 - c) FS Time-Out Calibration field
 - d) USB Turnaround Time field
3. The software must unmask the following bits in the GINTMSK register.
 - a) OTG Interrupt Mask
 - b) Mode Mismatch Interrupt Mask
4. The software can read the GINTSTS.CurMod bit to determine whether the USB core is operating in Host or Device mode. The software then follows either the **“Host Initialization” on Page 17-12** or **“Device Initialization” on Page 17-72** sequence.

Note: The core is designed to be interrupt-driven. Polling interrupt mechanism is not recommended: this may result in undefined resolutions.

Note: In device mode, just after Power On Reset or a Soft Reset, the GINTSTS.Sof bit is set to 1_B for debug purposes. This status must be cleared and can be ignored.

17.4 Host Programming Overview

This section discusses how to program the USB core when it is in Host mode.

17.4.1 Host Initialization

To initialize the core as host, the application must perform the following steps.

1. Program GINTMSK.PrtIntMsk to unmask.
2. Program the HCFG register to select full-speed host.
3. Program the HPRT.PrtPwr bit to 1_B. This drives VBUS on the USB.
4. Wait for the HPRT.PrtConnDet interrupt. This indicates that a device is connected to the port.
5. Program the HPRT.PrtRst bit to 1_B. This starts the reset process.
6. Wait at least 10 ms for the reset process to complete.

7. Program the HPRT.PrtRst bit to 0_B.
8. Wait for the HPRT.PrtEnChng interrupt.
9. Read the HPRT.PrtSpd field to get the enumerated speed.
10. Program the HFIR register with a value corresponding to the selected PHY clock.¹⁾
11. Program the GRXFSIZ register to select the size of the receive FIFO.
12. Program the GNPTXFSIZ register to select the size and the start address of the Non-periodic Transmit FIFO for non-periodic transactions.
13. Program the HPTXFSIZ register to select the size and start address of the Periodic Transmit FIFO for periodic transactions.

To communicate with devices, the system software must initialize and enable at least one channel as described in **“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14**. If the core is operating in Scatter/Gather DMA mode, see **“Channel Initialization in Scatter-Gather DMA Mode” on Page 17-64**.

17.4.2 Host Connection

The host connect flow is as follows:

1. When the USB cable is plugged to the host port, the core triggers GINTSTS.ConIDStsChng interrupt.
2. When the host application detects GINTSTS.ConIDStsChng interrupt, it can perform one of the following actions:
 - a) Turn on VBUS by setting HPRT.PrtPwr = 1_B, or
 - b) Wait for SRP Signaling from Device to turn on VBUS.
3. The PHY indicates VBUS power-on by asserting utmi_vbusvalid.
4. When the host core detects the device connection, it triggers the Host Port Interrupt (GINTSTS.PrtInt) to the application.
5. When GINTSTS.PrtInt is triggered, the application reads the HPRT register to check if the HPRT.Port Connect Detected (PrtConnDet) bit is set or not.

17.4.3 Host Disconnection

The host disconnect flow is as follows:

1. When the device is disconnected from the USB cable (but the cable is still connected to the USB host), the core triggers GINTSTS.DisconnInt (Disconnect Detected) interrupt.
 - a) If the USB cable is disconnected from the host port without removing the device, the core generates an additional interrupt - GINTSTS.ConIDStsChng (Connector ID Status Change).

¹⁾ At this point, the host is up and running and the port register begins to report device disconnects, etc. The port is active with SOFs occurring down the enabled port.

2. The host application can choose to turn off the VBUS by programming HPRT.PrtPwr = 0_B.

17.4.4 Channel Initialization in Buffer DMA or Slave Mode

To communicate with devices, the application must initialize and enable at least one channel.

To initialize and enable a channel when the host core is in Buffer DMA or Slave mode, the application must perform the following steps.

1. Program the GINTMSK register to unmask the following:
 - a) Non-periodic Transmit FIFO Empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the Packet Count field programmed with more than one).
 - b) Non-periodic Transmit FIFO Half-Empty for OUT transactions (applicable for Slave mode that operates in pipelined transaction-level with the Packet Count field programmed with more than one).
2. Program the HAINTRMSK register to unmask the selected channels' interrupts.
3. Program the HCINTMSK register to unmask the transaction-related interrupts of interest given in the Host Channel Interrupt register.
4. Program the selected channel's HCTSIZx register with the total transfer size, in bytes, and the expected number of packets, including short packets. The application must program the PID field with the initial data PID (to be used on the first OUT transaction or to be expected from the first IN transaction).
5. Program the Transfer Size field so that the channel's transfer size is a multiple of the maximum packet size.

```
if (mps[epnum] mod 4) == 0
transfer size[epnum] = n * (mps[epnum]) //Dword Aligned
else
transfer size[epnum] = n * (mps[epnum] + 4 - (mps[epnum] mod 4))
//Non-Dword Aligned
packet count[epnum] = n
n > 0
```
6. Program the HCCHARx register of the selected channel with the device's endpoint characteristics, such as type, speed, direction, and so forth. (The channel can be enabled by setting the Channel Enable bit to 1_B only when the application is ready to transmit or receive any packet).

Repeat steps 1-6 for other channels.

Note: De-allocate channel means after the transfer has completed, the channel is disabled. When the application is ready to start the next transfer, the application re-initializes the channel by following these steps.

17.4.5 Halting a Channel

The application can disable any channel by programming the HCCHARx register with the HCCHARx.ChDis and HCCHARx.ChEna bits set to 1_B. This enables the USB host to flush the posted requests (if any) and generates a Channel Halted interrupt. The application must wait for the HCINTx.ChHltd interrupt before reallocating the channel for other transactions. The USB host does not interrupt the transaction that has been already started on USB.

In Slave mode operation, before disabling a channel, the application must ensure that there is at least one free space available in the Non-periodic Request Queue (when disabling a non-periodic channel) or the Periodic Request Queue (when disabling a periodic channel). The application can simply flush the posted requests when the Request queue is full (before disabling the channel), by programming the HCCHARx register with the HCCHARx.ChDis bit set to 1_B, and the HCCHARx.ChEna bit reset to 0_B.

The core generates a RxFLvl interrupt when there is an entry in the queue. The application must read/pop the GRXSTSP register to generate the Channel Halted interrupt.

To disable a channel in DMA mode operation, the application need not check for space in the Request queue. The USB host checks for space in which to write the Disable request on the disabled channel's turn during arbitration. Meanwhile, all posted requests are dropped from the Request queue when the HCCHARx.ChDis bit is set to 1_B.

The application is expected to disable a channel under any of the following conditions:

1. When a HCINTx.XferCompl interrupt is received during a non-periodic IN transfer or high- bandwidth interrupt IN transfer (Slave mode only)
2. When a HCINTx.STALL, HCINTx.XactErr, HCINTx.BblErr, or HCINTx.DataTglErr interrupt is received for an IN or OUT channel (Slave mode only). For high-bandwidth interrupt INs in Slave mode, once the application has received a DataTglErr interrupt it must disable the channel and wait for a Channel Halted interrupt. The application must be able to receive other interrupts (DataTglErr, Nak, Data, XactErr, BabbleErr) for the same channel before receiving the halt.
3. When a GINTSTS.DisconnInt (Disconnect Device) interrupt is received. The application must check for the HPRT.PrtConnSts, because when the device directly connected to the host is disconnected, HPRT.PrtConnSts is reset. The software must issue a soft reset to ensure that all channels are cleared. When the device is reconnected, the host must issue a USB Reset.
4. When the application aborts a transfer before normal completion (Slave and DMA modes).

Note

In buffer DMA mode, the following guidelines must be considered:

Universal Serial Bus (USB)

- Channel disable must not be programmed for non-split periodic channels. At the end of the next frame (in the worst case), the core generates a channel halted and disables the channel automatically.
- For split enabled channels (both non-periodic and periodic), channel disable must not be programmed randomly. However, channel disable can be programmed for specific scenarios such as NAK and FrmOvrn as defined in the Host programming model.

17.4.6 Selecting the Queue Depth

Choose the Periodic and Non-periodic Request Queue depths carefully to match the number of periodic/non-periodic endpoints accessed.

The Non-periodic Request Queue depth affects the performance of non-periodic transfers. The deeper the queue (along with sufficient FIFO size), the more often the core is able to pipeline non-periodic transfers. If the queue size is small, the core is able to put in new requests only when the queue space is freed up.

The core's Periodic Request Queue depth is critical to performing periodic transfers as scheduled. Select the periodic queue depth, based on the number of periodic transfers scheduled in a frame. In Slave mode, however, the application must also take into account the disable entry that must be put into the queue. So, if there are two non-high-bandwidth periodic endpoints, the Periodic Request Queue depth must be at least 4. If at least one high-bandwidth endpoint supported, the queue depth must be 8. If the Periodic Request Queue depth is smaller than the periodic transfers scheduled in a frame, a frame overrun condition results.

17.4.7 Handling Special Conditions

This section discusses how to handle certain special conditions.

17.4.7.1 Handling Babble Conditions

USB core handles two cases of babble: packet babble and port babble. Packet babble occurs if the device sends more data than the maximum packet size for the channel. Port babble occurs if the core continues to receive data from the device at EOF2 (the end of frame 2, which is very close to SOF).

When USB core detects a packet babble, it stops writing data into the Rx buffer and waits for the end of packet (EOP). When it detects an EOP, it flushes already-written data in the Rx buffer and generates a Babble interrupt to the application.

When USB core detects a port babble, it flushes the Rx FIFO and disables the port. The core then generates a Port Disabled Interrupt (GINTSTS.PrtInt, HPRT.PrtEnChng). On receiving this interrupt, the application must determine that this is not due to an overcurrent condition (another cause of the Port Disabled interrupt) by checking

HPRT.PrtOvrCurrAct, then perform a soft reset. The core does not send any more tokens after it has detected a port babble condition.

17.4.7.2 Handling Disconnects

If the device is disconnected suddenly, a GINTSTS.DisconnInt interrupt is generated. When the application receives this interrupt, it must issue a soft reset by programming the GRSTCTL.CSftRst bit.

17.4.8 Host HFIR Functionality

The Host Frame Interval Register (HFIR) specifies the interval between two consecutive SOFs. This field contains the number of PHY clocks that constitute the required frame interval and is primarily used to regulate the SOF duration based on the phy_clk frequency.

17.4.8.1 HFIR Behaviour when HFIR.HFIRIdCtrl = 0_B

This section describes the core behavior when HFIR.HFIRIdCtrl = 0_B using the waveform shown in [Figure 17-7](#).

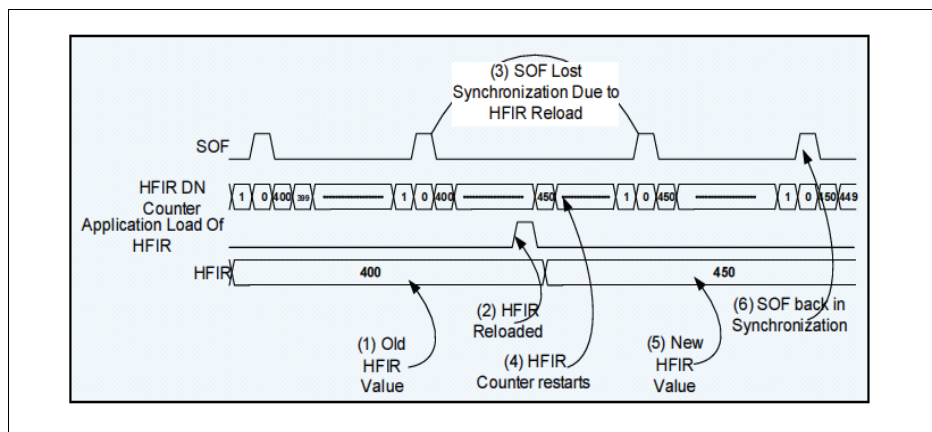

Figure 17-7 Functionality when HFIRIdCtrl = 0_B

The following numbered steps correspond to those in [Figure 17-7](#):

1. Depicts the present HFIR value programmed by the application after power on reset.
2. The application reloads the HFIR register with a new value.
3. Because the HFIR down counter is reloaded, it starts counting again immediately because of which the SOF synchronization is lost.
4. The HFIR counter is restarted.

5. The HFIR register receives the new programmed value.
6. After the first SOF is generated with the new HFIR functionality, SOF synchronization is regained.

17.4.8.2 HFIR Behaviour when HFIR.HFIRIdCtrl = 1_B

This section describes the core behavior when HFIR.HFIRIdCtrl = 1_B using the waveform shown in [Figure 17-8](#).

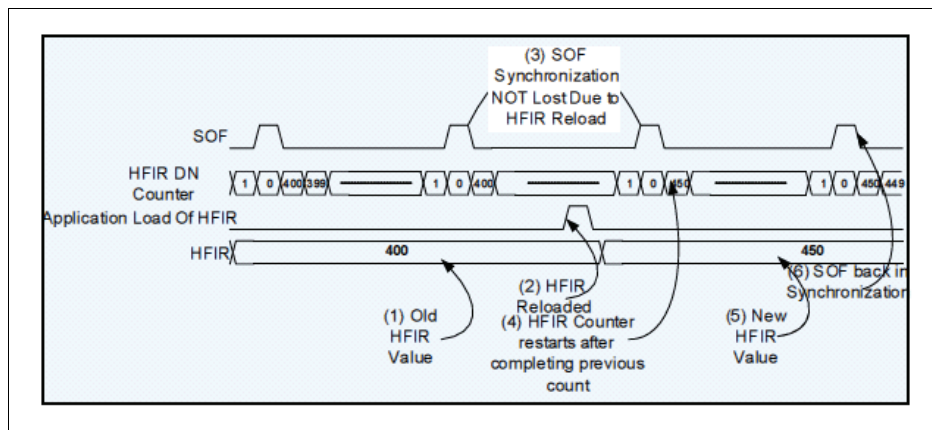

Figure 17-8 Functionality when HFIRIdCtrl = 1_B

The following numbered steps correspond to those in [Figure 17-8](#):

1. Depicts the present HFIR value programmed by the application after power on reset.
2. The application loads the new HFIR value; the HFIR counter does not take this new value and continues counting till the counter reaches zero.
3. The SOF is generated when the counter reaches zero with the old HFIR programmed value.
4. The HFIR counter takes the new value.
5. The new HFIR value takes effect.
6. The SOF is back in synchronization.

17.4.9 Host Programming for Various USB Transactions

[Table 17-2](#) provides links to the programming sequence for the different types of USB transactions.

17.5 Host Programming in Slave mode

This section discusses how to program the Host core when it is configured in Slave mode.

17.5.1 Writing the Transmit FIFO in Slave Mode

Figure 17-9 shows the flow diagram for writing to the transmit FIFO in Slave mode. The USB host automatically writes an entry (OUT request) to the Periodic/Non-periodic Request Queue, along with the last DWORD write of a packet. The application must ensure that at least one free space is available in the Periodic/Non-periodic Request Queue before starting to write to the transmit FIFO. The application must always write to the transmit FIFO in DWORDs. If the packet size is non-DWORD aligned, the application must use padding. The USB host determines the actual packet size based on the programmed maximum packet size and transfer size.

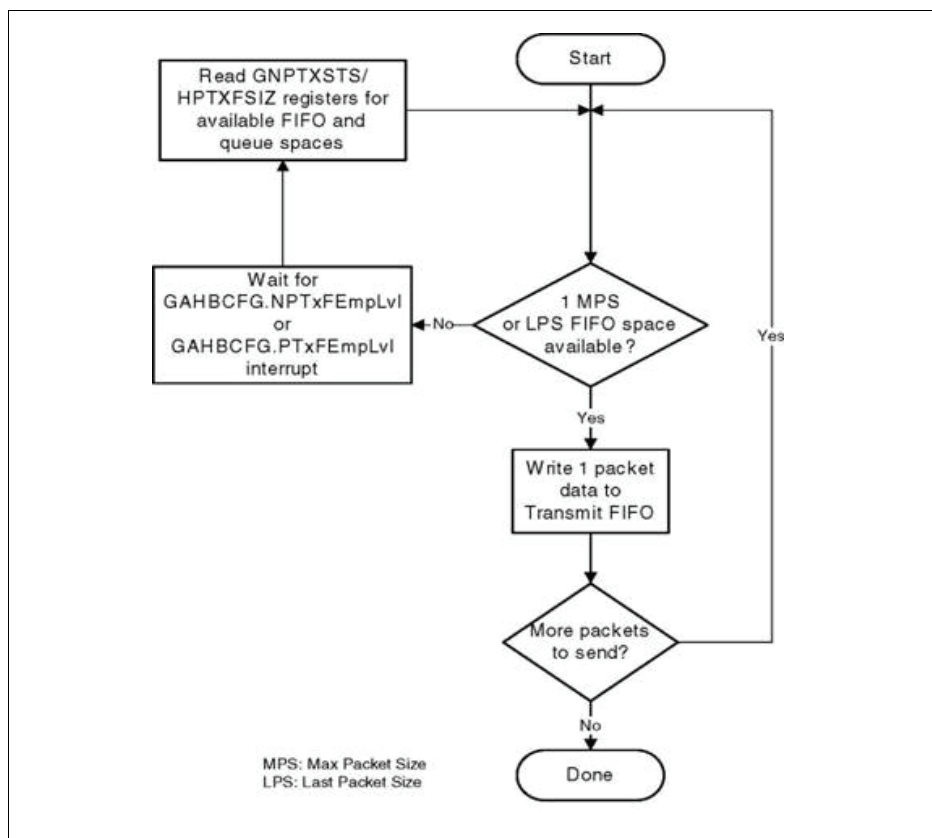

Figure 17-9 Transmit FIFO Write Task in Slave Mode

17.5.2 Reading the Receive FIFO in Slave Mode

Figure 17-10 shows the flow diagram for reading the receive FIFO in Slave mode. The application must ignore all packet statuses other than IN Data Packet (0010_B).

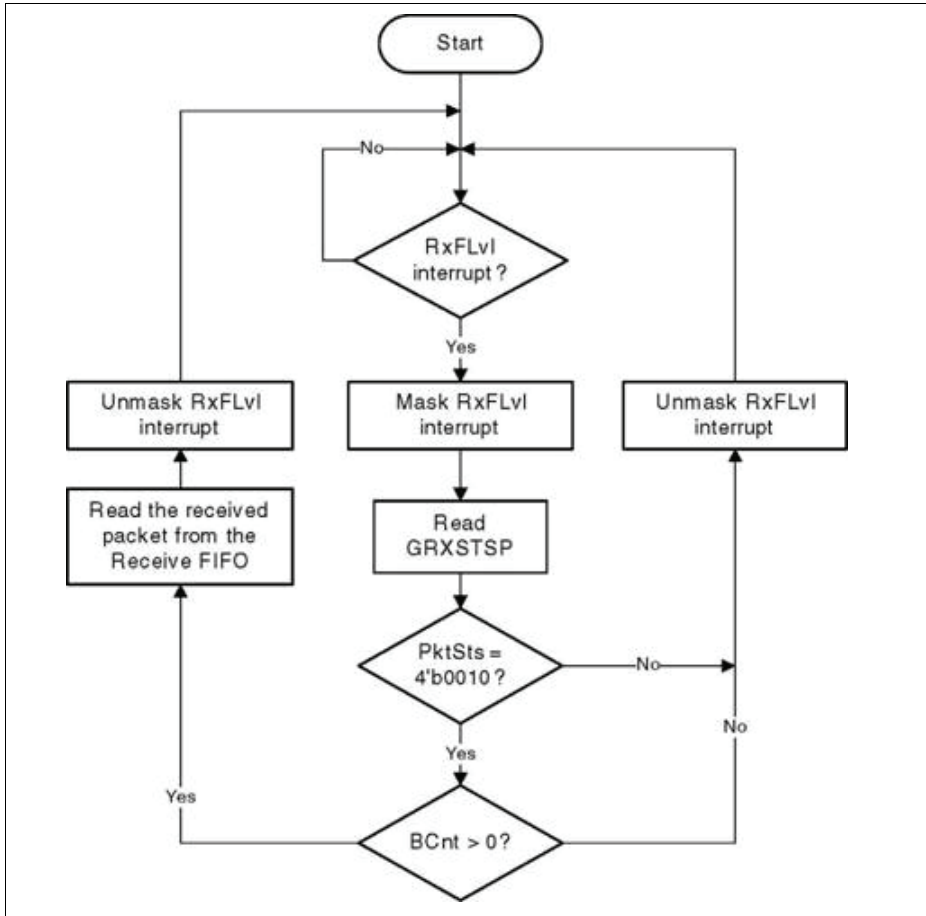

Figure 17-10 Receive FIFO Read Task in Slave Mode

17.5.3 Control Transactions in Slave Mode

Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup-, Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained in **“Bulk and Control OUT/SETUP Transactions in Slave Mode” on Page 17-25**. Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained in **“Bulk and Control IN Transactions in Slave Mode” on Page 17-23**. For all three stages, the application is expected to set the HCCHAR1.EPType field to Control. During the Setup stage, the application is expected to set the HCTSIZ1.PID field to SETUP.

17.5.4 Bulk and Control IN Transactions in Slave Mode

A typical bulk or control IN pipelined transaction-level operation in Slave mode is shown in **Figure 17-11**. See channel 2 (ch_2). The assumptions are:

- The application is attempting to receive two maximum-sized packets (transfer size = 1,024 bytes).
- The receive FIFO can contain at least one maximum-packet-size packet and two status DWORDs per packet (72 bytes for FS).
- The Non-periodic Request Queue depth = 4.

17.5.4.1 Normal Bulk and Control IN Operations

The sequence of operations in **Figure 17-11** (channel 2) is as follows:

1. Initialize channel 2 as explained in **“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14**.
2. Set the HCCHAR2.ChEna bit to write an IN request to the Non-periodic Request Queue.
3. The core attempts to send an IN token after completing the current OUT transaction.
4. The core generates an RxFLvl interrupt as soon as the received packet is written to the receive FIFO.
5. In response to the RxFLvl interrupt, mask the RxFLvl interrupt and read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. Following this, unmask the RxFLvl interrupt.
6. The core generates the RxFLvl interrupt for the transfer completion status entry in the receive FIFO.
7. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet ($\text{GRXSTSR.PktSts!} = 0010_{\text{B}}$).
8. The core generates the XferCompl interrupt as soon as the receive packet status is read.
9. In response to the XferCompl interrupt, disable the channel (see **“Halting a Channel” on Page 17-15**) and stop writing the HCCHAR2 register for further

Universal Serial Bus (USB)

requests. The core writes a channel disable request to the non-periodic request queue as soon as the HCCHAR2 register is written.

10. The core generates the RxFLvl interrupt as soon as the halt status is written to the receive FIFO.
11. Read and ignore the receive packet status.
12. The core generates a ChHltd interrupt as soon as the halt status is popped from the receive FIFO.
13. In response to the ChHltd interrupt, de-allocate the channel for other transfers.

Note: For Bulk/Control IN transfers, the application must write the requests when the Request queue space is available, and until the XferCompl interrupt is received.

17.5.4.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control IN transactions in Slave mode is shown in the following code samples.

Interrupt Service Routine for Bulk/Control IN Transactions in Slave Mode

```
Unmask (XactErr/XferCompl/BblErr/STALL/DataTglErr)
if (XferCompl)
{
    Reset Error Count
    Unmask ChHltd
    Disable Channel
    Reset Error Count
    Mask ACK
}
else if (XactErr or BblErr or STALL)
{
    Unmask ChHltd
    Disable Channel
    if (XactErr)
    {
        Increment Error Count
        Unmask ACK
    }
}
else if (ChHltd)
{
    Mask ChHltd
    if (Transfer Done or (Error_count == 3)
    {
        De-allocate Channel
    }
}
```

```

        }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}
else if (DataTglErr)
{
    Reset Error Count
}

```

17.5.5 Bulk and Control OUT/SETUP Transactions in Slave Mode

A typical bulk or control OUT/SETUP pipelined transaction-level operation in Slave mode is shown in [Figure 17-11](#). See channel 1 (ch_1). Two bulk OUT packets are transmitted. A control SETUP transaction operates the same way but has only one packet. The assumptions are:

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The Non-periodic Transmit FIFO can hold two packets (128 bytes for FS).
- The Non-periodic Request Queue depth = 4.

17.5.5.1 Normal Bulk and Control OUT/SETUP Operations

The sequence of operations in [Figure 17-11](#) (channel 1) is as follows:

1. Initialize channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. Write the first packet for channel 1.
3. Along with the last DWORD write, the core writes an entry to the Non-periodic Request Queue.
4. As soon as the non-periodic queue becomes non-empty, the core attempts to send an OUT token in the current frame.
5. Write the second (last) packet for channel 1.
6. The core generates the XferCompl interrupt as soon as the last transaction is completed successfully.
7. In response to the XferCompl interrupt, de-allocate the channel for other transfers

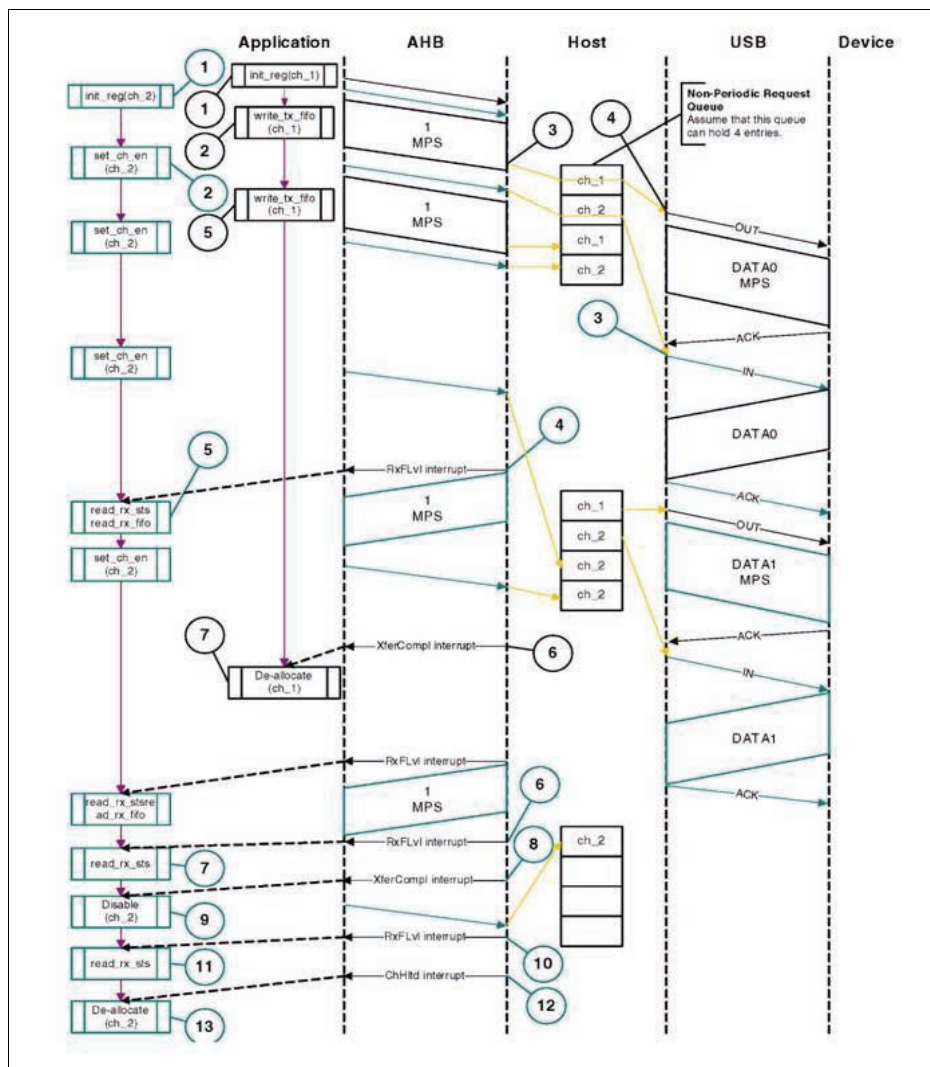

Figure 17-11 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in Slave Mode

17.5.5.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in Slave mode is shown in the following code samples.

Interrupt Service Routine for Bulk/Control OUT/SETUP Transactions in Slave Mode

Bulk/Control OUT/SETUP

```
Unmask (NAK/XactErr/NYET/STALL/XferCompl)
if (XferCompl)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL)
{
    Transfer Done = 1
    Unmask ChHltd
    Disable Channel
}
else if (NAK or XactErr or NYET)
{
    Rewind Buffer Pointers
    Unmask ChHltd
    Disable Channel
    if (XactErr)
    {
        Increment Error Count
        Unmask ACK
    }
    else
    {
        Reset Error Count
    }
}
else if (ChHltd)
{
    Mask ChHltd
    if (Transfer Done or (Error_count == 3))
```

```

        {
            De-allocate Channel
        }
    else
    {
        Re-initialize Channel
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

The application is expected to write the data packets into the transmit FIFO when space is available in the transmit FIFO and the Request queue. The application can make use of GINTSTS.NPTxFEmp interrupt to find the transmit FIFO space.

The application is expected to write the requests as and when the Request queue space is available and until the XferCompl interrupt is received.

The application must clear and never modify the DoPing bit after enabling the channel and until the XferCompl or ChHltd interrupt is received. The core uses the DoPing bit to flush the excessive IN requests after receiving the last or short packet.

17.5.6 Interrupt IN Transactions in Slave Mode

A typical interrupt-IN operation in Slave mode is shown in [Figure 17-12](#). See channel 2 (ch_2). The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame, starting with odd. (transfer size = 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,031 bytes for FS).
- Periodic Request Queue depth = 4.

17.5.6.1 Normal Interrupt IN Operation

The sequence of operations in [Figure 17-12](#) (channel 2) is as follows:

1. Initialize channel 2 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#). The application must set the HCCHAR2.OddFrm bit.
2. Set the HCCHAR2.ChEna bit to write an IN request to the Periodic Request Queue. For a high- bandwidth interrupt transfer, the application must write the HCCHAR2 register MC (maximum number of expected packets in the next frame) times before switching to another channel.

Universal Serial Bus (USB)

3. The USB host writes an IN request to the Periodic Request Queue for each HCCHAR2 register write with a ChEna bit set.
4. The USB host attempts to send an IN token in the next (odd) frame.
5. As soon as the IN packet is received and written to the receive FIFO, the USB host generates an RxFLvl interrupt.
6. In response to the RxFLvl interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RxFLvl interrupt before reading the receive FIFO, and unmask after reading the entire packet.
7. The core generates the RxFLvl interrupt for the transfer completion status entry in the receive FIFO. The application must read and ignore the receive packet status when the receive packet status is not an IN data packet (GRXSTS.R.PktSts! = 0010_B).
8. The core generates an XferCompl interrupt as soon as the receive packet status is read.
9. In response to the XferCompl interrupt, read the HCTSIZ2.PktCnt field. If HCTSIZ2.PktCnt! = 0, disable the channel (as explained in **“Halting a Channel” on Page 17-15**) before re-initializing the channel for the next transfer, if any). If HCTSIZ2.PktCnt == 0, reinitialize the channel for the next transfer. This time, the application must reset the HCCHAR2.OddFrm bit.

17.5.6.2 Handling Interrupts

The channel-specific interrupt service routine for an interrupt IN transaction in Slave mode is as follows.

Interrupt IN

```
Unmask (NAK/XactErr/XferCompl/BblErr/STALL/FrmOvrn/DataTglErr)
if (XferCompl)
{
    Reset Error Count
    Mask ACK
    if (HCTSIZx.PktCnt == 0)
    {
        De-allocate Channel
    }
    else
    {
        Transfer Done = 1
        Unmask ChHltd
        Disable Channel
    }
}
else if (STALL or FrmOvrn or NAK or DataTglErr or BblErr)
```

```

    {
    Mask ACK
    Unmask ChHltd
    Disable Channel
    if (STALL or BblErr)
        {
            Reset Error Count
            Transfer Done = 1
        }
    else if (!FrmOvrn)
        {
            Reset Error Count
        }
    }
else if (XactErr)
    {
        Increment Error Count
        Unmask ACK
        Unmask ChHltd
        Disable Channel
    }
else if (ChHltd)
    {
        Mask ChHltd
        if (Transfer Done or (Error_count == 3))
            {
                De-allocate Channel
            }
        else Re-initialize Channel (in next b_interval - 1
uF/F)
    }
}
else if (ACK)
    {
        Reset Error Count
        Mask ACK
    }

```

The application is expected to write the requests for the same channel when the Request queue space is available up to the count specified in the MC field before switching to another channel (if any).

17.5.7 Interrupt OUT Transactions in Slave Mode

A typical interrupt OUT operation in Slave mode is shown in [Figure 17-12](#). See channel 1 (ch_1). The assumptions are:

- The application is attempting to send one packet in every frame (up to 1 maximum packet size), starting with the odd frame (transfer size = 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB for FS).
- Periodic Request Queue depth = 4.

17.5.7.1 Normal Interrupt OUT Operation

The sequence of operations in [Figure 17-12](#) (channel 1) is as follows:

1. Initialize and enable channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#). The application must set the HCCHAR1.OddFrm bit.
2. Write the first packet for channel 1. For a high-bandwidth interrupt transfer, the application must write the subsequent packets up to MC (maximum number of packets to be transmitted in the next frame times before switching to another channel).
3. Along with the last DWORD write of each packet, the USB host writes an entry to the Periodic Request Queue.
4. The USB host attempts to send an OUT token in the next (odd) frame.
5. The USB host generates an XferCompl interrupt as soon as the last packet is transmitted successfully.
6. In response to the XferCompl interrupt, reinitialize the channel for the next transfer.

17.5.7.2 Handling Interrupts

The channel-specific interrupt service routine for Interrupt OUT transactions in Slave mode is shown in the following flow:

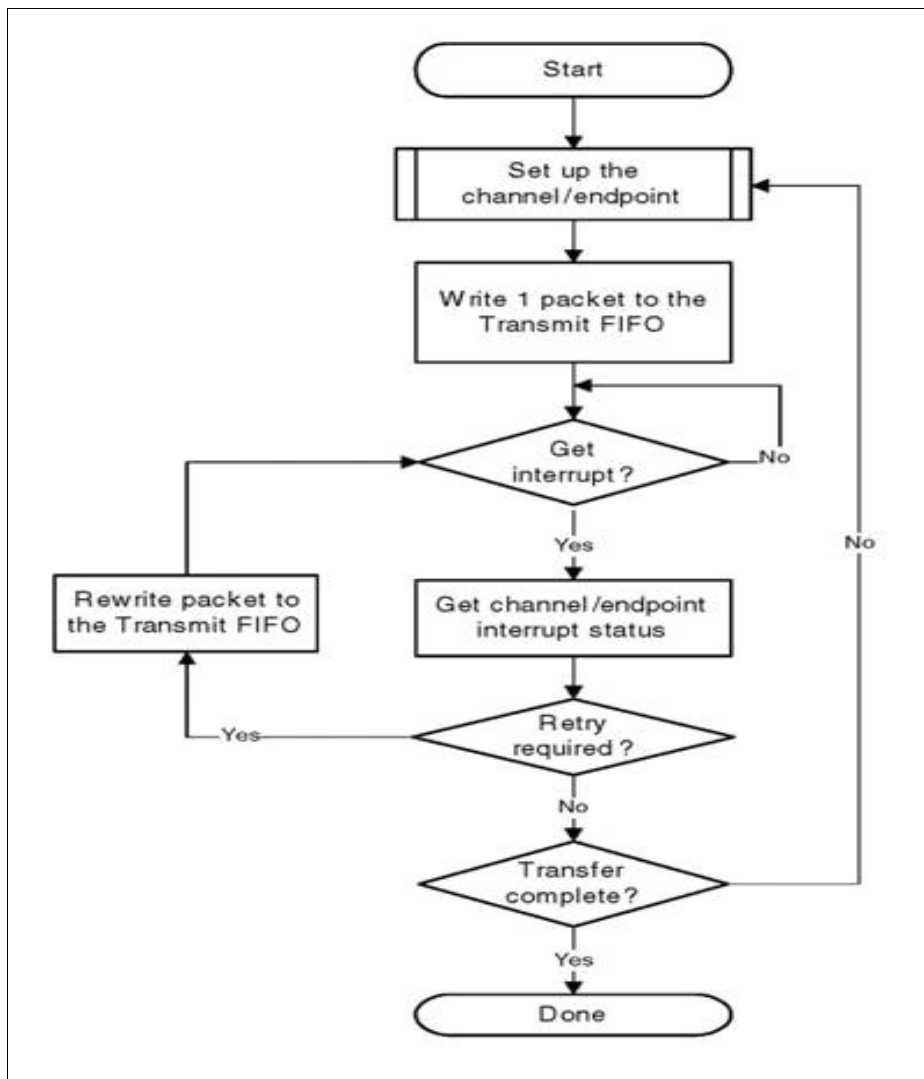

Figure 17-12 Normal Interrupt OUT/IN Transactions in Slave Mode

Interrupt Service Routine for Interrupt OUT Transactions in Slave Mode

Interrupt OUT

