Application Note
TLE8251VSJ

About this document

Scope and purpose
This document provides application information for the transceiver TLE8251VSJ from Infineon Technologies AG as Physical Medium Attachment within a Controller Area Network (CAN).

This document contains information about:
• set-ups for CAN application
• improved CAN FD parameters
• mode control
• fail safe behavior
• power supply concepts
• power consumption aspects
• PCB recommendations for CAN FD applications
• pin FMEA

This document refers to the data sheet of the Infineon CAN Transceiver TLE8251VSJ.

Note: The following information is given as a hint for the implementation of our devices only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

Intended audience
This document is intended for engineers who develop applications.

1 CAN Application

With the growing number of electronic modules in cars the amount of communication between modules increases. In order to reduce wires between the modules CAN was developed. CAN is a Class-C, multi master serial bus system. All nodes on the bus system are connected via a two wire bus. A termination of \( R_T = 120 \, \Omega \) or a split termination (\( R_{T/2} = 60 \, \Omega \) and \( C_T = 4.7 \, \text{nF} \)) on two nodes within the bus system is recommended.

An ECU typically consists of:
- power supply
- microcontroller with integrated CAN protocol controller
- CAN transceiver

The CAN protocol uses a lossless bit-wise arbitration method of conflict resolution called CSMA/CA (Carrier Sense Multiple Access/ Collision Avoidance). This requires all CAN nodes to be synchronized. The complexity of the network can range from a point-to-point connection to hundreds of nodes. A simple network concept using CAN is shown in Figure 1.

![Figure 1 CAN Example with Typical ECU Using TLE8251VSJ](image)

The CAN bus physical layer can have the following states (see Figure 2):
- dominant:
  - TxD pin set to “low” generates dominant state
  - voltage at CANH changes towards \( V_{CC} \)
  - voltage at CANL changes towards GND
- recessive:
  CANH and CANL are biased to \( V_{CC}/2 \)

See Table 1 for voltage levels specified for dominant and recessive state.
Application Note
Z8F55275753
CAN Application

ISO 11898-2 describes the CAN physical layer. The CAN transceiver TLE8251VSJ fulfills all parameters defined in ISO 11898-2. This document describes CAN applications with the TLE8251VSJ. It provides application hints and recommendations for the design of CAN electronic control units (ECUs) using the CAN transceiver TLE8251VSJ from Infineon.

2  TLE8251VSJ Description

The transceiver TLE8251VSJ represents the physical medium attachment, that is the interface between the CAN protocol controller and the CAN transmission medium. The CAN transceiver converted the transmit data stream of the protocol controller at the TxD input to a bus signal. The receiver of the TLE8251VSJ detects the data stream on the CAN bus and transmits it to the protocol controller via the RxD pin.

2.1  Features

The main features of the TLE8251VSJ are:

- Baud rate up to 2 Mbit/s with improved CAN FD parameters (see Chapter 4.2)
- Very low Electromagnetic Emission (EME) and high Electromagnetic Immunity (EMI)
- Excellent ESD performance according to HBM (+/-10 kV) and IEC (+/-8 kV)
- Very low current consumption in Stand-by mode: 14 µA
- Transmit data (TxD) dominant time-out function
- Supply voltage range 4.5 V to 5.5 V
- Control input levels compatible with 3.3 V and 5 V devices
- Remote wake-up in Stand-by mode

2.2  Mode Description

The TLE8251VSJ supports three different modes of operation. The mode of operation depends on the status of the reference power supply and the status of the mode selection pin STB:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Use Cases</th>

2.3 TLE825x-Family Pin-out Compatibility

The TLE825x-Family is pin-out and functional compatible to existing Infineon CAN transceivers (see Figure 4). The TLE825x-Family consists of:

- TLE8250SJ
- TLE8250VSJ
- TLE8250XSJ
- TLE8251VSJ

![Figure 4 TLE825x-Family Pin-out Compatibility]
3 In-Vehicle Network Applications

The TLE8250/51-Family offers a perfect match for various ECU requirements. TLE8251VSJ offers improved loop delay symmetry to support CAN FD data frames up to 2 MBit/s (see Chapter 4.2). For permanently supplied ECUs (Clamp 30) as well as for partially supplied ECUs (Clamp 15) the TLE8251VSJ is suitable. According to the requirements of automobile manufacturers, the modules can either be permanently supplied or unsupplied when the car is parked. The main purpose for unsupplied modules is saving battery energy. A CAN message can wake up permanently supplied modules.

3.1 Clamp 30 and Clamp 15

Clamp 30 (permanently supplied networks, connected to battery)

Body applications such as door modules, RF keyless entry receivers require permanently supplied modules. Permanently supplied modules are still powered when the car is not in use. The supply line from the battery is called clamp 30. Because battery voltage is present permanently, the voltage regulator, transceiver and microcontroller are always supplied. Voltage regulators, transceivers and microcontrollers need to be set to low-power mode. Low power mode reduces current consumption and prevents the battery from draining.

Clamp 15 (partially supplied networks, connected to ignition)

Under hood applications such as ECUs typically use partially supplied modules. When the car is parked a main switch or ignition key switches off the battery supply. This supply line is called clamp 15. When the battery voltage is not present, the voltage regulator and transceiver are switched off.

