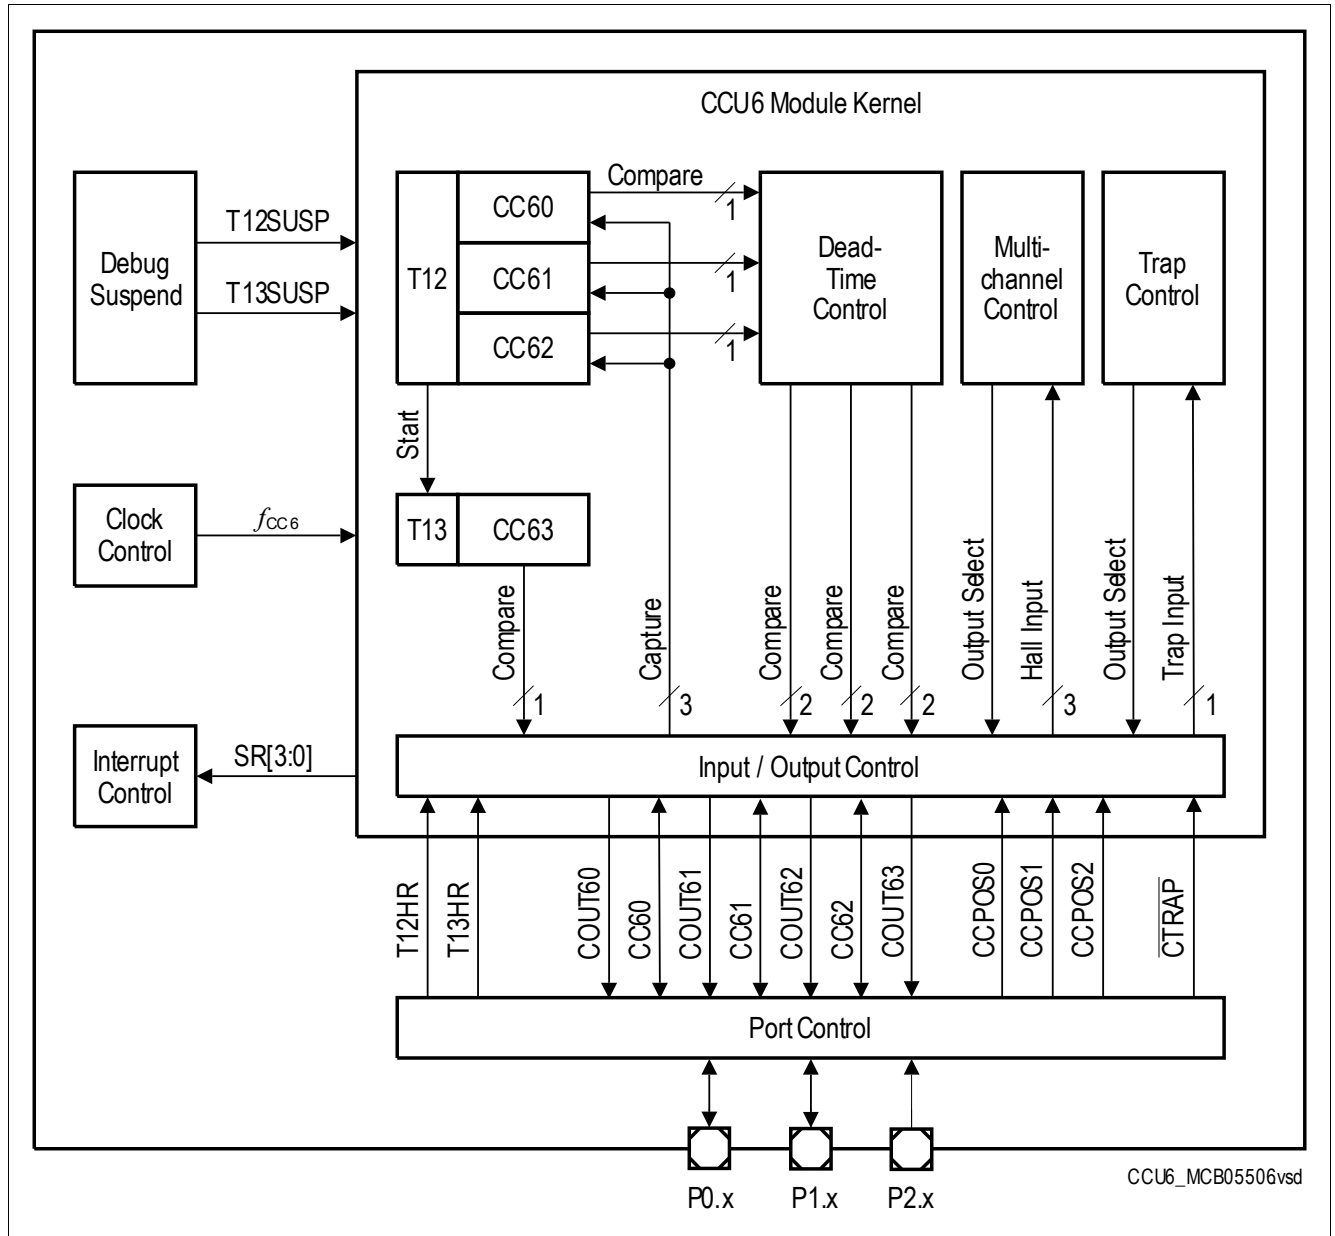

Figure 126 CCU6 Block Diagram

19.3 Operating Timer T12

The timer T12 block is the main unit to generate the 3-phase PWM signals. A 16-bit counter is connected to 3 channel registers via comparators, that generate a signal when the counter contents match one of the channel register contents. A variety of control functions facilitate the adaptation of the T12 structure to different application needs.

Besides the 3-phase PWM generation, the T12 block offers options for individual compare and capture functions, as well as dead-time control and hysteresis-like compare mode.

This section provides information about:

- T12 overview (see [Section 19.3.1](#))
- Counting scheme (see [Section 19.3.2](#))
- Compare modes (see [Section 19.3.3](#))
- Compare mode output path (see [Section 19.3.4](#))
- Capture modes (see [Section 19.3.5](#))
- Shadow transfer (see [Section 19.3.6](#))
- T12 operating mode selection (see [Section 19.3.7](#))

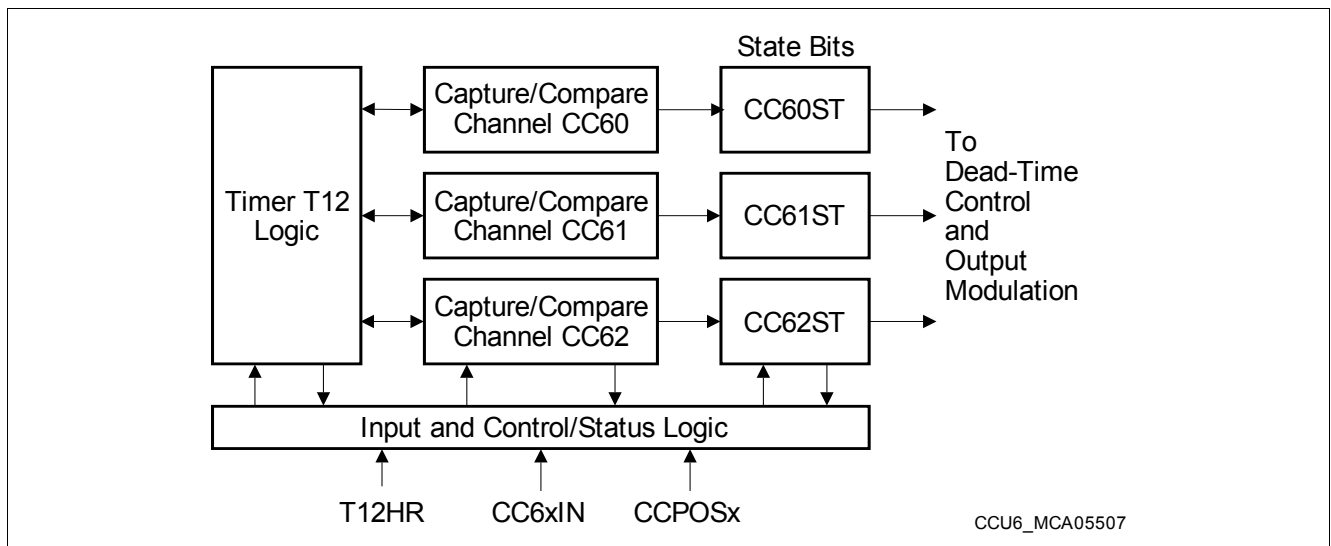

Figure 127 Overview Diagram of the Timer T12 Block

19.3.1 T12 Overview

Figure 128 shows a detailed block diagram of Timer T12. The functions of the timer T12 block are controlled by bits in registers TCTR0, TCTR2, and PISEL0.

Timer T12 receives its input clock (f_{T12}) from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T12HR. These options are controlled via bit fields T12CLK and T12PRE (see **Table 114**). T12 can count up or down, depending on the selected operation mode. A direction flag, CDIR, indicates the current counting direction.

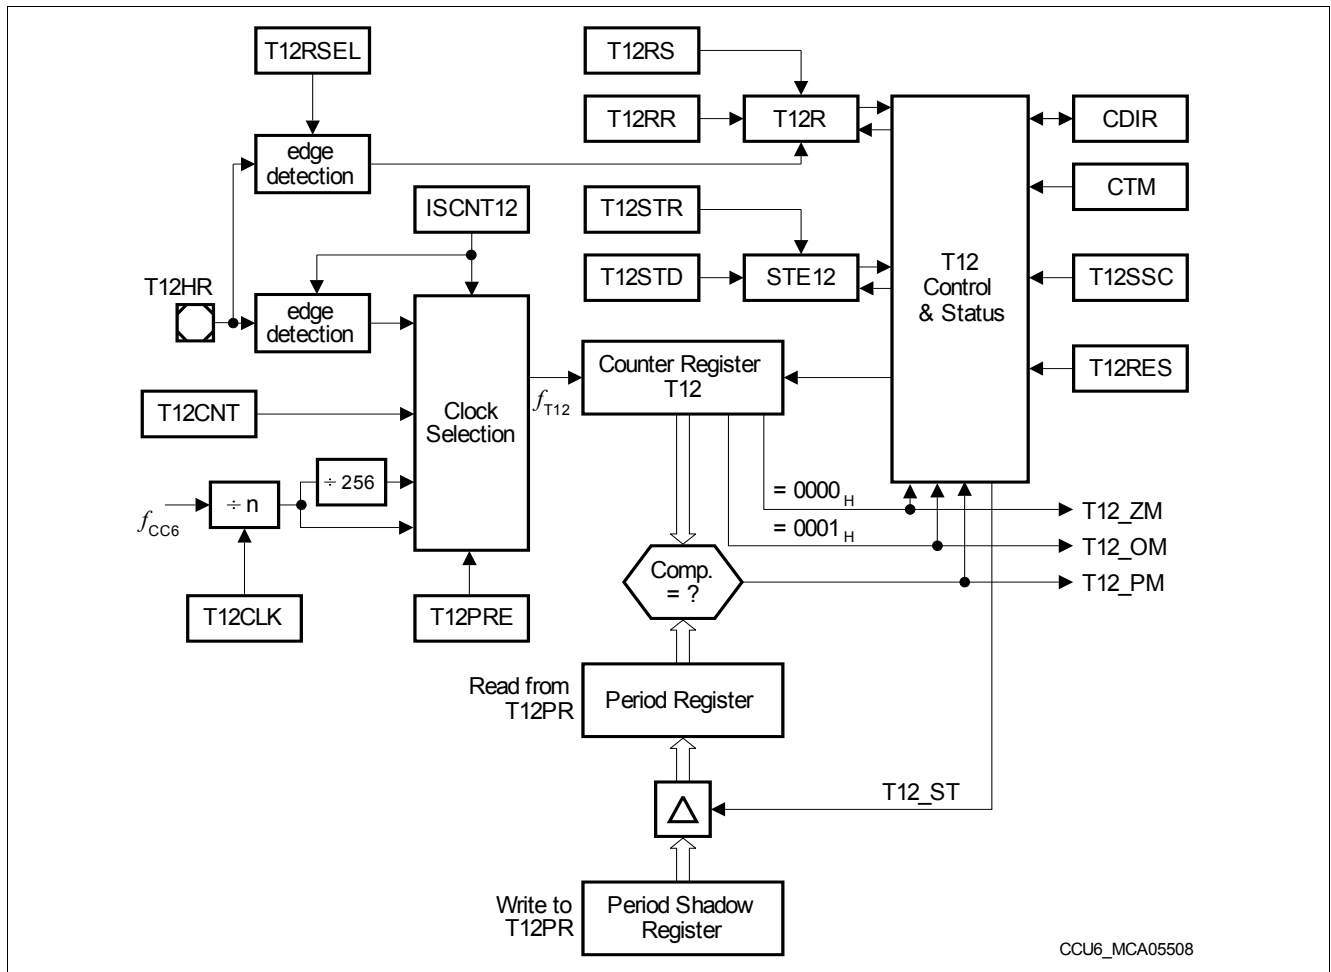

Figure 128 Timer T12 Logic and Period Comparators

Via a comparator, the T12 counter register T12 is connected to a Period Register T12PR. This register determines the maximum count value for T12.

In Edge-Aligned mode, T12 is cleared to 0000_H after it has reached the period value defined by T12PR. In Center-Aligned mode, the count direction of T12 is set from 'up' to 'down' after it has reached the period value (please note that in this mode, T12 exceeds the period value by one before counting down). In both cases, signal T12_PM (T12 Period Match) is generated. The Period Register receives a new period value from its Shadow Period Register.

A read access to T12PR delivers the current period value at the comparator, whereas a write access targets the Shadow Period Register to prepare another period value. The transfer of a new period value from the Shadow Period Register into the Period Register (see **Section 19.3.6**) is controlled via the 'T12 Shadow Transfer' control signal, T12_ST. The generation of this signal depends on the operating mode and on the shadow transfer enable bit STE12. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal allows a concurrent update by software for all relevant parameters.

Two further signals indicate whether the counter contents are equal to 0000_H (T12_ZM = zero match) or 0001_H (T12_OM = one match). These signals control the counting and switching behavior of T12.

The basic operating mode of T12, either Edge-Aligned mode ([Figure 129](#)) or Center-Aligned mode ([Figure 130](#)), is selected via bit CTM. A Single-Shot control bit, T12SSC, enables an automatic stop of the timer when the current counting period is finished (see [Figure 131](#) and [Figure 132](#)).

The start or stop of T12 is controlled by the Run bit T12R that can be modified by bits in register TCTR4. The run bit can be set/cleared by software via the associated set/clear bits T12RS or T12RR, it can be set by a selectable edge of the input signal T12HR (TCTR2.T12RSEL), or it is cleared by hardware according to preselected conditions.

The timer T12 run bit T12R must not be set while the applied T12 period value is zero. Timer T12 can be cleared via control bit T12RES. Setting this write-only bit does only clear the timer contents, but has no further effects, for example, it does not stop the timer.

The generation of the T12 shadow transfer control signal, T12_ST, is enabled via bit STE12. This bit can be set or reset by software indirectly through its associated set/clear control bits T12STR and T12STD.

While Timer T12 is running, write accesses to the count register T12 are not taken into account. If T12 is stopped and the Dead-Time counters are 0, write actions to register T12 are immediately taken into account.

19.3.2 T12 Counting Scheme

This section describes the clocking and counting capabilities of T12.

19.3.2.1 Clock Selection

In **Timer Mode** (PISEL2.ISCNT12 = 00_B), the input clock f_{T12} of Timer T12 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in [Table 114](#). The prescaler of T12 is cleared while T12 is not running (TCTR0.T12R = 0) to ensure reproducible timings and delays.

Table 114 Timer T12 Input Frequency Options

T12CLK	Resulting Input Clock f_{T12} Prescaler Off (T12PRE = 0)	Resulting Input Clock f_{T12} Prescaler On (T12PRE = 1)
000 _B	f_{CC6}	$f_{CC6} / 256$
001 _B	$f_{CC6} / 2$	$f_{CC6} / 512$
010 _B	$f_{CC6} / 4$	$f_{CC6} / 1024$
011 _B	$f_{CC6} / 8$	$f_{CC6} / 2048$
100 _B	$f_{CC6} / 16$	$f_{CC6} / 4096$
101 _B	$f_{CC6} / 32$	$f_{CC6} / 8192$
110 _B	$f_{CC6} / 64$	$f_{CC6} / 16384$
111 _B	$f_{CC6} / 128$	$f_{CC6} / 32768$

In **Counter Mode**, timer T12 counts one step:

- If a 1 is written to TCTR4.T12CNT and PISEL2.ISCNT12 = 01_B
- If a rising edge of input signal T12HR is detected and PISEL2.ISCNT12 = 10_B
- If a falling edge of input signal T12HR is detected and PISEL2.ISCNT12 = 11_B

19.3.2.2 Edge-Aligned / Center-Aligned Mode

In **Edge-Aligned Mode** (CTM = 0), timer T12 is always counting upwards (CDIR = 0). When reaching the value given by the period register (period-match T12_PM), the value of T12 is cleared with the next counting step (saw tooth shape).

Figure 129 T12 Operation in Edge-Aligned Mode

As a result, in Edge-Aligned mode, the timer period is given by:

$$T12_{PER} = \langle \text{Period-Value} \rangle + 1; \text{ in } T12 \text{ clocks } (f_{T12}) \quad (8)$$

In **Center-Aligned Mode** (CTM = 1), timer T12 is counting upwards or downwards (triangular shape). When reaching the value given by the period register (period-match T12_PM) while counting upwards (CDIR = 0), the counting direction control bit CDIR is changed to downwards (CDIR = 1) with the next counting step.

When reaching the value 0001_H (one-match T12_OM) while counting downwards, the counting direction control bit CDIR is changed to upwards with the next counting step.

As a result, in Center-Aligned mode, the timer period is given by:

$$T12_{PER} = (\langle \text{Period-Value} \rangle + 1) \times 2; \text{ in } T12 \text{ clocks } (f_{T12}) \quad (9)$$

- With the next clock event of f_{T12} the count direction is set to counting up (CDIR = 0) when the counter reaches 0001_H while counting down.
- With the next clock event of f_{T12} the count direction is set to counting down (CDIR = 1) when the Period-Match is detected while counting up.
- With the next clock event of f_{T12} the counter counts up while CDIR = 0 and it counts down while CDIR = 1.

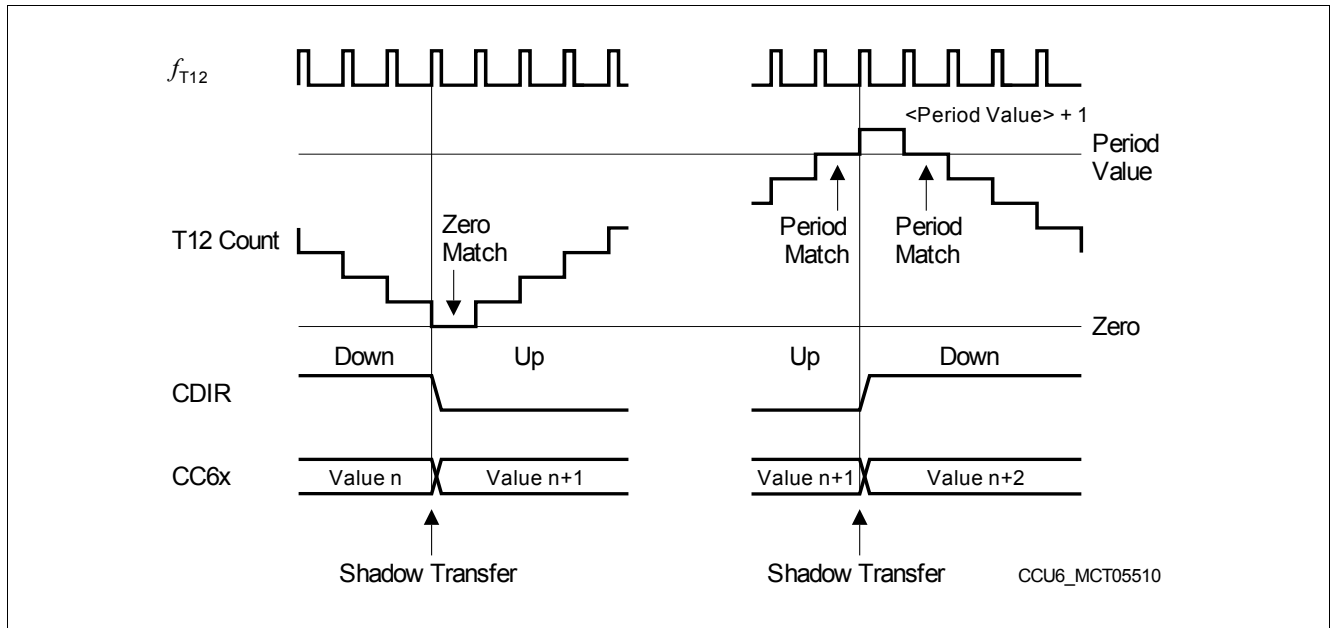

Figure 130 T12 Operation in Center-Aligned Mode

Note: Bit CDIR changes with the next timer clock event after the one-match or the period-match. Therefore, the timer continues counting in the previous direction for one cycle before actually changing its direction (see [Figure 130](#)).

19.3.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T12R is cleared by hardware. If bit T12SSC = 1, the timer T12 will stop when the current timer period is finished.

In Edge-Aligned mode, T12R is cleared when the timer becomes zero after having reached the period value (see [Figure 131](#)).

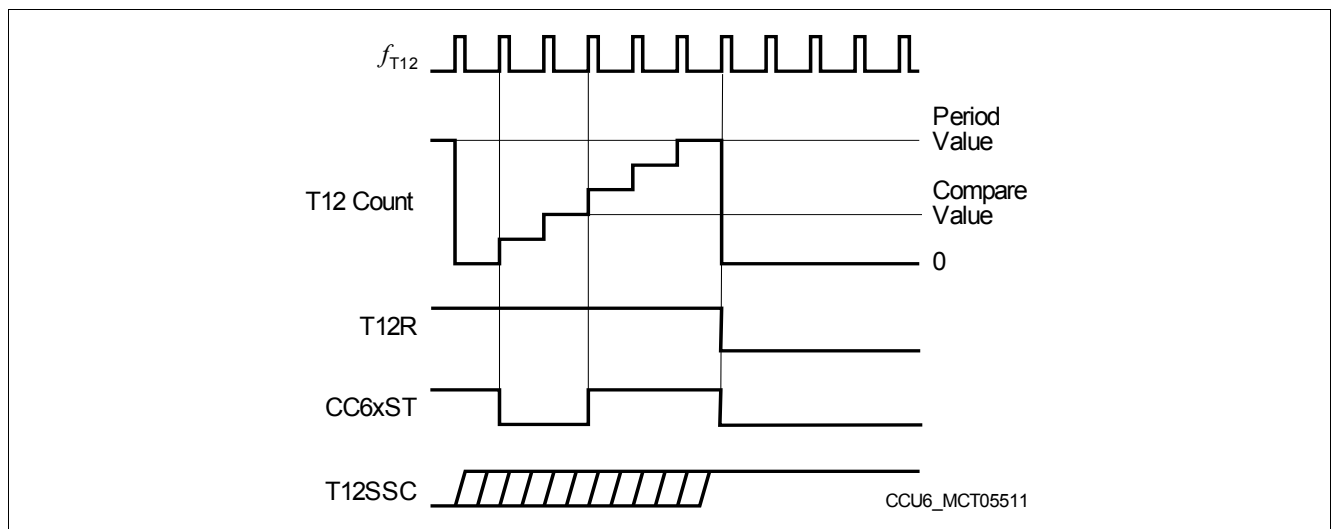

Figure 131 Single-Shot Operation in Edge-Aligned Mode

In Center-Aligned mode, the period is finished when the timer has counted down to zero (one clock cycle after the one-match while counting down, see [Figure 132](#)).

Figure 132 Single-Shot Operation in Center-Aligned Mode

19.3.3 T12 Compare Mode

Associated with Timer T12 are three individual capture/compare channels, that can perform compare or capture operations with regard to the contents of the T12 counter. The capture functions are explained in [Section 19.3.5](#).

19.3.3.1 Compare Channels

In Compare Mode (see [Figure 133](#)), the three individual compare channels CC60, CC61, and CC62 can generate a three-phase PWM pattern.

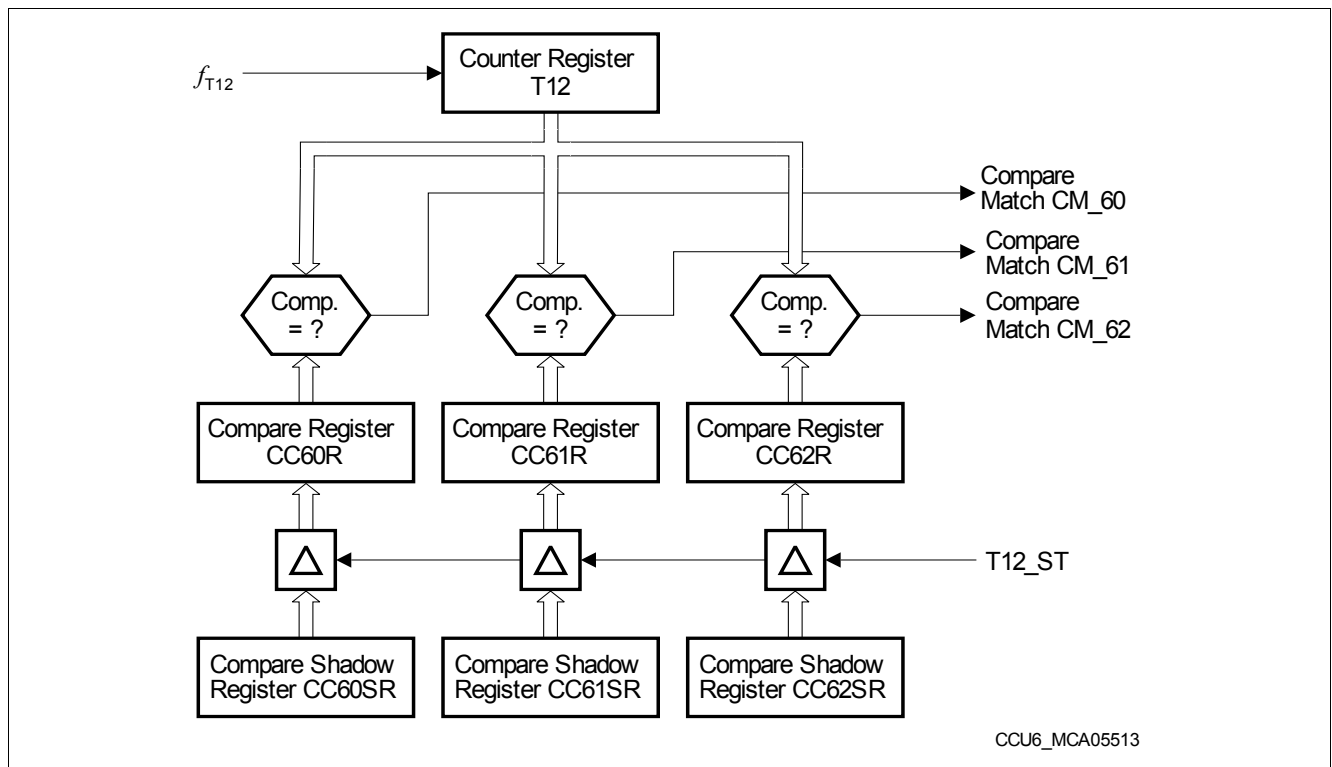

Figure 133 T12 Channel Comparators

Each compare channel is connected to the T12 counter register via its individual equal-to comparator, generating a match signal when the contents of the counter matches the contents of the associated compare register. Each channel consists of the comparator and a double register structure - the actual compare register CC6xR, feeding the comparator, and an associated shadow register CC6xSR, that is preloaded by software and transferred into the compare register when signal T12 shadow transfer, T12_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters of a three-phase PWM.

19.3.3.2 Channel State Bits

Associated with each (compare) channel is a State Bit, CMPSTAT.CC6xST, holding the status of the compare (or capture) operation (see [Figure 134](#)). In compare mode, the State Bits are modified according to a set of switching rules, depending on the current status of timer T12.

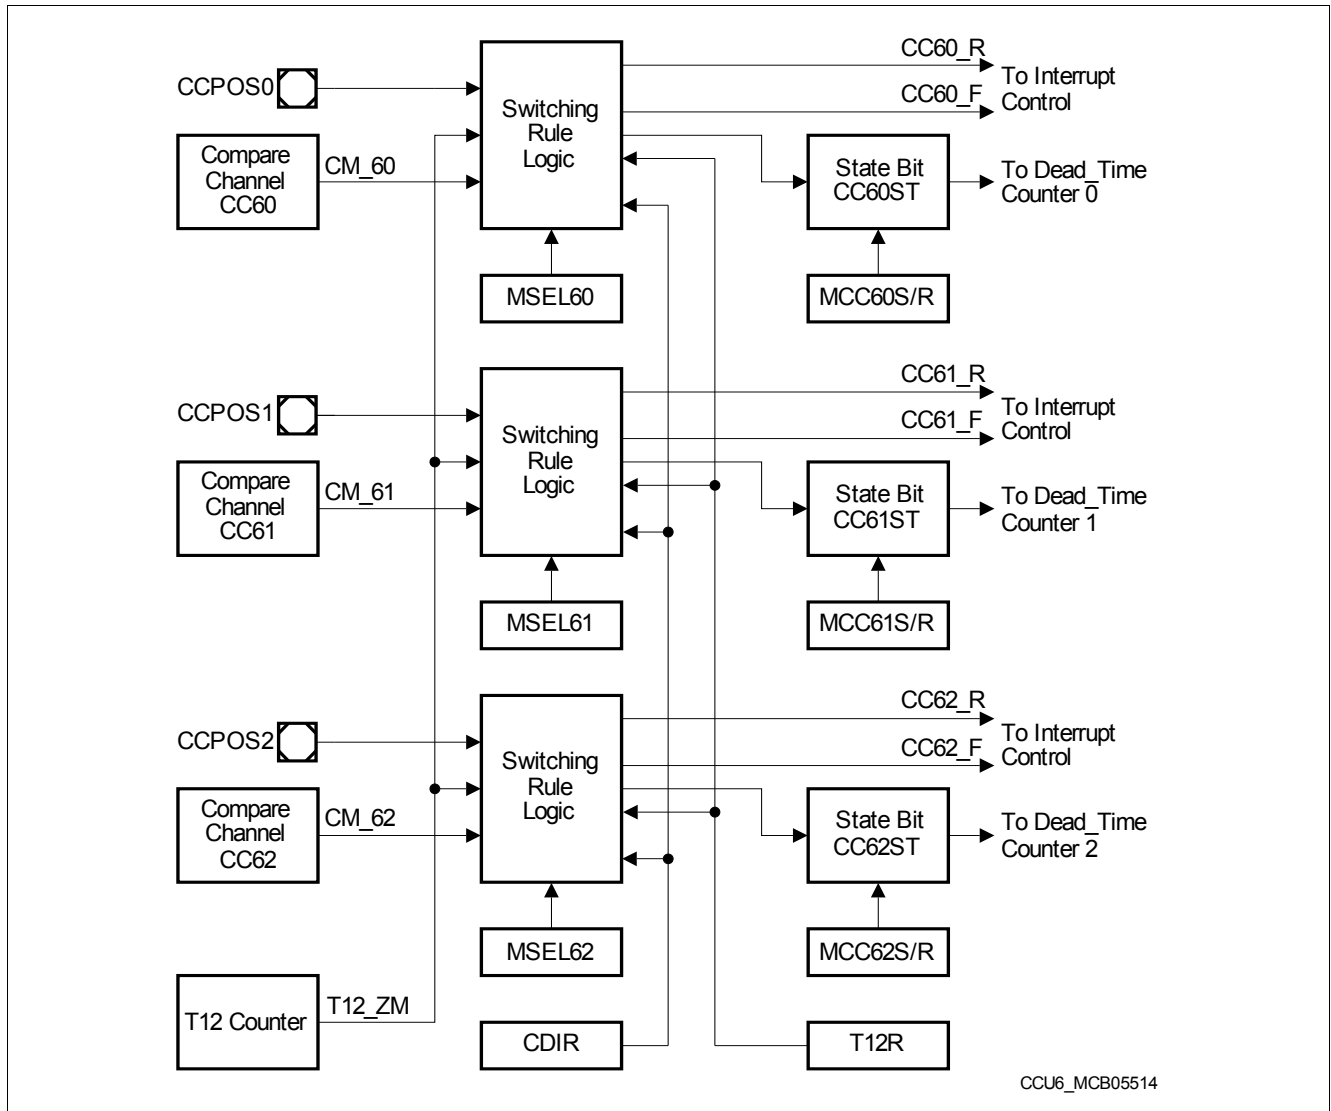

Figure 134 Compare State Bits for Compare Mode

The inputs to the switching rule logic for the CC6xST bits are the timer direction (CDIR), the timer run bit (T12R), the timer T12 zero-match signal (T12_ZM), and the actual individual compare-match signals CM_6x as well as the mode control bits, T12MSEL.MSEL6x.

In addition, each state bit can be set or cleared by software via the appropriate set and reset bits in register CMPMODIF, MCC6xS and MCC6xR. The input signals CCPOSx are used in hysteresis-like compare mode, whereas in normal compare mode, these inputs are ignored.

Note: In Hall Sensor, single shot or capture modes, additional/different rules are taken into account (see related sections).

A compare interrupt event CC6x_R is signaled when a compare match is detected while counting upwards, whereas the compare interrupt event CC6x_F is signaled when a compare match is detected while counting down. The actual setting of a State Bit has no influence on the interrupt generation in compare mode.

A modification of a State Bit CC6xST by the switching rule logic due to a compare action is only possible while Timer T12 is running (T12R = 1). If this is the case, the following switching rules apply for setting and clearing the State Bits in Compare Mode (illustrated in [Figure 135](#) and [Figure 136](#)):

A State Bit **CC6xST** is set to 1:

Capture/Compare Unit 6 (CCU6)

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting up (i.e., when the counter is incremented above the compare value);
- with the next T12 clock (f_{T12}) after a zero-match AND a parallel compare-match when T12 is counting up.

A State Bit **CC6xST** is cleared to 0:

- with the next T12 clock (f_{T12}) after a compare-match when T12 is counting down (i.e., when the counter is decremented below the compare value in center-aligned mode);
- with the next T12 clock (f_{T12}) after a zero-match AND NO parallel compare-match when T12 is counting up.

Figure 135 Compare Operation, Edge-Aligned Mode

Figure 137 illustrates some more examples for compare waveforms. It is important to note that in these examples, it is assumed that some of the compare values are changed while the timer is running. This change is performed via a software preload of the Shadow Register, CC6xSR. The value is transferred to the actual Compare Register CC6xR with the T12 Shadow Transfer signal, T12_ST, that is assumed to be enabled.

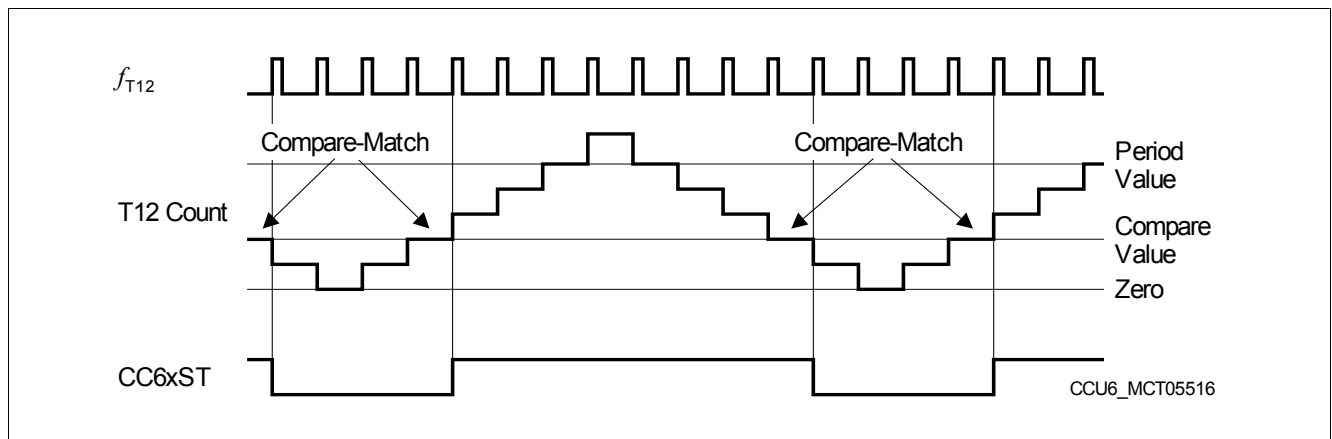

Figure 136 Compare Operation, Center-Aligned Mode

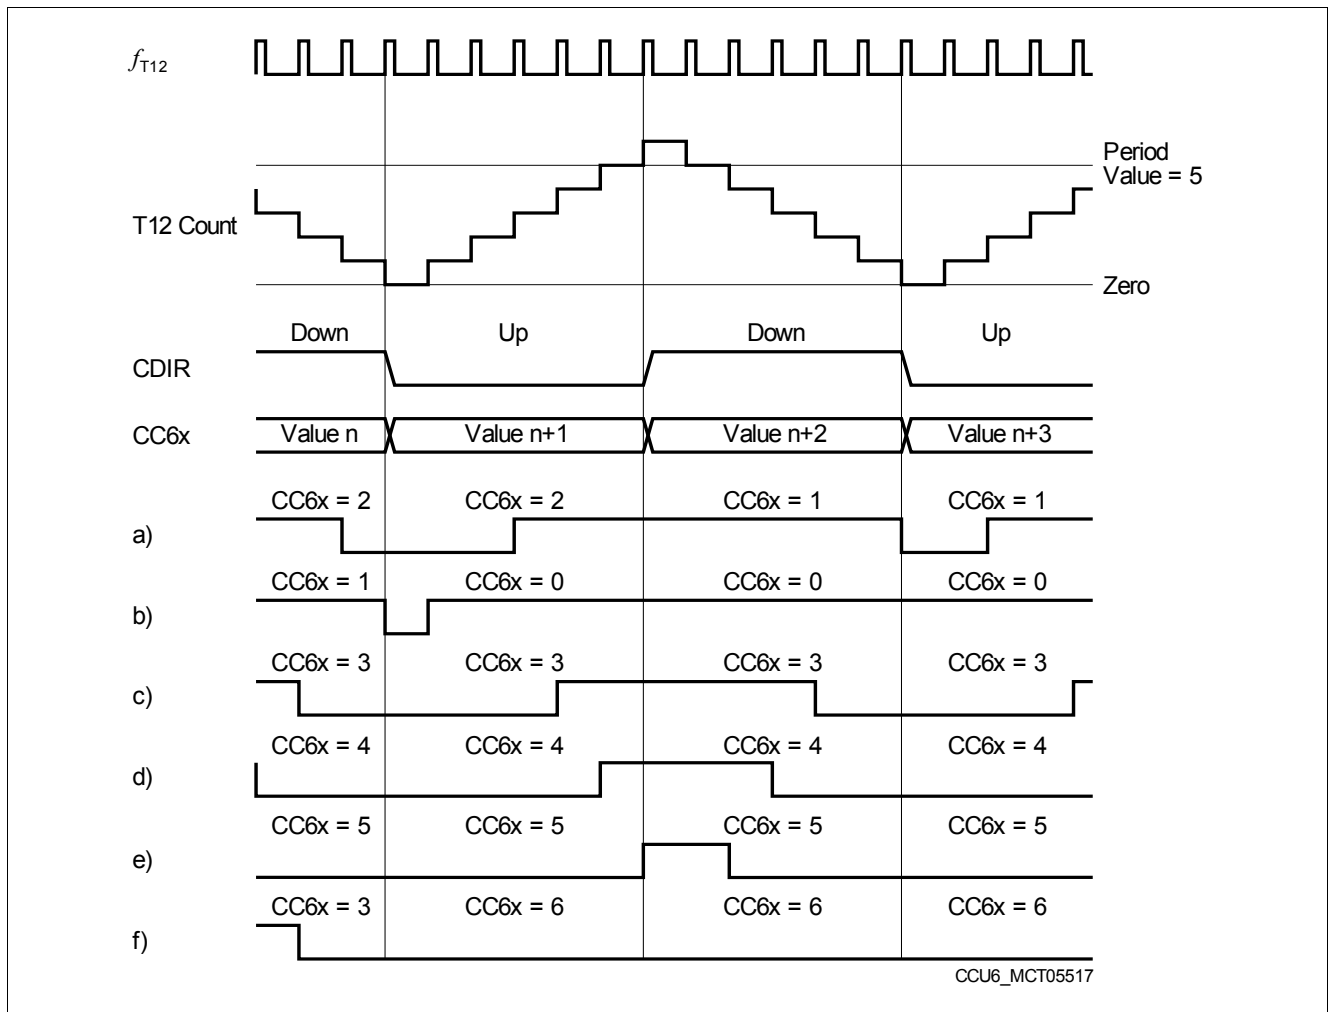

Figure 137 Compare Waveform Examples

Example b) illustrates the transition to a duty cycle of 100%. First, a compare value of 0001_H is used, then changed to 0000_H . Please note that a low pulse with the length of one T12 clock is still produced in the cycle where the new value 0000_H is in effect; this pulse originates from the previous value 0001_H . In the following timer cycles, the State Bit CC6xST remains at 1, producing a 100% duty cycle signal. In this case, the compare rule 'zero-match AND compare-match' is in effect.

Example f) shows the transition to a duty cycle of 0%. The new compare value is set to $\langle \text{Period-Value} \rangle + 1$, and the State Bit CC6ST remains cleared.

Figure 138 illustrates an example for the waveforms of all three channels. With the appropriate dead-time control and output modulation, a very efficient 3-phase PWM signal can be generated.

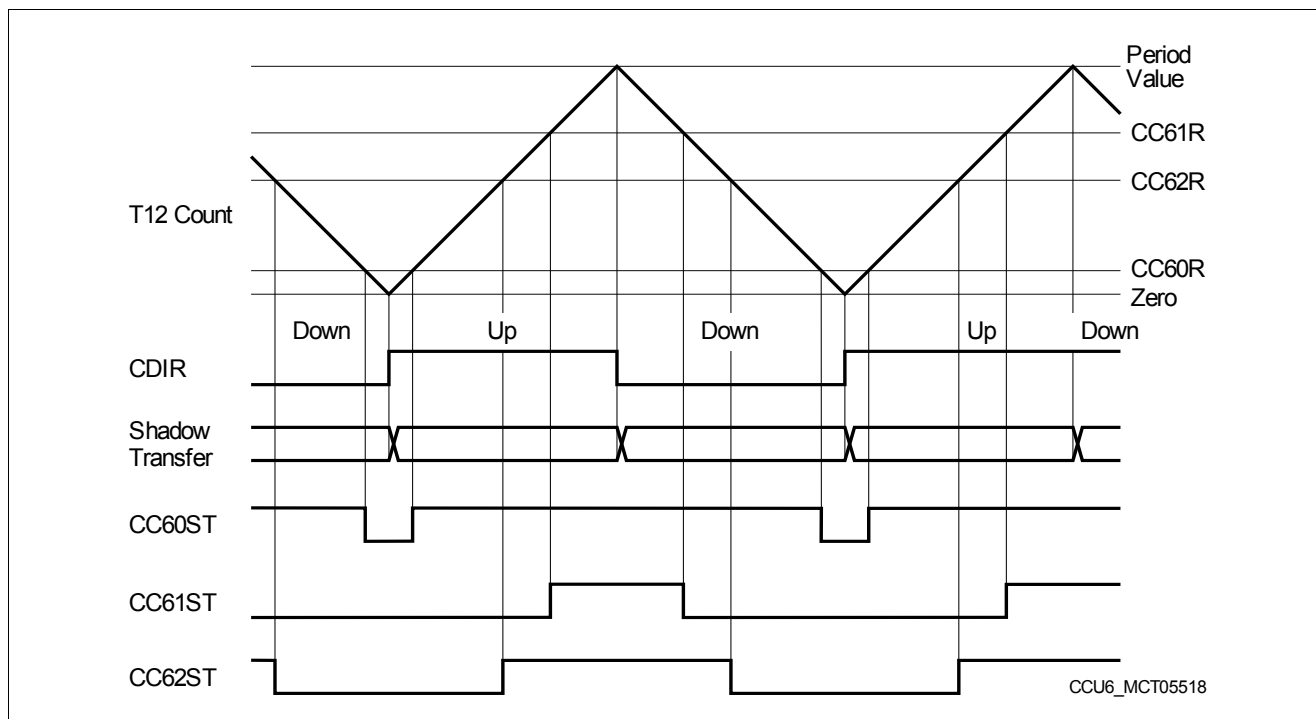

Figure 138 Three-Channel Compare Waveforms

19.3.3.3 Hysteresis-Like Control Mode

The hysteresis-like control mode ($T12MSEL.MSEL6x = 1001_B$) offers the possibility to switch off the PWM output if the input CCPOSx becomes 0 by clearing the State Bit CC6xST. This can be used as a simple motor control feature by using a comparator indicating, e.g., overcurrent. While CCPOSx = 0, the PWM outputs of the corresponding channel are driving their passive levels, because the setting of bit CC6xST is only possible while CCPOSx = 1.

As long as input CCPOSx is 0, the corresponding State Bit is held 0. When CCPOSx is at high level, the outputs can be in active state and are determined by bit CC6xST (see [Figure 134](#) for the state bit logic and [Figure 139](#) for the output paths). The CCPOSx inputs are evaluated with f_{CC6} .

This mode can be used to introduce a timing-related behavior to a hysteresis controller. A standard hysteresis controller detects if a value exceeds a limit and switches its output according to the compare result. Depending on the operating conditions, the switching frequency and the duty cycle are not fixed, but change permanently.

If (outer) time-related control loops based on a hysteresis controller in an inner loop should be implemented, the outer loops show a better behavior if they are synchronized to the inner loops. Therefore, the hysteresis-like mode can be used, that combines timer-related switching with a hysteresis controller behavior. For example, in this mode, an output can be switched on according to a fixed time base, but it is switched off as soon as a falling edge is detected at input CCPOSx.

This mode can also be used for standard PWM with overcurrent protection. As long as there is no low level signal at pin CCPOSx, the output signals are generated in the normal manner as described in the previous sections. Only if input CCPOSx shows a low level, e.g. due to the detection of overcurrent, the outputs are shut off to avoid harmful stress to the system.

19.3.4 Compare Mode Output Path

Figure 139 gives an overview on the signal path from a channel State Bit to its output pin in its simplest form. As illustrated, a user has a variety of controls to determine the desired output signal switching behavior in relation to the current state of the State Bit, CC6xST. Please refer to [Section 19.3.4.3](#) for details on the output modulation.

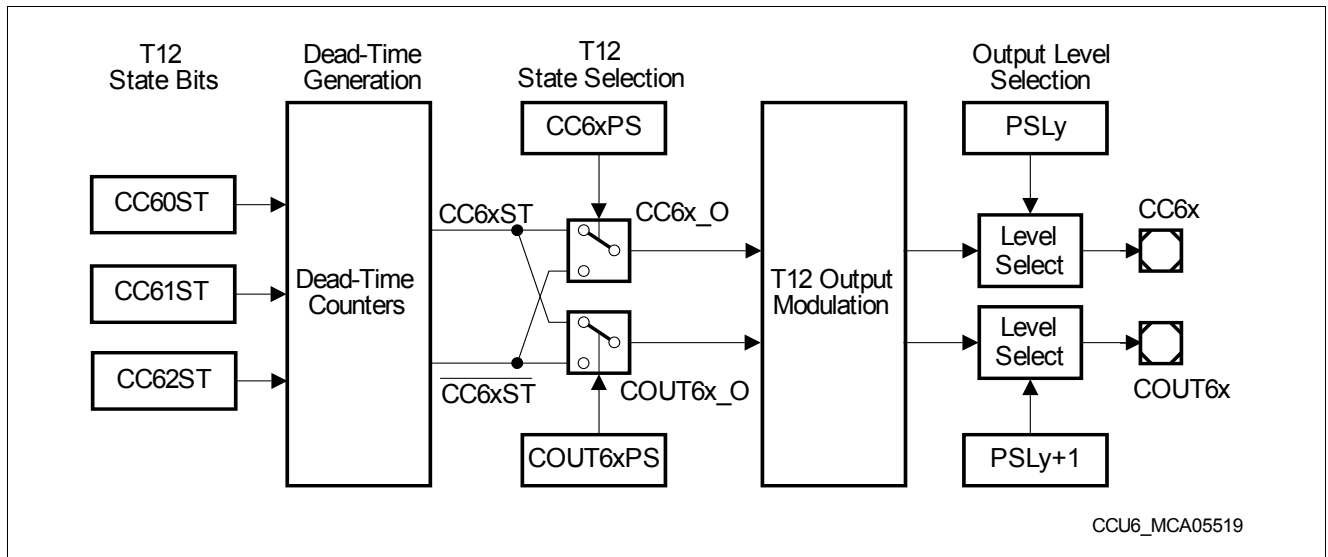

Figure 139 Compare Mode Simplified Output Path Diagram

The output path is based on signals that are defined as active or passive. The terms active and passive are not related to output levels, but to internal actions. This mainly applies for the modulation, where T12 and T13 signals are combined with the multi-channel signals and the trap function. The Output level Selection allows the user to define the output level at the output pin for the passive state (inverted level for the active state). It is recommended to configure this block in a way that an external power switch is switched off while the CCU6 delivers an output signal in the passive state.

19.3.4.1 Dead-Time Generation

The generation of (complementary) signals for the high-side and the low-side switches of one power inverter phase is based on the same compare channel. For example, if the high-side switch should be active while the T12 counter value is above the compare value (State Bit = 1), then the low-side switch should be active while the counter value is below the compare value (State Bit = 0).

In most cases, the switching behavior of the connected power switches is not symmetrical concerning the switch-on and switch-off times. A general problem arises if the time for switch-on is smaller than the time for switch-off of the power device. In this case, a short-circuit can occur in the inverter bridge leg, which may damage the complete system. In order to solve this problem by HW, this capture/compare unit contains a programmable Dead-Time Generation Block, that delays the passive to active edge of the switching signals by a programmable time (the active to passive edge is not delayed).

The Dead-Time Generation Block, illustrated in [Figure 140](#), is built in a similar way for all three channels of T12. It is controlled by bits in register T12DTC. Any change of a CC6xST State Bit activates the corresponding Dead-Time Counter, that is clocked with the same input clock as T12 (f_{T12}). The length of the dead-time can be programmed by bit field DTM. This value is identical for all three channels. Writing TCTR4.DTRES = 1 sets all dead-times to passive.

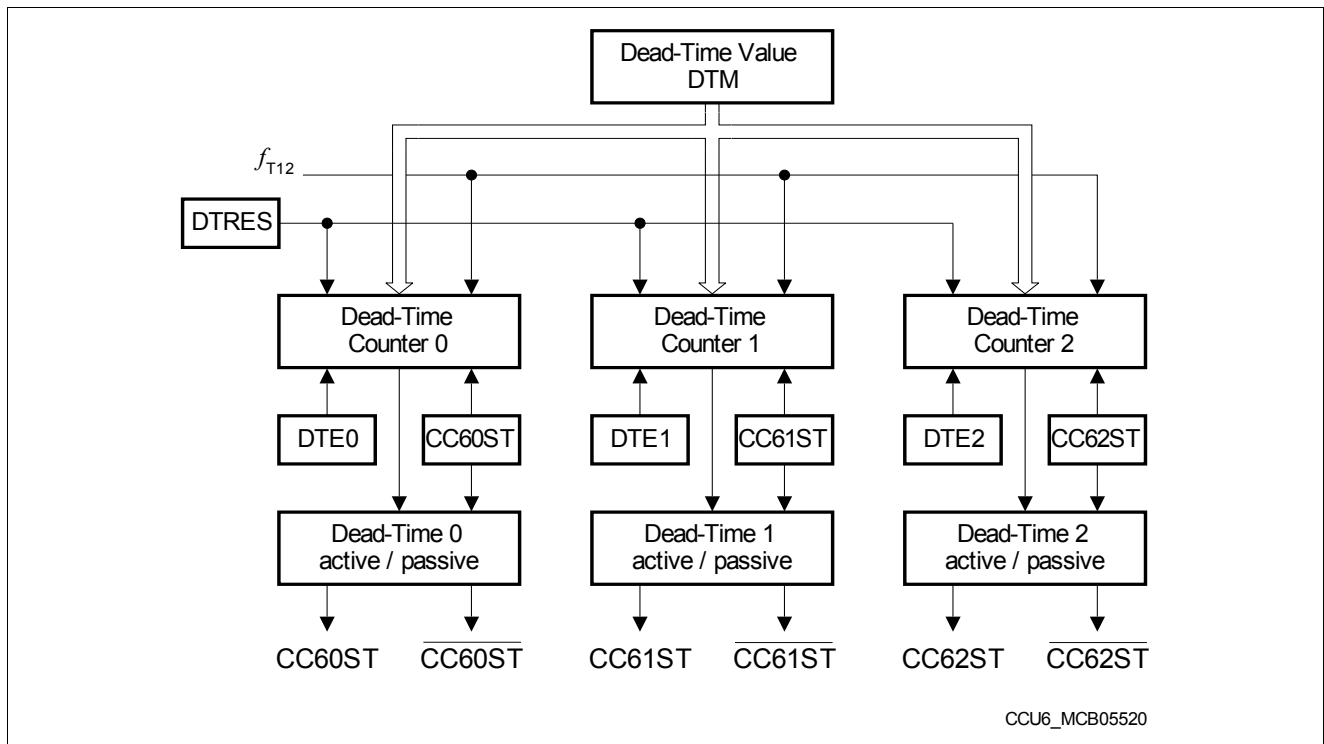

Figure 140 Dead-Time Generation Block Diagram

Each of the three dead-time counters has its individual dead-time enable bit, DTE_x. An enabled dead-time counter generates a dead-time delaying the passive-to-active edge of the channel output signal. The change in a State Bit CC6_xST is not taken into account while the dead-time generation of this channel is currently in progress (active). This avoids an unintentional additional dead-time if a State Bit CC6_xST changes too early.