```

Unmask (NAK/XactErr/STALL/XferCompl/FrmOvrn)
if (XferCompl)
{
    Reset Error Count
    Mask ACK
    De-allocate Channel
}
else if (STALL or FrmOvrn)
{
    Mask ACK
    Unmask ChHltd
    Disable Channel
    if ( STALL)
    {
        Transfer Done = 1
    }
}
else if (NAK or XactErr)
{
    Rewind Buffer Pointers
    Reset Error Count
    Mask ACK
    Unmask ChHltd
    Disable Channel
}
else if (ChHltd)
{
    Mask ChHltd
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
}
else
{
    Re-initialize Channel (in next b_interval - 1
uF/F)
}
}
else if (ACK)
{
    Reset Error Count

```

```
Mask ACK
}
```

The application is expected to write the data packets into the transmit FIFO when the space is available in the transmit FIFO and the Request queue up to the count specified in the MC field before switching to another channel. The application uses the GINTSTS.NPTxFEmp interrupt to find the transmit FIFO space.

17.5.8 Isochronous IN Transactions in Slave Mode

A typical isochronous IN operation in Slave mode is shown in [Figure 17-13](#). See channel 2 (ch_2). The assumptions are:

- The application is attempting to receive one packet (up to 1 maximum packet size) in every frame starting with the next odd frame. (transfer size = 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,031 bytes for FS).
- Periodic Request Queue depth = 4.

17.5.8.1 Normal Isochronous IN Operation

The sequence of operations in [Figure 17-13](#) (channel 2) is as follows:

1. Initialize channel 2 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#). The application must set the HCCHAR2.OddFrm bit.
2. Set the HCCHAR2.ChEna bit to write an IN request to the Periodic Request Queue. For a high- bandwidth isochronous transfer, the application must write the HCCHAR2 register MC (maximum number of expected packets in the next frame) times before switching to another channel.
3. The USB host writes an IN request to the Periodic Request Queue for each HCCHAR2 register write with the ChEna bit set.
4. The USB host attempts to send an IN token in the next odd frame.
5. As soon as the IN packet is received and written to the receive FIFO, the USB host generates an RxFLvl interrupt.
6. In response to the RxFLvl interrupt, read the received packet status to determine the number of bytes received, then read the receive FIFO accordingly. The application must mask the RxFLvl interrupt before reading the receive FIFO, and unmask it after reading the entire packet.
7. The core generates an RxFLvl interrupt for the transfer completion status entry in the receive FIFO. This time, the application must read and ignore the receive packet status when the receive packet status is not an IN data packet (GRXSTSR.PktSts!= 0010_B).
8. The core generates an XferCompl interrupt as soon as the receive packet status is read.
9. In response to the XferCompl interrupt, read the HCTSIZ2.PktCnt field. If HCTSIZ2.PktCnt!= 0, disable the channel (as explained in [“Halting a Channel” on](#)

Page 17-15) before re-initializing the channel for the next transfer, if any. If HCTSIZ2.PktCnt == 0, reinitialize the channel for the next transfer. This time, the application must reset the HCCHAR2.OddFrm bit.

17.5.8.2 Handling Interrupts

The channel-specific interrupt service routine for an isochronous IN transaction in Slave mode is as follows.

Isochronous IN

```
Unmask (XactErr/XferCompl/FrmOvrn/BblErr)
if ( XferCompl or FrmOvrn)
{
    if (XferCompl and (HCTSIZx.PktCnt == 0))
    {
        Reset Error Count
        De-allocate Channel
    }
    else
    {
        Unmask ChHltd
        Disable Channel
    }
}
else if (XactErr or BblErr)
{
    Increment Error Count
    Unmask ChHltd
    Disable Channel
}
else if (ChHltd)
{
    Mask ChHltd
    if (Transfer Done or (Error_count == 3))
    {
        De-allocate Channel
    }
    else
    {
        Re-initialize Channel
    }
}
```

17.5.9 Isochronous OUT Transactions in Slave Mode

A typical isochronous OUT operation in Slave mode is shown in [Figure 17-13](#). See channel 1 (ch_1). The assumptions are:

- The application is attempting to send one packet every frame (up to 1 maximum packet size), starting with an odd frame. (transfer size = 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB for FS).
- Periodic Request Queue depth = 4.

17.5.9.1 Normal Isochronous OUT Operation

The sequence of operations in [Figure 17-13](#) (channel 1) is as follows:

1. Initialize and enable channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#). The application must set the HCCHAR1.OddFrm bit.
2. Write the first packet for channel 1. For a high-bandwidth isochronous transfer, the application must write the subsequent packets up to MC (maximum number of packets to be transmitted in the next frame) times before switching to another channel.
3. Along with the last DWORD write of each packet, the USB host writes an entry to the Periodic Request Queue.
4. The USB host attempts to send the OUT token in the next frame (odd).
5. The USB host generates the XferCompl interrupt as soon as the last packet is transmitted successfully.
6. In response to the XferCompl interrupt, reinitialize the channel for the next transfer.

17.5.9.2 Handling Interrupts

The channel-specific interrupt service routine for isochronous OUT transactions in Slave mode is shown in the following flow:

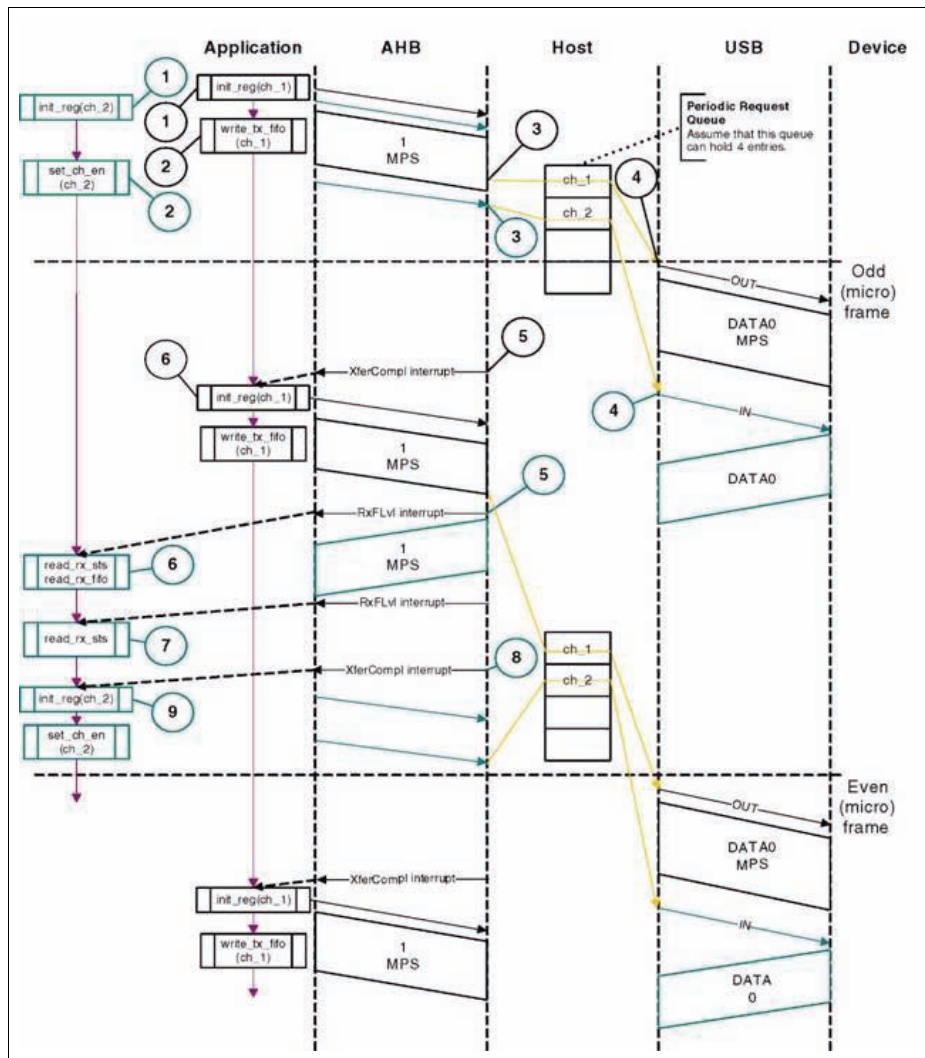

Figure 17-13 Normal Isochronous OUT/IN Transactions in Slave Mode

Interrupt Service Routine for Isochronous OUT Transactions in Slave Mode

Isochronous OUT

```

Unmask (FrmOvrn/XferCompl)
if (XferCompl)
{
    De-allocate Channel
}
else if (FrmOvrn)
{
    Unmask ChHltd
    Disable Channel
}
else if (ChHltd)
{
    Mask ChHltd
    De-allocate Channel
}

```

17.6 Host Programming in Buffer DMA Mode

This section discusses how to program the Host core when it is in Buffer DMA mode.

17.6.1 Control Transactions in Buffer DMA Mode

Setup, Data, and Status stages of a control transfer must be performed as three separate transfers. Setup- and Data- or Status-stage OUT transactions are performed similarly to the bulk OUT transactions explained in [“Bulk and Control OUT/SETUP Transactions in Buffer DMA Mode” on Page 17-40](#). Data- or Status-stage IN transactions are performed similarly to the bulk IN transactions explained in [“Bulk and Control IN Transactions in Buffer DMA Mode” on Page 17-38](#). For all three stages, the application is expected to set the HCCHAR1.EPType field to Control. During the Setup stage, the application is expected to set the HCTSIZ1.PID field to SETUP.

17.6.2 Bulk and Control IN Transactions in Buffer DMA Mode

A typical bulk or control IN operation in DMA mode is shown in [Figure 17-14](#). See channel 2 (ch_2).

The assumptions are:

- The application is attempting to receive two maximum-packet-size packets (transfer size = 1,024 bytes).

Universal Serial Bus (USB)

- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (72 bytes for FS).
- The Non-periodic Request Queue depth = 4.

17.6.2.1 Normal Bulk and Control IN Operations

The sequence of operations in [Figure 17-14](#) (channel 2) is as follows:

1. Initialize and enable channel 2 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. The USB host writes an IN request to the Request queue as soon as channel 2 receives the grant from the arbiter. (Arbitration is performed in a round-robin fashion, with fairness.).
3. The USB host starts writing the received data to the system memory as soon as the last byte is received with no errors.
4. When the last packet is received, the USB host sets an internal flag to remove any extra IN requests from the Request queue.
5. The USB host flushes the extra requests.
6. The final request to disable channel 2 is written to the Request queue. At this point, channel 2 is internally masked for further arbitration.
7. The USB host generates the ChHltd interrupt as soon as the disable request comes to the top of the queue.
8. In response to the ChHltd interrupt, de-allocate the channel for other transfers.

17.6.2.2 Handling Interrupts

The channel-specific interrupt service routine for bulk and control IN transactions in DMA mode is shown in the following flow:

Interrupt Service Routines for Bulk/Control Bulk/Control IN Transactions in DMA Mode

Bulk/Control IN

```
Unmask (ChHltd)
    if (ChHltd) {
        if (XferComp1 or STALL or BblErr) {
            Reset Error Count Mask ACK De-allocate Channel }
        else if (XactErr) {
            if (Error_count == 2) {
                De-allocate Channel
            }
        }
        else {
```

```

        Unmask ACK
        Unmask NAK
        Unmask DataTglErr
        Increment Error
        Count Re-initialize Channel
    }
}
}
else if (ACK or NAK or DataTglErr) {
    Reset Error Count
    Mask ACK
    Mask NAK Mask DataTglErr
}

```

The application must clear and never modify the DoPing bit after enabling the channel and until the ChHltd interrupt is received. The core uses the DoPing excessive IN requests after receiving the last or short packet.

17.6.3 Bulk and Control OUT/SETUP Transactions in Buffer DMA Mode

17.6.3.1 Overview

- The application is attempting to send two maximum-packet-size packets (transfer size = 1,024 bytes).
- The Non-periodic Transmit FIFO can hold two packets (128 bytes for FS).
- The Non-periodic Request Queue depth = 4.

17.6.3.2 Normal Bulk and Control OUT/SETUP Operations

The sequence of operations in [Figure 17-11](#) (channel 1) is as follows:

1. Initialize and enable channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. The USB host starts fetching the first packet as soon as the channel is enabled. For internal DMA mode, the USB host uses the programmed DMA address to fetch the packet.
3. After fetching the last DWORD of the second (last) packet, the USB host masks channel 1 internally for further arbitration.
4. The USB host generates a ChHltd interrupt as soon as the last packet is sent.
5. In response to the ChHltd interrupt, de-allocate the channel for other transfers.

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in DMA mode is shown in [“Handling Interrupts” on Page 17-43](#).

17.6.3.3 NAK and NYET Handling With Internal DMA

1. The USB Host sends a Bulk OUT Transaction.
2. The Device responds with NAK or NYET.
3. If the application has unmasked NAK or NYET, the core generates the corresponding interrupt(s) to the application.
The application is not required to service these interrupts, since the core takes care of rewinding of buffer pointers and re-initializing the Channel without application intervention.
4. The core automatically issues a ping token.
5. When the Device returns an ACK, the core continues with the transfer.

Note: The application must use the Do Ping bit to set the ping bit (HCTSIZ0[31]) for the next transfer and not rely on the NYET status. This ensures that the last response sent from the device (NYET/ACK) does not matter for a new transfer.

Optionally, the application can utilize these interrupts. If utilized by the application:

- The NAK or NYET interrupt is masked by the application.
- The core does not generate a separate interrupt when NAK or NYET is received by the Host functionality.

Application Programming Flow

1. The application programs a channel to do a bulk transfer for a particular data size in each transaction.
 - a) Packet Data size can be up to 512KBytes
 - b) Zero-length data must be programmed as a separate transaction.
2. Program the transfer size register with:
 - a) Transfer size
 - b) Packet Count
3. Program the DMA address.
4. Program the HCCHAR to enable the channel.
5. The application is not required to set the HCCHARx.DoPng bit for NAK/NYET responses. The core sends a Ping token automatically when the device responds with a NAK/NYET for OUT transfers. The core keeps sending the Ping token until an ACK response is received.
6. The Interrupt handling by the application is as depicted in the flow diagram.

Note: The NAK/NYET interrupts are still generated internally. The application can mask off these interrupts from reaching it. The application can use these interrupts optionally

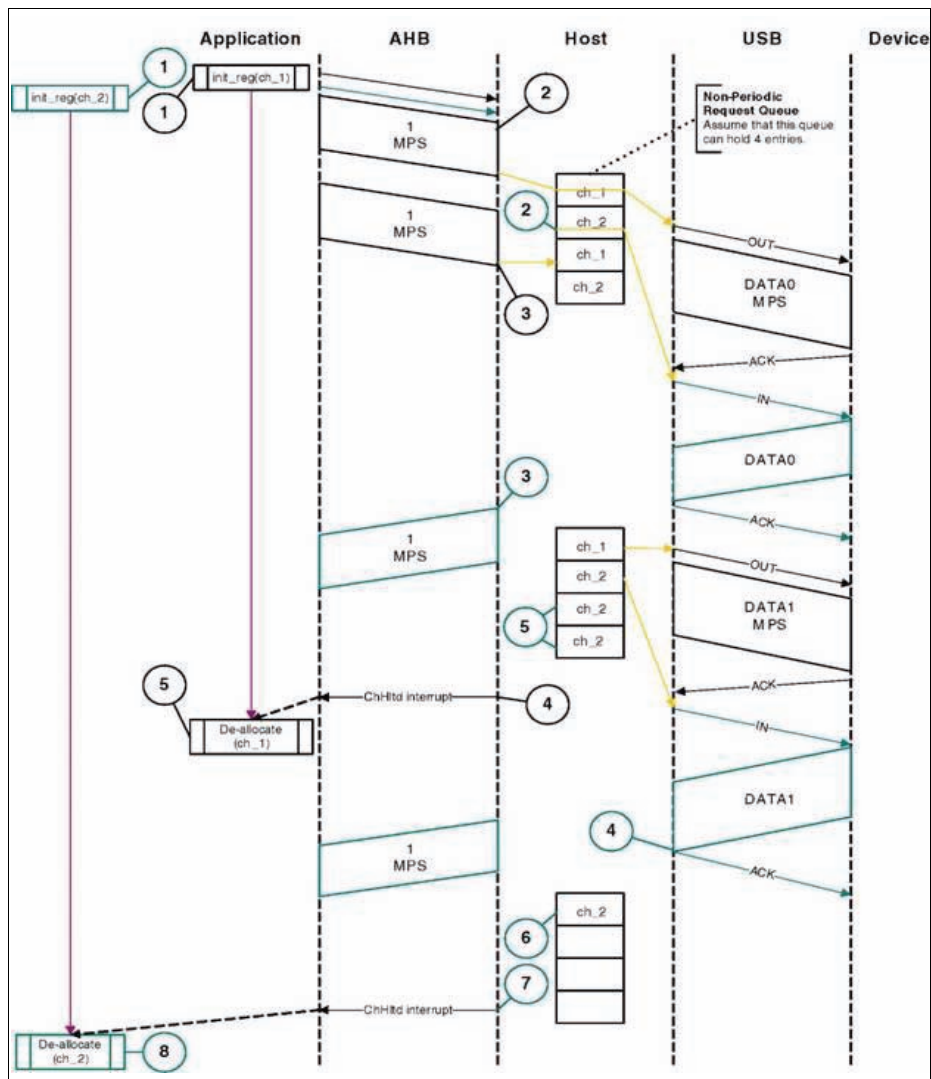

Figure 17-14 Normal Bulk/Control OUT/SETUP and Bulk/Control IN Transactions in DMA Mode

17.6.3.4 Handling Interrupts

The channel-specific interrupt service routine for bulk and control OUT/SETUP transactions in DMA mode is shown in the following code samples.

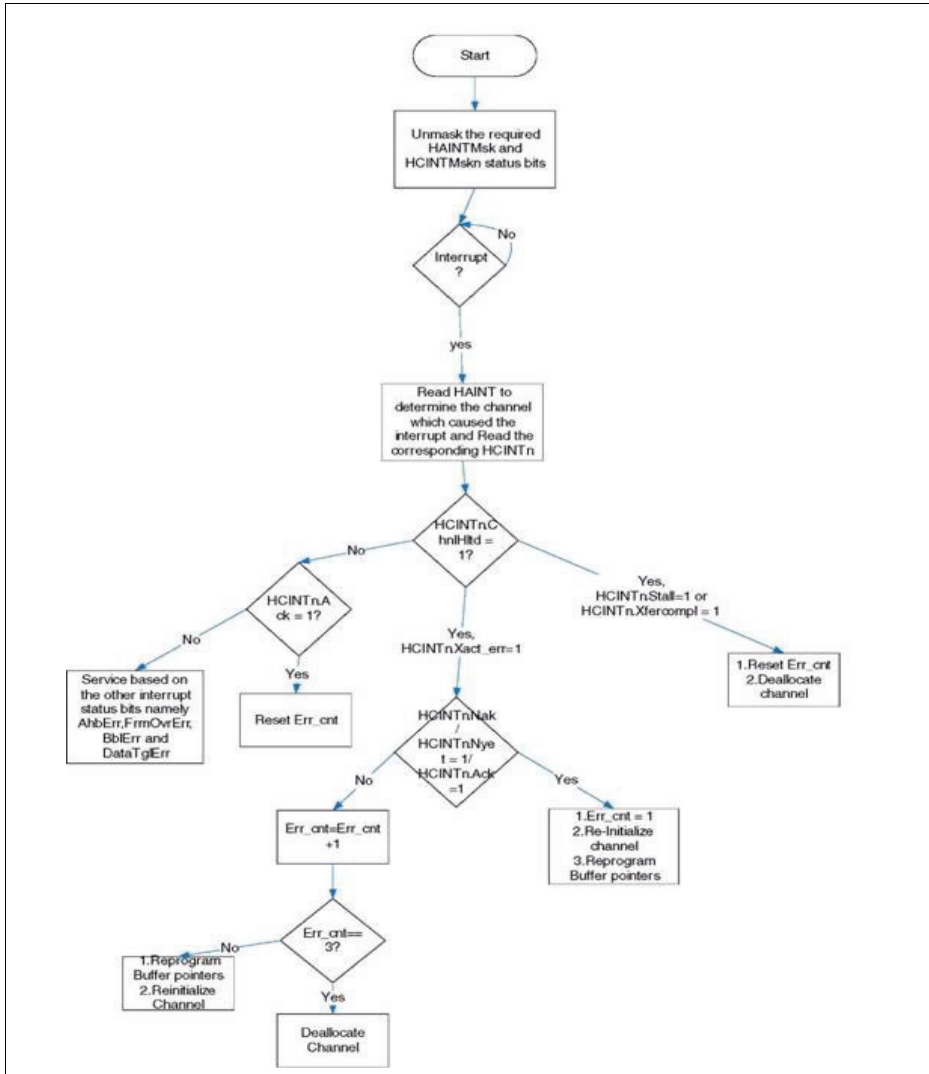

Figure 17-15 Interrupt Service Routine for Bulk/Control OUT Transaction in DMA Mode

Universal Serial Bus (USB)

In **Figure 17-15** that the Interrupt Service Routine is not required to handle NAK or NYET responses. The core internally sets the HCCHARx.DoPng bit once a NAK/NYET is received. The HCCHARx.DoPng is cleared only when the Ping token receives an ACK response. The application is not required to set the HCCHARx.DoPng bit for NAK/NYET scenarios. This is the difference of proposed flow with respect to current flow. Similar flow is applicable for Control flow also.

The NAK/NYET status bits in HCINTx registers are updated. The application can unmask these interrupts when it requires the core to generate an interrupt for NAK/NYET. The NAK/NYET status is updated because during Xact_err scenarios, this status provides a means for the application to determine whether the Xact_err occurred three times consecutively or there were NAK/NYET responses in between two Xact_err. This provides a mechanism for the application to reset the error counter accordingly. The application must read the NAK / NYET /ACK along with the xact_err. If NAK / NYET / ACK is not set, the Xact_err count must be incremented otherwise application must initialize the Xact_err count to 1.

Bulk/Control OUT/SETUP

```

Unmask (ChHltd)
if (ChHltd)
{
    if (XferCompl or STALL)
    {
        Reset Error Count (Error_count=1)
        Mask ACK
        De-allocate Channel
    }
    else if (XactErr)
    {
        if (Nak/Nyet/Ack)
        {
            Error_count = 1
            Re-initialize Channel
            Rewind Buffer Pointers }
        }
        else
        {
            Error_count = Error_count + 1
            if (Error_count == 3)
            {
                De allocate channel
            }
        }
    }
    else
    {

```

```

        {
            Re-initialize Channel
            Rewind Buffer Pointers
        }
    }
}
else if (ACK)
{
    Reset Error Count (Error_count=1)
    Mask ACK
}

```

As soon as the channel is enabled, the core attempts to fetch and write data packets, in multiples of the maximum packet size, to the transmit FIFO when space is available in the transmit FIFO and the Request queue. The core stops fetching as soon as the last packet is fetched.

While continuing the transfer to a high-speed device, the application must set the DoPing bit before enabling the channel if the previous transaction ended with XacrErr response. In this case, the core starts with the ping protocol, then automatically switches to Data Transfer mode.

17.6.4 Interrupt IN Transactions in Buffer DMA Mode

A typical interrupt IN operation in DMA mode is shown in [Figure 17-16](#). See channel 2 (ch_2). The assumptions are:

- The application is attempting to receive one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDs per packet (1,032 bytes for FS).
- Periodic Request Queue depth = 4.

17.6.4.1 Normal Interrupt IN Operation

The sequence of operations in [Figure 17-16](#) on [Page 17-48](#) (channel 2) is as follows:

1. Initialize and enable channel 2 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. The USB host writes an IN request to the Request queue as soon as the channel 2 gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the USB host writes consecutive writes up to MC times.
3. The USB host attempts to send an IN token at the beginning of the next (odd) frame.
4. As soon the packet is received and written to the receive FIFO, the USB host generates a ChHltd interrupt.

5. In response to the ChHltd interrupt, reinitialize the channel for the next transfer.

17.6.4.2 Handling Interrupts

The channel-specific interrupt service routine for Interrupt IN transactions in DMA mode is as follows.

Interrupt Service Routine for Interrupt IN Transactions in DMA Mode

```

Unmask (ChHltd)
if (ChHltd)
{
    if (XferCompl)
    {
        Reset Error Count
        Mask ACK
        if (Transfer Done)
        {
            De-allocate Channel
        }
        else
        {
            Re-initialize Channel (in next b_interval -
1 uF/F)
        }
    }
    else if (STALL or BblErr)
    {
        Reset Error Count
        Mask ACK
        De-allocate Channel
    }
    else if (NAK or DataTglErr or FrmOvrn)
    {
        Mask ACK
        Re-initialize Channel (in next b_interval - 1 uF/F)
        if (DataTglErr or NAK)
        {
            Reset Error Count
        }
    }
    else if (XactErr)
    {
        if (Error_count == 2)
    
```

```

        {
            De-allocate Channel
        }
    else
    {
        Increment Error Count
        Unmask ACK
        Re-initialize Channel (in next b_interval - 1
uF/F)
    }
}
}
else if (ACK)
{
    Reset Error Count
    Mask ACK

```

As soon as the channel is enabled, the core attempts to write the requests into the Request queue when the space is available up to the count specified in the MC field.

17.6.5 Interrupt OUT Transactions in Buffer DMA Mode

A typical interrupt OUT operation in DMA mode is shown in [Figure 17-16](#). See channel 1 (ch_1). The assumptions are:

- The application is attempting to transmit one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB for FS).
- Periodic Request Queue depth = 4.

17.6.5.1 Normal Interrupt OUT Operation

1. Initialize and enable channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. The USB host starts fetching the first packet as soon the channel is enabled and writes the OUT request along with the last DWORD fetch. In high-bandwidth transfers, the USB host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The USB host attempts to send the OUT token in the beginning of the next odd frame.
4. After successfully transmitting the packet, the USB host generates a ChHltd interrupt.
5. In response to the ChHltd interrupt, reinitialize the channel for the next transfer.

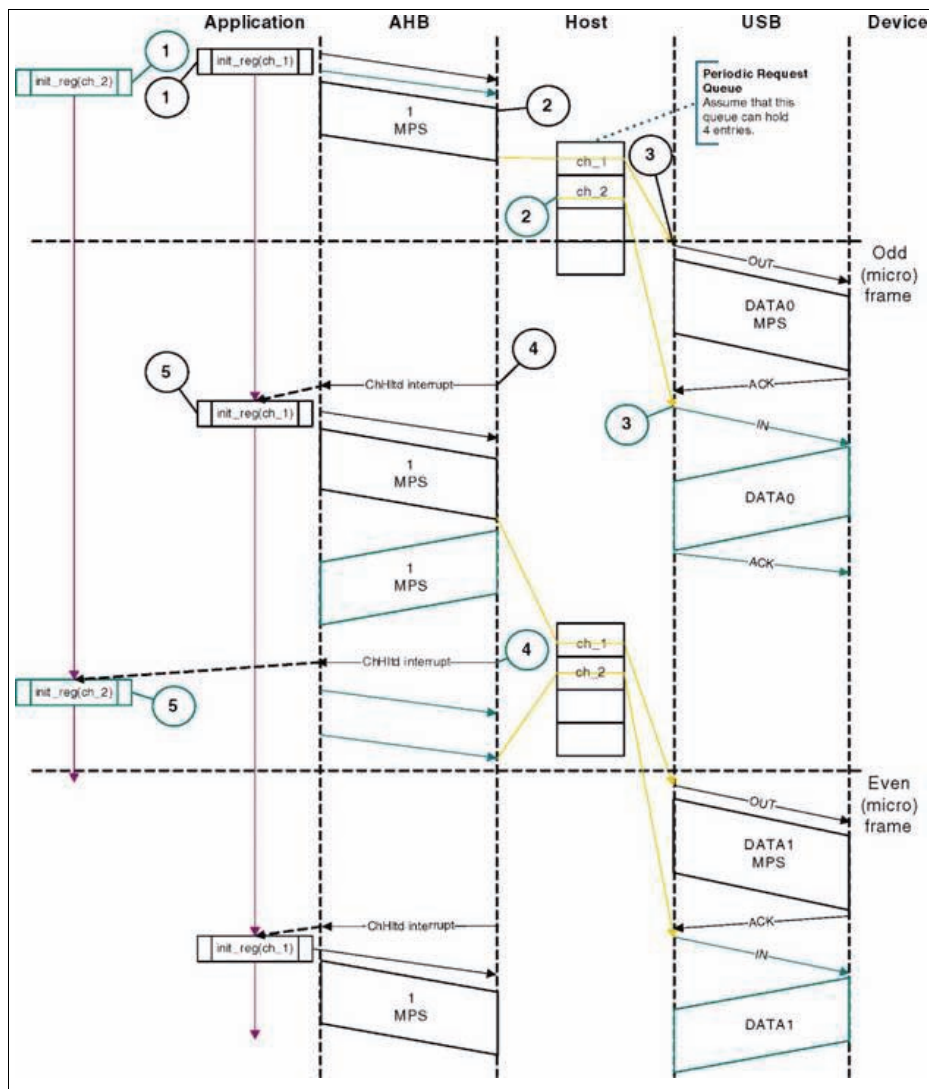

Figure 17-16 Normal Interrupt OUT/IN Transactions in DMA Mode

17.6.5.2 Handling Interrupts

The following code sample shows the channel-specific ISR for an interrupt OUT transaction in DMA mode.

Interrupt Service Routine for Interrupt OUT Transactions in DMA Mode

Interrupt OUT

```

Unmask (ChHltd)
    if (ChHltd)
    {
        if (XferCompl)
        {
            Reset Error Count
            Mask ACK
            if (Transfer Done)
            {
                De-allocate Channel
            }
            else
            {
                Re-initialize Channel (in next b_interval -
1 uF/F)
            }
        }
        else if (STALL)
        {
            Transfer Done = 1
            Reset Error Count
            Mask ACK
            De-allocate Channel
        }
        else if (NAK or FrmOvrn)
        {
            Mask ACK
            Rewind Buffer Pointers
            Re-initialize Channel (in next b_interval - 1
uF/F)
        }
        if (NAK)
        {
            Reset Error Count

```

```

        }
    }
    else if (XactErr)
    {
        if (Error_count == 2)
        {
            De-allocate Channel
        }
    }
    else
    {
        Increment Error Count
        Rewind Buffer Pointers
        Unmask ACK
        Re-initialize Channel (in next b_interval - 1
uF/F)
    }
}
else if (ACK)
{
    Reset Error Count
    Mask ACK
}

```

As soon as the channel is enabled, the core attempts to fetch and write data packets, in maximum packet size multiples, to the transmit FIFO when the space is available in the transmit FIFO and the Request queue. The core stops fetching as soon as the last packet is fetched (the number of packets is determined by the MC field of the HCCHARx register).

17.6.6 Isochronous IN Transactions in Buffer DMA Mode

A typical isochronous IN operation in DMA mode is shown in [Figure 17-17](#). See channel 2 (ch_2). The assumptions are:

- The application is attempting to receive one packet in every frame (up to 1 maximum packet size of 1,024 bytes).
- The receive FIFO can hold at least one maximum-packet-size packet and two status DWORDS per packet (1,032 bytes for FS).
- Periodic Request Queue depth = 4.

17.6.6.1 Normal Isochronous IN Operation

The sequence of operations in [Figure 17-17](#) (channel 2) is as follows:

Universal Serial Bus (USB)

1. Initialize and enable channel 2 as explained in “**Channel Initialization in Buffer DMA or Slave Mode**” on Page 17-14.
2. The USB host writes an IN request to the Request queue as soon as the channel 2 gets the grant from the arbiter (round-robin with fairness). In high-bandwidth transfers, the USB host performs consecutive writes up to MC times.
3. The USB host attempts to send an IN token at the beginning of the next (odd) frame.
4. As soon the packet is received and written to the receive FIFO, the USB host generates a ChHltd interrupt.
5. In response to the ChHltd interrupt, reinitialize the channel for the next transfer.

17.6.6.2 Handling Interrupts

The channel-specific interrupt service routine for an isochronous IN transaction in DMA mode is as follows.

Isochronous IN

```

Unmask (ChHltd)
if (ChHltd)
{
    if ( XferCompl or FrmOvrn)
    {
        if (XferCompl and (HCTSIZx.PktCnt == 0))
        {
            Reset Error Count
            De-allocate Channel
        }
        else
        {
            De-allocate Channel
        }
    }
    else if (XactErr or BblErr)
    {
        if (Error_count == 2)
        {
            De-allocate Channel
        }
        else
        {
            Increment Error Count
            Re-enable Channel (in next b_interval - 1 uF/F)
        }
    }
}

```

}

17.6.7 Isochronous OUT Transactions in Buffer DMA Mode

A typical isochronous OUT operation in DMA mode is shown in [Figure 17-17](#). See channel 1 (ch_1). The assumptions are:

- The application is attempting to transmit one packet every frame (up to 1 maximum packet size of 1,024 bytes).
- The Periodic Transmit FIFO can hold one packet (1 KB for FS).
- Periodic Request Queue depth = 4.

17.6.7.1 Normal Isochronous OUT Operation

1. Initialize and enable channel 1 as explained in [“Channel Initialization in Buffer DMA or Slave Mode” on Page 17-14](#).
2. The USB host starts fetching the first packet as soon as the channel is enabled, and writes the OUT request along with the last DWORD fetch. In high-bandwidth transfers, the USB host continues fetching the next packet (up to the value specified in the MC field) before switching to the next channel.
3. The USB host attempts to send an OUT token in the beginning of the next (odd) frame.
4. After successfully transmitting the packet, the USB host generates a ChHltd interrupt.
5. In response to the ChHltd interrupt, reinitialize the channel for the next transfer.

17.6.7.2 Handling Interrupts

The channel-specific interrupt service routine for Isochronous OUT transactions in DMA mode is shown in the following flow:

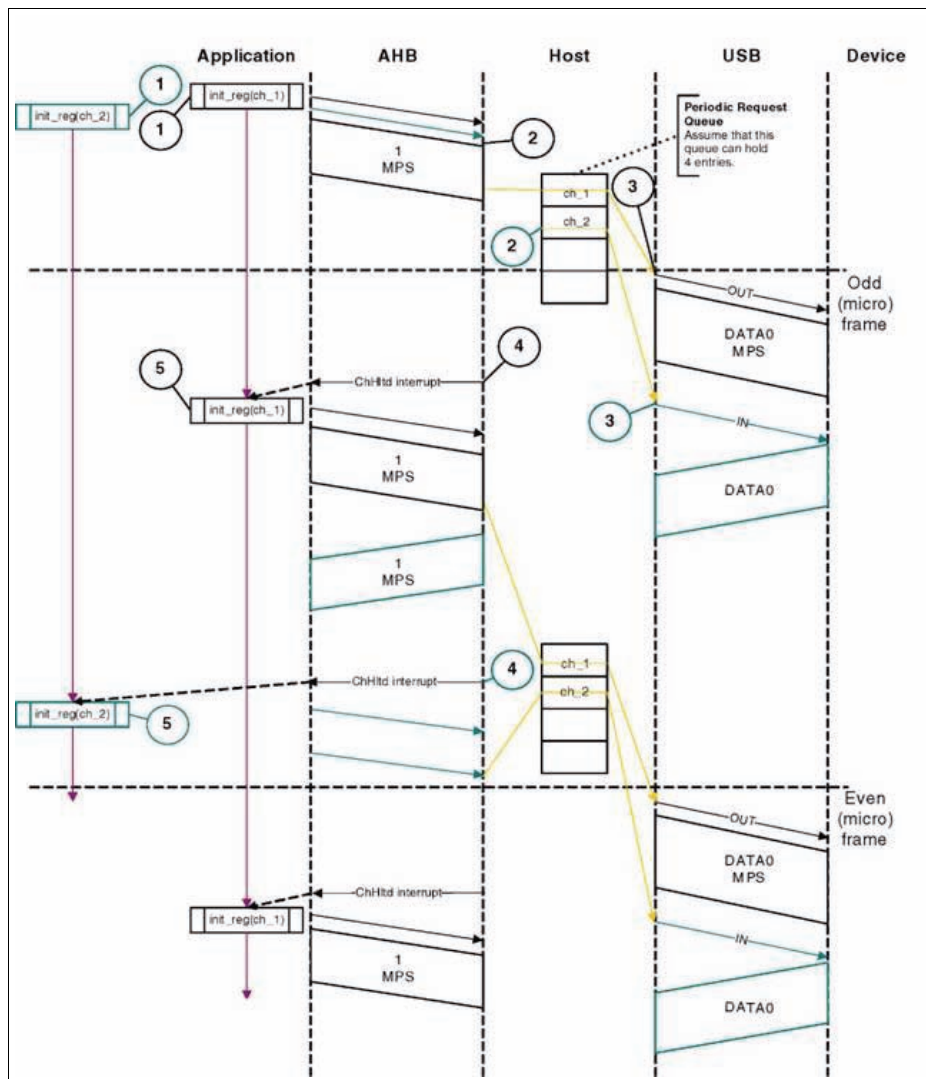

Figure 17-17 Normal Isochronous OUT/IN Transactions in DMA Mode

Interrupt Service Routine for Isochronous OUT Transactions in DMA Mode

Isochronous OUT

