About this document

Scope and purpose
This document provides application information for the transceiver TLE7250X from Infineon Technologies AG as Physical Medium Attachment within a Controller Area Network (CAN).

This document contains information about:
• set-ups for CAN application
• mode control
• fail safe behavior
• power supply concepts
• power consumption aspects

This document refers to the data sheet of the Infineon Technologies AG CAN Transceiver TLE7250X.

Note: The following information is given as a hint for the implementation of our devices only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

Intended audience
This document is intended for engineers who develop applications.

1 CAN Application

With the growing number of electronic modules in cars the amount of communication between modules increases. In order to reduce wires between the modules CAN was developed. CAN is a Class-C, multi master serial bus system. All nodes on the bus system are connected via a two wire bus. A termination of $R_T = 120 \, \Omega$ or a split termination ($R_T/2 = 60 \, \Omega$ and $C_T = 4.7 \, \text{nF}$) on two nodes within the bus system is recommended. Typically an ECU consists of:
- power supply
- microcontroller with integrated CAN protocol controller
- CAN transceiver

The CAN protocol uses a lossless bit-wise arbitration method of conflict resolution. This requires all CAN nodes to be synchronized. The complexity of the network can range from a point-to-point connection up to hundreds of nodes. A simple network concept using CAN is shown in Figure 1.

![Figure 1 CAN Example with Typical ECU Using TLE7250X](image_url)

The CAN bus physical layer has two defined states: dominant and recessive. In recessive state CANH and CANL are biased to $V_{CC}/2$ (typ. 2.5 V) and the differential output voltage $V_{\text{diff}}$ is below 0.5 V. A “low” signal applied to TxD pin generates a dominant state on CANH and CANL. The voltage on CANH changes towards $V_{CC}$ and CANL goes towards GND. The differential voltage $V_{\text{diff}}$ is higher than 0.9 V.
The CAN physical layer is described in ISO 11898-2. The CAN transceiver TLE7250X fulfills all parameters defined in ISO 11898-2. This document describes CAN applications with the TLE7250X. It provides application hints and recommendations for the design of CAN electronic control units (ECUs) using the CAN transceiver TLE7250X from Infineon Technologies AG.

2 TLE7250X Description

The transceiver TLE7250X represents the physical medium attachment, interfacing the CAN protocol controller to the CAN transmission medium. The transmit data stream of the protocol controller at the TxD input is converted by the CAN transceiver into a bus signal. The receiver of the TLE7250X detects the data stream on the CAN bus and transmits it via the RxD pin to the protocol controller.

2.1 Features

The main features of the TLE7250X are:

- Baud rate up to 2 Mbit/s
- Very low Electromagnetic Emission (EME) and high Electromagnetic Immunity (EMI)
- Excellent ESD performance according to HBM (+/-9 kV) and IEC (+/-8 kV)
- Very low current consumption in mode
- Transmit data (TxD) dominant time-out function
- Supply voltage range 4.5 V to 5.5 V
- Control input levels compatible with 3.3 V and 5 V devices
- Thermal shutdown protection

2.2 Mode Description

The TLE7250X supports three different modes of operation. The mode of operation depends on the status of the reference power supply and the status of the mode selection pin RM:

- Normal-operating mode: Used for communication on the HS CAN bus. Transmit and receive data on the bus.
- Receive-only mode: Allows diagnostics (to avoid the acknowledge bit (ACK) implemented by software), to check modules connections or to avoid communication errors on the bus due to microcontroller failure. Blocking babbling idiots from disturbing communication. Used for Pretended Networking to set ECU and microcontroller to low-power mode, waiting for a specific message to switch to Normal-operating mode. Pretended Networking is used to reduce current consumption of ECUs.
- Forced-power-save mode: Same behavior as Power-save mode implemented as a fail-safe mode for $V_{CC}$ undervoltage condition. Reduces current consumption in afterrun when there is no communication on the HS CAN bus with ECU still active. Emergency undervoltage state when the microcontroller detects undervoltage and starts saving internal information.