A disabled dead-time counter is always considered as passive and does not delay any edge of CC6_xST.

Based on the State Bits CC6_xST, the Dead-Time Generation Block outputs a direct signal CC6_xST and an inverted signal $\overline{\text{CC6xST}}$ for each compare channel, each masked with the effect of the related Dead-Time Counters (waveforms illustrated in [Figure 141](#)).

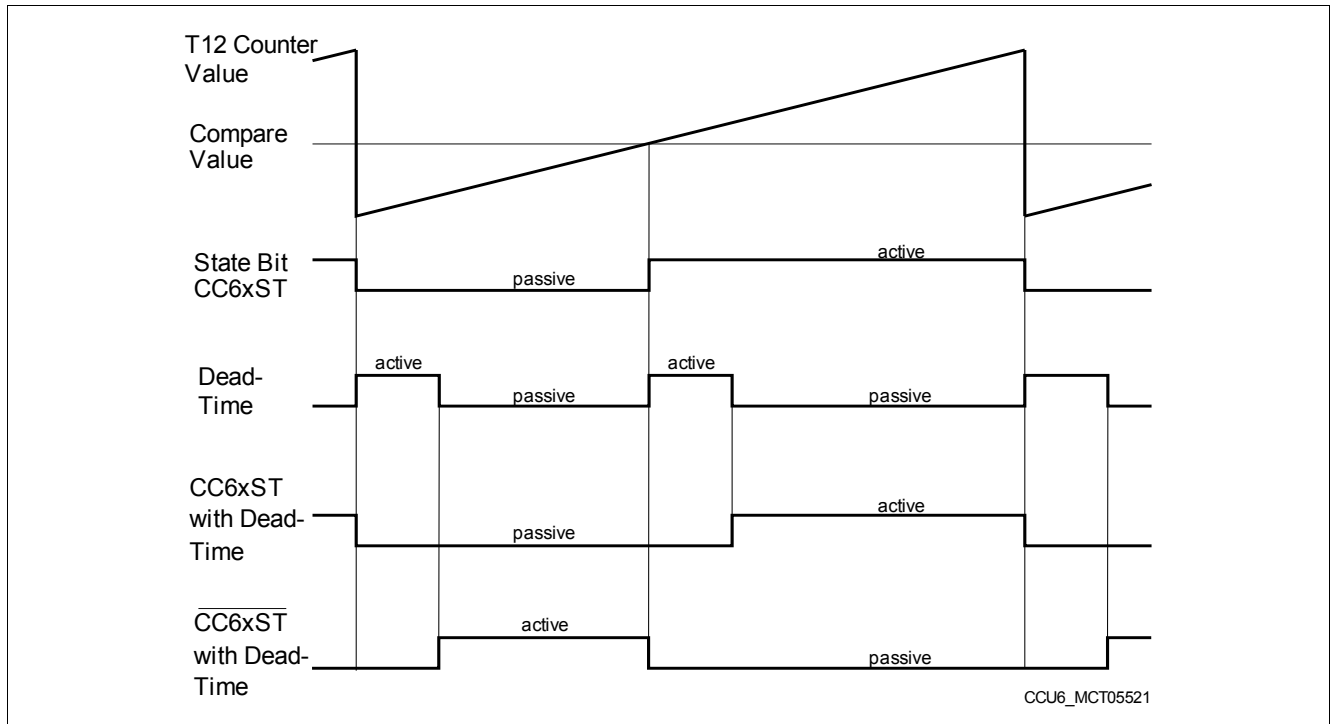

Figure 141 Dead-Time Generation Waveforms

19.3.4.2 State Selection

To support a wide range of power switches and drivers, the state selection offers the flexibility to define when an output can be active and can be modulated, especially useful for **complementary or multi-phase PWM** signals.

The state selection is based on the signals $CC6xST$ and $\overline{CC6xST}$ delivered by the dead-time generator (see [Figure 139](#)). Both signals are never active at the same time, but can be passive at the same time. This happens during the dead-time of each compare channel after a change of the corresponding State Bit $CC6xST$.

The user can select independently for each output signal $CC6xO$ and $COUT6xO$ if it should be active before or after the compare value has been reached (see register $CMPSTAT$). With this selection, the active (conducting) phases of complementary power switches in a power inverter bridge leg can be positioned with respect to the compare value (e.g. signal $CC6xO$ can be active before, whereas $COUT6xO$ can be active after the compare value is reached). Like this, the output modulation, the trap logic and the output level selection can be programmed independently for each output signal, although two output signals are referring to the same compare channel.

19.3.4.3 Output Modulation and Level Selection

The last block of the data path is the Output Modulation block. Here, all the modulation sources and the trap functionality are combined and control the actual level of the output pins (controlled by the modulation enable bits T1xMODENy and MCMEN in register MODCTR). The following signal sources can be combined here **for each T12 output signal** (see [Figure 142](#) for compare channel CC60):

- A **T12 related compare signal** CC6x_O (for outputs CC6x) or COUT6x_O (for outputs COUT6x) delivered by the T12 block (state selection with dead-time) with an individual enable bit T12MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- The **T13 related compare signal** CC63_O delivered by the T13 state selection with an individual enable bit T13MODENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)
- A **multi-channel output signal** MCMPy (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x) with a common enable bit MCMEN
- The **trap state** TRPS with an individual enable bit TRPENy per output signal (y = 0, 2, 4 for outputs CC6x and y = 1, 3, 5 for outputs COUT6x)

If one of the modulation input signals CC6x_O/COUT6x_O, CC63_O, or MCMPy of an output modulation block is enabled and is at passive state, the modulated is also in passive state, regardless of the state of the other signals that are enabled. Only if all enabled signals are in active state the modulated output shows an active state. If no modulation input is enabled, the output is in passive state.

If the Trap State is active (TRPS = 1), then the outputs that are enabled for the trap signal (by TRPENy = 1) are set to the passive state.

The output of each of the modulation control blocks is connected to a level select block that is configured by register PSLR. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLy. If the modulated output signal is in the passive state, the level specified directly by PSLy is output. If it is in the active state, the inverted level of PSLy is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSLy bits have shadow registers to allow for updates without undesired pulses on the output lines. The bits related to CC6x and COUT6x (x = 0, 1, 2) are updated with the T12 shadow transfer signal (T12_ST). A read action returns the actually used values, whereas a write action targets the shadow bits. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

[Figure 142](#) shows the output modulation structure for compare channel CC60 (output signals CC60 and COUT60). A similar structure is implemented for the other two compare channels CC61 and CC62.

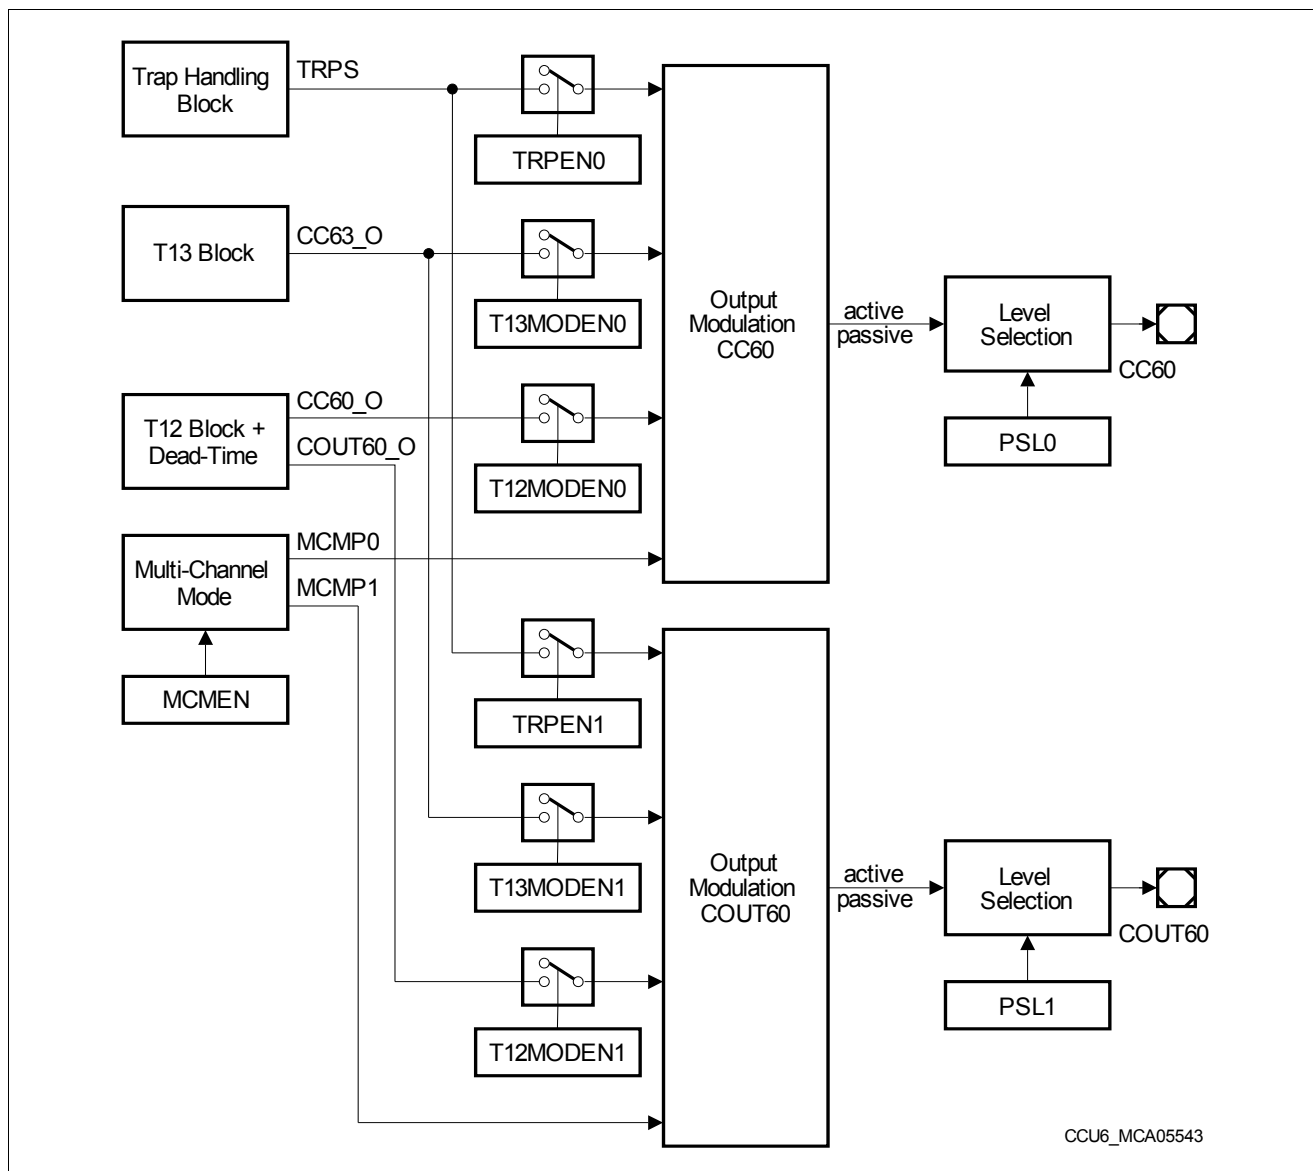

Figure 142 Output Modulation for Compare Channel CC60

19.3.5 T12 Capture Modes

Each of the three channels of the T12 Block can also be used to capture T12 time information in response to an external signal CC6xIN.

In capture mode, the interrupt event CC6x_R is detected when a rising edge is detected at the input CC6xIN, whereas the interrupt event CC6x_F is detected when a falling edge is detected.

There are a number of different modes for capture operation. In all modes, both of the registers of a channel are used. The selection of the capture modes is done via the T12MSEL.MSEL6x bit fields and can be selected individually for each of the channels.

Table 115 Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	CC6nSR Stored in	T12 Stored in
0100 _B	1	CC6xIN	Rising	–	CC6xR
		CC6xIN	Falling	–	CC6xSR
0101 _B	2	CC6xIN	Rising	CC6xR	CC6xSR
0110 _B	3	CC6xIN	Falling	CC6xR	CC6xSR
0111 _B	4	CC6xIN	Any	CC6xR	CC6xSR

Figure 143 illustrates **Capture Mode 1**. When a rising edge (0-to-1 transition) is detected at the corresponding input signal CC6xIN, the current contents of Timer T12 are captured into register CC6xR. When a falling edge (1-to-0 transition) is detected at the input signal CC6xIN, the contents of Timer T12 are captured into register CC6xSR.

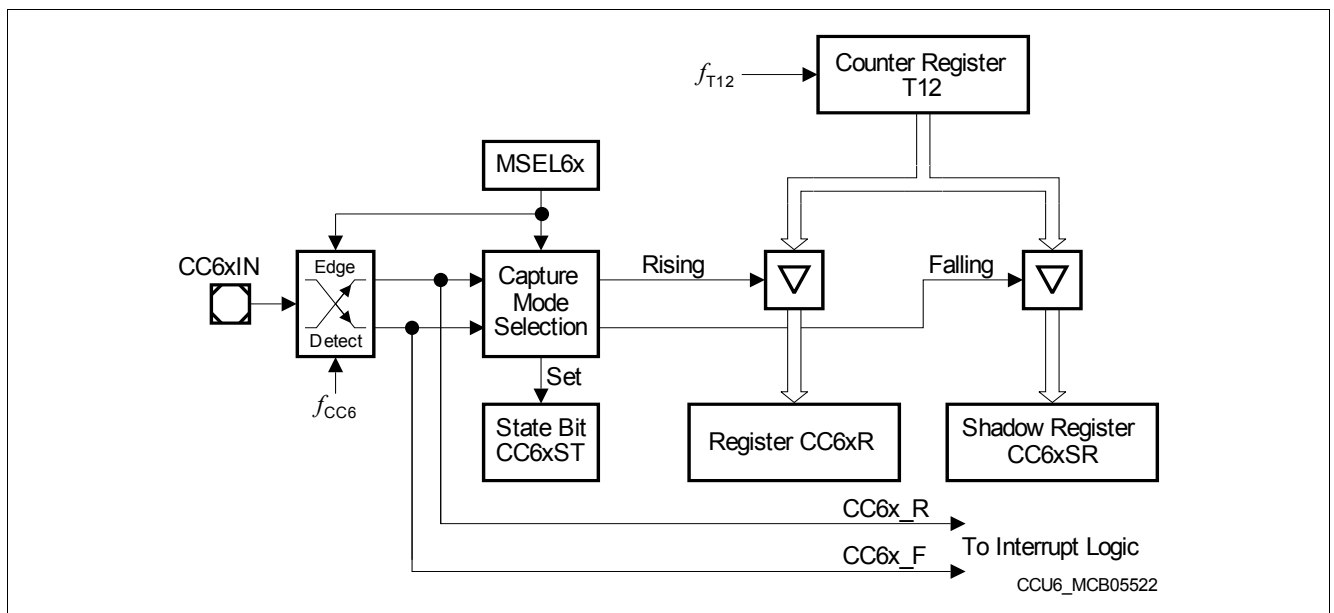

Figure 143 Capture Mode 1 Block Diagram

Capture Modes 2, 3 and 4 are shown in **Figure 144**. They differ only in the active edge causing the capture operation. In each of the three modes, when the selected edge is detected at the corresponding input signal CC6xIN, the current contents of the shadow register CC6xSR are transferred into register CC6xR, and the current Timer T12 contents are captured in register CC6xSR (simultaneous transfer). The active edge is a rising edge of CC6xIN for Capture Mode 2, a falling edge for Mode 3, and both, a rising or a falling edge for Capture Mode 4, as shown in **Table 115**. These capture modes are very useful in cases where there is little time between two consecutive edges of the input signal.

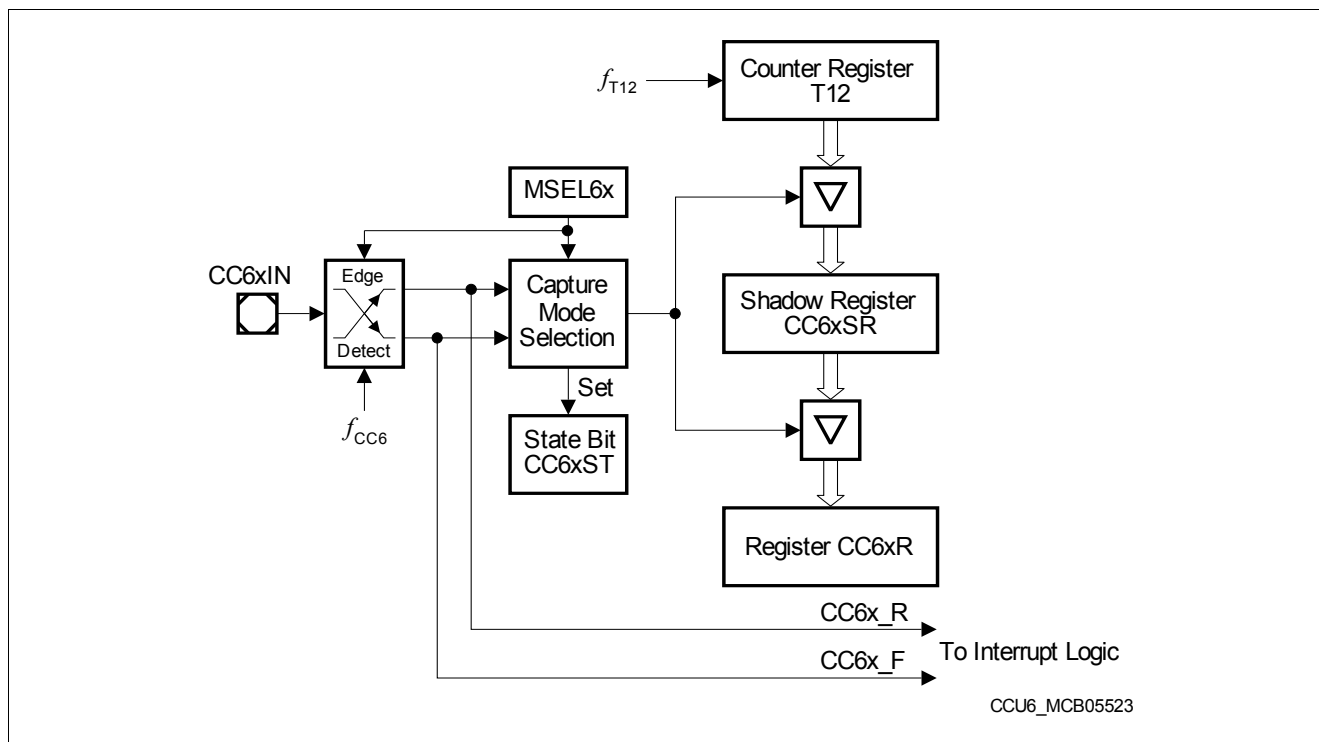

Figure 144 Capture Modes 2, 3 and 4 Block Diagram

Capture/Compare Unit 6 (CCU6)

Five further capture modes are called **Multi-Input Capture Modes**, as they use two different external inputs, signal CC6xIN and signal CCPOSx.

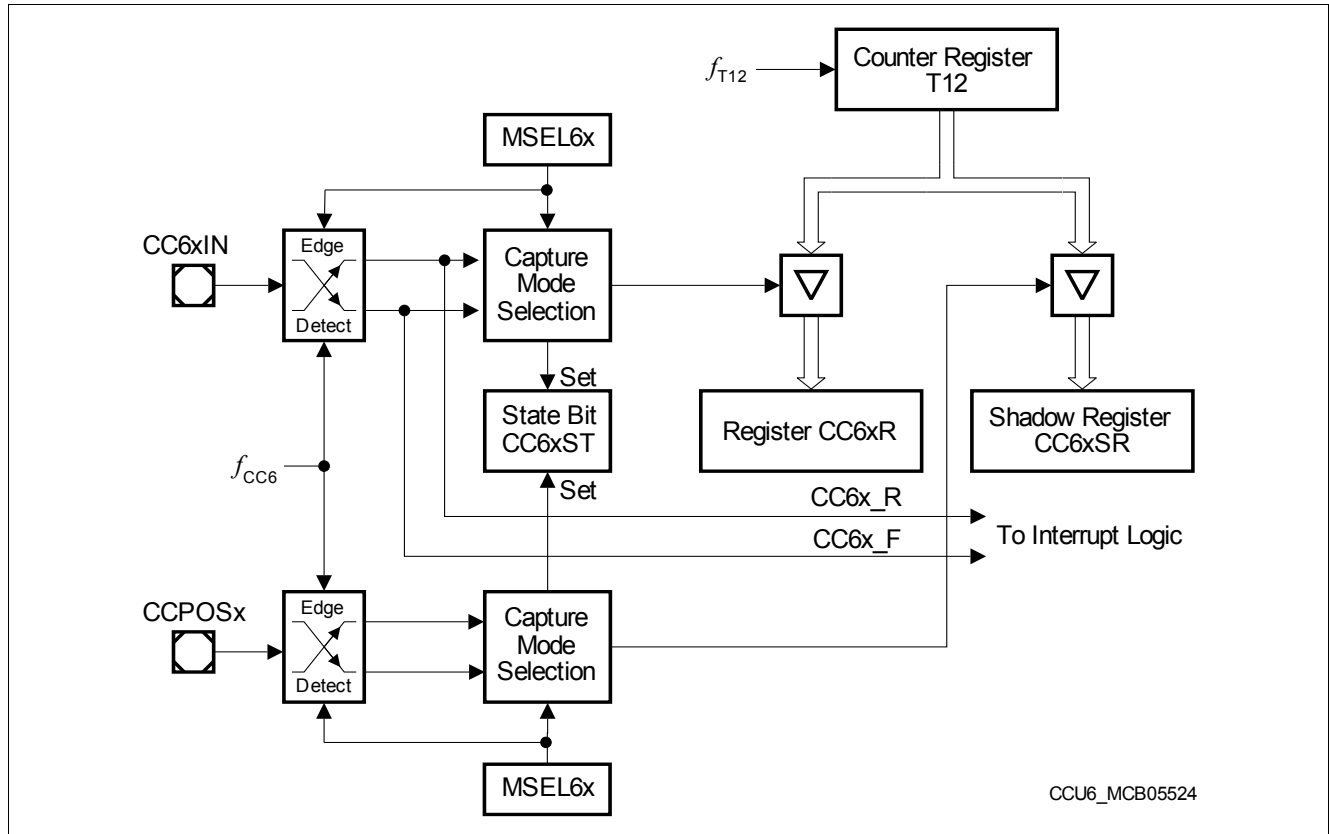

Figure 145 Multi-Input Capture Modes Block Diagram

In each of these modes, the current T12 contents are captured in register CC6xR in response to a selected event at signal CC6xIN, and in register CC6xSR in response to a selected event at signal CCPOSx. The possible events can be opposite input transitions, or the same transitions, or any transition at the two inputs. The different options are detailed in [Table 116](#).

In each of the various capture modes, the Channel State Bit, CC6xST, is set to 1 when the selected capture trigger event at signal CC6xIN or CCPOSx has occurred. The State Bit is not cleared by hardware, but can be cleared by software.

In addition, appropriate signal lines to the interrupt logic are activated, that can generate an interrupt request to the CPU. Regardless of the selected active edge, all edges detected at signal CC6xIN can lead to the activation of the appropriate interrupt request line (see also [Section 19.10](#)).

Table 116 Multi-Input Capture Modes Overview

MSEL6x	Mode	Signal	Active Edge	T12 Stored in
1010 _B	5	CC6xIN	Rising	CC6xR
		CCPOSx	Falling	CC6xSR
1011 _B	6	CC6xIN	Falling	CC6xR
		CCPOSx	Rising	CC6xSR
1100 _B	7	CC6xIN	Rising	CC6xR
		CCPOSx	Rising	CC6xSR
1101 _B	8	CC6xIN	Falling	CC6xR
		CCPOSx	Falling	CC6xSR
1110 _B	9	CC6xIN	Any	CC6xR
		CCPOSx	Any	CC6xSR
1111 _B	–	reserved (no capture or compare action)		

19.3.6 T12 Shadow Register Transfer

A special shadow transfer signal (T12_ST) can be generated to facilitate updating the period and compare values of the compare channels CC60, CC61, and CC62 synchronously to the operation of T12. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit TCTR0.STE12 (set by writing 1 to the write-only bit TCTR4.T12STR, cleared by writing 1 to the write-only bit TCTR4.T12STD).

Figure 146 shows the shadow register structure and the shadow transfer signals, as well as on the read/write accessibility of the various registers.

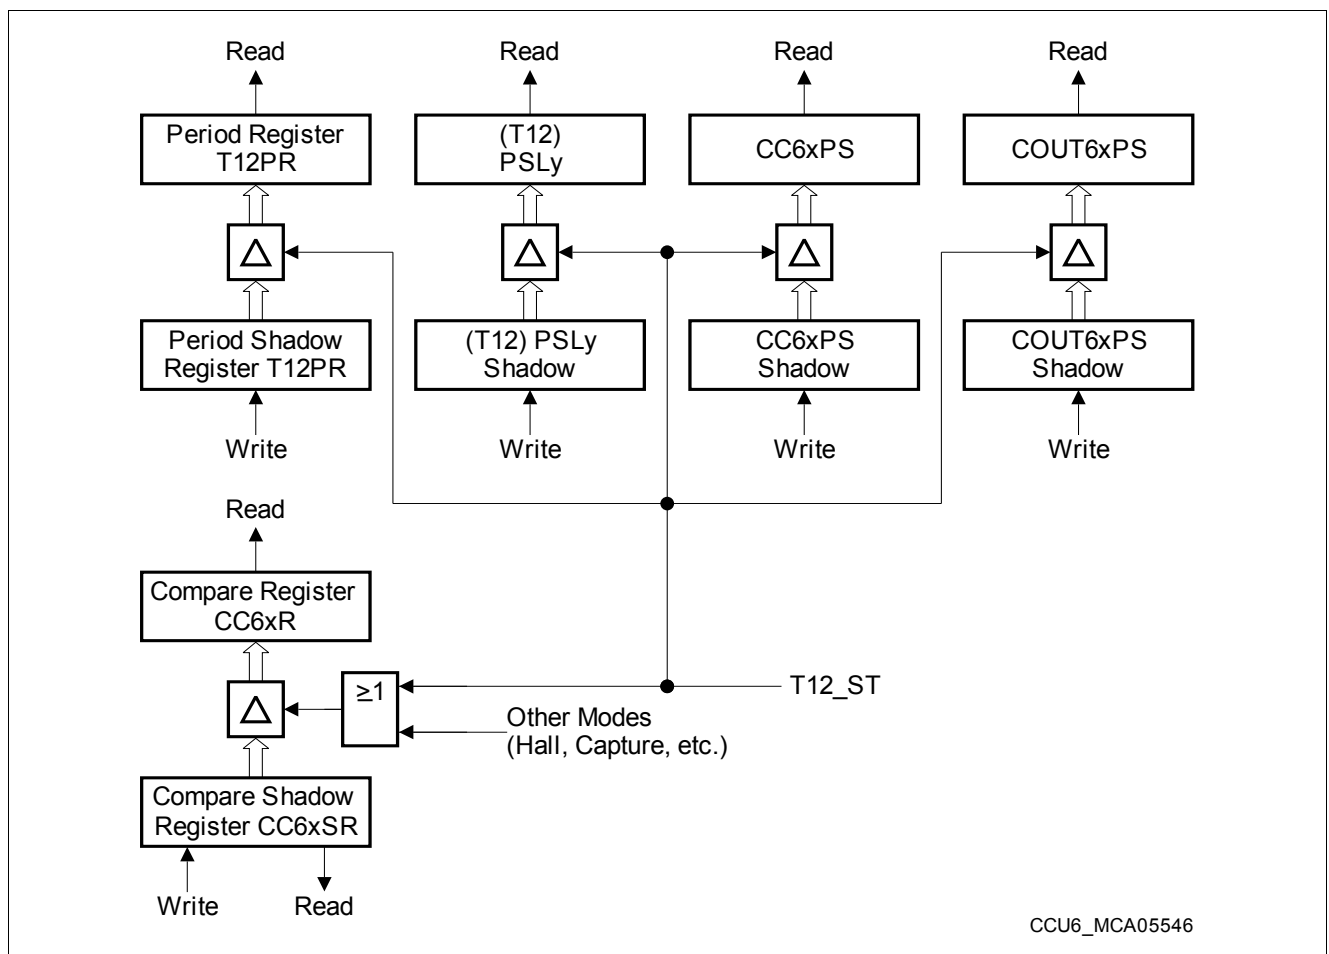

Figure 146 T12 Shadow Register Overview

A T12 shadow register transfer takes place (T12_ST active):

- STE12 = 1 and a Period-Match is detected while counting up, or
- STE12 = 1 and a One-Match is detected while counting down

When signal T12_ST is active, a shadow register transfer is triggered with the next cycle of the T12 clock. Bit STE12 is automatically cleared with the shadow register transfer.

19.3.7 Timer T12 Operating Mode Selection

The operating mode for the T12 channels are defined by the bit fields T12MSEL.MSEL6x.

Table 117 T12 Capture/Compare Modes Overview

MSEL6x	Selected Operating Mode
0000 _B , 1111 _B	Capture/Compare modes switched off
0001 _B , 0010 _B , 0011 _B	Compare mode, see Section 19.3.3 same behavior for all three codings
01XX _B	Double-Register Capture modes, see Section 19.3.5
1000 _B	Hall Sensor Mode, see Section 19.7 In order to properly enable this mode, all three MSEL6x fields have to be programmed to Hall Sensor mode.
1001 _B	Hysteresis-like compare mode, see Section 19.3.3.3
1010 _B , 1011 _B , 1100 _B , 1101 _B , 1110 _B	Multi-Input Capture modes, see Section 19.3.5

The clocking and counting scheme of the timers are controlled by the timer control registers TCTR0 and TCTR2. Specific actions are triggered by write operations to register TCTR4.

19.4 Operating Timer T13

Timer T13 is implemented similarly to Timer T12, but only with one channel in compare mode. A 16-bit up-counter is connected to a channel register via a comparator, that generates a signal when the counter contents match the contents of the channel register. A variety of control functions facilitate the adaptation of the T13 structure to different application needs. In addition, T13 can be started synchronously to timer T12 events.

This section provides information about:

- T13 overview (see [Section 19.4.1](#))
- Counting scheme (see [Section 19.4.2](#))
- Compare mode (see [Section 19.4.3](#))
- Compare output path (see [Section 19.4.4](#))
- Shadow register transfer (see [Section 19.4.5](#))

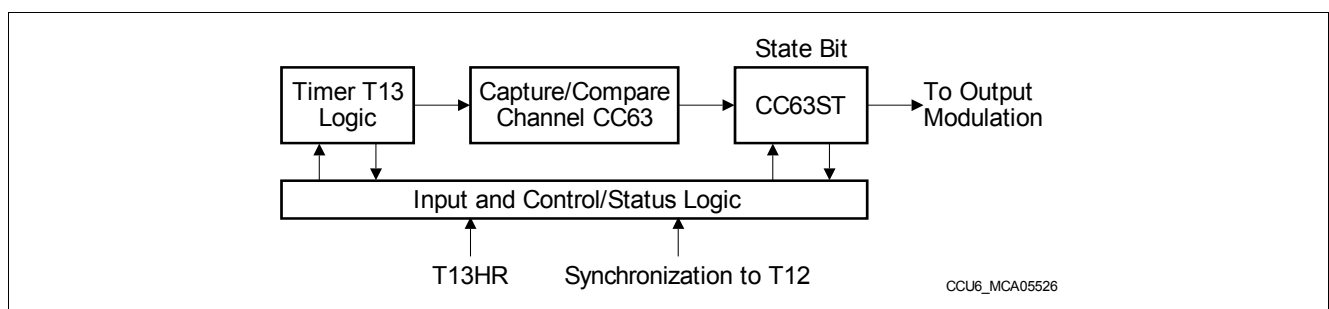

Figure 147 Overview Diagram of the Timer T13 Block

19.4.1 T13 Overview

Figure 148 shows a detailed block diagram of Timer T13. The functions of the timer T12 block are controlled by bits in registers TCTR0, TCTR2, and PISEL2.

Timer T13 receives its input clock, f_{T13} , from the module clock f_{CC6} via a programmable prescaler and an optional 1/256 divider or from an input signal T13HR. T13 can only count up (similar to the Edge-Aligned mode of T13).

Via a comparator, the timer T13 Counter Register T13 is connected to the Period Register T13PR. This register determines the maximum count value for T13. When T13 reaches the period value, signal T13_PM (T13 Period Match) is generated and T13 is cleared to 0000_H with the next T13 clock edge. The Period Register receives a new period value from its Shadow Period Register, T13PS, that is loaded via software. The transfer of a new period value from the shadow register into T13PR is controlled via the 'T13 Shadow Transfer' control signal, T13_ST. The generation of this signal depends on the associated control bit STE13. Providing a shadow register for the period value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters (refer to [Table 19.4.5](#)). Another signal indicates whether the counter contents are equal to 0000_H (T13_ZM).

A Single-Shot control bit, T13SSC, enables an automatic stop of the timer when the current counting period is finished (see [Figure 150](#)).

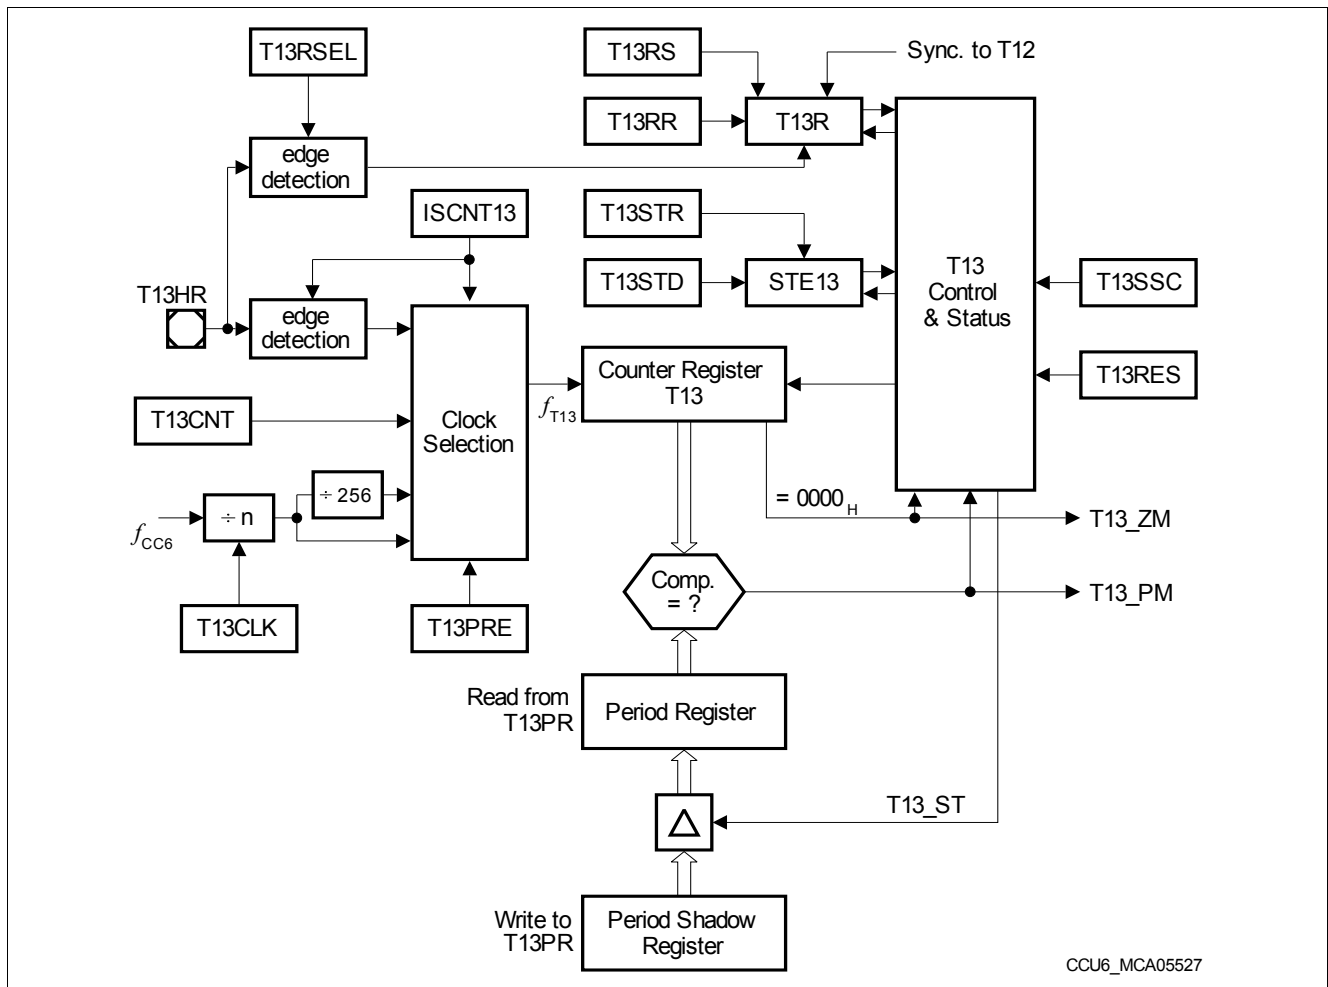

Figure 148 T13 Counter Logic and Period Comparators

The start or stop of T13 is controlled by the Run bit, T13R. This control bit can be set by software via the associated set/clear bits T13RS or T13RR in register TCTR4, or it is cleared by hardware according to preselected conditions (single-shot mode).

The timer T13 run bit T13R must not be set while the applied T13 period value is zero. Bit T13R can be set automatically if an event of T12 is detected to synchronize T13 timings to T12 events, e.g. to generate a programmable delay via T13 after an edge of a T12 compare channel before triggering an AD conversion (T13 can trigger ADC conversions).

Timer T13 can be cleared to 0000_H via control bit T13RES. Setting this write-only bit only clears the timer contents, but has no further effects, e.g., it does not stop the timer.

The generation of the T13 shadow transfer control signal, T13_ST, is enabled via bit STE13. This bit can be set or cleared by software indirectly through its associated set/reset control bits T13STR and T13STD.

Two bit fields, T13TEC and T13TED, control the synchronization of T13 to Timer T12 events. T13TEC selects the trigger event, while T13TED determines for which T12 count direction the trigger should be active.

While Timer T13 is running, write accesses to the count register T13 are not taken into account. If T13 is stopped, write actions to register T13 are immediately taken into account.

Note: The T13 Period Register and its associated shadow register are located at the same physical address. A write access to this address targets the Shadow Register, while a read access reads from the actual period register.

19.4.2 T13 Counting Scheme

This section describes the clocking and the counting capabilities of T13.

19.4.2.1 Clock Selection

In **Timer Mode** (PISEL2.ISCNT13 = 00_B), the input clock f_{T13} of Timer T13 is derived from the internal module clock f_{CC6} through a programmable prescaler and an optional 1/256 divider. The resulting prescaler factors are listed in **Table 118**. The prescaler of T13 is cleared while T13 is not running (TCTR0.T13R = 0) to ensure reproducible timings and delays.

Table 118 Timer T13 Input Clock Options

T13CLK	Resulting Input Clock f_{T13} Prescaler Off (T13PRE = 0)	Resulting Input Clock f_{T13} Prescaler On (T13PRE = 1)
000 _B	f_{CC6}	$f_{CC6} / 256$
001 _B	$f_{CC6} / 2$	$f_{CC6} / 512$
010 _B	$f_{CC6} / 4$	$f_{CC6} / 1024$
011 _B	$f_{CC6} / 8$	$f_{CC6} / 2048$
100 _B	$f_{CC6} / 16$	$f_{CC6} / 4096$
101 _B	$f_{CC6} / 32$	$f_{CC6} / 8192$
110 _B	$f_{CC6} / 64$	$f_{CC6} / 16384$
111 _B	$f_{CC6} / 128$	$f_{CC6} / 32768$

In **Counter Mode**, timer T13 counts one step:

- If a 1 is written to TCTR4.T13CNT and PISEL2.ISCNT13 = 01_B
- If a rising edge of input signal T13HR is detected and PISEL2.ISCNT13 = 10_B
- If a falling edge of input signal T13HR is detected and PISEL2.ISCNT13 = 11_B

19.4.2.2 T13 Counting

The period of the timer is determined by the value in the period Register T13PR according to the following formula:

$$T13_{PER} = \langle \text{Period-Value} \rangle + 1; \text{ in } T13 \text{ clocks } (f_{T13}) \quad (10)$$

Timer T13 can only count up, comparable to the Edge-Aligned mode of T12. This leads to very simple 'counting rule' for the T13 counter:

- The counter is cleared with the next T13 clock edge if a Period-Match is detected. The counting direction is always upwards.

The behavior of T13 is illustrated in [Figure 149](#).

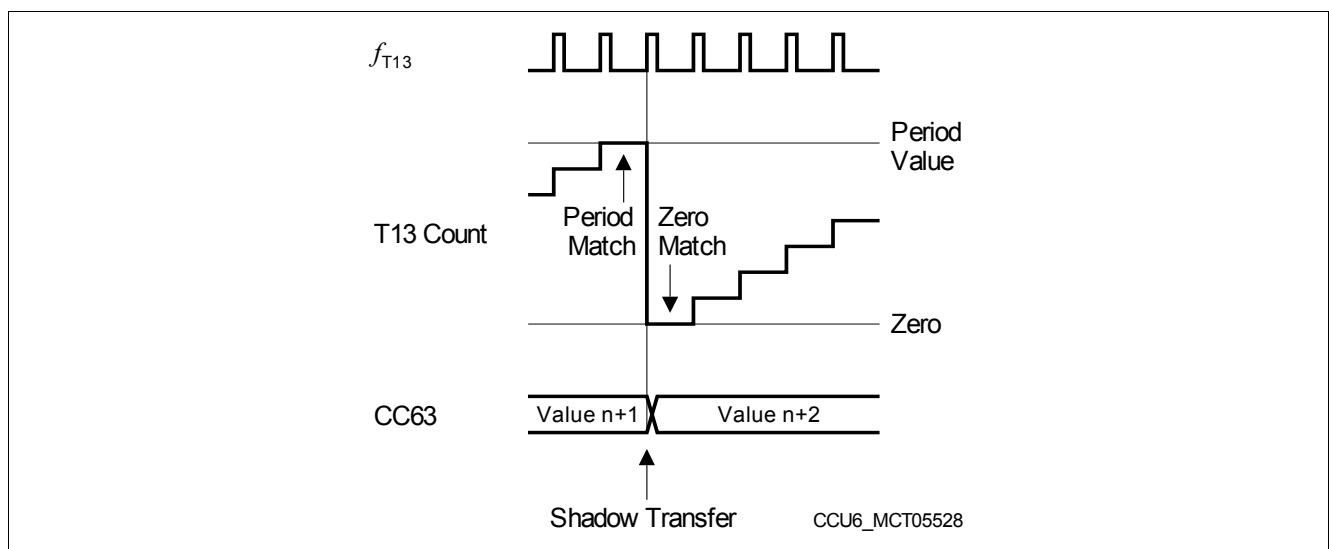

Figure 149 T13 Counting Sequence

19.4.2.3 Single-Shot Mode

In Single-Shot Mode, the timer run bit T13R is cleared by hardware. If bit T13SSC = 1, the timer T13 will stop when the current timer period is finished.

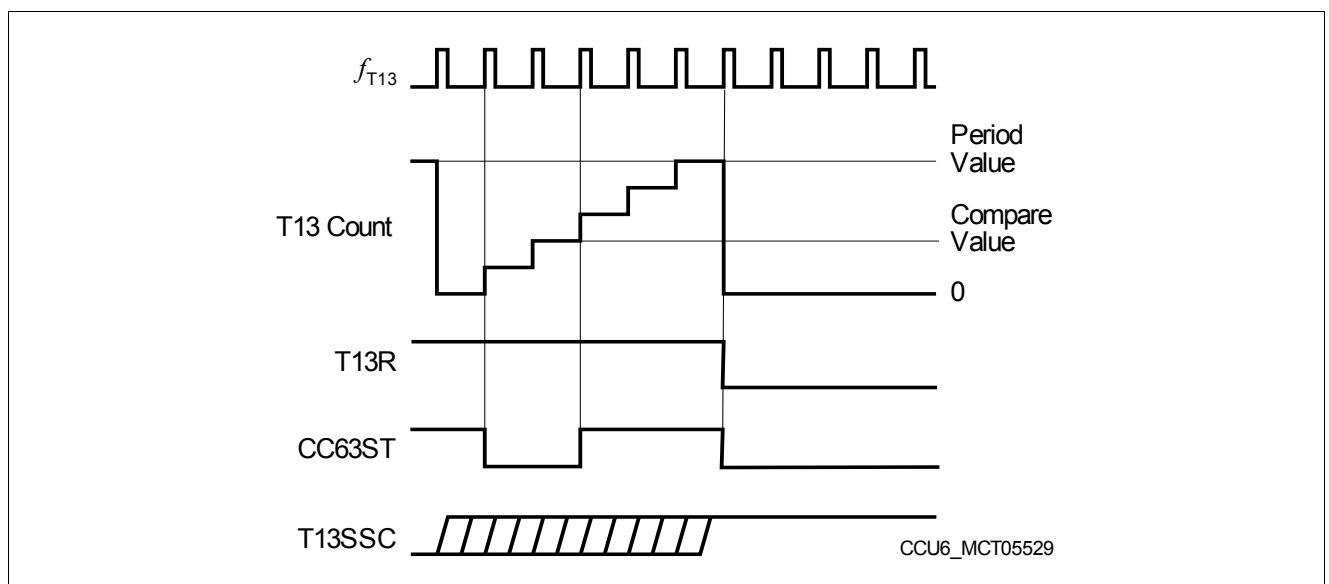

Figure 150 Single-Shot Operation of Timer T13

19.4.2.4 Synchronization to T12

Timer T13 can be synchronized to a T12 event. Bit fields T13TEC and T13TED select the event that is used to start Timer T13. The selected event sets bit T13R via HW, and T13 starts counting. Combined with the Single-Shot mode, this feature can be used to generate a programmable delay after a T12 event.

Figure 151 shows an example for the synchronization of T13 to a T12 event. Here, the selected event is a compare-match (compare value = 2) while counting up. The clocks of T12 and T13 can be different (other prescaler factor); the figure shows an example in which T13 is clocked with half the frequency of T12.

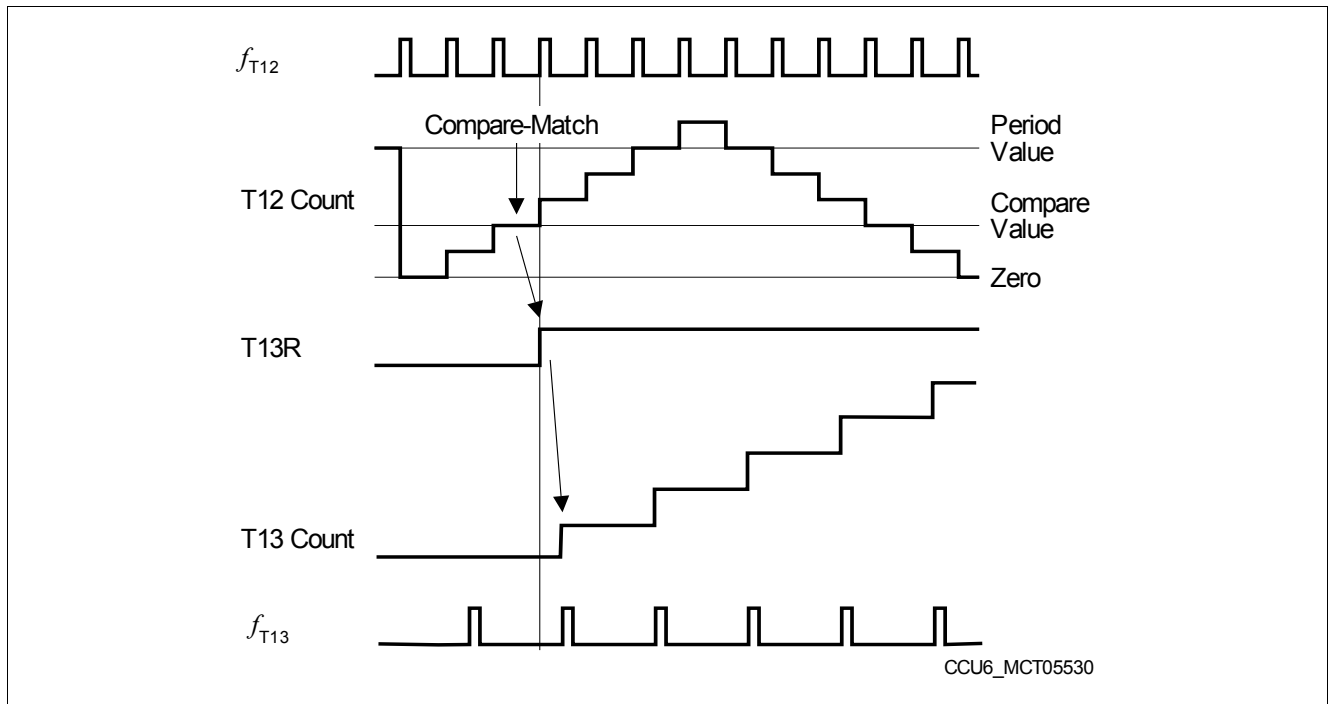

Figure 151 Synchronization of T13 to T12 Compare Match

Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to the combinations shown in [Table 119](#). Bit field T13TED additionally specifies for which count direction of T12 the selected trigger event should be regarded (see [Table 120](#)).

Table 119 T12 Trigger Event Selection

T13TEC	Selected Event
000 _B	None
001 _B	T12 Compare Event on Channel 0 (CM_CC60)
010 _B	T12 Compare Event on Channel 1 (CM_CC61)
011 _B	T12 Compare Event on Channel 2 (CM_CC62)
100 _B	T12 Compare Event on any Channel (0, 1, 2)
101 _B	T12 Period-Match (T12_PM)
110 _B	T12 Zero-Match while counting up (T12_ZM and CDIR = 0)
111 _B	Any Hall State Change

Table 120 T12 Trigger Event Additional Specifier

T13TED	Selected Event Specifier
00 _B	Reserved, no action
01 _B	Selected event is active while T12 is counting up (CDIR = 0)
10 _B	Selected event is active while T12 is counting down (CDIR = 1)
11 _B	Selected event is active independently of the count direction of T12

19.4.3 T13 Compare Mode

Associated with Timer T13 is one compare channel, that can perform compare operations with regard to the contents of the T13 counter.

Figure 147 gives an overview on the T13 channel in Compare Mode. The channel is connected to the T13 counter register via an equal-to comparator, generating a compare match signal when the contents of the counter matches the contents of the compare register.

The channel consists of the comparator and a double register structure - the actual compare register, CC63R, feeding the comparator, and an associated shadow register, CC63SR, that is preloaded by software and transferred into the compare register when signal T13 shadow transfer, T13_ST, gets active. Providing a shadow register for the compare value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

Associated with the channel is a State Bit, CMPSTAT.CC63ST, holding the status of the compare operation.

Figure 152 gives an overview on the logic for the State Bit.

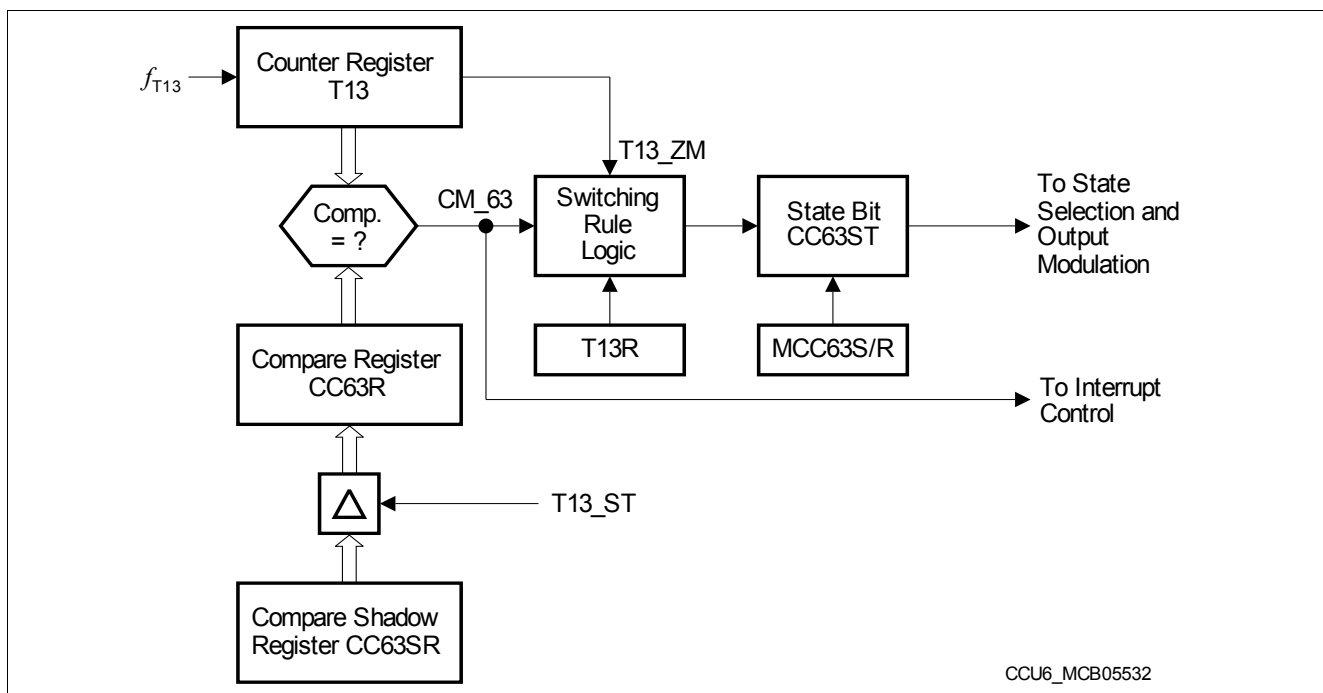

Figure 152 T13 State Bit Block Diagram

A compare interrupt event CM_63 is signaled when a compare match is detected. The actual setting of a State Bit has no influence on the interrupt generation.