```
Unmask (ChHltd)
if (ChHltd)
{
    if (XferCompl or FrmOvrn)
    {
        De-allocate Channel
    }
}
```

17.7 Host Programming in Scatter-Gather DMA Mode

This section describes the programming requirements for the USB core operating in Scatter-Gather (descriptor) DMA host mode. It provides information on programming the core to perform asynchronous transfers (bulk and control), and periodic transfers (isochronous and interrupt).

17.7.1 Programming Requirements

Consider the following points when using the host core in scatter-gather DMA mode:

- USB core supports non-DWORD aligned address access in Scatter/Gather DMA in Host mode only
- NAK/NYET scenario is handled by USB core in Scatter/Gather DMA mode without the application's intervention.
- CONCAT mode is not supported for any of the flows, that is, a single packet cannot span more than one descriptor.

17.7.2 SPRAM Requirements

For each channel, the current descriptor pointer and descriptor status are cached to avoid additional requests to system memory. These are stored in the SPRAM. In addition, the HCDMAx registers are also implemented in the SPRAM.

17.7.2.1 Descriptor Memory Structures

In Scatter/Gather DMA mode, the core implements a true scatter-gather memory distribution in which data buffers are scattered over the system memory. However, the descriptors themselves are continuous. Each channel memory structure is implemented as a contiguous list of descriptors; each descriptor points to a data buffer of predefined size. In addition to the buffer pointer (1 DWORD), the descriptor also has a status quadlet (1 DWORD). When the list is implemented as a ring buffer, the list processor switches to the first element of the list when it encounters last bit. All channels (control, bulk, interrupt, and isochronous) implement these structures in memory.

Note: The descriptors are stored in continuous locations. For example, descriptor 1 is stored in 0000'0000_H, descriptor 2 is stored in 0000'0008_H, descriptor 3 in 0000'0010_H and so on. The descriptors are always DWORD aligned.

The descriptor memory structures are displayed in **Figure 17-18**.

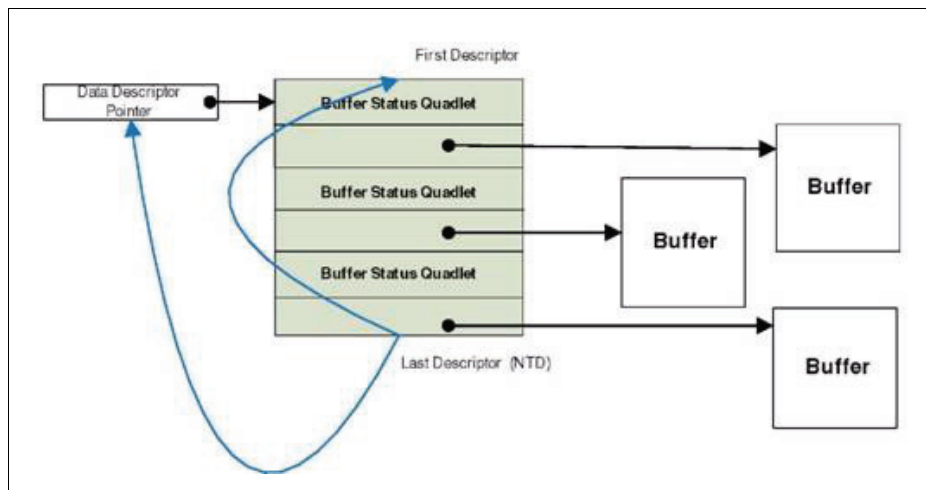

Figure 17-18 Descriptor Memory Structures

All channels must implement the following memory structure:

- Each channel has one memory structure
- Each data buffer must have a descriptor associated with it to provide the status of the buffer. The buffer itself contains only raw data.
- Each buffer descriptor is two quadlets in length. When the descriptor is ready, the DMA fetches and processes its data buffer. The buffers to which the descriptor points hold packet data for non- isochronous channels and packet data corresponding to the frame data for isochronous channels.
- The handshake between the application and core is accomplished by the Active Bit field in the status quadlet of the descriptor as described below:
- A=1 indicates that the descriptor is ready.
- A=0 indicates that the descriptor is not ready.

Universal Serial Bus (USB)

The IN and OUT data memory structures are shown in [Figure 17-19](#). The figure shows the definition of status quadlet bits for non-ISO and ISO channels.

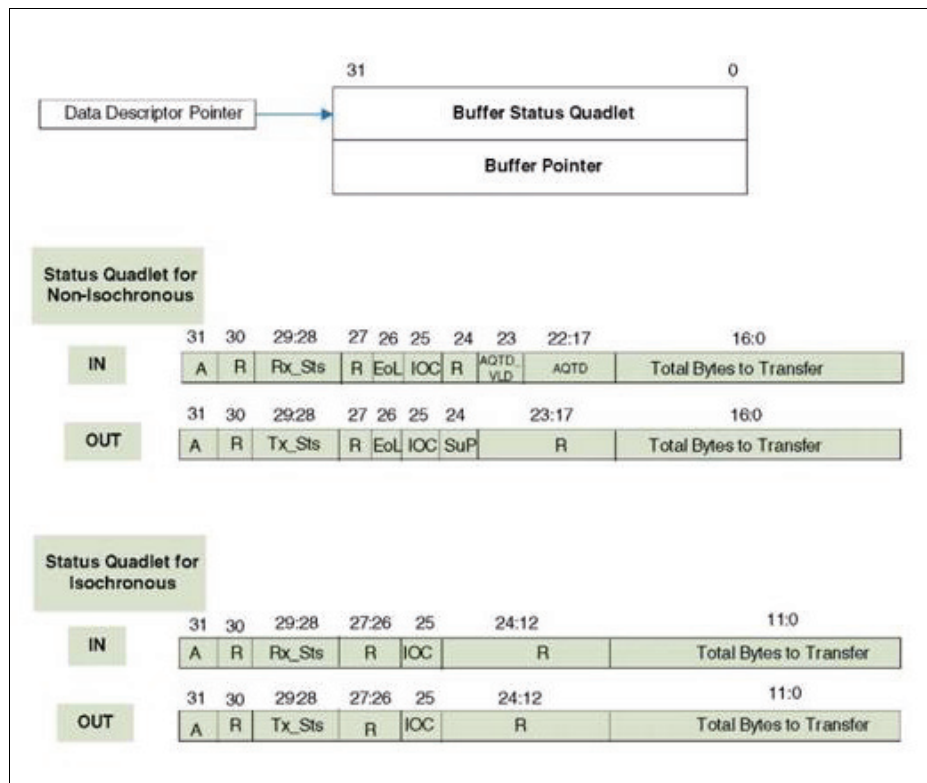

Figure 17-19 Memory Structure

Universal Serial Bus (USB)

In addition, a Frame list in memory for Isochronous and Interrupt channels contains information on the channels that need to be scheduled in a frame. For periodic channels, USB core reads the list corresponding to the frame number and schedules the channel that has Ch_sch=1 in the appropriate frame. **Figure 17-20** shows the frame list for periodic channels.

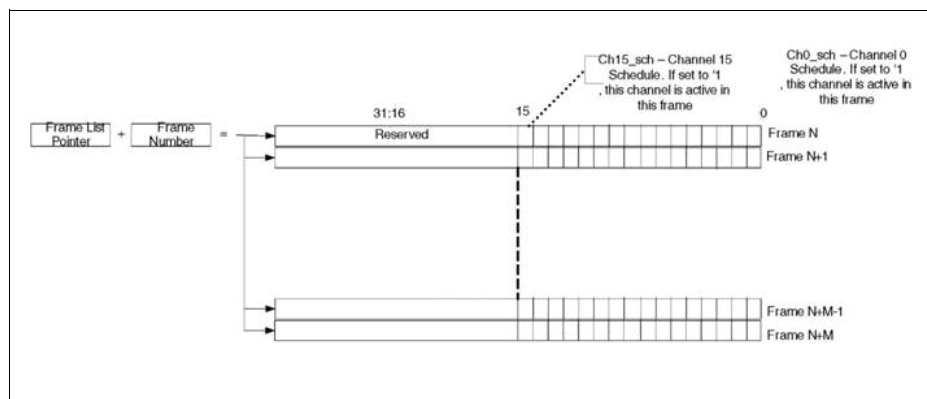

Figure 17-20 Frame List for Periodic Channels

17.7.2.2 IN Memory Structure

All channels that support IN direction transactions (channels that receive data from the USB device) must implement a memory structure with the following characteristics:

- Each data buffer must have a descriptor associated with it to provide the status of the buffer. The buffer itself contains only raw data.
- Each buffer descriptor is two quadlets in length. [Table 17-3](#) displays the IN Data Memory Structure fields.

Table 17-3 IN Data Memory Structure Values

| Bit | Bit ID | Description |
|----------------|----------------|--|
| A[31] | Active Bit | <p>This 1-bit value indicates whether the descriptor is ready.</p> <p>For non-isochronous channels, this bit indicates the following:</p> <ul style="list-style-type: none"> 0_B Descriptor is not ready 1_B Descriptor is ready. USB core can start processing the descriptor. <p>For Isochronous channels, this bit indicates the following:</p> <ul style="list-style-type: none"> 0_B Isochronous channel is not scheduled for the corresponding frame/frame. 1_B Isochronous channel is not scheduled for the corresponding frame/frame. <p>The application sets this bit when the descriptor is ready. USB core resets this bit while closing the descriptor. The application needs to set this bit as a last step after the entire descriptor is ready. The core resets this bit as a final step of processing the descriptor. This bit is accessed by both the core and the application.</p> |
| Rx Sts [29:28] | Receive Status | <p>This 2-bit field describes the status of the received data. The core updates this field when the descriptor is closed. PKTERR is set by the core when there was an error while receiving the packet. When updated with PKTERR, it is an indication that IN data has been received with errors. The error includes Xact_err scenarios. BUFERR is set by the core when AHB error is encountered during buffer access. The possible combinations are:</p> <ul style="list-style-type: none"> • 00_B Success, No AHB or packet errors • 01_B PKTERR. • 10_B Reserved • 11_B Reserved <p>This field has to be initialized to 00_B by the application and updated by the core subsequently.</p> |

Table 17-3 IN Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description |
|------------------|-----------------------|--|
| End of List [26] | End of List | For Non Isochronous, it indicates that this is the last descriptor in the list, if set. The core does not generate a BNA interrupt for the next descriptor, if it is unavailable. For Isochronous, this field is reserved. This field is controlled by the application. |
| IOC [25] | Interrupt On complete | Set by the application, this bit indicates that the core must generate a transfer complete interrupt (XferCompl) after this descriptor is finished. |
| [24] | Varies | Non Isochronous Reserved |
| [23] | Varies | Non Isochronous IN Bit: [23] Bit ID: AQTD_VALID Alternate Queue Transfer Descriptor Valid. When set by the application, if a Short packet is received, the core jumps to a new descriptor in the same list. The new descriptor address is obtained by replacing the CTD value of the corresponding channel with the AQTD value. When the application resets this bit, the core ignores AQTD. |
| [22:17] | Varies | Non Isochronous IN Bit: [23] Bit ID: AQTD_VALID Alternate Queue Transfer Descriptor Valid. This is valid only if AQTD_VALID is set. This field gives the offset value in DWORDS. The core will use this offset to jump to a new descriptor address in the same list. |
| | | Isochronous Bit: [24:23] Bit ID: R: Reserved |
| | | Isochronous IN Bit Bit: [22:12] Bit ID: R Reserved |

Table 17-3 IN Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description |
|---------|--------|---|
| [16:12] | Varies | Non Isochronous IN |
| [11] | Varies | Bit: [16:0] Bit ID: Total bytes to transfer This 17-bit value can take values from 0 to 128K-1 bytes, depending on the transfer size of data received from the USB device. The application programs the expected transfer size. When the descriptor is closed, this indicates remainder of the transfer size. This field must be in multiple of MPS for the corresponding end point. The MPS for the various packet types are as follows: <ul style="list-style-type: none"> Control - <ul style="list-style-type: none"> LS - 8 bytes FS - 8,16,32,64 bytes Bulk – <ul style="list-style-type: none"> FS - 8,16,32,64 bytes Interrupt <ul style="list-style-type: none"> LS - up to 8 bytes FS – up to 64 bytes |
| [10:0] | Varies | Isochronous IN Bit: 11:0 Bit ID: Received Isochronous IN Bit: [11:0] Bit ID: Total bytes to transfer This 11-bit value can take values from 0 to 4K bytes, depending on the packet size of data received from the USB host. The application programs the expected transfer size. When the descriptor is closed, it indicates remainder of the transfer size. The maximum payload size of each ISO packet as per USB specification 2.0 is as follows. <ul style="list-style-type: none"> FS - up to 1023 bytes <i>Note: Note: A value of 0 indicates zero bytes of data, 1 indicates 1 byte of data, and so on.</i> |

Table 17-4 displays the out buffer pointer field description.

Table 17-4 IN Buffer Pointer

| | | |
|----------------|----------------|--|
| Buf Addr[31:0] | Buffer Address | The Buffer pointer field in the descriptor is 32 bits wide and contains the address where the received data is to be stored in the system memory. The buffer address does not need to be aligned with DWORD. |
|----------------|----------------|--|

17.7.2.3 OUT Memory Structure

All channels that support OUT direction transactions (channels that transmit data to the USB device) must implement the following memory structure:

- Each buffer must have a descriptor associated with it.
- The application fills the data buffer, updates its status in the descriptor, and enables the channel.
- The DMA fetches this descriptor and processes it, moving on in this manner until it reaches the end of the descriptor chain.
- The buffer to which the descriptor points to holds packet data for non-isochronous channels and frame data for isochronous channels.

Table 17-5 displays the OUT Data Memory Structure fields. Bits that are not present are reserved to be set to zero by the application for writes and ignored during reads.

Table 17-5 OUT Data Memory Structure Values

| Bit | Bit ID | Description |
|----------------|-----------------------|---|
| A[31] | Active Bit | <p>This 1-bit value indicates whether the descriptor is ready.</p> <p>For non-isochronous channels, this bit indicates the following:</p> <p>0_B Descriptor is not ready</p> <p>1_B Descriptor is ready. USB core can start processing the descriptor.</p> <p>For Isochronous channels, this bit indicates the following:</p> <p>0_B Isochronous channel is not scheduled for the corresponding frame.</p> <p>1_B Isochronous channel is not scheduled for the corresponding frame.</p> <p>The application sets this bit when the descriptor is ready. USB core resets this bit while closing the descriptor. The application needs to set this bit as a last step after the entire descriptor is ready. The core resets this bit as a final step of processing the descriptor.</p> |
| Tx Sts [29:28] | Transmit Status | <p>The status of the transmitted data. This reflects if the OUT data has been transmitted correctly or with errors. BUFERR is set by core when there is a AHB error during buffer access along with asserting AHBERR interrupt (HCINTx register) for the corresponding channel.</p> <p>PKTERR is set by the core when there was an error while transmitting the packet. The error includes Xact_err scenarios.</p> <p>The possible combinations are as follows:</p> <p>00_B Success, No AHB errors</p> <p>01_B PKTERR</p> <p>10_B Reserved</p> <p>11_B Reserved</p> <p>This field has to be initialized to 00_B by the application and updated by the core subsequently.</p> |
| EoL [26] | End of List | <p>For Non Isochronous, it indicates that this is the last descriptor in the list, if set. The core does not generate a BNA interrupt for the next descriptor, if it is unavailable.</p> <p>For Isochronous, this field is reserved. This field is controlled by the application.</p> |
| IOC[25] | Interrupt On complete | <p>Set by the application, this bit indicates that the core must generate a transfer complete interrupt after this descriptor is finished.</p> |

Universal Serial Bus (USB)
Table 17-5 OUT Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description | |
|-----------------------|--------|---|--|
| [24] ¹⁾ | SuP | Non Isochronous OUT Setup Packet When set, it indicates that the buffer data pointed by this descriptor is a setup packet of 8 bytes | Isochronous Reserved: [24:12] |
| [23] ¹⁾ | R | Non Isochronous OUT Setup Packet Bit: Reserved [23] Bit ID: Reserved | |
| [22:17] ¹⁾ | Varies | Non Isochronous OUT Bit Reserved: [22:17] Bit ID: Reserved | |
| [16:12] ¹⁾ | Varies | Non Isochronous OUT OUT Bit: [16:0] Bit ID: Total bytes to transfer. This 17-bit value can take values from 0 to 128K-1 bytes, indicating the number of bytes of data to be transmitted to the USB device. Note: A Value of 0 indicates zero bytes of data, 1 indicates 1 byte of data and so on | Isochronous Bit [11:0] Bit ID: Total bytes to transfer. This 12-bit value can take values from 0 to 4K bytes, indicating the number of bytes of data to be trvValue of 0 indicates zero bytes of data, 1 indicates 1 byte of data, and so on. |
| [11:0] ¹⁾ | Varies | | |

1) The meaning of this field varies. See description.

Table 17-6 IN Buffer Pointer

| | | |
|----------------|----------------|--|
| Buf Addr[31:0] | Buffer Address | The Buffer pointer field in the descriptor is 32 bits wide and contains the address where the transmit data is to be stored in the system memory. The buffer address does not need to be aligned with DWORD. |
|----------------|----------------|--|

17.7.3 Channel Initialization in Scatter-Gather DMA Mode

The application must initialize one or more channels before it can communicate with connected devices. To initialize and enable a channel, the application must perform the following steps.

- Program the periodic frame list array (for periodic channels).

Universal Serial Bus (USB)

- Program the HFLBAddr register with the base address of the periodic frame list array (for periodic channels).
- Program the HCFG register with PerSchedEn bit set.
- Program at least one transfer descriptor in the system memory.
- Program the HCDMAx with the pointer to the corresponding descriptor.
- Program the GINTMSK register to unmask the Channel Interrupts.
- Program the HAIMTMSK register to unmask the selected channels' interrupts.
- Program the HCINTMSK register to unmask the ChHalt, XferCompl, and BNA.
- Program the HCTSIZx register with initial data PID and SCHED_INFO (for periodic channels).
- Program the HCCHARx register with the device's endpoint characteristics, such as type, speed, direction, and so on (The channel can be enabled by setting the channel enable bit to 1_B only when the application is ready to transmit or receive any packet).

17.7.4 Asynchronous Transfers

When the application enables an asynchronous (Bulk and Control) channel by writing into the HCCHARx register, the host controller begins servicing the asynchronous channel. It reads the referenced (CTD) transfer descriptor qTDn (pointed to by the HCDMAx register). If the read qTDn is active, the host controller caches the qTDn and then schedules a transaction. If the read qTDn is inactive, the host controller disables the channel and generates a Buffer Not Available (BNA) interrupt.

If multiple asynchronous channels are enabled simultaneously, the host controller caches the referenced transfer descriptor of the entire enabled channels. The host controller schedules transactions for each enabled channel in round-robin fashion.

When the host controller completes the transfer for a channel, it updates the status quadlet of the processed qTDn in the system memory.

For a normal completion, the host controller updates the status of the qTDn with no errors. The host controller completes a transfer normally if one of the following events occurs:

- Short or zero length packet is received for an IN channel.
- The allocated buffer is fulfilled with the received data packets for an IN channel.
- The allocated buffer is fully transferred to the device for an OUT channel.

When a transfer is completed normally, the host controller attempts to process the next qTDn from the descriptor list, if the End of List (EOL) bit is not set in the completed qTDn. where $m = \text{AQTD}$ (if IN channel with $\text{AQTD_VLD}=1$ received a short packet) or $m = (n + 1) \bmod (\text{NTD} + 1)$

If EOL is set, the host controller disables the channel and generates a Channel Halt interrupt. The transfer complete interrupt is generated for the following conditions.

- IOC is set.
- Short or zero length packet is received for an IN channel.

- EOL is set.

For an abnormal completion, the host controller updates the status of the qTDn with PKT_ERR. The host controller completes a transfer abnormally if one of the following events occurs:

- STALL response is received from the device.
- Excessive transaction errors occurred.
- Babble detected.

When a transfer is completed abnormally, the host controller disables the channel and then generates a Channel Halt interrupt with the appropriate status in HCINT register.

17.7.4.1 Asynchronous Transfer Descriptor

The application must use separate qTD for different stages of control transfers. A three stage control transfer uses three qTDs. The same qTD can be reused for performing different stages of control transfer. The combination of EPType, EPDir fields of the HCCHARx register, and the SuP flag of the qTD decides the stage of the control transfer. See [Table 17-7](#).

Table 17-7 Asynchronous Transfer Descriptor

| HCCHARx.EP Type | HCCHARx.EP Dir | qTD.SuP | Control Stage |
|-----------------|----------------|---------|-----------------------------------|
| 00 _B | 0 | 1 | SETUP |
| 00 _B | 0 | 0 | Data stage OUT / Status stage OUT |
| 00 _B | 1 | 0 | Data stage IN / Status stage IN |
| 00 _B | 1 | 1 | Invalid |

The host controller executes a zero-length OUT transaction if the "Num bytes to transmit" field of the qTD is initialized to zero for an OUT channel. For an IN channel, the "Num of bytes received" field of the qTD must be always initialized to an integer multiple of the maximum packet size.

The application can use one or multiple qTDs for bulk IN and OUT transfers. The number of qTDs depends on the available consecutive data buffer space and the size of the transfer. Each qTD can support up to 64KB of consecutive data buffer space.

17.7.5 Periodic Transfers

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. The periodic schedule is referenced from the register space using the HFLBAddrBase and the HFNUM registers. The periodic schedule is based on an array of scheduled channels called the periodic

Universal Serial Bus (USB)

frame list. The periodic frame list implements a sliding window of transactions over time. When the application enables the periodic schedule (PerSchedEna) in the HCFG register, the host controller attempts to read an entry from the frame list that corresponds to the next running frame number at the beginning of each frame.

The periodic frame list can be programmed to 8, 16, 32, or 64 elements. The size of the periodic frame list should be large enough to support the required b-interval of the least frequent channel. The least significant bits [15:0] in the periodic frame list elements are used to identify the scheduled periodic channels (0 through 15) for that corresponding frame. For example if channel 2 and 6 are periodic channels scheduled for a frame then the corresponding entry in the periodic frame list will be 0000_0044_H.

The host controller should program the SCHED_INFO to 1111_1111_B when operating in Full Speed for all the enabled periodic channels.

17.7.5.1 Isochronous Transactions

When the application enables an isochronous channel by writing into the HCCHARx register, the host controller begins servicing the isochronous channel based on the programmed scheduling (periodic frame list and SCHED_INFO). The application must use separate qTD for each frame. Each qTD handles a frame of transactions. The application is expected to allocate a qTD with Active bit zero even if no transaction is scheduled for a frame. The position of the active qTD determines the b-interval of the isochronous channel.

The host controller supports high-bandwidth isochronous transfer via the multi-count (MC) field of the HCCHARx register. The Multi Count represents a transaction count per frame for the endpoint. If the multi-count is zero, the operation of the host controller is undefined. Multi-count greater than one is not applicable for the FS host.

For OUT transfers, the value of the "Num bytes to transmit" field represents the total bytes to be sent during the frame. The application is expected to program the Mult count field to be the maximum number of packets to be sent in any frame. The host controller automatically selects the number of packets and its data PID based on the programmed Xfer Size.

For IN transfers, the host controller issues Mult count transactions. The application is expected to initialize the "Num bytes received" field to (MC * MaxPktSize).

The host controller does not execute all Multi-count transactions if:

- The channel is an OUT and the "Num bytes to transmit" goes to zero before all the Multi-count transactions have executed (ran out of transmit data) or
- The channel is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before all the Multi-count transaction have been executed.
- The channel is an IN and the endpoint delivers a packet with DATA0 PID before all the Multi-count transaction have been executed.

Universal Serial Bus (USB)

Each transfer descriptor (qTD) describes one frame of transactions. The host controller will cache one transfer descriptor in a frame prior to the scheduled frame.

When the application is adding new isochronous transactions to the schedule, it always performs a read of the HFNUM register to determine the current frame and frame the host is currently executing. Because there is no information about where in the frame the host controller is, a constant uncertainty factor of one frame for FS is assumed.

The end of frame (FS) may occur before all of the transaction opportunities are executed. When this happens, the host controller closes the corresponding descriptor and proceeds to processing the next scheduled descriptor. If the scheduled descriptor is not fetched by the host controller due to high system latency, the host controller does not execute any transaction for that scheduled frame and will skip the descriptor without any update (that is, without clearing the Active bit).

When a transfer is completed normally, the host controller generates the transfer complete interrupt only if IOC is set in the completed qTD.

When a transfer is completed abnormally (STALL response or Babble), the host controller disables the channel and then generates a Channel Halt interrupt with the appropriate status in HCINT register. The host controller updates the status of the qTD with PKT_ERR if one of the following conditions occurs:

- STALL response is received from the device
- Error packet received
- Babble detected
- Unable to complete all the transactions in the scheduled frame

An example for the FS isochronous scheduling is shown in [Figure 17-21](#). In this figure, channels 2 and 15 are isochronous channels with b-interval 1ms and 4ms respectively. The host controller fetches only the qTDs that corresponds to the scheduled frame (Periodic Frame List entry). The host controller initiates the qTD fetch in the frame prior to the scheduled frame. If the qTD is active and belongs to an OUT channel, the host controller also fetches the corresponding data in the previous frame. If this qTD is not active, the host controller ignores the qTD and does not generate any BNA interrupt.

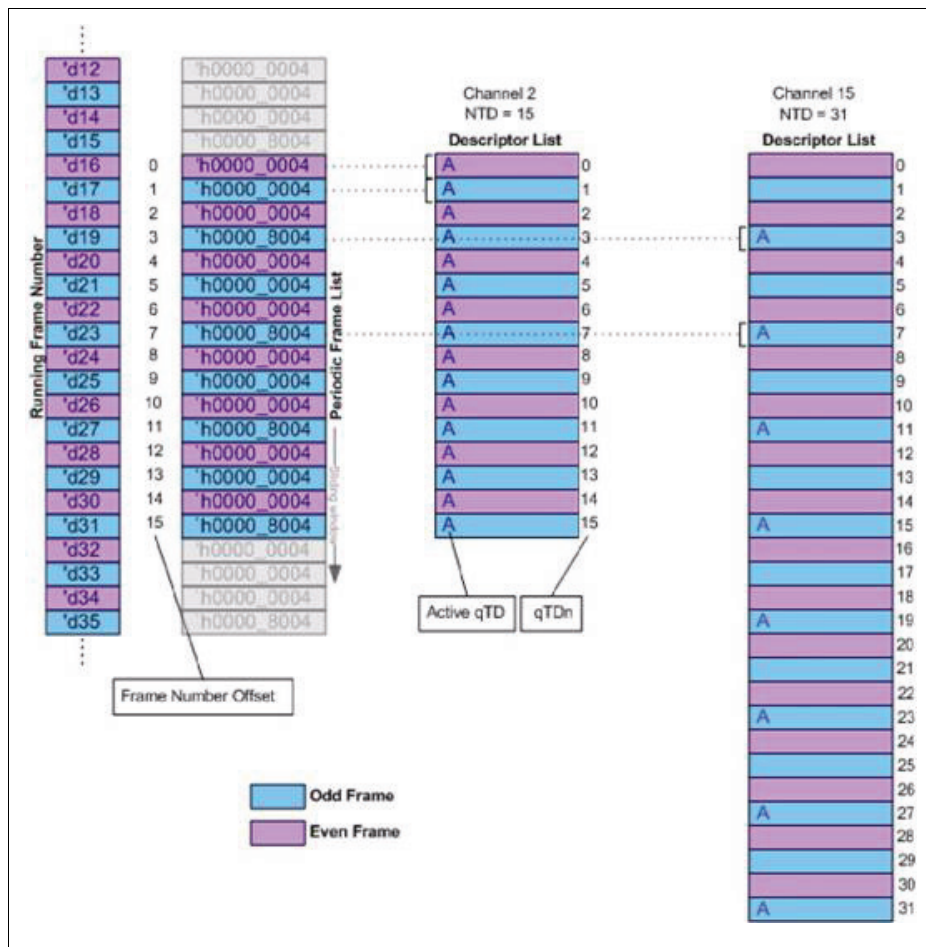

Figure 17-21 Full Speed Isochronous Transfer Scheduling

17.7.5.2 Interrupt Transactions

When the application enables an interrupt channel by writing into the HCCHARx register, the host controller begins servicing the interrupt channel based on the programmed scheduling (periodic frame list and SCHLD_INFO). It reads the referenced (CTD) transfer descriptor qTDn (pointed by the HCDMAX register) in the frame prior to the scheduled frame.

If the read qTDn is active, the host controller caches the qTDn and then schedules a transaction. If the read qTDn is inactive, the host controller disables the channel and generates a Buffer Not Available (BNA) interrupt.

When the host controller completes the transfer, it updates the status quadlet of the processed qTDn in the system memory.

For a normal completion, the host controller updates the status of the qTDn with no errors. The host controller completes a transfer normally if one of the following events occurs:

- Short or zero length packet is received for an IN channel.
- The allocated buffer is fulfilled with the received data packets for an IN channel.
- The allocated buffer is fully transferred to the device for an OUT channel.

When a transfer is completed normally, the host controller attempts to process the next qTDm from the descriptor list if the End of List (EOL) bit is not set in the completed qTDn.

Where $m = (n + 1) \bmod (NTD + 1)$

If EOL is set, the host controller disables the channel and generates Channel Halt interrupt. The transfer complete interrupt will be generated for the following conditions.

- IOC is set.
- Short or zero length packet is received for an IN channel.
- EOL is set.

For an abnormal completion, the host controller updates the status of the qTDn with PKT_ERR. The host controller completes a transfer abnormally if one of the following events occurs:

- STALL response is received from the device.
- Excessive transaction errors occurred.
- Babble detected.

When a transfer is completed abnormally, the host controller disables the channel and then generates a Channel Halt interrupt with the appropriate status in the HCINT register.

The host controller supports high-bandwidth interrupt transfer through the Multi-count (MC) field of HCCHARx register. The Multi-count represents a transaction count per frame for the endpoint. If the Multi-count is zero, the operation of the host controller is undefined. Multi-count greater than one is not applicable for FS host.

The host controller does not execute all Multi-count transactions in a frame if:

Universal Serial Bus (USB)

- The channel is an OUT and the "Num bytes to transmit" goes to zero before all the Multi-count transactions have executed (ran out of transmit data) or
- The channel is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before all the Multi-count transaction have been executed.
- The channel is an IN and the "Num bytes received" goes to zero before all the Multi-count transaction are executed (ran out of receive buffer space).

17.8 Device Programming Overview

This section discusses how to program the DWC_otg core when it is in Device mode.

17.8.1 Device Initialization

As prerequisites, the application must meet the following conditions to set up the device core to handle traffic:

- In Slave mode, GINTMSK.NPTxFEmpMsk, and GINTMSK.RxFLvIMsk must be unset.
- In DMA mode, the GINTMSK.NPTxFEmpMsk, and GINTMSK.RxFLvIMsk interrupts must be masked.

The application must perform the following steps to initialize the core at device on, power on, or after a mode change from Host to Device.

1. Program the following fields in DCFG register.
 - a) DescDMA bit
 - b) Device Speed
 - c) NonZero Length Status OUT Handshake
 - d) Periodic Frame Interval (If Periodic Endpoints are supported)
2. Clear the DCTL.SftDiscon bit. The core issues a connect after this bit is cleared.
3. Program the GINTMSK register to unmask the following interrupts.
 - a) USB Reset
 - b) Enumeration Done
 - c) Early Suspend
 - d) USB Suspend
 - e) SOF
4. Wait for the GINTSTS.USBReset interrupt, which indicates a reset has been detected on the USB and lasts for about 10 ms. On receiving this interrupt, the application must perform the steps listed in **“Initialization on USB Reset” on Page 17-74**.
5. Wait for the GINTSTS.EnumerationDone interrupt. This interrupt indicates the end of reset on the USB. On receiving this interrupt, the application must read the DSTS register to determine the enumeration speed and perform the steps listed in **“Initialization on Enumeration Completion” on Page 17-75**.

At this point, the device is ready to accept SOF packets and perform control transfers on control endpoint 0.

17.8.2 Device Connection

The device connect process varies depending if the VBUS is on or off when the device is connected to the USB cable.

VBUS is on when the device is connected

If VBUS is on when the device is connected to the USB cable, there is no SRP from the device. The device connection flow is as follows:

1. The device triggers the GINTSTS.SessReqInt [bit 30] interrupt bit.
2. When the device application detects the GINTSTS.SessReqInt interrupt, it programs the required bits in the DCFG register.
3. When the host drives reset, the device triggers GINTSTS.USBReset [bit 12] on detecting the reset. The host then follows the USB 2.0 Enumeration sequence.

VBUS is off when the device is connected

If VBUS is off when the device is connected to the USB cable, the device initiates SRP in OTG Revision 1.3 mode. The device connection flow is as follows:

1. The application initiates SRP by writing the Session Request bit in the OTG Control and Status register. The USB core performs data-line pulsing followed by VBUS pulsing.
2. The host starts a new session by turning on VBUS, indicating SRP success. The USB core interrupts the application by setting the Session Request Success Status Change bit in the OTG Interrupt Status register.
3. The application reads the Session Request Success bit in the OTG Control and Status register and programs the required bits in DCFG register.
4. When host drives reset, the device triggers GINTSTS.USBReset on detecting the reset. The host then follows the USB 2.0 Enumeration sequence.

17.8.3 Device Disconnection

The device session ends when the USB cable is disconnected or if the VBUS is switched off by the host.

The device disconnect flow is as follows:

1. When the USB cable is unplugged or when the VBUS is switched off by the host, the device core triggers GINTSTS.OTGInt [bit 2] interrupt bit.
2. When the device application detects GINTSTS.OTGInt interrupt, it checks that the GOTGINT.SesEndDet (Session End Detected) bit is set to 1.

17.8.3.1 Device Soft Disconnection

The application can also perform a soft disconnect by setting the DCTL.SftDiscon bit.

Send/Receive USB Transfers -> Soft disconnect->Soft reset->USB Device Enumeration

Sequence of operations:

1. The application configures the device to send or receive transfers.

Universal Serial Bus (USB)

2. The application sets the Soft disconnect bit (SftDiscon) in the Device Control Register (DCTL).
3. The application sets the Soft Reset bit (CSftRst) in the Reset Register (GRSTCTL).
4. Poll the GRSTCTL register until the core clears the soft reset bit, which ensures the soft reset is completed properly.
5. Initialize the core according to the instructions in **“Device Initialization” on Page 17-72.**

Suspend-> Soft disconnect->Soft reset->USB Device Enumeration

Sequence of operations:

1. The core detects a USB suspend and generates a Suspend Detected interrupt.
2. The application sets the Stop PHY Clock bit (StopPclk) in the Power and Clock Gating Control register (PCGCCTL), the core asserts suspend_n to the PHY, and the PHY clock stops.
3. The application clears the StopPclk bit and waits for the PHY clock to come back. The core de-asserts suspend_n to the PHY, and the PHY clock comes back.
4. The application sets the Soft disconnect bit (SftDiscon) in Device Control Register (DCTL).
5. The application sets the Soft Reset bit (CSftRst) in the Reset Register (GRSTCTL).
6. Poll the GRSTCTL register until the core clears the soft reset bit, which ensures the soft reset is completed properly.
7. Initialize the core according to the instructions in **“Device Initialization” on Page 17-72.**

17.8.4 Endpoint Initialization

17.8.4.1 Initialization on USB Reset

1. Set the NAK bit for all OUT endpoints
 - a) DOEPCTLx.SNAK = 1 (for all OUT endpoints)
2. Unmask the following interrupt bits:
 - a) DAINTMSK.INEP0 = 1 (control 0 IN endpoint)
 - b) DAINTMSK.OUTEPO = 1 (control 0 OUT endpoint)
 - c) DOEPMSK.SETUP = 1
 - d) DOEPMSK.XferCompl = 1
 - e) DIEPMSK.XferCompl = 1
 - f) DIEPMSK.TimeOut = 1
3. To transmit or receive data, the device must initialize more registers as specified in **“Device Initialization” on Page 17-72**

4. Set up the Data FIFO RAM for each of the FIFOs
 - a) Program the GRXFSIZ Register, to be able to receive control OUT data and setup data. At a minimum, this must be equal to 1 max packet size of control endpoint 0 + 2 DWORDs (for the status of the control OUT data packet) + 10 DWORDs (for setup packets).
 - b) Program the dedicated FIFO size register (depending on the FIFO number chosen) in Dedicated FIFO operation, to be able to transmit control IN data. At a minimum, this must be equal to 1 max packet size of control endpoint 0.
5. Reset the Device Address field in Device Configuration Register (DCFG).
6. (This step is not required if the Scatter/Gather DMA mode is used.) Program the following fields in the endpoint-specific registers for control OUT endpoint 0 to receive a SETUP packet
 - a) DOEPTSIZ0.SetUP Count = 3 (to receive up to 3 back-to-back SETUP packets)
 - b) In DMA mode, DOEPDMAO register with a memory address to store any SETUP packets received

At this point, all initialization required to receive SETUP packets is done, except for enabling control OUT endpoint 0 in DMA mode.

17.8.4.2 Initialization on Enumeration Completion

This section describes what the application must do when it detects an Enumeration Done interrupt.

1. On the Enumeration Done interrupt (GINTSTS.EnumDone, read the DSTS register to determine the enumeration speed.
2. Program the DIEPCTL0.MPS field to set the maximum packet size. This step configures control endpoint 0. The maximum packet size for a control endpoint depends on the enumeration speed.
3. In DMA mode, program the DOEPCTL0 register to enable control OUT endpoint 0, to receive a SETUP packet. In Scatter/Gather DMA mode, the descriptors must be set up in memory before enabling the endpoint.
 - a) DOEPCTL0.EPEna = 1
4. Unmask the SOF interrupt.

At this point, the device is ready to receive SOF packets and is configured to perform control transfers on control endpoint 0.

17.8.4.3 Initialization on SetAddress Command

This section describes what the application must do when it receives a SetAddress command in a SETUP packet.

1. Program the DCFG register with the device address received in the SetAddress command
2. Program the core to send out a status IN packet.

17.8.4.4 Initialization on SetConfiguration/SetInterface Command

This section describes what the application must do when it receives a SetConfiguration or SetInterface command in a SETUP packet.

1. When a SetConfiguration command is received, the application must program the endpoint registers to configure them with the characteristics of the valid endpoints in the new configuration.
2. When a SetInterface command is received, the application must program the endpoint registers of the endpoints affected by this command.
3. Some endpoints that were active in the prior configuration or alternate setting are not valid in the new configuration or alternate setting. These invalid endpoints must be deactivated.
4. For details on a particular endpoint's activation or deactivation, see **“Endpoint Activation” on Page 17-76** and **“Endpoint Deactivation” on Page 17-76**.
5. Unmask the interrupt for each active endpoint and mask the interrupts for all inactive endpoints in the DAINTR register.
6. Set up the Data FIFO RAM for each FIFO. See **“Data FIFO RAM Allocation” on Page 17-223** for more detail.
7. After all required endpoints are configured, the application must program the core to send a status IN packet.

At this point, the device core is configured to receive and transmit any type of data packet.

17.8.4.5 Endpoint Activation

This section describes the steps required to activate a device endpoint or to configure an existing device endpoint to a new type.

1. Program the characteristics of the required endpoint into the following fields of the DIEPCTLx register (for IN or bidirectional endpoints) or the DOEPCTLx register (for OUT or bidirectional endpoints).
 - a) Maximum Packet Size
 - b) USB Active Endpoint = 1
 - c) Set Endpoint Data Toggle bit to 0 (for interrupt and bulk endpoints)
 - d) Endpoint Type
 - e) TxFIFO Number
2. Once the endpoint is activated, the core starts decoding the tokens addressed to that endpoint and sends out a valid handshake for each valid token received for the endpoint.

17.8.4.6 Endpoint Deactivation

This section describes the steps required to deactivate an existing endpoint.

Before an endpoint can be de-activated, any pending transfers must first be stopped. For more information on stopping transfers, see **“Transfer Stop Programming for OUT Endpoints” on Page 17-79** or **“Transfer Stop Programming for IN Endpoints” on Page 17-82**.

1. In the endpoint to be deactivated, clear the USB Active Endpoint bit in the DIEPCTLx register (for IN or bidirectional endpoints) or the DOEPCTLx register (for OUT or bidirectional endpoints).
2. Once the endpoint is deactivated, the core ignores tokens addressed to that endpoint, resulting in a timeout on the USB.

17.8.5 Programming OUT Endpoint Features

17.8.5.1 Disabling an OUT Endpoint

The application must use this sequence to disable an OUT endpoint that it has enabled.

Application Programming Sequence

1. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, as described in **“Setting the Global OUT NAK” on Page 17-78**.
 - a) $DCTL.DCTL.SGOUTNak = 1_B$
2. Wait for the GINTSTS.GOUTNakEff interrupt
3. Disable the required OUT endpoint by programming the following fields.
 - a) $DOEPCTLx.EPDisable = 1_B$
 - b) $DOEPCTLx.SNAK = 1_B$
4. Wait for the DOEPINTx.EPDisabled interrupt, which indicates that the OUT endpoint is completely disabled. When the EPDisabled interrupt is asserted, the core also clears the following bits.
 - a) $DOEPCTLx.EPDisable = 0_B$
 - b) $DOEPCTLx.EPEnable = 0_B$
5. The application must clear the Global OUT NAK bit to start receiving data from other non-disabled OUT endpoints.