In Clamp 30 applications the most important feature is very low current consumption in order to prevent the battery from discharging. Therefore the application take advantage of the low-power mode of an ECU. TLE8251VSJ offers the Stand-by mode with optimized very low current consumption. In Stand-by mode the TLE8251VSJ can always detect a bus wake-up. If bus communication is monitored on the HS CAN bus, then the TLE8251VSJ indicates this wake-up event on the RxD output pin. The wake-up event wakes up the microcontroller, and the ECU starts working normally. TLE8251VSJ is also suitable for clamp 15 applications. The modes of operation are described in Chapter 2.2.
3.2 Baud Rate versus Bus Length

Table 3 Recommended Baud Rate versus Bus Length

<table>
<thead>
<tr>
<th>Baud Rate (kbit/s)</th>
<th>Bus Length (m) Maximum Distance between two Nodes</th>
</tr>
</thead>
<tbody>
<tr>
<td>1000</td>
<td>10</td>
</tr>
<tr>
<td>500</td>
<td>40</td>
</tr>
<tr>
<td>250</td>
<td>120</td>
</tr>
<tr>
<td>125</td>
<td>500</td>
</tr>
<tr>
<td>50</td>
<td>1000</td>
</tr>
</tbody>
</table>

Baud rate is limited by:
- bus length
- ringing
- propagation delay of cables
- propagation delay of the CAN controller of the transceiver

The two most distant nodes (A and B) in a CAN network are the limiting factor in transmission speed. The propagation delays must be considered because a round trip has to be made from the two most distant CAN controllers on the bus. Propagation delay of the cable depends on cable length and on temperature.

In the worst case scenario node A starts transmitting a dominant signal and it takes a certain period of time \( t = t_{\text{CANcontroller}} + t_{\text{Transceiver}} + t_{\text{Cable}} \) until the signal reaches node B.

Propagation delay is the sum of:
- CAN controller delay
- transceiver delay
- bus length delay

Assumption: 70 ns for CAN controller, 255 ns for transceiver, 5 ns per meter of cable. Example with 50 m cable length:

\[
t_{\text{prop}} = t_{\text{CANcontroller}} + t_{\text{Transceiver}} + t_{\text{Cable}} + t_{\text{CANcontroller}} + t_{\text{Transceiver}} + t_{\text{Cable}} = \\
70 \text{ ns} + 255 \text{ ns} + 50 \text{ m} \times 5 \text{ ns/m} + 70 \text{ ns} + 255 \text{ ns} + 50 \text{ m} \times 5 \text{ ns/m} = 1150 \text{ ns}
\]
With a total propagation delay of 1150 ns and assuming a nominal bit time of 2000 ns, the timing window for the sampling point is reduced to 850 ns not taking into account ringing or reflections. For correct bit sampling this timing window should include additional timing margin.

Other factors of strong influence on the maximum baud rate are:

- cable capacitance
- oscillator tolerance
- ringing
- reflections, depending on the network topology

The shorter the bus length, the timing window margin increases and a higher data rate can be achieved. Wire resistance increases with bus length and therefore the bus signal amplitude may be degraded. For additional information please refer to *The Physical Layer in the CAN FD World.*
CAN FD

CAN FD (Flexible Data Rate) is the advanced version of classical CAN.

CAN FD saves transmission time compared to classical CAN:
- increased data transmission rate
- increased payload per message

CAN FD includes additional timing parameters.

### Table 4 Classical CAN vs. CAN FD

<table>
<thead>
<tr>
<th></th>
<th>Data transmission rate [Mbit/s]</th>
<th>Maximum payload message length [byte]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Classical CAN</td>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>CAN FD</td>
<td>2</td>
<td>64</td>
</tr>
</tbody>
</table>

### 4.1 General Information

CAN FD uses the same physical layer as classical CAN does. During the arbitration phase and checksum the data transmission rate is identical to classical CAN (1 Mbit/s). As soon as one node in the CAN FD network starts transmitting the payload, the data rate is increased (2 Mbit/s). The increased baud rate is possible, because only one node transmits during the data transmission phase. All other nodes listen to the data on the CAN bus.

In order to ensure reliable data transmission, CAN FD requires a CAN transceiver with full ISO 11898-2 specification for Flexible Data rate up to 2 Mbit/s.

![Figure 7 Classical CAN Data Rate and CAN FD Data Rate](image-url)
4.2 TLE8251VSJ Improved CAN FD Parameters

The TLE8251VSJ from Infineon is the perfect match for CAN FD networks. TLE8251VSJ exceeds the CAN FD parameters according to ISO 11898-2 (Edition 2016) for 2 Mbit/s in order to enable smooth and safe usage within applications. The TLE8251VSJ offers improved loop delay symmetry to support CAN FD data frames up to 2 MBit/s (see Table 5).

![Transceiver Propagation Delay](image)

The tolerance of the received recessive bit width depends on:
- Transmitter Tx propagation delay symmetry (transceiver)
- Receiver Rx propagation delay symmetry (transceiver)
- Bit time tolerance (microcontroller)
- Network Effects like ringing and reflection (network)

![Improved CAN FD parameters: ISO 11898-2 (2016) vs. TLE82xx](image)

**Table 5** Improved CAN FD parameters: ISO 11898-2 (2016) vs. TLE8251VSJ

</tbody>
</table>
Figure 10 shows the maximum requested range of the received recessive bit width on the receiving node $t_{\text{Bit(RxRec)}}$ by Japanese OEMs. Infineon’s TLE8251VSJ Transceiver fulfills the requested maximum window of $t_{\text{Bit(RxRec)}}$. TLE8251VSJ has improved timing parameters for CAN Flexible Data Rate (2Mbit/s), which adds additional safety margin for network effects like ringing effects and network propagation delay.