![Figure 3 Pin Configuration of the TLE7250X](top-side-x-ray-view)
3 In Vehicle Network Applications

The TLE7250/51-Family offers a perfect match for various ECU requirements. For partially supplied ECUs (Clamp 15) the TLE7250X is suitable. According to the requirements of automobile manufacturers, the modules can either be permanently supplied or unsupplied during the car is parked. The main reason for unsupplied modules is saving battery energy. Permanently supplied modules can wake up quickly via CAN message.

3.1 Clamp 30 and Clamp 15

Clamp 30:
Permanently supplied modules, even when the car is parked are required by body applications such as door modules, RF keyless entry receivers, etc. Modules are directly connected to the battery. This supply line is called clamp 30. As battery voltage is present permanently, the voltage regulator, transceiver and microcontroller are always supplied. Therefore voltage regulator, transceiver and microcontroller need to be set to low-power mode in order to reduce current consumption to a minimum.

Clamp 15:
Partially supplied modules are typically used in under hood applications such as ECUs. When the car is parked a main switch or ignition key switches off the battery supply. This supply line is called clamp 15. When the battery voltage is not present, the voltage regulator and transceiver are switched off.

Figure 4 CAN with ECUs Using TLE7250X

In Clamp 15 applications there is no need to use transceivers with bus wake-up feature. Therefore TLE7250X offers three different modes, that make applications more flexible (see Chapter 2.2). For applications that do not use the bus wake-up feature, the TLE7250X offers the Power-save mode with very low current consumption. There is also the possibility to reduce the current consumption of the ECU more by disconnecting the TLE7250X from the power supply. If communication is still on the HS CAN bus, then the TLE7250X has a perfect passive bus behavior in order not to affect CAN bus communication, while the TLE7250X is switched off.
3.2 Baud Rate versus Bus Length

Table 2 Recommended Baud Rate versus Bus Length

<table>
<thead>
<tr>
<th>Baud Rate (kbit/s)</th>
<th>Bus Length (m) Maximum Distance between two Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>

<td>120</td>
</tr>
<tr>
<td>125</td>
<td>500</td>
</tr>
<tr>
<td>50</td>
<td>1000</td>
</tr>
</tbody>
</table>

Baud rate is limited by:
- bus length
- ringing
- propagation delay of cables
- propagation delay of the CAN controller of the transceiver

The two most distant nodes (A and B) in a CAN network are the limiting factor in transmission speed. The propagation delays must be considered because a round trip has to be made from the two most distant CAN controllers on the bus.

Worst case scenario: When node A starts transmitting a dominant signal, it takes a certain period of time \( t = t_{\text{CAN controller}} + t_{\text{Transceiver}} + t_{\text{Cable}} \) until the signal arrives at node B.

The propagation delay is estimated by: CAN controller delay, transceiver delay, bus length delay. Assumption: 70 ns for CAN controller, 255 ns for transceiver, 5 ns per meter of cable. Example with 50 m cable length:

\[
t_{\text{prop}} = t_{\text{CAN controller}} + t_{\text{Transceiver}} + t_{\text{Cable}} + t_{\text{CAN controller}} + t_{\text{Transceiver}} + t_{\text{Cable}} = 70 \text{ ns} + 255 \text{ ns} + 50 \times 5 \text{ ns/m} + 70 \text{ ns} + 255 \text{ ns} + 50 \times 5 \text{ ns/m} = 1150 \text{ ns}
\]

Some other factors of great influence on the maximum baud rate are cable capacitance, oscillator tolerance, ringing and reflection effects depending on the network topology. In addition to theoretical maximum propagation delay all other effects must be taken into account and an additional margin of safety must be added. Wire resistance increases with bus length and therefore the bus signal amplitude may be degraded.
4 CAN FD

CAN FD (Flexible Data Rate) is the advanced version of classical CAN. Classical CAN is specified by ISO 11898-2 for data transmission rate up to 1 Mbit/s. For CAN FD with higher data transmission rate (2 Mbit/s) ISO 11898-2 specifies additional timing parameters. CAN FD uses the same physical layer as classical CAN does, but allows higher data transmission rate and increased payload per message. During the arbitration phase and checksum the data transmission rate is the same as for classical CAN (1 Mbit/s). As soon as one node in the CAN FD network starts transmitting the payload, the data rate increases (2 Mbit/s). The increase in baud rate is possible as only one node transmits during the data transmission phase. All other nodes listen to the data on the CAN bus. Instead of 8 bytes per message (classical CAN) payload is increased up to maximum 64 byte per message. Using CAN FD saves transmission time and allows increased data payload. In order to ensure reliable data transmission, CAN FD requires a CAN transceiver with full ISO 11898-2 specification for Flexible Data rate up to 2 Mbit/s.