 - a) $DCTL.SGOUTNak = 0_B$

17.8.5.2 Stalling a Non-Isochronous OUT Endpoint

This section describes how the application can stall a non-isochronous endpoint.

1. Put the core in the Global OUT NAK mode, as described in **“Setting the Global OUT NAK” on Page 17-78**.
2. Disable the required endpoint, as described in **“Disabling an OUT Endpoint” on Page 17-77**.

Universal Serial Bus (USB)

- a) When disabling the endpoint, instead of setting the DOEPCTL.SNAK bit, set DOEPCTL.STALL = 1.
- b) The Stall bit always takes precedence over the NAK bit.
3. When the application is ready to end the STALL handshake for the endpoint, the DOEPCTLx.STALL bit must be cleared.

If the application is setting or clearing a STALL for an endpoint due to a SetFeature.Endpoint Halt or ClearFeature.Endpoint Halt command, the Stall bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

17.8.5.3 Setting the Global OUT NAK

Internal Data Flow

1. When the application sets the Global OUT NAK (DCTL.SGOUTNak), the core stops writing data, except SETUP packets, to the receive FIFO. Irrespective of the space availability in the receive FIFO, non-isochronous OUT tokens receive a NAK handshake response, and the core ignores isochronous OUT data packets.
2. The core writes the Global OUT NAK pattern to the receive FIFO. The application must reserve enough receive FIFO space to write this data pattern. See [“Data FIFO RAM Allocation” on Page 17-223](#).
3. When either the core (in DMA mode) or the application (in Slave mode) pops the Global OUT NAK pattern DWORD from the receive FIFO, the core sets the GINTSTS.GOUTNakEff interrupt.
4. Once the application detects this interrupt, it can assume that the core is in Global OUT NAK mode. The application can clear this interrupt by clearing the DCTL.SGOUTNak bit.

Application Programming Sequence

1. To stop receiving any kind of data in the receive FIFO, the application must set the Global OUT NAK bit by programming the following field.
 - a) DCTL.SGOUTNak = 1_B
2. Wait for the assertion of the interrupt GINTSTS.GOUTNakEff. When asserted, this interrupt indicates that the core has stopped receiving any type of data except SETUP packets.
3. The application can receive valid OUT packets after it has set DCTL.SGOUTNak and before the core asserts the GINTSTS.GOUTNakEff interrupt.
4. The application can temporarily mask this interrupt by writing to the GINTMSK.GINNAkEffMsk bit.
 - a) GINTMSK.GINNAkEffMsk = 0_B

Universal Serial Bus (USB)

5. Whenever the application is ready to exit the Global OUT NAK mode, it must clear the DCTL.SGOUTNak bit. This also clears the GINTSTS.GOUTNakEff interrupt.
 - a) DCTL.CGOUTNak = 1_B
6. If the application has masked this interrupt earlier, it must be unmasked as follows:
 - a) GINTMSK.GINNakEffMsk = 1_B

17.8.5.4 Transfer Stop Programming for OUT Endpoints

When the core is operating as a device, the following programming sequence can be used to stop any transfers (because of an interrupt from the host, typically a reset).

Note: The Rx FIFO is common for OUT endpoints, therefore there is only one transfer stop programming flow for OUT endpoints.

Sequence of operations:

1. Enable all OUT endpoints by setting DOEPCTL.EPEna = 1_B.
2. Before disabling any OUT endpoint, the application must enable Global OUT NAK mode in the core, according to the instructions in [“Setting the Global OUT NAK” on Page 17-78](#). This ensures that data in the RX FIFO is sent to the application successfully. Set DCTL.DCTL.SGOUTNak = 1_B.
3. Wait for the GINTSTS.GOUTNakEff interrupt.
4. Disable all active OUT endpoints by programming the following register bits:
 - a) DOEPCTL.EPEna = 1_B
 - b) DOEPCTLn.EPDisable = 1_B
 - c) DOEPCTLn.SNAK = 1_B
5. Wait for the DOEPINTn.EPDisabled interrupt for each OUT endpoint programmed in the previous step. The DOEPINTn.EPDisabled interrupt indicates that the corresponding OUT endpoint is completely disabled. When the EPDisabled interrupt is asserted, the DWC_otg core clears the following bits:
 - a) DOEPCTL.EPEna = 0_B
 - b) DOEPCTLn.EPDisable = 0_B
 - c) DOEPCTLn.EPEnable = 0_B

Note: The application must not flush the Rx FIFO, as the Global out NAK effective interrupt earlier ensures that there is no data left in the Rx FIFO.

17.8.6 Programming IN Endpoint Features

17.8.6.1 Setting IN Endpoint NAK

Internal Data Flow

1. When the application sets the IN NAK for a particular endpoint, the core stops transmitting data on the endpoint, irrespective of data availability in the endpoint's transmit FIFO.
2. Non-isochronous IN tokens receive a NAK handshake reply
 - a) Isochronous IN tokens receive a zero-data-length packet reply
3. The core asserts the DIEPINTx.IN NAK Effective interrupt in response to the DIEPCTL.Set NAK bit.
4. Once this interrupt is seen by the application, the application can assume that the endpoint is in IN NAK mode. This interrupt can be cleared by the application by setting the DIEPCTLx. Clear NAK bit.

Application Programming Sequence

1. To stop transmitting any data on a particular IN endpoint, the application must set the IN NAK bit. To set this bit, the following field must be programmed.
 - a) DIEPCTLx.SetNAK = 1_B
2. Wait for assertion of the DIEPINTx.NAK Effective interrupt. This interrupt indicates the core has stopped transmitting data on the endpoint.
3. The core can transmit valid IN data on the endpoint after the application has set the NAK bit, but before the assertion of the NAK Effective interrupt.
4. The application can mask this interrupt temporarily by writing to the DIEPMSK.NAK Effective bit.
 - a) DIEPMSK.NAK Effective = 0_B
5. To exit Endpoint NAK mode, the application must clear the DIEPCTLx.NAK status. This also clears the DIEPINTx.NAK Effective interrupt.
 - a) DIEPCTLx.ClearNAK = 1_B
6. If the application masked this interrupt earlier, it must be unmasked as follows:
 - a) DIEPMSK.NAK Effective = 1_B

17.8.6.2 IN Endpoint Disable

Use the following sequence to disable a specific IN endpoint (periodic/non-periodic) that has been previously enabled in dedicated FIFO operation.

Application Programming Sequence:

1. In Slave mode, the application must stop writing data on the AHB, for the IN endpoint to be disabled.
2. The application must set the endpoint in NAK mode. See **“Setting IN Endpoint NAK” on Page 17-79**.
 - a) DIEPCTLx.SetNAK = 1_B
3. Wait for DIEPINTx.NAK Effective interrupt.
4. Set the following bits in the DIEPCTLx register for the endpoint that must be disabled.

- a) DIEPCTLx.Endpoint Disable = 1
- b) DIEPCTLx.SetNAK = 1
- 5. Assertion of DIEPINTx.Endpoint Disabled interrupt indicates that the core has completely disabled the specified endpoint. Along with the assertion of the interrupt, the core also clears the following bits.
 - a) DIEPCTLx.ENABLE = 0_B
 - b) DIEPCTLx.EPDisable = 0_B
- 6. The application must read the DIEPTSIZx register for the periodic IN EP, to calculate how much data on the endpoint was transmitted on the USB.
- 7. The application must flush the data in the Endpoint transmit FIFO, by setting the following fields in the GRSTCTL register.
 - a) GRSTCTL.TxFIFONum = Endpoint Transmit FIFO Number
 - b) GRSTCTL.TxFFlush = 1

The application must poll the GRSTCTL register, until the TxFFlush bit is cleared by the core, which indicates the end of flush operation. To transmit new data on this endpoint, the application can re-enable the endpoint at a later point.

17.8.6.3 Timeout for Control IN Endpoints

The application must treat the TIMEOUT interrupt received for the last IN transaction of a Control Transfers Data Stage separately. This is done to take into account the TIMEOUT due to lost ACK case (core did not receive the ACK send by the host). Application must unmask timeout interrupt for control IN transfers Data phase only. On getting the timeout interrupt for control endpoint data phase, the application must also enable the OUT control endpoint for the status phase.

If the timeout is due to a lost ACK, the host switches to the Data stage, and the application receives Transfer Complete interrupt for the OUT endpoint. The application can then flush the IN packet and disable both the IN and OUT endpoints. If the timeout was due to lost data, the host sends the IN token again, and the application receives a Transfer Complete interrupt for the IN endpoint. The application can thus keep the OUT endpoint enabled for the status phase.

17.8.6.4 Stalling Non-Isochronous IN Endpoints

This section describes how the application can stall a non-isochronous endpoint.

Application Programming Sequence

1. Disable the IN endpoint to be stalled. See **“IN Endpoint Disable” on Page 17-80** for more details. Set the Stall bit as well.
2. DIEPCTLx.Endpoint Disable = 1, when the endpoint is already enabled
 - a) DIEPCTLx.STALL = 1
 - b) The Stall bit always takes precedence over the NAK bit

3. Assertion of the DIEPINTx.Endpoint Disabled interrupt indicates to the application that the core has disabled the specified endpoint.
4. The application must flush the Non-periodic or Periodic Transmit FIFO, depending on the endpoint type. In case of a non-periodic endpoint, the application must re-enable the other non-periodic endpoints, which do not need to be stalled, to transmit data.
5. Whenever the application is ready to end the STALL handshake for the endpoint, the DIEPCTLx.STALL bit must be cleared.
6. If the application sets or clears a STALL for an endpoint due to a SetFeature.Endpoint Halt command or ClearFeature.Endpoint Halt command, the Stall bit must be set or cleared before the application sets up the Status stage transfer on the control endpoint.

Special Case: Stalling the Control IN/OUT Endpoint

The core must stall IN/OUT tokens if, during the Data stage of a control transfer, the host sends more IN/OUT tokens than are specified in the SETUP packet. In this case, the application must enable DIEPINTx.INTknTXFemp and DOEINTx.OUTTknEPdis interrupts during the Data stage of the control transfer, after the core has transferred the amount of data specified in the SETUP packet. Then, when the application receives this interrupt, it must set the STALL bit in the corresponding endpoint control register, and clear this interrupt.

17.8.6.5 Transfer Stop Programming for IN Endpoints

When the core is operating as a device, the following programming sequence can be used to stop any transfers (because of an interrupt from the host, typically a reset).

Sequence of operations:

1. Disable the IN endpoint by programming DIEPCTLn.EPDis = 1_B.
2. Wait for the DIEPINTn.EPDisabled interrupt, which indicates that the IN endpoint is completely disabled. When the EPDisabled interrupt is asserted, the core clears the following bits:
 - a) DIEPCTLn.EPDisable = 0_B
 - b) DIEPCTLn.EPEnable = 0_B
3. Flush the TX FIFO by programming the following bits:
 - a) GRSTCTL.TxFFlsh = 1_B
 - b) GRSTCTL.TxFNum = <FIFO number specific to endpoint>
4. The application can start polling till GRSTCTL.TxFFlsh is cleared. When this bit is cleared, it ensures that there is no data left in the TX FIFO.

17.8.6.6 Non-Periodic IN Endpoint Sequencing

In DMA mode, the DIEPCTLx.NextEp value programmed controls the order in which the core fetches non- periodic data for IN endpoints.

Universal Serial Bus (USB)

If application requires the core to fetch data for the non-periodic IN endpoints in a certain endpoint order, it must program the DIEPCTLx.NextEP field accordingly before enabling the endpoints. To enable a single endpoint enabled at a time the application must set the DIEPCTLx.NextEP field to the endpoint number itself. The core uses the NextEP field irrespective of the DIEPCTLx.EPEna bit.

17.8.7 Worst-Case Response Time

When the USB core acts as a device, there is a worst case response time for any tokens that follow an isochronous OUT. This worst case response time depends on the AHB clock frequency.

The core registers are in the AHB domain, and the core does not accept another token before updating these register values. The worst case is for any token following an isochronous OUT, because for an isochronous transaction, there is no handshake and the next token could come sooner. This worst case value is 7 PHY clocks when the AHB clock is the same as the PHY clock. When AHB clock is faster, this value is smaller.

If this worst case condition occurs, the core responds to bulk/ interrupt tokens with a NAK and drops isochronous and SETUP tokens. The host interprets this as a timeout condition for SETUP and retries the SETUP packet. For isochronous transfers, the incomplISOCIN and incomplISOCOUT interrupts inform the application that isochronous IN/OUT packets were dropped.

17.8.8 Choosing the Value of GUSBCFG.USBTrdTim

The value in GUSBCFG.USBTrdTim is the time it takes for the Media Access Controller (MAC), in terms of PHY clocks after it has received an IN token, to get the FIFO status, and thus the first data. The MAC is the part of the USB core that handles USB transactions and protocols. This time involves the synchronization delay between the PHY and AHB clocks. The worst case delay for this is when the AHB clock is the same as the PHY clock. In this case, the delay is 5 clocks. If the PHY clock is running at 60 MHz and the AHB is running at 30 MHz, this value is 9 clocks.

If the AHB is running at a higher frequency than the PHY, the application can use a smaller value for GUSBCFG.USBTrdTim.

The application can use the following formula to calculate the value of GUSBCFG.USBTrdTim:

$$\begin{aligned} &4 * \text{AHB Clock} + 1 \text{ PHY Clock} \\ &= (2 \text{ clock sync} + 1 \text{ clock memory address} + 1 \text{ clock memory data from sync RAM}) + (1 \\ &\text{PHY Clock (next PHY clock MAC can sample the 2-clock FIFO output)}) \end{aligned}$$

17.8.9 Handling Babble Conditions

If USB core receives a packet that is larger than the maximum packet size for that endpoint, the core stops writing data to the Rx buffer and waits for the end of packet (EOP). When the core detects the EOP, it flushes the packet in the Rx buffer and does not send any response to the host.

If the core continues to receive data at the EOF2 (the end of frame 2, which is very close to SOF), the core generates an `early_suspend` interrupt (`GINTSTS.ErlySusp`). On receiving this interrupt, the application must check the `erratic_error` status bit (`DSTS.ErrticErr`). If this bit is set, the application must take it as a long babble and perform a soft reset.

17.8.10 Device Programming Operations in Buffer DMA or Slave Mode

Table 17-8 provides links to the programming sequence for different USB transaction types when the core is in Slave or Buffer DMA mode of operation.

For information on device programming operations when in Scatter/Gather DMA mode, see **Section 17.11**.

Table 17-8 Device Programming Operations

| Device Mode | IN | SETUP | OUT |
|----------------|--|---|---|
| Control | | | |
| Slave | “Non-Periodic (Bulk and Control) IN Data Transfers” on Page 17-98 | “OUT Data Transfers” on Page 17-94 | “Non-Isochronous OUT Data Transfers” on Page 17-104 |

17.9 Device Programming in Slave Mode

This section discusses how to program the core when it is acting as a Device in the Slave mode of operation.

17.9.1 Control Transfers

This section describes the various types of control transfers.

17.9.1.1 Control Write Transfers (SETUP, Data OUT, Status IN)

This section describes control write transfers.

Application Programming Sequence

1. Assertion of the DOEPINTx.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. See **“OUT Data Transfers” on**

Page 17-94 for more details. At the end of the Setup stage, the application must reprogram the DOEPTSIZE.SUPCn field to 3 to receive the next SETUP packet.

2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data OUT phase, program the core to perform a control OUT transfer as explained in **“Non-Isochronous OUT Data Transfers” on Page 17-104**.
3. In a single OUT data transfer on control endpoint 0, the application can receive up to 64 bytes. If the application is expecting more than 64 bytes in the Data OUT stage, the application must re-enable the endpoint to receive another 64 bytes, and must continue to do so until it has received all the data in the Data stage.
4. Assertion of the DOEPTINTx.Transfer Compl interrupt on the last data OUT transfer indicates the completion of the data OUT phase of the control transfer.
5. On completion of the data OUT phase, the application must do the following.
 - a) To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint as explained in section **“OUT Data Transfers” on Page 17-94**.
- DOEPTCTLx.EPEna = 1_B
 - b) To execute the received Setup command, the application must program the required registers in the core. This step is optional, based on the type of Setup command received.
6. For the status IN phase, the application must program the core as described in **“Non-Periodic (Bulk and Control) IN Data Transfers” on Page 17-98** to perform a data IN transfer.
7. Assertion of the DIEPTINTx.Transfer Compl interrupt indicates completion of the status IN phase of the control transfer.

17.9.1.2 Control Read Transfers (SETUP, Data IN, Status OUT)

This section describes control write transfers.

Application Programming Sequence

1. Assertion of the DOEPTINTx.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. See **“OUT Data Transfers” on Page 17-94** for more details. At the end of the Setup stage, the application must reprogram the DOEPTSIZE.SUPCn field to 3 to receive the next SETUP packet.
2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data IN phase, program the core to perform a control IN transfer as explained in **“Non-Periodic (Bulk and Control) IN Data Transfers” on Page 17-98**.
3. On a single IN data transfer on control endpoint 0, the application can transmit up to 64 bytes. To transmit more than 64 bytes in the Data IN stage, the application must re-enable the endpoint to transmit another 64 bytes, and must continue to do so, until it has transmitted all the data in the Data stage.

4. The DIEPINTx.Transfer Compl interrupt on the last IN data transfer marks the completion of the control transfer's Data stage.
5. To perform a data OUT transfer in the status OUT phase, the application must program the core as described in **"OUT Data Transfers" on Page 17-94**. The application must program the DCFG.NZStsOUTHShk handshake field to a proper setting before transmitting an data OUT transfer for the Status stage.
6. Assertion of the DOEPIINTx.Transfer Compl interrupt indicates completion of the status OUT phase of the control transfer. This marks the successful completion of the control read transfer.

17.9.1.3 Two-Stage Control Transfers (SETUP/Status IN)

This section describes two-stage control transfers.

Application Programming Sequence

1. Assertion of the DOEPIINTx.SetUp interrupt indicates that a valid SETUP packet has been transferred to the application. See **"OUT Data Transfers" on Page 17-94** for more detail. To receive the next SETUP packet, the application must reprogram the DOEPTSIz.SUPCn field to 3 at the end of the Setup stage.
2. Decode the last SETUP packet received before the assertion of the SETUP interrupt. If the packet indicates a two-stage control command, the application must do the following.
 - a) Set DOEPCTLx.EPEna = 1_B
 - b) Depending on the type of Setup command received, the application can be required to program registers in the core to execute the received Setup command.
3. For the status IN phase, the application must program the core described in **"Non-Periodic (Bulk and Control) IN Data Transfers" on Page 17-98** to perform a data IN transfer.
4. Assertion of the DIEPINTx.Transfer Compl interrupt indicates the completion of the status IN phase of the control transfer.

Example: Two-Stage Control Transfer

These notes refer to **Figure 17-22**.

1. SETUP packet #1 is received on the USB and is written to the receive FIFO, and the core responds with an ACK handshake. This handshake is lost and the host detects a timeout.
2. The SETUP packet in the receive FIFO results in a GINTSTS.RxFLvl interrupt to the application, causing the application to empty the receive FIFO.
3. SETUP packet #2 on the USB is written to the receive FIFO, and the core responds with an ACK handshake.
4. The SETUP packet in the receive FIFO sends the application the GINTSTS.RxFLvl interrupt and the application empties the receive FIFO.

Universal Serial Bus (USB)

5. After the second SETUP packet, the host sends a control IN token for the status phase. The core issues a NAK response to this token, and writes a Setup Stage Done entry to the receive FIFO. This entry results in a GINTSTS.RxFLvl interrupt to the application, which empties the receive FIFO. After reading out the Setup Stage Done DWORD, the core asserts the DOEPINTx.SetUp packet interrupt to the application.
6. On this interrupt, the application processes SETUP Packet #2, decodes it to be a two-stage control command, and clears the control IN NAK bit.
 - a) DIEPCTLx.CNAK = 1
7. When the application clears the IN NAK bit, the core interrupts the application with a DIEPINTx.INTknTXFEmp. On this interrupt, the application enables the control IN endpoint with a DIEPTSIZx.XferSize of 0 and a DIEPTSIZx.PktCnt of 1. This results in a zero-length data packet for the status IN token on the USB.
8. At the end of the status IN phase, the core interrupts the application with a DIEPINTx.XferCompl interrupt.

Universal Serial Bus (USB)

3. If the received packet's byte count is not 0, the byte count amount of data is popped from the receive Data FIFO and stored in memory. If the received packet byte count is 0, no data is popped from the Receive Data FIFO.
4. The receive FIFO's packet status readout indicates one of the following.
5. Global OUT NAK Pattern: PktSts = Global OUT NAK, BCnt = 11'h000, EPNum = Dont Care (4'h0), DPID = Dont Care (00_B). This data indicates that the global OUT NAK bit has taken effect.
 - a) SETUP Packet Pattern: PktSts = SETUP, BCnt = 11'h008, EPNum = Control EP Num, DPID = D0. This data indicates that a SETUP packet for the specified endpoint is now available for reading from the receive FIFO.
 - b) Setup Stage Done Pattern: PktSts = Setup Stage Done, BCnt = 11'h0, EPNum = Control EP Num, DPID = Don't Care (00_B). This data indicates that the Setup stage for the specified endpoint has completed and the Data stage has started. After this entry is popped from the receive FIFO, the core asserts a Setup interrupt on the specified control OUT endpoint.
 - c) Data OUT Packet Pattern: PktSts = DataOUT, BCnt = size of the Received data OUT packet (0 < BCnt < 1,024), EPNum = EPNum on which the packet was received, DPID = Actual Data PID.
 - d) Data Transfer Completed Pattern: PktSts = Data OUT Transfer Done, BCnt = 11'h0, EPNum = OUT EP Num on which the data transfer is complete, DPID = Dont Care (00_B). This data indicates that a OUT data transfer for the specified OUT endpoint has completed. After this entry is popped from the receive FIFO, the core asserts a Transfer Completed interrupt on the specified OUT endpoint.
The encoding for the PktSts is listed in **“Receive Status Debug Read/Status Read and Pop Registers (GRXSTSR/GRXSTSP)” on Page 17-266.**
6. After the data payload is popped from the receive FIFO, the GINTSTS.RxFLVL interrupt must be unmasked.
7. Steps 1-5 are repeated every time the application detects assertion of the interrupt line due to GINTSTS.RxFLVL. Reading an empty receive FIFO can result in undefined core behavior.

Figure 17-23 provides a flow chart of this procedure.

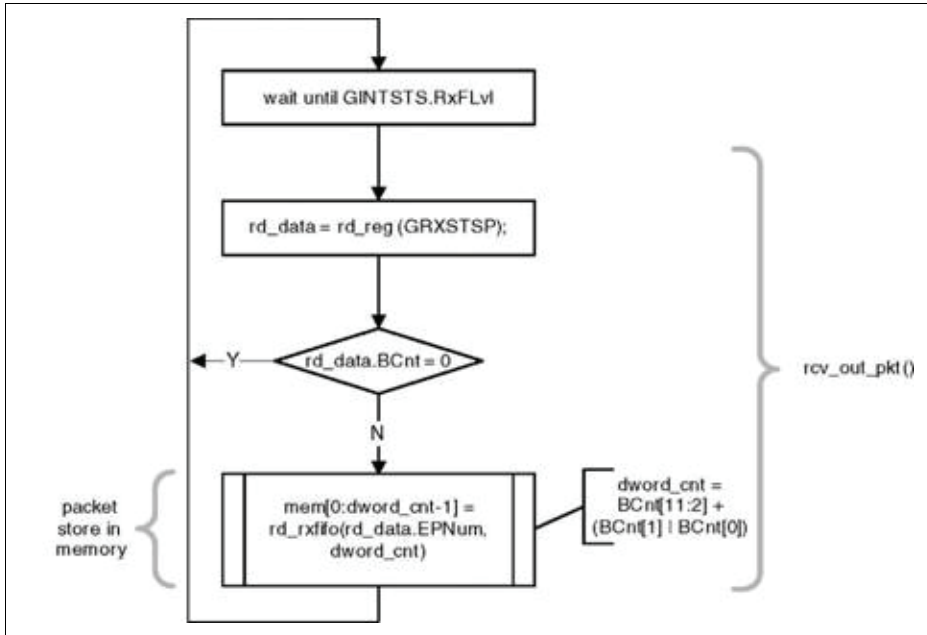

Figure 17-23 Receive FIFO Packet Read in Slave Mode

17.9.2 IN Data Transfers

This section describes the internal data flow and application-level operations during IN data transfers.

17.9.2.1 Packet Write

This section describes how the application writes data packets to the endpoint FIFO in Slave mode with dedicated transmit FIFOs.

1. The application can either choose polling or interrupt mode.
 - a) In polling mode, application monitors the status of the endpoint transmit data FIFO, by reading the `DTXFSTSx` register, to determine, if there is enough space in the data FIFO.
 - b) In interrupt mode, application waits for the `DIEPINTx.TxFEmp` interrupt and then reads the `DTXFSTSx` register, to determine, if there is enough space in the data FIFO.
 - c) To write a single non-zero length data packet, there must be space to write the entire packet in the data FIFO.

- d) For writing zero length packet, application must not look for FIFO space.
2. Using one of the above mentioned methods, when the application determines that there is enough space to write a transmit packet, the application must first write into the endpoint control register, before writing the data into the data FIFO. The application, typically must do a read modify write on the DIEPCTLx, to avoid modifying the contents of the register, except for setting the Endpoint Enable bit.

The application can write multiple packets for the same endpoint, into the transmit FIFO, if space is available. For periodic IN endpoints, application must write packets only for one frame. It can write packets for the next periodic transaction, only after getting transfer complete for the previous transaction.

17.9.3 OUT Data Transfers

This section describes the internal data flow and application-level operations during data OUT transfers and setup transactions.

17.9.3.1 Control Setup Transactions

This section describes how the core handles SETUP packets and the application's sequence for handling setup transactions. To initialize the core after power-on reset, the application must follow the sequence in [“Core Initialization” on Page 17-11](#). Before it can communicate with the host, it must initialize an endpoint as described in [“Endpoint Initialization” on Page 17-74](#). See [“Packet Read from FIFO” on Page 17-91](#).

Application Requirements

1. To receive a SETUP packet, the DOEPTSIZx.SUPCnt field in a control OUT endpoint must be programmed to a non-zero value. When the application programs the SUPCnt field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the DOEPCTLx.NAK status and DOEPCTLx.EPEna bit setting. The SUPCnt field is decremented every time the control endpoint receives a SETUP packet. If the SUPCnt field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the SUPCnt field, but the application possibly is not be able to determine the correct number of SETUP packets received in the Setup stage of a control transfer.
 - a) DOEPTSIZx.SUPCnt = 3
2. The application must always allocate some extra space in the Receive Data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
 - a) The space to be Reserved is 10 DWORDs. Three DWORDs are required for the first SETUP packet, 1 DWORD is required for the Setup Stage Done DWORD, and 6 DWORDs are required to store two extra SETUP packets among all control endpoints.

Universal Serial Bus (USB)

- b) 3 DWORDs per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (Setup Packet Pattern). The core reserves this space in the receive data
- c) FIFO to write SETUP data only, and never uses this space for data packets.
- 3. In Slave mode, the application must read the 2 DWORDs of the SETUP packet from the receive FIFO.
- 4. The application must read and discard the Setup Stage Done DWORD from the receive FIFO.

Internal Data Flow

- 1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and Stall bit settings.
 - a) The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
- 2. For every SETUP packet received on the USB, 3 DWORDs of data is written to the receive FIFO, and the SUPCnt field is decremented by 1.
 - a) The first DWORD contains control information used internally by the core
 - b) The second DWORD contains the first 4 bytes of the SETUP command
 - c) The third DWORD contains the last 4 bytes of the SETUP command
- 3. When the Setup stage changes to a Data IN/OUT stage, the core writes an entry (Setup Stage Done DWORD) to the receive FIFO, indicating the completion of the Setup stage.
- 4. On the AHB side, the application empties the SETUP packets.
- 5. When the application pops the Setup Stage Done DWORD from the receive FIFO, the core interrupts the application with a DOEPINTx.SETUP interrupt, indicating it can process the received SETUP packet.
- 6. The core clears the endpoint enable bit for control OUT endpoints.

Application Programming Sequence

- 1. Program the DOEPTSIz register.
 - a) DOEPTSIz.SUPCnt = 3
- 2. Wait for the GINTSTS.RxFLVL interrupt and empty the data packets from the receive FIFO, as explained in **“Packet Read from FIFO” on Page 17-91**. This step can be repeated many times.
- 3. Assertion of the DOEPINTx.SETUP interrupt marks a successful completion of the SETUP Data Transfer. On this interrupt, the application must read the DOEPTSIz register to determine the number of SETUP packets received and process the last received SETUP packet.

Note: If the application has not enabled EP0 before the host sends the SETUP packet, the core ACKs the SETUP packet and stores it in the FIFO, but does not write to the memory until EP0 is enabled. When the application enables the EP0 (first

Universal Serial Bus (USB)

enable) and clears the NAK bit at the same time the Host sends DATA OUT, the DATA OUT is stored in the RxFIFO. The USB core then writes the setup data to the memory and disables the endpoint. Though the application expects a Transfer Complete interrupt for the Data OUT phase, this does not occur, because the SETUP packet, rather than the DATA OUT packet, enables EP0 the first time. Thus, the DATA OUT packet is still in the RxFIFO until the application re-enables EP0. The application must enable EP0 one more time for the core to process the DATA OUT packet.

Figure 17-24 charts this flow.

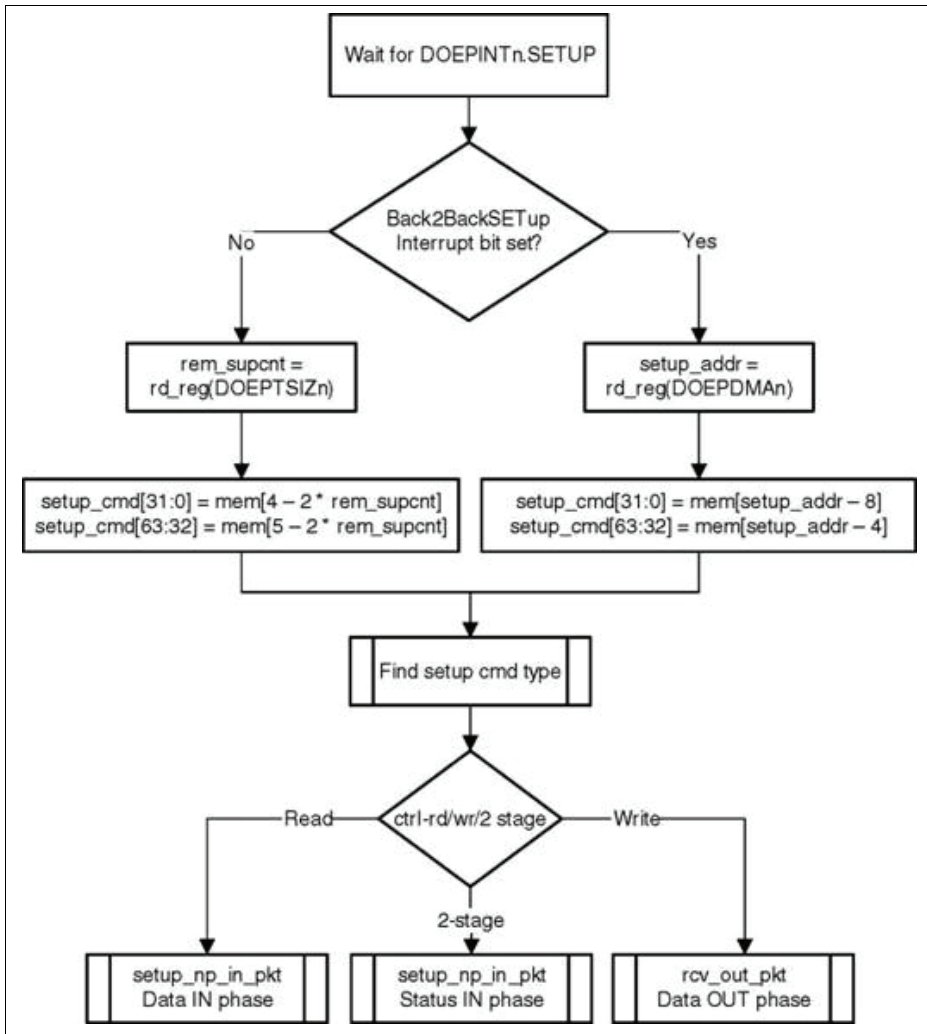

Figure 17-24 Processing a SETUP Packet

17.9.3.2 Handling More Than Three Back-to-Back SETUP Packets

According to the USB 2.0 specification, normally, during a SETUP packet error, a host does not send more than three back-to-back SETUP packets to the same endpoint. However, the USB 2.0 specification does not limit the number of back-to-back SETUP

packets a host can send to the same endpoint. When this condition occurs, the USB core generates an interrupt (DOEPINTx.Back2BackSETup).

17.9.4 Non-Periodic (Bulk and Control) IN Data Transfers

This section describes a regular non-periodic IN data transfer.

Application Requirements

1. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
 - a) To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 - b) $\text{Transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$
 (where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$)
 - If ($\text{sp} > 0$), then $\text{packet count}[\text{epnum}] = n + 1$.
 Otherwise, $\text{packet count}[\text{epnum}] = n$
 - c) To transmit a single zero-length data packet:
 - $\text{Transfer size}[\text{epnum}] = 0$
 - $\text{Packet count}[\text{epnum}] = 1$
 - d) To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
 - First transfer: $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}]$; $\text{packet count} = n$;
 - Second transfer: $\text{transfer size}[\text{epnum}] = 0$; $\text{packet count} = 1$;
 2. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with an Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.
 3. Data fetched into transmit FIFO = Application-programmed initial transfer size - core-updated final transfer size
 - a) $\text{Data transmitted on USB} = (\text{application-programmed initial packet count} - \text{Core updated final packet count}) * \text{mps}[\text{epnum}]$
 - b) $\text{Data yet to be transmitted on USB} = (\text{Application-programmed initial transfer size} - \text{data transmitted on USB})$

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. In Slave mode, the application must also write the required data to the transmit FIFO for the endpoint.

Universal Serial Bus (USB)

3. Every time the application writes a packet into the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the "number of packets in FIFO" count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data is written to the transmit FIFO, the core reads it out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a TIMEOUT.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the Packet Count field.
6. If there is no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates a IN Tkn Rcvd When FIFO Empty Interrupt for the endpoint, provided the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. In Dedicated FIFO operation, the core internally rewinds the FIFO pointers and no timeout interrupt is generated except for Control IN endpoint.
8. When the transfer size is 0 and the packet count is 0, the transfer complete interrupt for the endpoint is generated and the endpoint enable is cleared.

Application Programming Sequence

1. Program the DIEPTSIZx register with the transfer size and corresponding packet count.
2. Program the DIEPCTLx register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
3. When transmitting non-zero length data packet, the application must poll the DTXFSTSx register (where n is the FIFO number associated with that endpoint) to determine whether there is enough space in the data FIFO. The application can optionally use DIEPINTx.TxFEmp before writing the data.

17.9.4.1 Examples**Slave Mode Bulk IN Transaction**

These notes refer to **Figure 17-25**.

1. The host attempts to read data (IN token) from an endpoint.
2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO.

Universal Serial Bus (USB)

1. The host attempts to read data (IN token) from an endpoint.
2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO.
3. To indicate that there was no data to send, the core generates an DIEPINTx.InTkn Rcvd When TxFIFO Empty interrupt.
4. When data is ready, the application sets up the DIEPTSIZx register with the transfer size and packet count.
5. The application writes one maximum packet size or less of data to the Non-periodic TxFIFO.
6. The host reattempts the IN token.
7. Because data is now ready in the FIFO, the core responds with the data, and the host ACKs it.
8. When the TxFIFO level falls below the halfway mark, the core generates a GINTSTS.NonPeriodic TxFIFO Empty interrupt. This triggers the application to start writing additional data packets to the FIFO.
9. A data packet for the second transaction is ready in the TxFIFO.
10. A data packet for third transaction is ready in the TxFIFO while the data for the second packet is being sent on the bus.
11. The second data packet is sent to the host.
12. The last short packet is sent to the host.
13. Because the last packet is sent and XferSize is now zero, the intended transfer is complete. The core generates a DIEPINTx.XferCompl interrupt.
14. The application processes the interrupt and uses the setting of the DIEPINTx.XferCompl interrupt bit to determine that the intended transfer is complete

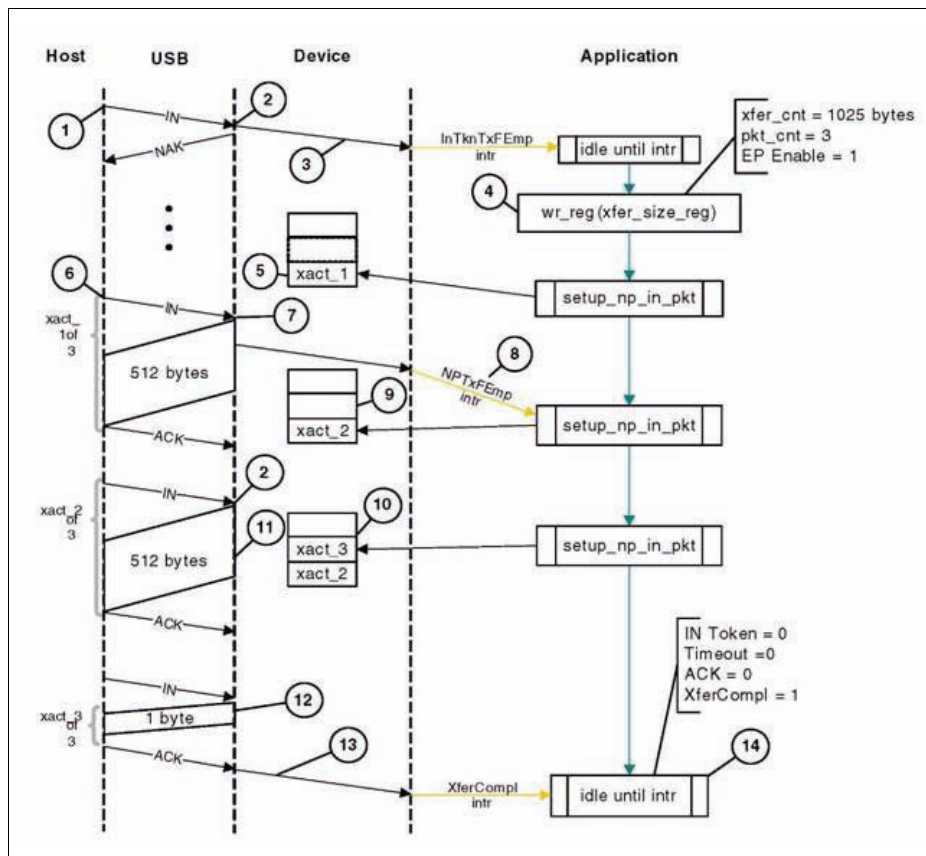

Figure 17-26 Slave Mode Bulk IN Transfer (Pipelined Transaction)

Slave Mode Bulk IN Two-Endpoint Transfer

These notes refer to [Figure 17-27](#).

1. The host attempts to read data (IN token) from endpoint 1.
2. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO for endpoint 1, and generates a DIEPINT1.InTkn Rcvd When Tx FIFO Empty interrupt.
3. The application processes the interrupt and initializes DIEPTSIZ1 register with the Transfer Size and Packet Count fields. The application starts writing the transaction data to the transmit FIFO.

Universal Serial Bus (USB)

4. The application writes one maximum packet size or less of data for endpoint 1 to the Non-periodic TxFIFO.
5. Meanwhile, the host attempts to read data (IN token) from endpoint 2.
6. On receiving the IN token on the USB, the core returns a NAK handshake, because no data is available in the transmit FIFO for endpoint 2, and the core generates a DIEPINT2.InTkn Rcvd When TxFIFO Empty interrupt.
7. Because the application has completed writing the packet for endpoint 1, it initializes the DIEPTSIZ2 register with the Transfer Size and Packet Count fields. The application starts writing the transaction data into the transmit FIFO for endpoint 2.
8. The host repeats its attempt to read data (IN token) from endpoint 1.
9. Because data is now ready in the TxFIFO, the core returns the data, which the host ACKs.
10. Meanwhile, the application has initialized the data for the next two packets in the TxFIFO (ep2.xact1 and ep1.xact2, in order).
11. The host repeats its attempt to read data (IN token) from endpoint 2.
12. Because endpoint 2's data is ready, the core responds with the data (ep2.xact_1), which the host ACKs.
13. Meanwhile, the application has initialized the data for the next two packets in the TxFIFO (ep2.xact2 and ep1.xact3, in order). The application has finished initializing data for the two endpoints involved in this scenario.
14. The host repeats its attempt to read data (IN token) from endpoint 1.
15. Because data is now ready in the FIFO, the core responds with the data, which the host ACKs.
16. The host repeats its attempt to read data (IN token) from endpoint 2.
17. With data now ready in the FIFO, the core responds with the data, which the host ACKs.
18. With the last packet for endpoint 2 sent and its XferSize now zero, the intended transfer is complete. The core generates a DIEPINT2.XferCompl interrupt for this endpoint.
19. The application processes the interrupt and uses the setting of the DIEPINT2.XferCompl interrupt bit to determine that the intended transfer on endpoint 2 is complete.
20. The host repeats its attempt to read data (IN token) from endpoint 1 (last transaction).
21. With data now ready in the FIFO, the core responds with the data, which the host ACKs.
22. Because the last endpoint one packet has been sent and XferSize is now zero, the intended transfer is complete. The core generates a DIEPINT1.XferCompl interrupt for this endpoint.
23. The application processes the interrupt and uses the setting of the DIEPINT1.XferCompl interrupt bit to determine that the intended transfer on endpoint 1 is complete.

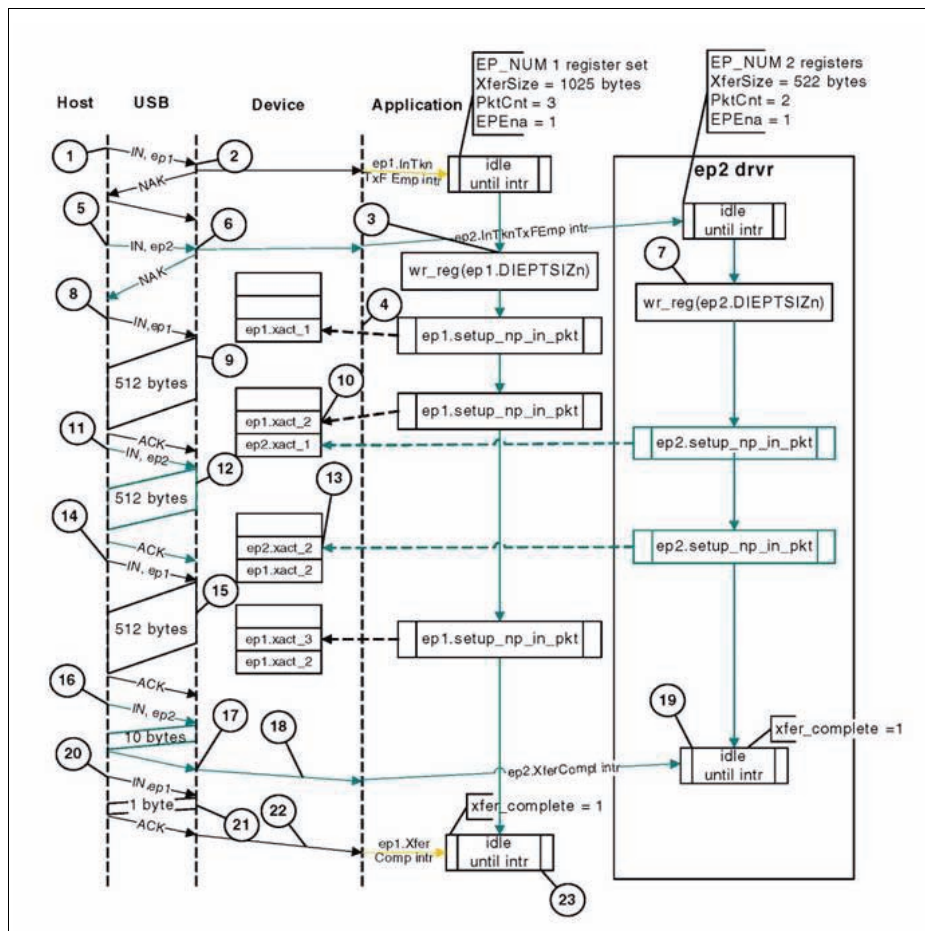

Figure 17-27 Slave Mode Bulk IN Two-Endpoint Transfer

17.9.5 Non-Isochronous OUT Data Transfers

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application Requirements

- For OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to the

DWORD boundary.