The inputs to the switching rule logic for the CC63ST bit are the timer run bit (T13R), the timer zero-match signal (T13_ZM), and the actual individual compare-match signal CM_63. In addition, the state bit can be set or cleared by software via bits MCC63S and MCC63R in register CMPMODIF.

A modification of the State Bit CC63ST by hardware is only possible while Timer T13 is running (T13R = 1). If this is the case, the following switching rules apply for setting and resetting the State Bit in Compare Mode:

State Bit CC63ST is set to 1

- with the next T13 clock (f_{T13}) after a compare-match (T13 is always counting up) (i.e., when the counter is incremented above the compare value);
- with the next T13 clock (f_{T13}) after a zero-match AND a parallel compare-match.

State Bit CC63ST is cleared to 0

- with the next T13 clock (f_{T13}) after a zero-match AND NO parallel compare-match.

Figure 153 T13 Compare Operation

19.4.4 Compare Mode Output Path

Figure 154 gives an overview on the signal path from the channel State Bit CC63ST to its output pin COUT63. As illustrated, a user can determine the desired output behavior in relation to the current state of CC63ST. Please refer to [Section 19.3.4.3](#) for detailed information on the output modulation for T12 signals.

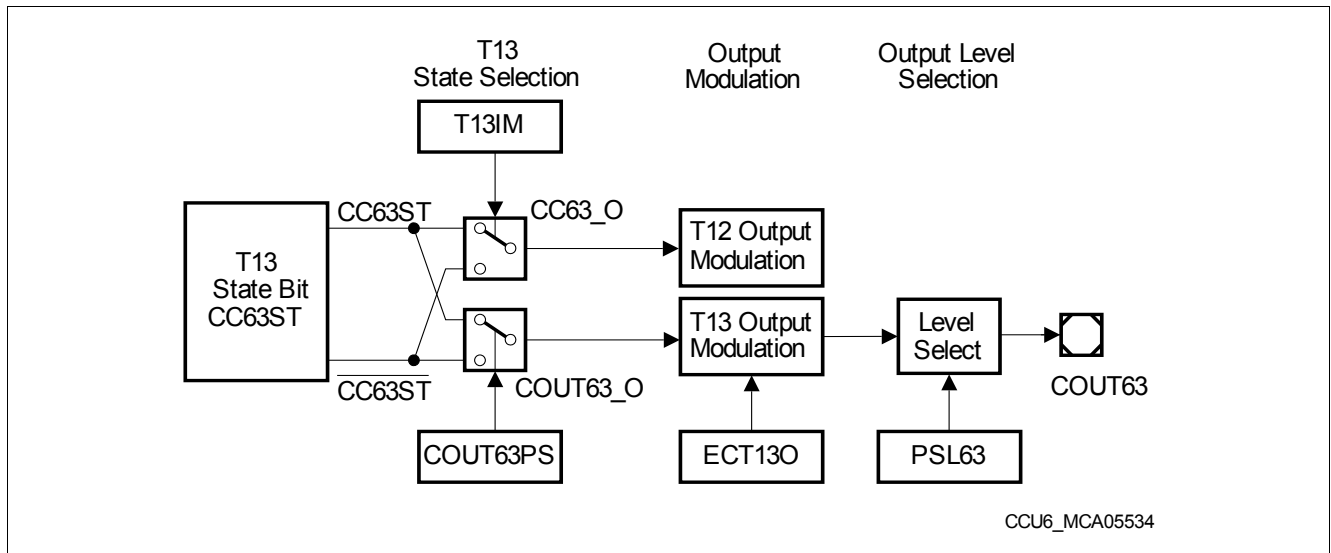

Figure 154 Channel 63 Output Path

The output line COUT63_O can generate a T13 PWM at the output pin COUT63. The signal CC63_O can be used to modulate the T12-related output signals with a T13 PWM. In order to decouple COUT63 from the internal modulation, the compare state leading to an active signal can be selected independently by bits T13IM and COUT63PS.

The last block of the data path is the Output Modulation block. Here, the modulation source T13 and the trap functionality are combined and control the actual level of the output pin COUT63 (see [Figure 155](#)):

- The **T13 related compare signal** COUT63_O delivered by the T13 state selection with the enable bit MODCTR.ECT13O
- The **trap state** TRPS with an individual enable bit TRPCTR.TRPEN13

If the modulation input signal COUT63_O is enabled (ECT13O = 1) and is at passive state, the modulated is also in passive state. If the modulation input is not enabled, the output is in passive state.

If the Trap State is active (TRPS = 1), then the output enabled for the trap signal (by TRPEN13 = 1) is set to the passive state.

The output of the modulation control block is connected to a level select block. It offers the option to determine the actual output level of a pin, depending on the state of the output line (decoupling of active/passive state and output polarity) as specified by the Passive State Select bit PSLR.PSL63. If the modulated output signal is in the passive state, the level specified directly by PSL63 is output. If it is in the active state, the inverted level of PSL63 is output. This allows the user to adapt the polarity of an active output signal to the connected circuitry.

The PSL63 bit has a shadow register to allow for updates with the T13 shadow transfer signal (T13_ST) without undesired pulses on the output lines. A read action returns the actually used value, whereas a write action targets the shadow bit. Providing a shadow register for the PSL value as well as for other values related to the generation of the PWM signal facilitates a concurrent update by software for all relevant parameters.

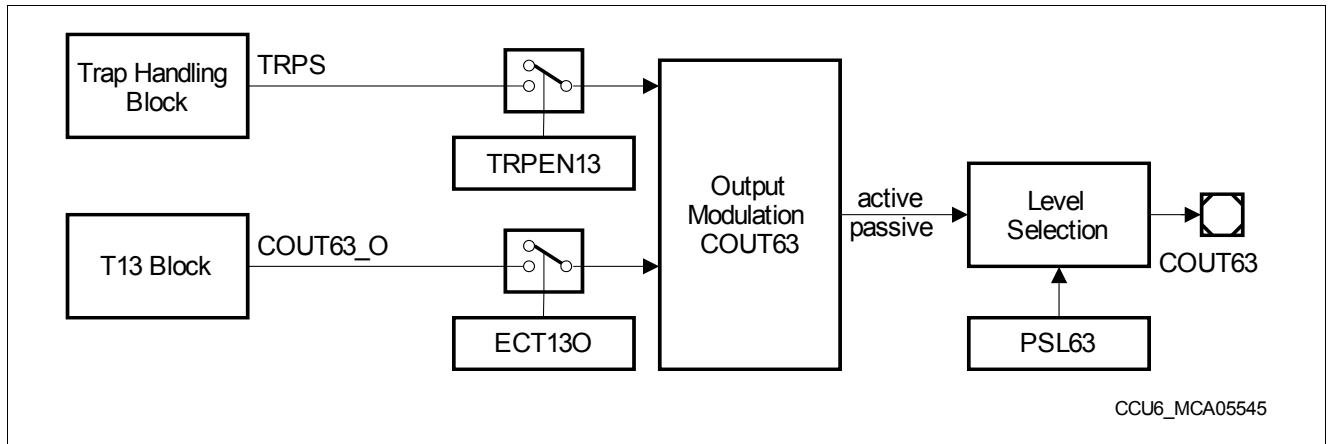

Figure 155 T13 Output Modulation

19.4.5 T13 Shadow Register Transfer

A special shadow transfer signal (T13_ST) can be generated to facilitate updating the period and compare values of the compare channel CC63 synchronously to the operation of T13. Providing a shadow register for values defining one PWM period facilitates a concurrent update by software for all relevant parameters. The next PWM period can run with a new set of parameters. The generation of this signal is requested by software via bit TCTR0.STE13 (set by writing 1 to the write-only bit TCTR4.T13STR, cleared by writing 1 to the write-only bit TCTR4.T13STD).

When signal T13_ST is active, a shadow register transfer is triggered with the next cycle of the T13 clock. Bit STE13 is automatically cleared with the shadow register transfer. A T13 shadow register transfer takes place (T13_ST active):

- while timer T13 is not running (T13R = 0), or
- STE13 = 1 and a Period-Match is detected while T13R = 1

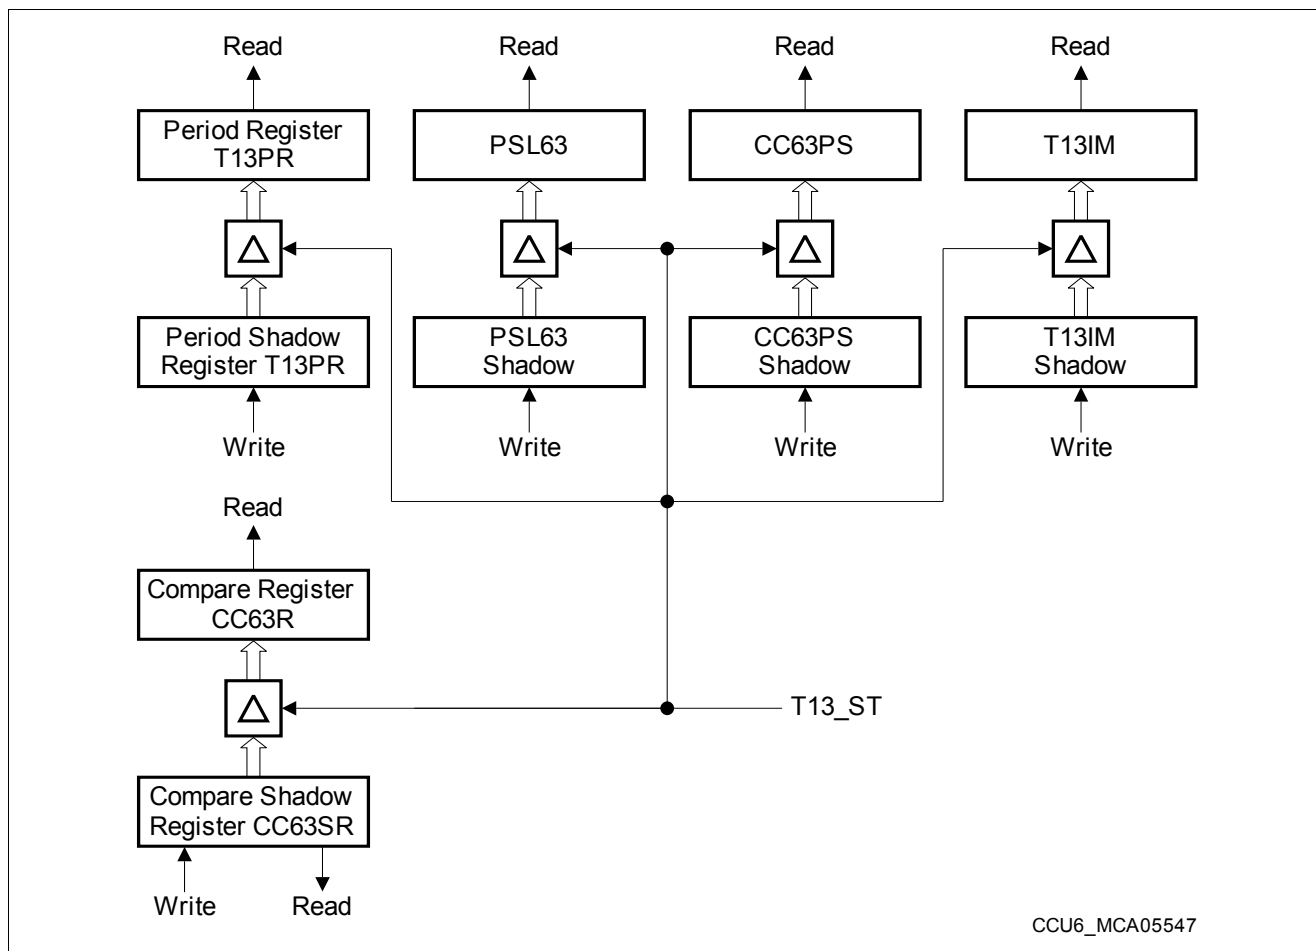

Figure 156 T13 Shadow Register Overview

19.5 Trap Handling

The trap functionality permits the PWM outputs to react on the state of the input signal $\overline{\text{CTRAP}}$. This functionality can be used to switch off the power devices if the trap input becomes active (e.g. to perform an emergency stop). The trap handling and the effect on the output modulation are controlled by the bits in the trap control register TRPCTR. The trap flags TRPF and TRPS are located in register IS and can be set/cleared by SW by writing to registers ISS and ISR.

Figure 157 gives an overview on the trap function.

The Trap Flag TRPF monitors the trap input and initiates the entry into the Trap State. The Trap State Bit TRPS determines the effect on the outputs and controls the exit of the Trap State.

When a trap condition is detected ($\overline{\text{CTRAP}} = 0$) and the input is enabled (TRPPEN = 1), both, the Trap Flag TRPF and the Trap State Bit TRPS, are set to 1 (trap state active). The output of the Trap State Bit TRPS leads to the Output Modulation Blocks (for T12 and for T13) and can there deactivate the outputs (set them to the passive state). Individual enable control bits for each of the six T12-related outputs and the T13-related output facilitate a flexible adaptation to the application needs.

There are a number of different ways to exit the Trap State. This offers SW the option to select the best operation for the application. Exiting the Trap State can be done either immediately when the trap condition is removed ($\overline{\text{CTRAP}} = 1$ or TRPPEN = 0), or under software control, or synchronously to the PWM generated by either Timer T12 or Timer T13.

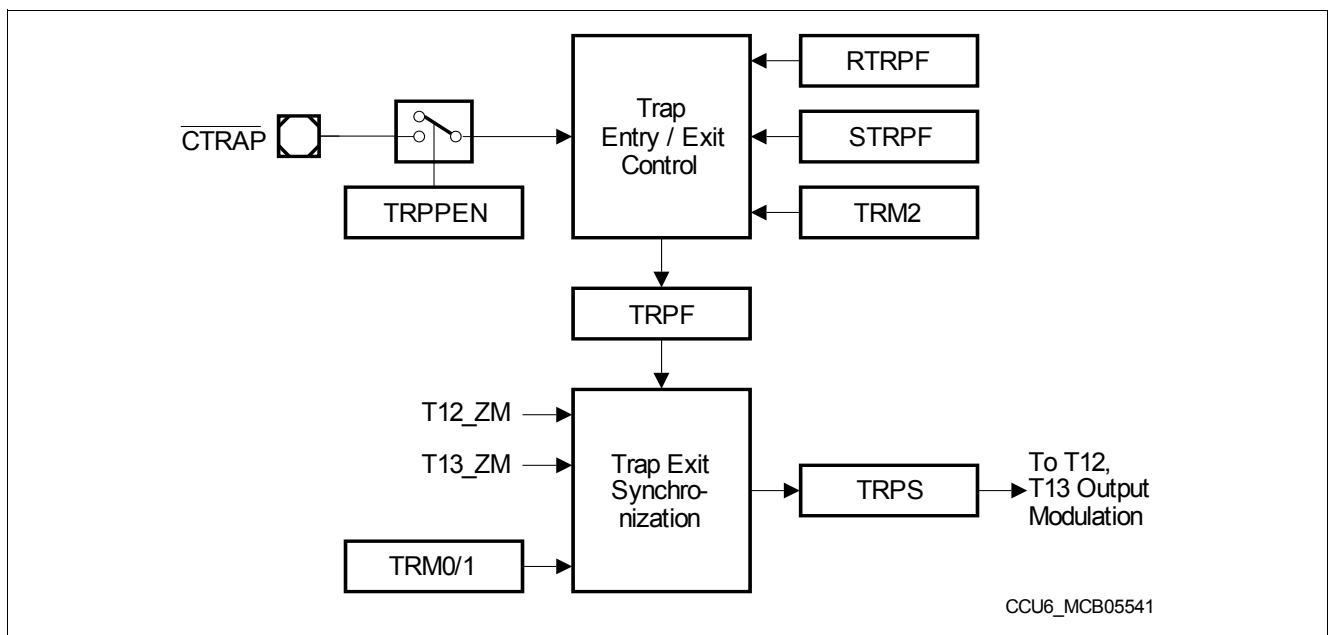

Figure 157 Trap Logic Block Diagram

Clearing of TRPF is controlled by the mode control bit TRPM2. If TRPM2 = 0, TRPF is automatically cleared by HW when $\overline{\text{CTRAP}}$ returns to the inactive level ($\overline{\text{CTRAP}} = 1$) or if the trap input is disabled (TRPPEN = 0). When TRPM2 = 1, TRPF must be reset by SW after $\overline{\text{CTRAP}}$ has become inactive.

Clearing of TRPS is controlled by the mode control bits TRPM1 and TRPM0 (located in the Trap Control Register TRPCTR). A reset of TRPS terminates the Trap State and returns to normal operation. There are three options selected by TRPM1 and TRPM0. One is that the Trap State is left immediately when the Trap Flag TRPF is cleared, without any synchronization to timers T12 or T13. The other two options facilitate the synchronization of the termination of the Trap State to the count periods of either Timer T12 or Timer T13. Figure 158 gives an overview on the associated operation.

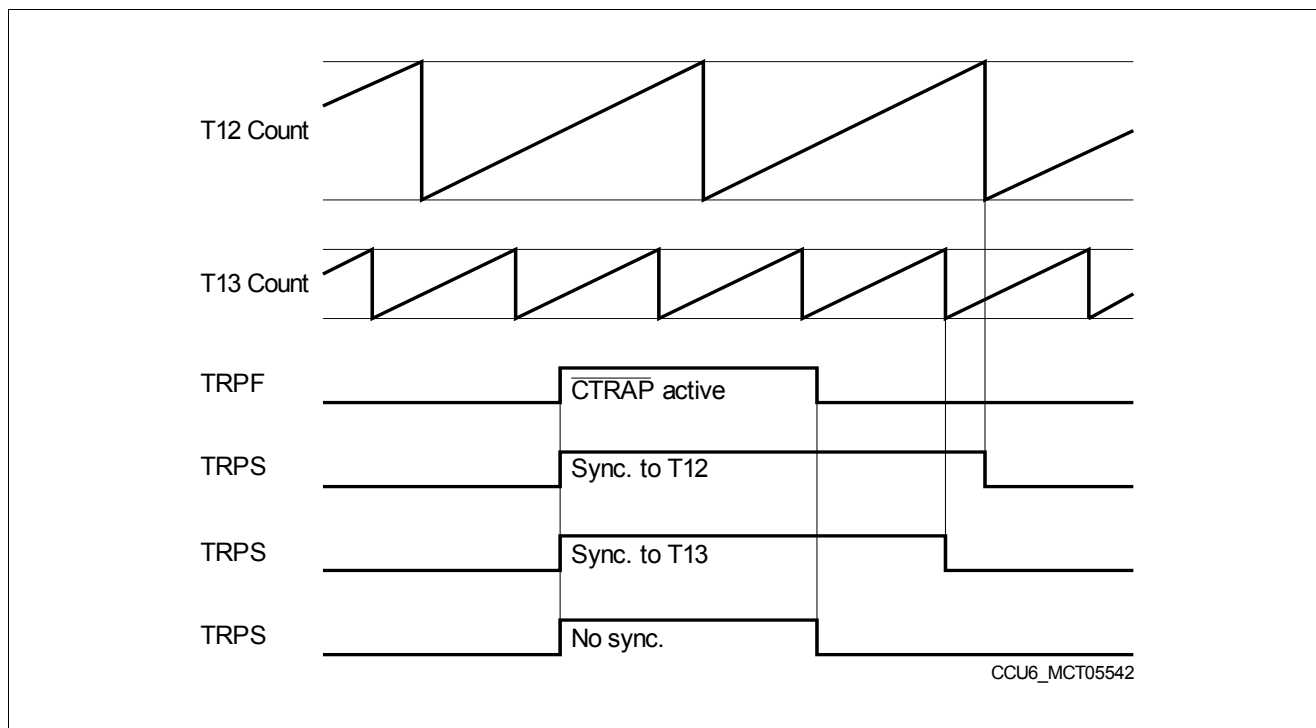

Figure 158 Trap State Synchronization (with TRM2 = 0)

19.6 Multi-Channel Mode

The Multi-Channel mode offers the possibility to modulate all six T12-related output signals with one instruction. The bits in bit field MCMOUT.MCMP are used to specify the outputs that may become active. If Multi-Channel mode is enabled (bit MODCTR.MCMEN = 1), only those outputs may become active, that have a 1 at the corresponding bit position in bit field MCMP.

This bit field has its own shadow bit field MCMOUTS.MCMPS, that can be written by software. The transfer of the new value in MCMPS to the bit field MCMP can be triggered by, and synchronized to, T12 or T13 events. This structure permits the software to write the new value, that is then taken into account by the hardware at a well-defined moment and synchronized to a PWM signal. This avoids unintended pulses due to unsynchronized modulation sources.

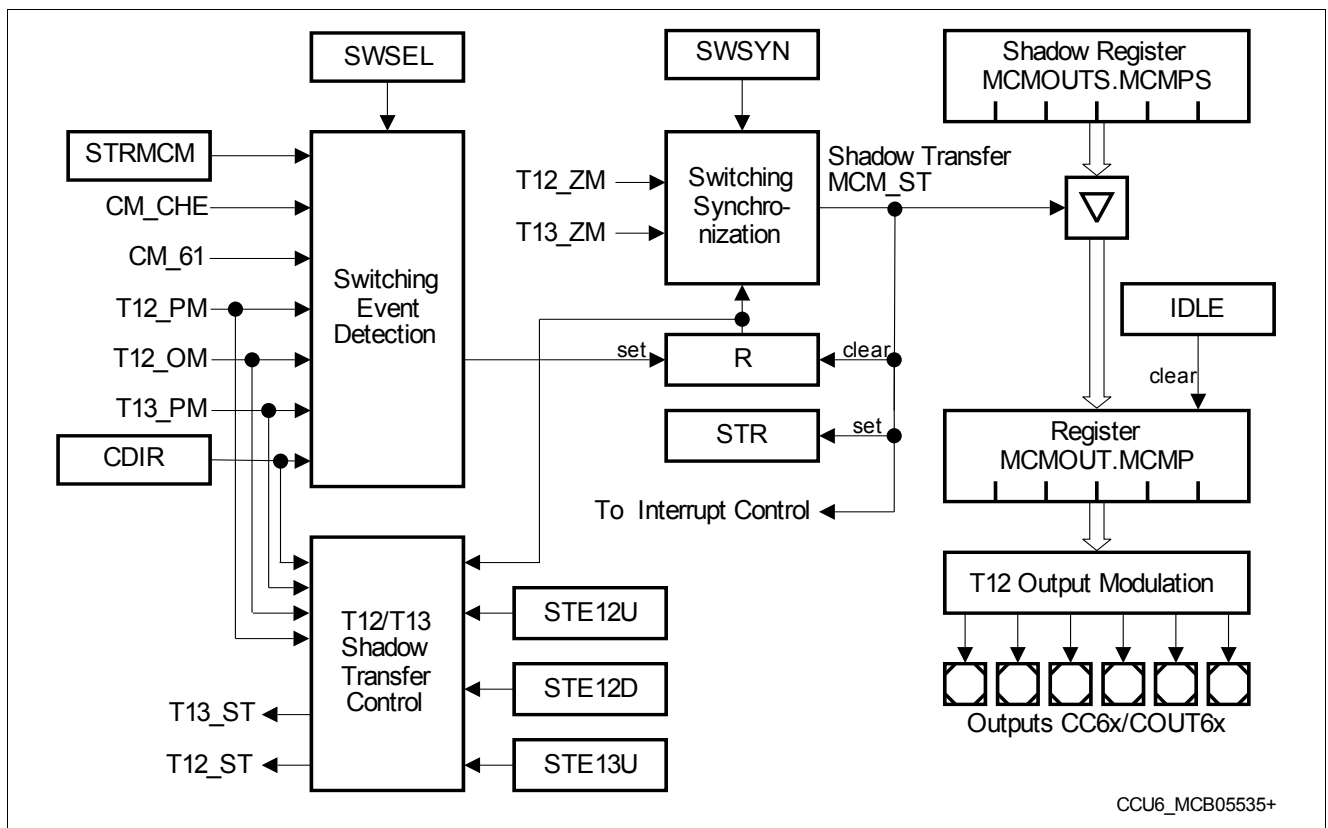

Figure 159 Multi-Channel Mode Block Diagram

Figure 159 shows the functional blocks for the Multi-Channel operation, controlled by bit fields in register MCMCTR. The event that triggers the update of bit field MCMP is chosen by SWSEL. In order to synchronize the update of MCMP to a PWM generated by T12 or T13, bit field SWSYN allows the selection of the synchronization event leading to the transfer from MCMPS to MCMP. Due to this structure, an update takes place with a new PWM period. A reminder flag R is set when the selected switching event occurs (the event is not necessarily synchronous to the modulating PWM), and is cleared when the transfer takes place. This flag can be monitored by software to check for the status of this logic block. If the shadow transfer from MCMPS to MCMP takes place, bit IS.STR becomes set and an interrupt can be generated.

In addition to the Multi-Channel shadow transfer event MCM_ST, the shadow transfers for T12 (T12_ST) and T13 (T13_ST) can be generated to allow concurrent updates of applied duty cycles for T12 and/or T13 modulation and Multi-Channel patterns.

If it is explicitly desired, the update takes place immediately with the occurrence of the selected event when the direct synchronization mode is selected. The update can also be requested by software by writing to bit field

MCMPs with the shadow transfer request bit STRMCM = 1. The option to trigger an update by SW is possible for all settings of SWSEL.

By using the direct mode and bit STRMCM = 1, the update takes place completely under software control.

Table 121 Multi-Channel Mode Switching Event Selection

SWSEL	Selected Event (see register MCMCTR)
000 _B	No automatic event detection
001 _B	Correct Hall Event (CM_CHE) detected at input signals CCPOSx without additional delay
010 _B	T13 Period-Match (T13_PM)
011 _B	T12 One-Match while counting down (T12_OM and CDIR = 1)
100 _B	T12 Compare Channel 1 Event while counting up (CM_61 and CDIR = 0) to support the phase delay function by CC61 for block commutation mode.
101 _B	T12 Period-Match while counting up (T12_PM and CDIR = 0)
110 _B , 111 _B	Reserved, no action

Table 122 Multi-Channel Mode Switching Synchronization

SWSYN	Synchronization Event (see register MCMCTR)
00 _B	Direct Mode: the trigger event directly causes the shadow transfer
01 _B	T13 Zero-Match (T13_ZM), the MCM shadow transfer is synchronized to a T13 PWM
10 _B	T12 Zero-Match (T12_ZM), the MCM shadow transfer is synchronized to a T12 PWM
11 _B	Reserved, no action

19.7 Hall Sensor Mode

For Brushless DC-Motors in block commutation mode, the Multi-Channel Mode has been introduced to provide efficient means for switching pattern generation. These patterns need to be output in relation to the angular position of the motor. For this, usually Hall sensors or Back-EMF sensing are used to determine the angular rotor position. The CCU6 provides three inputs, CCPOS0, CCPOS1, and CCPOS2, that can be used as inputs for the Hall sensors or the Back-EMF detection signals.

There is a strong correlation between the motor position and the output modulation pattern. When a certain position of the motor has been reached, indicated by the sampled Hall sensor inputs (the Hall pattern), the next, pre-determined Multi-Channel Modulation pattern has to be output. Because of different machine types, the modulation pattern for driving the motor can vary. Therefore, it is wishful to have a wide flexibility in defining the correlation between the Hall pattern and the corresponding Modulation pattern. Furthermore, a hardware mechanism significantly reduces the CPU for block-commutation.

The CCU6 offers the flexibility by having a register containing the currently assumed Hall pattern (CURH), the next expected Hall pattern (EXPH) and the corresponding output pattern (MCMP). A new Modulation pattern is output when the sampled Hall inputs match the expected ones (EXPH). To detect the next rotation phase (segment for block commutation), the CCU6 monitors the Hall inputs for changes. When the next expected Hall pattern is detected, the next corresponding Modulation pattern is output.

To increase for noise immunity (to a certain extend), the CCU6 offers the possibility to introduce a sampling delay for the Hall inputs. Some changes of the Hall inputs are not leading to the expected Hall pattern, because they are only short spikes due to noise. The Hall pattern compare logic compares the Hall inputs to the next expected pattern and also to the currently assumed pattern to filter out spikes.

For the Hall and Modulation output patterns, a double-register structure is implemented. While register MCMOUT holds the actually used values, its shadow register MCMOUTS can be loaded by software from a pre-defined table, holding the appropriate Hall and Modulation patterns for the given motor control.

A transfer from the shadow register into register MCMOUT can take place when a correct Hall pattern change is detected. Software can then load the next values into register MCMOUTS. It is also possible by software to force a transfer from MCMOUTS into MCMOUT.

Note: The Hall input signals CCPOSx and the CURH and EXPH bit fields are arranged in the following order:

CCPOS0 corresponds to CURH.0 (LSB) and EXPH.0 (LSB)

CCPOS1 corresponds to CURH.1 and EXPH.1

CCPOS2 corresponds to CURH.2 (MSB) and EXPH.2 (MSB)

19.7.1 Hall Pattern Evaluation

The Hall sensor inputs CCPOSx can be permanently monitored via an edge detection block (with the module clock f_{CC6}). In order to suppress spikes on the Hall inputs due to noise in rugged inverter environment, two optional noise filtering methods are supported by the Hall logic (both methods can be combined).

- Noise filtering with delay:
For this function, the mode control bit fields MSEL6x for all T12 compare channels must be programmed to 1000_B and DBYP = 0. The selected event triggers Dead-Time Counter 0 to generate a programmable delay (defined by bit field DTM). When the delay has elapsed, the evaluation signal HCRDY becomes activated. Output modulation with T12 PWM signals is not possible in this mode.
- Noise filtering by synchronization to PWM:
The Hall inputs are not permanently monitored by the edge detection block, but samples are taken only at defined points in time during a PWM period. This can be used to sample the Hall inputs when the switching noise (due to PWM) does not disturb the Hall input signals.

If neither the delay function of Dead-Time Counter 0 is not used for the Hall pattern evaluation nor the Hall mode for Brushless DC-Drive control is enabled, the timer T12 block is available for PWM generation and output modulation.

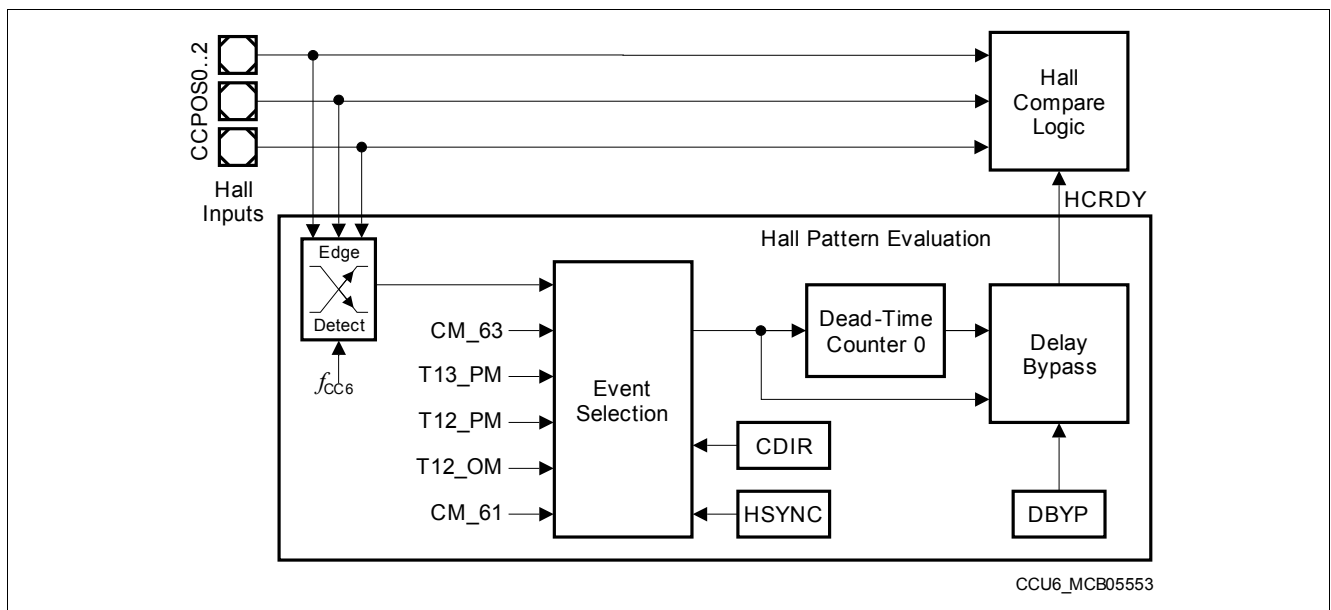

Figure 160 Hall Pattern Evaluation

If the evaluation signal HCRDY (Hall Compare Ready, see [Figure 161](#)) becomes activated, the Hall inputs are sampled and the Hall compare logic starts the evaluation of the Hall inputs.

[Figure 160](#) illustrates the events for Hall pattern evaluation and the noise filter logic, [Table 123](#) summarizes the selectable trigger input signals.

Table 123 Hall Sensor Mode Trigger Event Selection

HSYNC	Selected Event (see register T12MSEL)
000 _B	Any edge at any of the inputs CCPOSx, independent from any PWM signal (permanent check).
001 _B	A T13 Compare-Match (CM_63).
010 _B	A T13 Period-Match (T13_PM).
011 _B	Hall sampling triggered by HW sources is switched off.
100 _B	A T12 Period-Match while counting up (T12_PM and CDIR = 0).
101 _B	A T12 One-Match while counting down (T12_OM and CDIR = 1).
110 _B	A T12 Compare-Match of compare channel CC61 while counting up (CM_61 and CDIR = 0).
111 _B	A T12 Compare-Match of compare channel CC61 while counting down (CM_61 and CDIR = 1).

19.7.2 Hall Pattern Compare Logic

Figure 161 gives an overview on the double-register structure and the pattern compare logic. Software writes the next modulation pattern (MCMPS) and the corresponding current (CURHS) and expected (EXPHS) Hall patterns into the shadow register MCMOUTS. Register MCMOUT holds the actually used values CURH and EXPH. The modulation pattern MCMP is provided to the T12 Output Modulation block. The current (CURH) and expected (EXPH) Hall patterns are compared to the sampled Hall sensor inputs (visible in register CMPSTAT). Sampling of the inputs and the evaluation of the comparator outputs is triggered by the evaluation signal HCRDY (Hall Compare Ready), that is detailed in the next section.

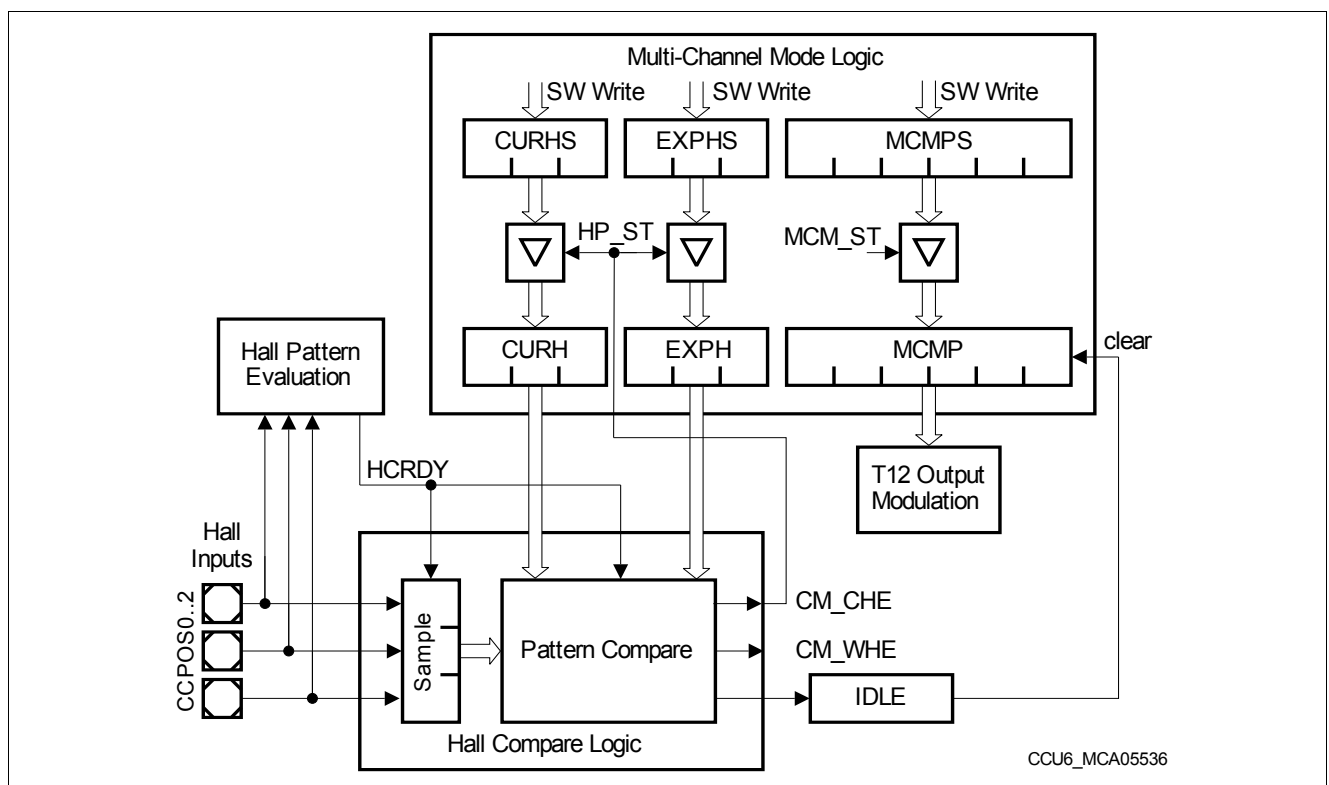

Figure 161 Hall Pattern Compare Logic

- If the sampled Hall pattern matches the value programmed in CURH, the detected transition was a spike (no Hall event) and no further actions are necessary.
- If the sampled Hall pattern matches the value programmed in EXPH, the detected transition was the expected event (correct Hall event CM_CHE) and the MCMP value has to change.
- If the sampled Hall pattern matches neither CURH nor EXPH, the transition was due to a major error (wrong Hall event CM_CWE) and can lead to an emergency shut down (IDLE).

At every correct Hall event (CM_CHE), the next Hall patterns are transferred from the shadow register MCMOUTS into MCMOUT (Hall pattern shadow transfer HP_ST), and a new Hall pattern with its corresponding output pattern can be loaded (e.g. from a predefined table in memory) by software into MCMOUTS. For the Modulation patterns, signal MCM_ST is used to trigger the transfer.

Loading this shadow register can also be done by writing MCMOUTS.STRHP = 1 (for EXPH and CURH) or MCMOUTS.STRMCMP = 1 (for MCMP).

19.7.3 Hall Mode Flags

Depending on the Hall pattern compare operation, a number of flags are set in order to indicate the status of the module and to trigger further actions and interrupt requests.

Flag IS.CHE (Correct Hall Event) is set by signal CM_CHE when the sampled Hall pattern matches the expected one (EXPH). This flag can also be set by SW by setting bit ISS.SCHE = 1. If enabled by bit IEN.ENCHE = 1, the set signal for CHE can also generate an interrupt request to the CPU. Bit field INP.INPCHE defines which service request output becomes activated in case of an interrupt request. To clear flag CHE, SW needs to write ISR.RCHE = 1.

Flag IS.WHE indicates a Wrong Hall Event. Its handling for flag setting and resetting as well as interrupt request generation are similar to the mechanism for flag CHE.

The implementation of flag STR is done in the same way as for CHE and WHE. This flag is set by HW by the shadow transfer signal MCM_ST (see also [Figure 159](#)).

Please note that for flags CHE, WHE, and STR, the interrupt request generation is triggered by the set signal for the flag. That means, a request can be generated even if the flag is already set. There is no need to clear the flag in order to enable further interrupt requests.

The implementation for the IDLE flag is different. It is set by HW through signal CM_WHE if enabled by bit ENIDLE. Software can also set the flag via bit SIDLE. As long as bit IDLE is set, the modulation pattern field MCM_P is cleared to force the outputs to the passive state. Flag IDLE must be cleared by software by writing RIDLE = 1 in order to return to normal operation. To fully restart from IDLE mode, the transfer requests for the bit fields in register MCMOUTS to register MCMOUT have to be initiated by software via bits STRMCM and STRHP in register MCMOUTS. In this way, the release from IDLE mode is under software control, but can be performed synchronously to the PWM signal.

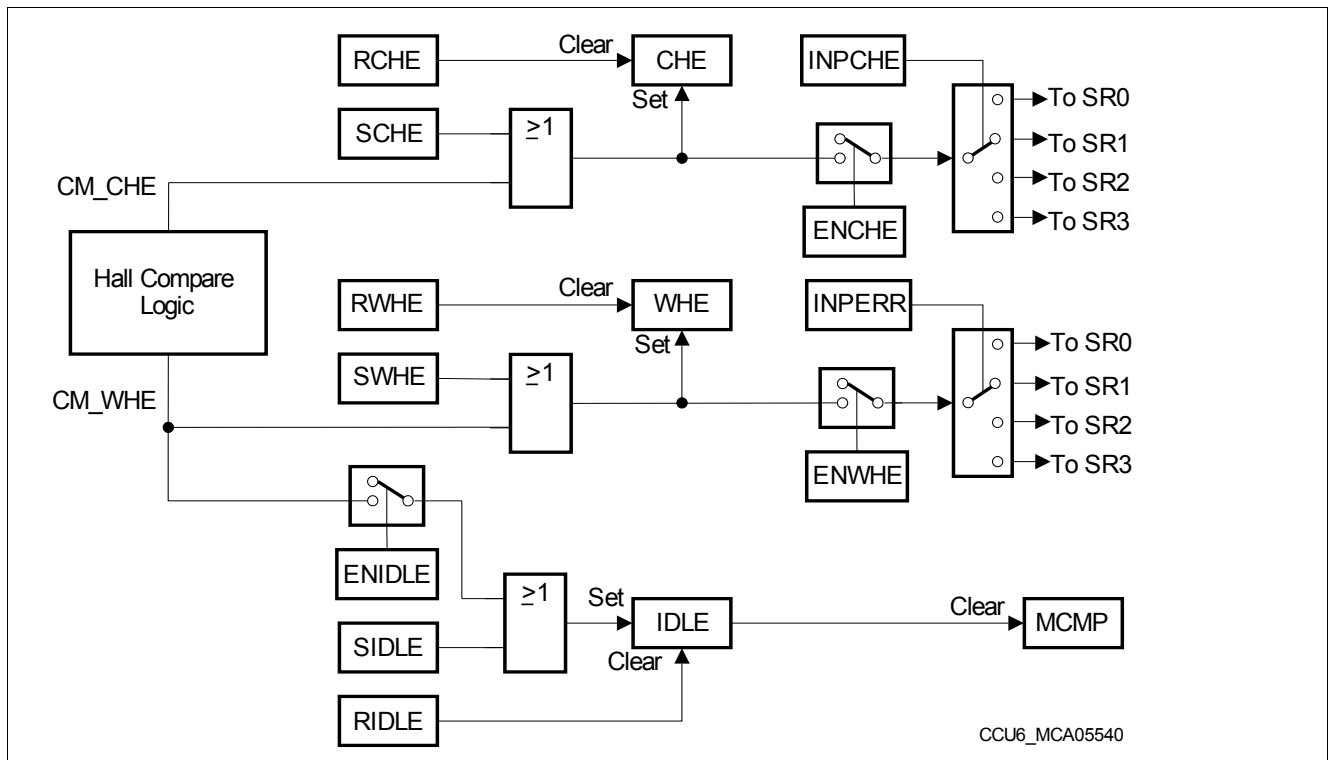

Figure 162 Hall Mode Flags

19.7.4 Hall Mode for Brushless DC-Motor Control

The CCU6 provides a mode for the Timer T12 Block especially targeted for convenient control of block commutation patterns for Brushless DC-Motors. This mode is selected by setting all T12MSEL.MSEL6x bit fields of the three T12 Channels to 1000_B.

In this mode, illustrated in [Figure 163](#), channel CC60 is placed in capture mode to measure the time elapsed between the last two correct Hall events, channel CC61 in compare mode to provide a programmable phase delay between the Hall event and the application of a new PWM output pattern, and channel CC62 also in compare mode as first time-out criterion. A second time-out criterion can be built by the T12 period match event.

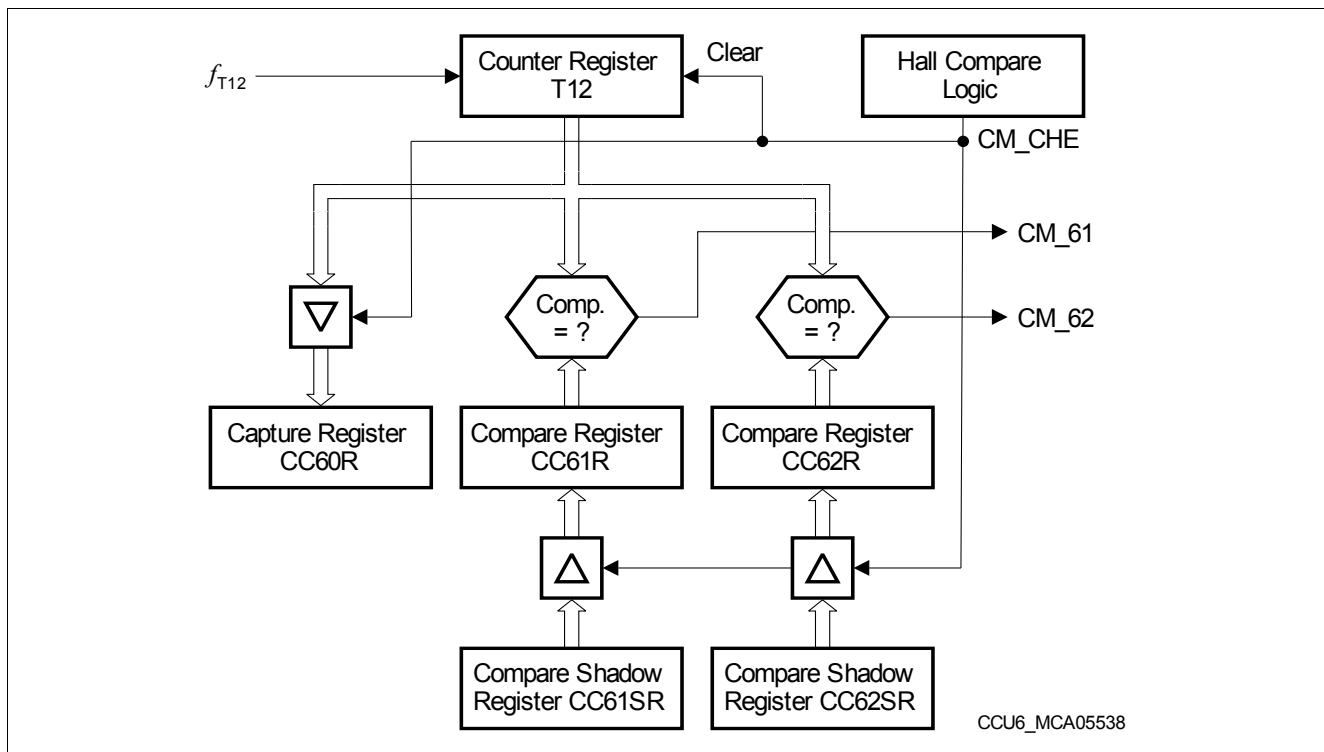

Figure 163 T12 Block in Hall Sensor Mode

The signal CM_CHE from the Hall compare logic is used to transfer the new compare values from the shadow registers CC6xSR into the actual compare registers CC6xR, performs the shadow transfer for the T12 period register, to capture the current T12 contents into register CC60R, and to clear T12.

Note: In this mode, the shadow transfer signal T12_ST is not generated. Not all shadow bits, such as the PSLy bits, will be transferred to their main registers. To program the main registers, SW needs to write to these registers while Timer T12 is stopped. In this case, a SW write actualizes both registers.

Figure 164 Brushless DC-Motor Control Example (all MSEL6x = 1000_B)

After the detection of an expected Hall pattern (CM_CHE active), the T12 count value is captured into channel CC60 (representing the actual rotor speed by measuring the elapsed time between the last two correct Hall events), and T12 is reset. When the timer reaches the compare value in channel CC61, the next multi-channel state is switched by triggering the shadow transfer of bit field MCMP (if enabled in bit field **SWEN**). This trigger event can be combined with the synchronization of the next multi-channel state to the PWM source (to avoid spikes on the output lines, see [Section 19.6](#)). This compare function of channel CC61 can be used as a phase delay from the position sensor input signals to the switching of the output signals, that is necessary if a sensorless back-EMF technique or Hall sensors are used. The compare value in channel CC62 can be used as a time-out trigger (interrupt), indicating that the actual motor speed is far below the desired destination value. An abnormal load change can be detected with this feature and PWM generation can be disabled.

19.8 General Module Operation

This section provides information about the:

- Input selection (see [Section 19.8.1](#))

19.8.1 Input Selection

Each CCU6 input signal can be selected from a vector of four or eight possible inputs by programming the port input select registers PISEL0 and PISEL2. This permits to adapt the pin functionality of the device to the application requirements.

The output pins for the module output signals are chosen in the ports.

Note: All functional inputs of the CCU6 are synchronized to f_{CC6} before they affect the module internal logic. The resulting delay of $2/f_{CC6}$ and for asynchronous signals an additional uncertainty of $1/f_{CC6}$ have to be taken into account for precise timing calculation. An edge of an input signal can only be correctly detected if the high phase and the low phase of the input signal are both longer than $1/f_{CC6}$.

19.9 Module Interfaces

This section describes the CCU6 module interfaces with the clock control, port connections, interrupt control, and address decoding.

19.9.1 Interfaces of the CCU6 Module

An overview of the CCU6 kernel I/O interface is shown in [Figure 165](#).

The interrupt lines of the CCU6 are connected to the CPU interrupt controller via the SCU. An interrupt pulse can be generated at one of the four interrupt output lines SRCx (x=0 to 4) of the module. More than one CCU6 interrupt source can be connected to each CCU6 interrupt line.

The General Purpose IO (GPIO) Ports provide the interface from the CCU6 to the external world. Please refer to [Chapter 15](#) for Port implementation details.

The CCU6 kernel is clocked on PCLK frequency where $f_{CCU} = f_{PCLK}$.

Debug Suspend of Timers

The timers of CCU6, T12 and T13, can be suspended immediately when Debug Mode enters Monitor Mode and has the Debug-Suspend signal activated – provided the respective timer suspend bits, T12SUSP and T13SUSP (in SCU SFR MODSUSP), are set. When suspended, the respective timer stops and its PWM outputs enabled for the trap condition ([TRPCTR](#).TRPENx = 1) are set to respective passive levels (similar to TRAP state). In addition, all CCU6 inputs are frozen. Refer to SCU [Chapter 7.9](#).

Flexible Peripheral Management (Kernel Clock Gating) of CCU6

When not in use, the CCU6 kernel may be disabled where the kernel clock input is gated. When the [PMCON1](#).CCU_DIS request bit is set, both T12 and T13 are immediately stopped and PWM outputs enabled for the trap condition ([TRPCTR](#).TRPENx = 1) are set to respective passive levels (similar to TRAP state). In addition, all CCU6 inputs are frozen. Finally, the kernel clock input is gated. Refer to SCU [Chapter 7.8](#).

The following figure shows all interrupt and interface signals and GPIO interface associated with the CCU6 module kernel.

Capture/Compare Unit 6 (CCU6)

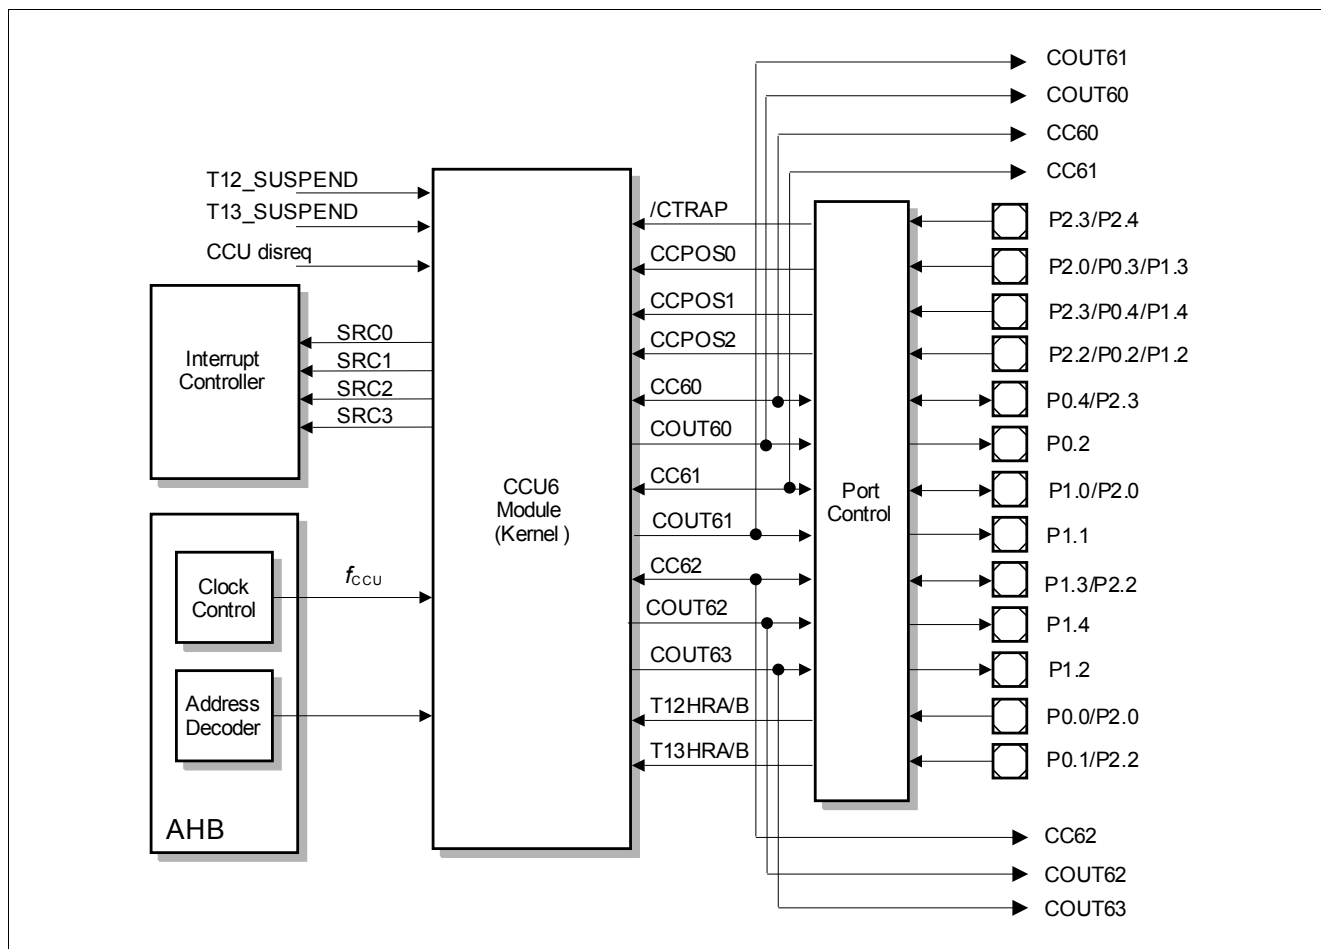

Figure 165 Interconnections of the CCU6 Module

19.10 Interrupt Handling

This section describes the interrupt handling of the CCU6 module.