The TLE7250X from Infineon Technologies AG is the perfect match for CAN FD networks. TLE7250X fulfills or exceeds all classical CAN and CAN FD parameters of ISO 11898-2 in order to enable smooth and safe usage within applications.

![Figure 6 Classical CAN Data Rate and CAN FD Data Rate](image-url)
5 Pin Description

5.1 VIO Pin
The VIO pin is needed for the operation with a microcontroller that is supplied by VIO < VCC, to get the correct level between microcontroller and transceiver. It can also be used to decouple microcontroller and transmitter supply. This concept improves EMC performance and the transmitter supply VCC can be switched off separately.

The digital reference supply voltage VIO has two functions:

- supply of the internal logic of the transceiver (state machine)
- voltage adaption for external microcontroller (3.0 V < VIO < 5.5 V)

As long as VIO is supplied (VIO > 3.0 V) the state machine of the transceiver works and mode changes can be performed. If a microcontroller uses low VIO < VCC = 5 V, then the VIO pin must be connected to the power supply of the microcontroller. Due to this feature, the TLE7250X can work with various microcontroller supplies. If VIO is available, then both transceiver and microcontroller are fully functional. Below VIO < 3.0 V the TLE7250X is in Power On Reset state. To enter Normal-operating mode VIO > 3.0 V is required.

5.2 VCC Pin
The VCC pin supplies the transmitter output stage. The transmitter operates according to data sheet specifications in the voltage range of 4.5 V < VCC < 5.5 V. Voltage VCC > 6 V can damage the device. If VCC < VCC_UV, then the transmitter is disabled. The undervoltage threshold VCC_UV is in the range from 3.65 V to 4.3 V. If VCC_UV < VCC < 4.5 V, then the transmitter is enabled and can then send data to the bus, but parameters may be outside the specified range.

5.3 RM Pin
The RM pin sets the mode of TLE7250X and is usually directly connected to an output port of a microcontroller. To set the device in Normal-operating mode, in order to activate the data stream from the microcontroller on the TxD pin, the RM pin must be set to “low”. Because the TLE7250X has an integrated pull-down resistor to GND, by default the device is in Normal-operating mode. If Receive-only mode is not used, then the RM pin must be connected to GND to protect the transceiver from disturbance. The user can deactivate the transmitter of TLE7250X either by setting the RM pin to “high” or by switching off VCC. This can be used to implement two different fail safe paths in case a failure is detected in the ECU. Table 3 shows mode changes by the RM pin, assuming VIO > VIO_UV. Features and modes of operation are described in Chapter 2.

</tr>
</tbody>
</table>

5.4 TxD Pin
TxD is an input pin. TxD pin is used to receive the data stream from the microcontroller. If VIO > VIO_UV, then the data stream is transmitted to the HS CAN bus. A “low” signal causes a dominant state on the bus and a “high” signal causes a recessive state on the bus. The “high” signal must be adapted according to the voltage on the
Pin Description

$V_{\text{IO}}$ pin. This means the “high” level must not exceed $V_{\text{IO}}$ voltage. The TxD input pin has an integrated pull-up resistor to $V_{\text{IO}}$. If TxD is permanently “low”, for example due to a short circuit to GND, then the TxD time-out feature will block the signal on the TxD input pin (see Chapter 8.1). It is not recommended to use a series resistor within the TxD line between transceiver and microcontroller. A series resistor may add delay, which degrades the performance of the transceiver, especially in high data rate applications. The data stream sent from the microcontroller to the TxD pin of the transceiver is only transmitted to the HS CAN bus in Normal-operating mode. In all other modes the TxD input pin is blocked.

5.5 RxD Pin

RxD is an output pin. The data stream received from the HS CAN bus is displayed on the RxD output pin in Normal-operating mode, Receive-only mode. It is not recommended to use a series resistor within the RxD line between transceiver and microcontroller. A series resistor may add delay, which degrades the performance of the transceiver, especially in high data rate applications.