```
if (mps[epnum] mod 4) == 0
transfer size[epnum] = n * (mps[epnum] //DWORD aligned
else
transfer size[epnum] = n * (mps[epnum] + 4 - (mps[epnum] mod 4))
//Non-DWORD aligned
packet count[epnum] = n
n > 0
```

2. On any OUT endpoint interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
 - a) Payload size in memory = application-programmed initial transfer size - core updated final transfer size
 - b) Number of USB packets in which this payload was received = application-programmed initial packet count - core updated final packet count

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
 - a) OUT data packets received with Bad Data CRC are flushed from the receive FIFO automatically.
 - b) After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.
 - c) If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
 - d) In all the above three cases, the packet count is not decremented because no data is written to the receive FIFO.
3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
4. After the data is written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.

Universal Serial Bus (USB)

5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
6. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
 - a) The transfer size is 0 and the packet count is 0
 - b) The last OUT data packet written to the receive FIFO is a short packet (0 < packet size < maximum packet size)
7. When the application pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application Programming Sequence

1. Program the DOEPTSIZE register for the transfer size and the corresponding packet count.
2. Program the DOEPCTL register with the endpoint characteristics, and set the Endpoint Enable and ClearNAK bits.
 - a) DOEPCTL.EPENA = 1
 - b) DOEPCTL.CNAK = 1
3. In Slave mode, wait for the GINTSTS.Rx StsQ level interrupt and empty the data packets from the receive FIFO as explained in **“Packet Read from FIFO” on Page 17-91**.
 - a) This step can be repeated many times, depending on the transfer size.
4. Asserting the DOEPINT.XferCompl interrupt marks a successful completion of the non- isochronous OUT data transfer.
5. Read the DOEPTSIZE register to determine the size of the received data payload.

Note: The XferSize is not decremented for the last packet.

Universal Serial Bus (USB)

6. When the application has read all the data (equivalent to XferSize), the core generates a DOEINTx.XferCompl interrupt.
7. The application processes the interrupt and uses the setting of the DOEINTx.XferCompl interrupt bit to determine that the intended transfer is complete.

17.9.6 Isochronous OUT Data Transfers

This section describes a regular isochronous OUT data transfer.

Application Requirements

1. All the application requirements for non-isochronous OUT data transfers also apply to isochronous OUT data transfers
2. For isochronous OUT data transfers, the Transfer Size and Packet Count fields must always be set to the number of maximum-packet-size packets that can be received in a single frame and no more. Isochronous OUT data transfers cannot span more than 1 frame.
 - a) $1 \leq \text{packet count}[\text{epnum}] \leq 3$
3. When isochronous OUT endpoints are supported in the device, the application must read all isochronous OUT data packets from the receive FIFO (data and status) before the end of the periodic frame (GINTSTS.EOPF interrupt).
4. To receive data in the following frame, an isochronous OUT endpoint must be enabled after the GINTSTS.EOPF and before the GINTSTS.SOF.

Internal Data Flow

1. The internal data flow for isochronous OUT endpoints is the same as that for non-isochronous OUT endpoints, but for a few differences.
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame bit must also be set appropriately. The core receives data on a isochronous OUT endpoint in a particular frame only if the following condition is met.
 - a) $\text{DOEPCTLx.Even/Odd frame} = \text{DSTS.SOFFN}[0]$
3. When the application completely reads an isochronous OUT data packet (data and status) from the receive FIFO, the core updates the DOEPTSiZx.Received DPID field with the data PID of the last isochronous OUT data packet read from the receive FIFO.

Application Programming Sequence

1. Program the DOEPTSiZx register for the transfer size and the corresponding packet count.
2. Program the DOEPCTLx register with the endpoint characteristics and set the Endpoint Enable, ClearNAK, and Even/Odd frame bits.

- a) Endpoint Enable = 1
- b) CNAK=1
- c) Even/Odd frame = (0: Even/1: Odd)
- 3. In Slave mode, wait for the GINTSTS.Rx StsQ level interrupt and empty the data packets from the receive FIFO as explained in **“Packet Read from FIFO” on Page 17-91**.
 - a) This step can be repeated many times, depending on the transfer size.
- 4. The assertion of the DOEPINTx.XferCompl interrupt marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
- 5. This interrupt can not always be detected for isochronous OUT transfers. Instead, the application can detect the GINTSTS.incomplete Isochronous OUT data interrupt. See **“Incomplete Isochronous OUT Data Transfers” on Page 17-114**, for more details
- 6. Read the DOEPTSIzX register to determine the size of the received transfer and to determine the validity of the data received in the frame. The application must treat the data received in memory as valid only if one of the following conditions is met.
 - a) DOEPTSIzX.RxDPID = D0 and the number of USB packets in which this payload was received = 1
 - b) DOEPTSIzX.RxDPID = D1 and the number of USB packets in which this payload was received = 2
 - c) DOEPTSIzX.RxDPID = D2 and the number of USB packets in which this payload was received = 3
- 7. The number of USB packets in which this payload was received = App Programmed Initial Packet Count - Core Updated Final Packet Count
 The application can discard invalid data packets.

17.9.7 Isochronous OUT Data Transfers Using Periodic Transfer Interrupt

This section describes a regular isochronous OUT data transfer with the Periodic Transfer Interrupt feature.

Application Requirements

- 1. Before setting up ISOC OUT transfers spanned across multiple frames, the application must allocate buffer in the memory to accommodate all data to be received as part of the OUT transfers, then program that buffer's size and start address in the endpoint-specific registers.
 - a) The application must mask the GINTSTS.incomp ISO OUT.
 - b) The application must enable the DCTL.IgnrFrmNum
- 2. For ISOC transfers, the Transfer Size field in the DOEPTSIzX.XferSize register must be a multiple of the maximum packet size of the endpoint, adjusted to the DWORD boundary. The Transfer Size programmed can span across multiple frames based on

Universal Serial Bus (USB)

the periodicity after which the application wants to receive the `DOEPINTx.XferCompl` interrupt

- a) $\text{transfer size}[\text{epnum}] = n * (\text{mps}[\text{epnum}] + 4 - (\text{mps}[\text{epnum}] \bmod 4))$
 - b) $\text{packet count}[\text{epnum}] = n$
 - c) $n > 0$ (Higher value of n reduces the periodicity of the `DOEPINTx.XferCompl` interrupt)
 - d) $1 \leq \text{packet count}[\text{epnum}] \leq n$ (Higher value of n reduces the periodicity of the `DOEPINTx.XferCompl` interrupt).
3. In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD. The application will not be informed about the frame number and the PID value on which a specific OUT packet has been received.
 4. The assertion of the `DOEPINTx.XferCompl` interrupt marks the completion of the isochronous OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
 - a) On `DOEPINTx.XferCompl`, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory.
 - b) Payload size in memory = application-programmed initial transfer size - core updated final transfer size
 - c) Number of USB packets in which this payload was received = application-programmed initial packet count - core updated final packet count.
 - d) If for some reason, the host stop sending tokens, there will be no interrupt to the application, and the application must timeout on its own.
 5. The assertion of the `DOEPINTx.XferCompl` can also mark a packet drop on USB due to unavailability of space in the `RxFifo` or due to any packet errors.
 - a) The application must read the `DOEPINTx.PktDrpSts` (`DOEPINTx.Bit[11]` is now used as the `DOEPINTx.PktDrpSts`) register to differentiate whether the `DOEPINTx.XferCompl` was generated due to the normal end of transfer or due to dropped packets. In case of packets being dropped on the USB due to unavailability of space in the `RxFifo` or due to any packet errors the endpoint enable bit is cleared.
 - b) In case of packet drop on the USB application must re-enable the endpoint after recalculating the values `DOEPTSIZx.XferSize` and `DOEPTSIZx.PktCnt`.
 - c) Payload size in memory = application-programmed initial transfer size - core updated final transfer size
 - d) Number of USB packets in which this payload was received = application-programmed initial packet count - core updated final packet count.

Note: Due to application latencies it is possible that `DOEPINT.XferComplete` interrupt is generated without `DOEPINT.PktDrpSts` being set, This scenario is possible only if back-to-back packets are dropped for consecutive frames and the `PktDrpSts` is merged, but the `XferSize` and `PktCnt` values for the endpoint are nonzero. In this

Universal Serial Bus (USB)

case, the application must proceed further by programming the `PktCnt` and `XferSize` register for the next frame, as it would if `PktDrpSts` were being set.

Figure 17-29 gives the application flow for Isochronous OUT Periodic Transfer Interrupt feature.

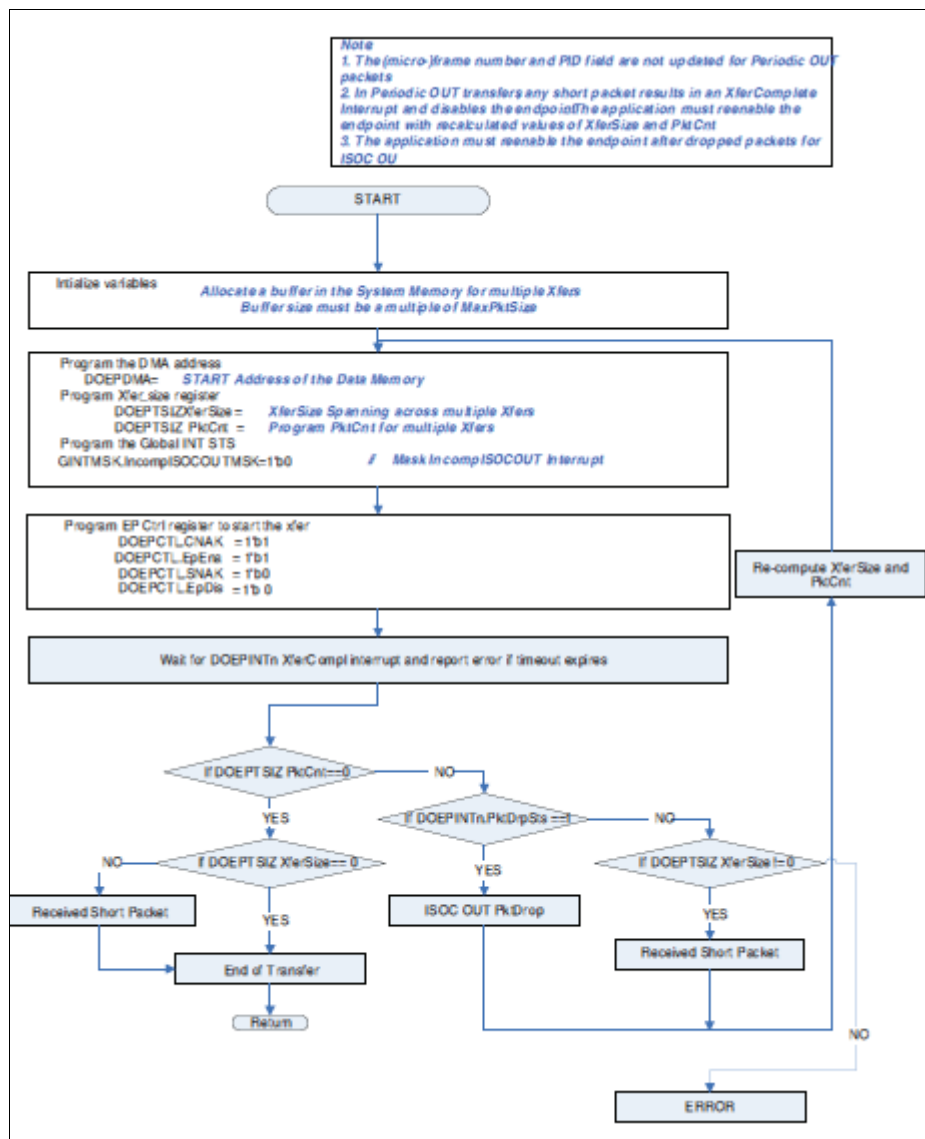

Figure 17-29 ISOC OUT Application Flow for Periodic Transfer Interrupt Feature

Internal Data Flow

1. The application must set the Transfer Size, Packets to be received in a frame and Packet Count Fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core.
3. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
4. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the ISOC packets are ignored and not written to the receive FIFO.
5. After the data is written to the receive FIFO, the core's DMA engine, reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
6. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
7. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
 - a) The transfer size is 0 and the packet count is 0
 - b) The last OUT data packet written to the receive FIFO is a short packet ($0 < \text{packet size} < \text{maximum packet size}$).
8. When the DMA pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint or the endpoint enable is cleared.
9. OUT data packets received with Bad Data CRC or any packet error are flushed from the receive FIFO automatically.

In these two cases, the packet count and transfer size registers are not decremented because no data is written to the receive FIFO. **Figure 17-30** illustrates the internal data flow.

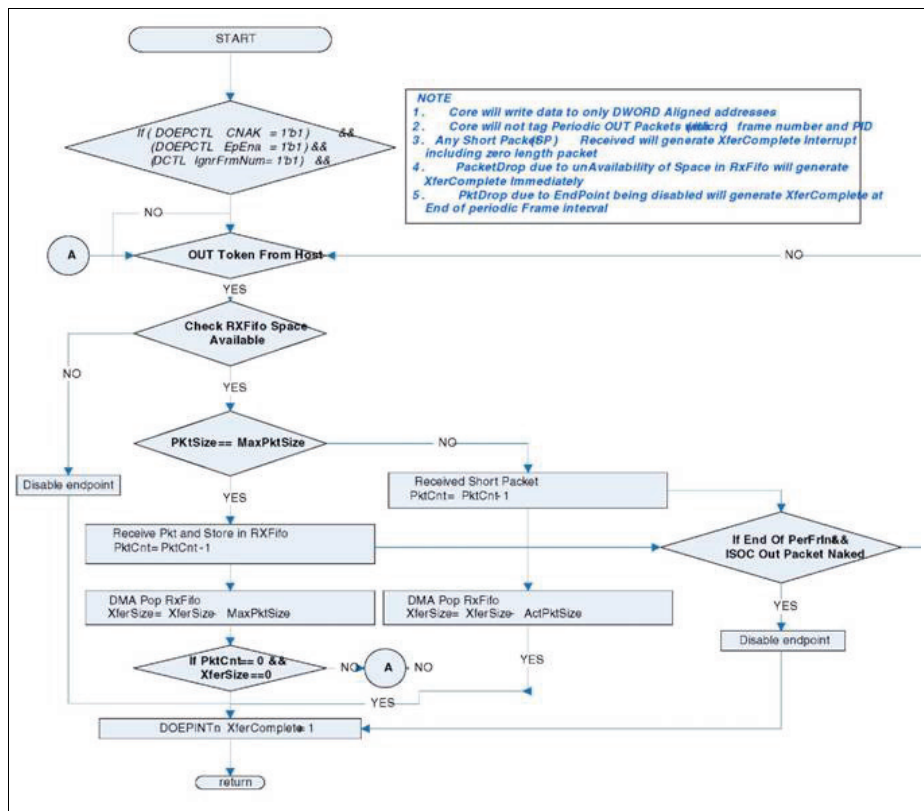

Figure 17-30 Isochronous OUT Core Internal Flow for Periodic Transfer Interrupt Feature

17.9.8 Incomplete Isochronous OUT Data Transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal Data Flow

1. For isochronous OUT endpoints, the DOEPINTx.XferCompl interrupt possibly is not always asserted. If the core drops isochronous OUT data packets, the application could fail to detect the DOEPINTx.XferCompl interrupt under the following circumstances.

Universal Serial Bus (USB)

- a) When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data.
- b) When the isochronous OUT data packet is received with CRC errors
- c) When the isochronous OUT token received by the core is corrupted
- d) When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the GINTSTS.incomplete Isochronous OUT data interrupt, indicating that a DOEPINTx.XferCompl interrupt is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remains in progress on this endpoint on the USB.
3. This step is applicable only if the USB core is operating in slave mode.

Application Programming Sequence

1. Asserting the GINTSTS.incomplete Isochronous OUT data interrupt indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must empty all isochronous OUT data (data and status) from the receive FIFO before proceeding.
 - a) When all data is emptied from the receive FIFO, the application can detect the DOEPINTx.XferCompl interrupt. In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame, as described in **“Isochronous OUT Data Transfers” on Page 17-108**.
3. When it receives a GINTSTS.incomplete Isochronous OUT data interrupt, the application must read the control registers of all isochronous OUT endpoints (DOEPCTLx) to determine which endpoints had an incomplete transfer in the current frame. An endpoint transfer is incomplete if both the following conditions are met.
 - a) DOEPCTLx.Even/Odd frame bit = DSTS.SOFFN[0]
 - b) DOEPCTLx.Endpoint Enable = 1
4. The previous step must be performed before the GINTSTS.SOF interrupt is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the DOEPCTLx.Endpoint Disable bit.
6. Wait for the DOEPINTx.Endpoint Disabled interrupt and enable the endpoint to receive new data in the next frame as explained in **“Isochronous OUT Data Transfers” on Page 17-108**.

Because the core can take some time to disable the endpoint, the application possibly is not able to receive the data in the next frame after receiving bad isochronous data.

17.9.9 Incomplete Isochronous IN Data Transfers

This section describes what the application must do on an incomplete isochronous IN data transfer.

Internal Data Flow

1. An isochronous IN transfer is treated as incomplete in one of the following conditions.
 - a) The core receives a corrupted isochronous IN token on at least one isochronous IN endpoint. In this case, the application detects a GINTSTS.incomplete Isochronous IN Transfer interrupt.
 - b) The application or DMA is slow to write the complete data payload to the transmit FIFO and an IN token is received before the complete data payload is written to the FIFO. In this case, the application detects a DIEPINTx.IN Tkn Rcvd When TxFIFO Empty interrupt. The application can ignore this interrupt, as it eventually results in a GINTSTS.incomplete Isochronous IN Transfer interrupt at the end of periodic frame.
 - The core transmits a zero-length data packet on the USB in response to the received IN token.
2. In either of the aforementioned cases, in Slave mode, the application must stop writing the data payload to the transmit FIFO as soon as possible.
3. The application must set the NAK bit and the disable bit for the endpoint.
4. The core disables the endpoint, clears the disable bit, and asserts the Endpoint Disable interrupt for the endpoint.

Application Programming Sequence

1. The application can ignore the DIEPINTx.IN Tkn Rcvd When TxFIFO empty interrupt on any isochronous IN endpoint, as it eventually results in a GINTSTS.incomplete Isochronous IN Transfer interrupt.
2. Assertion of the GINTSTS.incomplete Isochronous IN Transfer interrupt indicates an incomplete isochronous IN transfer on at least one of the isochronous IN endpoints.
3. The application must read the Endpoint Control register for all isochronous IN endpoints to detect endpoints with incomplete IN data transfers.
4. In Slave mode, the application must stop writing data to the Periodic Transmit FIFOs associated with these endpoints on the AHB.
5. In both modes of operation, program the following fields in the DIEPCTLx register to disable the endpoint. See **“IN Endpoint Disable” on Page 17-80** for more details.
 - a) DIEPCTLx.SetNAK = 1
 - b) DIEPCTLx.Endpoint Disable = 1
6. The DIEPINTx.Endpoint Disabled interrupt's assertion indicates that the core has disabled the endpoint.

7. At this point, the application must flush the data in the associated transmit FIFO or overwrite the existing data in the FIFO by enabling the endpoint for a new transfer in the next frame. To flush the data, the application must use the GRSTCTL register.

17.9.10 Periodic IN (Interrupt and Isochronous) Data Transfers

This section describes a typical periodic IN data transfer.

Application Requirements

1. Application requirements 1, 2, 3, and 4 of “**Non-Periodic (Bulk and Control) IN Data Transfers**” on **Page 17-98** also apply to periodic IN data transfers, except for a slight modification of Requirement 2.
 - a) The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum- packet-size packets and a short packet at the end of the transfer, the following conditions must be met.
 - $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$
 (where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$)
 - If $(\text{sp} > 0)$, $\text{packet count}[\text{epnum}] = n + 1$
 Otherwise, $\text{packet count}[\text{epnum}] = n$;
 - $\text{mc}[\text{epnum}] = \text{packet count}[\text{epnum}]$
 - b) The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet by it self. To transmit a single zero-length data packet,
 - c) $\text{transfer size}[\text{epnum}] = 0$
 - $\text{packet count}[\text{epnum}] = 1$
 - $\text{mc}[\text{epnum}] = \text{packet count}[\text{epnum}]$
2. The application can only schedule data transfers 1 frame at a time.
 - a) $(\text{DIEPTSIzX.MC} - 1) * \text{DIEPCTLx.MPS} < \text{DIEPTSIzX.XferSiz} < \text{DIEPTSIzX.MC} * \text{DIEPCTLx.MPS}$
 - b) $\text{DIEPTSIzX.PktCnt} = \text{DIEPTSIzX.MC}$
 - c) If $\text{DIEPTSIzX.XferSiz} < \text{DIEPTSIzX.MC} * \text{DIEPCTLx.MPS}$, the last data packet of the transfer is a short packet.
3. This step is not applicable for isochronous data transfers, only for interrupt transfers. The application can schedule data transfers for multiple frames, only if multiples of max packet sizes (up to 3 packets), must be transmitted every frame. This is can be done, only when the core is operating in DMA mode. This is not a recommended mode though.
 - a) $((n * \text{DIEPTSIzX.MC}) - 1) * \text{DIEPCTLx.MPS} \leq \text{DIEPTSIzX.Transfer Size} \leq n * \text{DIEPTSIzX.MC} * \text{DIEPCTLx.MPS}$
 - b) $\text{DIEPTSIzX.Packet Count} = n * \text{DIEPTSIzX.MC}$
 - c) n is the number of frames for which the data transfers are scheduled

Universal Serial Bus (USB)

Data Transmitted per frame in this case would be $\text{DIEPTSIZE} \times \text{MC} \times \text{DIEPCTL} \times \text{MPS}$, in all the frames except the last one. In the frame "n", the data transmitted would be $(\text{DIEPTSIZE} \times \text{TransferSize} -$

$(n-1) \times \text{DIEPTSIZE} \times \text{MC} \times \text{DIEPCTL} \times \text{MPS}$)

4. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.
5. The complete data to be transmitted in the frame must be written into the transmit FIFO (either by the application or the DMA), before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty, a zero data length packet would be transmitted on the USB for ISO IN endpoints. A NAK handshake is transmitted on the USB for INTR IN endpoints.
6. For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be $2 \times \text{max_pkt_size}$ and have the third packet load in after the first packet has been transmitted on the USB.

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The application must also write the required data to the associated transmit FIFO for the endpoint.
3. Every time either the core's internal DMA (in DMA mode) or the application (in Slave mode) writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for an periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO mode) for the frame is not present in the FIFO, then the core generates an IN Tkn Rcvd When TxF Empty Interrupt for the endpoint.
 - a) A zero-length data packet is transmitted on the USB for isochronous IN endpoints
 - b) A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
 - a) For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
 - b) For interrupt endpoints, when an ACK handshake is transmitted
 - c) When the transfer size and packet count are both 0, the Transfer Completed interrupt for the endpoint is generated and the endpoint enable is cleared.

6. At the "Periodic frame Interval" (controlled by DCFG.PerFrint), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates a GINTSTS.incomplISOIN interrupt.

Application Programming Sequence (Transfer Per Frame)

1. Program the DIEPTSIZx register.
2. Program the DIEPCTLx register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
3. In Slave mode, write the data to be transmitted in the next frame to the transmit FIFO as described in **"Packet Write" on Page 17-93**.
4. Asserting the DIEPINTx.In Token Rcvd When TxF Empty interrupt indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
5. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
 - a) If the isochronous endpoint is already enabled when this interrupt is detected, see **"Incomplete Isochronous IN Data Transfers" on Page 17-116** for more details.
6. The core handles timeouts internally, without application intervention. The application, thus, never detects a DIEPINTn.TimeOUT interrupt for periodic interrupt IN endpoints.
7. Asserting the DIEPINTx.XferCompl interrupt with no DIEPINTx.In Tkn Rcvd When TxF Empty interrupt indicates the successful completion of an isochronous IN transfer. A read to the DIEPTSIZx register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
8. Asserting the DIEPINTx.XferCompl interrupt, with or without the DIEPINTx.In Tkn Rcvd When TxF Empty interrupt, indicates the successful completion of an interrupt IN transfer. A read to the DIEPTSIZx register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
9. Asserting the GINTSTS.incomplete Isochronous IN Transfer interrupt with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

For isochronous IN endpoints, see **"Incomplete Isochronous IN Data Transfers" on Page 17-116**, for more details.

17.9.11 Periodic IN Data Transfers Using the Periodic Transfer Interrupt

This section describes a typical Periodic IN (ISOC / INTR) data transfer with the Periodic Transfer Interrupt feature.

1. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.

Universal Serial Bus (USB)

- a) To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 - $\text{Transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$
 (where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$. A higher value of n reduces the periodicity of the `DOEPINTx.XferCompl` interrupt)
 - If $(\text{sp} > 0)$, then $\text{packet count}[\text{epnum}] = n + 1$. Otherwise, $\text{packet count}[\text{epnum}] = n$
 - b) To transmit a single zero-length data packet:
 - $\text{Transfer size}[\text{epnum}] = 0$
 - $\text{Packet count}[\text{epnum}] = 1$
 - c) To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
 - First transfer: $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}]$; $\text{packet count} = n$;
 - Second transfer: $\text{transfer size}[\text{epnum}] = 0$; $\text{packet count} = 1$;
 - d) The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met.
 - $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$ (where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$)
 - If $(\text{sp} > 0)$, $\text{packet count}[\text{epnum}] = n + 1$ Otherwise, $\text{packet count}[\text{epnum}] = n$;
 - $\text{mc}[\text{epnum}] = \text{number of packets to be sent out in a frame}$.
 - e) The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet,
 - $\text{transfer size}[\text{epnum}] = 0$
 - $\text{packet count}[\text{epnum}] = 1$
 - $\text{mc}[\text{epnum}] = \text{packet count}[\text{epnum}]$
2. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with an Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.
