Low-side IGBT driver with over-current protection (negative current sense) and fault/enable

1ED44175N01B Technical description

About this document

Scope and purpose

This application note describes the features and key advantages of using Infineon’s 1ED44175N01B gate driver. This document will help the designer use the device within the recommended operating range by explaining how to select the current-sensing shunt resistor (R_cs), resistor and capacitor (RC) filter for overcurrent protection (OCP) and short-circuit protection (SCP), resistor and capacitor for fault clear time, and how to design the interfacing circuitry with the controller. A simple adapter board to evaluate 1ED44175N01B and the test result of the adapter board for one PFC demo board are also included. This application note provides detailed information to help speed up design time and avoid circuit problems that can occur due to incorrect usage of the driver.

Intended audience

This document is intended for people and designers who are looking to reduce their system cost and space while increasing the power density of their design with 1ED44175N01B.

Overcurrent detection pin
Pin 1: OCP

- The \( R_{CS} \) should be connected between the pin of system ground and the input power return to detect short-circuit current (refer to Figure 5). An RC filter needs to be connected between the shunt resistor and the OCP pin if the internal blanking time is not sufficient to eliminate the noise.
- The integrated comparator is triggered if the voltage of the OCP pin (\( V_{OCP} \)) is less than -246 mV. The shunt resistor should be selected to meet this level for the specific application. In case of a trigger event, the voltage at pin EN/FLT is pulled down to low.
- The connection length between the \( R_{CS} \) and OCP pin should be minimized.

Common supply ground pin
Pin 2: COM

- This pin connects the control ground for the internal circuit of the driver.

Gate drive output pin
Pin 3: OUT

- The pin is connected to the gate of the IGBT by the gate resistor to turn the power device on or off.
- To prevent oscillations, a gate resistor is needed to be in series with the pin and the gate of IGBT.

Bias voltage pin
Pin 4: \( V_{CC} \)

- This is the control supply pin for the internal IC.
- In order to prevent malfunctions caused by noise and ripple in the supply voltage, a good quality filter capacitor with low equivalent series resistance (ESR) and low equivalent series inductance (ESL) should be mounted very close to this pin and COM pin.

Fault output and enable pin
Pin 5: EN/FLT

- This is a multifunctional pin. One function is the fault output. An active low output is given on this pin for a fault state condition in the 1ED44175N01B. The fault conditions are over-current detection and \( V_{CC} \) undervoltage operation. The EN/FLT output is open-drain configured. The EN/FLT signal line should be pulled up to the logic power supply (5 V or 3.3 V) with proper resistance.
- The second function is enable. Externally pulling down the pin can disable the output. For normal operation, the pin needs to be pulled up.
- The third function is fault clear time program with external resistor and capacitor.

Signal input pin
Pin 6: IN

- This is the pin to control the operation of the external device.
- It is activated by voltage input signals. The terminal is internally connected to a Schmitt-trigger circuit.
- The signal logic of the pin is active-high. The device associated with the pin will be turned "ON" when a sufficient logic voltage is applied to the pin.
- The wiring of the input should be as short as possible to protect the 1ED44175N01B against noise influences.
- To prevent signal oscillations, an RC coupling is recommended as illustrated in Figure 3.

Input/Output signal connection

Figure 3 shows the I/O interface circuit between a micro-controller (µC) or digital signal processing (DSP) and the 1ED44175N01B. The 1ED44175N01B input logic is active-high. The EN/FLT output is an open-drain configuration. This signal should be pulled up to high by an external logic power supply with a pull-up resistor. RC (1 KΩ / 100 pF) is recommended for the “IN” pin to prevent input noise.

The input and fault output maximum rating voltages are listed in Table 3. Since the fault output is open-drain configured and its rating is $V_{CC}$ + 0.3 V, a 15 V supply interface is possible. However, it is recommended that the fault output be configured with the 3.3 V logic power supply which is similar to the input signal.