5.6 CANH and CANL Pins

CANH and CANL are the CAN bus input and output pins. The TLE7250X is connected to the bus via pin CANH and CANL. Transmitter output stage and receiver are connected to CANH and CANL. Data on the TxD pin is transmitted to CANH and CANL and is simultaneously received by the receiver input and signalled on the RxD output pin. For achieving optimum EME (Electromagnetic Emission) performance, transitions from dominant to recessive and from recessive to dominant are done as smooth as possible also at high data rate. Output levels of CANH and CANL in recessive and dominant state are described in Table 1. Due to the excellent ESD performance on CANH and CANL no external ESD components are necessary to fulfill OEM requirements.

5.7 GND Pin

The GND pin must be connected as close as possible to module ground in order to reduce ground shift. It is not recommended to place filter elements or an additional resistor between GND pin and module ground. GND must be the same for transceiver, microcontroller and HS CAN bus system.
6 Transceiver Supply

The internal logic of TLE7250X is supplied by the $V_{io}$ pin. The $V_{cc}$ pin 5 V supply is used to create the CANH and CANL signal. The transmitter output stage as well as the main CAN bus receiver are supplied by the $V_{cc}$ pin. This chapter describes aspects of power consumption and voltage supply concepts of TLE7250X.

6.1 Voltage Regulator

It is recommended to use one of the following Infineon low drop output (LDO) voltage regulators, depending on the $V_{io}$ power supply concept:

- 3.3 V $V_{io}$ power supply: TLS850D0TAV33 (500mA)$^{1)$, TLS850F0TAV33 (500mA)$^{1)$, TLS810B1LDV33$^{2)$ (100mA), TLE4266-2GS V33 (150mA),
- 5 V $V_{io}$ and $V_{cc}$ power supply: TLS850D0TAV50$^{1)$ (500mA), TLS850F0TA V50 (500mA), TLE810D1EJV50 (100mA), TLS810B1LDV50 (100mA), TLE4266-2 (150mA)
- 3.3 V and 5 V dual voltage power supply: TLE4476D
- Dual 5V voltage power supply: TLE4473GV55

Please refer to Infineon Linear Voltage Regulators for the Infineon voltage regulator portfolio, data sheets and application notes.

6.2 External Circuitry

In order to reduce EME and to improve the stability of input voltage level on $V_{cc}$ and $V_{io}$ of the transceiver, it is recommended to place capacitors on the PCB. During sending a dominant bit to the HS CAN bus, current consumption of TLE7250X is higher than during sending a recessive bit. Data transmission can change the load profile on $V_{cc}$. Changes in load profile may reduce the stability of $V_{cc}$. If several CAN transceivers are connected in parallel, and if these CAN transceivers are supplied by the same $V_{cc}$ and/or $V_{io}$ power supply (for example LDO), then the impact on the stability of $V_{cc}$ is even stronger. It is recommended to place a 100 nF capacitor as close as possible to $V_{cc}$ and $V_{io}$ pin. The output of the $V_{cc}$ and $V_{io}$ power supply (for example LDO) must be stabilized by a capacitor in the range of 1 to 50 µF, depending on the load profile. Ceramic capacitors are recommended for low ESR.

6.3 $V_{io}$ Feature

TLE7250X offers a $V_{io}$ supply pin, which is a voltage reference input for adjusting the voltage levels on the digital input and output pins to the voltage supply of the microcontroller. In order to use the $V_{io}$ feature, connect the power supply of the microcontroller to the $V_{io}$ input pin. Depending on the voltage supply of the microcontroller, TLE7250X can operate with the $V_{io}$ reference voltage input within the voltage range from 3.0 V to 5.5 V.

6.3.1 $V_{io}$ 3.3 V - 5.5 V Power Supply Concept

The $V_{io}$ pin supplies the internal logic of the TLE7250X. TLE7250X can operate with the $V_{io}$ reference voltage input in the range from 3.0 V to 5.5 V. The $V_{cc}$ pin (typ. = 5 V) supplies the transmitter of TLE7250X. Therefore the $V_{cc}$ supply input pin must be connected to a 5 V voltage regulator. Competitor devices use $V_{cc}$ to supply the internal logic and the transmitter output stage and $V_{io}$ as a simple level shifter. Infineon’s HS CAN transceivers can work in $V_{cc}$ undervoltage condition or even with $V_{cc}$ completely switched off in Forced-power-save mode.