 - a) $\text{Data fetched into transmit FIFO} = \text{Application-programmed initial transfer size} - \text{core-updated final transfer size}$
 - b) $\text{Data transmitted on USB} = (\text{application-programmed initial packet count} - \text{Core updated final packet count}) * \text{mps}[\text{epnum}]$
 - c) $\text{Data yet to be transmitted on USB} = (\text{Application-programmed initial transfer size} - \text{data transmitted on USB})$
 3. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.

Universal Serial Bus (USB)

4. The complete data to be transmitted in the frame must be written into the transmit FIFO, before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty,
 - a) A zero data length packet would be transmitted on the USB for ISOC IN endpoints
 - b) A NAK handshake would be transmitted on the USB for INTR IN endpoints
 - c) DIEPTSIZx.PktCnt is not decremented in this case.

For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be $2 * \text{max_pkt_size}$ and have the third packet load in after the first packet has been transmitted on the USB.

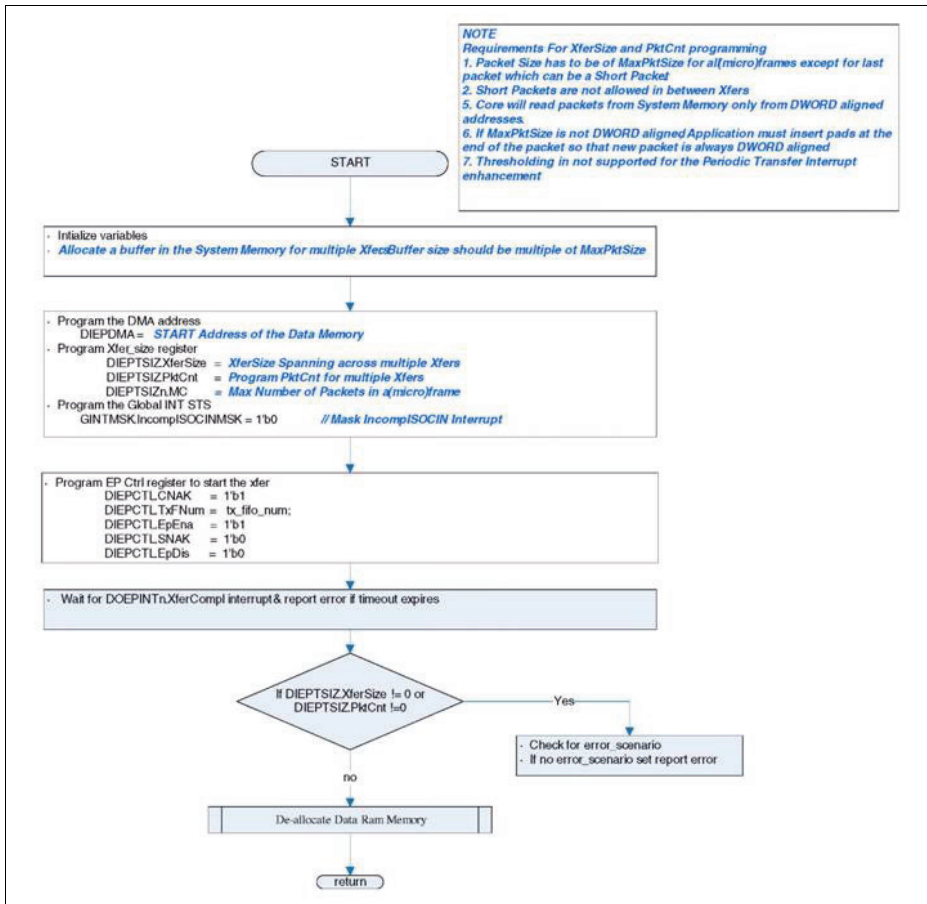

Figure 17-31 Periodic IN Application Flow for Periodic Transfer Interrupt Feature

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
 - a) The application must enable the DCTL.IgnrFrmNum
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core. Subsequently the core updates the Even / Odd bit on its own.
3. Every time the application writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete packet for the frame is not present in the FIFO, then the core generates an IN Tkn Rcvd When Tx Fifo Empty Interrupt for the endpoint.
 - a) A zero-length data packet is transmitted on the USB for isochronous IN endpoints
 - b) A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. If an IN token comes for an endpoint on the bus, and if the corresponding Tx FIFO for that endpoint has at least 1 packet available, and if the DIEPCTLx.NAK bit is not set, and if the internally maintained even/odd bit match with the bit 0 of the current frame number, then the core will send this data out on the USB. The core will also decrement the packet count. Core also toggles the MultCount in DIEPCTLx register and based on the value of MultCount the next PID value is sent.
 - a) If the IN token results in a timeout (core did not receive the handshake or handshake error), core rewind the FIFO pointers. Core does not decrement packet count. It does not toggle PID. DIEPINTx.TimeOut interrupt will be set which the application could check.
 - b) At the end of periodic frame interval (Based on the value programmed in the DCFG.PerFrmInt register, core will internally set the even/ odd internal bit to match the next frame.
6. The packet count for the endpoint is decremented by 1 under the following conditions:
 - a) For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
 - b) For interrupt endpoints, when an ACK handshake is transmitted
7. The data PID of the transmitted data packet is based on the value of DIEPTSIZx.MC programmed by the application. In case the DIEPTSIZx.MC value is set to 3 then, for a particular frame the core expects to receive 3 Isochronous IN token for the respective endpoint. The data PIDs transmitted will be D2 followed by D1 and D0 respectively for the tokens.
 - a) If any of the tokens responded with a zero-length packet due to non-availability of data in the Tx FIFO, the packet is sent in the next frame with the pending data PID. For example, in a frame, the first received token is responded to with data and data

Universal Serial Bus (USB)

PID value D2. If the second token is responded to with a zero-length packet, the host is expected not to send any more tokens for the respective endpoint in the current frame. When a token arrives in the next frame it will be responded to with the pending data PID value of D1.

- b) Similarly the second token of the current frame gets responded with D0 PID. The host is expected to send only two tokens for this frame as the first token got responded with D1 PID.
- 8. When the transfer size and packet count are both 0, the Transfer Completed interrupt for the endpoint is generated and the endpoint enable is cleared.
- 9. The GINTSTS.incomplSOIN will be masked by the application hence at the Periodic Frame interval (controlled by DCFG.PerFrint), even though the core finds non-empty any of the isochronous IN endpoint FIFOs, GINTSTS.incomplSOIN interrupt will not be generated.

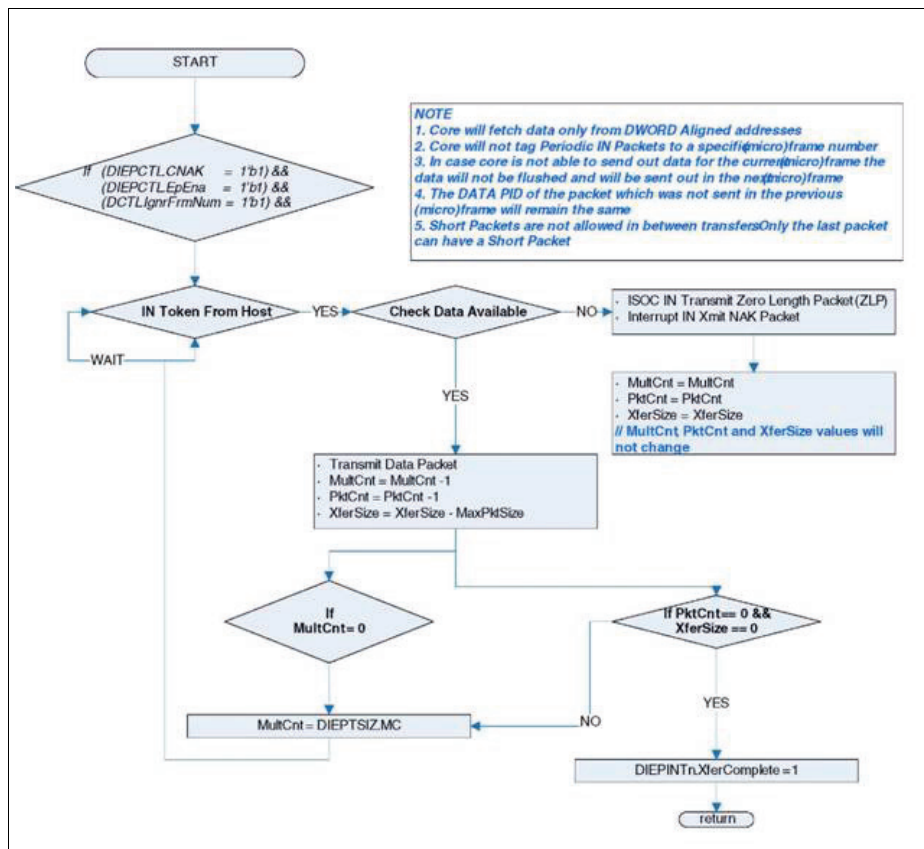

Figure 17-32 Periodic IN Core Internal Flow for Periodic Transfer Interrupt Feature

17.9.12 Interrupt OUT Data Transfers Using Periodic Transfer Interrupt

This section describes a regular INTR OUT data transfer with the Periodic Transfer Interrupt feature.

Application Requirements

1. Before setting up a periodic OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer, then program that buffer's size and start address in the endpoint-specific registers.
2. For Interrupt OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to

Universal Serial Bus (USB)

the DWORD boundary. The Transfer Size programmed can span across multiple frames based on the periodicity after which the application want to receive the DOEPINTx.XferCompl interrupt

- a) $\text{transfer size}[\text{epnum}] = n * (\text{mps}[\text{epnum}] + 4 - (\text{mps}[\text{epnum}] \bmod 4))$
 - b) $\text{packet count}[\text{epnum}] = n$
 - c) $n > 0$ (Higher value of n reduces the periodicity of the DOEPINTx.XferCompl interrupt)
 - d) $1 < \text{packet count}[\text{epnum}] < n$ (Higher value of n reduces the periodicity of the DOEPINTx.XferCompl interrupt)
3. On DOEPINTx.XferCompl interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
 - a) Payload size in memory = application-programmed initial transfer size - core updated final transfer size
 - b) Number of USB packets in which this payload was received = application-programmed initial packet count - core updated final packet count.
 - c) If for some reason, the host stops sending tokens, there are no interrupts to the application, and the application must timeout on its own.
 4. The assertion of the DOEPINTx.XferCompl interrupt marks the completion of the interrupt OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
 5. Read the DOEPTSIzX register to determine the size of the received transfer and to determine the validity of the data received in the frame.

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
 - a) The application must enable the DCTL.IgnrFrmNum
2. When an interrupt OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core.
3. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
 - a) OUT data packets received with Bad Data CRC or any packet error are flushed from the receive FIFO automatically.
 - b) Interrupt packets with PID errors are not passed to application. Core discards the packet, sends ACK and does not decrement packet count.
 - c) If there is no space in the receive FIFO, interrupt data packets are ignored and not written to the receive FIFO. Additionally, interrupt OUT tokens receive a NAK handshake reply.

Universal Serial Bus (USB)

4. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or interrupt data packets are ignored and not written to the receive FIFO, and interrupt OUT tokens receive a NAK handshake reply.
5. After the data is written to the receive FIFO, the application reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
6. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
7. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
 - a) The transfer size is 0 and the packet count is 0.
 - b) The last OUT data packet written to the receive FIFO is a short packet ($0 < \text{packet size} < \text{maximum packet size}$)
8. When the application pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

17.10 Device Programming in Buffer DMA Mode

This section discusses how to program the core when it is acting as a Device in the Slave mode of operation.

17.10.1 Control Transfers

This section describes the various types of control transfers.

17.10.1.1 Control Write Transfers (SETUP, Data OUT, Status IN)

This section describes control write transfers.

Application Programming Sequence

1. Assertion of the DOEPINTx.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. At the end of the Setup stage, the application must reprogram the DOEPTSiZx.SUPCnT field to 3 to receive the next SETUP packet.
2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data OUT phase, program the core to perform a control OUT transfer as explained in **“Non-Isochronous OUT Data Transfers” on Page 17-134**.
The application must reprogram the DOEPDMAx register to receive a control OUT data packet to a different memory location.
3. In a single OUT data transfer on control endpoint 0, the application can receive up to 64 bytes. If the application is expecting more than 64 bytes in the Data OUT stage, the application must re-enable the endpoint to receive another 64 bytes, and must continue to do so until it has received all the data in the Data stage.

4. Assertion of the DOEPI_{TX}.Transfer Compl interrupt on the last data OUT transfer indicates the completion of the data OUT phase of the control transfer.
5. On completion of the data OUT phase, the application must do the following.
 - a) To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint as explained in section **"OUT Data Transfers" on Page 17-129**.
 - DOEPI_{TX}.EPEna = 1_B
 - b) To execute the received Setup command, the application must program the required registers in the core. This step is optional, based on the type of Setup command received.
6. For the status IN phase, the application must program the core as described in **"Non-Periodic (Bulk and Control) IN Data Transfers" on Page 17-132** to perform a data IN transfer.
7. Assertion of the DIEPI_{TX}.Transfer Compl interrupt indicates completion of the status IN phase of the control transfer.

17.10.1.2 Control Read Transfers (SETUP, Data IN, Status OUT)

This section describes control write transfers.

Application Programming Sequence

1. Assertion of the DOEPI_{TX}.SETUP Packet interrupt indicates that a valid SETUP packet has been transferred to the application. At the end of the Setup stage, the application must reprogram the DOEPI_{TX}.SUPC_{NT} field to 3 to receive the next SETUP packet.
2. If the last SETUP packet received before the assertion of the SETUP interrupt indicates a data IN phase, program the core to perform a control IN transfer as explained in **"Non-Periodic (Bulk and Control) IN Data Transfers" on Page 17-132**.
3. On a single IN data transfer on control endpoint 0, the application can transmit up to 64 bytes. To transmit more than 64 bytes in the Data IN stage, the application must re-enable the endpoint to transmit another 64 bytes, and must continue to do so, until it has transmitted all the data in the Data stage.
4. The DIEPI_{TX}.Transfer Compl interrupt on the last IN data transfer marks the completion of the control transfer's Data stage.
5. To perform a data OUT transfer in the status OUT phase, the application must program the core as described in **"OUT Data Transfers" on Page 17-129**.
 - a) The application must program the DCFG.NZStsOUTHShk handshake field to a proper setting before transmitting an data OUT transfer for the Status stage.
 - b) The application must then reprogram the DOEPDMA_N register to receive the control OUT data packet to a different memory location.

6. Assertion of the DOEPINTx.Transfer Compl interrupt indicates completion of the status OUT phase of the control transfer. This marks the successful completion of the control read transfer.
 - a) To transfer a new SETUP packet, the application must re-enable the control OUT endpoint as explained in **“OUT Data Transfers” on Page 17-129**.
 - b) $\text{DOEPCTLn.EPEna} = 1_B$

17.10.1.3 Two-Stage Control Transfers (SETUP/Status IN)

This section describes two-stage control transfers.

Application Programming Sequence

1. Assertion of the DOEPINTx.SetUp interrupt indicates that a valid SETUP packet has been transferred to the application. To receive the next SETUP packet, the application must reprogram the DOEPSIZx.SUPCnt field to 3 at the end of the Setup stage.
2. Decode the last SETUP packet received before the assertion of the SETUP interrupt. If the packet indicates a two-stage control command, the application must do the following.
 - a) To transfer a new SETUP packet in DMA mode, the application must re-enable the control OUT endpoint. For more information, see **“OUT Data Transfers” on Page 17-129**.
 - Set $\text{DOEPCTLx.EPEna} = 1_B$
 - b) Depending on the type of Setup command received, the application can be required to program registers in the core to execute the received Setup command.
3. For the status IN phase, the application must program the core described in **“Non-Periodic (Bulk and Control) IN Data Transfers” on Page 17-132** to perform a data IN transfer.
4. Assertion of the DIEPINTx.Transfer Compl interrupt indicates the completion of the status IN phase of the control transfer.

17.10.2 OUT Data Transfers

This section describes the internal data flow and application-level operations during data OUT transfers and setup transactions.

17.10.2.1 Control Setup Transactions

This section describes how the core handles SETUP packets and the application's sequence for handling setup transactions. To initialize the core after power-on reset, the application must follow the sequence in **“Core Initialization” on Page 17-11**. Before it can communicate with the host, it must initialize an endpoint as described in **“Endpoint Initialization” on Page 17-74**. See **“Packet Read from FIFO” on Page 17-91**.

Application Requirements

1. To receive a SETUP packet, the DOEPTSIZx.SUPCnt field in a control OUT endpoint must be programmed to a non-zero value. When the application programs the SUPCnt field to a non-zero value, the core receives SETUP packets and writes them to the receive FIFO, irrespective of the DOEPCTLx.NAK status and DOEPCTLx.EPEna bit setting. The SUPCnt field is decremented every time the control endpoint receives a SETUP packet. If the SUPCnt field is not programmed to a proper value before receiving a SETUP packet, the core still receives the SETUP packet and decrements the SUPCnt field, but the application possibly is not be able to determine the correct number of SETUP packets received in the Setup stage of a control transfer.
 - a) DOEPTSIZx.SUPCnt = 3
2. In DMA mode, the OUT endpoint must also be enabled, to transfer the received SETUP packet data from the internal receive FIFO to the external memory.
 - a) DOEPCTLn.EPEna = 1_B
3. The application must always allocate some extra space in the Receive Data FIFO, to be able to receive up to three SETUP packets on a control endpoint.
 - a) The space to be Reserved is 10 DWORDs. Three DWORDs are required for the first SETUP packet, 1 DWORD is required for the Setup Stage Done DWORD, and 6 DWORDs are required to store two extra SETUP packets among all control endpoints.
 - b) 3 DWORDs per SETUP packet are required to store 8 bytes of SETUP data and 4 bytes of SETUP status (Setup Packet Pattern). The core reserves this space in the receive data
 - c) FIFO to write SETUP data only, and never uses this space for data packets.
4. The core writes the 2 DWORDs of the SETUP data to the memory.
5. The application must read and discard the Setup Stage Done DWORD from the receive FIFO.

Internal Data Flow

1. When a SETUP packet is received, the core writes the received data to the receive FIFO, without checking for available space in the receive FIFO and irrespective of the endpoint's NAK and Stall bit settings.
 - a) The core internally sets the IN NAK and OUT NAK bits for the control IN/OUT endpoints on which the SETUP packet was received.
2. For every SETUP packet received on the USB, 3 DWORDs of data is written to the receive FIFO, and the SUPCnt field is decremented by 1.
 - a) The first DWORD contains control information used internally by the core
 - b) The second DWORD contains the first 4 bytes of the SETUP command
 - c) The third DWORD contains the last 4 bytes of the SETUP command

Universal Serial Bus (USB)

3. When the Setup stage changes to a Data IN/OUT stage, the core writes an entry (Setup Stage Done DWORD) to the receive FIFO, indicating the completion of the Setup stage.
4. On the AHB side, SETUP packets are emptied either by the DMA or the application. In DMA mode, the SETUP packets (2 DWORDs) are written to the memory location programmed in the DOEPDMA_n register, only if the endpoint is enabled. If the endpoint is not enabled, the data remains in the receive FIFO until the enable bit is set.
5. When either the DMA or the application pops the Setup Stage Done DWORD from the receive FIFO, the core interrupts the application with a DOEPI_NT_n.SETUP interrupt, indicating it can process the received SETUP packet.
6. The core clears the endpoint enable bit for control OUT endpoints.

Application Programming Sequence

1. Program the DOEPT_SI_Zx register.
 - a) DOEPT_SI_Zx.SUPC_{nt} = 3
2. Program the DOEPDMA_n register and DOEPC_TL_n register with the endpoint characteristics and set the Endpoint Enable bit (DOEPC_TL_n.EPEna).
 - a) Endpoint Enable = 1
3. Assertion of the DOEPI_NT_x.SETUP interrupt marks a successful completion of the SETUP Data Transfer.
 - a) On this interrupt, the application must read the DOEPT_SI_Zx register to determine the number of SETUP packets received and process the last received SETUP packet.
 - b) In DMA mode, the application must also determine if the interrupt bit DOEPI_NT_n.Back2BackSETup is set. This bit is set if the core has received more than three back-to-back SETUP packets. If this is the case, the application must ignore the DOEPT_SI_Zn.SUPC_{nt} value and use the DOEPDMA_n directly to read out the last SETUP packet received. DOEPDMA₈ provides the pointer to the last valid SETUP data.

Note: If the application has not enabled EP0 before the host sends the SETUP packet, the core ACKs the SETUP packet and stores it in the FIFO, but does not write to the memory until EP0 is enabled. When the application enables the EP0 (first enable) and clears the NAK bit at the same time the Host sends DATA OUT, the DATA OUT is stored in the Rx FIFO. The USB core then writes the setup data to the memory and disables the endpoint. Though the application expects a Transfer Complete interrupt for the Data OUT phase, this does not occur, because the SETUP packet, rather than the DATA OUT packet, enables EP0 the first time. Thus, the DATA OUT packet is still in the Rx FIFO until the application re-enables EP0. The application must enable EP0 one more time for the core to process the DATA OUT packet.

Figure 17-24 charts this flow.

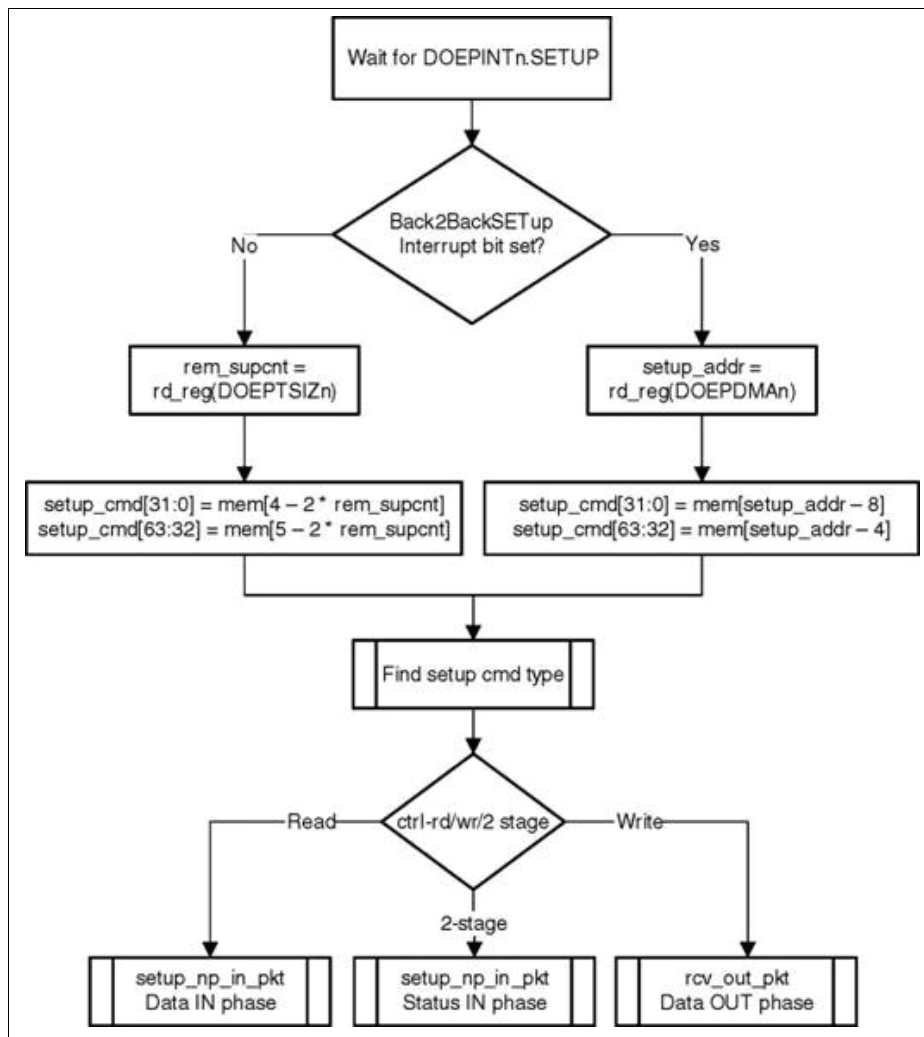

Figure 17-33 Processing a SETUP Packet

17.10.3 Non-Periodic (Bulk and Control) IN Data Transfers

This section describes a regular non-periodic IN data transfer.

Application Requirements

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer is part of a single buffer, and must program the size of that buffer and its start address (in DMA mode) to the endpoint-specific registers.
2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
 - a) To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 - b) $\text{Transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$
 (where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$)
 - If $(\text{sp} > 0)$, then $\text{packet count}[\text{epnum}] = n + 1$.
 Otherwise, $\text{packet count}[\text{epnum}] = n$
 - c) To transmit a single zero-length data packet:
 - $\text{Transfer size}[\text{epnum}] = 0$
 - $\text{Packet count}[\text{epnum}] = 1$
 - d) To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.
 - First transfer: $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}]$; $\text{packet count} = n$;
 - Second transfer: $\text{transfer size}[\text{epnum}] = 0$; $\text{packet count} = 1$;
3. In DMA mode, the core fetches an IN data packet from the memory, always starting at a DWORD boundary. If the maximum packet size of the IN endpoint is not a multiple of 4, the application must arrange the data in the memory with pads inserted at the end of a maximum-packet-size packet so that a new packet always starts on a DWORD boundary.
4. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with an Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.
5. Data fetched into transmit FIFO = Application-programmed initial transfer size - core-updated final transfer size
 - a) $\text{Data transmitted on USB} = (\text{application-programmed initial packet count} - \text{Core updated final packet count}) * \text{mps}[\text{epnum}]$
 - b) $\text{Data yet to be transmitted on USB} = (\text{Application-programmed initial transfer size} - \text{data transmitted on USB})$

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.

Universal Serial Bus (USB)

2. The core fetches the data from memory according to the application setting for the endpoint.
3. Every time the core's internal DMA writes a packet into the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from the memory, until the transfer size for the endpoint becomes 0. After writing the data into the FIFO, the "number of packets in FIFO" count is incremented (this is a 3-bit count, internally maintained by the core for each IN endpoint transmit FIFO. The maximum number of packets maintained by the core at any time in an IN endpoint FIFO is eight). For zero-length packets, a separate flag is set for each FIFO, without any data in the FIFO.
4. Once the data is written to the transmit FIFO, the core reads it out upon receiving an IN token. For every non-isochronous IN data packet transmitted with an ACK handshake, the packet count for the endpoint is decremented by one, until the packet count is zero. The packet count is not decremented on a TIMEOUT.
5. For zero length packets (indicated by an internal zero length flag), the core sends out a zero-length packet for the IN token and decrements the Packet Count field.
6. If there is no data in the FIFO for a received IN token and the packet count field for that endpoint is zero, the core generates a IN Tkn Rcvd When FIFO Empty Interrupt for the endpoint, provided the endpoint NAK bit is not set. The core responds with a NAK handshake for non-isochronous endpoints on the USB.
7. In Dedicated FIFO operation, the core internally rewinds the FIFO pointers and no timeout interrupt is generated except for Control IN endpoint.
8. When the transfer size is 0 and the packet count is 0, the transfer complete interrupt for the endpoint is generated and the endpoint enable is cleared.

Application Programming Sequence

1. Program the DIEPTSIZx register with the transfer size and corresponding packet count. Program also the DIEPDMAx register.
2. Program the DIEPCTLx register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
3. In DMA mode, ensure that the NextEp field is programmed so that the core fetches the data for IN endpoints in the correct order. See [“Non-Periodic IN Endpoint Sequencing” on Page 17-82](#) for details.
 - a) This step can be repeated multiple times, depending on the transfer size.

17.10.4 Non-Isynchronous OUT Data Transfers

This section describes a regular non-isochronous OUT data transfer (control, bulk, or interrupt).

Application Requirements

- Before setting up an OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer, then program that buffer's size and start address (in DMA mode) in the endpoint-specific registers.
- For OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to the DWORD boundary.