![Simplified input structure diagram of 1ED44175N01B](image)
The 1ED44175N01B input pin is internally clamped to COM by zener diodes. It also includes a pull-down resistor and an input Schmitt trigger for better noise immunity. The input pin has the capability to process input voltage up to supply voltage of the driver and is also compatible with 3.3 V µC or DSP. Table 4 shows the logic input threshold.

As shown in Figure 4, the 1ED44175N01B input signal section integrates a pull-down resistor. Therefore, when using an external filtering resistor between the micro-controller output and 1ED44175N01B input, pay attention to the signal voltage drop at the 1ED44175N01B input terminal. It should fulfill the logic "1" input voltage requirement. For instance, $R = 1$ kΩ and $C = 100$ pF are recommended for the parts shown in Figure 3.
2.2 General interface circuit example

Figure 5 shows a typical application circuit of 1ED44175N01B for the interface schematic with control signals connected directly to a XMC™ µC.

![Application circuit example of active power factor correction (APFC) with R_cs for OCP](image)

**Note:**

1. The input signal is active-high configured. There is an internal pull-down resistor from the input signal line to COM. When employing an RC coupling circuit between micro-controller and 1ED44175N01B, the RC values should be properly selected so that the input signal is compatible with the 1ED44175N01B logic “1”/logic “0” input voltages.
2. To avoid malfunction, the wiring of the input should be as short as possible (less than 2-3 cm).
3. The input of 1ED44175N01B can be directly connected to the micro-controller terminal without any opto-coupler or transformer isolation.
4. EN/FLT output is an open-drain output. This signal line should be pulled up to the positive side of the 5 V or 3.3 V logic power supply with a pull-up resistor. The fault clear program parts are RFLT and CFLTC. The wiring of the two parts should be placed as close to EN/FLT and COM pins as possible.
5. To prevent protection function errors, the RFLT and CFLTC wiring between OCP and power ground should be as short as possible. CFLTC wiring should be placed as close to OCP and COM pins as possible.
6. Each capacitor should be mounted as close to the pins of the 1ED44175N01B as possible.
7. It is recommended to connect the ground pin of the micro-controller directly to the COM pin.
2.3 Recommended layout pattern for overcurrent protection (OCP) & short-circuit protection (SCP) functions

As shown in Figure 6, it is recommended that the OCP filter capacitor connections to the 1ED44175N01B pins be as short as possible. It is also recommended to keep the current sense loop, which is shown in Figure 6, as small as possible for better noise immunity. External current-sensing resistors are applied to detect overcurrent. A high ESL $R_{CS}$ or a long wiring pattern between the $R_{CS}$ and low side IGBT will cause excessive surges that might damage the 1ED44175N01B and current detection components. This may also distort the sensing signals. To decrease the parasitic inductance, the wiring between the $R_{CS}$ and emitter of low side IGBT should be as short as possible. **Low ESL film resistors** are strongly recommended for the $R_{CS}$.

![Diagram of recommended layout pattern for OCP & SCP function](image1)

**Figure 6** Recommended layout pattern for OCP & SCP function

2.4 Recommended wiring of the bypass capacitors

It is recommended to place a low ESL ceramic bypass capacitor (C3) exceeding 1 µF connected between $V_{CC}$ and COM directly. Also connect the ground of the capacitor (C1, C2, C4) to COM. Finally, connect COM to system ground at $R_{CS}$. The signal ground and power ground at $R_{CS}$ are connected at only one point. It is also recommended to keep the driver output return loop, which is shown in Figure 7, as small as possible.

![Diagram of recommended wiring of bypass capacitors](image2)

**Figure 7** Recommended wiring of bypass capacitors
2.5 **Recommended PCB layout**

Proper PCB layout is important in high-current, fast-switching circuits to provide proper device operation and robustness of the design. Improper component and placement may cause errant switching, excessive voltage ringing or circuit latch-up.