1) Planned SOP Q2 2016
2) Planned SOP Q4 2016
6.3.2 \( V_{\text{IO}} \) 3.3 V Power Supply

In order to reduce power consumption of ECU, the microcontroller might not be supplied by \( V_{\text{CC}} \) but by a lower voltage (for example 3.3 V). Therefore the TLE7250X offers a \( V_{\text{IO}} \) supply pin, which is a voltage reference input in order to adjust the voltage levels on the digital input and output pins to the voltage supply of the microcontroller. The \( V_{\text{IO}} \) feature enables the TLE7250X to operate with a microcontroller, which is supplied by a voltage lower than \( V_{\text{CC}} \). With the \( V_{\text{IO}} \) reference voltage input the TLE7250X can operate from 3.0 V to 5.5 V.

![3.3 V Power Supply Concept](image)

6.3.3 \( V_{\text{IO}} \) 5 V Supply

TLE7250X can also operate with a 5 V supply because of the \( V_{\text{IO}} \) input voltage range from 3.0 V to 5.5 V. If the microcontroller uses \( V_{\text{CC}} = 5 \) V supply, then \( V_{\text{IO}} \) is connected to \( V_{\text{CC}} \). The \( V_{\text{IO}} \) input must be connected to the supply voltage of the microcontroller.

![5 V Power Supply Concept](image)

6.3.4 Dual 5 V Supply Concept

In order to decouple the microcontroller and the HS CAN Bus from each other with respect to noise and disturbances, it is possible to use a dual 5 V voltage regulator like TLE4473GV55. In this case two independent 5 V LDOs supply \( V_{\text{IO}} \) and \( V_{\text{CC}} \). This power supply concept improves EMC behavior and reduces noise.
6.4 Current Consumption

Current consumption depends on the mode of operation:

- Normal-operating mode:
  Maximum current consumption of TLE7250X on the $V_{CC}$ supply is specified as 60 mA in dominant state and 4 mA in recessive state. Maximum current consumption of TLE7250X on the $V_{IO}$ supply is specified as 1 mA.
  To estimate theoretical current consumption in Normal-operating mode, a duty cycle of 50% can be assumed, with fully loaded bus communication of 50% dominant and 50% recessive. In Normal-operating mode the TLE7250X consumes in worst case maximum:

  \[
  I_{CC\_AVG} = \frac{I_{CC\_REC} + I_{CC\_DOM}}{2} + I_{IO} = 32.5 \text{ mA}
  \]

  Typically the current consumption is less than 15 mA.

- Receive-only mode:
  In Receive-only mode the TLE7250X has a worst case maximum current consumption of $I_{ROM} = 3 \text{ mA}$.
  Typically the current consumption is less than 3mA.

- Power-save mode Forced-power-save mode:
  In Power-save mode most of the functions are turned off. The maximum current consumption is specified as 8 $\mu$A.

6.5 Loss of Battery (Unsupplied Transceiver)

When TLE7250X is unsupplied, CANH and CANL act as high impedance. The leakage current $I_{CANH,} I_{CANL}$ at CANH pin or CANL pin is limited to +/- 5 $\mu$A in worst case. When unsupplied, TLE7250X behaves like a 1 M$\Omega$ resistor towards the bus. Therefore the device perfectly fits applications that use both Clamp 15 and Clamp 30.

6.6 Loss of Ground

If loss of ground occurs, then the transceiver is unsupplied and behaves like in unpowered state.

In applications with inductive load connected to the same GND, for example a motor, the transceiver can be damaged due to loss of ground. Excessive current can flow through the CAN transceiver when the inductor demagnetizes after loss of ground. The ESD structure of the transceiver cannot withstand that kind of Electrical Overstress (EOS). In order to protect the transceiver and other components of the module, an inductive load must be equipped with a free wheeling diode.
Due to ground shift the GND levels of CAN transceivers within a network may vary. Ground shift occurs in high current applications or in modules with long GND wires. The receiver input stage acts like a resistor \(R_i\) to GND. Because the transmitting node has its GND shifted to \(V_{shift}\), the recessive voltage level \(V_{rec}\) from the chassis ground is no longer 2.5 V but \(V_{rec} + V_{shift}\). The same ground shift voltage \(V_{shift}\) must be taken into account for the dominant signal. Because CAN uses a differential signal and because of the wide common mode range of +/-12 V for Infineon transceivers, any CANH and CANL DC value within absolute maximum ratings works.