19.10.1 Interrupt Structure

The HW interrupt event or the SW setting of the corresponding interrupt set bit (in register ISS) sets the event indication flags (in register IS) and can trigger the interrupt generation. The interrupt pulse is generated independently from the interrupt status flag in register IS (it is not necessary to clear the related status bit to be able to generate another interrupt). The interrupt flag can be cleared by SW by writing to the corresponding bit in register ISR.

If enabled by the related interrupt enable bit in register IEN, an interrupt pulse can be generated on one of the four service request outputs (SR0 to SR3) of the module. If more than one interrupt source is connected to the same interrupt node pointer (in register INP), the requests are logically OR-combined to one common service request output (see [Figure 166](#)).

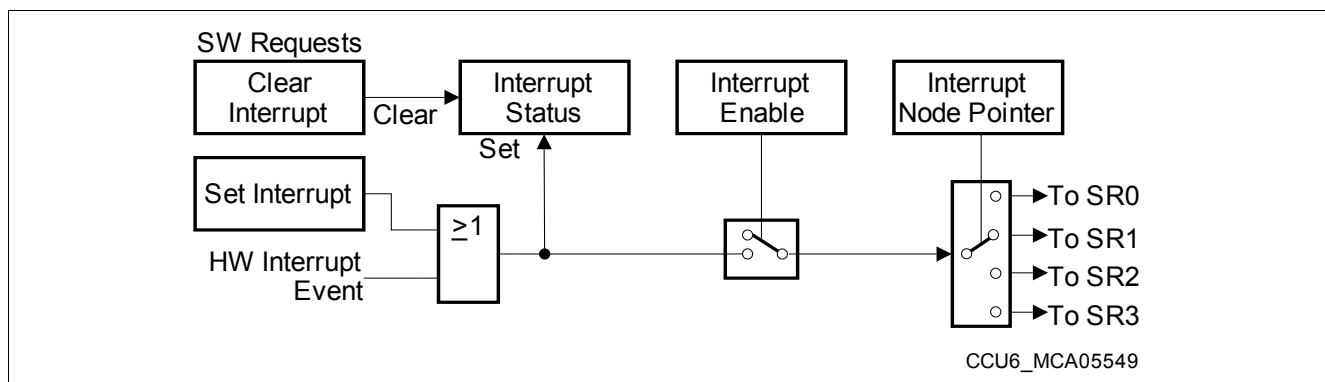

Figure 166 General Interrupt Structure

The available interrupt events in the CCU6 are shown in [Figure 167](#).

Capture/Compare Unit 6 (CCU6)

19.11 Register Definition

19.11.1 CCU6 Register Description

All CCU6 kernel register names described in this section will be referenced in other parts of this specification with the module name prefix "CCU6_".

Note: If a hardware and a software request to modify a bit occur simultaneously, the software wins.

ISCNT12	3:2	rw	Input Select for T12 Counting Input This bit field defines the input event leading to a counting action of T12. 00 _B The T12 prescaler generates the counting events. Bit TCTR4.T12CNT is not taken into account. 01 _B Bit TCTR4.T12CNT written with 1 is a counting event. The T12 prescaler is not taken into account. 10 _B The timer T12 is counting each rising edge detected in the selected T12HR signal. 11 _B The timer T12 is counting each falling edge detected in the selected T12HR signal.
ISCNT13	5:4	rw	Input Select for T13 Counting Input This bit field defines the input event leading to a counting action of T13. 00 _B The T13 prescaler generates the counting events. Bit TCTR4.T13CNT is not taken into account. 01 _B Bit TCTR4.T13CNT written with 1 is a counting event. The T13 prescaler is not taken into account. 10 _B The timer T13 is counting each rising edge detected in the selected T13HR signal. 11 _B The timer T13 is counting each falling edge detected in the selected T13HR signal.
T12EXT	6	rw	Extension for T12HR Inputs This bit extends the 2-bit field IST12HR. 0 _B One of the signals T12HR[D:A] is selected. 1 _B One of the signals T12HR[H:E] is selected.
T13EXT	7	rw	Extension for T13HR Inputs This bit extends the 2-bit field IST13HR. 0 _B One of the signals T13HR[D:A] is selected. 1 _B One of the signals T13HR[H:E] is selected.

19.11.2 Timer 12 – Related Registers

The generation of the patterns for a 3-channel PWM is based on timer T12. The registers related to timer T12 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the three PWM channels. Timer T12 supports capture and compare modes, which can be independently selected for the three channels CC60, CC61, and CC62.

Register T12MSEL contains control bits to select the capture/compare functionality of the three channels of timer T12. [Table 125](#), [Table 126](#) and [Table 127](#) define and elaborate some of the capture/compare modes selectable. Refer to the following register description for the selection.

Table 125 Double-Register Capture Modes

Description	
0100	The contents of T12 are stored in CC6nR after a rising edge and in CC6nSR after a falling edge on the input pin CC6n.
0101	The value stored in CC6nSR is copied to CC6nR after a rising edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive rising edges on pins CC6n. COUT6n is I/O.
0110	The value stored in CC6nSR is copied to CC6nR after a falling edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive falling edges on pins CC6n. COUT6n is I/O.
0111	The value stored in CC6nSR is copied to CC6nR after any edge on the input pin CC6n. The actual timer value of T12 is simultaneously stored in the shadow register CC6nSR. This feature is useful for time measurements between consecutive edges on pins CC6n. COUT6n is I/O.

Table 126 Combined T12 Modes

Description	
1000	Hall Sensor mode: Capture mode for channel 0, compare mode for channels 1 and 2. The contents of T12 are captured into CC60 at a valid hall event (which is a reference to the actual speed). CC61 can be used for a phase delay function between hall event and output switching. CC62 can act as a time-out trigger if the expected hall event comes too late. The value 1000 _B must be programmed to MSEL0, MSEL1 and MSEL2 if the hall signals are used. In this mode, the contents of timer T12 are captured in CC60 and T12 is reset after the detection of a valid hall event. In order to avoid noise effects, the dead-time counter channel 0 is started after an edge has been detected at the hall inputs. On reaching the value of 000001 _B , the hall inputs are sampled and the pattern comparison is done.
1001	Hysteresis-like control mode with dead-time generation: The negative edge of the CCPOSx input signal is used to reset bit CC6nST. As a result, the output signals can be switched to passive state immediately and switch back to active state (with dead-time) if the CCPOSx is high and the bit CC6nST is set by a compare event.

Table 127 Multi-Input Capture Modes

Description	
1010	The timer value of T12 is stored in CC6nR after a rising edge at the input pin CC6n. The timer value of T12 is stored in CC6nSR after a falling edge at the input pin CCPOSx.
1011	The timer value of T12 is stored in CC6nR after a falling edge at the input pin CC6n. The timer value of T12 is stored in CC6nSR after a rising edge at the input pin CCPOSx.
1100	The timer value of T12 is stored in CC6nR after a rising edge at the input pin CC6n. The timer value of T12 is stored in CC6nSR after a rising edge at the input pin CCPOSx.
1101	The timer value of T12 is stored in CC6nR after a falling edge at the input pin CC6n. The timer value of T12 is stored in CC6nSR after a falling edge at the input pin CCPOSx.
1110	The timer value of T12 is stored in CC6nR after any edge at the input pin CC6n. The timer value of T12 is stored in CC6nSR after any edge at the input pin CCPOSx.
11111	reserved (no capture or compare action)

In order to enable the hall edge detection, all three MSEL6x must be programmed to Hall Sensor mode. 1001 _B Hysteresis-like mode, see Table 126 . 101X _B Multi-Input Capture modes, see Table 127 . 11XX _B Multi-Input Capture modes, see Table 127 .

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
MSEL62	11:8	rw	Capture/Compare Mode Selection These bit fields select the operating mode of the three timer T12 capture/compare channels. Each channel (n = 0, 1, 2) can be programmed individually either for compare or capture operation according to: 0000 _B Compare outputs disabled, pins CC6n and COUT6n can be used for I/O. No capture action. 0001 _B Compare output on pin CC6n, pin COUT6n can be used for I/O. No capture action. 0010 _B Compare output on pin COUT6n, pin CC6n can be used for I/O. No capture action. 0011 _B Compare output on pins COUT6n and CC6n. 01XX _B Double-Register Capture modes, see Table 125 . 1000 _B Hall Sensor mode, see Table 126 . In order to enable the hall edge detection, all three MSEL6x must be programmed to Hall Sensor mode. 1001 _B Hysteresis-like mode, see Table 126 . 101X _B Multi-Input Capture modes, see Table 127 . 11XX _B Multi-Input Capture modes, see Table 127 .
HSYNC	14:12	rw	Hall Synchronization Bit field HSYNC defines the source for the sampling of the Hall input pattern and the comparison to the current and the expected Hall pattern bit fields. In all modes, a trigger by software by writing a 1 to bit SWHC is possible. 000 _B Any edge at one of the inputs CCPOSx (x = 0, 1, 2) triggers the sampling. 001 _B A T13 compare-match triggers the sampling. 010 _B A T13 period-match triggers the sampling. 011 _B The Hall sampling triggered by hardware sources is switched off. 100 _B A T12 period-match (while counting up) triggers the sampling. 101 _B A T12 one-match (while counting down) triggers the sampling. 110 _B A T12 compare-match of channel 1 (while counting up) triggers the sampling. 111 _B A T12 compare-match of channel 1 (while counting down) triggers the sampling.
DBYP	15	rw	Delay Bypass Bit DBYP defines if the source signal for the sampling of the Hall input pattern (selected by HSYNC) uses the dead-time counter DTC0 of timer T12 as additional delay or if the delay is bypassed. 0 _B The delay bypass is not active. The dead-time counter DTC0 is generating a delay after the source signal becomes active. 1 _B The delay bypass is active. The dead-time counter DTC0 is not used by the sampling of the Hall pattern.

Register T12 represents the counting value of timer T12. It can only be written while the timer T12 is stopped. Write actions while T12 is running are not taken into account. Register T12 can always be read by software.

In edge-aligned mode, T12 only counts up, whereas in center-aligned mode, T12 can count up and down.

T12

Timer T12 Counter Register

(78_H)

Reset Value: 00_H

Field	Bits	Type	Description
T12CV	15:0	rwh	Timer T12 Counter Value This register represents the 16-bit counter value of timer T12.

Note: While timer T12 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

Note: The timer period, compare values, passive state selects bits and passive levels bits for both timers are written to shadow registers and not directly to the actual registers. Thus, the values for a new output signal can be programmed without disturbing the currently generated signal(s). The transfer from the shadow registers to the actual registers is enabled by setting the respective shadow transfer enable bit STEx. If the transfer is enabled, the shadow registers are copied to the respective registers as soon as the associated timer reaches the value zero the next time (being cleared in edge-aligned mode or counting down from 1 in center-aligned mode). When timer T12 is operating in center-aligned mode, it will also copy the registers (if enabled by STE12) if it reaches the currently programmed period value (counting up). When a timer is stopped (TxR = 0), the shadow transfer takes place immediately if the corresponding bit STEx is set. After the transfer, the respective bit STEx is cleared automatically.

Register T12PR contains the period value for timer T12. The period value is compared to the actual counter value of T12 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE12. A read action by software delivers the value which is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T12-related values.

Capture/Compare Unit 6 (CCU6)

T12PR

Timer T12 Period Register

(24_H)

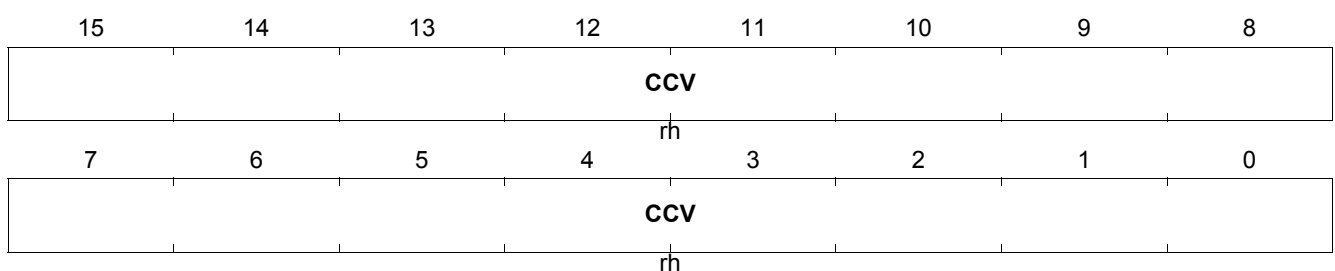

Reset Value: 0000_H

Field	Bits	Type	Description
T12PV	15:0	rwh	T12 Period Value The value T12PV defines the counter value for T12, which leads to a period-match. On reaching this value, the timer T12 is set to zero (edge-aligned mode) or changes its count direction to down counting (center-aligned mode). Note: T12PV = 0xFFFF shall not be used to avoid overflow conditions when using the Zero Match and Period Match Trigger signals (PM and ZM)

In compare mode, the registers CC6xR (x = 0, 1, 2) are the actual compare registers for T12. The values stored in CC6xR are compared (all three channels in parallel) to the counter value of T12. In capture mode, the current value of the T12 counter register is captured by registers CC6xR if the corresponding capture event is detected.

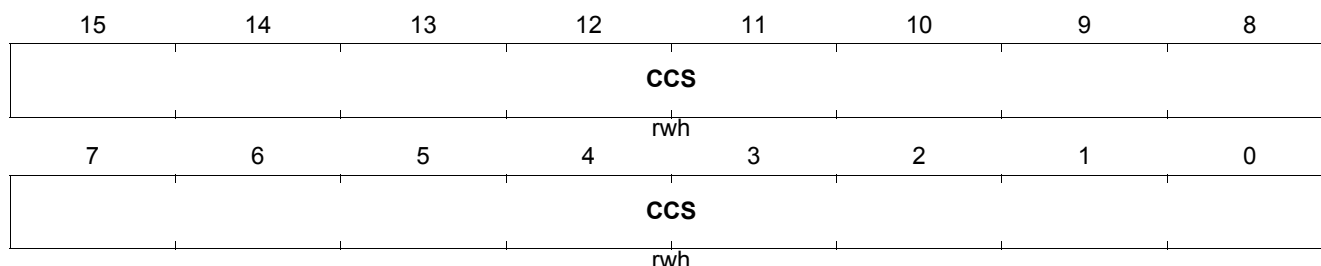

CC6xR (x = 0-2)

Capture/Compare Register for Channel CC6x (34_H+x*4_H)

Reset Value: 0000_H

Field	Bits	Type	Description
CCV	15:0	rh	Channel x Capture/Compare Value In compare mode, the bit fields CCV contain the values that are compared to the T12 counter value. In capture mode, the captured value of T12 can be read from these registers.

The registers CC6xR can only be read by software, the modification of the value is done by a shadow register transfer from register CC6xSR. The corresponding shadow registers CC6xSR can be read and written by software. In capture mode, the value of the T12 counter register can also be captured by registers CC6xSR if the selected capture event is detected (depending on the selected mode).

CC6xSR (x = 0-2)
Capture/Compare Shadow Register for Channel CC6x
 $(14_H + x \cdot 4_H)$
Reset Value: 0000_H

Field	Bits	Type	Description
CCS	15:0	rwh	Shadow Register for Channel x Capture/Compare Value In compare mode, the contents of bit field CCS are transferred to the bit field CCV for the corresponding channel during a shadow transfer. In capture mode, the captured value of T12 can be read from these registers.

Note: The shadow registers can also be written by SW in capture mode. In this case, the HW capture event wins over the SW write if both happen in the same cycle (the SW write is discarded).

Register T12DTC controls the dead-time generation for the timer T12 compare channels. Each channel can be independently enabled/disabled for dead-time generation. If enabled, the transition from passive state to active state is delayed by the value defined by bit field DTM. The dead-time counter can only be reloaded while it is zero. The dead time counters are clocked with the same frequency as T12. This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode. A duty cycle of 50% leads to CC6x, COUT6x switched on for: $0.5 \cdot \text{period} - \text{dead time}$.

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

T12DTC

DTM							
rw							

Field	Bits	Type	Description
DTM	7:0	rw	Dead-Time Bit field DTM determines the programmable delay between switching from the passive state to the active state of the selected outputs. The switching from the active state to the passive state is not delayed.
DTE0, DTE1, DTE2	8, 9, 10	rw	Dead-Time Enable Bits Bits DTE0..DTE2 enable and disable the dead-time generation for each compare channel (0, 1, 2) of timer T12. 0 _B Dead-time generation is disabled. The corresponding outputs switch from the passive state to the active state (according to the actual compare status) without any delay. 1 _B Dead-time generation is enabled. The corresponding outputs switch from the passive state to the active state (according to the compare status) with the delay programmed in bit field DTM.
DTR0, DTR1, DTR2	12, 13, 14	rh	Dead-Time Run Indication Bits Bits DTR0..DTR2 indicate the status of the dead-time generation for each compare channel (0, 1, 2) of timer T12. 0 _B The value of the corresponding dead-time counter channel is 0. 1 _B The value of the corresponding dead-time counter channel is not 0.
Res	11, 15	r	Reserved Returns 0 if read; should be written with 0.

Note: The dead-time counters are clocked with the same frequency as T12.

*This structure allows symmetrical dead-time generation in center-aligned and in edge-aligned PWM mode.
A duty cycle of 50% leads to CC6x, COUT6x switched on for: 0.5 * period - dead-time.*

Note: The dead-time counters are not reset by bit T12RES, but by bit DTRES.

19.11.3 Timer 13 – Related Registers

The generation of the patterns for a single channel pulse width modulation (PWM) is based on timer T13. The registers related to timer T13 can be concurrently updated (with well-defined conditions) in order to ensure consistency of the PWM signal. T13 can be synchronized to several timer T12 events.

Timer T13 supports only compare mode on its compare channel CC63.

Register T13 represents the counting value of timer T13. It can only be written while the timer T13 is stopped. Write actions while T13 is running are not taken into account. Register T13 can always be read by software.

Timer T13 supports only edge-aligned mode (counting up).

T13

Timer T13 Counter Register

(7C_H)

Reset Value: 0000_H

Field	Bits	Type	Description
T13CV	15:0	rwh	Timer T13 Counter Value This register represents the 16-bit counter value of timer T13.

Note: While timer T13 is stopped, the internal clock divider is reset in order to ensure reproducible timings and delays.

Register T13PR contains the period value for timer T13. The period value is compared to the actual counter value of T13 and the resulting counter actions depend on the defined counting rules. This register has a shadow register and the shadow transfer is controlled by bit STE13. A read action by software delivers the value which is currently used for the compare action, whereas the write action targets a shadow register. The shadow register structure allows a concurrent update of all T13-related values.

Capture/Compare Unit 6 (CCU6)

T13PR

Timer T13 Period Register

Reset Value: 0000_H

Field	Bits	Type	Description
T13PV	15:0	rwh	T13 Period Value The value T13PV defines the counter value for T13, which leads to a period-match. On reaching this value, the timer T13 is set to zero.

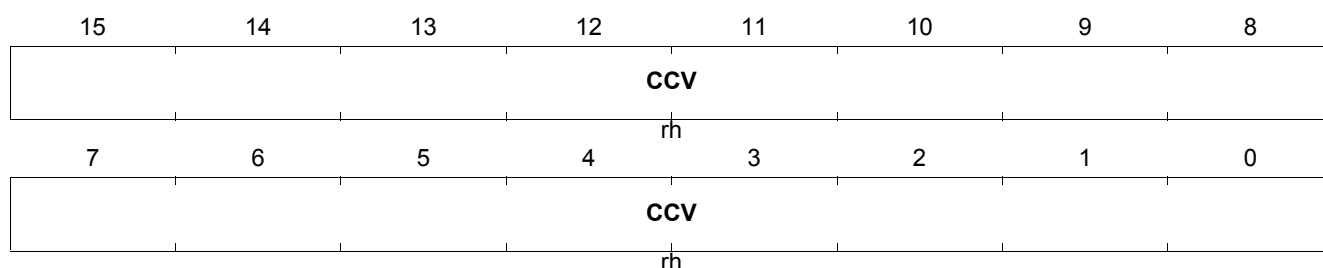

Register CC63R is the actual compare register for T13. The value stored in CC63R is compared to the counter value of T13. The State Bit CC63ST is located in register CMPSTAT.

CC63R

Capture/Compare Register for Channel CC63

(00_H)

Reset Value: 0000_H

Field	Bits	Type	Description
CCV	15:0	rh	Channel CC63 Compare Value The bit field CCV contains the value that is compared to the T13 counter value.

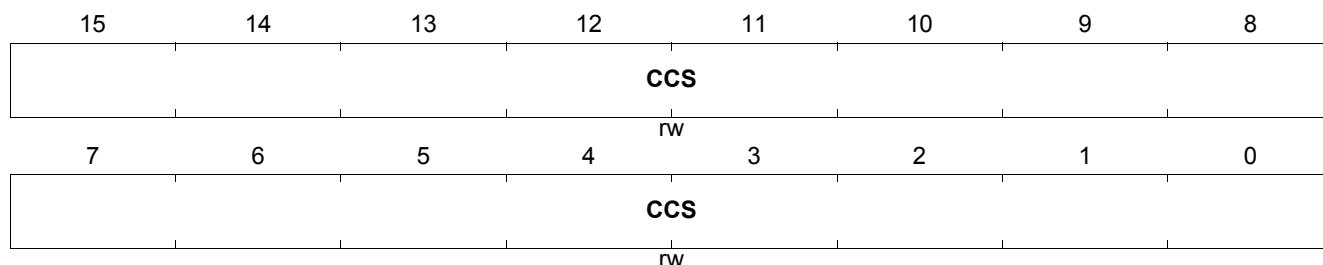

The register CC63R can only be read by software and the modification of the value is done by a shadow register transfer from register CC63SR. The corresponding shadow register CC63SR can be read and written by software.

Capture/Compare Unit 6 (CCU6)

CC63SR

Capture/Compare Shadow Register for Channel CC63 (20_H)

Reset Value: 0000_H

Field	Bits	Type	Description
CCS	15:0	rw	Shadow Register for Channel CC63 Compare Value The contents of bit field CCS are transferred to the bit field CCV during a shadow transfer.

19.11.4 Capture/Compare Control Registers

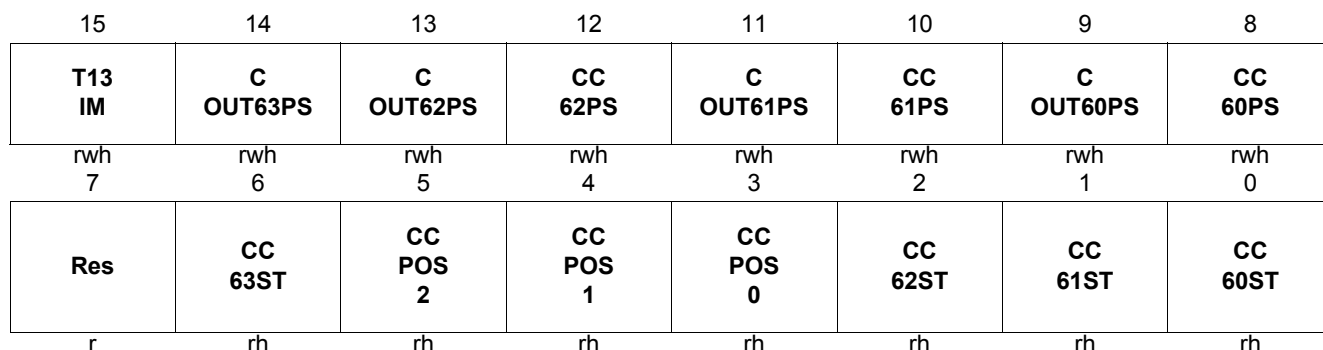

The Compare State Register CMPSTAT contains status bits monitoring the current capture and compare state, and control bits defining the active/passive state of the compare channels.

CMPSTAT

Compare State Register

(80_H)

Reset Value: 0000_H

Field	Bits	Type	Description
CC60ST, CC61ST, CC62ST, CC63ST	0, 1, 2, 6	rh	Capture/Compare State Bits (x = 0, 1, 2, 3) Bits CC6xST monitor the state of the capture/compare channels. Bits CC6xST are related to T12; bit CC63ST is related to T13. These bits are set and reset according to the T12 and T13 switching rules. 0 _B In compare mode, the timer count is less than the compare value. In capture mode, the selected edge has not yet been detected since the bit has been reset by software the last time. 1 _B In compare mode, the counter value is greater than or equal to the compare value. In capture mode, the selected edge has been detected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
CCPOS0, CCPOS1, CCPOS2	3, 4, 5	rh	Sampled Hall Pattern Bits (x = 0, 1, 2) Bits CCPOSx indicate the value of the input Hall pattern that has been compared to the current and expected value. The value is sampled when the event hcrdy (Hall compare ready) occurs. 0 _B The input CCPOSx has been sampled as 0. 1 _B The input CCPOSx has been sampled as 1.
Res	7	r	Reserved Returns 0 if read; should be written with 0.
CC60PS, CC61PS, CC62PS, COUT60PS, COUT61PS, COUT62PS, COUT63PS	8, 10, 12, 9, 11, 13, 14	rwh	Passive State Select for Compare Outputs Bits CC6xPS (x = 0, 1, 2), COUT6xPS (x = 0, 1, 2, 3) select the state of the corresponding compare channel, which is considered to be the passive state. During the passive state, the passive level (defined in register PSLR) is driven by the output pin. Bits CC6xPS, COUT6xPS (x = 0, 1, 2) are related to T12, bit COUT63PS is related to T13. These bits have shadow bits and are updated in parallel to the capture/compare registers of T12 and T13, respectively. A read action targets the actually used values, whereas a write action targets the shadow bits. In capture mode, these bits are not used. 0 _B The corresponding compare output drives passive level while CC6xST is 0. 1 _B The corresponding compare output drives passive level while CC6xST is 1.
T13IM	15	rwh	T13 Inverted Modulation Bit T13IM inverts the T13 signal for the modulation of the CC6x and COUT6x (x = 0, 1, 2) signals. This bit has a shadow bit and is updated in parallel to the compare and period registers of T13. A read action targets the actually used values, whereas a write action targets the shadow bit. 0 _B T13 output is not inverted. 1 _B T13 output is inverted for further modulation.

The Compare Status Modification Register CMPMODIF provides software-control (independent set and clear conditions) for the channel state bits CC6xST. This feature enables the user to individually change the status of the output lines by software, for example when the corresponding compare timer is stopped.

Capture/Compare Unit 6 (CCU6)

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13R	12	rh	Timer T13 Run Bit T13R starts and stops timer T13. It is set/reset by software by setting bits T13RS or T13RR or it is set/reset by hardware according to the function defined by bit fields T13SSC, T13TEC and T13TED. A concurrent set/reset action on T13R (from T13SSC, T13TEC, T13RR or T13RS) will have no effect. The bit T13R will remain unchanged. 0 _B Timer T13 is stopped. 1 _B Timer T13 is running.
STE13	13	rh	Timer T13 Shadow Transfer Enable Bit STE13 enables or disables the shadow transfer of the T13 period value, the compare value and passive state select bit and level from their shadow registers to the actual registers if a T13 shadow transfer event is detected. Bit STE13 is cleared by hardware after the shadow transfer. A T13 shadow transfer event is a period-match. 0 _B The shadow register transfer is disabled. 1 _B The shadow register transfer is enabled.
Res	15:14	r	Reserved Returns 0 if read; should be written with 0.

Register TCTR2 controls the single-shot and the synchronization functionality of both timers T12 and T13. Both timers can run in single-shot mode. In this mode, they stop their counting sequence automatically after one counting period with a count value of zero. The single-shot mode and the synchronization feature of T13 to T12 allow the generation of events with a programmable delay after well-defined PWM actions of T12. For example, this feature can be used to trigger AD conversions, after a specified delay (to avoid problems due to switching noise), synchronously to a PWM event.

In parallel to the reset action of bit T12R, the bits CC6xST (x = 0, 1, 2) are reset.
T13SSC	1	rw	Timer T13 Single Shot Control This bit controls the single shot-mode of T13. 0 _B No hardware action on T13R 1 _B The single-shot mode is enabled, the bit T13R is reset by hardware if T13 reaches its period value. In parallel to the reset action of bit T13R, the bit CC63ST is reset.
T13TEC	4:2	rw	T13 Trigger Event Control Bit field T13TEC selects the trigger event to start T13 (automatic set of T13R for synchronization to T12 compare signals) according to following combinations: 000 _B no action 001 _B set T13R on a T12 compare event on channel 0 010 _B set T13R on a T12 compare event on channel 1 011 _B set T13R on a T12 compare event on channel 2 100 _B set T13R on any T12 compare event on the channels 0, 1, or 2 101 _B set T13R upon a period-match of T12 110 _B set T13R upon a zero-match of T12 (while counting up) 111 _B set T13R on any edge of inputs CCPOSx
T13TED	6:5	rw	Timer T13 Trigger Event Direction Bit field T13TED delivers additional information to control the automatic set of bit T13R in the case that the trigger action defined by T13TEC is detected. 00 _B no action 01 _B while T12 is counting up 10 _B while T12 is counting down 11 _B independent on the count direction of T12
Res	7	r	Reserved Returns 0 if read; should be written with 0.
T12RSEL	9:8	rw	Timer T12 External Run Selection Bit field T12RSEL defines the event of signal T12HR that can set the run bit T12R by hardware. 00 _B The external setting of T12R is disabled. 01 _B Bit T12R is set if a rising edge of signal T12HR is detected. 10 _B Bit T12R is set if a falling edge of signal T12HR is detected. 11 _B Bit T12R is set if an edge of signal T12HR is detected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13RSEL	11:10	rw	Timer T13 External Run Selection Bit field T13RSEL defines the event of signal T13HR that can set the run bit T13R by hardware. 00 _B The external setting of T13R is disabled. 01 _B Bit T13R is set if a rising edge of signal T13HR is detected. 10 _B Bit T13R is set if a falling edge of signal T13HR is detected. 11 _B Bit T13R is set if an edge of signal T13HR is detected.
Res	15:12	r	Reserved Returns 0 if read; should be written with 0.

Example

If the timer T13 is intended to start at any compare event on T12 (T13TEC = 100_B), the trigger event direction can be programmed to:

- counting up >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting up
- counting down >> a T12 channel 0, 1, 2 compare match triggers T13R only while T12 is counting down
- independent from bit CDIR >> each T12 channel 0, 1, 2 compare match triggers T13R

The timer count direction is taken from the value of bit CDIR. As a result, if T12 is running in edge-aligned mode (counting up only), T13 can only be started automatically if bit field T13TED = 01_B or 11_B.

Register TCTR4 provides software-control (independent set and clear conditions) for the run bits T12R and T13R. Furthermore, the timers can be reset (while running) and bits STE12 and STE13 can be controlled by software. Reading these bits always returns 0.

TCTR4

Field	Bits	Type	Description
T12RR	0	w	Timer T12 Run Reset Setting this bit resets the T12R bit. 0 _B T12R is not influenced. 1 _B T12R is cleared, T12 stops counting.
T12RS	1	w	Timer T12 Run Set Setting this bit sets the T12R bit. 0 _B T12R is not influenced. 1 _B T12R is set, T12 counts.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T12RES	2	w	Timer T12 Reset 0_B No effect on T12. 1_B The T12 counter register is reset to zero. The switching of the output signals is according to the switching rules. Setting of T12RES has no impact on bit T12R.
DTRES	3	w	Dead-Time Counter Reset 0_B No effect on the dead-time counters. 1_B The three dead-time counter channels are reset to zero.
T12CNT	5	w	Timer T12 Count Event 0_B No action 1_B If enabled (PISEL2), timer T12 counts one step.
T12STR	6	w	Timer T12 Shadow Transfer Request 0_B No action 1_B STE12 is set, enabling the shadow transfer.
T12STD	7	w	Timer T12 Shadow Transfer Disable 0_B No action 1_B STE12 is reset without triggering the shadow transfer.
Res	4	r	Reserved Returns 0 if read; should be written with 0.
T13RR	8	w	Timer T13 Run Reset Setting this bit resets the T13R bit. 0_B T13R is not influenced. 1_B T13R is cleared, T13 stops counting.
T13RS	9	w	Timer T13 Run Set Setting this bit sets the T13R bit. 0_B T13R is not influenced. 1_B T13R is set, T13 counts.
T13RES	10	w	Timer T13 Reset 0_B No effect on T13. 1_B The T13 counter register is reset to zero. The switching of the output signals is according to the switching rules. Setting of T13RES has no impact on bit T13R.
T13CNT	13	w	Timer T13 Count Event 0_B No action 1_B If enabled (PISEL2), timer T13 counts one step.
T13STR	14	w	Timer T13 Shadow Transfer Request 0_B No action 1_B STE13 is set, enabling the shadow transfer.
T13STD	15	w	Timer T13 Shadow Transfer Disable 0_B No action 1_B STE13 is reset without triggering the shadow transfer.
Res	12:11	r	Reserved Returns 0 if read; should be written with 0.

Note: A simultaneous write of a 1 to bits which set and reset the same bit will trigger no action. The corresponding bit will remain unchanged.

19.11.5 Global Modulation Control Registers

Register MODCTR contains control bits enabling the modulation of the corresponding output signal by PWM pattern generated by the timers T12 and T13. Furthermore, the multi-channel mode can be enabled as additional modulation source for the output signals.

MODCTR

Modulation Control Register

(5C_H)

The bit positions are corresponding to the following output signals: Bit 0: modulation of CC60 Bit 1: modulation of COUT60 Bit 2: modulation of CC61 Bit 3: modulation of COUT61 Bit 4: modulation of CC62 Bit 5: modulation of COUT62 The enable feature of the modulation is defined as follows: 0 _B The modulation of the corresponding output signal by a T12 PWM pattern is disabled. 1 _B The modulation of the corresponding output signal by a T12 PWM pattern is enabled.
MCMEN	7	rw	Multi-Channel Mode Enable 0 _B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is disabled. 1 _B The modulation of the corresponding output signal by a multi-channel pattern according to bit field MCMOUT is enabled.
Res	6	r	Reserved Returns 0 if read; should be written with 0.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
T13MODEN	13:8	rw	T13 Modulation Enable Setting these bits enables the modulation of the corresponding compare channel by a PWM pattern generated by timer T13. The bit positions are corresponding to the following output signals: Bit 0: modulation of CC60 Bit 1: modulation of COUT60 Bit 2: modulation of CC61 Bit 3: modulation of COUT61 Bit 4: modulation of CC62 Bit 5: modulation of COUT62 The enable feature of the modulation is defined as follows: 0 _B The modulation of the corresponding output signal by a T13 PWM pattern is disabled. 1 _B The modulation of the corresponding output signal by a T13 PWM pattern is enabled.
ECT130	15	rw	Enable Compare Timer T13 Output 0 _B The alternate output function COUT63 is disabled. 1 _B The alternate output function COUT63 is enabled for the PWM signal generated by T13.
Res	14	r	Reserved Returns 0 if read; should be written with 0.

The register TRPCTR controls the trap functionality. It contains independent enable bits for each output signal and control bits to select the behavior in case of a trap condition. The trap condition is a low-level on the $\overline{\text{CTRAP}}$ input pin, which is monitored (inverted level) by bit IS.TRPF. While TRPF = 1 (trap input active), the trap state bit IS.TRPS is set to 1.

TRPCTR

Res					TRP M2	TRP M1	TRP M0
r					rw	rw	rw

Field	Bits	Type	Description
TRPM0, TRPM1	0, 1	rw	Trap Mode Control Bits 1, 0 These two bits define the behavior of the selected outputs when leaving the trap state after the trap condition has become inactive again. A synchronization to the timer driving the PWM pattern permits to avoid unintended short pulses when leaving the trap state. See Table 129 .

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
TRPM2	2	rw	Trap Mode Control Bit 2 0_B The trap state can be left (return to normal operation = bit TRPS = 0) as soon as the input $\overline{\text{CTRAP}}$ becomes inactive. Bit TRPF is automatically cleared by hardware if the input pin $\overline{\text{CTRAP}}$ becomes 1. Bit TRPS is automatically cleared by hardware if bit TRPF is 0 and if the synchronization condition (according to TRPM0,1) is detected. 1_B The trap state can be left (return to normal operation = bit TRPS = 0) as soon as bit TRPF is reset by software after the input $\overline{\text{CTRAP}}$ becomes inactive (TRPF is not cleared by hardware). Bit TRPS is automatically cleared by hardware if bit TRPF = 0 and if the synchronization condition (according to TRPM0,1) is detected.
Res	7:3	r	Reserved Returns 0 if read; should be written with 0.
TRPEN	13:8	rw	Trap Enable Control Setting these bits enables the trap functionality for the following corresponding output signals: Bit 0: trap functionality of CC60 Bit 1: trap functionality of COUT60 Bit 2: trap functionality of CC61 Bit 3: trap functionality of COUT61 Bit 4: trap functionality of CC62 Bit 5: trap functionality of COUT62 The enable feature of the trap functionality is defined as follows: 0_B The trap functionality of the corresponding output signal is disabled. The output state is independent from bit TRPS. 1_B The trap functionality of the corresponding output signal is enabled. The output is set to the passive state while TRPS = 1.
TRPEN13	14	rw	Trap Enable Control for Timer T13 0_B The trap functionality for T13 is disabled. Timer T13 (if selected and enabled) provides PWM functionality even while TRPS = 1. 1_B The trap functionality for T13 is enabled. The timer T13 PWM output signal is set to the passive state while TRPS = 1.
TRPPEN	15	rw	Trap Pin Enable 0_B The trap functionality based on the input pin $\overline{\text{CTRAP}}$ is disabled. A trap can only be generated by software by setting bit TRPF. 1_B The trap functionality based on the input pin $\overline{\text{CTRAP}}$ is enabled. A trap can be generated by software by setting bit TRPF or by $\overline{\text{CTRAP}} = 0$.

Table 129 Trap Mode Control Bits 1, 0

Field	Bits	Description
TRPM0, TRPM1	0 1	<p>A synchronization to the timer driving the PWM pattern permits to avoid unintended short pulses when leaving the trap state. The combination (TRPM1, TRPM0) leads to:</p> <p>00_B The trap state is left (return to normal operation according to TRPM2) when a zero-match of T12 (while counting up) is detected (synchronization to T12).</p> <p>01_B The trap state is left (return to normal operation according to TRPM2) when a zero-match of T13 is detected (synchronization to T13).</p> <p>10_B reserved</p> <p>11_B The trap state is left (return to normal operation according to TRPM2) immediately without any synchronization to T12 or T13.</p>

Register PSLR defines the passive state level driven by the output pins of the module. The passive state level is the value that is driven by the port pin during the passive state of the output. During the active state, the corresponding output pin drives the active state level, which is the inverted passive state level. The passive state level permits the adaptation of the driven output levels to the driver polarity (inverted, not inverted) of the connected power stage. The bits in this register have shadow bit fields to permit a concurrent update of all PWM-related parameters (bit field PSL is updated with T12_ST, whereas PSL63 is updated with T13_ST). The actually used values can be read (attribute "rh"), whereas the shadow bits can only be written (attribute "w").

Capture/Compare Unit 6 (CCU6)

PSLR

Passive State Level Register

(50_H)

Reset Value: 00_H

Field	Bits	Type	Description
PSL	5:0	rwh	Compare Outputs Passive State Level The bits of this bit field define the passive level driven by the module outputs during the passive state. The bit positions are: Bit 0: passive level for output CC60 Bit 1: passive level for output COUT60 Bit 2: passive level for output CC61 Bit 3: passive level for output COUT61 Bit 4: passive level for output CC62 Bit 5: passive level for output COUT62 The value of each bit position is defined as: 0 _B The passive level is 0. 1 _B The passive level is 1.
PSL63	7	rwh	Passive State Level of Output COUT63 This bit field defines the passive level of the output pin COUT63. 0 _B The passive level is 0. 1 _B The passive level is 1.
Res	6	r	Reserved Returns 0 if read; should be written with 0.

Notes

1. Bit field PSL has a shadow register to allow for updates without undesired pulses on the output lines. The bits are updated with the T12 shadow transfer. A read action targets the actually used values, whereas a write action targets the shadow bits.
2. Bit field PSL63 has a shadow register to allow for updates without undesired pulses on the output line. The bit is updated with the T13 shadow transfer. A read action targets the actually used values, whereas a write action targets the shadow bits.

19.11.6 Multi-Channel Modulation Control Registers

Register MCMOUTS contains bits used as pattern input for the multi-channel mode and the Hall mode. This register is a shadow register (that can be read and written) for register MCMOUT, which indicates the currently active signals.

MCMOUTS

Multi-Channel Mode Output Shadow Register (08_H)

Reset Value: 0000_H

STR MCM	Res	MCMPS					
w	r	rw					

Field	Bits	Type	Description
MCMPS	5:0	rw	Multi-Channel PWM Pattern Shadow Bit field MCMPS is the shadow bit field for bit field MCMP. The multi-channel shadow transfer is triggered according to the transfer conditions defined by register MCMCTR.
STRMCM	7	w	Shadow Transfer Request for MCMPS Setting this bit during a write action leads to an immediate update of bit field MCMP by the value written to bit field MCMPS. This functionality permits an update triggered by software. When read, this bit always delivers 0. 0 _B Bit field MCMP is updated according to the defined hardware action. The write access to bit field MCMPS does not modify bit field MCMP. 1 _B Bit field MCMP is updated by the value written to bit field MCMPS.
Res	6	r	Reserved Returns 0 if read; should be written with 0.
EXPHS	10:8	rw	Expected Hall Pattern Shadow Bit field EXPHS is the shadow bit field for bit field EXPH. The bit field is transferred to bit field EXPH if an edge on the hall input pins CCPOS _x (x = 0, 1, 2) is detected.
CURHS	13:11	rw	Current Hall Pattern Shadow Bit field CURHS is the shadow bit field for bit field CURH. The bit field is transferred to bit field CURH if an edge on the hall input pins CCPOS _x (x = 0, 1, 2) is detected.

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
STRHP	15	w	Shadow Transfer Request for the Hall Pattern Setting these bits during a write action leads to an immediate update of bit fields CURH and EXPH by the value written to bit fields CURHS and EXPH. This functionality permits an update triggered by software. When read, this bit always delivers 0. 0_B The bit fields CURH and EXPH are updated according to the defined hardware action. The write access to bit fields CURHS and EXPHS does not modify the bit fields CURH and EXPH. 1_B The bit fields CURH and EXPH are updated by the value written to the bit fields CURHS and EXPHS.
Res	14	r	Reserved Returns 0 if read; should be written with 0.

Register MCMOUT shows the multi-channel control bits that are currently used. Register MCMOUT is defined as follows:

MCMOUT

Multi-Channel Mode Output Register

(64_H)

Reset Value: 0000_H

15	14	13	12	11	10	9	8
Res			CURH			EXPH	
r			rh			rh	
7	6	5	4	3	2	1	0
Res	R				MCMP		
r	rh				rh		

Field	Bits	Type	Description
MCMP	5:0	rh	Multi-Channel PWM Pattern Bit field MCMP is written by a shadow transfer from bit field MCMPHS. It contains the output pattern for the multi-channel mode. If this mode is enabled by bit MCMEN in register MODCTR, the output state of the following output signal can be modified: Bit 0: multi-channel state for output CC60 Bit 1: multi-channel state for output COUT60 Bit 2: multi-channel state for output CC61 Bit 3: multi-channel state for output COUT61 Bit 4: multi-channel state for output CC62 Bit 5: multi-channel state for output COUT62 The multi-channel patterns can set the related output to the passive state. While IDLE = 1, bit field MCMP is cleared. 0_B The output is set to the passive state. The PWM generated by T12 or T13 is not taken into account. 1_B The output can deliver the PWM generated by T12 or T13 (according to register MODCTR).

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
R	6	rh	Reminder Flag This reminder flag indicates that the shadow transfer from bit field MCMPS to MCMP has been requested by the selected trigger source. This bit is cleared when the shadow transfer takes place and while MCMEN = 0. 0_B Currently, no shadow transfer from MCMPS to MCMP is requested. 1_B A shadow transfer from MCMPS to MCMP has been requested by the selected trigger source, but it has not yet been executed, because the selected synchronization condition has not yet occurred.
Res	7	r	Reserved Returns 0 if read; should be written with 0.
EXPH	10:8	rh	Expected Hall Pattern Bit field EXPH is written by a shadow transfer from bit field EXPHS. The contents are compared after every detected edge at the hall input pins with the pattern at the hall input pins in order to detect the occurrence of the next desired (= expected) hall pattern or a wrong pattern. If the current hall pattern at the hall input pins is equal to the bit field EXPH, bit CHE (correct hall event) is set and an interrupt request is generated (if enabled by bit ENCHE). If the current hall pattern at the hall input pins is not equal to the bit fields CURH or EXPH, bit WHE (wrong hall event) is set and an interrupt request is generated (if enabled by bit ENWHE).
CURH	13:11	rh	Current Hall Pattern Bit field CURH is written by a shadow transfer from bit field CURHS. The contents are compared after every detected edge at the hall input pins with the pattern at the hall input pins in order to detect the occurrence of the next desired (= expected) hall pattern or a wrong pattern. If the current hall input pattern is equal to bit field CURH, the detected edge at the hall input pins has been an invalid transition (e.g. a spike).
Res	15:14	r	Reserved Returns 0 if read; should be written with 0.

Note: The bits in the bit fields EXPH and CURH correspond to the hall patterns at the input pins CCPOS_x (x = 0, 1, 2) in the following order (EXPH.2, EXPH.1, EXPH.0), (CURH.2, CURH.1, CURH.0), (CCPOS.2, CCPOS.1, CCPOS.0).

Register MCMCTR contains control bits for the multi-channel functionality.

MCMCTR
Multi-Channel Mode Control Register

Field	Bits	Type	Description
SWSEL	2:0	rw	Switching Selection Bit field SWSEL selects one of the following trigger request sources (next multi-channel event) for the shadow transfer from MCMPs to MCMP. The trigger request is stored in the reminder flag R until the shadow transfer is done and flag R is cleared automatically with the shadow transfer. The shadow transfer takes place synchronously with an event selected in bit field SWSYN. 000 _B no trigger request will be generated 001 _B correct hall pattern on CCPOSx detected 010 _B T13 period-match detected (while counting up) 011 _B T12 one-match (while counting down) 100 _B T12 channel 1 compare-match detected (phase delay function) 101 _B T12 period match detected (while counting up) else reserved, no trigger request will be generated
SWSYN	5:4	rw	Switching Synchronization Bit field SWSYN triggers the shadow transfer between MCMPs and MCMP if it has been requested before (flag R set by an event selected by SWSEL). This feature permits the synchronization of the outputs to the PWM source, that is used for modulation (T12 or T13). 00 _B direct; the trigger event directly causes the shadow transfer 01 _B T13 zero-match triggers the shadow transfer 10 _B a T12 zero-match (while counting up) triggers the shadow transfer 11 _B reserved; no action
Res	3, 6, 7	r	Reserved Returns 0 if read; should be written with 0.
STE12U	8	rw	Shadow Transfer Enable for T12 Upcounting This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 period match is detected while counting up. 0 _B No action 1 _B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.

Field	Bits	Type	Description
STE12D	9	rw	Shadow Transfer Enable for T12 Downcounting This bit enables the shadow transfer T12_ST if flag MCMOUT.R is set or becomes set while a T12 one match is detected while counting down. 0 _B No action 1 _B The T12_ST shadow transfer mechanism is enabled if MCMEN = 1.
STE13U	10	rw	Shadow Transfer Enable for T13 Upcounting This bit enables the shadow transfer T13_ST if flag MCMOUT.R is set or becomes set while a T13 period match is detected. 0 _B No action 1 _B The T13_ST shadow transfer mechanism is enabled if MCMEN = 1.
Res	15:11	r	Reserved Returns 0 if read; should be written with 0.

19.11.7 Interrupt Control Registers

Register IS contains the individual interrupt request bits. This register can only be read; write actions have no impact on the contents of this register. The software can set or reset the bits individually by writing to the registers ISS (to set the bits) or to register ISR (to reset the bits).

The interrupt generation is independent from the value of the bits in register IS, e.g. the interrupt will be generated (if enabled) even if the corresponding bit is already set. The trigger for an interrupt generation is the detection of a set condition (by HW or SW) for the corresponding bit in register IS.

In compare mode (and hall mode), the timer-related interrupts are only generated while the timer is running (T1xR = 1). In capture mode, the capture interrupts are also generated while the timer T12 is stopped.

Note: Not all bits in register IS can generate an interrupt. Other status bits have been added, that have a similar structure for their set and clear actions. It is recommended that SW checks the interrupt bits bit-wisely (instead of common OR over the bits).

IS

Capture/Compare Interrupt Status Register

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
ICC60R, CC61R, CC62R	0, 2, 4	rh	Capture, Compare-Match Rising Edge Flag (x = 0, 1, 2) In compare mode, a compare-match has been detected while T12 was counting up. In capture mode, a rising edge has been detected at the input CC6x. 0 _B The event has not yet occurred since this bit has been reset for the last time. 1 _B The event described above has been detected.
ICC60F, ICC61F, ICC62F	1, 3, 5	rh	Capture, Compare-Match Falling Edge Flag (x = 0, 1, 2) In compare mode, a compare-match has been detected while T12 was counting down. In capture mode, a falling edge has been detected at the input CC6x. 0 _B The event has not yet occurred since this bit has been reset for the last time. 1 _B The event described above has been detected.
T12OM	6	rh	Timer T12 One-Match Flag 0 _B A timer T12 one-match (while counting down) has not yet been detected since this bit has been reset for the last time. 1 _B A timer T12 one-match (while counting down) has been detected.
T12PM	7	rh	Timer T12 Period-Match Flag 0 _B A timer T12 period-match (while counting up) has not yet been detected since this bit has been reset for the last time. 1 _B A timer T12 period-match (while counting up) has been detected.
T13CM	8	rh	Timer T13 Compare-Match Flag 0 _B A timer T13 compare-match has not yet been detected since this bit has been reset for the last time. 1 _B A timer T13 compare-match has been detected.
T13PM	9	rh	Timer T13 Period-Match Flag 0 _B A timer T13 period-match has not yet been detected since this bit has been reset for the last time. 1 _B A timer T13 period-match has been detected.
TRPF	10	rh	Trap Flag The trap flag TRPF will be set by hardware if TRPPEN = 1 and CTRAP = 0 or by software. If TRPM2 = 0, bit TRPF is reset by hardware if the input CTRAP becomes inactive (TRPPEN = 1). If TRPM2 = 1, bit TRPF must be reset by software in order to leave the trap state. 0 _B The trap condition has not been detected. 1 _B The trap condition has been detected (input CTRAP has been 0 or by software).

Capture/Compare Unit 6 (CCU6)

Field	Bits	Type	Description
TRPS	11	rh	Trap State During the trap state, the selected outputs are set to the passive state. The logic level driven during the passive state is defined by the corresponding bit in register PSLR. Bit TRPS = 1 and TRPF = 0 can occur if the trap condition is no longer active but the selected synchronization has not yet taken place. 0 _B The trap state is not active. 1 _B The trap state is active. Bit TRPS is set while bit TRPF = 1. It is reset according to the mode selected in register TRPCTR.
CHE	12	rh	Correct Hall Event On every valid hall edge, the contents of EXPH are compared with the pattern on pin CCPOSx and if equal bit CHE is set. 0 _B A transition to a correct (= expected) hall event has not yet been detected since this bit has been reset for the last time. 1 _B A transition to a correct (= expected) hall event has been detected.
WHE	13	rh	Wrong Hall Event On every valid hall edge, the contents of EXPH are compared with the pattern on pin CCPOSx. If both comparisons (CURH and EXPH with CCPOSx) are not true, bit WHE (wrong hall event) is set. 0 _B A transition to a wrong hall event (not the expected one) has not yet been detected since this bit has been reset for the last time. 1 _B A transition to a wrong hall event (not the expected one) has been detected.
IDLE	14	rh	IDLE State This bit is set together with bit WHE (wrong hall event) and it must be reset by software. 0 _B No action. 1 _B Bit field MCMP is cleared and held to 0, the selected outputs are set to passive state.
STR	15	rh	Multi-Channel Mode Shadow Transfer Request This bit is set when a shadow transfer from MCMOUTS to MCMOUT takes places in multi-channel mode. 0 _B The shadow transfer has not yet taken place. 1 _B The shadow transfer has taken place.