Here is the recommended PCB layout:

1. PCB trace loop area and inductance must be minimized.
   - This is accomplished by placing the 1ED44175N01B directly at the power switch (IGBT).
   - Placing the bypass capacitor (C3) directly at Vcc and COM.
   - Locating ground planes or ground return traces directly above or beneath 1ED44175N01B can reduce trace inductance.

2. A ground plane also helps as a radiated noise shield, and provides some heat sinking for power dissipated within the device.

Figure 8 is the example of the PCB layout for the schematic of Figure 7.
3 Protection features

3.1 Undervoltage lockout protection (UVLO)

The 1ED44175N01B has an internal UVLO protection feature on the \( V_{cc} \) pin supply circuit blocks. Table 5 shows the UVLO threshold.

Upon power-up, if the \( V_{cc} \) voltage fails to reach the \( V_{CCUV+} \) threshold, the driver cannot turn on. Additionally, if the \( V_{cc} \) voltage decreases below the \( V_{CCUV} \) threshold and the \( V_{cc} \) bias voltage remains lower than the \( V_{CCUV} \) threshold exceeding UVLO filter time \( t_{VCCUV} \) during operation, the undervoltage lockout circuitry will recognize a fault condition and shut-down the drive output. The EN/FLT will then pull down to inform the controller of the fault condition, regardless of the status of the IN input pin. The \( t_{VCCUV} \) about 2 μs helps to suppress noise from the UVLO circuit, so that negative-going voltage spikes at the supply pin will avoid parasitic UVLO events.

When \( V_{cc} \) is higher than \( V_{CCUV+} \) and longer than \( t_{FLTC} \), EN/FLT becomes high and the 1ED44175N01B is enabled. (Figure 9 shows the UVLO protection.) The UVLO function is latched up. 1ED44175N01B will wait for a new input signal on IN before it activates the output stage.

![Figure 9 Vcc undervoltage protection](image-url)
Low-side driver with over-current protection and fault/enable (negative current sense)

Protection features

The UVLO protection ensures that the IC drives the external power devices only when the gate supply voltage is sufficient to fully enhance the power devices. Without this feature, the gates of the external power device could be driven with a low voltage, resulting in the power device conducting current while the channel impedance is high. This could result in very high conduction losses within the power device, and lead to power device failure.

The $V_{CC}$ power for the 1ED44175N01B is normally provided by a single 15 V supply that is connected to the $V_{CC}$ and COM terminals. The $V_{CC}$ power supply should be well filtered with a low impedance electrolytic capacitor and a high-frequency decoupling capacitor connected at the 1ED44175N01B’s pins. High-frequency noise on the supply might cause the internal control circuit to malfunction and to generate erroneous fault signals. To avoid these problems, the maximum ripple on the supply should be less than ±1 V.
Low-side driver with over-current protection and fault/enable (negative current sense)

Protection features

3.2 Overcurrent protection (OCP)

3.2.1 Timing chart of OCP

The 1ED44175N01B has an over-current shutdown function. Its internal comparator monitors the voltage of the OCP pin. If this voltage exceeds the OCP threshold \( V_{OCTH} \), which is specified in Table 6, a fault signal is activated and the OUT is turned off. The tolerance of the OCP threshold is ±5%; it keeps the accurate OCP in the system design.

</table>

Typically the maximum short-circuit current magnitude of the IGBT is gate-voltage dependent. A higher gate voltage results in a larger short-circuit current. Generally the maximum overcurrent trip level is set to below 2 times the nominal rated collector current. The overcurrent protection timing chart is shown in Figure 10.

![Figure 10: Timing chart of OCP](image-url)
Low-side driver with over-current protection and fault/enable (negative current sense)

Protection features

3.2.2 Selecting $R_{CS}$

The value of the $R_{CS}$ is calculated by the following equation:

$$R_{CS} = \frac{V_{OCTH}}{I_{OC}}$$  \hspace{1cm} (1)

Where $I_{OC}$ is the current of the overcurrent (OC) detection level.