The recessive CAN bus level \(V_{rec}\) during a ground shifted node transmitting is equal to the average recessive voltage level of all transceivers:

\[
V_{rec} = \frac{\left( V_{rec,1} + V_{shift,1} \right) + \left( V_{rec,2} + V_{shift,2} \right) + \left( V_{rec,3} + V_{shift,3} \right) + \ldots + \left( V_{rec,n} + V_{shift,n} \right)}{n}
\]

\(n\): number of connected CAN nodes

\(V_{rec,1}, V_{rec,2}, \ldots, V_{rec,n}\): specific recessive voltage level of the transceiver at nodes 1, 2, .. n

\(V_{shift,1}, V_{shift,2}, \ldots, V_{shift,n}\): specific ground shift voltage level of the transceiver at nodes 1, 2, .. n

The supply current of a ground shifted transceiver increases by \(I_{CC_{shift}} = \frac{V_{shift}}{R_{i,n} / n}\), assuming all input resistances at CANH and CANL of the transceivers are identical.
7 Transceiver Control

The modes of the TLE7250X are controlled by the pin RM and by transmitter voltage $V_{CC}$.

7.1 Mode Change by RM

The mode of operation is set by the mode selection pin RM. By default the RM input pin is “low” due to the internal pull-down resistor to GND.

If $V_{CC} > V_{CC_{UV}}$, then the TLE7250X is in Receive-only mode. In order to change the mode to Normal-operating mode, RM must be switched to “low” and $V_{CC}$ must be available.

7.2 Mode Change Delay

The HS CAN transceiver TLE7250X changes the mode of operation within the transition time period $t_{Mode}$. The transition time period $t_{Mode}$ must be considered in developing software for the application. After the mode change from Receive-only mode to Normal-operating Mode the transmitter is enabled.

Figure 11 Receiving and Transmitting Node during Mode Change (Normal-Operating Mode to Receive-Only Mode)

The RxD output pin is not blocked nor be set to “high” during the following mode changes:

- Normal-operating mode → Receive-only mode
- Receive-only mode → Normal-operating mode

7.3 Mode Change due to $V_{CC}$ Undervoltage

A mode change due to $V_{CC}$ undervoltage is only possible in Normal-operating mode and in Receive-only mode. If $V_{CC}$ Undervoltage persists longer than $t_{Delay(UV)}$, then the TLE7250X changes from Normal-operating mode or Receive-only mode to Forced-receive-only mode Forced-power-save mode. As soon as TLE7250X detects an undervoltage, it disables the transmitter output stage so that no faulty data is sent to the HS CAN bus.

In order to reduce current consumption during $V_{CC} < V_{CC_{UV}}$ fault condition, the TLE7250X has a optimized
current consumption in Forced-power-save mode.
If $V_{CC}$ recovers, then $V_{CC} > V_{CC_{UV}}$ triggers a mode change back to Normal-operating mode.

Figure 12  $V_{CC}$ Undervoltage and Recovery

Figure 13  Recovery of $V_{CC}$ in Forced Power-Save Mode
8 Failure Management

This chapter describes typical bus communication failures.

8.1 TxD Dominant Time-out Detection

The TxD dominant time-out detection of TLE7250X protects the CAN bus from being permanently driven to dominant level. When detecting a TxD dominant time-out, the TLE7250X disables the transmitter in order to release the CAN bus. Without the TxD dominant time-out detection, a CAN bus would be clamped to the dominant level and therefore would block any data transmission on the CAN bus. This failure may occur for example due to TxD pin shorted to ground.

The TxD dominant time-out detection can be reset after a dominant to recessive transition at the TxD pin. A “high” signal must be applied to the TxD input for at least $t_{\text{TxD,release}} = 200$ ns to reset the TxD dominant timer.