### 4.3 TLE8251VSJ Approval in Conjunction with Common Mode Choke

For applications using Classical CAN and CAN Flexible Data Rate, Japanese OEMs require always a Common Mode Choke. Infineon TLE8251VSJ CAN Transceiver is qualified and approved at Japanese OEMs with all major Common Mode Chokes:

- ACT45B type
- ACT45C type
- DLW43 type
5 Pin Description

5.1 $V_{\text{IO}}$ Pin

The $V_{\text{IO}}$ pin is needed for the operation with a microcontroller that is supplied by $V_{\text{IO}} < V_{\text{CC}}$, to match the voltage level between microcontroller and transceiver. It can also be used to decouple microcontroller and transmitter supply.

Benefits of using the $V_{\text{IO}}$ pin:

- improved EMC performance
- the transmitter supply $V_{\text{CC}}$ can be switched off separately

The digital reference supply voltage $V_{\text{IO}}$ has two functions:

- supply of the internal logic of the transceiver (state machine)
- voltage adaption for external microcontroller ($3.0 \text{ V} < V_{\text{IO}} < 5.5 \text{ V}$)

As long as $V_{\text{IO}}$ is supplied ($V_{\text{IO}} > 3.0 \text{ V}$) the state machine of the transceiver supports mode changes. If a microcontroller uses low $V_{\text{IO}} < V_{\text{CC}} = 5 \text{ V}$, then the $V_{\text{IO}}$ pin must be connected to the power supply of the microcontroller. Due to the $V_{\text{IO}}$ pin feature, the TLE8251VSJ can work with various microcontroller supplies. If $V_{\text{IO}}$ is available, then both transceiver and microcontroller are fully functional. Below $V_{\text{IO}} < 3.0 \text{ V}$ the TLE8251VSJ is in Power On Reset state. To enter Normal-operating mode $V_{\text{IO}} \geq 3.0 \text{ V}$ is required.

5.2 $V_{\text{CC}}$ Pin

The $V_{\text{CC}}$ pin supplies the transmitter output stage.

<table>

</tr>
<tr>
<td>$V_{\text{CC}} &gt; 6 \text{ V}$</td>
<td>damage of TLE8251VSJ possible</td>
<td>-</td>
</tr>
</tbody>
</table>

5.3 GND Pin

The GND pin must be connected as close as possible to module ground in order to reduce ground shift. It is not recommended to place filter elements or an additional resistor between GND pin and module ground. GND must be the same for transceiver, microcontroller and HS CAN bus system.

5.4 RxD Pin

RxD is an output pin. The data stream received from the HS CAN bus is displayed on the RxD output pin in Normal-operating mode. If a bus wake-up is detected in Stand-by mode or in Forced-stand-by mode, then the RxD pin is “high” and switches to “low” and follows the bus with the parameters of the low-power receiver specified in the datasheet. Do not use a series resistor within the RxD line between transceiver and microcontroller. A series resistor may add delay, which degrades the performance of the transceiver, especially in high data rate applications.
5.5 TxD Pin
TxD is an input pin. TxD pin receives the data stream from the microcontroller. If in Normal-operating mode \( V_{IO} > V_{IO,UV} \), then the data stream is transmitted to the HS CAN bus. In all other modes the TxD input pin is blocked. A “low” signal causes a dominant state on the bus and a “high” signal causes a recessive state on the bus. The “high” signal must be adapted to the voltage on the \( V_{IO} \) pin. This means the “high” level must not exceed \( V_{IO} \) voltage. The TxD input pin has an integrated pull-up resistor to \( V_{IO} \). If TxD is permanently “low”, for example due to a short circuit to GND, then the TxD time-out feature will block the signal on the TxD input pin (see Chapter 8.1). Do not use a series resistor within the TxD line between transceiver and microcontroller. A series resistor may add delay, which degrades the performance of the transceiver, especially in high data rate applications.

5.6 STB Pin
The STB pin sets the mode of TLE8251VSJ and is usually directly connected to an output port of a microcontroller. If the mode pin is not connected and TLE8251VSJ is supplied by \( V_{IO} \), then the device enters Stand-by mode due to the internal pull-up resistor to \( V_{IO} \). The purpose of the Stand-by mode is to reduce current consumption, while the TLE8251VSJ can detect a bus wake-up. To put the device into Normal-operating mode, the STB pin must be set to “low”. The user can deactivate transmitter and receiver of TLE8251VSJ either by setting the STB pin to “high” or by switching off \( V_{CC} \). This can be used to implement two different fail safe paths in case a failure is detected in the ECU. Table 7 shows mode changes by the STB pin, assuming \( V_{IO} > V_{IO,UV} \). Chapter 2 describes features and modes of operation.

</tr>
</tbody>
</table>

\(^1\) “X”: don’t care

5.7 CANH and CANL Pins
CANH and CANL are the CAN bus input and output pins. The TLE8251VSJ is connected to the bus via pin CANH and CANL. Both transmitter output stage and the receiver are connected to CANH and CANL.

Data on the TxD pin is:
- transmitted to CANH and CANL
- simultaneously received by the receiver input and signalled on the RxD output pin.

For achieving optimum EME (Electromagnetic Emission) performance, transitions from dominant to recessive and from recessive to dominant are performed as smooth as possible also at high data rate. Output levels of CANH and CANL in recessive and dominant state are described in Table 1. Due to the excellent ESD performance on CANH and CANL no external ESD components are necessary to fulfill OEM requirements.
Transceiver Supply

6 Transceiver Supply

The internal logic of TLE8251VSJ is supplied by the \( V_{\text{IO}} \) pin. The \( V_{\text{CC}} \) pin is used to create the CANH and CANL signal. The transmitter output stage as well as the main CAN bus receiver are supplied by the \( V_{\text{CC}} \) pin. This chapter describes aspects of power consumption and voltage supply concepts of TLE8251VSJ.