Register ISS contains individual interrupt request set bits to generate a CCU6 interrupt request by software. Writing a 1 sets the bit(s) in register IS at the corresponding bit position(s) and can generate an interrupt event (if available and enabled). All bit positions read as 0.

20 UART1/UART2

20.1 Features

- Full-duplex asynchronous modes
 - 8-bit or 9-bit data frames, LSB first
 - fixed or variable baud rate
- Receive buffered
- Multiprocessor communication
- Interrupt generation on the completion of a data transmission or reception
- Baud-rate generator with fractional divider for generating a wide range of baud rates
- Hardware logic for break and synch Byte detection

20.2 Introduction

The UART provides a full-duplex asynchronous receiver/transmitter, i.e., it can transmit and receive simultaneously. It is also receive-buffered, i.e., it can commence reception of a second byte before a previously received byte has been read from the receive register. However, if the first byte still has not been read by the time reception of the second byte is complete, one of the bytes will be lost. The serial port receive and transmit registers are both accessed at Special Function Register (SFR) SBUF. Writing to SBUF loads the transmit register, and reading SBUF accesses a physically separate receive register.

20.2.1 Block Diagram

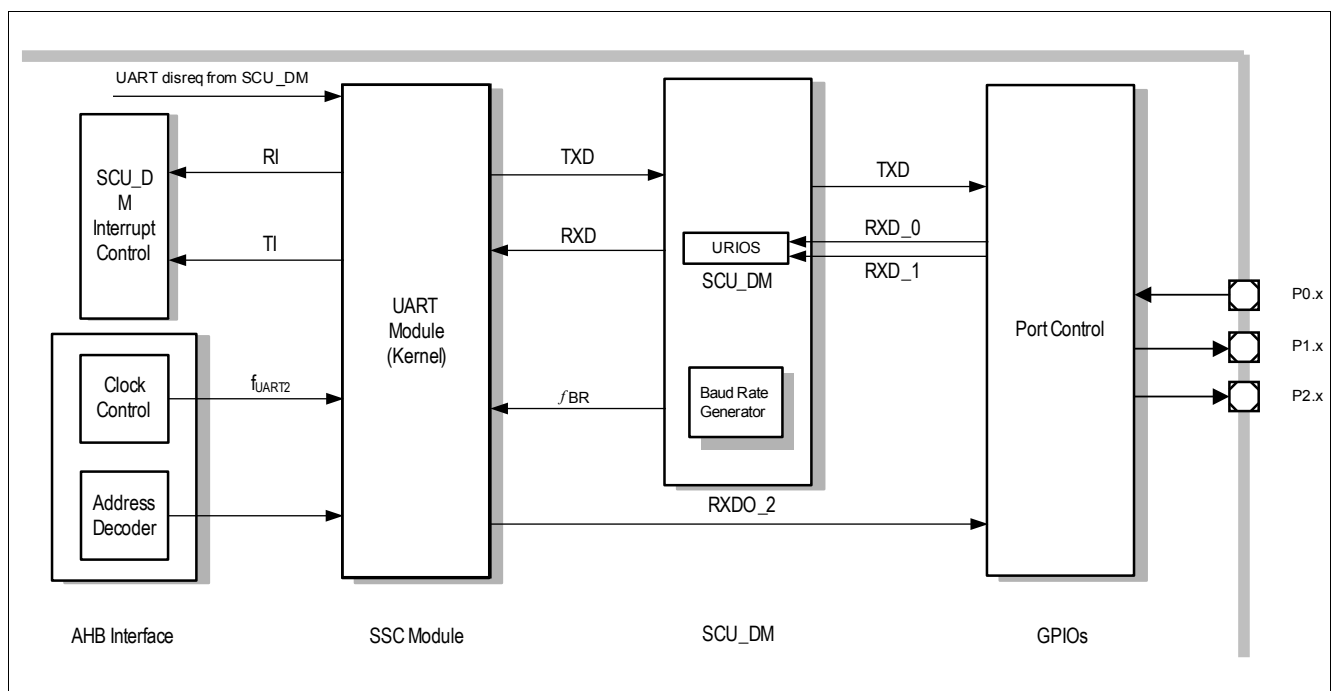

Figure 168 UART Block Diagram

20.3 UART Modes

The UART can be used in four different modes. In mode 0, it operates as an 8-bit shift register. In mode 1, it operates as an 8-bit serial port. In modes 2 and 3, it operates as a 9-bit serial port. The only difference between mode 2 and mode 3 is the baud rate, which is fixed in mode 2 but variable in mode 3. The variable baud rate is set by the underflow rate on the dedicated baud-rate generator.

The different modes are selected by setting bits SM0 and SM1 to their corresponding values, as shown in [Table 132](#).

Table 132 UART Modes

SM0	SM1	Operating Mode	Baud Rate
0	0	Mode 0: 8-bit shift register	$f_{PCLK}/2$
0	1	Mode 1: 8-bit shift UART	Variable
1	0	Mode 2: 9-bit shift UART	$f_{PCLK}/64$
1	1	Mode 3: 9-bit shift UART	Variable

The UART1 is connected to the integrated LIN transceiver, and to GPIO for test purpose. The UART2 is connected to GPIO only.

20.3.1 Mode 0, 8-Bit Shift Register, Fixed Baud Rate

In mode 0, the serial port behaves as an 8-bit shift register. Data is shifted in through RXD, and out through RXDO, while the TXD line is used to provide a shift clock which can be used by external devices to clock data in and out. The transmission cycle is activated by a write to SBUF. For the next seven machine cycles, the contents of the transmit shift register are shifted right one position and a zero shifted in from the left so that when the MSB of the data byte is at the output position, it has a 1 and a sequence of zeros to its left. The control block then executes one last shift before setting the TI bit.

Reception is started by the condition $REN = 1$ and $RI = 0$. At the start of the reception cycle, 11111110_B is written to the receive shift register. In each machine cycle that follows, the contents of the shift register are shifted left one position and the value sampled on the RXD line in the same machine cycle is shifted in from the right. When the 0 of the initial byte reaches the leftmost position, the control block executes one last shift, loads SBUF and sets the RI bit.

The baud rate for the transfer is fixed at $f_{PCLK}/2$ where f_{PCLK} is the input clock frequency, i.e. one bit per machine cycle.

20.3.2 Mode 1, 8-Bit UART, Variable Baud Rate

In mode 1, the UART behaves as an 8-bit serial port. A start bit (0), 8 data bits, and a stop bit (1) are transmitted on TXD or received on RXD at a variable baud rate.

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit shift register and a 1 is loaded to the 9th bit position (as in mode 0). At phase 1 of the machine cycle after the next rollover in the divide-by-16 counter, the start bit is copied to TXD, and data is activated one bit time later. One bit time after the data is activated, the data starts getting shifted right with zeros shifted in from the left. When the MSB gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baud rate). The divide-by-16 counter is then reset and 11111111_B is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8

(SCON.2) with the stop bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see [Section 20.4](#)) or the received stop bit = 1. If none of these conditions is met, the received byte is lost.

The associated timings for transmit/receive in mode 1 are illustrated in [Figure 169](#).

Figure 169 Serial Interface, Mode 1, Timing Diagram

20.3.3 Mode 2, 9-Bit UART, Fixed Baud Rate

In mode 2, the UART behaves as a 9-bit serial port. A start bit (0), 8 data bits plus a programmable 9th bit and a stop bit (1) are transmitted on TXD or received on RXD. The 9th bit for transmission is taken from TB8 (SCON.3) while for reception, the 9th bit received is placed in RB8 (SCON.2).

The transmission cycle is activated by a write to SBUF. The data is transferred to the transmit shift register and TB8 is copied into the 9th bit position. At phase 1 of the machine cycle following the next rollover in the divide-by-16 counter, the start bit is copied to TXD and data is activated one bit time later. One bit time after the data is activated, the data starts shifting right. For the first shift, a stop bit (1) is shifted in from the left and for subsequent shifts, zeros are shifted in. When the TB8 bit gets to the output position, the control block executes one last shift and sets the TI bit.

Reception is started by a high to low transition on RXD (sampled at 16 times the baud rate). The divide-by-16 counter is then reset and $1111\ 1111_B$ is written to the receive register. If a valid start bit (0) is then detected (based on two out of three samples), it is shifted into the register followed by 8 data bits. If the transition is not followed by a valid start bit, the controller goes back to looking for a high to low transition on RXD. When the start bit reaches the leftmost position, the control block executes one last shift, then loads SBUF with the 8 data bits, loads RB8 (SCON.2) with the 9th data bit, and sets the RI bit, provided RI = 0, and either SM2 = 0 (see [Section 20.4](#)) or the 9th bit = 1. If none of these conditions is met, the received byte is lost.

The baud rate for the transfer is fixed at $f_{PCLK}/64$.

20.3.4 Mode 3, 9-Bit UART, Variable Baud Rate

Mode 3 is the same as mode 2 in all respects except that the baud rate is variable.

In all modes, transmission is initiated by any instruction that uses SBUF as a destination register. Reception is initiated in the modes by the incoming start bit if REN = 1.

The serial interface also provides interrupt requests when transmission or reception of the frames has been completed. The corresponding interrupt request flags are TI or RI, respectively. If the serial interrupt is not used (i.e., serial interrupt not enabled), TI and RI can also be used for polling the serial interface.

The associated timings for transmit/receive in modes 2 and 3 are illustrated in [Figure 170](#).

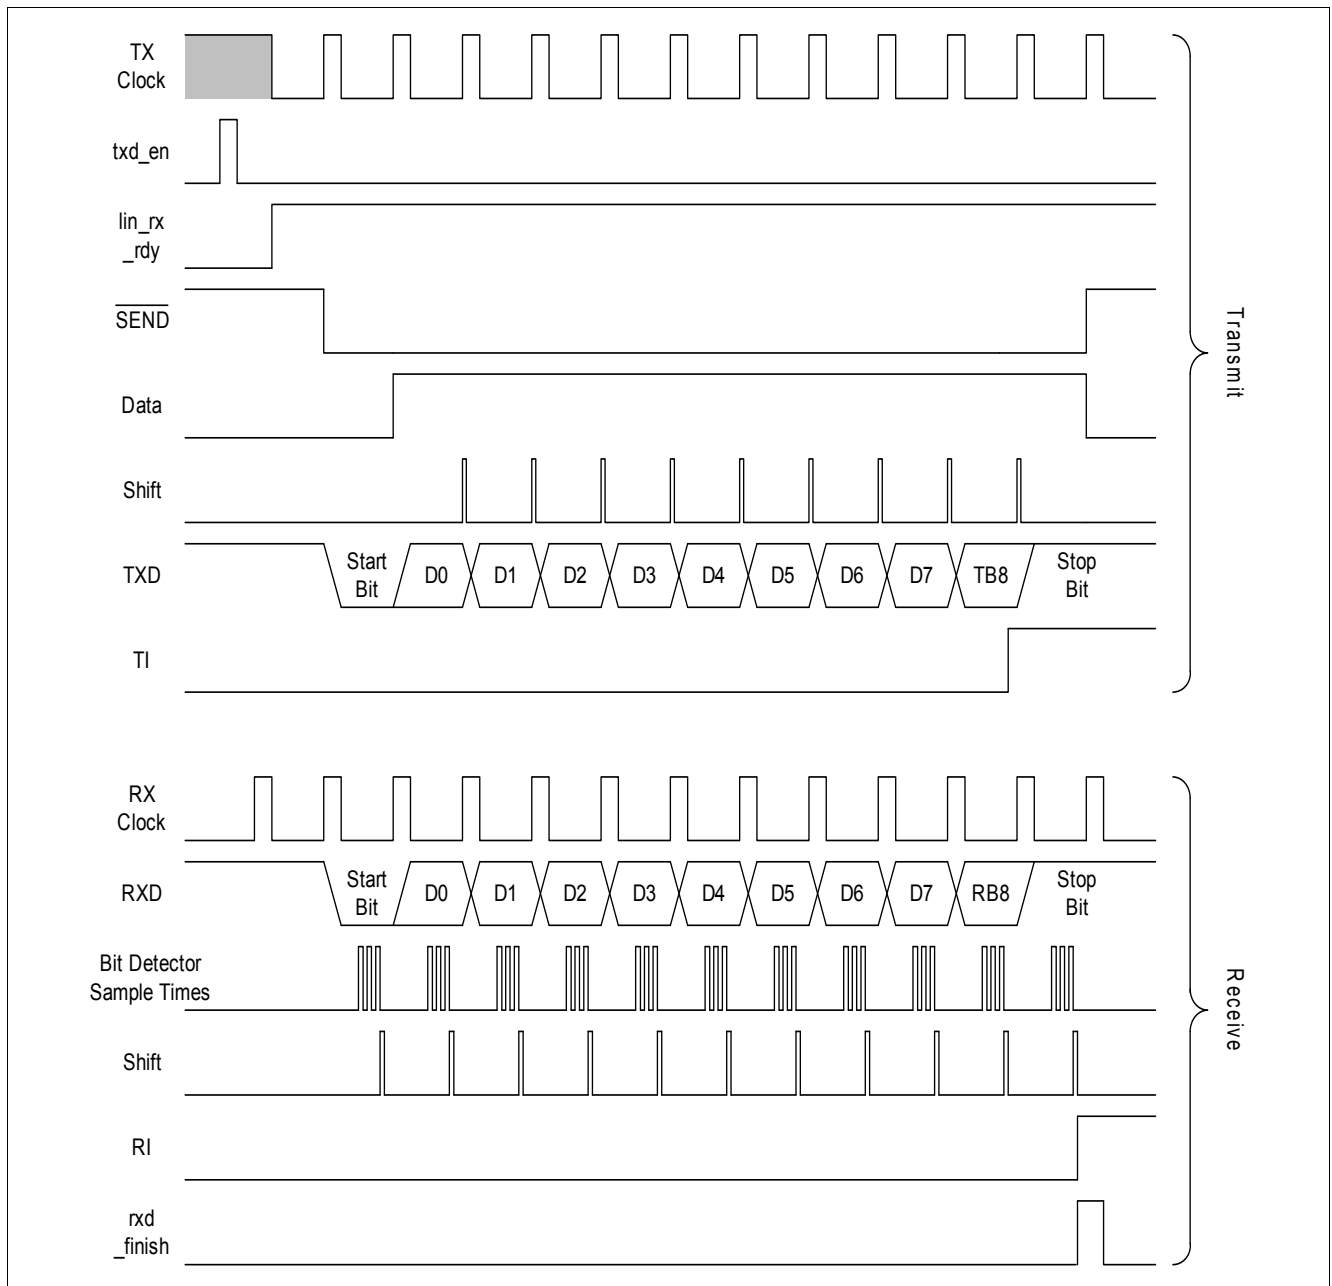

Figure 170 Serial Interface, Modes 2 and 3, Timing Diagram

20.4 Multiprocessor Communication

Modes 2 and 3 have a special provision for multiprocessor communication using a system of address bytes with bit 9 = 1 and data bytes with bit 9 = 0. In these modes, 9 data bits are received. The 9th data bit goes into RB8. The communication always ends with one stop bit. The port can be programmed such that when the stop bit is received, the serial port interrupt will be activated only if RB8 = 1.

This feature is enabled by setting bit SM2 in SCON. One of the ways to use this feature in multiprocessor systems is described in the following paragraph.

When the master processor wants to transmit a block of data to one of several slaves, it first sends out an address byte that identifies the target slave. An address byte differs from a data byte in that the 9th bit is 1 in an address byte and 0 in a data byte. With SM2 = 1, no slave will be interrupted by a data byte. An address byte, however, will interrupt all slaves, so that each slave can examine the received byte and see if it is being addressed. The addressed slave will clear its SM2 bit and prepare to receive the data bytes that will be coming. The slaves that were not being addressed retain their SM2s as set and ignore the incoming data bytes.

Bit SM2 has no effect in mode 0. SM2 can be used in mode 1 to check the validity of the stop bit. In a mode 1 reception, if SM2 = 1, the receive interrupt will not be activated unless a valid stop bit is received.

20.5 Baud Rate Generation

There are several ways to generate the baud rate clock for the serial port, depending on the mode in which they are operating.

The baud rates in modes 0 and 2 are fixed to $f_{PCLK}/2$ and $f_{PCLK}/64$ respectively, while the variable baud rate in modes 1 and 3 is generated based on the setting of the Baud-rate generator in SCU (see [Section 20.5.1](#)).

“Baud rate clock” and “baud rate” must be distinguished from each other. The serial interface requires a clock rate that is 16 times the baud rate for internal synchronization. Therefore, the UART baud-rate generator must provide a “baud rate clock” to the serial interface where it is divided by 16 to obtain the actual “baud rate”. The abbreviation f_{PCLK} refers to the input clock frequency.

20.5.1 Baud-rate Generator

The baud-rate generator in SCU is used to generate the variable baud rate for the UART in modes 1 and 3. It has programmable 11-bit reload value, 3-bit prescaler and 5-bit fractional divider.

The baud-rate generator is clocked derived via a prescaler (f_{DIV}) from the input clock f_{PCLK} . The baud rate timer counts downwards and can be started or stopped through the baud rate control run bit BCON.R. Each underflow of the timer provides one clock pulse to the serial channel. The timer is reloaded with the 11-bit BR_VALUE stored in its reload register BG each time it underflows. The duration between underflows depends on the ‘n’ value in the fractional divider, which can be selected by the bits BG.FD_SEL. ‘n’ times out of 32, the timer counts one cycle more than specified by BR_VALUE. The prescaler is selected by the bits BCON.BRPRE.

Register BG is the dual-function Baud-rate Generator/Reload register. Reading BG returns the contents of the timer, while writing to BG (low byte) always updates the reload register.

The BG should be written only when BCON.R is 0. An auto-reload of the timer with the contents of the reload register is performed one instruction cycle after the next time BCON.R is set. Any write to BG, while BCON.R is set, will be ignored.

The baud rate of the baud-rate generator depends on the following bits and register values:

- Input clock f_{PCLK}
- Value of bit field BCON.BRPRE.
- Value of bit field BG.FD_SEL
- Value of the 11-bit reload value BG.BR_VALUE

Figure 171 shows a simplified block diagram of the baud rate generator.

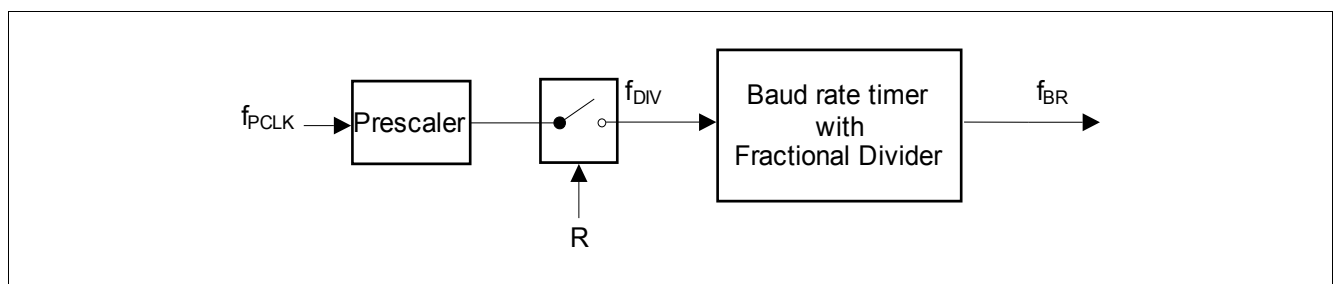

Figure 171 Simplified Baud Rate Generator Block Diagram

The following formula calculate the final baud rate.

(11)

$$\text{Baud rate} = \frac{f_{PCLK}}{16 \times \text{PRE} \times \left(\text{BR_VALUE} + \frac{n}{32} \right)}$$

The value of PRE (prescaler) is chosen by the bit field BCON.BRPRE. BR_VALUE represents the contents of the reload value, taken as unsigned 11-bit integer from the bit field BG.BR_VALUE. n/32 is defined by the fractional divider selection in bit field BG.FDSEL.

The maximum baud rate that can be generated is limited to $f_{PCLK}/32$. Hence, for module clocks of 40 MHz and 24 MHz, the maximum achievable baud rate is 1.25 MBaud and 0.75 MBaud respectively.

Table 133 and **Table 134** list various commonly used baud rates together with their corresponding parameter settings and the deviation errors compared to the intended baud rate.

Table 133 Typical Baud Rates of UART ($f_{PCLK} = 40$ MHz)

Baud rate ($f_{PCLK} = 40$ MHz)	PRE	Reload Value (BR_VALUE)	Fractional Divider Selection (FD_NUM)	BG Register ¹⁾	Deviation Error
115.2 kBaud	1 (BRPRE = 000)	21 (15 _H)	22 (16 _H)	02B6 _H	+0.06%
20 kBaud	1 (BRPRE = 000)	125 (7D _H)	0 (0 _H)	0FA0 _H	0.00%
19.2 kBaud	1 (BRPRE = 000)	130 (82 _H)	7 (7 _H)	1047 _H	-0.01%
9600 Baud	2 (BRPRE = 001)	130 (82 _H)	7 (7 _H)	1047 _H	-0.01%
4800 Baud	4 (BRPRE = 010)	130 (82 _H)	7 (7 _H)	1047 _H	-0.01%
2400 Baud	8 (BRPRE = 011)	130 (82 _H)	7 (7 _H)	1047 _H	-0.01%

1) The value of the 16-bit BG register is obtained by concatenation the 11-bit BRVALUE and 5-bit FD_NUM into a 16-bit value.

Table 134 Typical Baud Rates of UART ($f_{PCLK} = 24$ MHz)

Baud rate ($f_{PCLK} = 24$ MHz)	PRE	Reload Value (BR_VALUE)	Fractional Divider Selection (FD_NUM)	BG Register ¹⁾	Deviation Error
115.2 kBaud	1 (BRPRE = 000)	13 (0D _H)	1 (01 _H)	01A1 _H	-0.08%
20 kBaud	1 (BRPRE = 000)	75 (4B _H)	0 (00 _H)	0960 _H	+0.00%
19.2 kBaud	1 (BRPRE = 000)	78 (4E _H)	4 (04 _H)	09C4 _H	+0.00%
9600 Baud	2 (BRPRE = 001)	78 (4E _H)	4 (04 _H)	09C4 _H	+0.00%
4800 Baud	4 (BRPRE = 010)	78 (4E _H)	4 (04 _H)	09C4 _H	+0.00%
2400 Baud	8 (BRPRE = 011)	78 (4E _H)	4 (04 _H)	09C4 _H	+0.00%

1) The value of the 16-bit BG register is obtained by concatenation the 11-bit BRVALUE and 5-bit FD_NUM into a 16-bit value.

20.6 LIN Support in UART

The UART module can be used to support the Local Interconnect Network (LIN) protocol for both master and slave operations. The LIN baud rate detection feature, which consists of the hardware logic for Break and Synch Byte detection, provides the capability to detect the baud rate within LIN protocol using Timer 2. This allows the UART module to be synchronized to the LIN baud rate for data transmission and reception.

20.6.1 LIN Protocol

LIN is a holistic communication concept for local interconnected networks in vehicles. The communication is based on the SCI (UART) data format, a single-master/multiple-slave concept, a clock synchronization for nodes without stabilized time base. An attractive feature of LIN is self-synchronization of the slave nodes without a crystal or ceramic resonator, which significantly reduces the cost of hardware platform. Hence, the baud rate must be calculated and returned with every message frame.

The structure of a LIN frame is shown in [Figure 172](#). The frame consists of the:

- header, which comprises a Break (13-bit time low), Synch Byte (55_H), and ID field
- response time
- data bytes (according to UART protocol)
- checksum

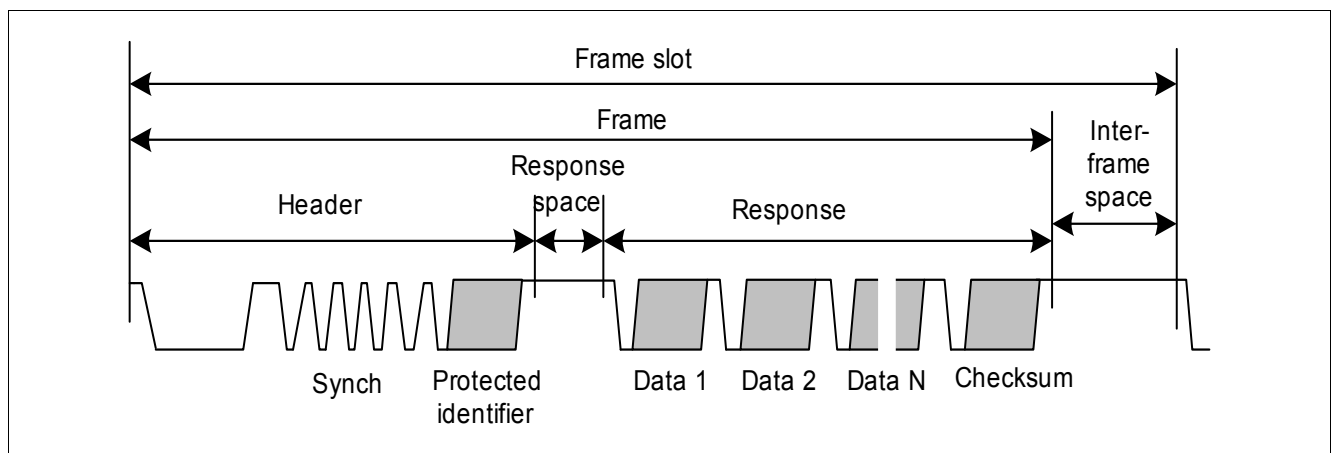

Figure 172 The Structure of LIN Frame

Each byte field is transmitted as a serial byte, as shown in [Figure 173](#). The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and the stop bit is encoded as a bit with value one (recessive).

Figure 173 The Structure of Byte Field

The break is used to signal the beginning of a new frame. It is the only field that does not comply with [Figure 173](#). A break is always generated by the master task (in the master mode) and it must be at least 13 bits of dominant value, including the start bit, followed by a break delimiter, as shown in [Figure 174](#). The break delimiter will be at least one nominal bit time long.

A slave node will use a break detection threshold of 11 nominal bit times.

Figure 174 The Break Field

Synch Byte is a specific pattern for determination of time base. The byte field is with the data value 55_H, as shown in [Figure 175](#).

A slave task is always able to detect the Break/Synch sequence, even if it expects a byte field (assuming the byte fields are separated from each other). If this happens, detection of the Break/Synch sequence will abort the transfer in progress and processing of the new frame will commence.

Figure 175 The Synch Byte Field

The slave task will receive and transmit data when an appropriate ID is sent by the master:

1. Slave waits for Synch Break
2. Slave synchronizes on Synch Byte
3. Slave snoops for ID
4. According to ID, slave determines whether to receive or transmit data, or do nothing
5. When transmitting, the slave sends 2, 4 or 8 data bytes, followed by check byte

20.6.2 LIN Header Transmission

LIN header transmission is only applicable in master mode. In the LIN communication, a master task decides when and which frame is to be transferred on the bus. It also identifies a slave task to provide the data transported by each frame. The information needed for the handshaking between the master and slave tasks is provided by the master task through the header portion of the frame.

The header consists of a break and synch pattern followed by an identifier. Among these three fields, only the break pattern cannot be transmitted as a normal 8-bit UART data. The break must contain a dominant value of 13 bits or more to ensure proper synchronization of slave nodes.

In the LIN communication, a slave task is required to be synchronized at the beginning of the protected identifier field of frame. For this purpose, every frame starts with a sequence consisting of a break field followed by a synch byte field. This sequence is unique and provides enough information for any slave task to detect the beginning of a new frame and be synchronized at the start of the identifier field.

20.6.2.1 Automatic Synchronization to the Host

Upon entering LIN communication, a connection is established and the transfer speed (baud rate) of the serial communication partner (host) is automatically synchronized in the following steps that are to be included in user software:

- STEP 1: Initialize interface for reception and timer for baud rate measurement
- STEP 2: Wait for an incoming LIN frame from host
- STEP 3: Synchronize the baud rate to the host

STEP 4: Enter for Master Request Frame or for Slave Response Frame

The next sections, [Section 20.6.2.2](#), [Section 20.6.2.3](#) and [Section 20.6.2.4](#) provide some hints on setting up the microcontroller for baud rate detection of LIN.

*Note: Re-synchronization and setup of baud rate are always done for **every** Master Request Header or Slave Response Header LIN frame.*

20.6.2.2 Initialization of Break/Synch Field Detection Logic

The LIN baud rate detection feature provides the capability to detect the baud rate within the LIN protocol using Timer 2. Initialization consists of:

- Serial port of the microcontroller set to Mode 1 (8-bit UART, variable baud rate) for communication.
- Provide the baud rate range via bit field BCON.BGSEL.
- Toggle BCON.BRDIS bit (set the bit to 1 before clearing it back to 0) to initialize the Break/Synch detection logic.
- Clear all status flags LINST.BRK, LINST.EOFSYN and LINST.ERRSYN to 0.
- Timer 2 is set to capture mode with falling edge trigger at pin T2EX. Bit T2MOD.EDGESEL is set to 0 by default and bit T2CON.CP/RL2 is set to 1.
- Timer 2 external events are enabled. T2CON.EXEN2 is set to 1. (EXF2 flag is set when a negative transition occurs at pin T2EX)
- fT2 can be configured by bit field T2MOD.T2PRE.

20.6.2.3 Baud Rate Range Selection

The Break/Synch Field detection logic supports a maximum number of bits in the Break field as defined by [Equation \(12\)](#).

(12)

$$\text{Maximum number of bits} = \text{Baud Rate} \times \frac{4095}{\text{Sample Frequency}}$$

The sample frequency is given by [Equation \(13\)](#).

(13)

$$\text{Sample Frequency} = \frac{f_{\text{PCLK}}}{8 \times 2^{\text{BGSEL}}}$$

If the maximum number of bits in the Break field is exceeded, the internal counter will overflow, which results in a baudrate detection error. Therefore, an appropriate BGSEL value has to be selected for the required baudrate detection range.

The baud rate range defined by different BGSEL settings is shown in [Table 135](#).

Table 135 BGSEL Bit Field Definition for Different Input Frequencies

f_{PCLK}	BGSEL	Baud Rate Select for Detection $f_{pclk}/(2184 \cdot 2^{BGSEL})$ to $f_{pclk}/(72 \cdot 2^{BGSEL})$
40 MHz	00 _B	18.3 kHz to 555.6 kHz
	01 _B	9.2 kHz to 277.8 kHz
	10 _B	4.6 kHz to 138.9 kHz
	11 _B	2.3 kHz to 69.4 kHz
24 MHz	00 _B	11 kHz to 333.3 kHz
	01 _B	5.5 kHz to 166.7 kHz
	10 _B	2.8 kHz to 83.3 kHz
	11 _B	1.4 kHz to 41.7 kHz

Each BGSEL setting supports a range of baud rate for detection. If the baud rate used is outside the defined range, the baud rate may not be detected correctly.

When $f_{pclk} = 40$ MHz, the baud rate range between 18.3 kHz to 555.6 kHz can be detected. The following examples serve as a guide to select BGSEL value:

- If the baud rate falls in the range of 2.3 kHz to 4.6 kHz, selected BGSEL value is "11_B".
- If the baud rate falls in the range of 4.6 kHz to 9.2 kHz, selected BGSEL value is "10_B".
- If the baud rate falls in the range of 9.2 kHz to 18.3 kHz, selected BGSEL value is "01_B".
- If the baud rate falls in the range of 18.3 kHz to 555.6 kHz, selected BGSEL value is "00_B". If the baud rate is 20 kHz, the possible values of BGSEL that can be selected are "00_B", "01_B", "10_B", and "11_B". However, it is advisable to select "00_B" for better detection accuracy.

The baud rate can also be detected when $f_{pclk} = 24$ MHz, for which the baud rate range that can be detected is between 1.4 kHz to 333.3 kHz.

20.6.2.4 LIN Baud Rate Detection

The baud rate detection for LIN is shown in [Figure 176](#), the Header LIN frame consists of the:

- SYN Break (13 bit times low)
- SYN byte (55_H)
- Protected ID field

Figure 176 LIN Auto Baud Rate Detection

With the first falling edge:

- The Timer 2 External Start Enable bit (T2MOD.T2RHEN) is set. The falling edge at pin T2EX is selected by default for Timer 2 External Start (bit T2MOD.T2REGS is 0).

With the second falling edge:

- Start Timer 2 by the hardware.

With the third falling edge:

- Timer 2 captures the timing of 2 bits of SYN byte.
- Check the Break Field Flag bit LINST.BRK.

If the Break Field Flag LINST.BRK is set, software may continue to capture 4/6/8 bits of SYN byte. Finally, the End of SYN Byte Flag (LINST.EOFSYN) is set, Timer 2 is stopped. T2 Reload/Capture register (RC2H/L) is the time taken for 2/4/6/8 bits according to the implementation. Then the LIN routine calculates the actual baud rate, sets the PRE and BG values if the UART module uses the baud-rate generator for baud rate generation.

After the third falling edge, the software may discard the current operation and continue to detect the next header LIN frame if the following conditions were detected:

- The Break Field Flag LINST.BRK is not set, or
- The SYN Byte Error Flag LINST.ERRSYN is set, or

20.7 Module Interfaces

An overview of the UART I/O interface is shown in [Figure 177](#) (UART1) and [Figure 178](#) (UART2).

In mode 0 (the serial port behaves as shift register), data is shifted in through RXD and out through RXDO, while the TXD line is used to provide a shift clock which can be used by external devices to clock data in and out. In modes 1, 2 and 3, the port behaves as an UART. Data is transmitted on TXD and received on RXD.

UART1:

As RXDO is not connected to I/O for UART1, mode 0 is not supported on UART1.

Data that is shifted into and out of the UART through RXD and TXD respectively.

RXD from UART1 can be selected from different sources (LIN or RXD1). This selection is performed within the SCU via SFR bit MODPSEL.URIOS1.

RXD and TXD from UART1 are connected to LIN can be monitored via RXD1 and TXD1 outputs on GPIO (by enabling the alternate outputs), UART1 in LIN mode or LIN monitoring mode.

In addition, UART1 transmission can be disconnected from LIN and provided via input port TXD1 (selected via .MODPSEL.U_TX_CONDIS), UART1 not used.

If UART1 is used as UART, RXD1 is input and TXD1 is output.

UART2:

RXD and TXD from UART2 can be selected from different sources. This selection is performed by the SCU via SFR bit MODPSEL3.URIOS2.

Figure 177 UART1 Module I/O Interface

Figure 178 UART2 Module I/O Interface

20.8 Interrupts

The two UART interrupts can be separately enabled or disabled by setting or clearing their corresponding enable bits in SCU SFR MODIEN. An overview of the UART interrupt sources is shown in [Table 136](#) and [Table 137](#).

Table 136 UART1 Interrupt Sources

20.9 Register Definition

20.9.1 UART Registers

20.9.1.1 UART Control Registers

UART contains the two Special Function Registers (SFRs), SCON and SBUF. SCON is the control register and SBUF is the data register. On reset, both SCON and SBUF return 00_H. The serial port control and status register is the SFR SCON. This register contains not only the mode selection bits, but also the 9th data bit for transmit and receive (TB8 and RB8) and the serial port interrupt bits (TI and RI).

SBUF is the receive and transmit buffer of the serial interface. Writing to SBUF loads the transmit register and initiates transmission. This register is used for both transmit and receive data. Transmit data is written to this location and receive data is read from this location, but the two paths are independent.

Reading out SBUF accesses a physically separate receive register.

RES	7	r	Reserved Returns 0 if read; should be written with 0.

20.9.1.3 Baud-rate Generator Timer/Reload Registers

The low and high bytes of the baud rate timer/reload register BG contains the 11-bit reload value for the baud rate timer and the 5-bit fractional divider selection.

Reading the low byte of register BG returns the content of the lower three bits of the baud rate timer and the FD_SEL setting, while reading the high byte returns the content of the upper 8 bits of the baud rate timer.

Writing to register BG loads the baud rate timer with the reload and fractional divider values from the BG register, the first instruction cycle after BCON.R is set.

BG should only be written if R = 0.

Note: The Baud-rate Generator Timer/Reload registers are located inside the SCU_DM module. For accessing them, the base address of the SCU_DM module has to be used.

20.9.2 Register Map

There are two UART kernels in the TLE9869QXA20, namely UART1 and UART2. UART1 is dedicated for LIN transmission. UART2 is dedicated for external UART communication.

Table 139 lists the addresses of the UART SFRs. **Table 140** lists the addresses of the SCU SFRs dedicated for UART1/2 functionality.

Table 138 shows the UART module base addresses.

Table 138 Registers Address Space

Module	Base Address	End Address	Note
UART1	4802 0000 _H	4802 1FFF _H	
UART2	4802 2000 _H	4802 3FFF _H	
SCU	5000 5000 _H	5000 5FFF _H

21 LIN Transceiver

21.1 Features

General Functional Features

- Compliant to LIN2.2 standard, backward compatible to LIN1.3, LIN2.0 and LIN 2.1
- Compliant to SAE J2602 (slew rate, receiver hysteresis)

Special Features

- Measurement of LIN master baudrate via Timer 21
- LIN can be used as input/output with SFR bits.
- TxD timeout feature (optional, on by default)

Operation Modes Features

- LIN Sleep Mode (LSLM)
- LIN Receive-Only Mode (LROM)
- LIN Normal Mode (LNM)
- High Voltage Input / Output Mode (LHVIO)

Supported Baudrates

- Mode for a transmission up to 10.4 kBaud
- Mode for a transmission up to 20 kBaud
- Mode for a transmission up to 40 kBaud
- Mode for a transmission up to 115.2 kBaud

Slope Modes Features

- Normal Slope Mode (20 kbit/s)
- Low Slope Mode (10.4 kbit/s)
- Flash Mode (115.2 kbit/s)

Wake-Up Features

- LIN bus wake-up

21.2 Introduction

The LIN Module is a transceiver for the Local Interconnect Network (LIN) compliant to the LIN2.2 standard, backward compatible to LIN1.3, LIN2.0 and LIN2.1. It operates as a bus driver between the protocol controller and the physical network. The LIN bus is a single wire, bi-directional bus typically used for in-vehicle networks, using baud rates between 2.4 kBaud and 20 kBaud. Additionally baud rates up to 115.2 kBaud are implemented.

The LIN Module offers several different operation modes, including a LIN Sleep Mode and the LIN Normal Mode. The integrated slope control allows to use several data transmission rates with optimized EMC performance. For data transfer at the end of line, a Flash Mode up to 115.2 kBaud is implemented. This Flash Mode can be used for data transfer under special conditions for up to 250 kbits/s (in production environment, point-to-point communication with reduced wire length and limited supply voltage).

21.2.1 Block Diagram

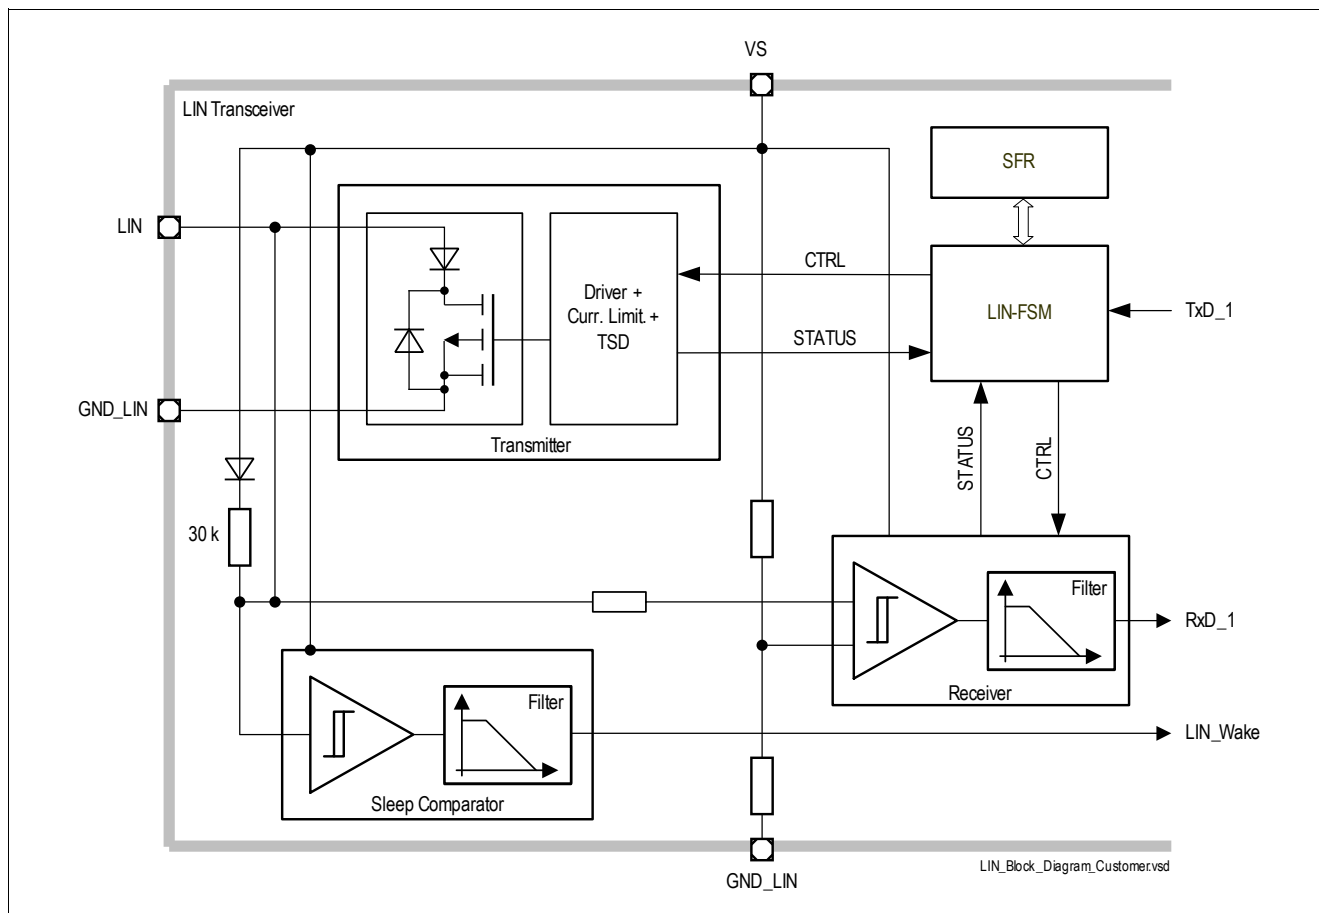

Figure 179 LIN Transceiver Block Diagram

21.3 Functional Description

21.3.1 LIN Transceiver Modes

The LIN Module is controlled by an internal state machine which determines the actual state of the transceiver. This state machine is controllable by the SFR interface.

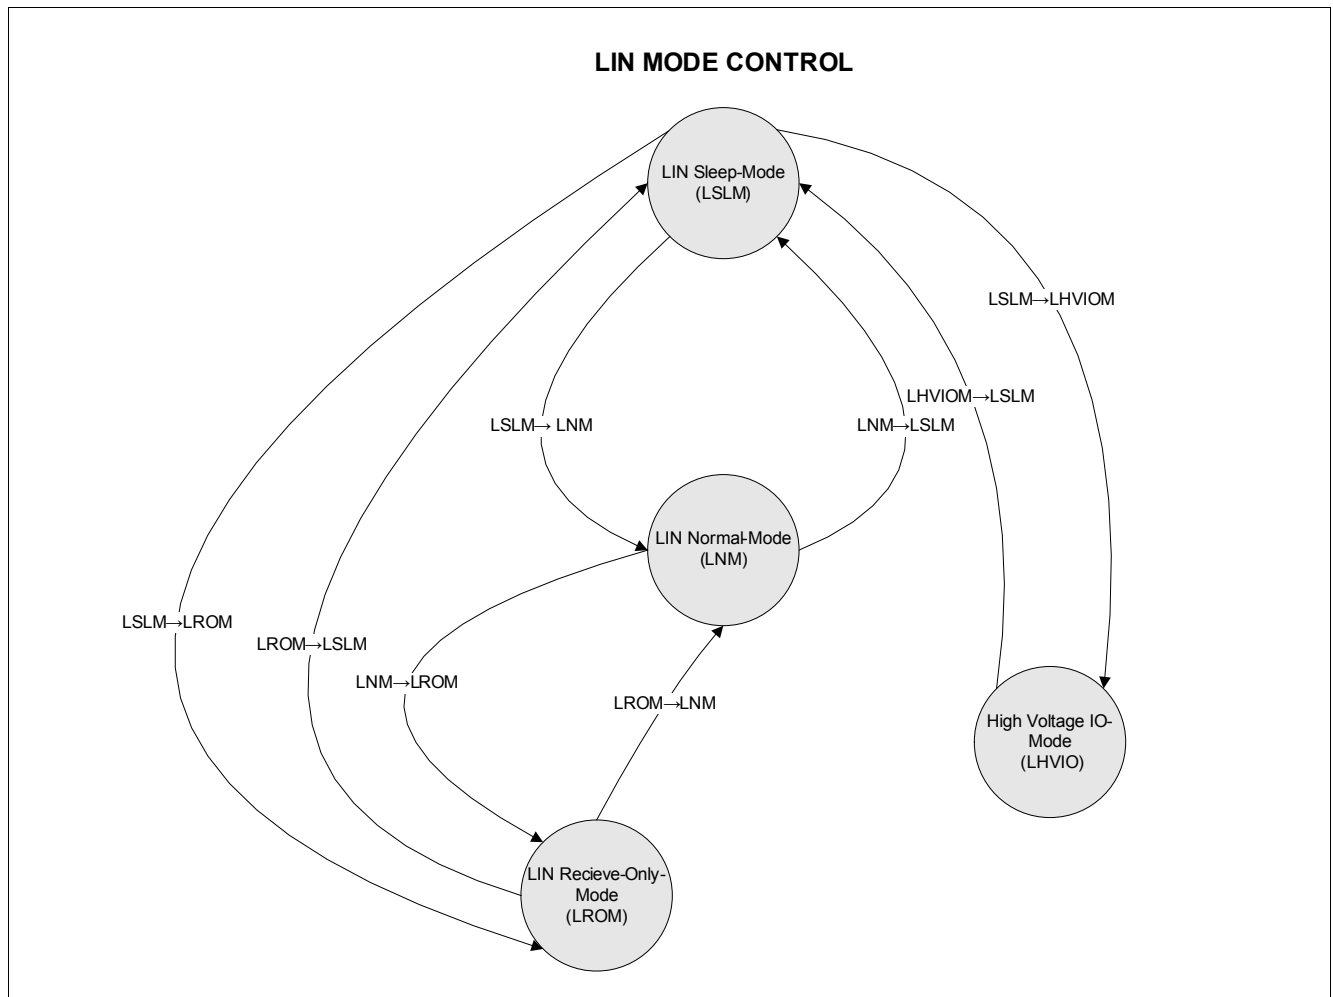

Figure 180 SFR controlled LIN Transceiver State machine

LIN Normal Mode (LNM)

In this mode it is possible to receive and transmit data with low slope, normal slope, fast slope or flash mode. Slope setting is locked during LIN Normal Mode to avoid destruction of communication process. This is blocked by hardware.

LIN Receive-Only Mode (LROM)

In LIN Receive-Only Mode the transmitter is disabled. The receiver is active. This mode can be directly selected by application software or is automatically set upon error detection.

LIN Sleep Mode (LSLM)

In this mode, the transmit and receive functions are disabled, the wake receiver is active. Minimum current consumption is achieved. Wake up via LIN is possible. To disable the wake capability via LIN, the LIN wake can be disabled within the PMU.

LIN High Voltage Input / Output (LHVIO)

This mode is dedicated for using the LIN transceiver as high voltage input/output. In LHVIO Mode the transceiver is controlled by [CTRL_STS.LIN_TXD](#).

The Input status is controlled by [CTRL_STS.LIN_TXD](#) and can be read by [CTRL_STS.LIN_RXD](#).

The transitions between the described states can only be executed when corresponding conditions are fulfilled. The detailed description of the transitions can be found below.

LIN Sleep Mode (LSLM) - LIN Receive-Only Mode (LROM) Transition Description

- LSLM - LROM transition is executed when:
 - MODE is configured to LIN Receive-Only Mode and
 - Feedback signals of Mode and Slope Mode are ok and
 - HV_Mode bit is not set
- LROM - LSLM transition is executed when:
 - MODE is configured to LIN Sleep Mode

LIN Sleep Mode (LSLM) - LIN Normal Mode (LNM) Transition Description

- LSLM - LNM transition is executed when:
 - MODE is configured to LIN Normal Mode and
 - Feedback signals of Mode and Slope Mode are ok and
 - HV_Mode bit is not set and
 - VS undervoltage flag (VS_UV_STS) is not set
 - LIN transceiver OT_STS and OC_STS are not set and
 - no TXD_TMOUT is set
- LNM - LSLM transition is executed when:
 - MODE is configured LIN Sleep Mode

LIN Normal Mode (LNM) - LIN Receive-Only Mode (LROM) Transition Description

- LNM - LROM transition is executed when
 - MODE is configured to LIN Receive-Only Mode or
 - Feedback signals of Mode and Slope Mode are not ok or
 - VS undervoltage flag (VS_UV_STS) is set or
 - LIN transceiver OT_STS or OC_STS are set or
 - TXD_TMOUT is set
- LROM - LNM transition is executed when:
 - MODE is configured to LIN Normal Mode and
 - Feedback signals of Mode and Slope Mode are ok (see [Chapter 21.3.2](#)) and
 - VS undervoltage flag (VS_UV_STS) is not set and
 - LIN transceiver OT_STS and OC_STS are not set and
 - no TXD_TMOUT is set

LIN Sleep Mode (LSLM) - LIN High Voltage Input / Output Mode (LHVIO) Transition Description

- LSLM - LHVIO transition is executed when
 - HV_MODE flag is set and
 - MODE is configured to LIN Normal Mode after HV_MODE flag was set and
 - Feedback signals of Mode and Slope Mode are ok and
 - LIN transceiver OT_STS and OC_STS are not set
- LHVIO - LSLM transition is executed when:
 - MODE is configured to LIN Sleep Mode and
 - HV_MODE flag is set or
 - Feedback signals of Mode and Slope Mode are not ok or
 - LIN transceiver OT_STS or OC_STS are set

LIN Specifications 1.3 and 2.0, 2.1

The LIN specification 2.0 is a superset of the 1.3 version offering some additional features. However, it is possible to use the LIN 1.3 slave node in a 2.0 node cluster, as long as the new features are not used. Vice versa it is possible to use a LIN 2.0 node in the 1.3 cluster without using the new features.

The latest version of the LIN specification 2.1 has no changes regarding the physical layer specification of LIN 2.0.

21.3.2 LIN Transceiver Status for Mode Selection

The LIN transceiver provides the possibility to monitor the on chip status through internally generated feedback signals. This provides additional protection functionality for the application to avoid wrong configuration of the transceiver, which may lead to a blocking of communication on the LIN Bus. The table below shows the decoding of feedback signals to check the current status of the transceiver.

Table 141 Decoding of Feedback Signals for LIN Transmitter Mode Settings

MODE_FB[2]	MODE_FB[1]	MODE_FB[0]	Remarks
0	0	0	Mode Error
0	0	1	LIN Sleep Mode
0	1	0	Mode Error
0	1	1	Mode Error
1	0	0	Mode Error
1	0	1	LIN Receive-Only Mode
1	1	0	Mode Error
1	1	1	LIN Normal Mode

A Mode Error indicates a problem in the LIN configuration. If that applies, check the LIN software configuration, and whenever this does not improve the mode feedback it is recommended to enter Sleep Mode.

21.3.3 LIN Transceiver Error Handling

The LIN Module provides error handling for three different cases:

LIN Transceiver TxD Timeout

If the internal UART TxD signal is dominant for the time $t > t_{\text{timeout}}$, the TxD timeout function deactivates the LIN transmitter output stage temporarily by entering the LIN Receive-Only Mode. The transceiver remains in recessive state. The TxD timeout function prevents the LIN bus from being blocked by a permanent low signal on the TxD pin, caused by a failure. The failure is stored in the TXD_TMOUT flag. The transmitter stage is activated again after the dominant timeout condition is removed and after the TXD_TMOUT flag is cleared by software.

LIN Transceiver Overcurrent

If the LIN transmitter detects an overcurrent condition $I > I_{\text{BUS,sc}}$, the LIN transceiver stays in LIN Normal Mode and the overcurrent status will be stored in the OC_STS flag. The short circuit current is limited to $I_{\text{BUS,sc}}$. The OC_STS flag can be cleared by software and will be set again as long as the above condition remains.

To generate an interrupt in case of LIN overcurrent detection, the corresponding interrupt can be enabled by setting the OC_IE in the SYS_IRQ_CTRL_1 register. This interrupt is routed to INTISR[10].

LIN Transceiver Overtemperature

If the LIN transmitter detects an overtemperature condition the transmitter will be deactivated temporarily by entering the LIN Receive-Only Mode. The transceiver remains in recessive state. The failure is stored in the LIN_OT_STS flag. The transmitter stage is activated again after the overtemperature condition is gone and after the LIN_OT_STS flag is cleared by software.

To generate an interrupt in case of LIN overtemperature detection, the corresponding interrupt can be enabled by setting the LIN_OT_IE in the SYS_IRQ_CTRL_1 register. This interrupt is routed to INTISR[10].

21.3.4 Slope Modes

The LIN Module provides some additional slope mode features which can be used for EoL (End of Line) programming or to reduce emission in case of usage of lower baudrates. The configurable slope modes are:

Normal Slope Mode

This mode is usually used to transmit and receive messages on the bus. The selected slew rate setting allows a transmission rate of up to 20 kBaud.

Low Slope Mode

The usage of this mode is linked to a communication with lower baudrate. With this setting the emission of the transmitter can be reduced. The selected slew rate setting allows a transmission rate of up to 10.4 kBaud.