```
if (mps[epnum] mod 4) == 0
transfer size[epnum] = n * (mps[epnum] //DWORD aligned
else
transfer size[epnum] = n * (mps[epnum] + 4 - (mps[epnum] mod 4))
//Non-DWORD aligned
packet count[epnum] = n
n > 0
```

- In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD.
- On any OUT endpoint interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
 - Payload size in memory = application-programmed initial transfer size - core updated final transfer size
 - Number of USB packets in which this payload was received = application-programmed initial packet count - core updated final packet count

Internal Data Flow

- The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
- Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
 - OUT data packets received with Bad Data CRC are flushed from the receive FIFO automatically.
 - After sending an ACK for the packet on the USB, the core discards non-isochronous OUT data packets that the host, which cannot detect the ACK, re-sends. The application does not detect multiple back-to-back data OUT packets on the same endpoint with the same data PID. In this case the packet count is not decremented.

Universal Serial Bus (USB)

- c) If there is no space in the receive FIFO, isochronous or non-isochronous data packets are ignored and not written to the receive FIFO. Additionally, non-isochronous OUT tokens receive a NAK handshake reply.
- d) In all the above three cases, the packet count is not decremented because no data is written to the receive FIFO.
- 3. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or non-isochronous data packets are ignored and not written to the receive FIFO, and non-isochronous OUT tokens receive a NAK handshake reply.
- 4. After the data is written to the receive FIFO, the core's DMA engine reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
- 5. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
- 6. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
 - a) The transfer size is 0 and the packet count is 0
 - b) The last OUT data packet written to the receive FIFO is a short packet (0 < packet size < maximum packet size)
- 7. When either the application or the DMA pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

Application Programming Sequence

1. Program the DOEPTSIzX register for the transfer size and the corresponding packet count. Additionally, in DMA mode, program the DOEPDMAx register.
2. Program the DOEPCTLx register with the endpoint characteristics, and set the Endpoint Enable and ClearNAK bits.
 - a) DOEPCTLx.EPEna = 1
 - b) DOEPCTLx.CNAK = 1
3. Asserting the DOEPINTx.XferCompl interrupt marks a successful completion of the non- isochronous OUT data transfer.
4. Read the DOEPTSIzX register to determine the size of the received data payload.

Note: The XferSize is not decremented for the last packet.

17.10.5 Incomplete Isochronous OUT Data Transfers

This section describes the application programming sequence when isochronous OUT data packets are dropped inside the core.

Internal Data Flow

1. For isochronous OUT endpoints, the DOEPINTx.XferCompl interrupt possibly is not always asserted. If the core drops isochronous OUT data packets, the application could fail to detect the DOEPINTx.XferCompl interrupt under the following circumstances.
 - a) When the receive FIFO cannot accommodate the complete ISO OUT data packet, the core drops the received ISO OUT data.
 - b) When the isochronous OUT data packet is received with CRC errors
 - c) When the isochronous OUT token received by the core is corrupted
 - d) When the application is very slow in reading the data from the receive FIFO
2. When the core detects an end of periodic frame before transfer completion to all isochronous OUT endpoints, it asserts the GINTSTS.incomplete Isochronous OUT data interrupt, indicating that a DOEPINTx.XferCompl interrupt is not asserted on at least one of the isochronous OUT endpoints. At this point, the endpoint with the incomplete transfer remains enabled, but no active transfers remains in progress on this endpoint on the USB.

Application Programming Sequence

1. Asserting the GINTSTS.incomplete Isochronous OUT data interrupt indicates that in the current frame, at least one isochronous OUT endpoint has an incomplete transfer.
2. If this occurs because isochronous OUT data is not completely emptied from the endpoint, the application must empty all isochronous OUT data (data and status) from the receive FIFO before proceeding.
 - a) When all data is emptied from the receive FIFO, the application can detect the DOEPINTx.XferCompl interrupt. In this case, the application must re-enable the endpoint to receive isochronous OUT data in the next frame, as described in **“Control Read Transfers (SETUP, Data IN, Status OUT)” on Page 17-128**.
3. When it receives a GINTSTS.incomplete Isochronous OUT data interrupt, the application must read the control registers of all isochronous OUT endpoints (DOEPCTLx) to determine which endpoints had an incomplete transfer in the current frame. An endpoint transfer is incomplete if both the following conditions are met.
 - a) DOEPCTLx.Even/Odd frame bit = DSTS.SOFFN[0]
 - b) DOEPCTLx.Endpoint Enable = 1
4. The previous step must be performed before the GINTSTS.SOF interrupt is detected, to ensure that the current frame number is not changed.
5. For isochronous OUT endpoints with incomplete transfers, the application must discard the data in the memory and disable the endpoint by setting the DOEPCTLx.Endpoint Disable bit.
6. Wait for the DOEPINTx.Endpoint Disabled interrupt and enable the endpoint to receive new data in the next frame as explained in **“Control Read Transfers (SETUP, Data IN, Status OUT)” on Page 17-128**.

Because the core can take some time to disable the endpoint, the application possibly is not able to receive the data in the next frame after receiving bad isochronous data.

17.10.6 Periodic IN (Interrupt and Isochronous) Data Transfers

This section describes a typical periodic IN data transfer.

Application Requirements

1. Application requirements 1, 2, 3, and 4 of “**Non-Periodic (Bulk and Control) IN Data Transfers**” on Page 17-132 also apply to periodic IN data transfers, except for a slight modification of Requirement 2.
 - a) The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum- packet-size packets and a short packet at the end of the transfer, the following conditions must be met.
 - $\text{transfer size}[\text{epnum}] = n * \text{mps}[\text{epnum}] + \text{sp}$
(where n is an integer > 0 , and $0 < \text{sp} < \text{mps}[\text{epnum}]$)
 - If $(\text{sp} > 0)$, $\text{packet count}[\text{epnum}] = n + 1$
Otherwise, $\text{packet count}[\text{epnum}] = n$;
 - $\text{mc}[\text{epnum}] = \text{packet count}[\text{epnum}]$
 - b) The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet by it self. To transmit a single zero-length data packet,
 - c) $\text{transfer size}[\text{epnum}] = 0$
 - $\text{packet count}[\text{epnum}] = 1$
 - $\text{mc}[\text{epnum}] = \text{packet count}[\text{epnum}]$
2. The application can only schedule data transfers 1 frame at a time.
 - a) $(\text{DIEPTSIZx.MC} - 1) * \text{DIEPCTLx.MPS} < \text{DIEPTSIZx.XferSiz} < \text{DIEPTSIZx.MC} * \text{DIEPCTLx.MPS}$
 - b) $\text{DIEPTSIZx.PktCnt} = \text{DIEPTSIZx.MC}$
 - c) If $\text{DIEPTSIZx.XferSiz} < \text{DIEPTSIZx.MC} * \text{DIEPCTLx.MPS}$, the last data packet of the transfer is a short packet.
3. This step is not applicable for isochronous data transfers, only for interrupt transfers. The application can schedule data transfers for multiple frames, only if multiples of max packet sizes (up to 3 packets), must be transmitted every frame. This is can be done, only when the core is operating in DMA mode. This is not a recommended mode though.
 - a) $((n * \text{DIEPTSIZx.MC}) - 1) * \text{DIEPCTLx.MPS} \leq \text{DIEPTSIZx.Transfer Size} \leq n * \text{DIEPTSIZx.MC} * \text{DIEPCTLx.MPS}$
 - b) $\text{DIEPTSIZx.Packet Count} = n * \text{DIEPTSIZx.MC}$
 - c) n is the number of frames for which the data transfers are scheduled

Universal Serial Bus (USB)

Data Transmitted per frame in this case would be $\text{DIEPTSIZE} \times \text{MC} \times \text{DIEPCTL} \times \text{MPS}$, in all the frames except the last one. In the frame "n", the data transmitted would be $(\text{DIEPTSIZE} \times \text{TransferSize} -$

$(n-1) \times \text{DIEPTSIZE} \times \text{MC} \times \text{DIEPCTL} \times \text{MPS})$

4. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.
5. The complete data to be transmitted in the frame must be written into the transmit FIFO (either by the application or the DMA), before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty, a zero data length packet would be transmitted on the USB for ISO IN endpoints. A NAK handshake is transmitted on the USB for INTR IN endpoints.
6. For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be $2 \times \text{max_pkt_size}$ and have the third packet load in after the first packet has been transmitted on the USB.

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
2. The core fetches the data for the endpoint from memory, according to the application setting.
3. Every time either the core's internal DMA writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for an periodic endpoint, the core transmits the data in the FIFO, if available. If the complete data payload (complete packet, in dedicated FIFO mode) for the frame is not present in the FIFO, then the core generates an IN Tkn Rcvd When TxF Empty Interrupt for the endpoint.
 - a) A zero-length data packet is transmitted on the USB for isochronous IN endpoints
 - b) A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. The packet count for the endpoint is decremented by 1 under the following conditions:
 - a) For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
 - b) For interrupt endpoints, when an ACK handshake is transmitted
 - c) When the transfer size and packet count are both 0, the Transfer Completed interrupt for the endpoint is generated and the endpoint enable is cleared.
6. At the "Periodic frame Interval" (controlled by DCFG.PerFrmInt), when the core finds non-empty any of the isochronous IN endpoint FIFOs scheduled for the current frame non-empty, the core generates a $\text{GINTSTS.incomplISOIN}$ interrupt.

Application Programming Sequence (Transfer Per Frame)

1. Program the DIEPTSIZE and DIEPDMA registers.
2. Program the DIEPCTL register with the endpoint characteristics and set the CNAK and Endpoint Enable bits.
3. Asserting the DIEPINTx.In Token Rcvd When TxF Empty interrupt indicates that the application has not yet written all data to be transmitted to the transmit FIFO.
4. If the interrupt endpoint is already enabled when this interrupt is detected, ignore the interrupt. If it is not enabled, enable the endpoint so that the data can be transmitted on the next IN token attempt.
 - a) If the isochronous endpoint is already enabled when this interrupt is detected, see **“Incomplete Isochronous IN Data Transfers” on Page 17-116** for more details.
5. The core handles timeouts internally, without application intervention. The application, thus, never detects a DIEPINTn.TimeOUT interrupt for periodic interrupt IN endpoints.
6. Asserting the DIEPINTx.XferCompl interrupt with no DIEPINTx.In Tkn Rcvd When TxF Empty interrupt indicates the successful completion of an isochronous IN transfer. A read to the DIEPTSIZE register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
7. Asserting the DIEPINTx.XferCompl interrupt, with or without the DIEPINTx.In Tkn Rcvd When TxF Empty interrupt, indicates the successful completion of an interrupt IN transfer. A read to the DIEPTSIZE register must indicate transfer size = 0 and packet count = 0, indicating all data is transmitted on the USB.
8. Asserting the GINTSTS.incomplete Isochronous IN Transfer interrupt with none of the aforementioned interrupts indicates the core did not receive at least 1 periodic IN token in the current frame.

For isochronous IN endpoints, see **“Incomplete Isochronous IN Data Transfers” on Page 17-116**, for more details.

17.10.7 Periodic IN Data Transfers Using the Periodic Transfer Interrupt

This section describes a typical Periodic IN (ISOC / INTR) data transfer with the Periodic Transfer Interrupt feature.

1. Before setting up an IN transfer, the application must ensure that all data to be transmitted as part of the IN transfer is part of a single buffer, and must program the size of that buffer and its start address (in DMA mode) to the endpoint-specific registers.
2. For IN transfers, the Transfer Size field in the Endpoint Transfer Size register denotes a payload that constitutes multiple maximum-packet-size packets and a single short packet. This short packet is transmitted at the end of the transfer.
 - a) To transmit a few maximum-packet-size packets and a short packet at the end of the transfer:
 - Transfer size[epnum] = $n * mps[epnum] + sp$

Universal Serial Bus (USB)

(where n is an integer > 0 , and $0 < sp < mps[epnum]$. A higher value of n reduces the periodicity of the $DOEPINTx.XferCompl$ interrupt)

- If ($sp > 0$), then $packet\ count[epnum] = n + 1$. Otherwise, $packet\ count[epnum] = n$

b) To transmit a single zero-length data packet:

- Transfer size[epnum] = 0

- Packet count[epnum] = 1

c) To transmit a few maximum-packet-size packets and a zero-length data packet at the end of the transfer, the application must split the transfer in two parts. The first sends maximum-packet-size data packets and the second sends the zero-length data packet alone.

- First transfer: transfer size[epnum] = $n * mps[epnum]$; packet count = n ;

- Second transfer: transfer size[epnum] = 0; packet count = 1;

d) The application can only transmit multiples of maximum-packet-size data packets or multiples of maximum-packet-size packets, plus a short packet at the end. To transmit a few maximum-packet-size packets and a short packet at the end of the transfer, the following conditions must be met.

- transfer size[epnum] = $n * mps[epnum] + sp$ (where n is an integer > 0 , and $0 < sp < mps[epnum]$)

- If ($sp > 0$), $packet\ count[epnum] = n + 1$ Otherwise, $packet\ count[epnum] = n$;

- $mc[epnum]$ = number of packets to be sent out in a frame.

e) The application cannot transmit a zero-length data packet at the end of transfer. It can transmit a single zero-length data packet by itself. To transmit a single zero-length data packet,

- transfer size[epnum] = 0

- packet count[epnum] = 1

- $mc[epnum] = packet\ count[epnum]$

3. In DMA mode, the core fetches an IN data packet from the memory, always starting at a DWORD boundary. If the maximum packet size of the IN endpoint is not a multiple of 4, the application must arrange the data in the memory with pads inserted at the end of a maximum-packet-size packet so that a new packet always starts on a DWORD boundary.

4. Once an endpoint is enabled for data transfers, the core updates the Transfer Size register. At the end of IN transfer, which ended with an Endpoint Disabled interrupt, the application must read the Transfer Size register to determine how much data posted in the transmit FIFO was already sent on the USB.

a) Data fetched into transmit FIFO = Application-programmed initial transfer size - core-updated final transfer size

b) Data transmitted on USB = (application-programmed initial packet count - Core updated final packet count) * $mps[epnum]$

c) Data yet to be transmitted on USB = (Application-programmed initial transfer size - data transmitted on USB)

Universal Serial Bus (USB)

5. The application can schedule data transfers for multiple frames, only if multiples of max packet sizes (up to 3 packets), must be transmitted every frame. This is can be done, only when the core is operating in DMA mode.
 - a) $((n * \text{DIEPTSIZE}_n.MC) - 1) * \text{DIEPCTL}_n.MPS \leq \text{DIEPTSIZE}_n.Transfer\ Size \leq n * \text{DIEPTSIZE}_n.MC * \text{DIEPCTL}_n.MPS$
 - b) $\text{DIEPTSIZE}_n.Packet\ Count = n * \text{DIEPTSIZE}_n.MC$
 - c) n is the number of frames for which the data transfers are scheduled. Data Transmitted per frame in this case is $\text{DIEPTSIZE}_n.MC * \text{DIEPCTL}_n.MPS$ in all frames except the last one. In frame n, the data transmitted is $(\text{DIEPTSIZE}_n.TransferSize - (n - 1) * \text{DIEPTSIZE}_n.MC * \text{DIEPCTL}_n.MPS)$
6. For Periodic IN endpoints, the data must always be prefetched 1 frame ahead for transmission in the next frame. This can be done, by enabling the Periodic IN endpoint 1 frame ahead of the frame in which the data transfer is scheduled.
7. The complete data to be transmitted in the frame must be written into the transmit FIFO, before the Periodic IN token is received. Even when 1 DWORD of the data to be transmitted per frame is missing in the transmit FIFO when the Periodic IN token is received, the core behaves as when the FIFO was empty. When the transmit FIFO is empty,
 - a) A zero data length packet would be transmitted on the USB for ISOC IN endpoints
 - b) A NAK handshake would be transmitted on the USB for INTR IN endpoints
 - c) $\text{DIEPTSIZE}_x.PktCnt$ is not decremented in this case.

For a High Bandwidth IN endpoint with three packets in a frame, the application can program the endpoint FIFO size to be $2 * \text{max_pkt_size}$ and have the third packet load in after the first packet has been transmitted on the USB.

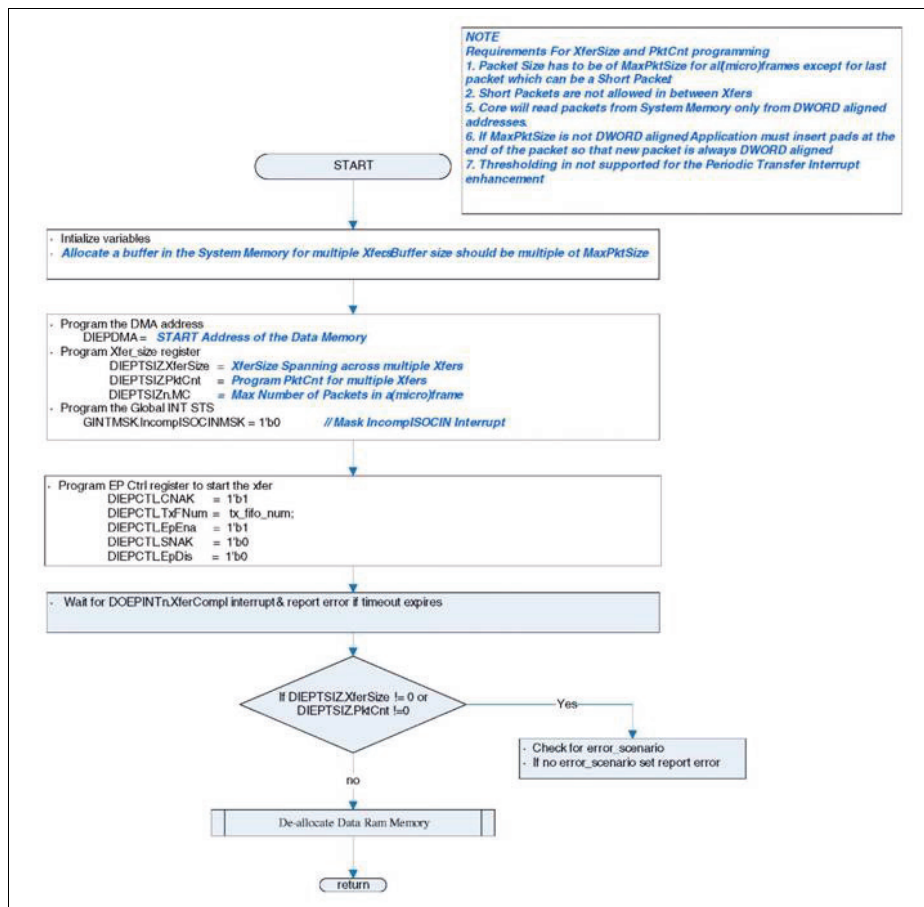

Figure 17-34 Periodic IN Application Flow for Periodic Transfer Interrupt Feature

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers and enable the endpoint to transmit the data.
 - a) The application must enable the DCTL.IgnrFrmNum
2. When an isochronous OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core. Subsequently the core updates the Even / Odd bit on its own.
3. Every time either the core's internal DMA writes a packet to the transmit FIFO, the transfer size for that endpoint is decremented by the packet size. The data is fetched from DMA or application memory until the transfer size for the endpoint becomes 0.
4. When an IN token is received for a periodic endpoint, the core transmits the data in the FIFO, if available. If the complete packet for the frame is not present in the FIFO, then the core generates an IN Tkn Rcvd When Tx Fifo Empty Interrupt for the endpoint.
 - a) A zero-length data packet is transmitted on the USB for isochronous IN endpoints
 - b) A NAK handshake is transmitted on the USB for interrupt IN endpoints
5. If an IN token comes for an endpoint on the bus, and if the corresponding Tx FIFO for that endpoint has at least 1 packet available, and if the DIEPCTLx.NAK bit is not set, and if the internally maintained even/odd bit match with the bit 0 of the current frame number, then the core will send this data out on the USB. The core will also decrement the packet count. Core also toggles the MultCount in DIEPCTLx register and based on the value of MultCount the next PID value is sent.
 - a) If the IN token results in a timeout (core did not receive the handshake or handshake error), core rewind the FIFO pointers. Core does not decrement packet count. It does not toggle PID. DIEPINTx.TimeOut interrupt will be set which the application could check.
 - b) At the end of periodic frame interval (Based on the value programmed in the DCFG.PerFrmInt register, core will internally set the even/ odd internal bit to match the next frame.
6. The packet count for the endpoint is decremented by 1 under the following conditions:
 - a) For isochronous endpoints, when a zero- or non-zero-length data packet is transmitted
 - b) For interrupt endpoints, when an ACK handshake is transmitted
7. The data PID of the transmitted data packet is based on the value of DIEPTSIZx.MC programmed by the application. In case the DIEPTSIZx.MC value is set to 3 then, for a particular frame the core expects to receive 3 Isochronous IN token for the respective endpoint. The data PIDs transmitted will be D2 followed by D1 and D0 respectively for the tokens.
 - a) If any of the tokens responded with a zero-length packet due to non-availability of data in the Tx FIFO, the packet is sent in the next frame with the pending data PID. For example, in a frame, the first received token is responded to with data and data

Universal Serial Bus (USB)

PID value D2. If the second token is responded to with a zero-length packet, the host is expected not to send any more tokens for the respective endpoint in the current frame. When a token arrives in the next frame it will be responded to with the pending data PID value of D1.

- b) Similarly the second token of the current frame gets responded with D0 PID. The host is expected to send only two tokens for this frame as the first token got responded with D1 PID.
- 8. When the transfer size and packet count are both 0, the Transfer Completed interrupt for the endpoint is generated and the endpoint enable is cleared.
- 9. The GINTSTS.incomplSOIN will be masked by the application hence at the Periodic Frame interval (controlled by DCFG.PerFrint), even though the core finds non-empty any of the isochronous IN endpoint FIFOs, GINTSTS.incomplSOIN interrupt will not be generated.

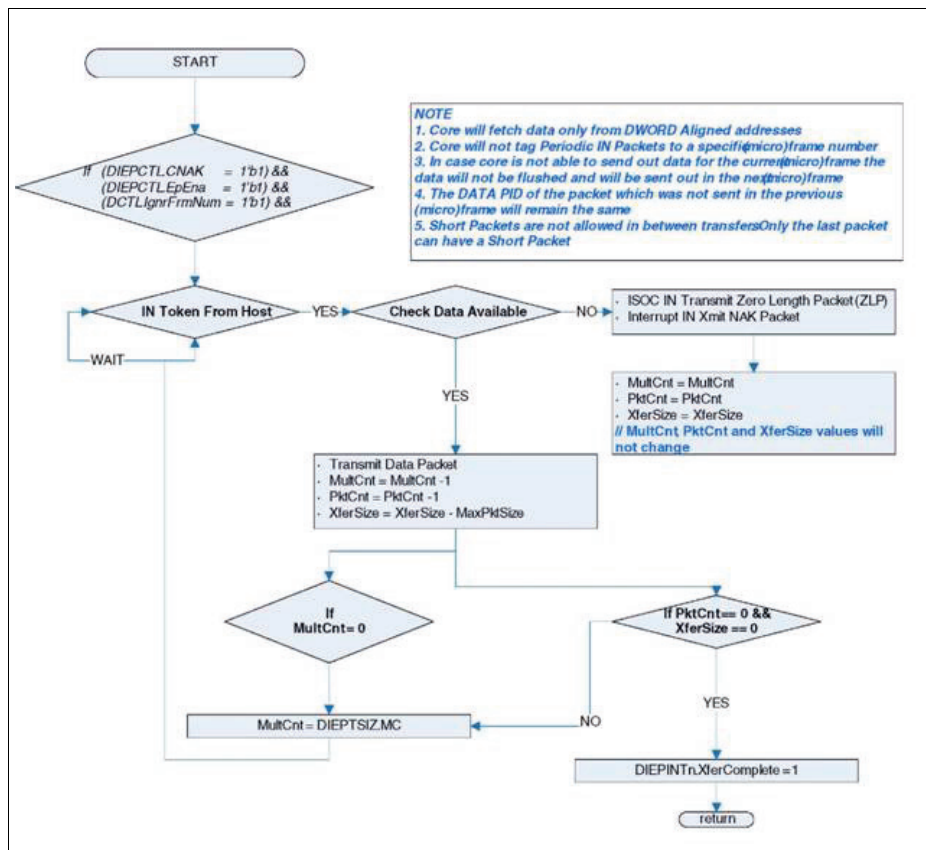

Figure 17-35 Periodic IN Core Internal Flow for Periodic Transfer Interrupt Feature

17.10.8 Interrupt OUT Data Transfers Using Periodic Transfer Interrupt

This section describes a regular INTR OUT data transfer with the Periodic Transfer Interrupt feature.

Application Requirements

1. Before setting up a periodic OUT transfer, the application must allocate a buffer in the memory to accommodate all data to be received as part of the OUT transfer, then program that buffer's size and start address in the endpoint-specific registers.
2. For Interrupt OUT transfers, the Transfer Size field in the endpoint's Transfer Size register must be a multiple of the maximum packet size of the endpoint, adjusted to

Universal Serial Bus (USB)

the DWORD boundary. The Transfer Size programmed can span across multiple frames based on the periodicity after which the application want to receive the DOEPINTx.XferCompl interrupt

- a) $\text{transfer size}[\text{epnum}] = n * (\text{mps}[\text{epnum}] + 4 - (\text{mps}[\text{epnum}] \bmod 4))$
 - b) $\text{packet count}[\text{epnum}] = n$
 - c) $n > 0$ (Higher value of n reduces the periodicity of the DOEPINTx.XferCompl interrupt)
 - d) $1 < \text{packet count}[\text{epnum}] < n$ (Higher value of n reduces the periodicity of the DOEPINTx.XferCompl interrupt)
3. In DMA mode, the core stores a received data packet in the memory, always starting on a DWORD boundary. If the maximum packet size of the endpoint is not a multiple of 4, the core inserts byte pads at end of a maximum-packet-size packet up to the end of the DWORD. The application will not be informed about the (micro)frame number on which a specific packet has been received.
 4. On DOEPINTx.XferCompl interrupt, the application must read the endpoint's Transfer Size register to calculate the size of the payload in the memory. The received payload size can be less than the programmed transfer size.
 - a) $\text{Payload size in memory} = \text{application-programmed initial transfer size} - \text{core updated final transfer size}$
 - b) $\text{Number of USB packets in which this payload was received} = \text{application-programmed initial packet count} - \text{core updated final packet count.}$
 - c) If for some reason, the host stops sending tokens, there are no interrupts to the application, and the application must timeout on its own.
 5. The assertion of the DOEPINTx.XferCompl interrupt marks the completion of the interrupt OUT data transfer. This interrupt does not necessarily mean that the data in memory is good.
 6. Read the DOEPTISIZx register to determine the size of the received transfer and to determine the validity of the data received in the frame.

Internal Data Flow

1. The application must set the Transfer Size and Packet Count fields in the endpoint-specific registers, clear the NAK bit, and enable the endpoint to receive the data.
 - a) The application must enable the DCTL.IgnrFrmNum
2. When an interrupt OUT endpoint is enabled by setting the Endpoint Enable and clearing the NAK bits, the Even/Odd frame will be ignored by the core.
3. Once the NAK bit is cleared, the core starts receiving data and writes it to the receive FIFO, as long as there is space in the receive FIFO. For every data packet received on the USB, the data packet and its status are written to the receive FIFO. Every packet (maximum packet size or short packet) written to the receive FIFO decrements the Packet Count field for that endpoint by 1.
 - a) OUT data packets received with Bad Data CRC or any packet error are flushed from the receive FIFO automatically.

Universal Serial Bus (USB)

- b) Interrupt packets with PID errors are not passed to application. Core discards the packet, sends ACK and does not decrement packet count.
- c) If there is no space in the receive FIFO, interrupt data packets are ignored and not written to the receive FIFO. Additionally, interrupt OUT tokens receive a NAK handshake reply.
- 4. When the packet count becomes 0 or when a short packet is received on the endpoint, the NAK bit for that endpoint is set. Once the NAK bit is set, the isochronous or interrupt data packets are ignored and not written to the receive FIFO, and interrupt OUT tokens receive a NAK handshake reply.
- 5. After the data is written to the receive FIFO, the core's DMA engine reads the data from the receive FIFO and writes it to external memory, one packet at a time per endpoint.
- 6. At the end of every packet write on the AHB to external memory, the transfer size for the endpoint is decremented by the size of the written packet.
- 7. The OUT Data Transfer Completed pattern for an OUT endpoint is written to the receive FIFO on one of the following conditions.
 - a) The transfer size is 0 and the packet count is 0.
 - b) The last OUT data packet written to the receive FIFO is a short packet ($0 < \text{packet size} < \text{maximum packet size}$)
- 8. When either the application or the DMA pops this entry (OUT Data Transfer Completed), a Transfer Completed interrupt is generated for the endpoint and the endpoint enable is cleared.

17.11 Device Programming in Scatter-Gather DMA Mode

This chapter describes the programming requirements for the Device core operating in Scatter/Gather DMA mode. It describes how to initialize the channel and provides information on asynchronous transfers (bulk and control) and periodic transfers (isochronous and interrupt).

17.11.1 Programming Overview

When the Scatter/Gather DMA mode is enabled data buffers are presented through descriptor structures

- 1. The application prepares the descriptors, and sets the bit DIEPCTLx/DOEPCTLx.EPEna.
- 2. DMA fetches the corresponding descriptor (initially determined by DIEPDMAXx/DOEPDMAXx).
- 3. DMA internally sets the transfer size from descriptor back to DIEPTSIZx/DOEPTSIZx.
- 4. From this point, the current USB flow executes.
- 5. Once the transfer size data is moved by DMA, the DMA checks for further links in the descriptor chain.

Universal Serial Bus (USB)

6. If this is the last descriptor, the DMA sets the DIOEPINTn.XferCompl interrupt.
7. If there are further active links, the DMA continues to process them.

Note: The registers DIEPTSIZE_x/DOEPTSIZE_x must not be written by the application in Scatter/Gather DMA mode.

In Scatter/Gather DMA mode, the core implements a true scatter-gather memory distribution in which data buffers are scattered over the system memory. Each endpoint memory structure is implemented as a contiguous list of descriptors, in which each descriptor points to a data buffer of predefined size. In addition to the buffer pointer (1 DWORD), the descriptor also has a status quadlet (1 DWORD). When the list is implemented as a ring buffer, the list processor switches to the first element of the list when it encounters last bit. All endpoints (control, bulk, interrupt, and isochronous) implement these structures in memory.

Note: The descriptors are stored in continuous locations. For example descriptor 1 is stored in 0000'0000_H, descriptor 2 is stored in 0000'0008_H, descriptor 3 in 0000'0010_H and so on. The descriptors are always DWORD aligned.

17.11.2 SPRAM Requirements

For each endpoint the current descriptor pointer and descriptor status are cached to avoid additional requests to system memory. These are stored in SPRAM. In addition DIEPDMA_x/DOEPDMA_x registers are also implemented in SPRAM.

17.11.3 Descriptor Memory Structures

The descriptor memory structures are displayed in [Figure 17-36](#).

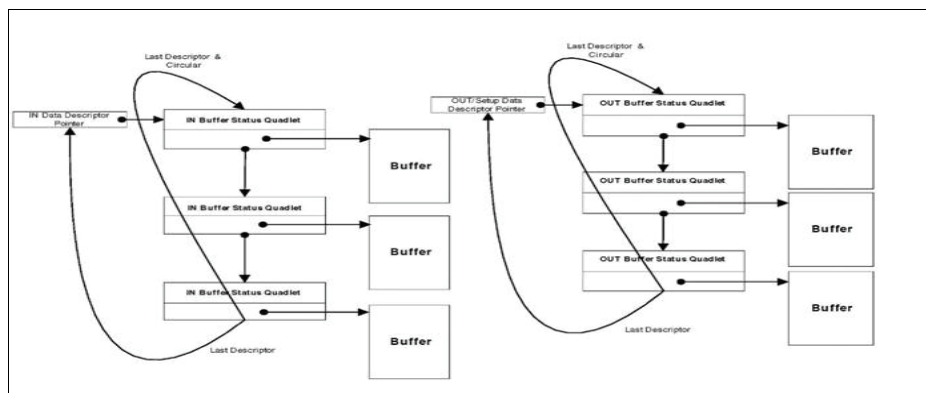

Figure 17-36 Descriptor Memory Structures

17.11.3.1 OUT Data Memory Structure

All endpoints that support OUT direction transactions (endpoints that receive data from the USB host), must implement a memory structure with the following characteristics:

- Each data buffer must have a descriptor associated with it to provide the status of the buffer. The buffer itself contains only raw data.
- Each buffer descriptor is two quadlets in length.

When the buffer status of the first descriptor is host Ready, the DMA fetches and processes its data buffer; otherwise the DMA optionally skips to the next descriptor until it reaches the end of the descriptor chain. The buffers to which the descriptor points hold packet data for non-isochronous endpoints and frame (FS)/μframe (FS) data for isochronous endpoints.

Host Ready — indicates that the descriptor is available for the DMA to process.

DMA Busy — indicates that the DMA is still processing the descriptor.

DMA Done—indicates that the buffer data transfer is complete.

Host Busy—indicates that the application is processing the descriptor.

The OUT data memory structure is shown in [Figure 17-37](#), which shows the definition of status quadlet bits for non-ISO and ISO end points

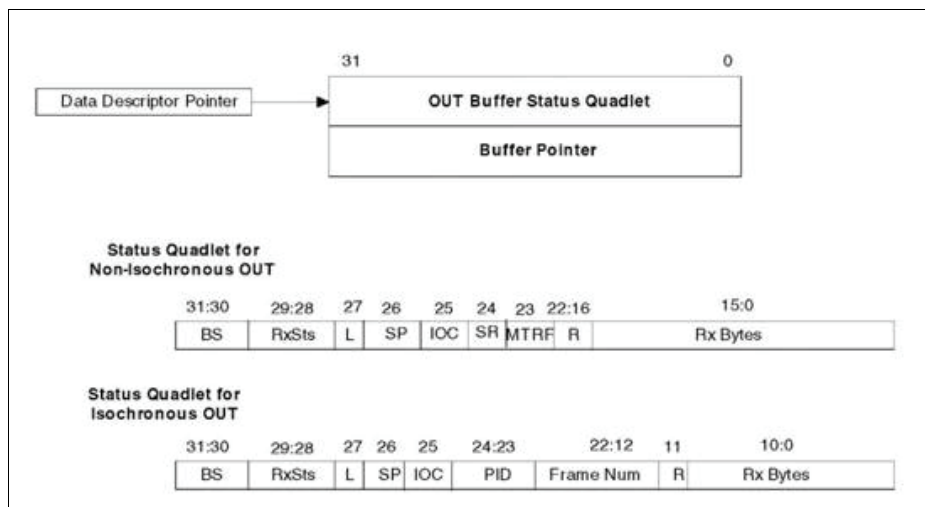

Figure 17-37 Out Data Memory Structure

The status quadlet interpretation depends on the end point type field (DOEPCTLx.EPType) for the corresponding end point. For example, if an end point is OUT and periodic, then the status quadlet is interpreted as Status Quadlet for Isochronous OUT.

Table 17-9 displays the OUT Data Memory Structure fields.

Note: Note that some fields change depending on the mode.

Table 17-9 OUT Data Memory Structure Values

| Bit | Bit ID | Description |
|----------------|---------------|--|
| BS [31:30] | Buffer Status | <p>This 2-bit value describes data buffer status. Possible options are:</p> <ul style="list-style-type: none"> 00_B Host Ready 01_B DMA Busy 10_B DMA Done 11_B Host Busy <p>Application sets to Host Ready if the descriptor is ready or to Host Busy if the descriptor is not ready. Core sets to DMA busy if the descriptor is being serviced or to DMA Done if the transfer finished associated with the descriptor.</p> <p>The application needs to make these bits as 00_B (Host Ready) as a last step after preparing the entire descriptor ready. Once the software makes these bits as Host Ready then it must not alter the descriptor until DMA completes</p> |
| Rx Sts [29:28] | Receive Statu | <p>This 2-bit value describes the status of the received data. Core updates this when the descriptor is closed. This reflects whether OUT data has been received correctly or with errors. BUFERR is set by the core when AHB error is encountered during buffer access. BUFERR is set by the core after asserting AHBErr for the corresponding end point. The possible combinations are:</p> <ul style="list-style-type: none"> • 00_B Success, No AHB errors • 01_B Reserved • 10_B Reserved • 11_B BUFERR |
| L [27] | Last | <p>Set by the application, this bit indicates that this descriptor is the last one in the chain. Note - L Bit is interpreted by the core even when BS value is other than Host ready. For example, BNA is set, the core keeps traversing all the descriptors until it encounters a descriptor whose L bit is set after which the core disables the corresponding endpoint.</p> |
| SP[26] | Short Packet | <p>Set by the Core, this bit indicates that this descriptor closed after short packet. When reset it indicates that the descriptor is closed after requested amount of data is received.</p> |

Universal Serial Bus (USB)

Table 17-9 OUT Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description |
|--------------------|-----------------------|---|
| IOC[25] | Interrupt On complete | Set by the application, this bit indicates that the core must generate a transfer complete interrupt(XferCompl) after this descriptor is finished. |
| [24] ¹⁾ | Varies | <div> <div> Non Isochronous Out Bit: SR[24] Bit ID: Setup Packet Received Set by the Core, this bit indicates that this buffer holds 8 bytes of setup data. There is only one setup packet per descriptor. On reception of a setup packet, the descriptor is closed and the corresponding endpoint is disabled after SETUP_COMPLETE status is seen in the Rx fifo. The core puts a SETUP_COMPLETE status into the Rx FIFO when it sees the first IN/OUT token after the SETUP packet for that particular endpoint. However, if the L bit of the descriptor is set, the endpoint is disabled and the descriptor is closed irrespective of the SETUP_COMPLETE status. The application has to re-enable for receiving any OUT data for the control transfer. (It also need to reprogram the descriptor start address) Note - Because of the above behavior, the core can receive any number of back to back setup packets and one descriptor for every setup packet is used. </div> <div> Isochronous Out Bit: Reserved [24:23] Bit ID: This field is reserved and the core writes 00_B. </div> </div> |