6.1 Voltage Regulator

It is recommended to use one of the following Infineon low drop output (LDO) voltage regulators:

- 3.3 V \( V_{\text{IO}} \) power supply: TLS850D0TAV33 (500mA), TLS850F0TAV33 (500mA), TLS810B1LDV33 (100mA), TLE4266-2GS V33 (150mA),
- 5 V \( V_{\text{IO}} \) and \( V_{\text{CC}} \) power supply: TLS850D0TAV50 (500mA), TLS810B1LDV50 (100mA), TLS810D1EJV50 (100mA), TLE4266-2 (150mA)
- 3.3 V and 5 V dual voltage power supply: TLE4476D
- Dual 5V voltage power supply: TLE4473GV55

Please refer to Infineon Linear Voltage Regulators for the Infineon voltage regulator portfolio and data sheets.

6.2 External Circuitry

In order to reduce EME and to improve the stability of input voltage level on \( V_{\text{CC}} \) and \( V_{\text{IO}} \) of the transceiver, it is recommended to place capacitors (low impedance and low ESR) close to \( V_{\text{IO}} \) and \( V_{\text{CC}} \) on the PCB. During sending a dominant bit to the HS CAN bus, current consumption of TLE8251VSJ is higher than during sending a recessive bit. Data transmission can change the load profile on \( V_{\text{CC}} \). Changes in load profile may reduce the stability of \( V_{\text{CC}} \). If several CAN transceivers are connected in parallel, and if these CAN transceivers are supplied by the same \( V_{\text{CC}} \) and/or \( V_{\text{IO}} \) power supply (for example LDO), then the impact on the stability of \( V_{\text{CC}} \) is even stronger. It is recommended to place a 100 nF capacitor as close as possible to \( V_{\text{CC}} \) and \( V_{\text{IO}} \) pin. The output of the \( V_{\text{CC}} \) and \( V_{\text{IO}} \) power supply (for example LDO) must be stabilized by a capacitor in the range of 1 to 50 \( \mu \)F, depending on the load profile. Ceramic capacitors are recommended for low ESR.

6.3 Power-up Sequence for \( V_{\text{IO}} \) and \( V_{\text{CC}} \)

As TLE8251VSJ has \( V_{\text{CC}} \) and \( V_{\text{IO}} \) supply pin, this chapter describes possible scenarios for powering up the device. \( V_{\text{CC}} \) supplies the transmitter output stage and \( V_{\text{IO}} \) the internal state machine of TLE8251VSJ. There is no limitation for the start-up sequence for TLE8251VSJ:

- Scenario 1: If \( V_{\text{IO}} \) is supplied first, the internal state machine will start to work for \( V_{\text{IO}} > V_{\text{IO,UV}} \). Then the mode of operation can be changed by the mode selection pins. The transmitter of TLE8251VSJ remains disabled in Normal-operating Mode if \( V_{\text{CC}} > V_{\text{CC,UV}} \) and also in all other modes.
- Scenario 2: If \( V_{\text{CC}} \) is supplied first, only the transmitter output stage is supplied. But as \( V_{\text{IO}} \) is not yet supplied the transmitter is High-Z (disabled) by default, in order to not disturb the bus communication.
- Scenario 3: If \( V_{\text{CC}} \) and \( V_{\text{IO}} \) are connected to the same supply voltage (5V), the state machine will start to work for \( V_{\text{IO}} > V_{\text{IO,UV}} \) (max. 3.0V) and the transmitter will be enabled if \( V_{\text{CC}} > V_{\text{CC,UV}} \) (max. 4.5V).

6.4 \( V_{\text{IO}} \) Feature

TLE8251VSJ offers a \( V_{\text{IO}} \) supply pin, which is a voltage reference input for adjusting the voltage levels on the digital input and output pins to the voltage supply of the microcontroller. In order to use the \( V_{\text{IO}} \) feature, connect the power supply of the microcontroller to the \( V_{\text{IO}} \) input pin. Depending on the voltage supply of the microcontroller, TLE8251VSJ can operate with the \( V_{\text{IO}} \) reference voltage input within the voltage range from 3.0 V to 5.5 V.
6.4.1 $V_{IO}$ 3.0 V - 5.5 V Power Supply Concept

The $V_{IO}$ pin supplies the internal logic of the TLE8251VSJ. TLE8251VSJ can operate with the $V_{IO}$ reference voltage input in the range from 3.0 V to 5.5 V. The $V_{CC}$ pin (typ. = 5 V) supplies the transmitter of TLE8251VSJ. Therefore the $V_{CC}$ supply input pin must be connected to a 5 V voltage regulator. Competitor devices use $V_{CC}$ to supply the internal logic and the transmitter output stage and $V_{IO}$ as a simple level shifter. Infineon’s HS CAN transceivers can work in $V_{CC}$ undervoltage condition or even with $V_{CC}$ completely switched off in Forced-stand-by mode and Stand-by Mode.

6.4.2 $V_{IO}$ 3.3 V Power Supply

In order to reduce power consumption of ECU, the microcontroller might not be supplied by $V_{CC}$ but by a lower voltage (for example 3.3 V). Therefore the TLE8251VSJ offers a $V_{IO}$ supply pin, which is a voltage reference input in order to adjust the voltage levels on the digital input and output pins to the voltage supply of the microcontroller. The $V_{IO}$ feature enables the TLE8251VSJ to operate with a microcontroller, which is supplied by a voltage lower than $V_{CC}$. With the $V_{IO}$ reference voltage input the TLE8251VSJ can operate from 3.0 V to 5.5 V.