Fast Slope Mode

In this mode it is also possible to transmit and receive messages on the bus. The selected slew rate setting allows a transmission rate of up to 40 kBaud.

Flash Mode

In this mode it is possible to transmit and receive messages on the bus. Transmission rates of up to 115.2 kBaud are allowed due the internal slew rate control. This mode can be used for EoL programming.

Changing Slope Modes

It is not possible to change slope modes when the module is operating in LIN Normal Mode because this would cause transmission errors. For example, to change from Normal Slope Mode to Flash Mode, proceed as follows:

- change to LIN Receive-Only Mode or LIN Sleep Mode;
- configure the desired slope mode; and
- go back to LIN Normal Mode.

21.3.5 LIN Transceiver Slope Mode Status

The LIN transceiver provides the possibility to monitor the on chip status of the slope control through internally generated feedback signals. The table shows the decoding of the feedback signals.

Table 142 Slope Mode Status

FB_SM3	FB_SM2	FB_SM1	Remarks
0	0	0	LIN module not enabled
0	0	1	Low Slope Mode
0	1	0	Normal Slope Mode
0	1	1	Fast Slope mode
1	0	0	Flash Mode
1	0	1	Slope Mode Error
1	1	0	Slope Mode Error
1	1	1	Slope Mode Error

22 High-Speed Synchronous Serial Interface (SSC1/SSC2)

22.1 Features

- Master and Slave Mode operation
 - Full-duplex or half-duplex operation
- Transmit and receive buffered
- Flexible data format
 - Programmable number of data bits: 2 to 16 bits
 - Programmable shift direction: Least Significant Bit (LSB) or Most Significant Bit (MSB) shift first
 - Programmable clock polarity: idle low or high state for the shift clock
 - Programmable clock/data phase: data shift with leading or trailing edge of the shift clock
- Variable baud rate
- Compatible with Serial Peripheral Interface (SPI)
- Interrupt generation
 - On a transmitter empty condition
 - On a receiver full condition
 - On an error condition (receive, phase, baud rate, transmit error)

22.2 Introduction

The High-Speed Synchronous Serial Interface (SSC) supports both full-duplex and half-duplex serial synchronous communication. The serial clock signal can be generated by the SSC internally (master mode), using its own 16-bit baud rate generator, or can be received from an external master (slave mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices or devices using other synchronous serial interfaces.

Data is transmitted or received on lines TXD and RXD, which are normally connected to the pins MTSR (MasterTransmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output via line MS_CLK (Master Serial Shift Clock) or input via line SS_CLK (Slave Serial Shift Clock). Both lines are normally connected to the pin SCLK. Transmission and reception of data are double-buffered.

22.2.1 Block Diagram

Figure 181 shows all functional relevant interfaces associated with the SSC Kernel.

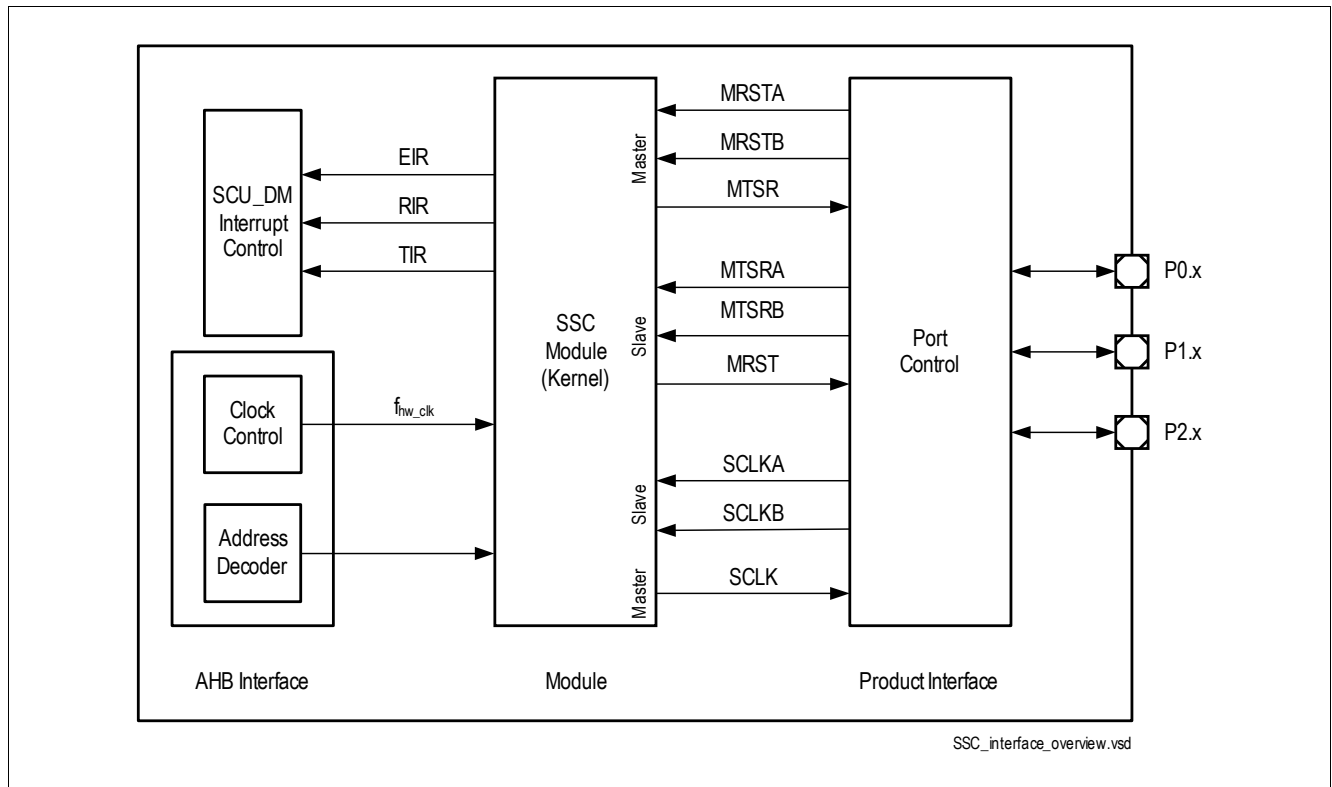

Figure 181 SSC Interface Diagram

22.3 Functional Description

22.3.1 SSC1 and SSC2 Modes Overview

The SSC supports full-duplex and half-duplex synchronous communication up to 20 MBaud (@ 40 MHz module clock). The serial clock signal can be generated by the SSC itself (Master Mode) or can be received from an external master (Slave Mode). Data width, shift direction, clock polarity, and phase are programmable. This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit baud-rate generator provides the SSC with a separate serial clock signal.

The SSC can be configured in a very flexible way, so it can be used with other synchronous serial interfaces, can serve for master/slave or multimaster interconnections or can operate compatible with the popular SPI interface. Thus, the SSC can be used to communicate with shift registers (I/O expansion), peripherals (e.g. EEPROMs, etc.) or other controllers (networking). The SSC supports half-duplex and full-duplex communication. Data is transmitted or received on lines TXD and RXD, normally connected with pins MTSR (Master Transmit/Slave Receive) and MRST (Master Receive/Slave Transmit). The clock signal is output via line MS_CLK (Master Serial Shift Clock) or input via line SS_CLK (Slave Serial Shift Clock). Both lines are normally connected to pin SCLK.

High-Speed Synchronous Serial Interface (SSC1/SSC2)

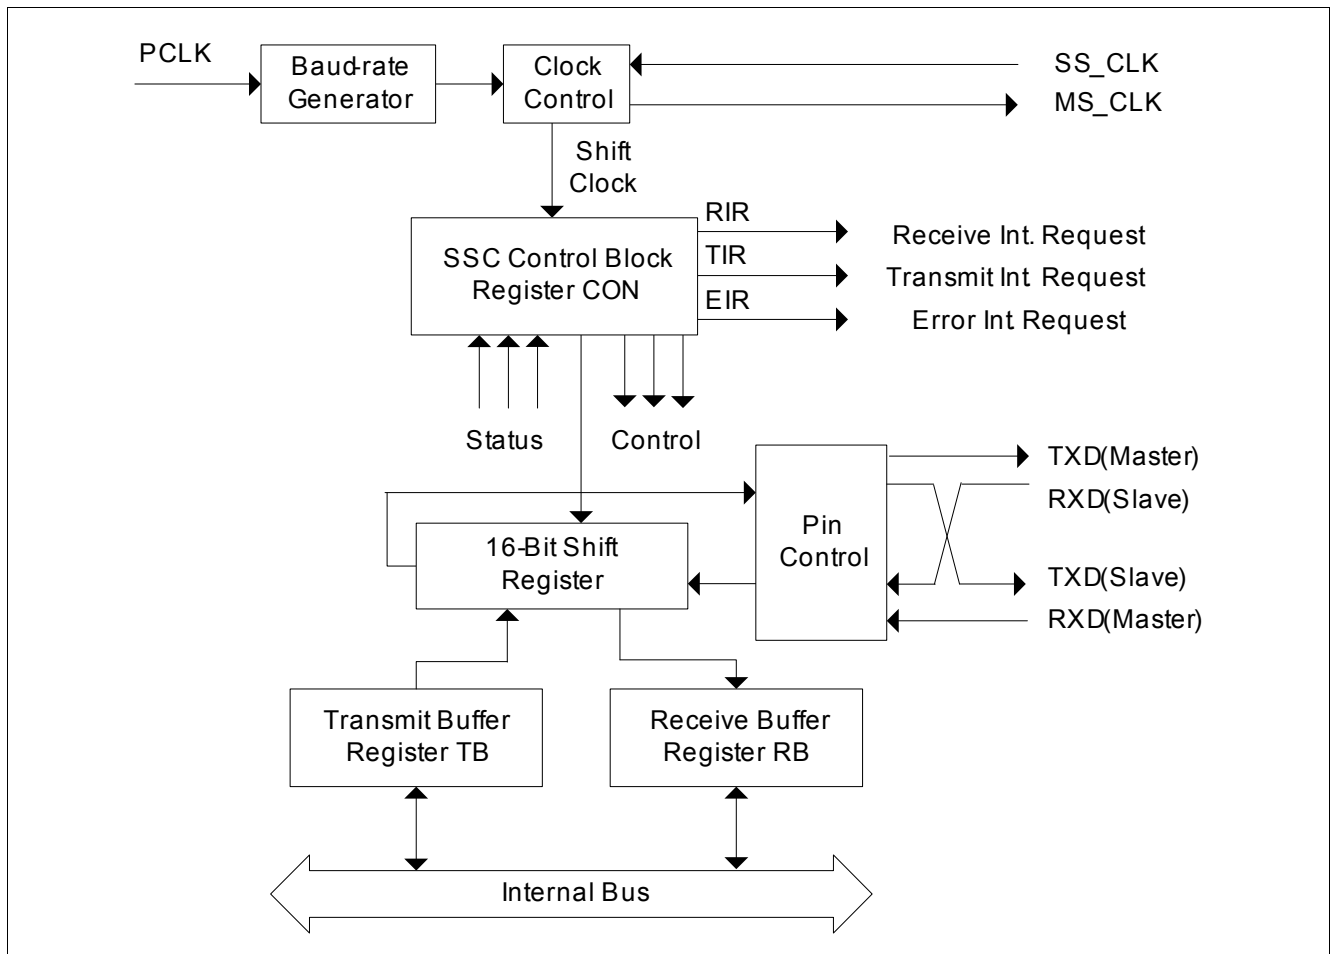

Figure 182 Synchronous Serial Channel SSC Block Diagram

22.3.2 Operating Mode Selection

The operating mode of the serial channel SSC is controlled by its control register CON. This register serves two purposes:

- During programming (SSC disabled by CON.EN = 0), it provides access to a set of control bits
- During operation (SSC enabled by CON.EN = 1), it provides access to a set of status flags.

The shift register of the SSC is connected to both the transmit lines and the receive lines via the pin control logic (see block diagram in [Figure 182](#)). Transmission and reception of serial data are synchronized and take place at the same time, i.e. the same number of transmitted bits is also received. Transmit data is written into the Transmit Buffer (TB) and is moved to the shift register as soon as this is empty. An SSC master (CON.MS = 1) immediately begins transmitting, while an SSC slave (CON.MS = 0) will wait for an active shift clock. When the transfer starts, the busy flag CON.BSY is set and the Transmit Interrupt Request line TIR will be activated to indicate that register TB may be reloaded again. When the programmed number of bits (2 ... 16) has been transferred, the contents of the shift register are moved to the Receive Buffer RB and the Receive Interrupt Request line RIR will be activated. If no further transfer is to take place (TB is empty), CON.BSY will be cleared at the same time. Software should not modify CON.BSY, as this flag is hardware controlled.

Note: The SSC starts transmission and sets CON.BSY minimum two clock cycles after transmit data is written into TB. Therefore, it is not recommended to poll CON.BSY to indicate the start and end of a single transmission. Instead, interrupt service routine should be used if interrupts are enabled, or the interrupt flags IRCON1.TIR and IRCON1.RIR should be polled if interrupts are disabled.

High-Speed Synchronous Serial Interface (SSC1/SSC2)

Note: Only one SSC (etc.) can be master at a given time.

The transfer of serial data bits can be programmed in many respects:

- The data width can be specified from 2 bits to 16 bits
- A transfer may start with either the LSB or the MSB
- The shift clock may be idle low or idle high
- The data bits may be shifted with the leading edge or the trailing edge of the shift clock signal
- The baud rate may be set from 305.18 Baud up to 20 MBaud (@ 40 MHz module clock)
- The shift clock can be generated (MS_CLK) or can be received (SS_CLK)

These features allow the adaptation of the SSC to a wide range of applications requiring serial data transfer.

The Data Width Selection supports the transfer of frames of any data length, from 2-bit “characters” up to 16-bit “characters”. Starting with the LSB (CON.HB = 0) allows communication with SSC devices in Synchronous Mode or with 8051 like serial interfaces for example. Starting with the MSB (CON.HB = 1) allows operation compatible with the SPI interface.

Regardless of the data width selected and whether the MSB or the LSB is transmitted first, the transfer data is always right-aligned in registers TB and RB, with the LSB of the transfer data in bit 0 of these registers. The data bits are rearranged for transfer by the internal shift register logic. The unselected bits of TB are ignored; the unselected bits of RB will not be valid and should be ignored by the receiver service routine.

The Clock Control allows the adaptation of transmit and receive behavior of the SSC to a variety of serial interfaces. A specific shift clock edge (rising or falling) is used to shift out transmit data, while the other shift clock edge is used to latch in receive data. Bit CON.PH selects the leading edge or the trailing edge for each function. Bit CON.PO selects the level of the shift clock line in the idle state. Thus, for an idle-high clock, the leading edge is a falling one, a 1-to-0 transition (see [Figure 183](#)).

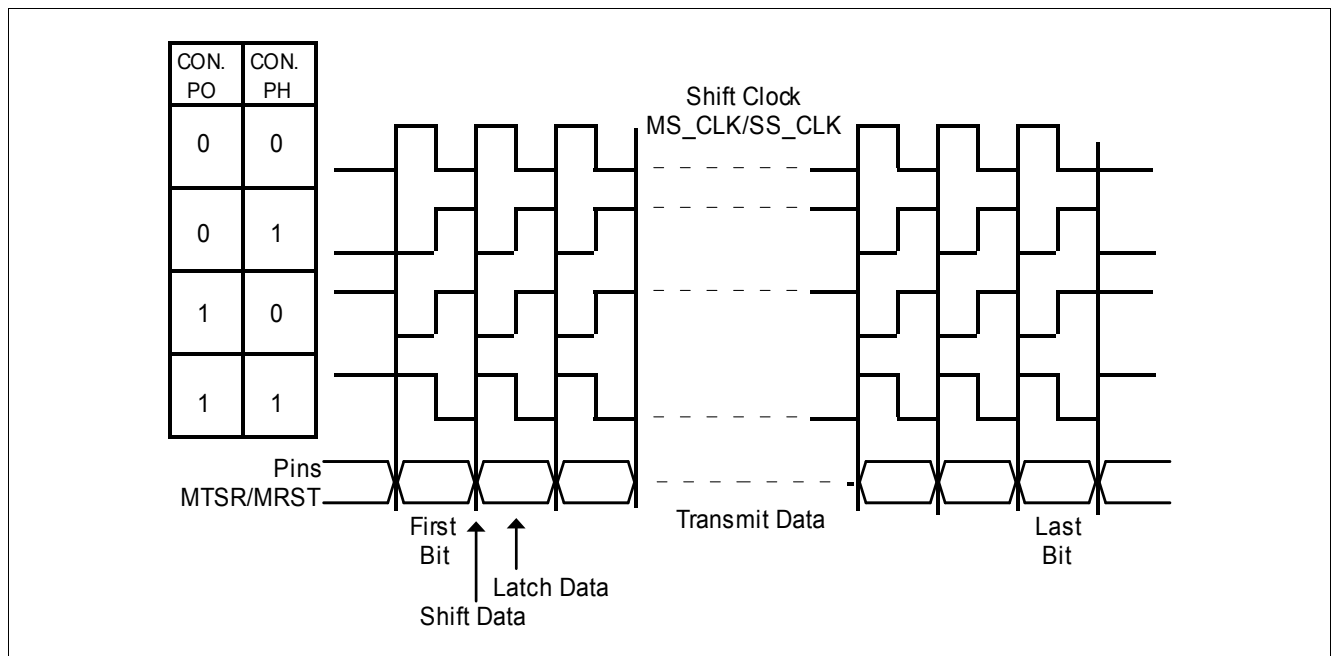

Figure 183 Serial Clock Phase and Polarity Options

22.3.3 Full-Duplex Operation

The various devices are connected through three lines. The definition of these lines is always determined by the master: the line connected to the master's data output line TXD is the transmit line; the receive line is connected to its data input line RXD; the shift clock line is either MS_CLK or SS_CLK. Only the device selected for master operation generates and outputs the shift clock on line MS_CLK. Since all slaves receive this clock, their pin SCLK must be switched to input mode. The output of the master's shift register is connected to the external transmit line, which in turn is connected to the slaves' shift register input. The output of the slaves' shift register is connected to the external receive line in order to enable the master to receive the data shifted out of the slave. The external connections are hard-wired, the function and direction of these pins is determined by the master or slave operation of the individual device.

Note: The shift direction shown in the figure applies for MSB-first operation as well as for LSB-first operation.

When initializing the devices in this configuration, one device must be selected for master operation while all other devices must be programmed for slave operation. Initialization includes the operating mode of the device's SSC and also the function of the respective port lines.

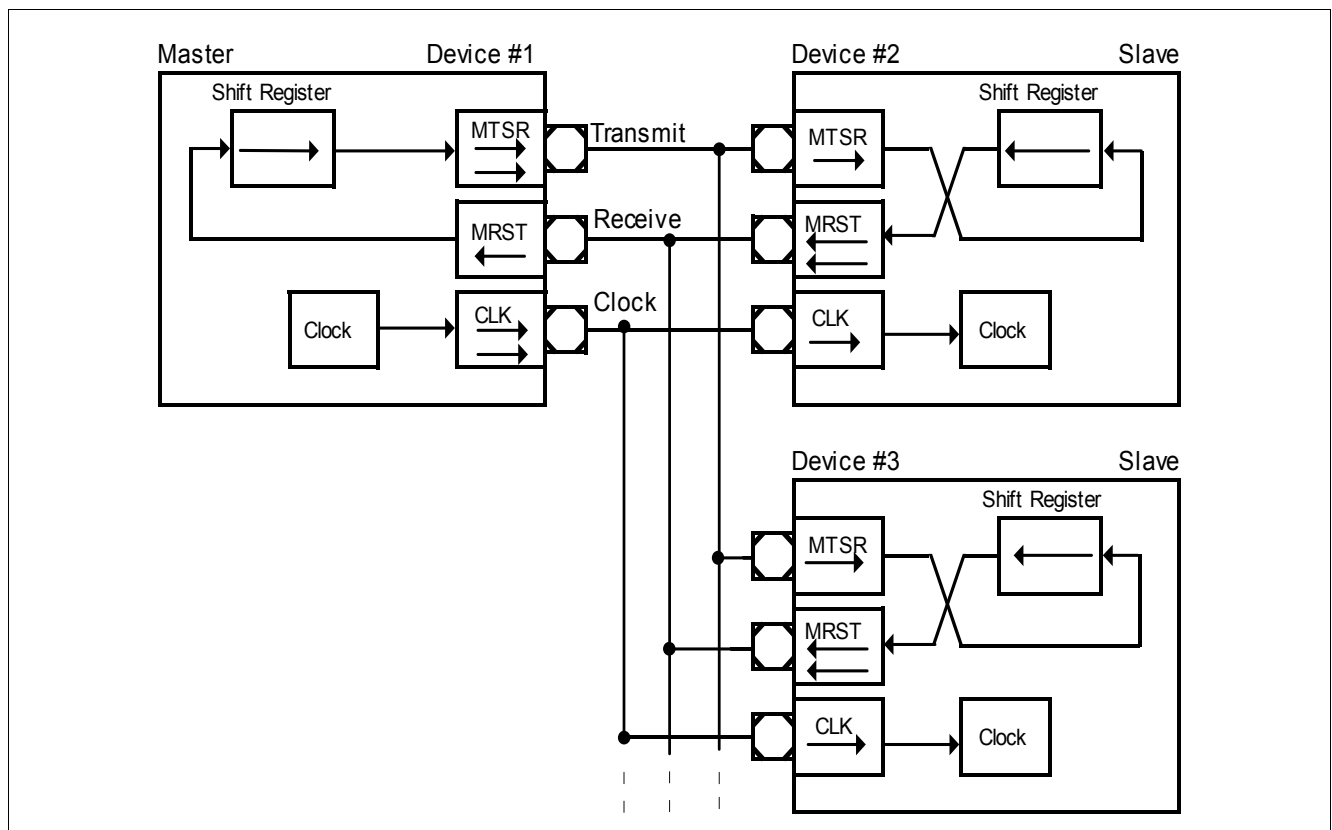

Figure 184 SSC Full-Duplex Configuration

The data output pins MRST of all slave devices are connected together onto the one receive line in the configuration shown in [Figure 184](#). During a transfer, each slave shifts out data from its shift register. There are two ways to avoid collisions on the receive line due to different slave data:

- Only one slave drives the line, i.e. enables the driver of its MRST pin. All the other slaves must have their MRST pins programmed as input so only one slave can put its data onto the master's receive line. Only receiving data from the master is possible. The master selects the slave device from which it expects data either by separate select lines, or by sending a special command to this slave. The selected slave then switches its MRST line to output until it gets a de-selection signal or command.
- The slaves use open drain output on MRST. This forms a wired-AND connection. The receive line needs an external pull-up in this case. Corruption of the data on the receive line sent by the selected slave is avoided

High-Speed Synchronous Serial Interface (SSC1/SSC2)

when all slaves not selected for transmission to the master only send ones (1s). Because this high level is not actively driven onto the line, but only held through the pull-up device, the selected slave can pull this line actively to a low-level when transmitting a zero bit. The master selects the slave device from which it expects data either by separate select lines or by sending a special command to this slave.

After performing the necessary initialization of the SSC, the serial interfaces can be enabled. For a master device, the alternate clock line will now go to its programmed polarity. The alternate data line will go to either 0 or 1 until the first transfer starts. After a transfer, the alternate data line will always remain at the logic level of the last transmitted data bit.

When the serial interfaces are enabled, the master device can initiate the first data transfer by writing the transmit data into register TB. This value is copied into the shift register (assumed to be empty at this time), and the selected first bit of the transmit data will be placed onto the TXD line on the next clock from the baud-rate generator (transmission starts only if CON.EN = 1). Depending on the selected clock phase, a clock pulse will also be generated on the MS_CLK line. At the same time, with the opposite clock edge, the master latches and shifts in the data detected at its input line RXD. This “exchanges” the transmit data with the receive data. Because the clock line is connected to all slaves, their shift registers will be shifted synchronously with the master’s shift register — shifting out the data contained in the registers, and shifting in the data detected at the input line. After the preprogrammed number of clock pulses (via the data width selection), the data transmitted by the master is contained in all the slaves’ shift registers, while the master’s shift register holds the data of the selected slave. In the master and all slaves, the contents of the shift register are copied into the receive buffer RB and the receive interrupt line RIR is activated.

A slave device will immediately output the selected first bit (MSB or LSB of the transfer data) at line RXD when the contents of the transmit buffer are copied into the slave's shift register. Bit CON.BSY is not set until the first clock edge at SS_CLK appears. The slave device will not wait for the next clock from the baud-rate generator, as the master does. The reason for this is that, depending on the selected clock phase, the first clock edge generated by the master may already be used to clock in the first data bit. Thus, the slave’s first data bit must already be valid at this time.

*Note: On the SSC, a transmission **and** a reception takes place at the same time, regardless of whether valid data has been transmitted or received.*

Note: The initialization of the CLK pin on the master requires some attention in order to avoid undesired clock transitions, which may disturb the other devices. Before the clock pin is switched to output via the related direction control register, the clock output level will be selected in the control register CON and the alternate output be prepared via the related ALTSEL register, or the output latch must be loaded with the clock idle level.

22.3.4 Half-Duplex Operation

In a Half-Duplex Mode, only one data line is necessary for both receiving **and** transmitting of data. The data exchange line is connected to both the MTSR and MRST pins of each device, the shift clock line is connected to the SCLK pin.

The master device controls the data transfer by generating the shift clock, while the slave devices receive it. Due to the fact that all transmit and receive pins are connected to the one data exchange line, serial data may be moved between arbitrary stations.

Similar to Full-Duplex Mode, there are two ways to avoid collisions on the data exchange line:

- Only the transmitting device may enable its transmit pin driver
- The non-transmitting devices use open drain output and send only ones.

Because the data inputs and outputs are connected together, a transmitting device will clock in its own data at the input pin (MRST for a master device, MTSR for a slave). By this method, any corruptions on the common data exchange line are detected if the received data is not equal to the transmitted data.

Figure 185 SSC Half-Duplex Configuration

22.3.5 Continuous Transfers

When the transmit interrupt request flag is set, it indicates that the transmit buffer TB is empty and ready to be loaded with the next transmit data. If TB has been reloaded by the time the current transmission is finished, the data is immediately transferred to the shift register and the next transmission will start without any additional delay. On the data line, there is no gap between the two successive frames. For example, two byte transfers would look the same as one word transfer. This feature can be used to interface with devices that can operate with or require more than 8 data bits per transfer. It is just a matter of software, how long a total data frame length can be. This option can also be used to interface to byte-wide and word-wide devices on the same serial bus, for instance.

Note: Of course, this can happen only in multiples of the selected basic data width, because it would require disabling/enabling of the SSC to reprogram the basic data width on-the-fly.

22.3.6 Baud Rate Generation

The serial channel SSC has its own dedicated 16-bit baud-rate generator with 16-bit reload capability, allowing baud rate generation independent of the timers. In addition to [Figure 182](#), [Figure 186](#) shows the baud-rate generator of the SSC in more detail.

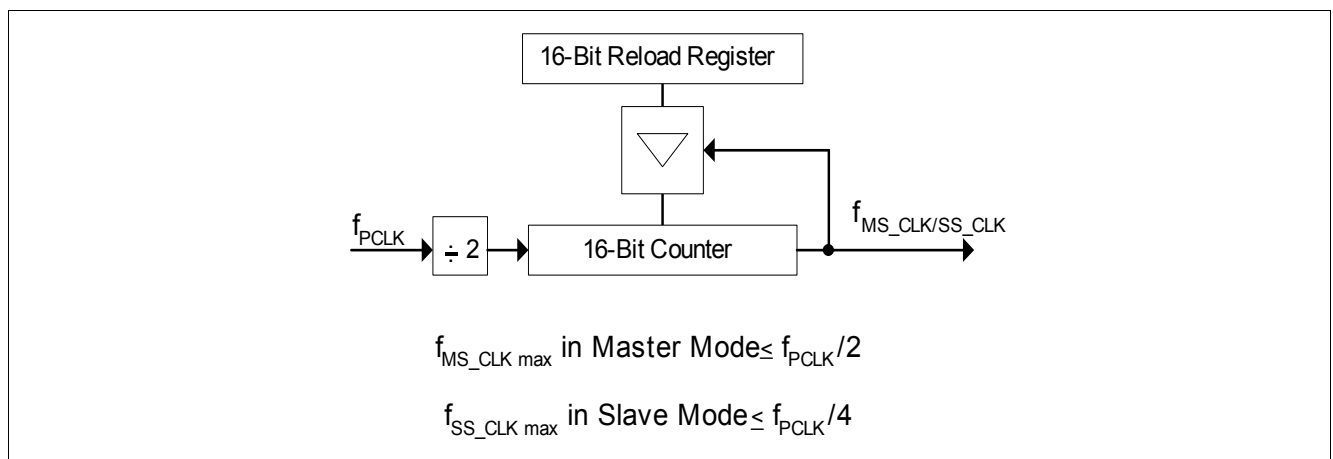

Figure 186 SSC Baud-rate Generator

The baud-rate generator is clocked with the module clock $f_{\text{hw_clk}}$. The timer counts downwards. Register BR is the dual-function Baud-rate Generator/Reload register. Reading BR, while the SSC is enabled, returns the contents of the timer. Reading BR, while the SSC is disabled, returns the programmed reload value. In this mode, the desired reload value can be written to BR.

Note: Never write to BR while the SSC is enabled.

The formulas below calculate either the resulting baud rate for a given reload value, or the required reload value for a given baud rate:

$$\text{Baud rate} = \frac{f_{\text{hw_clk}}}{2 \cdot (\text{BR} + 1)} \quad \text{BR} = \frac{f_{\text{hw_clk}}}{2 \cdot \text{Baud rate}} - 1 \quad (14)$$

 represents the contents of the reload register, taken as an unsigned 16-bit integer, while baud rate is equal to $f_{\text{MS_CLK/SS_CLK}}$ as shown in [Figure 186](#).

The maximum baud rate that can be achieved when using a module clock of 40 MHz is 20 MBaud in Master Mode (with
 = 0000_H) or 10 MBaud in Slave Mode (with
 = 0001_H).

[Table 145](#) lists some possible baud rates together with the required reload values and the resulting bit times, assuming a module clock of 40 MHz.

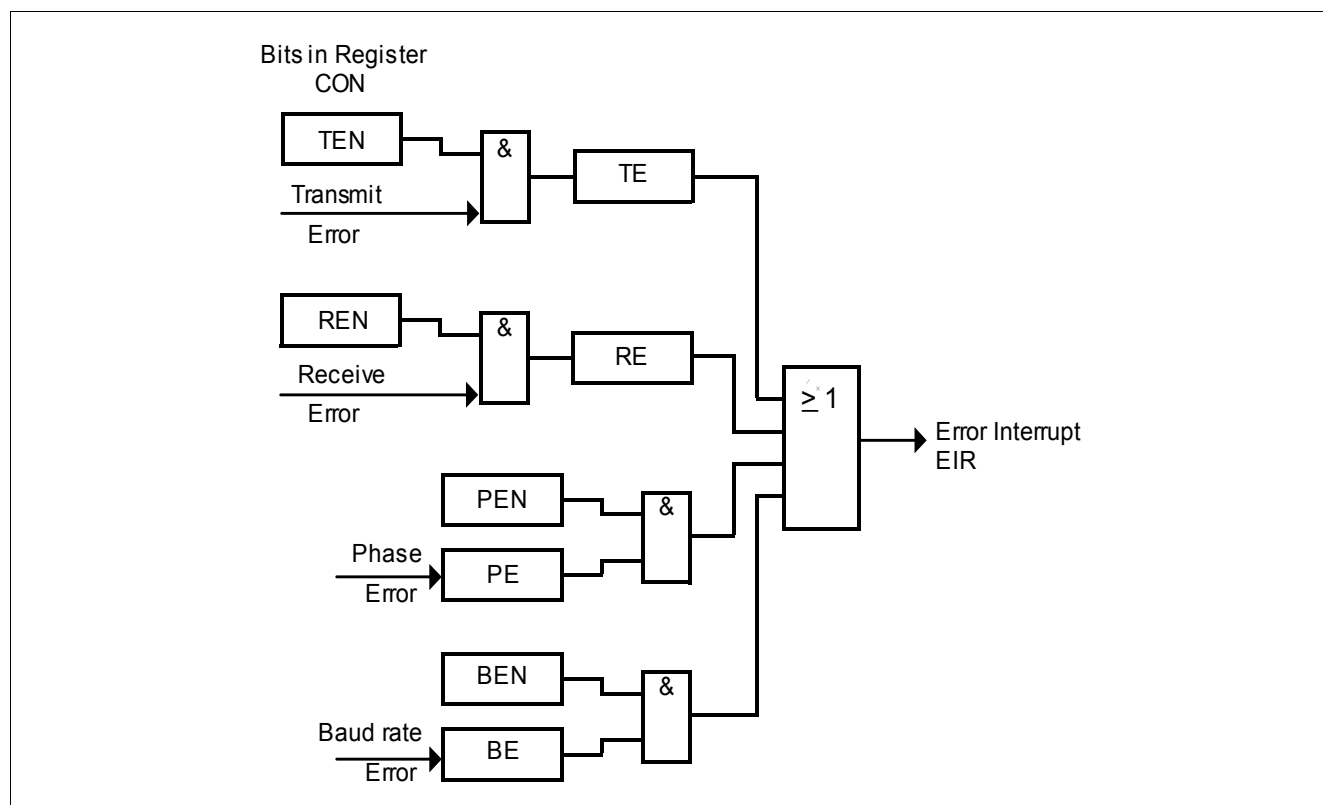

Table 145 Typical Baud Rates of the SSC ($f_{hw_clk} = 40 \text{ MHz}$)

Reload Value	Baud Rate ($= f_{MS_CLK/SS_CLK}$)	Deviation
0000 _H	20 MBaud (only in Master Mode)	0.0%
0001 _H	10 MBaud	0.0%
0013 _H	1 MBaud	0.0%
0027 _H	500 kBaud	0.0%
00C7 _H	100 kBaud	0.0%
07CF _H	10 kBaud	0.0%
4E1F _H	1 kBaud	0.0%
FFFF _H	305.18 Baud	0.0%

22.3.7 Error Detection Mechanisms

The SSC is able to detect four different error conditions. Receive Error and Phase Error are detected in all modes; Transmit Error and Baud Rate Error apply only to Slave Mode. When an error is detected, the respective error flag is/can be set and an error interrupt request will be generated by activating the EIR line (see [Figure 187](#)) if enabled. The error interrupt handler may then check the error flags to determine the cause of the error interrupt. The error flags are not reset automatically but must be cleared by software after servicing. This allows servicing of some error conditions via interrupt, while the others may be polled by software.

Note: The error interrupt handler must clear the associated (enabled) error flag(s) to prevent repeated interrupt requests.

Figure 187 SSC Error Interrupt Control

A **Receive Error** (Master or Slave Mode) is detected when a new data frame is completely received but the previous data was not read out of the receive buffer register RB. This condition sets the error flag CON.RE and

High-Speed Synchronous Serial Interface (SSC1/SSC2)

the error interrupt request line EIR, when enabled via CON.REN. The old data in the receive buffer RB will be overwritten with the new value and is irretrievably lost.

A **Phase Error** (Master or Slave Mode) is detected when the incoming data at pin MRST (Master Mode) or MTSR (Slave Mode), sampled with the same frequency as the module clock, changes between one cycle before and two cycles after the latching edge of the shift clock signal SCLK. This condition sets the error flag CON.PE and, when enabled via CON.PEN, the error interrupt request line EIR.

Note: When receiving and transmitting data in parallel, phase errors occur if the baud rate is configured to $f_{hw_clk} / 2$.

A **Baud Rate Error** (Slave Mode) is detected when the incoming clock signal deviates from the programmed baud rate by more than 100%, i.e. it is either more than double or less than half the expected baud rate. This condition sets the error flag CON.BE and, when enabled via CON.BEN, the error interrupt request line EIR. Using this error detection capability requires that the slave's baud-rate generator is programmed to the same baud rate as the master device. This feature detects false additional, or missing pulses on the clock line (within a certain frame).

Note: If this error condition occurs and bit CON.REN = 1, an automatic reset of the SSC will be performed in case of this error. This is done to re-initialize the SSC if too few or too many clock pulses have been detected.

Note: This error can occur after any transfer if the communication is stopped. This is the case due to the fact that the SSC module supports back-to-back transfers for multiple transfers. In order to handle this, the baud rate detector expects after a finished transfer immediately a next clock cycle for a new transfer.

A **Transmit Error** (Slave Mode) is detected when a transfer was initiated by the master (SS_CLK gets active) but the transmit buffer TB of the slave was not updated since the last transfer. This condition sets the error flag CON.TE and the error interrupt request line EIR, when enabled via CON.TEN. If a transfer starts while the transmit buffer is not updated, the slave will shift out the 'old' contents of the shift register, which normally is the data received during the last transfer. This may lead to corruption of the data on the transmit/receive line in half-duplex mode (open drain configuration) if this slave is not selected for transmission. This mode requires that slaves not selected for transmission only shift out ones; that is, their transmit buffers must be loaded with 'FFFF_H' prior to any transfer.

Note: A slave with push/pull output drivers not selected for transmission, will normally have its output drivers switched. However, in order to avoid possible conflicts or misinterpretations, it is recommended to always load the slave's transmit buffer prior to any transfer.

The cause of an error interrupt request (receive, phase, baud rate, transmit error) can be identified by the error status flags in control register CON.

Note: In contrast to the error interrupt request line EIR, the error status flags CON.TE, CON.RE, CON.PE, and CON.BE, are not reset automatically upon entry into the error interrupt service routine, but must be cleared by software.

22.3.7.1 Port Control

The SSC uses three lines to communicate with the external world. Pin SCLK serves as the clock line, while pins MRST (Master Receive/Slave Transmit) and MTSR (Master Transmit/Slave Receive) serve as the serial data input/output lines. As shown in [Figure 181](#) these three lines (SCLK as input, Master Receive, Slave Receive) have all two inputs at the SSC Module kernel. Three bits in register PISEL define which of the two kernel inputs (A or B) are connected. This feature allows for each of the three SSC communication lines to be connected to two inputs coming from different port pins.

Operation of the SSC I/O lines depends on the selected operating mode (master or slave). The direction of the port lines depends on the operating mode. The SSC will automatically use the correct kernel output or kernel input line of the ports when switching modes. Port pins assigned as SSC I/O lines can be controlled in two ways:

- By hardware
- By software

When the SSC I/O lines are connected with dedicated pins typically hardware I/O control should be used. In this case, the two output signals reflect directly the state of the CON.EN and CON.MS bits (the M/S select line is inverted to the CON.MS bit definition).

When the SSC I/O lines are connected with bidirectional lines of general purpose I/O ports, typically software I/O control should be used. In this case port registers must be programmed for alternate output and input selection. When switching between master and slave mode, port registers must be reprogrammed.

22.4 Module Interfaces

This section describes:

- The SSC module related interfaces such as port connections and interrupt control
- All SSC module related registers with its addresses

22.4.1 Interfaces of the SSC Module

An overview of the SSC kernel I/O interface is shown in [Figure 188](#) (SSC1) and [Figure 189](#) (SSC2).

The interrupt requests of the SSC are not connected directly to the Interrupt Controller, but via the System Control Unit (SCU). The interrupt request signals of the SSC are mapped to the Interrupt Controller by the SCU.

Note: Please refer to [Chapter 7](#) for the SCU description.

The General Purpose IO (GPIO) Port provides the interface from the SSC to the external world. There are two SSC kernels in the TLE9869QXA20, namely SSC1 and SSC2.

Note: Please refer to [Chapter 15](#) for the Ports description.

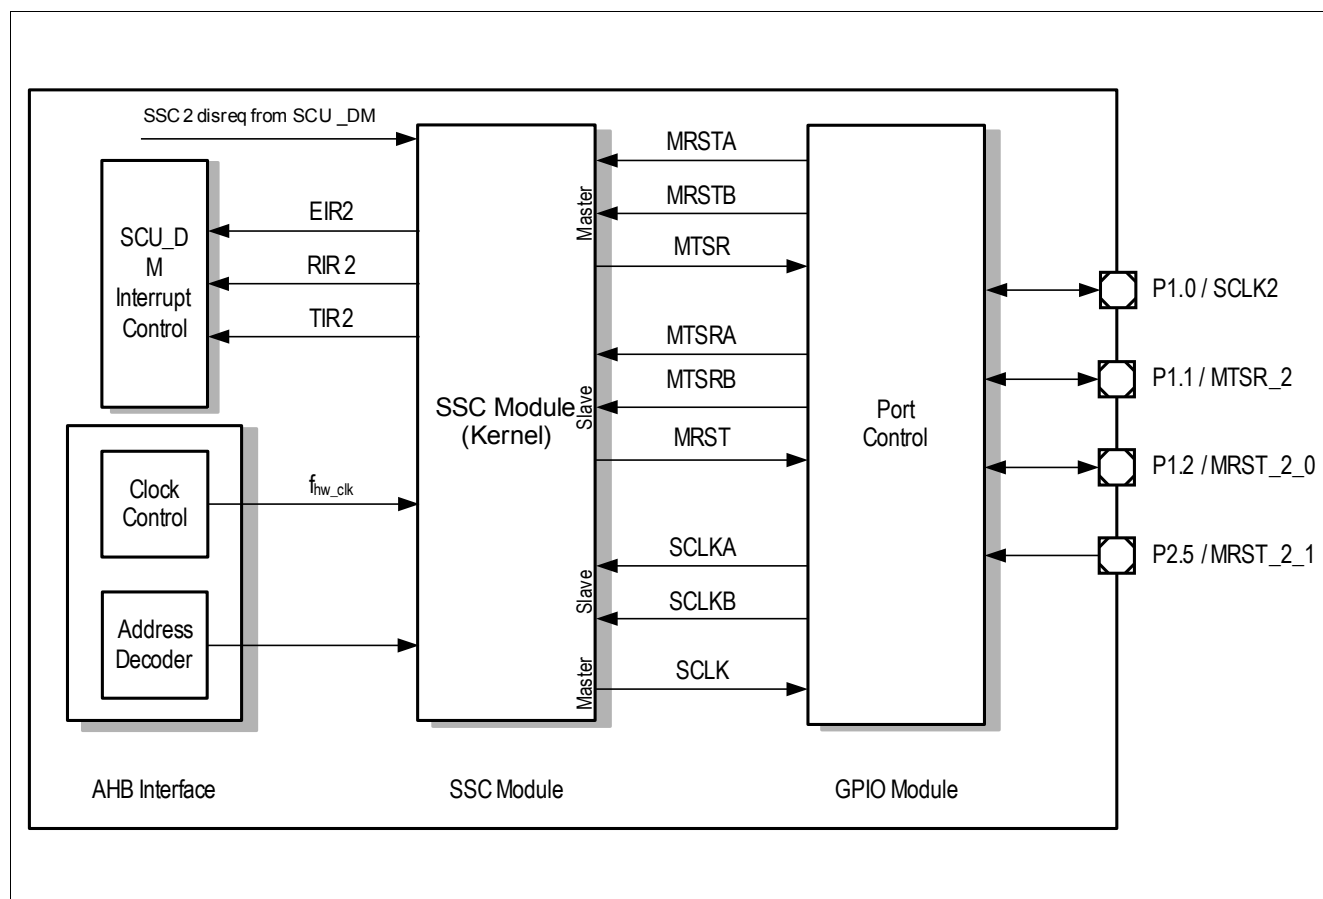

Figure 189 SSC2 Module I/O Interface

22.5 Interrupts

The three SSC interrupts can be separately enabled or disabled by setting or clearing their corresponding enable bits in SFR SCU_MODIEN.

For a detailed description of the various interrupts see [Section 22.4](#). An overview is given in [Table 147](#).

Table 147 SSC Interrupt Sources

Interrupt	Signal	Description
Transmission starts	TIR	Indicates that the transmit buffer can be reloaded with new data.
Transmission ends	RIR	The configured number of bits have been transmitted and shifted to the receive buffer.
Receive Error	EIR	This interrupt occurs if a new data frame is completely received and the last data in the receive buffer was not read.
Phase Error	EIR	This interrupt is generated if the incoming data changes between one cycle before and two cycles after the latching edge of the shift clock signal SCLK.
Baud Rate Error (Slave Mode only)	EIR	This interrupt is generated when the incoming clock signal deviates from the programmed baud rate by more than 100%.
Transmit Error (Slave Mode only)	EIR	This interrupt is generated when TB was not updated since the last transfer if a transfer is initiated by a master.

22.6 Register Definition

22.6.1 SSC1 and SSC2 Register Definition

22.6.2 Port Input Select Register

The PISEL register controls the receiver input selection of the SSC module. In the implementation of TLE9869QXA20, the PISEL register is not used.

Note: Port A and Port B inputs of the SSC kernel are connected to the external pins of Port 0 and Port 1 respectively.

22.6.2.1 Configuration Register

The operating mode of the serial channel SSC is controlled by the control register CON. This register contains control bits for mode and error check selection, and status flags for error identification. Depending on bit EN, either control functions or status flags and master/slave control are enabled.

High-Speed Synchronous Serial Interface (SSC1/SSC2)

23 Measurement Unit

23.1 Features

- 1 x 8-bit ADC with 10 Inputs including attenuator allowing measurement of high voltage input signals
- Supply Voltage Attenuators with attenuation of **VBAT_SENSE**, **VS**, **VDDP** and **VDDC**.
- VBG monitoring of 8-bit ADC to guarantee functional safety requirements.
- Bridge Driver Diagnosis Measurement (VDH, VCP).
- Temperature Sensor for monitoring the chip temperature and PMU Regulator temperature.
- Supplement Block with Reference Voltage Generation, Bias Current Generation, Voltage Buffer for NVM Reference Voltage, Voltage Buffer for Analog Module Reference Voltage and Test Interface.

23.2 Introduction

The measurement unit is a functional unit that comprises the following associated sub-modules:

Table 150 Measurement Functions and Associated Modules

Module Name	Modules	Functions
Central Functions Unit	Bandgap reference circuit	The bandgap-reference sub-module provides two reference voltages 1. a trimmable reference voltage for the 8-bit ADCs. A local dedicated bandgap circuit is implemented to avoid deterioration of the reference voltage arising e.g. from crosstalk or ground voltage shift. 2. the reference voltage for the NVM module
8-bit ADC (ADC2)	8-bit ADC module with 10 multiplexed inputs, including HV input attenuator	5 high voltage full supply range capable inputs (2.5V...30,7V(FS)) 2 medium voltage inputs (0..5V/7V FS). 3 low voltage inputs (0..1.2V/1.6V FS) (allocation see following overview figure)
10-bit ADC (ADC1)	10-bit ADC module with 8 multiplexed inputs	Five (5V) analog inputs from Port 2.x
Monitoring Input Voltage Attenuator	Monitoring input voltage attenuator	Scales down V(MON) to the input voltage range of ADC1.CH6
Temperature Sensor	Temperature sensor with two multiplexed sensing elements: <ul style="list-style-type: none"> • PMU located sensor • Central chip located sensor 	Generates output voltage which is a linear function of the local chip (junction) temperature.
Measurement Core Module	Digital signal processing and ADC2 control unit	1. Generates the control signal for the 8-bit ADC2 and the synchronous clock for the switched capacitor circuits, 2. Performs digital signal processing functions and provides status outputs for interrupt generation.

23.2.1 Block Diagram

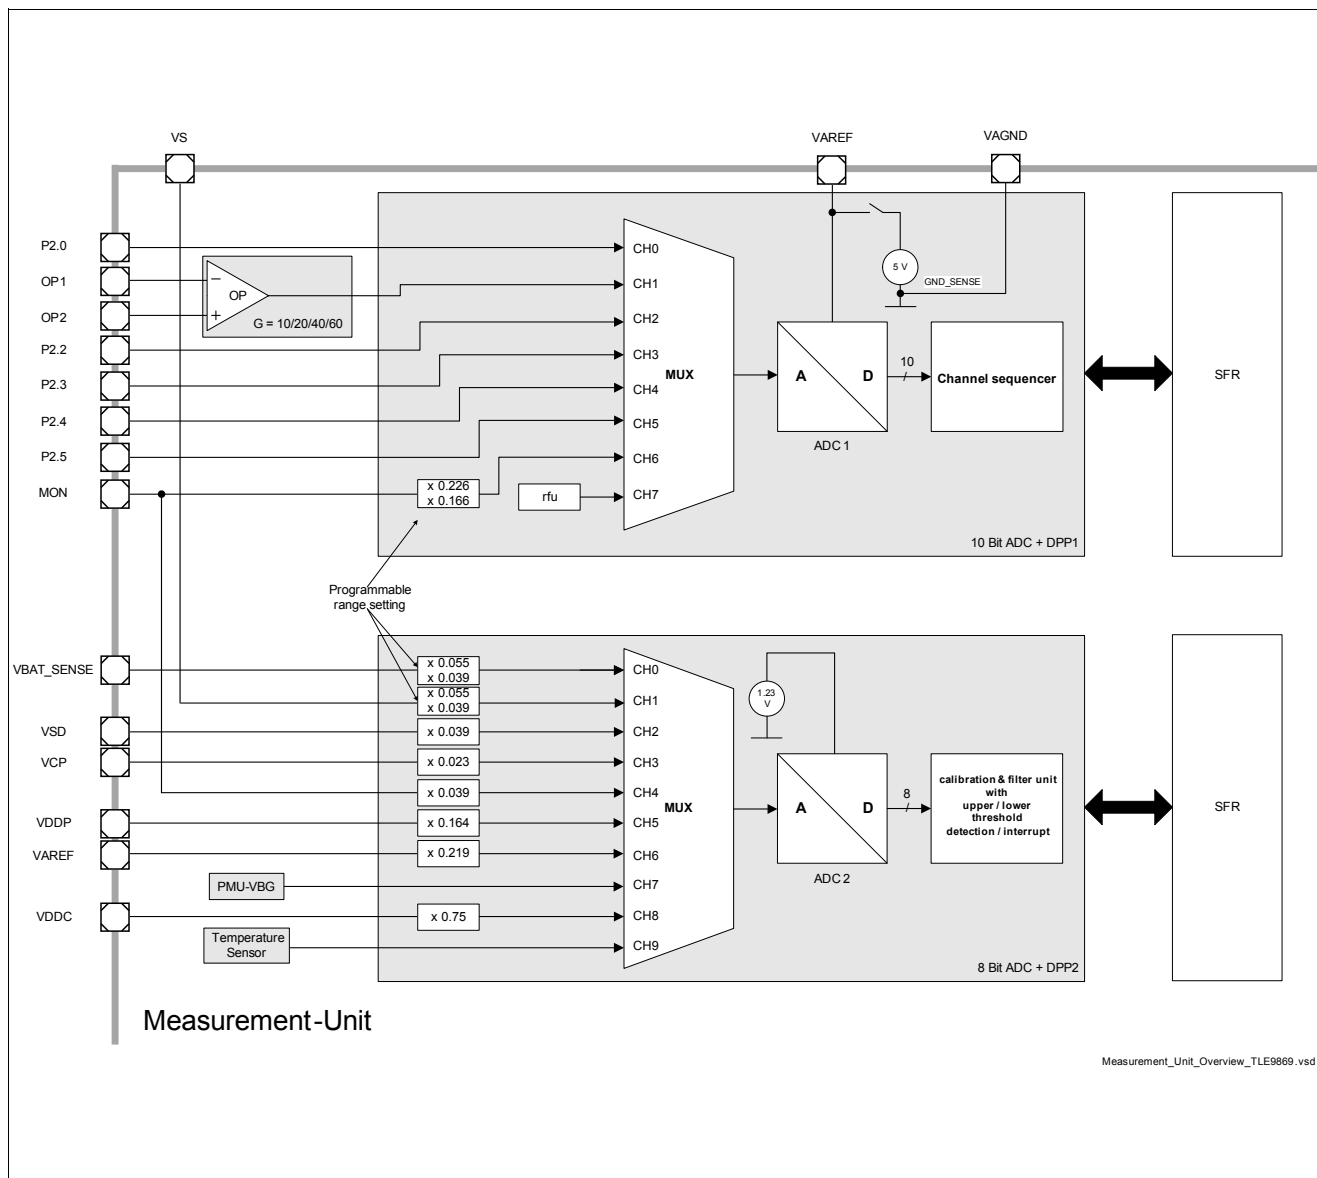

Figure 190 Measurement Unit-Overview (with opamp)

23.2.2 Measurement Unit Register Overview

All registers of blocks that belong to the measurement unit are mapped to base address see below.

Table 151 Register Address Space for Measurement Unit Registers

Module	Base Address	End Address	Note

REF2_CTRL	Reference 2 Control Register	18 _H	0000 0001 _H

The registers are addressed wordwise.

23.3 8-bit - 10 Channel ADC Core (ADC2)

The 8-bit ADC Core operates at the VDDC Supply Voltage. This enables the user to operate the measurement system down to VS reset threshold. The ADC can also be operated independently from the DPP (Data Post Processing) unit. This enables the user to build up a software controlled measurement cycle. The main features of the 8-bit ADC core are listed below.

Module Features

- Conversion time = 15 system clock cycles.
- programmable sampling time (4 to 22 MICLK cycles, default: 12)
- Scalable clock frequency from 10 - 30 MHz.