The maximum value of the OC protection level should be set lower than the repetitive peak collector current in the datasheet considering the tolerance of $R_{CS}$.

For example, if the OCP is 25 A, the recommended value of the $R_{CS}$ is calculated as

$$R_{CS}(\text{min}) = \frac{0.25}{25} = 10 \text{ mΩ}$$

For the power rating of the $R_{CS}$, the following list should be considered:

- Maximum load current ($I_{\text{rms}}$)
- $R_{CS}$ value at $T_c = 25 °C$
- Power derating ratio of $R_{CS}$ at $T_c = 100 °C$ according to the manufacturer’s datasheet
- Safety margin

The $R_{CS}$ power rating is calculated by the following equation:

$$P_{SC} = \frac{I_{\text{rms}}^2 \times R_{SC} \times \text{margin}}{\text{derating ratio}}$$  \hspace{1cm} (2)

For example, if $R_{SC} = 10 \text{ mΩ}$:

- Max. load current: 4 A (rms)
- Power derating ratio of $R_{CS}$ at $T_c = 100 °C$ : 80%
- Safety margin : 50%

$$P_{SC} = \frac{4^2 \times 0.01 \times 1.5}{0.8} = 0.3 \text{ W}$$

A proper power rating of $R_{CS}$ is over 0.3 W, e.g. 0.5 W.

A proper resistance and power rating higher than the minimum value should be chosen considering the OCP level required in the application.

3.2.3 OCP delay time

The internal OCP blanking time ($t_{BL}$, Table 7 shows the specification) is necessary in the OC sensing circuit to prevent malfunction of the OCP caused by noise. If the internal blanking time is not sufficient to suppress the noise, an additional external RC filter is necessary. The RC time constant is determined by considering the noise duration and the short-circuit withstand time capability of the IGBT.
Low-side driver with over-current protection and fault/enable
(negative current sense)

Protection features

The sensing voltage on $R_{CS}$ is applied to the OCP pin of 1ED44175N01B via the RC filter. The filter delay time ($t_{FILTER}$) that the input voltage of OCP pin negatively rises to the OCP minus threshold voltage is caused by RC filter time constant.

In addition there is a shutdown propagation delay of OCP ($t_{OCPDEL}$, the time from OCP happening to output shutdown). Please refer to Table 8.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Item</td>
<td>Min.</td>
</tr>
<tr>
<td>OCP to output shutdown propagation delay $t_{OCPDEL}$</td>
<td>—</td>
</tr>
</tbody>
</table>

Therefore, the total delay time from OCP threshold ($V_{OCTH}$) to the shutdown of the IGBT becomes:

$$t_{TOTAL} = t_{FILTER} + t_{OCPDEL}$$  \hspace{1cm} (3)

Shutdown propagation delay is inversely proportional to the current rating, therefore the $t_{TOTAL}$ is reduced at higher current conditions. The total delay must be less than the short-circuit withstanding time ($t_{SC}$) of the IGBT in the datasheet. If the $t_{SC} = 3 \mu s$, the RC time constant should be set in the range of 1 $\mu$s. Recommended values for the filter components are $R = 680 \Omega$ and $C = 1 \text{nF}$.
3.3 Fault output circuit and fault clear time setup

The 1ED44175N01B provides an integrated fault reporting output and an adjustable fault clear timer. There are two situations that would cause the driver to report a fault via the EN/FLT pin. The first is an undervoltage condition of $V_{CC}$ and the second is if the OCP pin recognizes a fault. Once the fault condition occurs, the EN/FLT pin is internally pulled to COM. The EN/FLT output stays in the low state until the fault condition has been removed and the internal pull down MOSFET $Q_{FLT}$ turns off, the voltage on the EN/FLT pin is charged up with internal and external pull-up voltage.