![3.3 V Power Supply Concept](image1)

6.4.3 $V_{IO}$ 5 V Supply

TLE8251VSJ can also operate with a 5 V supply because of the $V_{IO}$ input voltage range from 3.0 V to 5.5 V. If the microcontroller uses $V_{CC} = 5$ V supply, then $V_{IO}$ is connected to $V_{CC}$. The $V_{IO}$ input must be connected to the supply voltage of the microcontroller.

![5 V Power Supply Concept](image2)
6.4.4 Dual 5 V Supply Concept

In order to decouple the microcontroller and the HS CAN Bus from each other with respect to noise and disturbances, it is possible to use a dual 5 V voltage regulator like TLE4473GV55. In this case two independent 5 V LDOs supply $V_{IO}$ and $V_{CC}$. This power supply concept improves EMC behavior and reduces noise.

![Dual 5 V Power Supply Concept](image)

6.5 Current Consumption

Current consumption depends on the mode of operation:

- **Normal-operating mode:**
  Maximum current consumption of TLE8251VSJ on the $V_{CC}$ supply is specified as 60 mA in dominant state and 4 mA in recessive state. Maximum current consumption of TLE8251VSJ on the $V_{IO}$ supply is specified as 1 mA. To estimate theoretical current consumption in Normal-operating mode, a duty cycle of 50% can be assumed, with fully loaded bus communication of 50% dominant and 50% recessive. In Normal-operating mode the TLE8251VSJ consumes in worst case maximum:

\[
I_{CC, AVG} = \frac{I_{CC, REC} + I_{CC, DOM}}{2} + I_{IO} = 32.5 \text{ mA}
\]

Typically the current consumption is less than 15 mA.

- **Stand-by mode and Forced-Stand-by mode:**
  Most of the functions are turned off but the TLE8251VSJ monitors the HS CAN bus for a bus wake-up. In Stand-by mode the maximum current consumption is specified as $I_{IO, max} = 14 \mu A$ for $T < 150 \, ^{\circ}C$. The TLE8251V has an optimized current consumption in stand-by mode for $T < 105^{\circ}C$ specified as $I_{IO, max} = 12.5 \, \mu A$. 

6.6 Loss of Battery (Unsupplied Transceiver)

When TLE8251VSJ is unsupplied, CANH and CANL act as high impedance. The leakage current \( I_{CANH, \text{lk}} \), \( I_{CANL, \text{lk}} \) at CANH pin or CANL pin is limited to \(+/-5 \, \mu A\) in worst case. When unsupplied, TLE8251VSJ behaves like a 1 M\( \Omega \) resistor towards the bus. Therefore the device perfectly fits applications that use both Clamp 15 and Clamp 30.

6.7 Loss of Ground

If loss of ground occurs, then the transceiver is unsupplied and behaves like in unpowered state. Due to the internal input resistors on CANH and CANL on the unpowered transceiver, the HS CAN Bus Signal gets shifted. In applications with inductive load connected to the same GND, for example a motor, the transceiver can be damaged due to loss of ground. Excessive current can flow through the CAN transceiver when the inductor demagnetizes after loss of ground. The ESD structure of the transceiver cannot withstand that kind of Electrical Overstress (EOS). In order to protect the transceiver and other components of the module, an inductive load must be equipped with a free wheeling diode.
6.8 Ground Shift

Due to ground shift the GND levels of CAN transceivers within a network may vary. Ground shift occurs in high current applications or in modules with long GND wires. The receiver input stage acts like a resistor \( R_i \) to GND. Because the transmitting node has its GND shifted to \( V_{\text{shift}} \), the recessive voltage level \( V_{\text{rec}} \) from the chassis ground is no longer 2.5 V but \( V_{\text{rec}} + V_{\text{shift}} \). The same ground shift voltage \( V_{\text{shift}} \) must be taken into account for the dominant signal. Because CAN uses a differential signal and because of the wide common mode range of +/-12 V for Infineon transceivers, any CANH and CANL DC value within absolute maximum ratings works.

The recessive CAN bus level \( V_{\text{rec}} \) during a ground shifted node transmitting is equal to the average recessive voltage level of all transceivers:

\[
V_{\text{rec}} = \frac{(V_{\text{rec,1}} + V_{\text{shift,1}}) + (V_{\text{rec,2}} + V_{\text{shift,2}}) + (V_{\text{rec,3}} + V_{\text{shift,3}}) + \ldots + (V_{\text{rec,n}} + V_{\text{shift,n}})}{n}
\]

\( n \): number of connected CAN nodes

\( V_{\text{rec,1}}, V_{\text{rec,2}}, \ldots, V_{\text{rec,n}} \): specific recessive voltage level of the transceiver at nodes 1, 2, .. n

\( V_{\text{shift,1}}, V_{\text{shift,2}}, \ldots, V_{\text{shift,n}} \): specific ground shift voltage level of the transceiver at nodes 1, 2, .. n

The supply current of a ground shifted transceiver increases by \( I_{\text{CC,Shift}} = \frac{V_{\text{Shift}}}{(R_{i,n}/n)} \), assuming all input resistances at CANH and CANL of the transceivers are identical.

The higher the ground shift of one node to the other, the higher the Electromagnetic Emission.
Transceiver Control

7 Transceiver Control

The modes of the TLE8251VSJ are controlled by the pin STB and by transmitter voltage $V_{CC}$.

7.1 Mode Change by STB

The mode of operation is set by the mode selection pin STB. By default the STB input pin is “high” due to the internal pull-up resistor to $V_{IO}$.

The TLE8251VSJ is in Stand-by mode independent of the status of $V_{CC}$. In order to change the mode to Normal-operating mode, STB must be switched to “low” and $V_{CC}$ must be available.