The ADC2 is controlled in two different ways by the control module DPP2:

- Fully controlled by the sequencer inside DPP2.
- Partly controlled by the user within defined timeslots of Sequencer (EIM, Exceptional Interrupt Measurement)

23.3.1 8-bit ADC Channel Allocation

The allocation of the 10 Channels of ADC2 is sketched below:

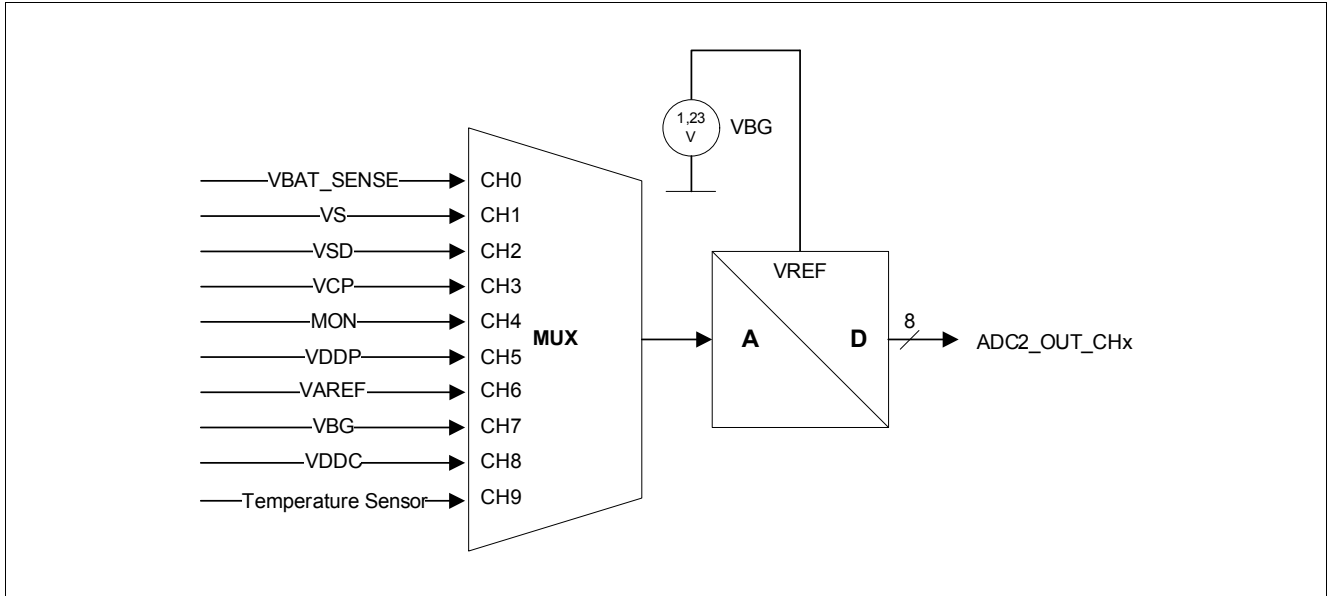

Figure 191 8-bit ADC (ADC2) Channel Allocation

ADC2 Channel Assignment:

- VBAT_SENSE Pin Voltage Measurement.
- VS Pin Voltage Measurement.
- VSD Pin Voltage Measurement.
- Charge Pump Output Voltage(VCP).
- MON Pin Voltage Measurement
- VDDP Pin Voltage Measurement.
- ADC1 Reference Voltage Check (VAREF).
- ADC2 Reference Voltage Check (VBG).
- VDDC Pin Voltage Measurement.
- Device Temperature Measurement (T_j).

23.3.2 Transfer Characteristics of ADC2

The transfer function of ADC2 can be expressed by the equation below:

(15)

$$ADC2_{out} = \text{floor} \left(\frac{V_{inCHx} * Gain_{CHx}}{V_{LSB}} + 1 \right)$$

where V_{in} is the input voltage and $Gain_{CHx}$ the individual Channel Gain. The LSB Voltage is calculated:

(16)

$$V_{LSB} = \frac{V_{BG}}{256}$$

where V_{BG} is **1.227 V @ 27 °C**. With $V_{BG} = 1.227$ we get $V_{LSB} = 4.8 \text{ mV}$:

A detailed specification of both A/D-converters is given in Chapter **Electrical Characteristics in the Data Sheet**. The attenuation for each channel can be found in the table included in the following chapter.

23.3.3 Detailed ADC2 Measurement Channel Description

Table 153 ADC2 Channel Selection and Voltage Ranges

Channel #	Measurement Input Pin	Attenuation	Settings	Vin_FS [V] @Vbg=1.23V	Resolution [mV]	Input Voltage Range	Note
0	VBAT_SENSE	0.0547	CRTL_STS.VBAT_RANGE = '1'	22.49	88	2.4V to FS

9	TEMP	1	HV_CTRL.ANA_I_N_GAIN = '10'	1.23	5	0.6V to FS	–

23.3.4 8-bit - 10 Channel Control Registers

The ADC2 control registers are located in the **Measurement Core Module** Block (see [Chapter 24](#)). Also the configurable attenuator factors are located there (see registers CTRL_STS and HV_CTRL).

23.4 Monitoring Input Voltage Attenuator

23.4.1 Functional Description

The function of the monitoring voltage attenuator is to scale down the incoming voltages for the on-chip 10-Bit ADC. The voltage attenuator has the following features:

Features

- Two selectable attenuation factors: **0.226 for a range between 0 and 22V** and **0.167 for a range between 0 and 30V**
- Analog Mux switching time < 30 μ s
- Input resistance: > 200 k Ω

Note: External series resistor affects measurement resolution accuracy by changing the internal attenuation factor.

The next chapter lists the user configuration possibilities of the monitoring input voltage attenuators.

Note: It is important to disable the monitoring attenuators before entering Stop Mode. Otherwise false wake-ups may be generated!

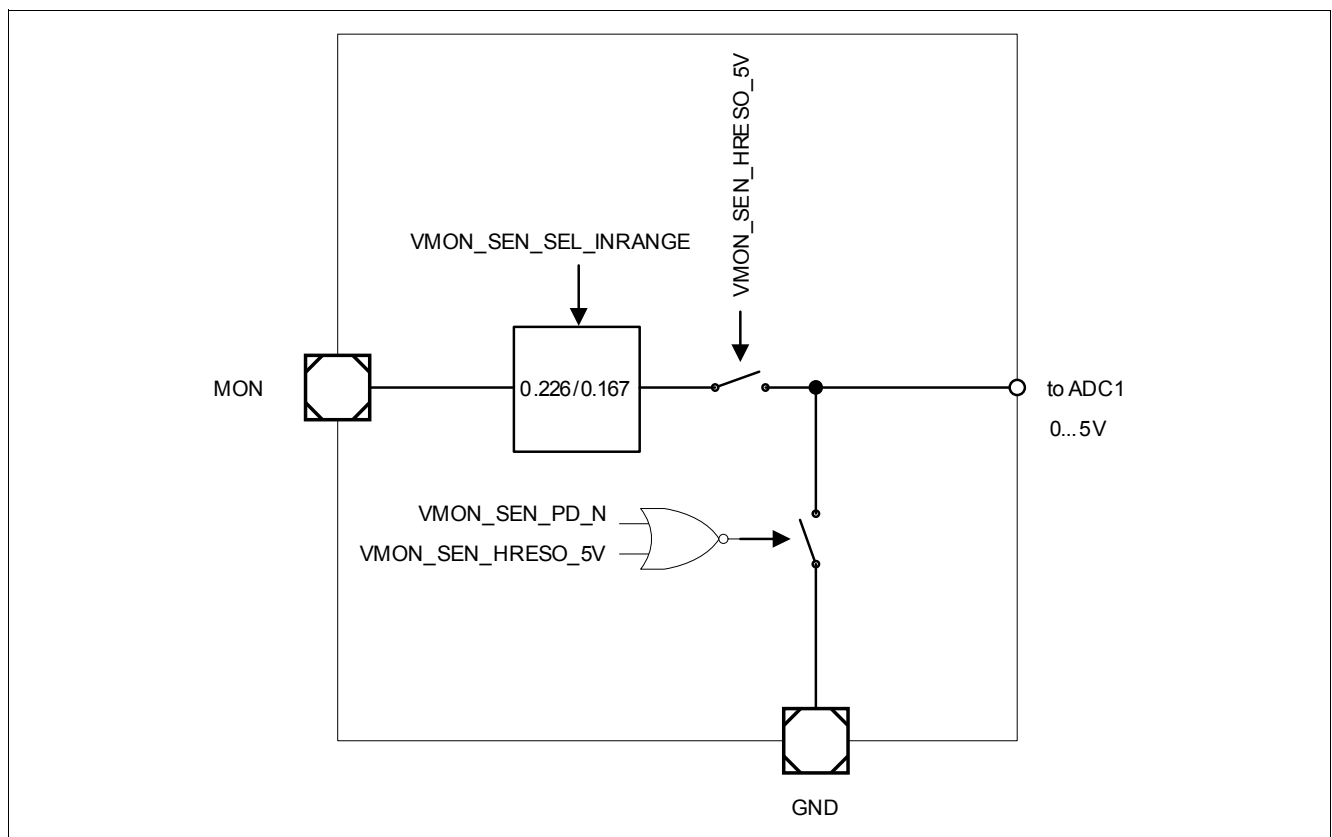

Figure 192 Input Structure of HV-Monitoring Attenuator

23.4.2 Monitoring Input Attenuator Control Register

Measurement Unit

23.5 Central and PMU Regulator Temperature Sensor

23.5.1 Functional Description

This module is a quasi combination of a main on-chip temperature sensor and a PMU Regulator temperature sensor.

Modules Features

- Temperature range -40 ... 175°C
- Temperature range corresponds to single ended output voltage range 0.6 ... 1.2V, resolution approx. 1.8°C
- The combined system temperature sensor plus ADC can be calibrated in software using calibration figures that are stored in the NVM at the production test.
- A dedicated calibration transistor facilitates on-chip reference temperature measurement. Hardware trimming is not implemented.

This temperature sensor, including two sensing elements, monitors the chip temperature (T_j) and PMU Regulator temperature. One sensing element is placed in the centre of the device to get the average device temperature status and the other sensing element is close to the PMU Regulator.

The ADC output value is given by:

$$\text{ADC2out} = \text{floor} \left(\frac{V_{Temp}}{V_{LSB}} + 1 \right) \quad (17)$$

The LSB Voltage is calculated:

$$V_{LSB} = \frac{V_{BG}}{256} \quad (18)$$

Vtemp is the direct proportional to temperature input voltage and is calculated by:

$$V_{TEMP}(T) = a + b * (T - T_0) \quad (19)$$

where the coefficient **a** is **666 mV**, **b** is **2,31 mV/K** and **T₀** is **273 K**.

The next chapter lists the available registers to configure temperature sensors.

Figure 193 Measured Characteristic of On Chip Temperature Sensor

23.5.2 Temperature Sensor Control Register

The Temperature Sensor is fully controllable by the below listed SFR Register.

Table 155 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Temperature Sensor Control Register			
TEMPSENSE_CTRL	Temperature Sensor Control Register	10 _H	0000 0003 _H

The registers are addressed byte-wise.

Temperature Sensor Control Register

The register is reset by RESET_TYPE_3.

Res	3:0	r	Reserved Always read as 0

23.6 Supplement Modules

23.6.1 Functional Description

The purpose of the supplement modules is to enable a certain infrastructure on the device to guarantee a fail safe operation:

Module Features

- Bandgap Reference Voltage with accuracy $\pm 1.5\%$ over complete temperature range.
- Bandgap is monitored by an independent reference voltage.
- ADC1 Reference with accuracy $\pm 1\%$.
- ADC1 Reference has overload detection.

23.6.1.1 ADC2 Functional Safety Feature

ADC2 offers a functional safety feature, which allows to monitor the consistency of ADC2 results. The channel 7 of ADC2 monitors a voltage which is generated by a resistor of 26.66k and a 40 μA current. This 40 μA current is generated by a similar second resistor and a voltage, which is a second independent reference voltage in the system.

The root cause for a code change of channel 7 of ADC2 can only be explained by a ADC2 reference voltage variation. This feature can be used to validate the reference voltage of ADC2 and the results of the conversion.

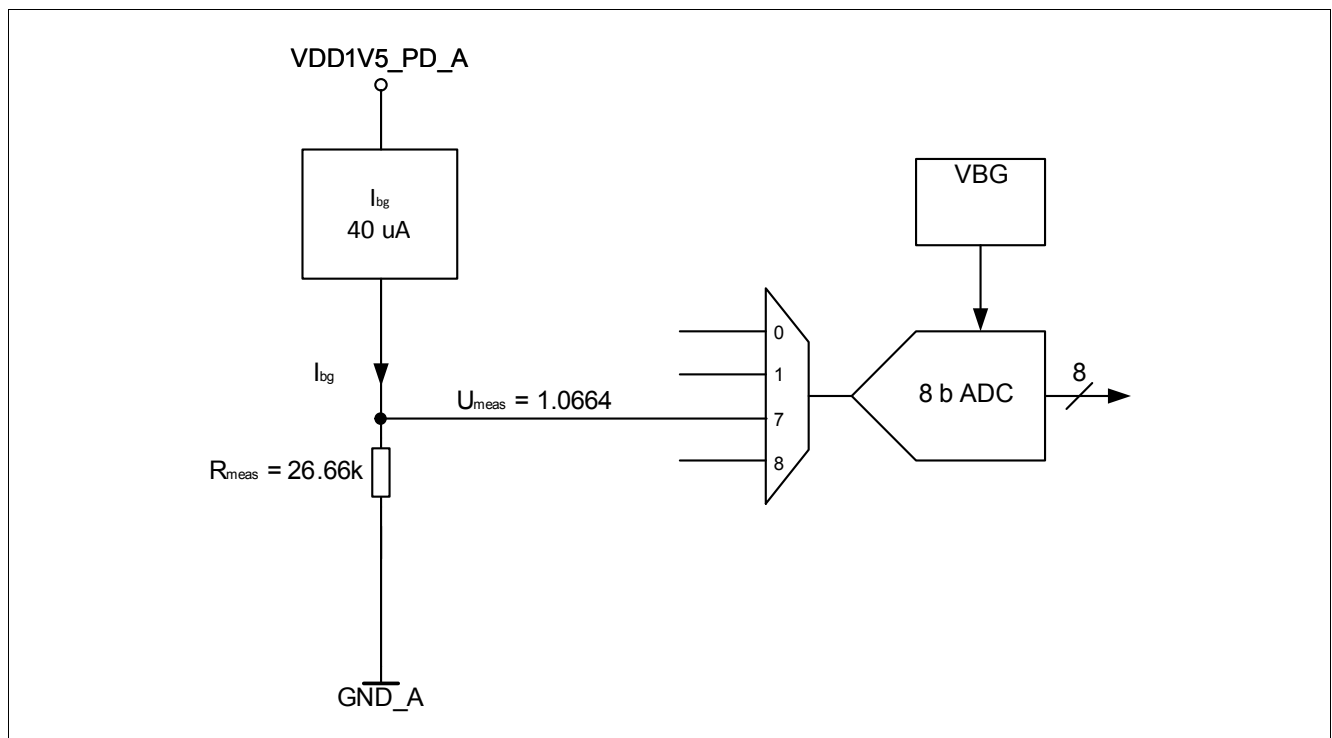

Figure 194 Principle of ADC2 functional safety feature

23.6.2 Supplement Modules Control and Status Register

The next chapter lists the diagnosis and configuration possibilities of the supplement modules.

Table 156 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Supplement Modules Control and Status Register			
REF1_STS	Reference 1 Status Register	14 _H	0000 00C1 _H

24.2.2 Measurement Core Module Modes Overview

The basic function of this unit, is the digital signal processing of several analog digitized measurement signals by means of filtering, level comparison and interrupt generation. The Measurement Core module processes ten channels in a quasi parallel process.

As shown in the figure above, the ADC2 postprocessing consists of a channel controller (Sequencer), an 10-channel demultiplexer and the signal processing block, which filters and compares the sampled ADC2 values for each channel individually. The channel control block controls the multiplexer sequencing on the analog side before the ADC2 and on the digital domain after the ADC2. As described in the following section, the channel sequence can be controlled in a flexible way, which allows a certain degree of channel prioritization.

This capability can be used e.g. to set a higher priority to supply voltage channels compared to the other channel measurements. The Measurement Core Module offers additionally two different post-processing measurement modes for over-/undervoltage detection and for two-level threshold detection.

Usually the external register settings should only be changed during the start-up phase of the postprocessing module. Otherwise the signal processing might be disturbed.

The channel controller (Sequencer) runs in one of the following mode:

“Normal Sequencer Mode”, channels are selected according to the 10 Sequence register which contain individual enables for each of the 10 channels.

“Exceptional Interrupt Measurement”, upon a hardware event, a high priority channel is inserted into the current sequence. The current actual measurement is not destroyed.

“Exceptional Sequence Measurement”, upon a hardware event, a complete sequence is inserted after the current measurement is finished. The current sequence is interrupted by the exception sequence.

The threshold counter can be bypassed [FILT_UP_CTRL](#) and [FILT_LO_CTRL](#).

24.3 ADC2 - Core (8-bit ADC)

24.3.1 Functional Description

The different sequencer modes are controlled by SFR Register:

- “Normal Sequencer Mode” described in the Chapter [Channel Controller](#).
- “Exceptional Interrupt Measurement” (EIM), upon hardware event, the channel programmed in [CHx_EIM](#) is inserted after the current measurement is finished. Afterwards the current sequence will be continued with the next measurement from the current sequence.
- “Exceptional Sequence Measurement” (ESM), upon hardware event, the sequence programmed in [CHx_ESM](#) is inserted after the current measurement is finished. After the sequence (up to 10 measurements) exception is finished the next measurement from the interrupted sequence is selected. After the Exceptional Sequence Measurement is finished an interrupt is issued.

Debug Suspend Mode:

During Debug Suspend Mode the Sequencer is stopped once the current measurement is finished (after the next EOC event). As long as the Debug Suspend Mode is active no measurements are performed by the Sequencer. Once the Debug Suspend Mode is left, the Sequencer continues immediately with the next pending measurement. Measurements can be still triggered in Debug Suspend Mode. EIM and ESM events are ignored during Debug Suspend Mode.

24.4 Channel Controller

24.4.1 Functional Description

The task of channel controller is a prioritization of the individual measurement channels. The sequencing scheme is illustrated in the example of following table and can be programmed.

Table 159 Measurement channel sequence definition example (used as default sequence)

Measurement channel n SQ' _z = {SQ' _{x_y_int} [3:0], SQ' _z [5:0]}	MSB CH9	CH8	CH7	CH6	CH5	CH4	CH3	CH2	CH1	LSB CH0
Registers SQ' ₁ [9:0]	1	0	1	1	1	1	0	1	1	1
Registers SQ' ₂ [9:0]	0	1	1	1	1	0	1	0	0	0
Registers SQ' ₃ [9:0]	1	0	1	1	1	1	0	1	1	0
Registers SQ' ₄ [9:0]	0	1	1	1	1	0	1	0	0	1
Registers SQ' ₅ [9:0]	1	0	1	1	1	1	0	1	1	0
Registers SQ' ₆ [9:0]	0	1	1	1	1	0	1	0	0	0
Registers SQ' ₇ [9:0]	1	0	1	1	1	1	0	1	1	1
Registers SQ' ₈ [9:0]	0	1	1	1	1	0	1	0	0	0

Table 159 Measurement channel sequence definition example (used as default sequence) (cont'd)

Measurement channel n SQ'_z = {SQ'_x_y_int[3:0], SQ'_z[5:0]}	MSB CH9	CH8	CH7	CH6	CH5	CH4	CH3	CH2	CH1	LSB CH0
Registers SQ'_9[9:0]	1	0	1	1	1	1	0	1	1	0
Registers SQ'_10[9:0]	0	1	1	1	1	0	1	0	0	1

The sequence registers SQ_n and SQ_n_int define the time sequence of the measurement channels by the following rules:

- The sequence registers define the measurement sequence and are evaluated from register 1 to 10 and for each register from MSB to LSB, which defines a max. overall measurement periodicity of 100 sampling and conversion cycles.
- If the individual bit in the sequence register is set to '1', the corresponding channel is measured.
- If the individual bit in the sequence register is set to '0', the corresponding channel is skipped.

In the upper example, the resulting channel sequence is defined as:

CH9, CH7, CH6, CH5, CH4, CH2, CH1, CH0, CH8, CH7, CH6, CH5, CH3,....., CH8, CH7, CH6, CH5, CH3, CH0

In TLE9869QXA20 Channels 0 - 5 can be fully programmed. Several Sequence registers, especially for channels 6-9, are protected to ensure a fast update of measurement results used for internal diagnosis. Hence the channels 6 and 7 are prioritized and are measured more often, the overall periodicity is mainly determined by these two channels. The channels 0-5 are measured depending on the amount of '1' bits, written in the sequence registers. The following equations can be used to calculate the periodicity of the required channel measurement.

The total number of measurement done by the sequencer in a complete run-through expressed in A/D conversion cycles is defined as:

(20)

$$N_{\text{meas}} = \sum_{m=1}^{10} \left(\sum_{n=1}^{10} SQ'_m[n] \right)$$

The average measurement periodicity of channel n in A/D conversion cycles is defined as:

(21)

$$\frac{1}{T_{\text{meas}, n}} = \frac{\left(\sum_{m=1}^{10} SQ'_m[n] \right)}{T_{\text{meas}}}$$

Where T_{meas} is defined as:

(22)

$$T_{\text{meas}} = N_{\text{meas}} * (T_{\text{samp}, n} * T_{\text{conv}})$$

N_{meas} is the number of measurements programmed in the SQ' registers, T_{samp,n} is the sampling time setting for channel n and T_{conv} is the ADC2 conversion time.

The timing of the analog MUX and the digital DEMUX is controlled by the channel controller accordingly. The analog MUX with sample and hold stage needs one clock cycle for channel switching and the ADC consumes, as default setting, 12 clock cycles for the sampling of the input voltage. The conversion time for a single channel measurement value is 10 clock cycles.

As already mentioned above, the channel controller has a partly fixed sequence register setting which cannot be changed by the user. The fixed register setting is needed, to fulfill the sampling frequency requirements of the internal circuits, e.g. shutdown in case of overtemperature and protection for the bridge drivers (BDRV).

The minimum measurement periodicity, which can be achieved, by enabling only channel 1 in the sequence registers, depends on the MI_CLK frequency and is given by:

(23)

$$\overline{T_{\text{meas_CH1_min}}} = \frac{32}{f_{\text{MI_CLK}}}$$

This following calculations include already the sampling time of ADC2. If all programmable channels are enabled, the maximum periodicity is calculated:

(24)

$$\overline{T_{\text{meas_CH1_max}}} = \frac{320}{f_{\text{MI_CLK}}}$$

For a MI_CLK frequency of 24 MHz, the channel 1 is measured with min. 4 µs. The maximum update time of channel 1 with 24 MHz clock frequency is 10 µs. As mentioned before, this is calculated with the assumption, that all channels are enabled and channel1 is enabled in every sequence register. As a prerequisite for this calculation we take **CTRL2** = 4 (sample period = 14 MI_CLK clock cycles).

24.4.2 Channel Controller Control Registers

The Channel Controller can be configured by the **SFR** Register listed in [Table 160](#). The registers which cannot be written by the user have the attribute **rwp**. Those registers are:

[SQ1_8_int](#),

[SQ9_10_int](#)

Table 160 Register Overview

24.5 Calibration Unit

24.5.1 Functional Description

The calibration unit of the Measurement Core module is dedicated to cancel offset and gain errors out of the signal chain. The upcoming two chapters describe usage and setup of the calibration unit.

24.5.1.1 Method for determining the Calibration Parameters

As mentioned in the introduction of the calibration unit, the module can be used to correct gain and offset errors caused by non-idealities in the measurement chain. These non-idealities are caused by the corresponding measurement chain modules.

Those first order non-idealities are:

- Offset and Gain Error of ADC2.
- Offset and Gain Error of the Attenuator (especially voltage measurement).
- Offset and Gain Error of Reference Voltage caused by non-ideality of reference voltage.

All these factors are summed up in the overall Gain (factor **b**) and overall Offset (adder **a**) of the complete measurement chain. They are calculated from a two point test result and stored inside the NVM.

Note: *The calibration of the MON/VBAT_SENSE-Pin and the HV-Monitoring-Pins was done with an external 1 kΩ resistor. The usage of a resistor with a bigger value requires a recalibration of the signal path due to a finite resistor value of the attenuator.*

24.5.1.2 Setup of Calibration Unit

Each channel has its own calibration unit and thus also its dedicated Gain and Offset parameter. These parameters are stored in a 100TP page of the Flash Module. After each reset of RESET_TYPE_4 these coefficients are downloaded from NVM into the corresponding registers. The user may not take care about the configuration of these parameters. After this has been done, the values are used for the correction procedure. The figure below shows the formula performed by the calibration unit and the required **sfr**-Register to control its functionality in a generic way.

The parameters ADC2_CALOFFS_CHx and ADC2_CALGAIN_CHx are stored in an 8 bit, 2th complement format.

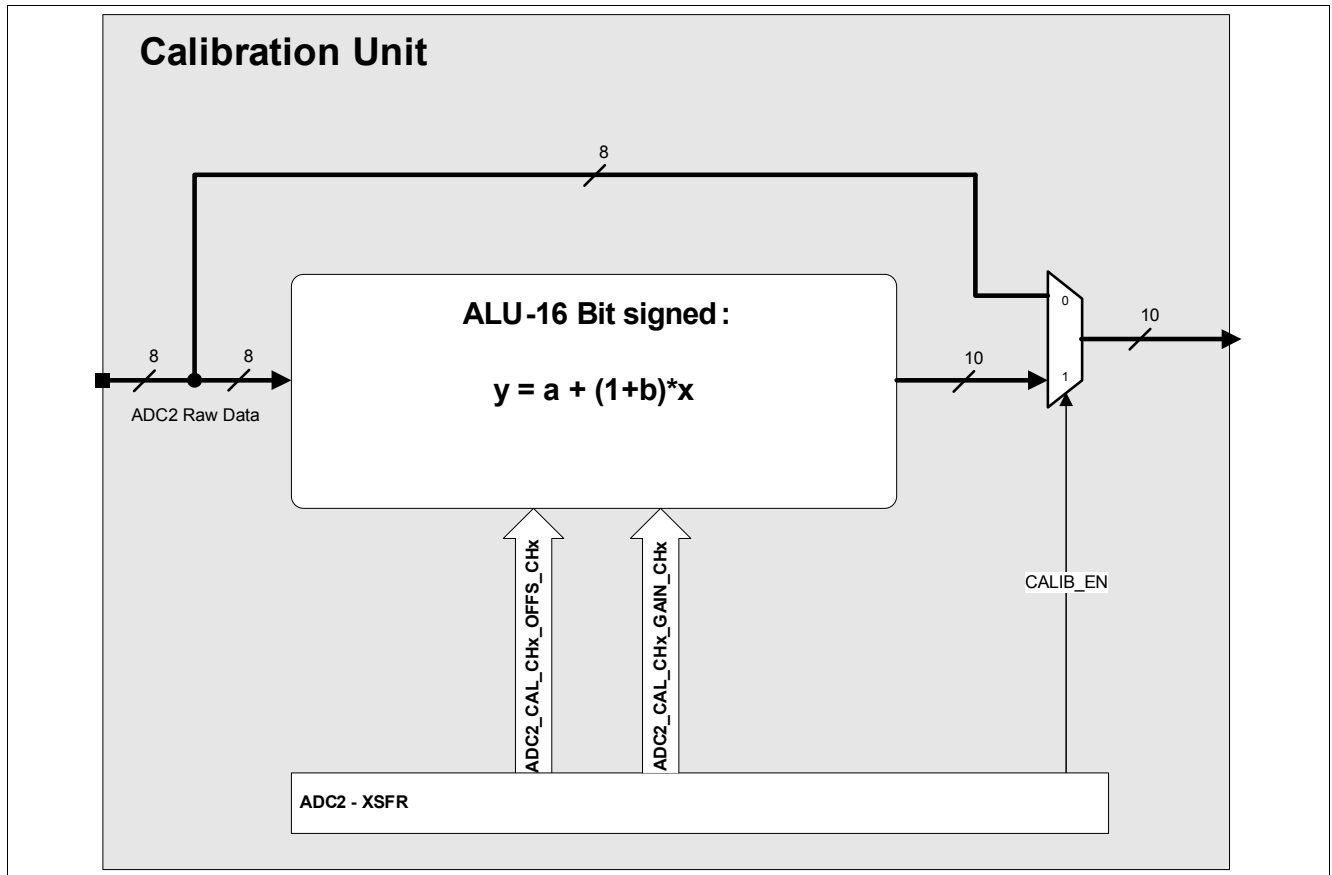

Figure 196 Structure of Calibration Unit

The function applied to calculate the calibrated ADC2 value is:

(25)

$$ADC2_CHx_cal = \left(1 + \frac{ADC2_CALGAIN_CHx}{256}\right) * ADC2_CHx_uncal + \frac{ADC2_CALOFFS_CHx}{2}$$

24.5.2 Calibration Unit Control Registers

The Calibration Unit can be configured by the **SFR** Register shown below. The registers which cannot be written by the user have the attribute **rwp**. Those registers are:

[CAL_CH6_7](#),
[CAL_CH8_9](#)

Table 161 Register Overview

OFFS_CH8	7:0	rwp	Offset Calibration for channel 8 For ADC output set CALIB_EN_8 = 0

24.6 IIR-Filter

24.6.1 Functional Description

To cancel low frequency noise out of the measured signal, every channel of the digital signal includes a first order IIR Filter. The structure of the IIR Filter is shown in the picture below.

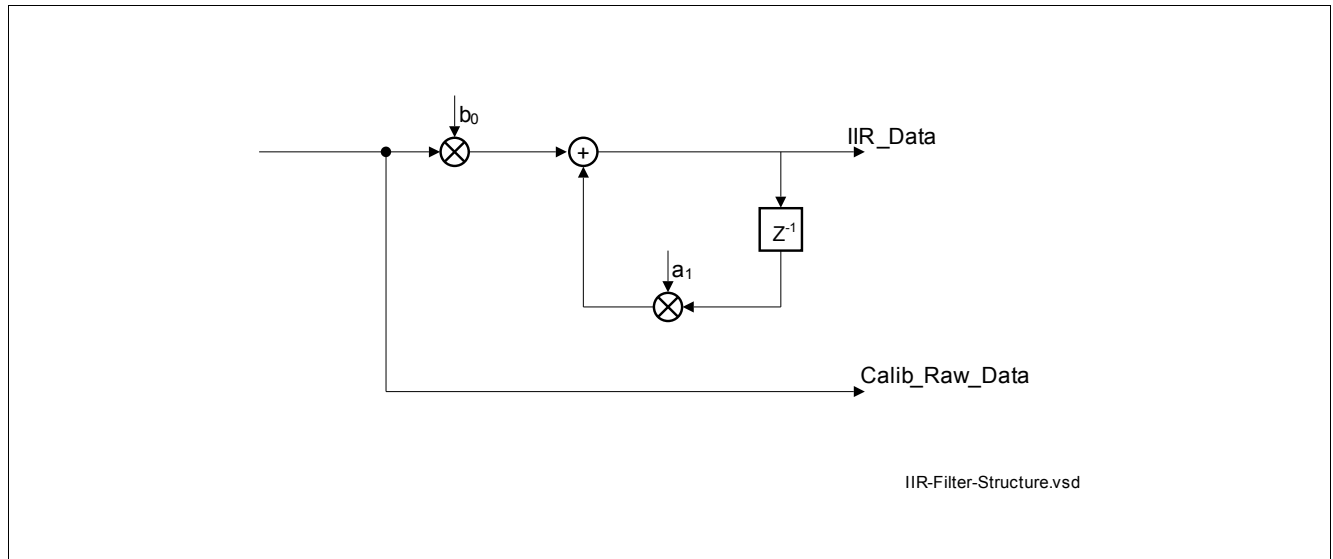

Figure 197 IIR-Filter Implementation Structure

(26)

$$H_{IIR}(z) = \frac{b_0}{(1 - a_1^* z^{-1})}$$

This filter allows an effective suppression of high-frequency components like noise or crosstalk caused by HF-components in order to avoid the generation of unwanted interrupts. The coefficient b can be expressed as:

(27)

$$b_0 = 1 - a_1$$

With the coefficient b implemented in the IIR Filter transfer function, it looks like:

(28)

$$H_{IIR}(z) = \frac{1 - a_1}{(1 - a_1^* z^{-1})}$$

Figure 198 IIR Filter Transfer Function for different filter length fl (sampling frequency is assumed to be 125 kHz)

24.6.1.1 Step Response

The IIR filter's step response time is shown in the figure below:

Figure 199 IIR Step Response Time

Table 162 summarizes the main filter characteristics.

Table 162 IIR filter characteristics

Filter coefficient	Group delay at ω_0
a	τ[samples]
-2^{-1}	2
-2^{-2}	4
-2^{-3}	8
-2^{-4}	16

24.6.2 IIR Filter Control Registers

The IIR Filter can also be configured by the **sfr** Register shown below. The registers which cannot be written by the user have the attribute **rwp**. Those registers are:

FILTCOEFF6_9

The **FILT_OUT0** to **FILT_OUT9** registers are 10 bits wide, but the ADC delivers only a resolution of 8 bits. **Table 163** shows how the lower two bits are determined.

Table 163 ADC2_FILT_OUT register setting

CTRL1.CALIB_EN	CTRL4.FILT_OUT_SEL	FILT_OUT0.OUT_CH0
0	0	"00"
0	1	"filt_out(3:2)"
1	0	"calib_out(1:0)"
1	1	"filt_out(3:2)"

The result of the calibration unit is 10 bits, the output is feed into the IIR filter. The internal result of the IIR filter is 12 bits, the output is converted to 10 bit and fed into the postprocessing. The user can monitor the calculated values in the **FILT_OUT0** to **FILT_OUT9** registers and gets access to 10 bit wide result information.

24.7 Signal Processing

24.7.1 Functional Description

Figure 200 Postprocessing channel block diagram for voltage and temperature measurements

As shown in [Figure 200](#) an adjustable filter can be applied for the upper and the lower measurement channel, which averages 2, 4, 8 or 16 measurement values continuously. The filtered signal or the demultiplexed ADC output signal `ADC_OUTx` is compared with an upper threshold `THy_z_UPPER.CHx` and a lower threshold `THy_z_LOWER.CHx`. When the thresholds are exceeded, the comparator outputs get active. For all measurement modes a freely adjustable hysteresis can be defined which is defined with the `CNTy_z_LOWER.HYST_UP_CHx` and `CNTy_z_LOWER.HYST_LO_CHx` values.

In addition to the first filter stage, the second filters (counters) integrate the comparator output values `STH_UP/LO_CHX` until an individual upper and lower timing threshold $2^{CNT_UP/LO_CHX}$ is reached. When reaching the upper timing threshold $2^{CNT_UP_CHX}$, the upper counter increment is stalled and the status output `CHx_UP_STS` is set. For `MMODE_OV = 1`, the inverted lower comparator output signal `STH_LO_CHX` is normalized again. When the output signal is above `THy_z_LOWER.CHx`, the lower counter is incremented until the max. threshold $2^{CNT_LO_CHX}$ is reached. Individual interrupts for the upper and lower channel can be triggered with the rising edge of the status signals `UP/LO_x_STS`.

In general the IIR filter stage suppresses higher frequency noise efficiently and triggering with the upper and lower threshold `TH_UP/LO_CHx` are dependent on the measured values. Hence short high-level spikes might pass the thresholds. In opposite to the first stage the nature of the second filter stage is more a time filter, which is less dependent on the measurement values but on event durations of `STH_LO/UP_CHX` as generated by the first comparator stage. Therefore the second stage has a lower noise suppression performance for higher frequencies and also adds a delay for the trigger time proportional to $2^{CNT_LO/UP_CHX}$.

Figure 201 Measurement examples of a measurement channel with disabled filters

Figure 201 shows three examples, a range-control and an over- and undervoltage detection (e.g. VBAT_SENSE monitoring), a 2-step overvoltage and a 2-step undervoltage detection. The modes MMODE_OV/UV = 1 can be used as prewarning for the application software (e.g. close to over-temperature or supply undervoltage).

24.7.2 Postprocessing Control Registers

The Temperature Sensor is fully controllable by the below listed sfr Registers.

Table 165 Register Overview

24.8 Start-up Behavior after Reset

After the end of a reset phase the measurement sources and the post-processing units need some time for settling. In order to avoid undesired triggering of interrupts until the measurement signal acquisition is in a steady state, the status signals are forced to zero during the start-up phase.

The end of the start-up phase is indicated by the ready signal MCM_RDY.

Measurement Core start-up procedure: the startup time of the complete signal chain is 2200 EoC cycles. The IIR-filter coefficient is set to $a=2^{-1}$ (fastest response time of the IIR-filter).

During the startup phase, the DPP will use SQ=11_1111_1111, regardless of the sequence registers configuration.

24.9 Postprocessing Default Values

The following table shows the assigned measurements of the particular channels and the reset default values which are read from Firmware during power-up. Since the channels 6-9 of the unit are exclusively used for internal measurements, they can only be partly accessed by the application software.

Table 166 Channel allocation and postprocessing default settings (effective after reset)

Channel / MMODE ¹⁾	Analog	Digital ²⁾	Hyste- resis ³⁾	IIR - Filter ⁴⁾	Counters ⁵⁾	Functional Description

Measurement Core Module (incl. ADC2)

- 1) MMODE of each channel is defined by sfr reset values: 00_B range control, 01_B under-voltage mode, 10_B over-voltage mode. The measurement mode for CH6 - CH9 can not be programmed by the user.
- 2) register: THx_y_LOWER / THx_y_UPPER
- 3) register: CNTx_y_LOWER / CNTx_y_UPPER; selectable decimal values [0, 4, 8, 16]
- 4) register: FILT_UP_CTRL / ADC2_FILT_LO_CTRL
- 5) register: CNTx_y_UPPER.CNT_LO_CHx / CNTx_y_LOWER.CNT_UP_CHx

25 10-Bit Analog Digital Converter (ADC1)

25.1 Features

The principal features of the ADC1 are:

- Up to 8 analog input channels (channel 7 reserved for future use)
- Flexible results handling
 - 8 and 10-bit resolution
- Flexible source selection due to sequencer
 - insert one exceptional sequence (ESM)
 - insert one interrupt measurement into the current sequence (EIM), single or up to 128 times
 - software mode
- Conversion sample time (separate for each channel) adjustable to adapt to sensors and reference
- Standard external reference (VAREF) to support ratiometric measurements and different signal scales
- DMA support, transfer ADC conversion results via DMA into RAM
- Support of suspend and power saving modes
- Result data protection for slow CPU access (wait-for-read mode)
- Programmable clock divider
- Integrated sample and hold circuitry

25.2 Introduction

The TLE9869QXA20 includes a high-performance 10-bit Analog-to-Digital Converter (ADC1) with eight multiplexed analog input channels. The ADC1 uses a successive approximation technique to convert the analog voltage levels from up to eight different sources. The analog input channels of the ADC1 are available at AN0, AN2 - AN5.

10-Bit Analog Digital Converter (ADC1)

25.2.1 Block Diagram

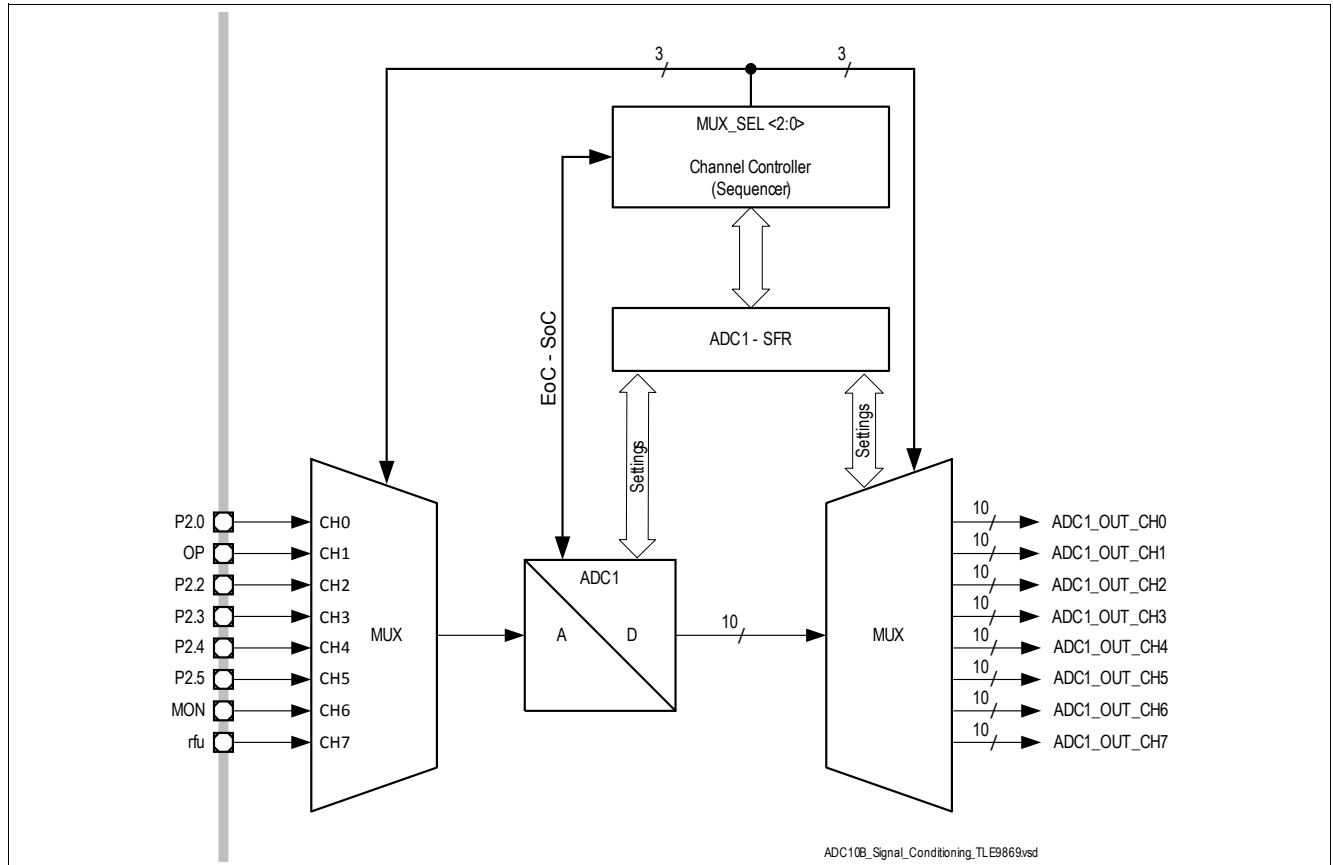

Figure 202 ADC1 Top Level Block Diagram

As shown in the figure above, the ADC1 postprocessing consists of a channel controller (Sequencer) and an 8-channel demultiplexer. The channel control block controls the multiplexer sequencing on the analog side before the ADC1 and on the digital domain after the ADC1. As described in the following section, the channel sequence can be controlled in a flexible way, which allows a certain degree of channel prioritization.

This capability can be used e.g. to set a higher priority to some channels compared to the other channel measurements.

25.2.2 ADC1 Modes Overview

The channel controller (Sequencer) runs in one of the following modes:

“Normal Sequencer Mode”, channels are selected out of 8 Sequence registers which contain individual enables for each of the 8 channels (SQ_FB.SQ_RUN = 1).

“Exceptional Interrupt Measurement”, upon a hardware event, a high priority channel is inserted into the current sequence.

“Exceptional Sequence Measurement”, upon a hardware event, a complete sequence is inserted into the current sequence. The current sequence (up to 8 measurements) is interrupted before the ESM sequence is inserted.

“Suspend Mode”: Exceptional Sequencer and Interrupt Measurement can be triggered, (all sequence register loaded with “00” and SQ_FB.SQ_RUN = 1, measurements by software can not be triggered).

“Debug Suspend Mode”: The corresponding bit MODSUSP2.ADC1_SUSP is set.

“Software Mode”, Exceptional Sequencer and Interrupt Measurement are ignored, each measurement is triggered by software, SQ_FB.SQ_RUN = 0

25.3 ADC1 - Core (10-Bit ADC)

25.3.1 Functional Description

In order to enable the ADC1 the following registers need to be set in order to enable the ADC1

- PMCON1.ADC1DIS = 0
- GLOBCTR.ANON = 11
- ADC1->CTRL_STS.PD_N = 1
- program sequencer (via ADC1->SQ_1_4 and ADC1->SQ_5_8)
- start sequencer ADC1->SQ_FB.SQ_RUN = 1

The different sequencer modes are controlled by SFR Register:

- “Normal Sequencer Mode” described in the Chapter [Channel Controller](#).
- “Exceptional Interrupt Measurement” (EIM), upon hardware event, the channel programmed in [CHx_EIM](#) is inserted immediately. The current measurement is aborted. Afterwards the current sequence will be continued (with the aborted measurement).
- “Exceptional Sequence Measurement” (ESM), upon hardware event, the sequence programmed in [CHx_ESM](#) is inserted immediately. The current measurement is aborted. After the sequence exception is finished the aborted sequence is selected and continued with the aborted measurement. After the Exceptional Sequence Measurement is finished an interrupt is issued.
- “Software Mode”, in Software Mode the control of the Channel Controller (Sequencer) is disabled, instead the conversions are fully controlled by software. During Software Mode EIM and ESM hardware events are ignored.

The default mode after reset of the ADC10B is Software Mode.

In case EIM and ESM hardware events occur at the same time, the EIM event is processed first.

While an ESM sequence is running, the sequence can be interrupted by one or more EIMs.

The end of ESM and EIM is flagged via interrupt. In case of repeat count of EIM, the EIM interrupt is generated at the end of EIM sequence when the last EIM measurement is done.

Software Mode:

- Software mode is entered
 - by disabling the Sequencer ADC1.[SQ_FB](#).SQ_RUN to zero. The Software mode is entered when the current measurement is finished.
 - In software mode, the conversion are controlled via [CTRL_STS](#).
- The Software Mode is left
 - by enabling the Sequencer ADC1.[SQ_FB](#).SQ_RUN to one. If the Sequencer is enabled, the Sequencer always starts with SQ1.

In Software Mode measurements are triggered by writing the [CTRL_STS](#).SOC bit. This bit is active as long as the conversion is in progress. The user polls the [CTRL_STS](#).EOC bit. Once this bit is ‘1’ the conversion is finished

10-Bit Analog Digital Converter (ADC1)

and the EOC bit is cleared on read (rh). After the EOC bit is cleared a new conversion can be started **CTRL_STS.SOC**.

In Software Mode DMA requests and interrupts are generated.

Suspend Mode:

Suspend Mode is entered if all Sequences are programmed to zero but the Sequencer is still enabled, **SQ_FB.ASQ_RUN** is set to one. Exceptional Sequencer and Interrupt Measurement can be triggered, measurements by software can not be triggered (via **CTRL_STS.SOC**).

In Suspend Mode DMA requests and interrupts (for ESM and EIM) are generated.

Debug Suspend Mode:

During Debug Suspend Mode the Sequencer is stopped once the current measurement is finished (after the next EOC event). As long as the Debug Suspend Mode is active no measurements are performed by the Sequencer. EIM and ESM are ignored during Debug Suspend Mode.

During Debug Suspend Mode, conversions can be triggered via **CTRL_STS.SOC** bit in Software Mode.

25.3.2 ADC1 Control and Status Registers

Table 167 shows the module base address.

25.4 Channel Controller

25.4.1 Functional Description

The task of each channel controller is a prioritization of the individual measurement channels. The sequencing scheme is illustrated in the example of following table and can be programmed individually for measurement unit.

Table 169 Measurement Channel Sequence (Definition Example)

Measurement channel n	MSB CH7	CH6	CH5	CH4	CH3	CH2	CH1	LSB CH0
SQ ₁ [7:0]	1	1	1	1	0	1	1	1
SQ ₂ [7:0]	1	1	1	0	1	0	0	0
SQ ₃ [7:0]	1	1	1	1	0	1	1	0
SQ ₄ [7:0]	1	1	1	0	1	0	0	1
SQ ₅ [7:0]	1	1	1	1	0	1	1	0
SQ ₆ [7:0]	1	1	1	0	1	0	0	0
SQ ₇ [7:0]	1	1	1	1	0	1	1	1
SQ ₈ [7:0]	1	1	1	0	1	0	0	0

The sequence registers SQ_n define the time sequence of the measurement channels by the following rules:

- The sequence registers define the measurement sequence and are evaluated from register 1 to 8 and for each bit from MSB to LSB, which defines a max. overall measurement count of 64 sampling and conversion cycles.
- If the individual bit in the sequence register is set to '1', the corresponding channel is measured.
- If the individual bit in the sequence register is set to '0', the corresponding channel is skipped.

In the upper example, the resulting channel sequence is defined as:

CH7, CH6, CH5, CH4, CH2, CH1, CH0, CH7, CH6, CH5, CH3,....

The following equations can be used to calculate the periodicity of the required channel measurement.

The overall measurement periodicity of all measurements in A/D conversion cycles is defined as:

(29)

$$N_{\text{meas}} = \sum_{m=1}^8 \left(\sum_{n=1}^8 SQ_m[n] \right)$$

The average measurement periodicity of channel n in A/D conversion cycles is defined as

(30)

$$T_{\text{meas}, n} = \frac{\left(\sum_{m=1}^8 SQ_m[n] \right)}{T_{\text{meas}}}$$

Once a channel is selected by the sequence, the corresponding

- Data Width selection: 8- or 10-bit, **DWSEL**
- Sample Time $t_{\text{SAMPLE}} = (2 + \text{STC}) / f_{\text{ADC1}}$, **STC_0_3** and **STC_4_7** is selected.

Conversion Time

The total time required for a conversion depends on several user-definable factors:

- The ADC conversion clock frequency, where $f_{\text{ADCl}} = f_{\text{ADC}} / (\text{DIVA} + 1)$.
- The selected sample time, where $t_{\text{sample}} = (2 + \text{STC}) \times t_{\text{ADCl}}$ (STC = additional sample time defined in [STC_0_3](#) and [STC_4_7](#))
- The selected result width N (8/10 bits), defined in [DWSEL](#)
- Synchronization steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and synchronization. It can be computed with the following formula:

$$t_{\text{conv}} = (3 + \text{STC} + N) \times t_{\text{ADCl}} + 1 \times t_{\text{ADC}} \quad (31)$$

Minimum conversion time: $t_{\text{CN}} = [3 + 0 + 8(\text{result width})] \times 1 \text{ (min DIVA)} + 1 = 12 \text{ clock cycles}$

25.4.2 Channel Controller Control Registers

Table 170 Register Overview

25.5 Conversion Result Handling

25.5.1 Functional Description

Each Result Register **RES_OUT0** - **RES_OUT7** has a valid flag and an optional wait-for-read mode (WFR) configuration bit.

The valid flag indicates if the corresponding result register contains valid data. The valid bit is set by hardware once the ADC conversion is ready and stored in the corresponding result register. It is cleared once the result is read by software (or DMA request).

Wait-for-read mode

The wait-for-read mode is a feature to prevent data loss due to overwriting a result register with a new conversion result before the CPU (or DMA transfer) has read the previous data.

Wait-for-read mode prevents overwriting of result register. The conversion is always started, however the result is only written to the result register in case the valid bit is set to zero. In case the valid bit is set to one, the result of the ADC is ignored.

25.5.2 Result Registers

In Software Mode, the WFR configuration bit is ignored. In software mode the result register is always updated, but VF is still set and OF retains its value.

Table 171 Register Overview

25.6 DMA Requests

The DMA Controller implements the following hardware DMA requests:

- ADC1 one sequence done, burst request
- ADC1 exceptional sequence (ESM) done, burst request
- ADC1 channel 0 conversion done
- ADC1 channel 1 conversion done
- ADC1 channel 2 conversion done
- ADC1 channel 3 conversion done
- ADC1 channel 4 conversion done
- ADC1 channel 5 conversion done
- ADC1 channel 6 conversion done
- ADC1 channel 7 conversion done

DMA requests are generated if the VFx flag of the respective result register is set to '1' (in all sequencer mode except software mode).

25.7 Interrupts

The ADC1 generates the following interrupts:

- ADC1 Exceptional Sequence Measurement finished, status bit **IS**.ESM_STS
- ADC1 Exceptional Interrupt Measurement finished, status bit **IS**.EIM_STS
- ADC1 channel 0 conversion done interrupt, **IS**.CH0
- ADC1 channel 1 conversion done interrupt, **IS**.CH1
- ADC1 channel 2 conversion done interrupt, **IS**.CH2
- ADC1 channel 3 conversion done interrupt, **IS**.CH3
- ADC1 channel 4 conversion done interrupt, **IS**.CH4
- ADC1 channel 5 conversion done interrupt, **IS**.CH5
- ADC1 channel 6 conversion done interrupt, **IS**.CH6
- ADC1 channel 7 conversion done interrupt, **IS**.CH7

Interrupts are generated if the VFx flag of the respective result register is set to '1' (in all sequencer modes except software mode).

Figure 203 shows the interrupt generation of ADC1.

25.8 Module Interfaces

25.8.1 ADC1 Hardware Trigger Selection

Hardware Trigger Inputs

Figure 204 shows the ADC1 trigger selection.