![Figure 14 Resetting TxD Dominant Time-out Detection](image)

The input signal on RM input pin does not modify the TxD dominant timer state and therefore ensures no dominant CAN Signal is driven to the CAN bus.

8.2 Minimum Baud Rate and Maximum TxD Dominant Phase

Due to the TxD dominant time-out detection of the TLE7250X the maximum TxD dominant phase is limited by the minimum TxD dominant time-out time $t_{\text{TxD}} = 4.5$ ms. The CAN protocol allows a maximum of 11 subsequent dominant bits at TxD pin (worst case dominant bits followed immediately by an error frame). With a minimum value of 4.5 ms given in the datasheet and maximum possible 11 dominant bits, the minimum baud rate of the application must be higher than 2.44 kbit/s.
8.3 Short Circuit

Figure 15 shows short circuit types on the HS CAN bus. The CANH and CANL pins are short circuit proof to GND and to supply voltage. A current limiting circuit protects the transceiver from damage. If the device heats up due to a permanent short at CANH or CANL, then the overtemperature protection switches off the transmitter. Depending on the type of short circuit on CANH and CANL, communication might be still possible. If only CANH is shorted to GND or only CANL is shorted to \( V_{BAT} \), then dominant and recessive states may be recognized by the receiver. Timings and/or differential output voltages might be not valid according to ISO11898 but still in the range for the receiver working properly.

Communication on the HS CAN bus is blocked in the following cases:

- CANH and CANL shorted (Case 7)
- CANH shorted to GND (Case 5)
- CANL shorted to \( V_{BAT} \) (Case 2) or \( V_{CC} \) (Case 4)

If a short circuit occurs, the \( V_{CC} \) supply current for the transceiver can increase significantly. It is recommended to dimension the voltage regulator for the worst case, especially when \( V_{CC} \) also supplies the microcontroller. \( V_{CC} \) supply current only increases in dominant state. The recessive current remains almost unchanged.

**CANH shorted to GND**

The datasheet specifies a maximum short circuit current of 100mA. Transmitting a dominant state to the bus, 5V is shorted to GND through the transmitter output stage. Power dissipation with 10% duty cycle (DCD) is:

\[
P = \text{DCD} \times U \times I = 0.1 \times 5V \times 100mA = 0.05W.
\]

The average fault current with worst case parameters and assuming a realistic duty cycle of 10% is:

\[
l_{CC,Fault} = l_{CC,rec} \times 0.9 + l_{CANH,SC} \times 0.1 = 13.6mA.
\]

**CANL shorted to \( V_{BAT} \)**

If CANL is shorted to \( V_{BAT} \), then the current through the CANL output stage is even higher and the device heats up faster. The datasheet specifies a maximum short circuit current of 100mA. When transmitting a dominant state to the bus, \( V_{BAT} \) is shorted to GND through the transmitter output stage. Assuming a realistic duty cycle of 10% for this case and the power dissipation is:

\[
P = \text{DCD} \times U \times I = 0.1 \times V_{BAT} \times 100mA = 0.1 \times 18V \times 100mA = 0.18W.
\]

**CANH shorted to \( V_{BAT} \)**

Short circuit of CANH to \( V_{BAT} \) can result in a permanent dominant state on the HS CAN bus, due to the voltage drop at the termination resistor. Therefore the termination resistor has to be chosen accordingly. If a short circuit of CANH to \( V_{BAT} \) occurs, then the power loss in the termination resistor must be taken into account. Figure 16 shows the current in case CANH is shorted to \( V_{BAT} \). When transmitting a dominant state to the bus, the current flows through the termination resistor an CANL to GND. Power loss in the termination resistor and
Application Note
Z8F54978224

Failure Management

CANL assuming a battery voltage of 18 V and a duty cycle of 10% is:
\[ P_{\text{Loss, Termination}} = 0.1 \times (R_{\text{Termination}} \times I_{\text{CANL,SC}}) \times I_{\text{CANL,SC}} = (60\,\Omega \times 100\,\text{mA}) \times 100\,\text{mA} = 0.6\,\text{W} \]
\[ P_{\text{Loss, CANL}} = 0.1 \times (V_{\text{BAT}} - (R_{\text{Termination}} \times I_{\text{CANL,SC}})) \times I_{\text{CANL,SC}} = 0.1 \times (18\,\text{V} - 6\,\text{V}) \times 100\,\text{mA} = 0.1 \times 12\,\text{V} \times 100\,\text{mA} = 0.12\,\text{W} \]