7.2 Mode Change Delay

The HS CAN transceiver TLE8251VSJ changes the mode of operation within the transition time period $t_{Mode}$. The transition time period $t_{Mode}$ must be considered in developing software for the application. After the mode change from Stand-by mode to a non-low power mode the receiver and/or transmitter is enabled. During the period $t_{Mode}$ the RxD output pin is permanently set to “high” and does not reflect the status on the CANH and CANL input pins. In addition, during $t_{Mode}$, the TxD path is blocked as well. When the mode change is completed, the TLE8251VSJ releases the RxD output pin. Figure 16 shows this scenario.

Figure 16 RxD Behavior during Mode Change
Figure 17 Communication on the CAN Bus: RxD Behavior during Mode Change (Stand-by Mode to Normal-Operating Mode)
7.3 Mode Change due to $V_{CC}$ Undervoltage

A mode change due to $V_{CC}$ undervoltage is only possible in Normal-operating mode. If $V_{CC}$ undervoltage persists longer than $t_{\text{Delay(UV)}}$, then the TLE8251VSJ changes from Normal-operating mode to Forced-stand-by mode. As soon as TLE8251VSJ detects an undervoltage, it disables the transmitter output stage so that no faulty data is sent to the HS CAN bus.

In order to reduce current consumption during $V_{CC} < V_{CC(UV)}$ fault condition, the TLE8251VSJ has an optimized current consumption in Forced-stand-by mode. In Forced-stand-by mode the TLE8251VSJ detects a wake-up on the HS CAN bus and indicates the wake-up at RxD output pin.

If $V_{CC}$ recovers, then $V_{CC} > V_{CC_{UV}}$ TLE8251VSJ

![Figure 18: $V_{CC}$ Undervoltage and Recovery](image)

![Figure 19: Recovery of $V_{CC}$ in Forced Stand-by Mode](image)
7.4 Remote Wake-up Detection

In order to reduce current consumption of permanently supplied applications (Clamp 30), ECUs are set to a low power mode. Low-power mode reduces quiescent current. Usually the microcontroller is in stop mode and the transceiver is Stand-by mode. In Stand-by mode the transceiver can wake up the microcontroller in order to set the ECU back to normal operation.

The TLE8251VSJ has a remote wake-up feature. In Stand-by mode TLE8251VSJ monitors activity on the CAN bus. If TLE8251VSJ detects a wake-up pattern, then it indicates the wake-up signal on the RxD output pin. In Stand-by mode the transmitter supply $V_{CC}$ can be turned off.

In Stand-by mode a wake-up event on the HS CAN is indicated on the RxD output pin. The transceiver remains in the current mode of operation.

![Remote Wake-up Detection](image)

Figure 20  Remote Wake-up Detection
7.5 Benefit of $V_{IO}$-supplied Wake Receiver

Infineon’s HS CAN transceivers use the $V_{IO}$ pin to supply the low-power-receiver. For transceivers with bus wake-up TLE8251VSJ, only $V_{IO}$ must be supplied in Stand-by mode. The application saves current with the ECU in Stand-by mode while waiting for a bus wake-up. In Stand-by mode $V_{CC}$ can be switched off, while the receiver can still wake up the microcontroller via a bus wake-up. Common CAN transceivers use $V_{CC}$ to supply both the receiver and the logic, thus requiring two voltage regulators in operation for $V_{CC}$ and $V_{IO}$ for detecting bus wake-up. This increases current consumption in Stand-by mode. With Infineon’s TLE8251VSJ the user can switch off the $V_{CC}$ voltage regulator, so no permanent current $I_{BAT,LDO}$ flows to the 5 V LDO. A permanently flowing current through the $V_{CC}$-LDO might be an issue for the ECU’s efficiency.

In order to take advantage of the bus wake-up feature, the microcontroller must set the TLE8251VSJ to Stand-by mode by setting the STB pin to “high” and needs to switch off the $V_{CC}$ LDO by a Control Output, before the microcontroller itself changes to low-power mode.

Procedure for bus wake-up:
1) Bus-wake up is signaled by TLE8251VSJ on the RxD output pin to the microcontroller
2) Microcontroller wakes up
3) Microcontroller must switch on the $V_{CC}$ LDO by the Control Output
4) Then the STB input pin of TLE8251VSJ must be changes to “low” in order to trigger a mode change to “Normal-operating mode
5) After the mode change time $t_{Mode}$ TLE8251VSJ can send and receive data to the HS CAN Bus as soon as $V_{CC} > V_{CC,UV}$

![Figure 21 Benefit of $V_{IO}$-supplied Wake Receiver](image-url)
7.6 Transition from Stand-by Mode to Forced-Stand-by Mode

From Normal-operating mode the TLE8251VSJ enters Forced-stand-by mode on detecting $V_{CC}$ undervoltage. However, in Stand-by mode $V_{CC}$ undervoltage detection is disabled. With $V_{CC}$ below the undervoltage threshold $V_{CC,UV}$ the TLE8251VSJ in Stand-by mode, when STB is switched from “high” to “low” the TLE8251VSJ changes to Normal-operating mode. In Normal-operating mode $V_{CC}$ undervoltage detection is enabled, and thus the undervoltage event is detected. This in turn triggers a mode change to Forced-stand-by mode. The overall transition time period from Stand-by mode to Forced-stand-by mode is $t < t_{Mode}$. During the mode change from Power-save mode to Forced-receive-only mode the RxD output pin is permanently set to “high” and does not reflect the status of the CANH and CANL input pins. After mode change to Forced-stand-by mode is completed, the TLE8251VSJ releases the RxD output pin.

8 Failure Management

This chapter describes typical bus communication failures.