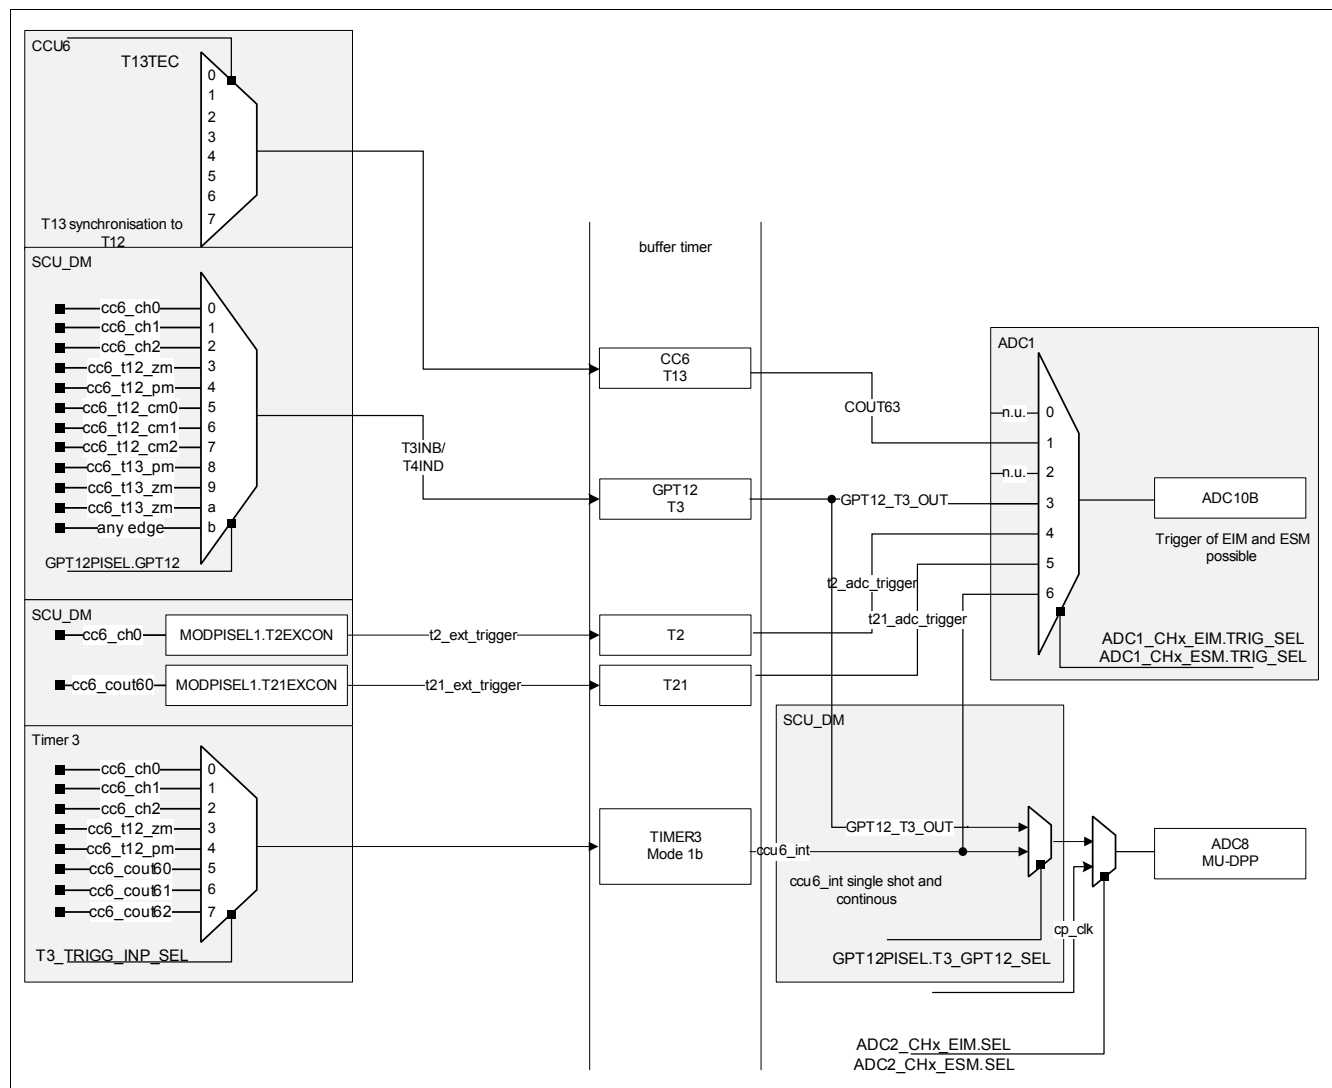

Figure 204 ADC1 Trigger Selection

26 High-Voltage Monitor Input

26.1 Features

- High-voltage input with $V_S/2$ threshold voltage
- Integrated selectable pull-up and pull-down current sources
- Wake capability for power saving modes
- Sensitive on level change configurable for transitions from low to high, high to low or both directions
- MON inputs can also be evaluated with **ADC 1** in active mode (see also Chapter **Analog Digital Converter**).

26.2 Introduction

This module is dedicated to monitor external voltage levels above or below a specified threshold or it can be used to detect a wake-up event at the high-voltage MON pin in low-power mode. The input is sensitive to a input level monitoring, this is available when the module is switched to active mode with the SFR bit EN.

To use the Wake function during low power mode of the IC, the monitoring pin is switched to Sleep Mode via the SFR bit EN.

26.2.1 Block Diagram

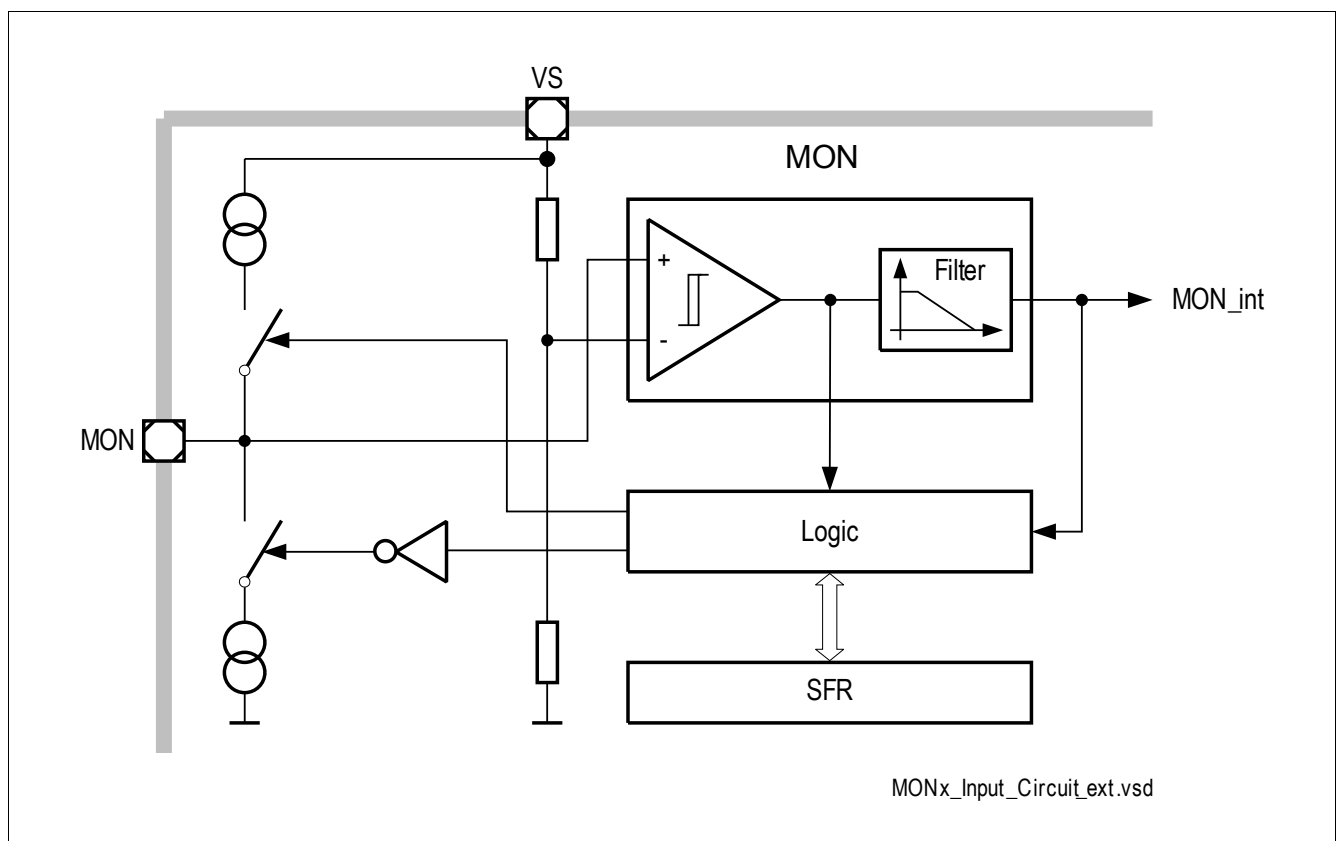

Figure 205 Monitoring Input Block Diagram

26.3 Functional Description

For a wake-up on a positive voltage transition, the **RISE** bit has to be configured. For a wake-up on a negative voltage transition, the corresponding bit **FALL** has to be set. This configuration can also be used for level change detection in active mode.

As the system provides the functionality of cyclic sense, the IN can be configured as a wake-up source for this mode. This is done by setting the bit **CYC**.

The IN also includes an input circuit with pull-up (can be activated by **PU** bit) and pull-down (can be activated by **PD** Bit) current sources to define a certain voltage level with open inputs and a filter function to avoid wake-up events caused by unwanted voltage transients at the module input.

When automatic current source selection is enabled, a voltage level at the IN input of $V_{MON_th} < V_{MONx} < V_S - 1V$ activates the pull-up current source. If the IN voltage is between $1V < V_{MONx} < V_{MON_th}$ the pull-down sink is activated, providing stable levels at the monitoring/wake-up inputs. Below and above these voltage ranges the current is minimized to a leakage current. This automatic activation of the current sources, has to be done by setting **PU** and **PD** bit to one at the same time.

Note: In case a Monitoring Input is deactivated by setting bit EN to zero, it can neither be used as a wake-up source nor can it be used to detect logic levels!

Figure 206 Module - HV_MON Input Characteristics for switchable pull current and static pull-down (on top) or pull-up

High-Voltage Monitor Input

The following tables provides an overview of the configuration possibilities on the INs via **SFR**.

Table 173 includes all pull-up and pull-down setup scenarios which can be chosen for one IN. **Table 174** shows an overview of the available states of a IN.

Table 173 Pull-Up / Pull-Down Input Current

PU	PD	Output Current	Description
0	0	leakage current ¹⁾	pull-up/down current source disabled
0	1	pull-down	pull-down current source enabled (for low active switches)
1	0	pull-up	pull-up current source enabled (for high active switches)
1	1	switchable ²⁾	pull-up/down depending on input voltage

1) all current sources switched off.

2) will be automatically switched by the MON_IN circuit depending on level of input signal.

Table 174 EN MON Mode definition

EN	Mode	Description
0	disabled ¹⁾	Monitoring input is disabled (no wake-up possible!)
1	Sleep Mode	Monitoring input is set to low power mode (use for device Low Power Mode)
1	normal mode	Monitoring input is in active mode

1) if a IN is disabled it cannot be used as a wake-up source anymore.

26.4 Register Definition

This chapter describes the configuration register for MON1.

The **Base Address** for this Register is 50004000_H.

The registers listed below are located in the **SFR** address space. To access them, no paging is required.

Table 175 Register Address Space

Module	Base Address	End Address	Note
MON	50004000 _H	50004FFF _H	Monitor Inputs

Table 176 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition, Monitor Input Registers			
CNF	Settings Monitor 1	034 _H	0100 0111 _B

The registers are addressed wordwise.

26.4.1 Monitor Input Registers

The monitor input registers are part of the PMU. This is due to the fact that this circuit requires supply and clock, during system wide low power modes.

Settings Monitor 1

The register is reset by RESET_TYPE_2.

CNF	Offset	Reset Value

27 Bridge Driver (incl. Charge Pump)

27.1 Features

The MOSFET Driver is intended to drive external normal level FET transistors in bridge configuration. The driver provides many diagnostic possibilities to detect faults.

Functional Features

- External Power NFET Transistor Driver Stage with driver capability for max. 100 nC gate charge @ 25 kHz switching frequency.
- Implemented adjustable cross conduction protection.
- Supply voltage (VSD) monitoring incl. adjustable over- and undervoltage shutdown with configurable interrupt signalling.
- VSD operating range down to 5.4 V
- VDS comparators for short circuit detection in on- and off-state
- Open-Load detection in off-state

27.2 Introduction

The MOSFET Driver Stage can be used for controlling external Power NFET Transistors (normal level). The module output is controlled by SFR or System PWM Machine (CCU6).

27.3 Functional Description

27.3.1 Normal Operation

For Normal Operation the output stages are controlled by software, using SFR registers. The driver is designed to drive mainly capacitive loads with a small resistance. The maximum load dc current is 10 mA. The main features provided by the Driver module are the following:

- **Adjustable Slew Rate** for improved EMI behavior. The slew rate can be adapted by the corresponding bits in the **DRV_CTRL3** register.
- **Off-State Open-Load Detection** with two different thresholds and currents. The detailed principle of the Off-State Open-Load detection is shown in the chapter **OFF-State Short Circuit Detection**.

27.3.2 Slew Rate Control

For Slew Rate Control the charge and discharge current of the MOSFET gate can be adjusted. This is done by programming the corresponding bits in the SFR.

A separate slew rate control is implemented for both, turn-on and turn-off control phases

The drive current for the MOSFET gate can be shaped for the charge and discharge phase. Therefore 4 current steps with timings can be programmed for charge and discharge phase. The drive current for each current step can be programmed with 5 bits (32 levels) and the length of the current step with 3 bits (50ns each step).

Figure 208 Driver Slew Rate Control

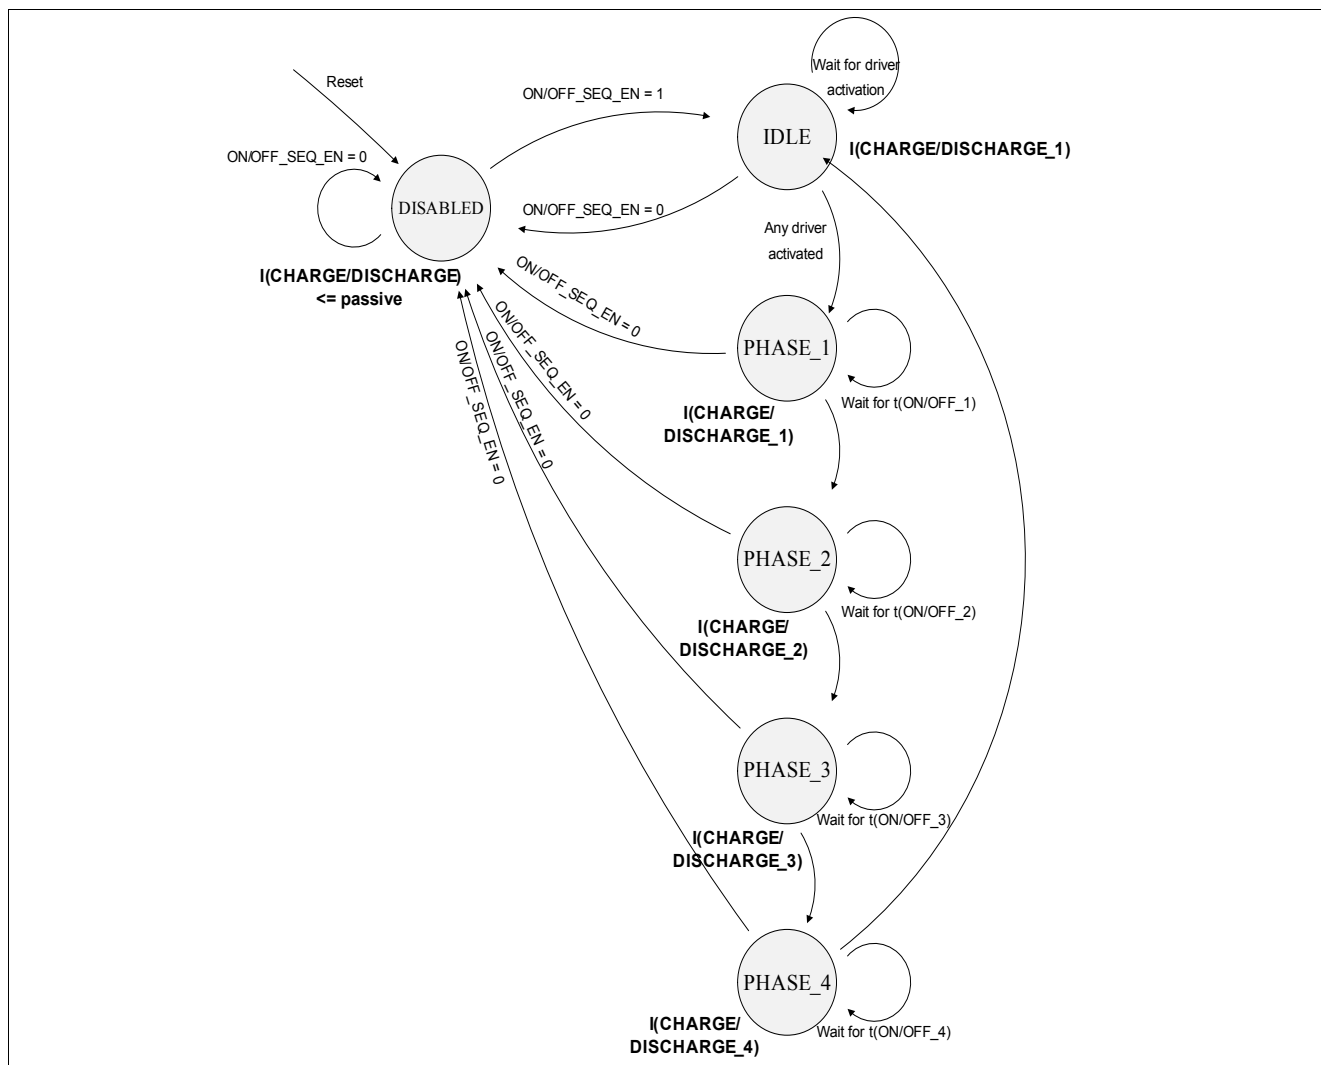

Figure 209 Driver Slew Rate Control Sequencer

27.3.3 PWM Operation

In PWM Mode the Driver Stages are controlled by the PWM State Machine (CCU6). The PWM Mode is enabled by the corresponding bit in **DRV_CTRL1** and **DRV_CTRL2**. The PWM configuration must be done in the System PWM Module (CCU6).

In PWM Mode the Driver should be enabled by the corresponding bits in the **DRV_CTRLx** register, first. If this has been done the PWM State Machine can be enabled to deliver the PWM Signal. This procedure is recommended to avoid any unwanted glitches at the driver output.

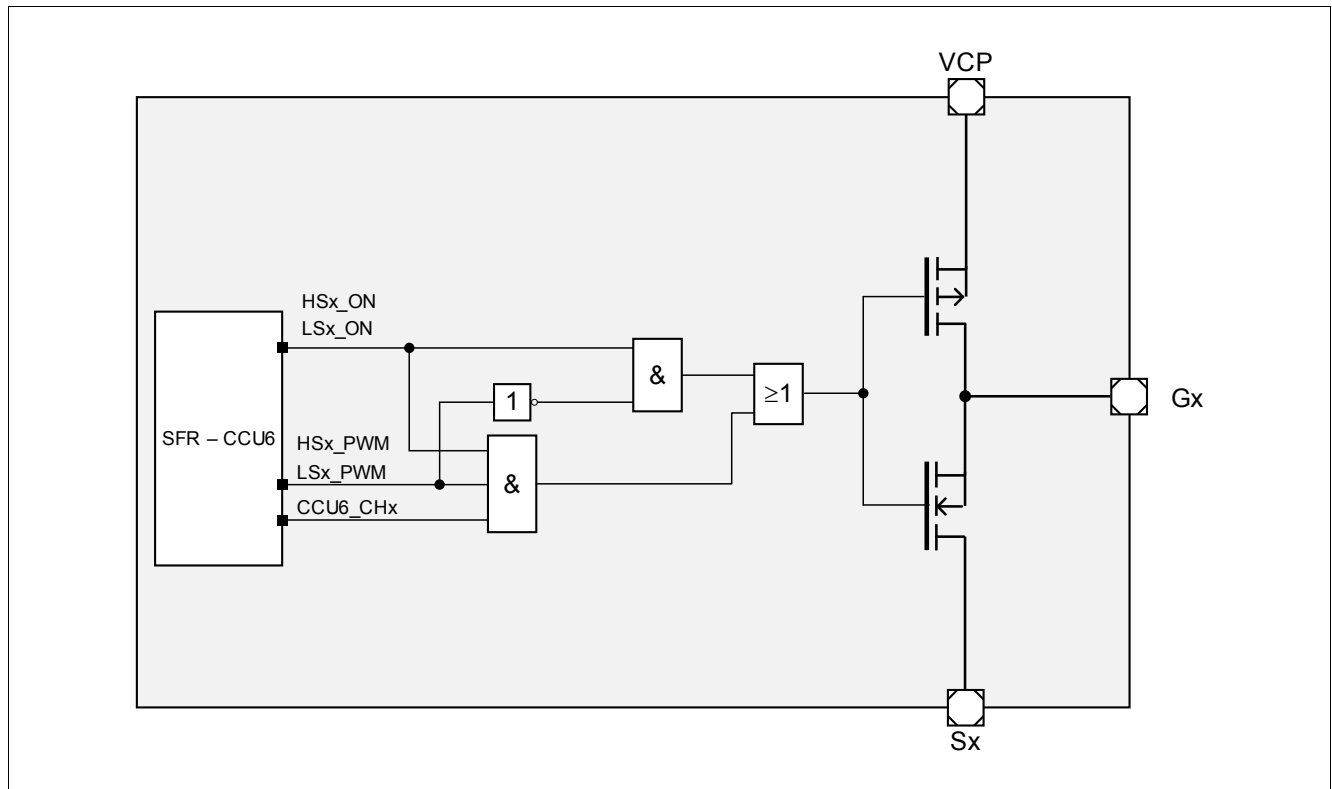

Figure 210 Control Logic of Driver in PWM Mode

The MOSFET Drivers are mapped to following CCU6 channels:

Table 177 Driver Control by CCU6

Driver dedicated to external FET:	Corresponding CCU6 channel (CCU6_Chx)	Comment
LS1	COUT60	
LS2	COUT61	
HS1	CC60	
HS2	CC61	

27.3.4.1 Clock Generator of Driver Supply

The clock generator of the charge pump uses a spread spectrum technique to minimize emission caused by the charge pump operation on the supply voltage VSD. The structure of the clock generation for the charge pump is shown in the figure below:

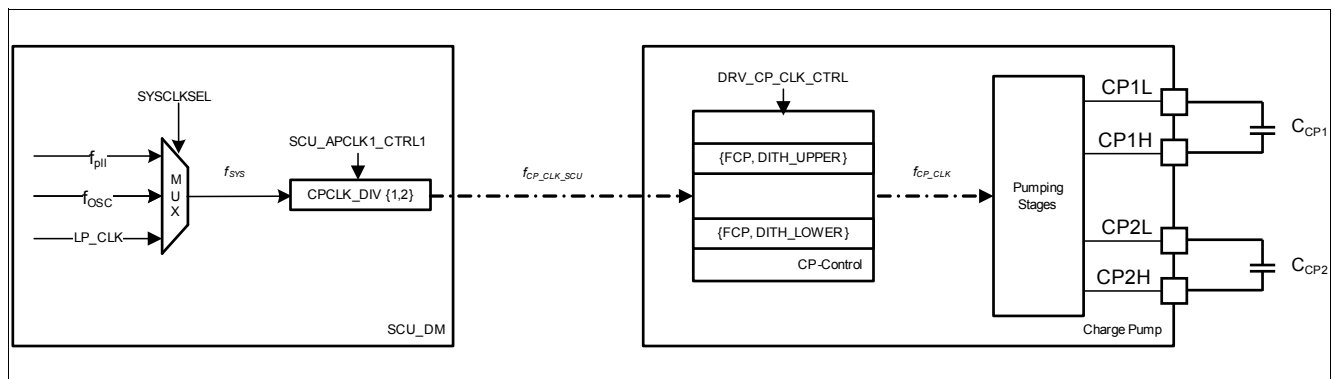

Figure 212 Clock Generation of Charge Pump Block

The charge pump clock f_{CP_CLK} is derived from the system clock f_{sys} . Inside the SCU_DM the system clock is divided by a configurable value and provided as $f_{CP_CLK_SCU}$ to the charge pump control block. During operation the frequency of the charge pump is varied between two frequency boundaries. These boundaries are defined by the concatenation of {FCP, DITH_UPPER} bits for the upper boundary and {FCP, DITH_LOWER} bits for the lower boundary (the concatenated bits represent a frequency divider value for $f_{CP_CLK_SCU}$).

27.3.5 Overcurrent Detection - VDS measurement

The Drain Source Voltage (VDS) of each MOSFET is monitored by a comparator. In case the VDS voltage is higher than the limit set in DSMONVTH during the on phase of the MOSFET all drivers are switched off. The bit HSx_OC_STS or LSx_OC_STS is set. The feature can be disabled by bit HSx_OC_DIS / LSx_OC_DIS.

The filter time for the VDS measurements can be adjusted by the bits HSDRV_DS_TFILT_SEL and LSDRV_DS_TFILT_SEL.

The blank time for the VDS measurement can be adjusted by the bits LS_HS_BT_TFILT_SEL.

27.3.6 OFF-State Short Circuit Detection

The Short circuit detection in OFF State is mainly performed by an internally generated test current and the built-in Drain-Source monitoring.

To perform the short circuit detection in off state the following procedure has to be executed:

- The MOSFET Drivers are in off-state
- To detect short circuit on the low side MOSFET, a test current I_{TEST} out of SH1 is activated by a high side current source on pin SH1. This is done by setting the bit HS1_DCS_EN.
- After the test current has settled the VDS Status flag shows the status on the low side MOSFET. If VDS status flag is set the complete voltage drop is across the high side current source, VDS measurement on the LS MOSFET is below the VDS threshold, indicating a short on the low side FET.

27.3.7 Channel turn on/off delay measurement

For functional test and drive scheme timing optimization a dedicated timer is available to measure the delay between intended external MOS activation and actual turn on (VDS supervision). The principle function is shown in the following figure:

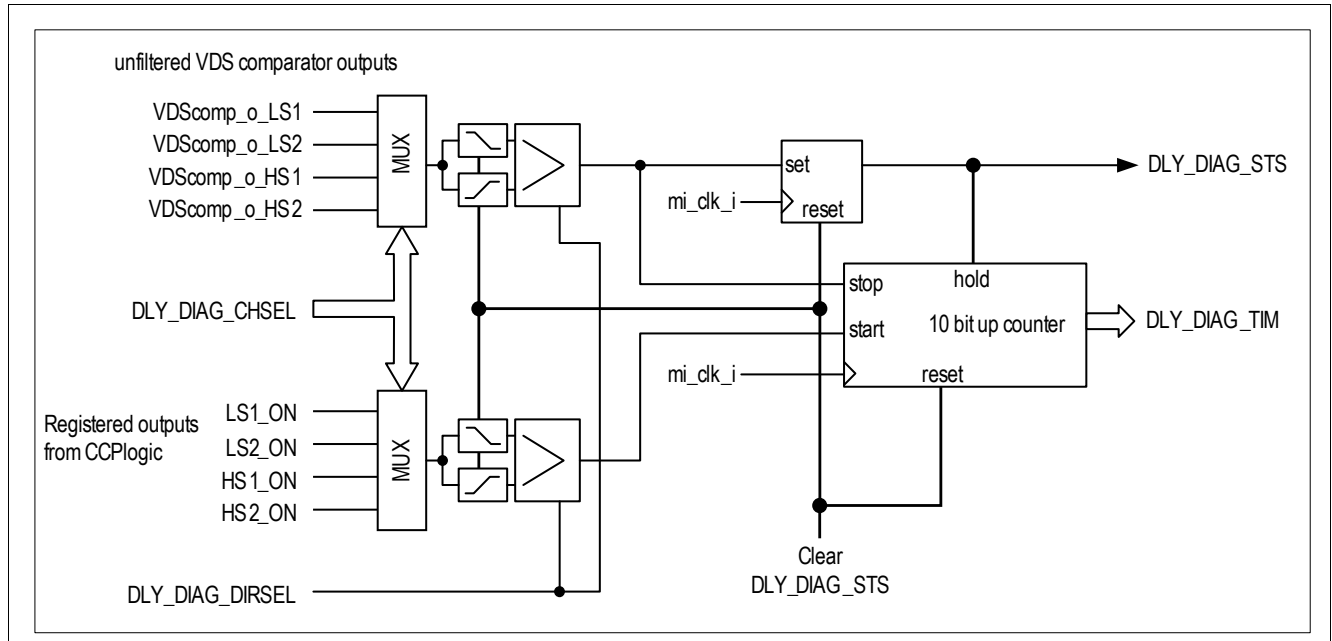

Figure 213 Principle of channel turn on/off timing measurement.

27.4 Application Hints

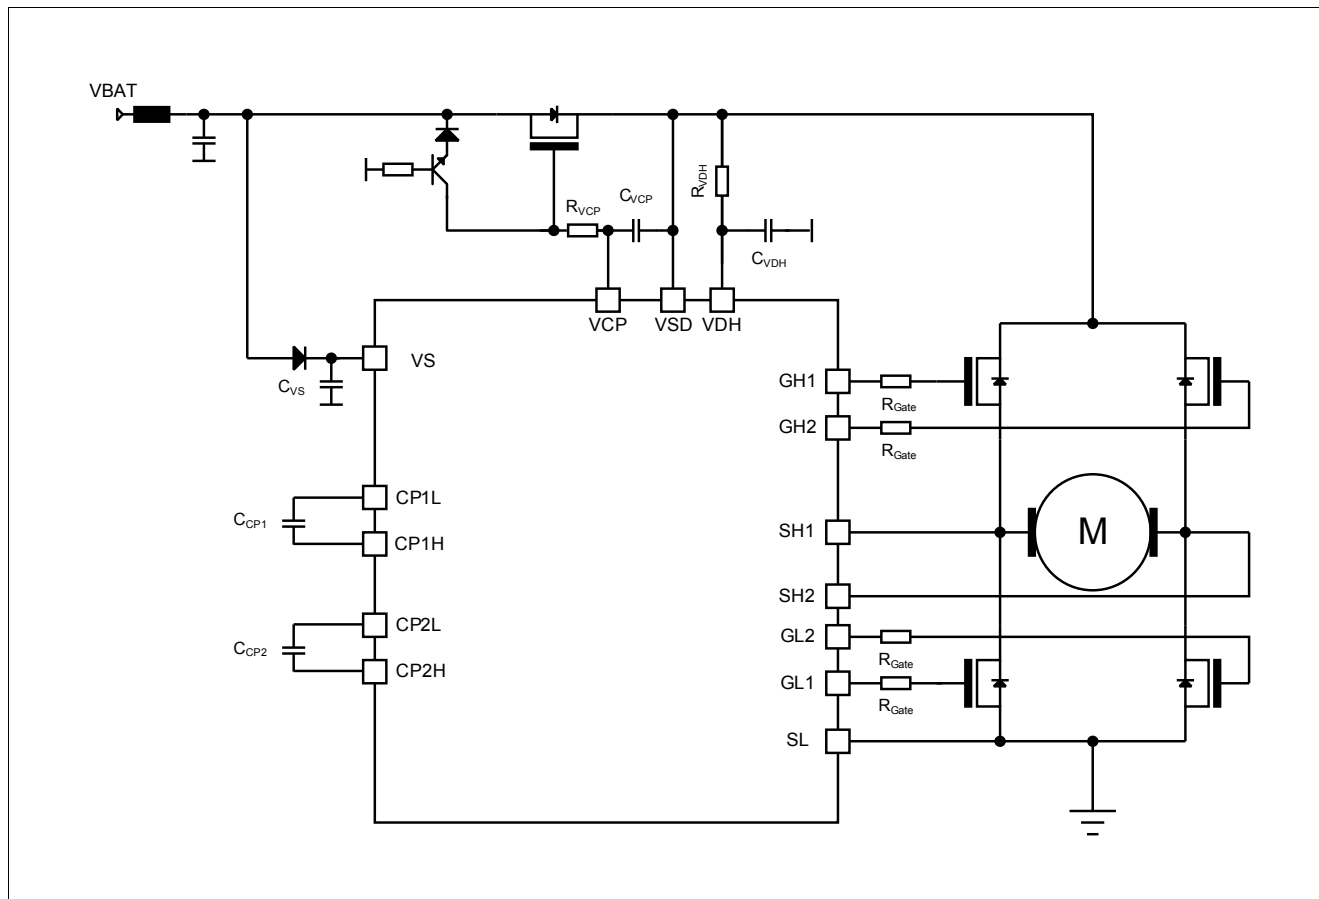

Figure 214 Application Example for Bridge Driver, TLE9869QXA20

27.4.1 Bridge Driver Diagnosis

27.4.1.1 Off-Diagnosis

Off-Diagnosis describes the capability to recognize a short on a motor contact to either VBAT or GND without the need to set the MOSFETs in "ON"-state. An unwanted cross-current flow through the bridge MOSFETs can be prevented that way.

27.4.1.1.1 Preparation

In order to run the Off-Diagnosis the following settings needs to be applied to the Bridge Driver registers:

A: All phases must be switched in "Enabled"-state (but not "ON"-state)

31	30	29	28	27	26	25	24
HS2_OC_ DIS	HS2_OC_ STS	HS2_SUP ERR_STS	HS2_DS_ STS	HS2_DCS _EN	HS2_ON	HS2_PWM	HS2_EN
rw	rwh	r	rwh	rw	rwhir	rwhir	rw
23	22	21	20	19	18	17	16

rw	rwh	r	rwh	rw	rwhir	rwhir	rw

Figure 215 BDRV->CTRL1

The DS-Status Flags are still set in this state of the Bridge Driver, but since the Drain-Source-Current Sources are not enabled these flags do not have a meaning yet.

B:

For a detection of a short of the motor contacts to GND or VBAT the value of the BDRV->CTRL3.DSMONVTH shall be set to the minimum value. The BDRV->CTRL3.IDISCHARGE_TRIM value, which sets the current driven by the DS-Current sources, shall be set to a very small value. A value of 2 would be sufficient.

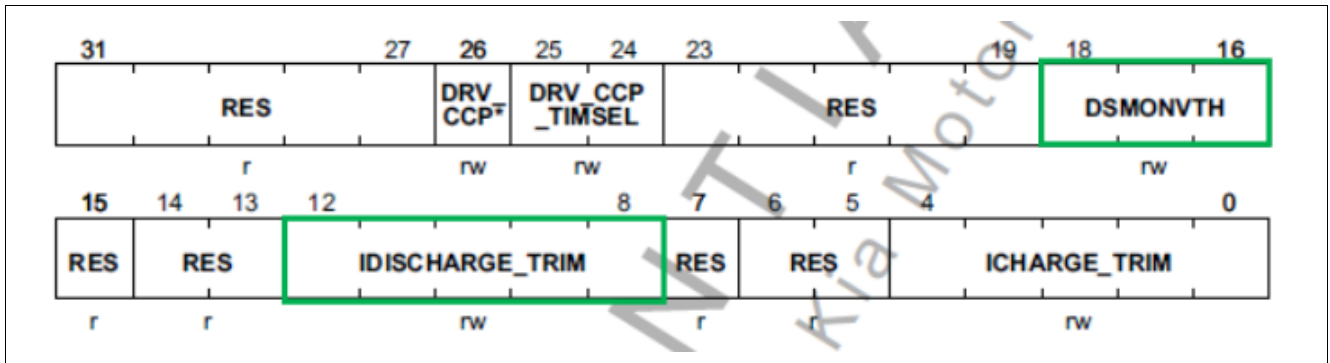

Figure 216 BDRV->CTRL3

C: Enable Drain-Source Current Sources on the High-Side (HSx) drivers

The DS-Current sources are internally connected to the corresponding SHx pins of the device. The "Enable"-Flags of each phase remains set. It is recommended to even enable the DS-Current source flag for the LSx drivers, just to be able to recognize the validity of the LSx_DS_STS flags inside the BDRV interrupt service routine, but it is not required for the Off-Diagnosis.

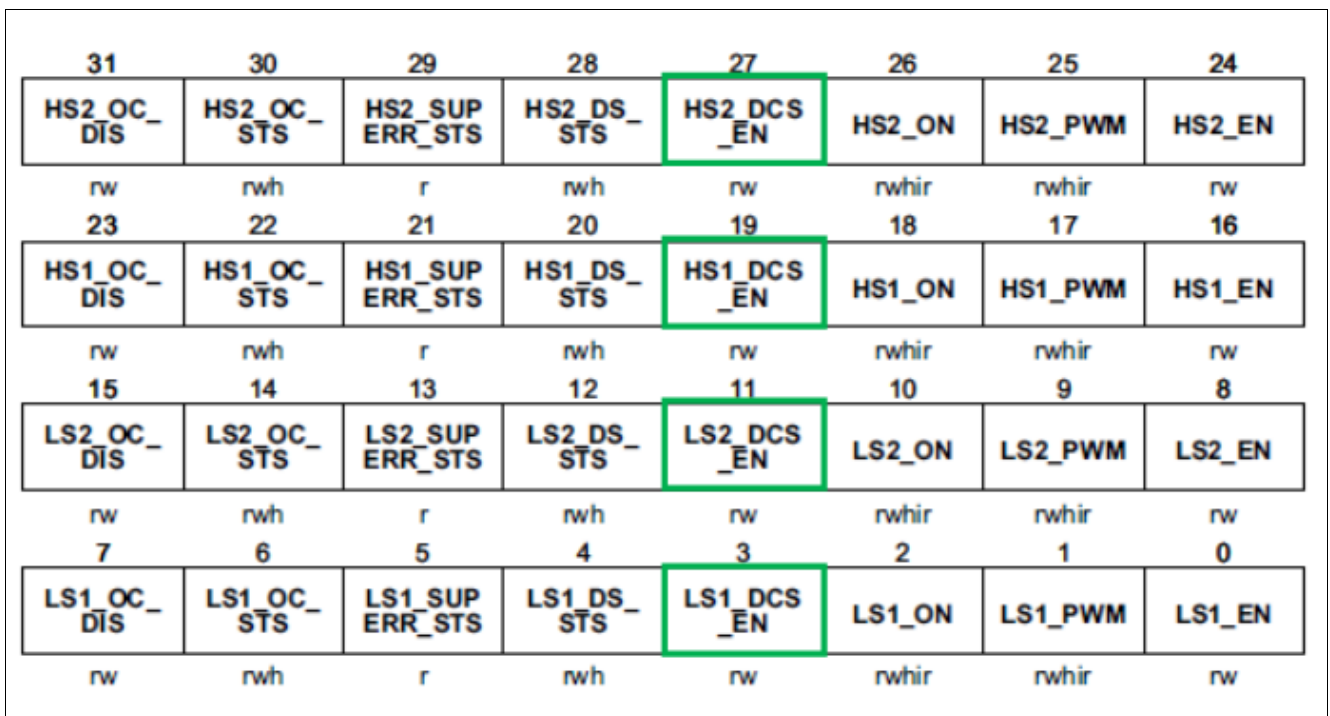

Figure 217 BDRV->CTRL1

D:

Assuming the motor contacts do not have a short to VBAT or to GND, all the DS-Status flags of each phase can be cleared now, and shall stay cleared.

31	30	29	28	27	26	25	24

rw	rwh	r	rwh	rw	rwhir	rwhir	rw

Figure 218 BDRV->CTRL1

In case one of these flags cannot be cleared then this is already an indication of a short of a motor contact to VBAT or to GND.

27.4.1.1.2 Detection

Evaluate the state of the HSx_DS_STS flags and of the LSx_DS_STS flags in order to check if a short is present. If any HSx_DS_STS flag is set, then it means at least one of the motor contacts has a short to VBAT. If any LSx_DS_STS flag is set, then it means at least one of the motor contacts has a short to GND. Due to the fact that the motor coils do have a very low resistance usually all HSx_DS_STS flags are set together and analogue for the LSx_DS_STS flags as well. In case no motor is connected, then only the flags for the phase which sees the short are set.

To return to normal operation, disable the DS-Current sources for each phase, the value of the DS-STs flags have to be ignored from now on.

27.4.1.2 On-Diagnosis

The On-Diagnosis supervises the current flowing through the MOSFETs with the internal Drain-Source monitoring. The enabling of the integrated Drain-Source-Current source is not required for the On-Diagnosis.

27.4.1.2.1 Preparation

The bridge driver will be operated in a normal way. All the phases are enabled and those phases which are required to operate the motor in the required way are either statically "ON" or set to "PWM" (connection to CCU6). These settings are defined by the application in order to drive the motor.

The bit field BDRV->CTRL3.DSMONVTH defines the threshold for the DS-monitoring to recognize an over-current condition in one of the MOSFETs. The DSMONVTH value defines a voltage across the drain-source path of a voltage, the required current flowing through the MOSFET needs to be calculated based on the RDS_ON value of the MOSFET.

Example: 8mOhm MOSFET (RDS_ON=8mOhm), DSMONVTH = 0.5V

(32)

$$I = \frac{U}{R} = \frac{0.5V}{8mOhm} = 62.5A$$

If the current flow through the MOSFET exceeds 62.5A the DS-monitoring will recognize an over-current condition and shut off the phase, or even the entire bridge (see **CTRL1** registerbits).

27.4.1.2.2 Detection

Two ways of evaluating the On-Diagnosis are possible:

1. Polling: the user application shall read the BDRV->CTRL1/2 registers and check the OC_STS flags of each phase to recognize whether an over-current condition has happened.
2. Interrupt based: the user shall enable the BDRV interrupt node CPU->NVIC_ISER0.Int_BDRV = 1; the user shall enable the HSx_OC_IE flags, along with the LSx_OC_IE flags inside the SCUPM->BDRV_IRQ_CTRL register.

Inside the BDRV Interrupt service routine the user shall check the HSx_OC_STS and LSx_OC_STS flags to see which MOSFET has detected the overcurrent condition. These flags need to be cleared before the ISR will be exited.

27.4.1.3 Open-Load Detection

The Open-Load detection can be used to check whether a motor is connected to the bridge or not.

The Open-Load detection operates similar to the Off-Diagnosis

27.4.1.3.1 Preparation

In order to run the Off-Diagnosis the following settings need to be applied to the bridge driver registers

1. All phases must be switched in "Enabled"-state (but not "ON"-state).
2. For a detection of a motor, BDRV->CTRL3.DSMONVTH shall be set to the maximum value. The BDRV->CTRL3.IDISCHARGE_TRIM value, which sets the current driven by the DS-Current sources, shall be set to a very small value. A value of 2 would be sufficient.
3. Enable Drain-Source Current Sources on the High-Side (HSx) drivers. The DS-Current sources are internally connected to the corresponding SHx pins of the device. The "Enable"-Flags of each phase remains set. The LSx DS-Current Source flag remains disabled.
4. Apply some settlement time (few μ s) for the voltage at each MOSFET to stabilize.
5. Assuming the motor contacts are all connected, all the DS-Status flags of each phase can be cleared now, and shall stay cleared. If a flag cannot be cleared of a phase then the DS_STS flags remain set and will signal an unconnected motor contact.

27.5 Register Definition

The Bridge Driver registers are located in the address space below.

Table 178 Register Address Space

Module	Base Address	End Address	Note
BDRV	40034000 _H	40037FFF _H	Bridge Driver

Table 179 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value

28 Current Sense Amplifier

28.1 Features

Main Features

- Programmable gain settings: $G = 10, 20, 40, 60$
- Differential input voltage: $\pm 1.5V / G$
- Wide common mode input range $\pm 2V$
- Low setting time $< 1.4 \mu s$

28.2 Introduction

The current sense amplifier in [Figure 219](#) can be used to measure near ground differential voltages via the 10-bit ADC. Its gain is digitally programmable through internal control registers.

Linear calibration has to be applied to achieve high gain accuracy, e.g. end-of-line calibration including the shunt resistor.

[Figure 219](#) shows how the current sense amplifier can be used as a low-side current sense amplifier where the motor current is converted to a voltage by means of a shunt resistor R_{SH} . A differential amplifier input is used in order to eliminate measurement errors due to voltage drop across the stray resistance R_{Stray} and differences between the external and internal ground. If the voltage at one or both inputs is out of the operating range it has to be taken into account that the input circuit is overloaded and needs a certain specified **recovery time**.

In general, the external low pass filter should provide suppression of EMI.

28.2.1 Block Diagram

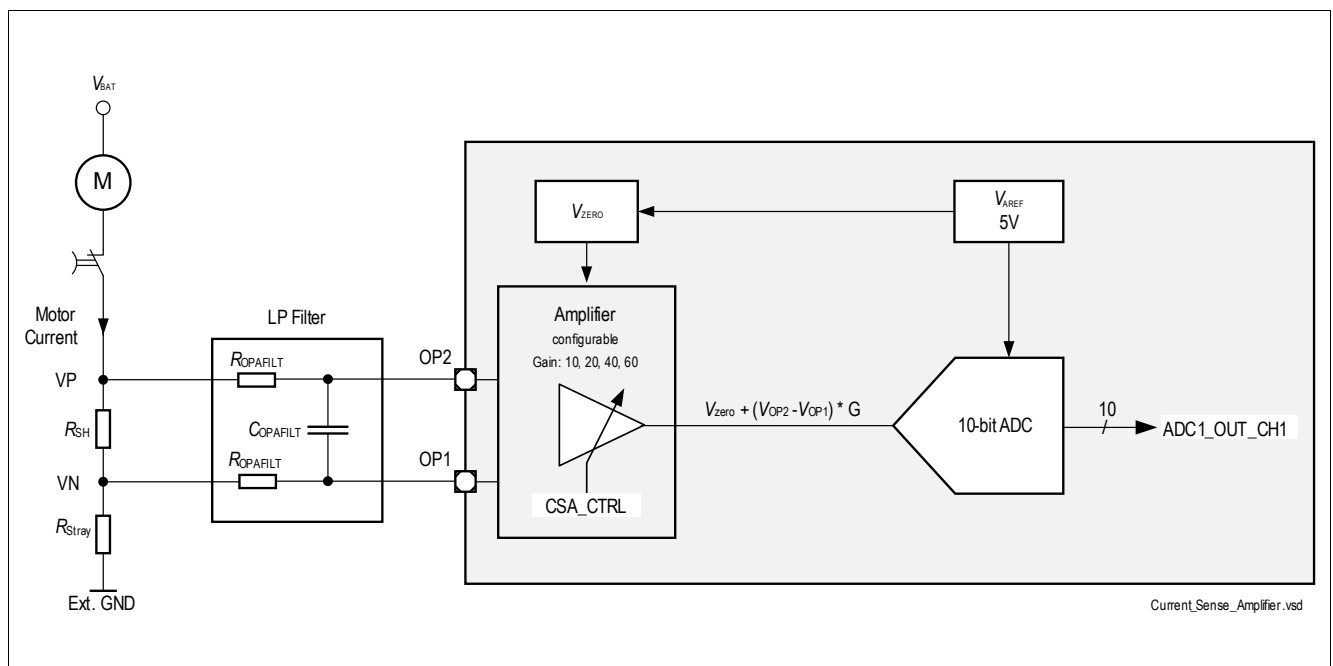

Figure 219 Simplified Application Diagram

28.3 Functional Description

28.3.1 ADC Code Calculation

The differential input voltage $V_{OP1} - V_{OP2}$ of the embedded Current Sense Amplifier (CSA) is converted to an ADC code by the following equation:

$$\text{ADC1out} = \text{floor} \left(\frac{V_{\text{zero}} + (V_{OP1} - V_{OP2}) * G}{V_{\text{LSB}}} \right) \quad (33)$$

wherein the parameter V_{OP1} and V_{OP2} are the voltages at the inputs of the amplifier and G is the configured gain. The CSA output voltage $V_{\text{CSAout}} = (V_{OP1} - V_{OP2}) * G$ is centered around an offset voltage V_{Zero} which has the following dependency on the reference voltage V_{AREF} of ADC1:

$$V_{\text{Zero}} = 0.4 * V_{\text{AREF}} \quad (34)$$

The value of V_{AREF} is 5V @ 27 °C. V_{LSB} defined as follows:

$$V_{\text{LSB}} = \frac{V_{\text{ref}}}{1024} \quad (35)$$

28.4 Register Definition

The next chapter lists the configuration possibilities of the Current Sense Amplifier (CSA) which can be used for external current sensing.

Table 180 Amplifier Module Base Address List

Module	Base Address
CSA	48018000 _H

The base address of the module is the same as for the measurement unit (MU) as the current sense amplifier is a sub-block of the MU.

Table 181 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
Register Definition			
CTRL	Operational Amplifier Control and Status	0C _H	0000 0000 _H

The registers are addressed wordwise.

Operational Amplifier Control and Status

The following register consists of control and status bits. This Register is cleared by every reset.

The register is reset by RESET_TYPE_3.

CTRL	Offset	Reset Value
Operational Amplifier Control and Status	0C_H	0000 0000_H

29 Application Information

29.1 TLE9869: H-Bridge Driver

Figure 220 shows the TLE9869QXA20 in an electric drive application setup controlling a H-Bridge motor.

Note: The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

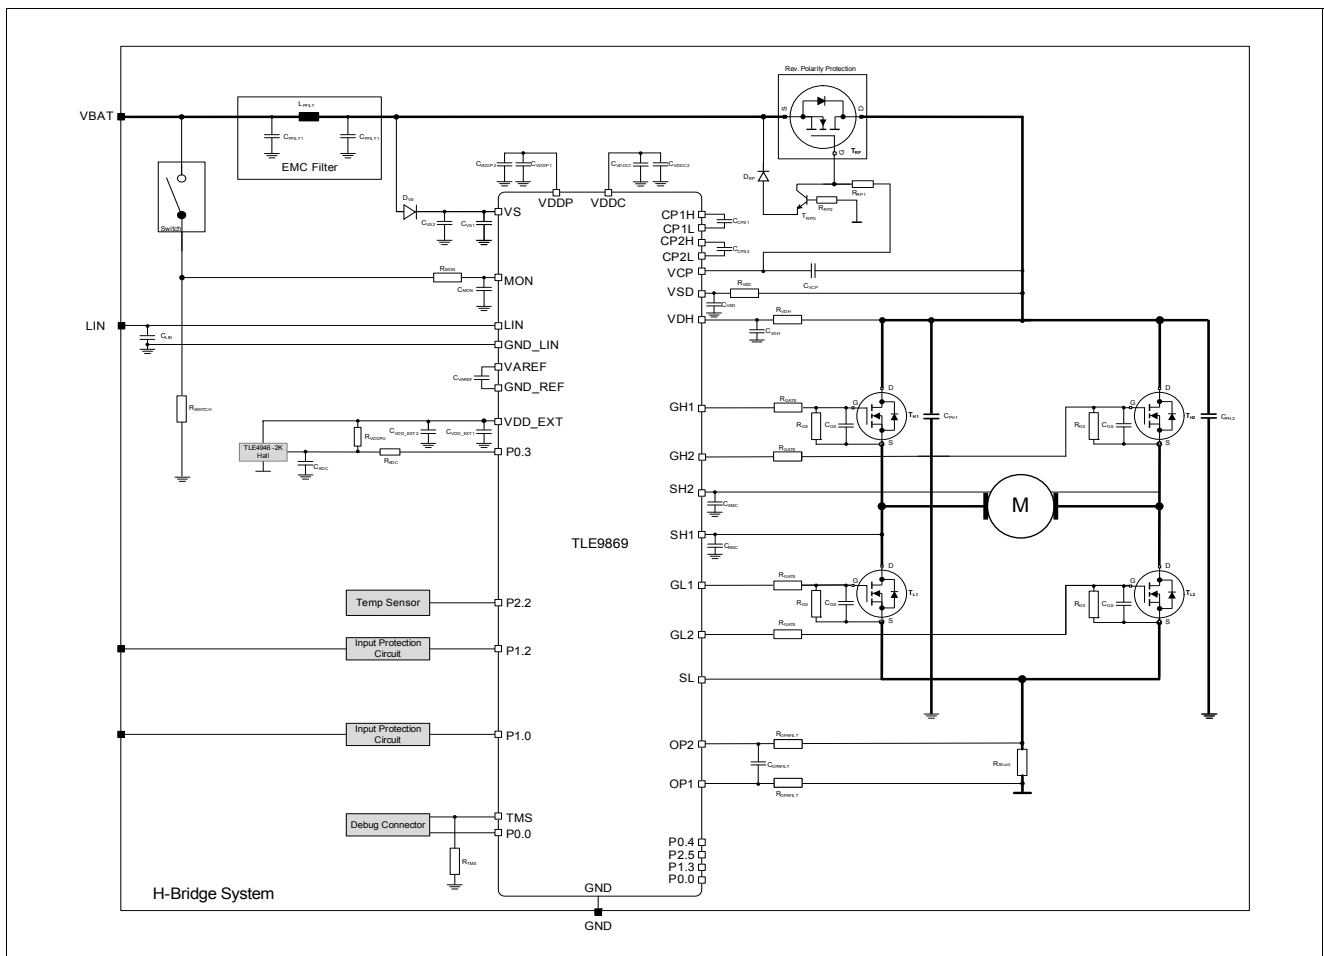

Figure 220 Simplified Application Diagram Example

Note: This is a very simplified example of an application circuit and bill of material. The function must be verified in the actual application.

Table 182 External Components (BOM)

Symbol	Function	Component
C_{VS}	Blocking capacitor at VS pin	> 20 μ F Elco + 100 nF Ceramic, ESR < 1 Ω

R_{MON1}	Resistor at MON pin	1k Ω
R_{VSD}	Limitation of reverse current due to transient (-2V, 8ms)	2 Ω
R_{VDH}	Resistor	1k Ω
R_{GATE}	Resistor	2 Ω
$R_{OPAFILT}$	Resistor	12 Ω
R_{VBAR_SENSE}	Resistor	
R_{SH1}	Resistor	optional
R_{SH2}	Resistor	optional
L_{PFILT}		
D_{VS}	Revers-polarity protection diode	–

29.2 ESD Immunity According to IEC61000-4-2

Note: Tests for ESD immunity according to IEC61000-4-2 “Gun test” (150pF, 330 Ω) has been performed. The results and test condition will be available in a test report.

Table 183 ESD “Gun Test”

Performed Test	Result	Unit	Remarks
ESD at pin LIN, versus GND ¹⁾	> 6	kV	²⁾ positive pulse
ESD at pin LIN, versus GND ¹⁾	< -6	kV	²⁾ negative pulse

1) ESD test “ESD GUN” is specified with external components see application diagram:

$C_{MON} = 100\text{nF}$, $R_{MON} = 1\text{k}\Omega$, $C_{LIN} = 220\text{pF}$, $C_{VS} = >20\mu\text{F}$ ELCO + 100nF ESR < 1 Ω , $C_{VSD} = 1\mu\text{F}$, $R_{VSD} = 2\Omega$.

2) ESD susceptibility “ESD GUN” according LIN EMC Test Specification, Section 4.3 (IEC 61000-4-2). Tested by external test house (IBEE Zwickau, EMC Test report Nr. 09-07-14)