The length of the fault clear time period ($t_{FLTC}$) is determined by exponential charging characteristics of the capacitor where the time constant is set by $R_{FLTC}$ and $C_{FLTC}$. Figure 11 and Figure 5 show that $R_{FLTC}$ is connected between the external supply ($V_{dd} = 3.3$ V) and the EN/FLT pin, while $C_{FLTC}$ is placed between the EN/FLT and COM pins. Actually the EN/FLT pin is pulled up to 3.3 V with a 2.15 MΩ pull-up resistor internally.

If the $V_{dd} = 3.3$ V, the length of the fault clear time period can be determined by using the formula below.

$$t_{FLTC} = \left(\frac{R_{FLTC} \times 2.15M}{R_{FLTC} + 2.15M}\right) \times C_{FLTC} \times \ln\left(1 - \frac{V_{ENH}}{V_{dd}}\right)$$

Where $V_{ENH}$ is fault clear threshold voltage (typical 2.1 V).

The sample of $t_{FLTC}$ setup:

If $C_{FLTC} = 150$ pF, $R_{FLTC} = 1$ MΩ, $V_{dd} = 3.3$ V, then

$$t_{FLTC} = \left(\frac{1 \times 2.15M}{1M + 2.15M}\right) \times 150\text{pF} \times \ln\left(1 - \frac{2.1V}{3.3V}\right) = 103\text{us}$$

![Figure 11 Diagram of the fault output circuit and fault clear time setup](image)

If the $C_{FLTC}$ is not connected and $R_{FLTC}$ is pulled up to $V_{CC}$ with 10 kΩ resistor, the gate driver can implement overcurrent protection cycle by cycle. The feature of OCP with cycle by cycle can limit the peak inductor current in low-line voltage and prevent the saturation of the PFC inductor.

3.4 Enable input circuit

1ED44175N01B provides an enable functionality that allows to shutdown or to enable the output. When EN/FLT is pulled up (the enable voltage is higher than \( V_{ENH} \)), the output is able to operate normally, pulling EN/FLT low (the enable voltage is lower than \( V_{ENL} \)), the output is disable. The enable function is latched up. After a disable event, 1ED44175N01B will wait for a new input signal on IN before it activates the output stage. See the threshold voltage of \( V_{ENH} \) and \( V_{ENL} \) in Table 9 and Figure 12.

The relationships between the input (IN), output (OUT) and enable (EN/FLT) signals of the 1ED44175N01B are illustrated below in Figure 13.

From Figure 14, we can see the definitions of the timing parameter \( t_{\text{DISA}} \) associated with this device. \( t_{\text{DISA}} \) is the delay time from enable signal pulling down to output shutting down. Please refer to Table 10.

4 Driving capability

4.1 $I_{O+}$ and $I_{O-}$

The 1ED44173N01B provides minimum 2 A source or sink driving capability (see Table 11) which is large enough to drive most discrete PFC switches, e.g. the IGBT.

5 EVAL-1ED44175N01B adapter board

A small, dual purpose adapter board (EVAL-1ED44175N01B, see Figure 15) is available for testing the 1ED44175N01B inside an actual switched-mode application.

The board includes a 1ED44175N01B SOT-236 low-side driver with OCP and enable/fault output, TO-247 footprint of gate and emitter for IGBT, and other SMD components. The adapter board can be easily connected into an existing switched-mode power circuit for fast in-circuit evaluation.

6  Recommended related products

The 1ED4175N01B is able to drive up to 75 A/650 V IGBTs from Infineon at frequency up to 50 kHz for PFC applications. The power rating is up to 3 kW. If the higher frequency is required for the application, Infineon’s CoolSiC™ SiC MOSFET is a good choice. Some parts of the IGBT, CoolSiC™, rapid switching emitter-controlled diode and silicon carbide CoolSiC™ Schottky diode from Infineon in PFC applications are recommended in Table 12, Error! Reference source not found., Table 14 and Table 15. Table 16 shows Infineon’s CIPOS™ Mini IPM with integrated PFC Stage.