8.1 TxD Dominant Time-out Detection

The TxD dominant time-out detection of TLE8251VSJ protects the CAN bus from being permanently driven to dominant level. When detecting a TxD dominant time-out, the TLE8251VSJ disables the transmitter in order to release the CAN bus. Without the TxD dominant time-out detection, a CAN bus would be clamped to the dominant level and therefore would block any data transmission on the CAN bus. This failure may occur for example due to TxD pin shorted to ground.

The TxD dominant time-out detection can be reset after a dominant to recessive transition at the TxD pin. A “high” signal must be applied to the TxD input for at least $t_{TXD\_release} = 200$ ns to reset the TxD dominant timer.

![Figure 23 Resetting TxD Dominant Time-out Detection](image)

If a TxD Dominant Time-out is present, then a mode change to Stand-by mode clears the TxD dominant timer state.

![Figure 24 Measurement: TxD Dominant Time-out Detection](image)
8.2 Minimum Baud Rate and Maximum TxD Dominant Phase

Due to the TxD dominant time-out detection of the TLE8251VSJ the maximum TxD dominant phase is limited by the minimum TxD dominant time-out time $t_{\text{TxD}} = 4.5\text{ ms}$. The CAN protocol allows a maximum of 11 subsequent dominant bits at TxD pin (worst case dominant bits followed immediately by an error frame). With a minimum value of 4.5 ms given in the datasheet and maximum possible 11 dominant bits, the minimum baud rate of the application must be higher than 2.44 kbit/s.

8.3 Short Circuit

Figure 25 shows short circuit types on the HS CAN bus. The CANH and CANL pins are short circuit proof to GND and to supply voltage. A current limiting circuit protects the transceiver from damage. If the device heats up due to a permanent short at CANH or CANL, then the overtemperature protection switches off the transmitter. Depending on the type of short circuit on CANH and CANL, communication might be still possible. If only CANL is shorted to GND or only CANH is shorted to $V_{\text{BAT}}$, then dominant and recessive states may be recognized by the receiver. Timings and/or differential output voltages might be not valid according to ISO11898 but still in the range for the receiver working properly.

![Figure 25 HS CAN Bus Short Circuit Types](image)

Communication on the HS CAN bus is blocked in the following cases:

- CANH and CANL shorted (Case7)
- CANH shorted to GND (Case 5)
- CANL shorted to $V_{\text{BAT}}$ (Case 2) or $V_{\text{CC}}$ (Case 4)

If a short circuit occurs, then the $V_{\text{CC}}$ supply current for the transceiver can increase significantly. It is recommended to dimension the voltage regulator for the worst case, especially when $V_{\text{CC}}$ also supplies the microcontroller. $V_{\text{CC}}$ supply current increases in dominant state. The recessive current remains unchanged.

### CANH shorted to GND

The datasheet specifies a maximum short circuit current of 100mA. When transmitting a dominant state to the bus, 5V is shorted to GND through the transmitter output stage. Power dissipation with 10% duty cycle (DCD) is:

$$P = \text{DCD} \times U \times I = 0.1 \times 5\text{V} \times 100\text{mA} = 0.05\text{W}.$$  

The average fault current with worst case parameters and assuming a realistic duty cycle of 10% is:

$$I_{\text{CC,Fault}} = I_{\text{CC,rec}} \times 0.9 + I_{\text{CANH,SC}} \times 0.1 = 13.6\text{mA}.$$  

### CANL shorted to $V_{\text{BAT}}$

If CANL is shorted to $V_{\text{BAT}}$, then the current through the CANL output stage is even higher and the device heats up faster. The datasheet specifies a maximum short circuit current of 100mA. When transmitting a dominant state to the bus, $V_{\text{BAT}}$ is shorted to GND through the transmitter output stage. Assuming a realistic duty cycle
of 10% for this case and the power dissipation is:
\[ P = D \times C \times U \times I = 0.1 \times V_{\text{BAT}} \times 100\text{mA} = 0.1 \times 18\text{V} \times 100\text{mA} = 0.18\text{W}. \]

**CAN shorted to \( V_{\text{BAT}} \)**

Short circuit of CANH to \( V_{\text{BAT}} \) can result in a permanent dominant state on the HS CAN bus, due to the voltage drop at the termination resistors of the network. Therefore the termination resistor has to be chosen accordingly. If a short circuit of CANH to \( V_{\text{BAT}} \) occurs, then the power loss in the termination resistor must be taken into account. Figure 26 shows the current in case CANH is shorted to \( V_{\text{BAT}} \). When transmitting a dominant state to the bus, the current flows through the termination resistor an CANL to GND. Power loss in the termination resistor and CANL assuming a battery voltage of 18 V and a duty cycle of 10% is:

\[
P_{\text{Loss_Termination}} = 0.1 \times (R_{\text{Termination}} \times I_{\text{CANL,SC}}) \times I_{\text{CANL,SC}} = (60\Omega \times 100\text{mA}) \times 100\text{mA} = 0.6\text{W}
\]

\[
P_{\text{Loss_CANL}} = 0.1 \times (V_{\text{BAT}} - (R_{\text{Termination}} \times I_{\text{CANL,SC}})) \times I_{\text{CANL,SC}} = 0.1 \times (18\text{V}-6\text{V}) \times 100\text{mA} = 0.1 \times 12\text{V} \times 100\text{mA} = 0.12\text{W}
\]

![Figure 26](image_url)

**8.4 TLE8251VSJ Junction Temperature**

In Normal-operating mode highest power dissipation occurs with 50% duty cycle (D) at an ambient temperature of 150 °C:

\[
P_{\text{NM,MAX}} = D \times (I_{\text{CC,R}} \times V_{\text{CC,MAX}}) + D \times (I_{\text{CC,D}} \times V_{\text{CC,MAX}}) + (I_{\text{O}} \times V_{\text{IO,MAX}}) =
\]

\[
= 0.5 \times (4\text{mA} \times 5.5\text{V}) + 0.5 \times (60\text{mA} \times 5.5\text{V}) + (1.5\text{mA} \times 5.5\text{V}) = 184.25\text{mW}.
\]

Junction temperature increases due to power dissipation and depending on the package.