Figure 16  Current Flowing in Case of a Short Circuit CANH to \( V_{\text{BAT}} \)

8.4  TLE7250X Junction Temperature

In Normal-operating mode highest power dissipation occurs with 50% duty cycle (D) at an ambient temperature of 150 °C:
\[ P_{\text{NM,MAX}} = D \times (I_{\text{CC,R}} \times V_{\text{CC,MAX}}) + D \times (I_{\text{CC,D}} \times V_{\text{CC,MAX}}) + (I_{\text{O}} \times V_{\text{IO,MAX}}) =
\]
\[ = 0.5 \times (4\,\text{mA} \times 5.5\,\text{V}) + 0.5 \times (60\,\text{mA} \times 5.5\,\text{V}) + (1.5\,\text{mA} \times 5.5\,\text{V}) = 184.25\,\text{mW}. \]

Junction temperature increases due to power dissipation and depending on the package. However, typical conditions are more like this: ambient temperature is below 150 °C, overall duty cycle is less than 50%, and supply voltages \( V_{\text{CC}} \) and \( V_{\text{IO}} \) have their typical values instead of maximum values.

Power dissipation is much lower for such typical conditions:
\[ P_{\text{NM,AVG}} = D \times (I_{\text{CC,R,Typ}} \times V_{\text{CC,Typ}}) + D \times (I_{\text{CC,D,Typ}} \times V_{\text{CC,Typ}}) + (I_{\text{O,Typ}} \times V_{\text{IO,Typ}}) =
\]
\[ = 0.9 \times (2\,\text{mA} \times 5\,\text{V}) + 0.1 \times (38\,\text{mA} \times 5\,\text{V}) + (1\,\text{mA} \times 3.3\,\text{V}) = 23.3\,\text{mW}. \]

</table>

If a short circuit occurs, then the TLE7250X heats up. The higher the duty cycle, the higher the power dissipation. If a thermal shutdown occurs due to high temperature, then the receiver is still enabled with only the transmitter disabled. The behavior is identical to Receive-only mode.
9 PCB Layout Recommendations for CAN FD

The following layout rules should be considered to achieve best performance of the transceiver and the ECU:

- **TxD and RxD connections to microcontroller should be as short as possible.**
- For each microcontroller the TxD driver output stage current capability may vary depending on the selected port and pin. The driver output stage current capability should be strong enough to guarantee a maximum propagation delay from μC port to transceiver TxD pin of less than 30ns.
- Place two individual 100nF capacitors close to $V_{CC}$ and $V_{IO}$ pins for local decoupling. Due to their low resistance and lower inductance compared to other capacitor types, it is recommended to use ceramic capacitors.
- If a common mode choke is used, it has to be placed as close as possible to the bus pins CANH and CANL.
- Avoid routing CANH and CANL in parallel to fast-switching lines or off-board signals in order to reduce noise injection to the bus.
- It is recommended to place the transceiver as close as possible to the ECU connector in order to minimize track length of bus lines.
- Avoid routing digital signals in parallel to CANH and CANL.
- CANH and CANL tracks should have the same length. They should be routed symmetrically close together with smooth edges.
- GND connector should be placed as close as possible to the transceiver.
- Avoid routing transceiver GND and microcontroller GND in series in order to reduce coupled noise to the transceiver. This also applies for high current applications, where the current should not flow through the GND line of transceiver and microcontroller in serial.
- Avoid routing transceiver $V_{CC}$ supply and microcontroller $V_{CC}$ supply in series in order to reduce coupled noise to the transceiver.
- Same dimensions and lengths for all wire connections from the transceiver to CMC and/or termination.
- In case an external ESD protection circuit is used, make sure the total capacitance is lower than 50pF. Use equal ESD protection for CANH and CANL in order to improve signal symmetry.
- For CAN FD application it is recommended to use a Common Mode Choke with 100µH impedance and a Split termination with a capacitance of 4.7nF in order to achieve excellent EME performance in automotive applications.