However, typical conditions are more like this: ambient temperature is below 150 °C, overall duty cycle is less than 50%, and supply voltages \( V_{\text{CC}} \) and \( V_{\text{IO}} \) have their typical values instead of maximum values.

Power dissipation is much lower for such typical conditions:

\[
P_{\text{NM,AVG}} = D \times (I_{\text{CC,R,Typ}} \times V_{\text{CC,Avg}}) + D \times (I_{\text{CC,D,Typ}} \times V_{\text{CC,Avg}}) + (I_{\text{O,Typ}} \times V_{\text{IO,Avg}}) =
\]

\[
= 0.9 \times (2\text{mA} \times 5\text{V}) + 0.1 \times (38\text{mA} \times 5\text{V}) + (1\text{mA} \times 3.3\text{V}) = 23.3\text{mW}.
\]

Figure 29 Simulation Result ($R_{th, jcbot}$ vs. Power)
PCB Layout Recommendations for CAN FD

The following layout rules should be considered to achieve best performance of the transceiver and the ECU:

- TxD and RxD connections to microcontroller should be as short as possible.

- For each microcontroller the TxD driver output stage current capability may vary depending on the selected port and pin. The driver output stage current capability should be strong enough to guarantee a maximum propagation delay from µC port to transceiver TxD pin of less than 30ns.

- Place two individual 100nF capacitors close to $V_{CC}$ and $V_{IO}$ pins for local decoupling. Due to their low resistance and lower inductance compared to other capacitor types, it is recommended to use ceramic capacitors.

- If a common mode choke is used, it has to be placed as close as possible to the bus pins CANH and CANL.

- Avoid routing CANH and CANL in parallel to fast-switching lines or off-board signals in order to reduce noise injection to the bus.

- It is recommended to place the transceiver as close as possible to the ECU connector in order to minimize track length of bus lines.

- Avoid routing digital signals in parallel to CANH and CANL.

- CANH and CANL tracks should have the same length. They should be routed symmetrically close together with smooth edges.

- GND connector should be placed as close as possible to the transceiver.

- Avoid routing transceiver GND and microcontroller GND in series in order to reduce coupled noise to the transceiver. This also applies for high current applications, where the current should not flow through the GND line of transceiver and microcontroller in serial.

- Avoid routing transceiver $V_{CC}$ supply and microcontroller $V_{CC}$ supply in series in order to reduce coupled noise to the transceiver.

- Same dimensions and lengths for all wire connections from the transceiver to CMC and/or termination.

- In case an external ESD protection circuit is used, make sure the total capacitance is lower than 50pF. Use equal ESD protection for CANH and CANL in order to improve signal symmetry.

- For CAN FD application it is recommended to use a Common Mode Choke with 100µH impedance and a Split termination with a capacitance of 4.7nF in order to achieve excellent EME performance in automotive applications.

Figure 30  Example CAN transceiver PCB layout
11 Pin FMEA

This chapter provides an Pin FMEA (Failure Mode and Effect Analysis) for typical failure situations. Typical failure scenarios for dedicated pins of TLE8251VSJ are:

- Short circuit to battery voltage $V_{BAT}$
- Short circuit to supply voltage $V_{CC}$
- Short circuit to reference voltage $V_{IO}$
- Short circuit to PCB Ground GND
- Short circuit between neighbored pins
- Pin is not connected

The possible failures are classified according to possible failure effects (see Table 9)

<tr>
<td>RxD</td>
<td>Short Circuit to $V_{CC}$</td>
<td>RxD remains “dominant”. If $V_{IO} &lt; V_{CC}$ the device gets damaged due to violation of absolute maximum ratings.</td>
<td>A</td>
</tr>
<tr>
<td>RxD</td>
<td>Short Circuit to $V_{IO}$</td>
<td>RxD remains “dominant”. The RxD signal does not reflect the signal on the HS CAN bus. In this case the microcontroller is able to place a message on the CAN bus at any time and corrupts the CAN messages on the bus. The device is stressed if a “dominant” signal is driven. In this case the RxD output short circuits the $V_{IO}$ to GND. The device gets damaged due to violation of absolute maximum ratings.</td>
<td>A</td>
</tr>
<tr>

IMPORTANT NOTICE
The information contained in this application note is given as a hint for the implementation of the product only and shall in no event be regarded as a description or warranty of a certain functionality, condition or quality of the product. Before implementation of the product, the recipient of this application note must verify any function and other technical information given herein in the real application. Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind (including without limitation warranties of non-infringement of intellectual property rights of any third party) with respect to any and all information given in this application note.

The data contained in this document is exclusively intended for technically trained staff. It is the responsibility of customer’s technical departments to evaluate the suitability of the product for the intended application and the completeness of the product information given in this document with respect to such application.

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

WARNINGS
Due to technical requirements products may contain dangerous substances. For information on the types in question please contact your nearest Infineon Technologies office.

Except as otherwise explicitly approved by Infineon Technologies in a written document signed by authorized representatives of Infineon Technologies, Infineon Technologies’ products may not be used in any applications where a failure of the product or any consequences of the use thereof can reasonably be expected to result in personal injury.