Universal Serial Bus (USB)

Table 17-9 OUT Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description | |
|-----------------------|--------|--|--|
| [23] ¹⁾ | Varies | Non Isochronous Out Bit: MTRF[23] Bit ID: Multiple Transfer Set by the application, this bit indicates the Core can continue processing the list after it encountered last descriptor. This is to support multiple transfers without application intervention. Reserved for ISO OUT and Control OUT endpoints. | See description for bit [24] |
| [22:16] ¹⁾ | Varies | Non Isochronous Out Bit: [22:12] Bit ID: R Reserved | Isochronous Out Bit: Frame Number [22:12] Bit ID: Frame number The 11-bit frame number corresponds to full speed frame number. |

Universal Serial Bus (USB)

Table 17-9 OUT Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description | |
|-----------------------|--------|---|---|
| [15:12] ¹⁾ | Varies | Non Isochronous Out Bit: Rx Bytes [15:0] | See description for bits [22:16] |
| [11] ¹⁾ | Varies | Bit ID: Received number of bytes remaining This 16-bit value can take values from 0 to (64K-1) bytes, depending on the transfer size of data received from the USB host. The application programs the expected transfer size. When the descriptor is done this indicates remainder of the transfer size. Here, Rx Bytes must be in terms of multiple of MPS for the corresponding end point. The MPS for the various packet types are as follows: <ul style="list-style-type: none"> • Control <ul style="list-style-type: none"> – LS - 8 bytes – FS - 8,16,32,64 bytes • Bulk <ul style="list-style-type: none"> – FS - 8,16,32,64 bytes • Interrupt <ul style="list-style-type: none"> – LS - up to 8 bytes – FS - up to 64 bytes Note: In case of Interrupt packets, the MPS may not be a multiple of 4. If the MPS in an interrupt packet is not a multiple of 4, then a single interrupt packet corresponds to a single descriptor. If MPS is a multiple of 4 for an interrupt packet, then a single descriptor can have multiple MPS packets. | Isochronous Out Bit: 11 Bit ID: Reserved |
| [10:0] ¹⁾ | Varies | | Isochronous Out Bit: Rx Bytes [10:0] Bit ID: Received number of bytes This 11-bit value can take values from 0 to (2K-1) bytes, depending on the packet size of data received from the USB host. Application programs the expected transfer size. When the descriptor is done this indicates remainder of the transfer size. The maximum payload size of each ISO packet as per USB specification 2.0 is as follows. FS - up to 1023 bytes Note: A Value of 0 indicates zero bytes of data, 1 indicates 1 byte of data and so on. |

1) The meaning of this field varies. See description.

Table 17-10 displays the matrix of L bit and MTRF bit options.

Table 17-10 OUT - L Bit and MTRF Bit

| L Bit | MTRF bit | Functionality |
|-------|----------|---|
| 1 | 1 | Continue to process the list after the last descriptor encountered. Use DOEPDMAx as next descriptor. The Endpoint is not disabled. |
| 1 | 0 | For non-Isochronous endpoints, Stop processing list after last descriptor encountered. The application intervenes and programs the list pointer into DOEPDMAx register when a list is created in a new location otherwise enables the endpoint. Start processing when the endpoint is enabled again with DOEPDMAx register pointing to start of list. For Isochronous endpoints, the DMA engine always goes back to the base descriptor address after the last descriptor. |
| 0 | 1 | If a short packet is received or expected transfer is done, close the current descriptor, continue with the next descriptor. If a short packet or Zero length packet is received, the corresponding endpoint is not disabled. |
| 0 | 0 | After processing the current descriptor go to next descriptor. If a short packet OR zero length packet is received disable the endpoint and a transfer complete interrupt is generated irrespective of IOC bit setting for that descriptor. |

Table 17-11 displays the out buffer pointer field description.

Note: For Bulk and Interrupt End Points, if MTRF bit is set for the last descriptor in a list, then all the descriptors in that list need to have their MTRF bit set.

Table 17-11 OUT Buffer Pointer

| | | |
|----------------|----------------|--|
| Buf Addr[31:0] | Buffer Address | The Buffer pointer field in the descriptor is 32 bits wide and contains the address where the received data is to be stored in the system memory. The starting buffer address must be DWORD aligned. The buffer size must be also DWORD aligned. |
|----------------|----------------|--|

17.11.3.2 Isochronous OUT

- The application must create one descriptor per packet.
- End point is not disabled by the core based on L bit. The DMA always goes back to the base descriptor address after the last descriptor.
- The bit MTRF is not applicable.

17.11.3.3 Non-Isochronous OUT

- The core uses one descriptor per setup packet.
- The core closes the descriptor after receiving a short packet.
- Bit combinations for L and MTRF appear in [Table 17-10](#).
- Multiple Interrupt packets in the same buffer is allowed only if the MPS is multiple of 4.

17.11.3.4 IN Data Memory Structure

All endpoints that support IN direction transactions (transmitting data to the USB host) must implement the following memory structure. Each buffer must have a descriptor associated with it. The application fills the data buffer, updates its status in the descriptor, and enables the endpoint. The DMA fetches this descriptor and processes it, moving on in this fashion until it reaches the end of the descriptor chain. The buffer to which the descriptor points to hold packet data for non-isochronous endpoints and frame data for isochronous endpoints.

The definition of status quadlet bits for non-periodic and periodic end points are as shown in the figure. The status quadlet interpretation depends on the end point type field (DIEPCTLx.EPType) for the corresponding end point. For example, if an end point is IN and periodic, then the status quadlet is interpreted as "Status Quadlet for Isochronous IN".

The IN data memory structure is shown in **Figure 17-38**.

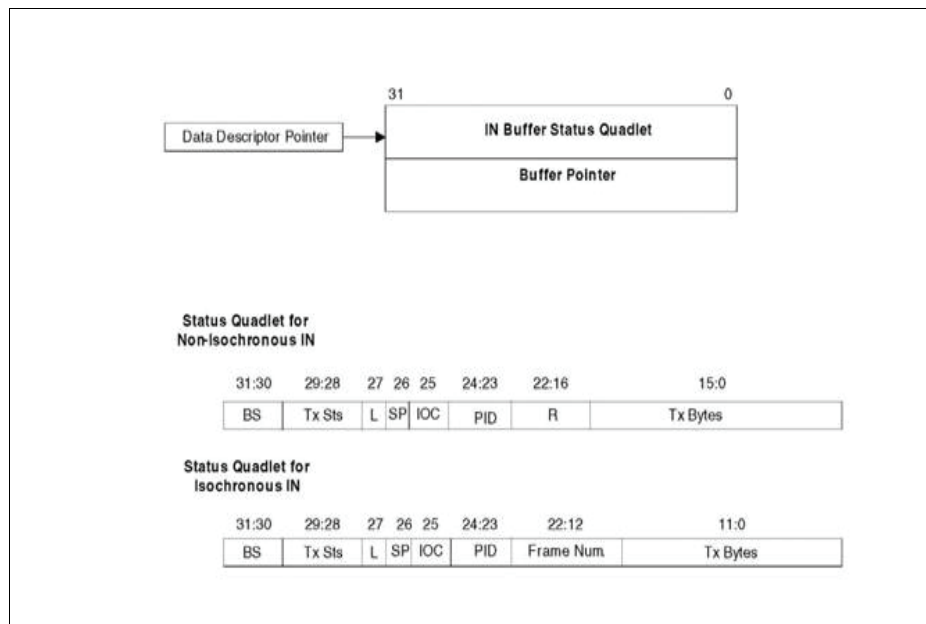

Figure 17-38 IN Data Memory Structure

Table 17-12 displays the IN Data Memory Structure fields.

Note: Some fields change depending on the mode

Table 17-12 IN Data Memory Structure Values

| Bit | Bit ID | Description |
|-------------------|-----------------------|--|
| BS [31:30] | Buffer Status | <p>This 2-bit value describes the status of the data buffer. The possible options are:</p> <ul style="list-style-type: none"> • 00_B Host ready • 01_B DMA busy • 10_B DMA done • 11_B Host busy <p>The application needs to make these bits as 00_B (Host Ready) as a last step after preparing the entire descriptor ready. Once the software makes these bits as HostReady then it must not alter the descriptor until DMA done</p> |
| Tx Sts [29:28] | Transmit Status | <p>The status of the transmitted data. This reflects if the IN data has been transmitted correctly or with errors. BUFERR is set by core when there is a AHB error during buffer access. When ilgnrFrmNum is not set, BUFLUSH is set by the core when</p> <ul style="list-style-type: none"> • the core is fetching data pertaining to the current frame (N) and finds that the frame has incremented (N+1) during the data fetch • or • when it fetches a descriptor for which the frame number has already elapsed. The possible combinations are: • 00_B Success, No AHB errors • 01_B BUFLUSH • 10_B Reserved • 11_B BUFERR |
| L [27] | Last | When set by the application, this bit indicates that this descriptor is the last one in the chain. |
| SP[26] | Short Packet | When set, this bit indicates that this descriptor points to a short packet or a zero length packet. If there is more than one packet in the descriptor, it indicates that the last packet is a short packet or a zero length packet. |
| IOC[25] | Interrupt On complete | When set by the application, this bit indicates that the core must generate a transfer complete interrupt after this descriptor is finished. |

Universal Serial Bus (USB)

Table 17-12 IN Data Memory Structure Values (cont'd)

| Bit | Bit ID | Description |
|-----------------------|--------|---|
| [24:23] ¹⁾ | Varies | Non Isochronous In Bit: Reserved[24:16] Bit ID: Reserved |
| [22:12] ¹⁾ | Varies | Isochronous In Bit: Reserved[24:23] Bit ID: Reserved |
| [15:12] ¹⁾ | Varies | Non Isochronous In Bit: Tx bytes [15:0] Bit ID: Number of bytes to be transmitted This 16-bit value can take values from 0 to (64K-1) bytes, indicating the number of bytes of data to be transmitted to the USB host. Note: A Value of 0 indicates zero bytes of data, 1 indicates 1 byte of data and so on. |
| [11:0] ¹⁾ | Varies | Isochronous In Bit: Tx bytes [11:0] Bit ID: Number of bytes to transmit Tx bytes [11:0] Number of bytes to be transmitted This 12-bit value can take values from 0 to (4K-1) bytes, indicating the number of bytes of data to be transmitted to the USB host. Note: A Value of 0 indicates zero bytes of data, 1 indicates 1 byte of data and so on. |

1) The meaning of this field varies. See description.

Table 17-13 displays the matrix of IN - L Bit, SP Bit and Tx bytes options.

Table 17-13 IN - L Bit, SP Bit and Tx bytes

| L Bit | SP bit | Tx Bytes | Functionality |
|--------------|---------------|--|---|
| 0 | 1 | Multiple of endpoint maximum packet size | Transmit a zero length packet after the last packet |
| 0 | 1 | Not multiple of maximum packet size | Send short packet at the end after normal packets are sent out. Then move onto next descriptor |
| 0 | 1 | 0 | Transmit zero length packet. Then move on to next descriptor. |
| 0 | 0 | Multiple of endpoint maximum packet size | Send normal packets and then move to next descriptor. |
| 0 | 0 | Not a multiple of maximum packet size | Transmit the normal packets and concatenate the remaining bytes with next buffer from the next descriptor. This combination is valid only for bulk end points. |
| 0 | 0 | 0 | Invalid. The behavior of the core is undefined. |
| 1 | 1 | Multiple of endpoint maximum packet size | Transmit a zero length packet after the last packet If this IN descriptor is for a ISO endpoint, then move onto the first descriptor in the list. If this IN descriptor is for a non-ISO endpoint, then stop processing this list and disable the corresponding end point. |
| 1 | 1 | Not multiple of maximum packet size | Send short packet after sending the normal packets If this IN descriptor is for a ISO endpoint, move onto the first descriptor in the list. If this IN descriptor is for a non-ISO endpoint, then stop processing this list and disable the corresponding end point. |

Universal Serial Bus (USB)
Table 17-13 IN - L Bit, SP Bit and Tx bytes (cont'd)

| L Bit | SP bit | Tx Bytes | Functionality |
|-------|--------|--|---|
| 1 | 1 | 0 | Transmit zero length packet If this IN descriptor is for a ISO endpoint, move onto the first descriptor in the list. If this IN descriptor is for a non-ISO endpoint, then stop processing this list and disable the corresponding end point. |
| 1 | 0 | Multiple of endpoint maximum packet size | Send normal packets If this IN descriptor is for a ISO endpoint, Move onto the first descriptor in the list after current transfer done. If this IN descriptor is for a non-ISO endpoint, then stop processing the list and disable the corresponding end point. |
| 1 | 0 | Not multiple of maximum packet size. | Invalid. The behavior of the core is undefined for these values. |
| 1 | 0 | 0 | invalid. The behavior of the core is undefined for these values. |

The descriptions provided for the different combinations in [Table 17-13](#) depend on the previous descriptor L, SP, and Tx Bytes values. Consider [Table 17-14](#). The MPS for this example is 512.

Table 17-14 IN - Buffer Pointer

| DESC NO | L bit | SP bit | Txbytes | Description |
|---------|-------|--------|---------|---|
| 1 | 0 | 0 | 520 | Send a normal packet of size 512, and concatenate the remaining 8 bytes with the next descriptor's buffer data |
| 2 | 0 | 1 | 512 | For this combination of L,SP and TxBytes, as per the above table, we need to send a zero length packet instead of a short packet. However, a normal packet followed by a short packet of length 8-bytes is sent. This is to illustrate the context dependency based on previous descriptor L,SP and TxByte combinations. |

Table 17-15 displays the IN buffer pointer field description.

Table 17-15 IN Buffer Pointer

| Bit | Bit ID | Description |
|----------------|----------------|--|
| Buf Addr[31:0] | Buffer Address | The Buffer pointer field in the descriptor is 32 bits wide and contains the address where the transmit data is stored in the system memory. The address can be non- DWORD aligned. |

17.11.3.5 Descriptor Update Interrupt Enable Modes

If IOC bit is set for a descriptor and if the corresponding Transfer Completed Interrupt Mask (XferComplMask) is unmasked, this interrupt (DIOEPINTn.XferCompl) is asserted while closing that descriptor.

17.11.3.6 DMA Arbitration in Scatter/Gather DMA Mode

The arbiter grants receive higher priority than transmit. Within transmit, the priority is as follows.

- The highest priority is given to periodic endpoints. The periodic endpoints are serviced in a round robin fashion.
- The non periodic endpoints are serviced after the periodic scheduling interval has elapsed. The duration of the periodic scheduling interval is programmable, as specified by register bits DCFG[25:24]. When the periodic interval is active, the periodic endpoints are given priority.
- Amongst the periodic endpoints, the priority is round robin.
- Amongst the non periodic endpoints, the Global Multi Count field in the Device Control Register (DCTL) specifies the number of packets that need to be serviced for that end point before moving to the next endpoint.

The arbiter disables an endpoint and moves on to the next endpoint in the following scenarios as well, for all the endpoint types:

- Descriptor Fetch and AHB Error occurs.
- Buffer Not Available (BNA), such as when buffer status is Host busy.
- AHB Error during Descriptor update stage and Data transfer stage.

17.11.3.7 Buffer Data Access on AHB in Scatter/Gather DMA Mode

The buffer address whose data needs to be accessed in the system memory can be non DWORD aligned for transmit.

For buffer data read, the core arranges the buffer data to form a quadlet internally before populating the TXFIFO within the core as per the following scenarios

Universal Serial Bus (USB)

- The packet starts in a non DWORD aligned address, the core does two reads on AHB before appending the relevant bytes to form a quadlet internally. Hence the core stores the bytes before pushing to the TXFIFO.
- The packet ends in a non DWORD aligned address and it is not the end of the buffer or expected transfer, the core may switch to service another end point and come back to service the initial end point. In this case, the core reads the same DWORD location again and then samples only the relevant bytes. This eliminates the storage of the bytes for the initial end point.

For buffer data write, the core always performs DWORD accesses.

17.11.4 Control Transfer Handling

Control transfers (3-Stage Control R/WR or 2-Stage), can be handled effectively in the Descriptor-Based Scatter/Gather DMA mode by following the procedure explained in this section. By following this procedure the application is able to handle all normal control transfer flow and any of the following abnormal cases.

- More than one SETUP packet (back to back) — Host could send any number of SETUP packets back to back, before sending any IN/OUT token. In this case, the application is suppose to take the last SETUP packet, and ignore the others.
- More OUT/IN tokens during data phase than what is specified in the wlength field — If the host sends more OUT/IN data tokens than what is specified in the wlength field of the SETUP data, then the device must STALL.
- Premature SETUP packet during data/status phase — Device application must be able to handle this SETUP packet and ignore the previous control transfer.
- Lost ACK for the last data packet of a Three-Stage Control Read Status Stage.

17.11.5 Interrupt Usage for Control Transfers

The application checks the following OUT interrupts status bits for the proper decoding of control transfers.

- DIEPINTx.XferCompl (Transfer complete, based on IOC bit in the descriptor)
- DIEPINTx.InTknTxfEmp (In token received when Tx FIFO is empty)
- DOEPINTx.XferCompl (Transfer complete, based on IOC bit in the descriptor)
- DOEPINTx.SetUp (Setup Complete interrupt, generated when the core receives IN/OUT token after a SETUP packet.
- DOEPINTx.StsPhseRcvd (Status phase received interrupt (Also called SI), generated when host has switched to status phase of a Control Write transfer).

The core performs some optimization of these interrupt settings, when it sees multiple interrupt bits need to be set for OUT endpoints. This reduces the number of valid combinations of interrupts and simplifies the application.

Universal Serial Bus (USB)

The core gives priority for DOEPINTx.XferCompl over DOEPINTx.SetUp and DOEPINTx.StsPhseRcvd (SI) interrupts. When setting the XferCompl interrupts, it clears the SetUp and SI interrupt bits.

- The core gives priority to DOEPINTx.SI interrupt over DOEPINTx.SetUp. When setting DOEPINTx.StsPhseRcvd (SI), the core clears DOEPINTx.SetUp interrupt bit.

Based on this, the application needs only to decode the combinations of interrupts for OUT endpoints shown in [Table 17-16](#).

Table 17-16 Combinations of OUT Endpoint Interrupts for Control Transfer

| StsPhse Rcvd (SI) | SetUp (SPD) | XferCompl (IOC) | Description | Template Used |
|-------------------|-------------|-----------------|--|---------------|
| 0 | 0 | 1 | Core has updated the OUT descriptor. Check the "SR" (Setup Received) bit in the descriptor to see if the data is for a SETUP or OUT transaction. | Case A |
| 0 | 1 | 0 | Setup Phase Done Interrupt for the previously decoded SETUP packet. | Case B |
| 0 | 1 | 1 | The core has updated the OUT descriptor for a SETUP packet, and the core is indicating a SETUP complete status also. | Case C |
| 1 | 0 | 0 | Host has switched to Status phase of a Control OUT transfer | Case D |
| 1 | 0 | 1 | Core has updated the OUT descriptor. Check the SR" (Setup Received) bit in the descriptor to see if the data is for a SETUP or OUT transaction. Also, the host has already switched to Control Write Status phase. | Case E |

17.11.6 Application Programming Sequence

This section describes the application programming sequence to take care of normal and abnormal Control transfer scenarios.

All the control transfer cases can be handled by five separate descriptor lists. The descriptor lists are shown in [Figure 17-39](#).

- Three lists are for SETUP. The SETUP descriptors also take data for the Status stage of Control Read.
- The first two (index 0 and 1) act in a ping-pong fashion.

Universal Serial Bus (USB)

- The third list is an empty list, linked to one of the OUT descriptors when premature SETUP comes during the data/ status phase.
- Two lists are for IN and OUT data respectively.
- **Figure 17-39** displays setup_index 0, 1, and 2 as elements of array of pointers called setup_index. The first two elements of this array point to SETUP descriptors. The third element of this array is initially a NULL pointer, but is eventually linked to a SETUP descriptor. These array elements could also point to a descriptor for Control Read Status phase.

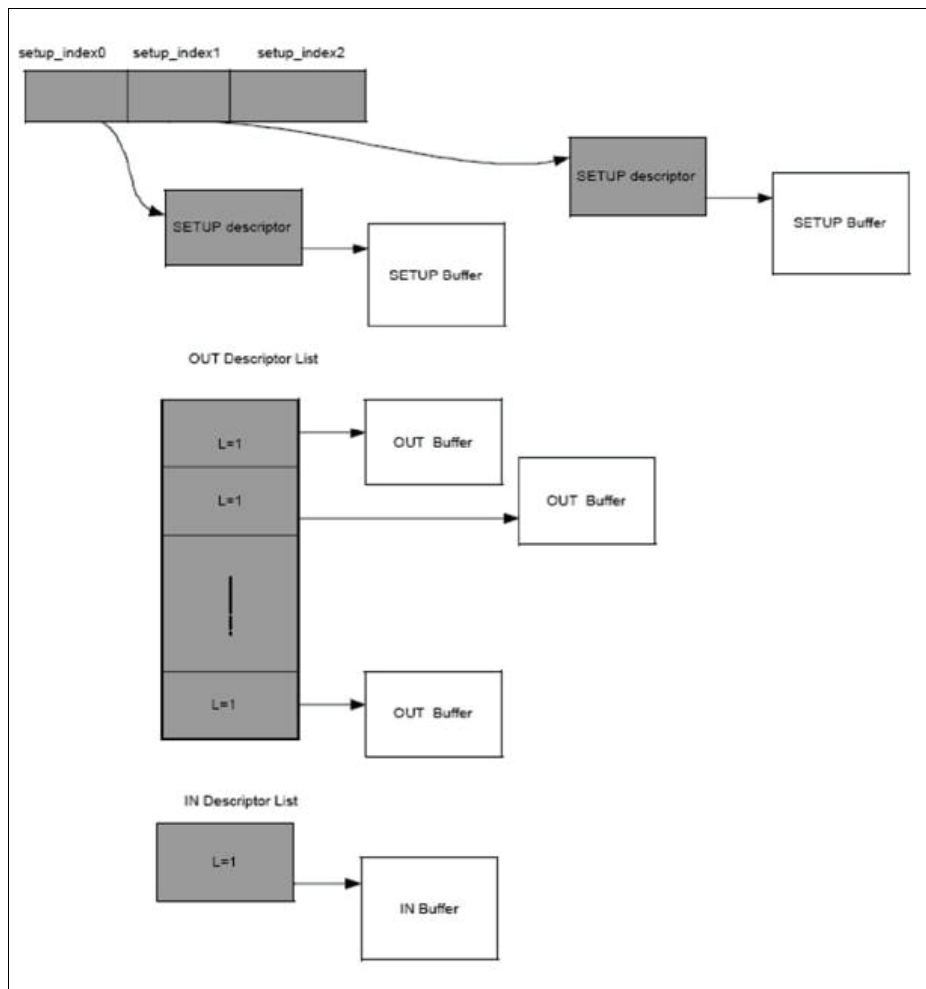

Figure 17-39 Descriptor Lists for Handling Control Transfers

The following are the steps that need to be followed by the application driver.

1. **Set up Desc for SETUP/Ctrl-Rd-Sts** — Setup 2 descriptor lists in memory for taking in SETUP packets. Each of this list must have only one descriptor, with the descriptor fields set to the following
 - a) `Rx_bytes` — Set it to Max packet size of the control endpoint.
 - b) `IOC` =1.
 - c) `MTRF`=0.

d) L=1.

2. **Enable DMA**—If current setup_index =0, then setup_index=1. The application pings between these two descriptors. Program the address of the current setup descriptor (specified by setup_index) to DOEPDMAx. Write to DOEPCTLx with the following fields.
 - a) DOEPCTL.MPS — Max Packet size of the endpoint
 - b) DOEPCTL.EPEna — Set to 1 to enable the DMA for the endpoint.
 3. **Wait for Interrupt**—Wait for OUT endpoint interrupt (GINTSTS.OEPInt). Then read the corresponding DOEPINT.
 4. If Control Read Data Stage in progress
 - a) Case A—Check SR bit (In this case SR bit is set, because the host cannot send OUT at this point. If it sends OUT it is NAKed. GOTO Step 24.
 - b) Case B —GOTO Step 26.
 - c) Case C:—Check SR bit (In this case SR bit is set because host cannot send OUT packets without SETUP at this stage). GOTO Step 24.
 - d) Case D — Cannot happen at this stage because SI cannot come alone without a SETUP, at this stage.
 - e) Case E — Indicates that host has switched to another SETUP (Three-Stage control write) and then has switched to status phase without and data phase (core clears SUP with SI in this case). Decode SETUP packet and if ok, GOTO Step 11.
- else If Ctrl Write Status Stage in progress OR Two-Stage Status Stage in progress
- f) Case A—Check SR bit (In this case SR bit is set, because the host cannot send OUT at this point. If it sends OUT it is NAKed.) GOTO Step 24.
 - g) Case B — (Could happen for Two-Stage Ctrl Transfer.) GOTO Step 26.
 - h) Case C—GOTO Step 24.
 - i) Case D — Clear SI interrupt and wait Step 3.
 - j) Case E — Cannot happen at this stage.

else

- k) Case A—GOTO Check Desc.
- l) Case B — Normally, this does not occur at this stage. Either IOC comes first or IOC comes with SUP (Case C).
- m) Case C — GOTO Check Desc.
- n) Case D — Cannot happen at this point.
- o) Case E — If SR==1, Indicates Three stage control Transfer SETUP and that the host has switched to status phase. Decode the SETUP packet and Goto Step 11.
- p) Check Desc

Read the Descriptor status quadlet corresponding to the setup_index and check the SR field. (Application might also want to check the BS and RxSts fields and

Universal Serial Bus (USB)

- take necessary actions if there is any abnormalities). If SR field is 1 GOTO Step 5 (If Step Step 20 is active, terminate it). If SR field is 0 GOTO Step 22 (Control Rd Status phase) (This must also terminate Step 20).
5. Decode SETUP—Decode the SETUP packet. If it is a Three-Stage Control Write, GOTO Step 20. If it is a Three-Stage Control Read, GOTO Step 15. If it is a Two-Stage Control transfer, GOTO Step 11 (Same as Status stage for 3-Stage Control Write).
 6. Desc list for Ctrl Wr data— Setup descriptor list for Control write data phase. This must be based on the Wlength field in the SETUP data. The descriptors in the list must be setup such that there must be one descriptor per packet. Each of these descriptors must have the control fields set as follows.
 - a) Rx_Bytes — Set to the Max Packet Size of the control Endpoint.
 - b) IOC = 1
 - c) MTRF = 0.
 - d) L=1.
 - e) At this point we are not enabling and clearing the NAK for the IN endpoint for status phase. This is because, the status phase for Control Write can be ACKed only after decoding the complete data for the data phase.
 GOTO Step 7.
 7. Enable DMA for Ctrl Wr Data—Write the start address of this list to DOEPDMAx. Program the DOEPCTLx with the following bits set
 - a) DOEPCTL.MPS — Max Packet size of the endpoint
 - b) DOEPCTL.EPena — Set to 1 to enable the DMA for the endpoint. GOTO Step 8.
 8. Wait for Ctrl Wr Data Interrupt—Wait for OUT endpoint interrupt (GINTSTS.OEPInt). Then read the corresponding DOEPINTx.
 - a) Case A—check the SR field. Also clear DOEPINTx.XferCompl by writing to DOEPINTx.(Application might also want to check the BS and RxSts fields and take necessary actions if there is any abnormalities). If SR field is 0 GOTO Step 9.If SR field is 1, GOTO Step 23. (This indicates that the host has switched to a new control transfer).
 - b) Case B —GOTO Step 25.
 - c) Case C—GOTO Step 23. (This indicates that the host has switched to a new control transfer).
 - d) Case D — Host has switched to status phase. Decode the data received so far.
 GOTO Step 10.
 - e) Case E — Check SR bit. If SR==0, decode the data received so far. GOTO Step 10. If SR==1, decode the SETUP packet and Goto Step10.
 9. Check Desc — If it's not the last packet of data phase, Re-enable the endpoint and clear the Nak. This is because the core sets NAK after receiving each OUT packet for control write data phase. This is to allow application to STALL in case the host sends more data than what is specified in the Wlength field. GOTO Step 8. Re-enabling and clearing the NK involves the following steps.
 - a) Write to DOEPDMA with the new descriptor address.

- b) Write to DOEPCTLx with the following fields.
 - DOEPCTL.MPS — Max Packet size of the endpoint
 - DOEPCTL.CNAK—Set to 1 to clear the NAK.
 - DOEPCTL.EPEna — Set to 1 to enable the DMA for the endpoint.
 If it is the last packet of the data phase, GOTO Step 10.
10. **STALL Extra Bytes**— Write to DOEPCTLx with Stall set so that the core could STALL any further OUT tokens from host.If the received Bytes so far is greater than what is specified in Wlength field OR is there were any unsupported commands in the data phase, then write to DIEPCTLx with the Stall bit set so that the Status phase could be Stalled.(The STALL bit is automatically cleared by the core with the next SETUP). GOTO Step 11.
11. **Disc list for Ctrl Wr Sts**— The following two process must run in parallel. This is because, we are preparing for the status phase (IN) of Control write but at the same time the host could send another SETUP. So IN and OUT descriptor list must be ready.
 - a) Do Step 2— Step 5 (This is for handling SETUP or Ctrl Wr Status). If the OUT DMA is already enabled (OUT DMA was enabled for data phase of Three-Stage Control Write, but there was a premature status phase), GOTO Step 3.
 - b) Setup descriptor list for Status phase IN, depending on the data in the status phase. Normally it is always a zero length packet.
 - c) Tx_Bytes — Size of status phase,
 - d) BS — Host Ready,
 - e) L=1.
 - f) IOC=1.
 - g) SP=1 (Depending on the Tx_Bytes).
 - h) Write to DIEPDMAx with the start address of the descriptor.Write to DIEPCTLx clear the NAK and enable the endpoint. Flush the corresponding TX FIFO.
 - i) If SI has not been received in the data stage prior to the status stage, then wait for SI before clearing the NAK(DIEPCTLx.CNAK=1)
 - j) DIEPCTLx.EpEna=1.
 - k) GOTO Step 12.
12. **Wait for Interrupt**—Wait for IN endpoint interrupt (GINTSTS.IEPInt).
13. If IN endpoint Interrupt, and DIEPINTx.XferCompl, then GOTO Step 14.
14. **Check Desc** —Read the Status field of the descriptor. Check Tx_bytes in the descriptor.(Application might also want to check the BS and RxSts fields and take necessary actions if there is any abnormalities). This is end of Three-Stage Control Write OR Two-Stage Control transfer. We are now ready for the next control transfer (Already taken care by process "a" is Step 11.
15. **Desc for Ctrl Rd Data**—The following two steps must be run in parallel. This is because, we are preparing for Data phase of Control read, but at the same time, the host could abnormally abort this control transfer and send a SETUP, or switch to status phase.

Universal Serial Bus (USB)

16. Do Step 2— Step 5 (This is for handling SETUP and also Control Read Status phase.).
17. Setup descriptor list for Data phase IN, depending on the WLength field in the SETUP data. The setup can be for a single descriptor OR multiple descriptors. If it is multiple descriptors, ensure that IOC for the last descriptor is set.
 - a) Tx_Bytes — Size of data phase (Wlength field).
 - b) BS — Host Ready
 - c) L=1.
 - d) IOC=1. It is mandatory to set the IOC when it is the last descriptor.
 - e) SP=1 (Depending on the Tx_Bytes).
 - f) Write to DIEPDMAx with the start address of the descriptor list.
 - g) Write to DIEPCTLx clear the NAK and enable the endpoint.
 - h) Flush the corresponding TX FIFO.
 - i) DIEPCTLx.MPS = Max_packet size of the endpoint,
 - j) DIEPCTLx.CNAK=1 only if SPD already set (Case C in Step 3).
 - k) Also set the DOEPTLx.CNAK for the corresponding OUT endpoint after SPD because a premature status stage (OUT) can come which must be acked.
 - l) DIEPCTLx.EpEna=1.
 - m)GOTO Step 18.
18. **Wait for Interrupt**—Wait for IN endpoint interrupt (GINTSTS.IEPInt)
19. If IN endpoint interrupt, read the corresponding DIEPINTx and if XferCompl is set GOTO Step 20.
20. **Check_Desc**—Wait for the DIEPINTx.IOC interrupt. Go to Step 21.
21. **Set Stall**—Write to DIEPCTLx with STALL bit set. (The STALL bit is automatically cleared by the core with the next SETUP). The function of this process initiated in step Step 15 is over, and must be terminated. The next control transfer is already taken care by the process that is running from Step 2.
22. **Ctrl Rd Sts Desc Check** — Read the descriptor to check the Rxbytes and also check the SP field. The Three-Stage control Read is complete here. GOTO Step 2, in preparation for the next SETUP.
23. The unexpected SETUP packet now received during the control write data phase, is sitting in the descriptor allocated for Data. Link this to the setup descriptor pointer. setup_desc_index = 2. Point setup_desc_index to the current OUT descriptor (which has the SETUP). GOTO Step 5.
24. Disable IN Endpoint DMA. Core flushes the corresponding Tx FIFO in order to flush the data that was meant for Control Write Status phase OR Control Read data phase. If Step 12 or Step 18 is active, terminate it. GOTO Step .
25. Read Modify write DOEPTLx to clear the NAK. Then GOTO Step 8 again.
 - a) DOEPTLx.CNAK—Set to 1 to clear the NAK.
26. Read Modify write DIEPCTLx to clear the NAK. Then GOTO Step 3 again.
 - a) DIEPCTLx.CNAK—Set to 1 to clear the NAK.
27. Read Modify write DIEPCTLx to clear the NAK. Then Step 12 again
 - a) DIEPCTLx.CNAK—Set to 1 to clear the NAK.

- b) **DOEPCTLx.CNAK**: Set to 1 to clear the NAK for the out endpoint. This clears the NAK to accept status stage data in case of control read.

17.11.7 Internal Data Flow

This section explains the cores internal data flow for control transfers.

17.11.7.1 Three-Stage Control Write

Figure 17-40 displays the core behavior for Three-Stage control write transfers.

1. On receiving **SETUP**, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint. Additionally, the clearing of the NAK bit is blocked by the core until the following SPD or SI is read by the application and cleared.
2. The DMA detects the Rx FIFO as non-empty and does the following:
 - a) Fetch the descriptor pointed by **DOEPMA**.
 - b) Transfer the **SETUP** packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with **DMA_DONE** status.
3. On receiving the first data phase OUT token after the **SETUP**, the core push a **SETUP_COMPLETE** status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the **SETUP** packet.
4. The core generates **DOEPINT.XferCompl** interrupt after having transferred the **SETUP** packet into memory (Step 2).
5. The core generates **DOEPINT.SetUp** interrupt after the DMA has popped the **SETUP_COMPLETE** status out of the Rx FIFO.
6. Application clears NAK for the data phase, after receiving **DOEPINTx.SetUp** interrupt.
7. The core ACKs and the next OUT token because the NAK has been cleared (provided there is enough space in the Rx FIFO).
8. DMA detects the OUT packet in Rx FIFO and starts transferring the OUT packet to the system memory.
 - a) Fetch the descriptor pointed by **DOEPMA**.
 - b) Transfer the OUT packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close descriptor with **DMA_DONE** status.
9. The core NAKs the next OUT token because the core internally sets the NAK after every control write data phase packets. This is to allow application to Stall any extra tokens.
10. The core generates **DOEPINT.XferCompl** after closing the OUT descriptor (Step 8).
11. Application clear NAK on receiving **DOEPINTx.XferCompl** interrupt.
12. Host starts the Status phase by sending the IN token which is NAKed by the core. The core push **DATA_PHASE_DONE** status into the Rx FIFO.

Universal Serial Bus (USB)

13. The core generates DOEPINTx.XferCompl for the last OUT packet transfer to system memory.
14. The core generates DOEPINT.StsPhsRcvd interrupt after the DMA has popped the DATA_PHASE_DONE status from the RxFIFO.
15. Application clears the NAK and enables the IN endpoint for status phase.
16. The core starts fetching the data for the Status phase
 - a) Fetch the descriptor pointed by DIEPDMA.
 - b) Fetch the packet (if size >0) to Tx fifo.
 - c) Close the descriptor with DMA_DONE status
 - d) The core generates DIEPINTx.XferCompl interrupt after closing the descriptor.
17. The core sends out data in response to the Status Phase IN token.

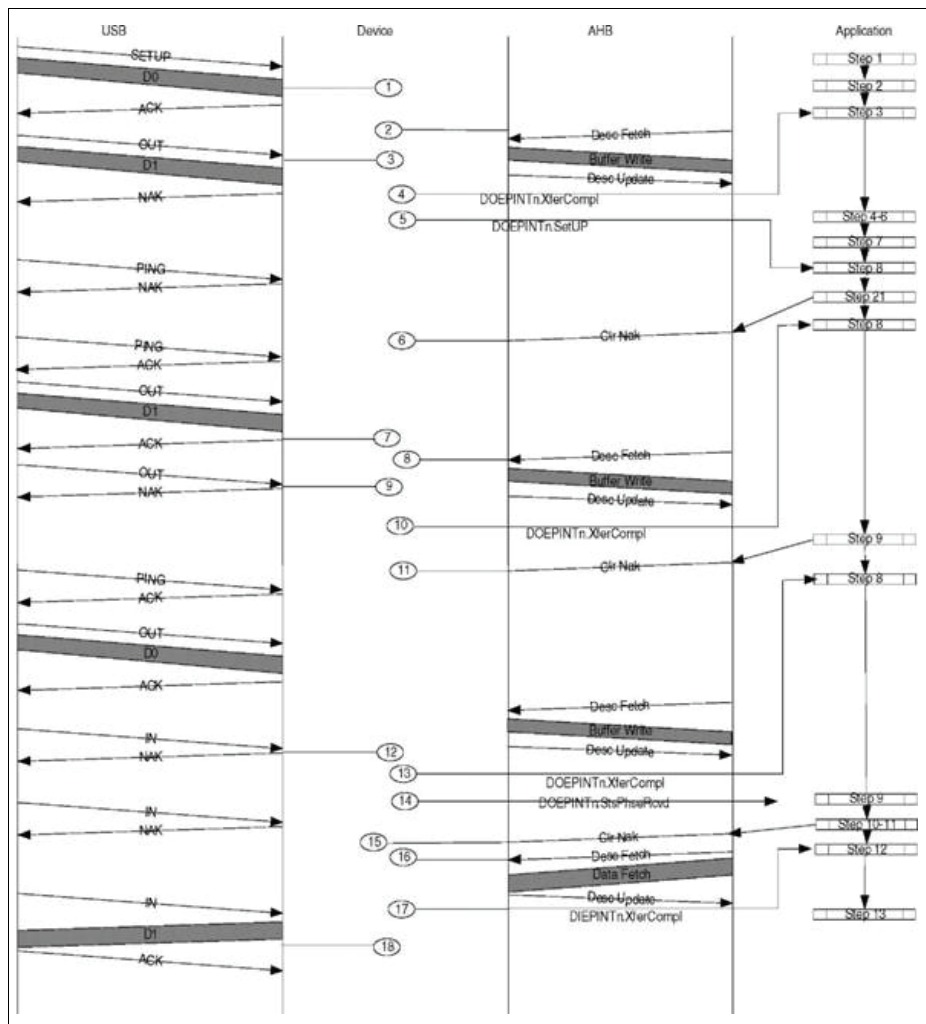

Figure 17-40 Three-Stage Control Write

17.11.7.2 Three-Stage Control Read

Figure 17-41 displays the core flow for three-stage control read transfers

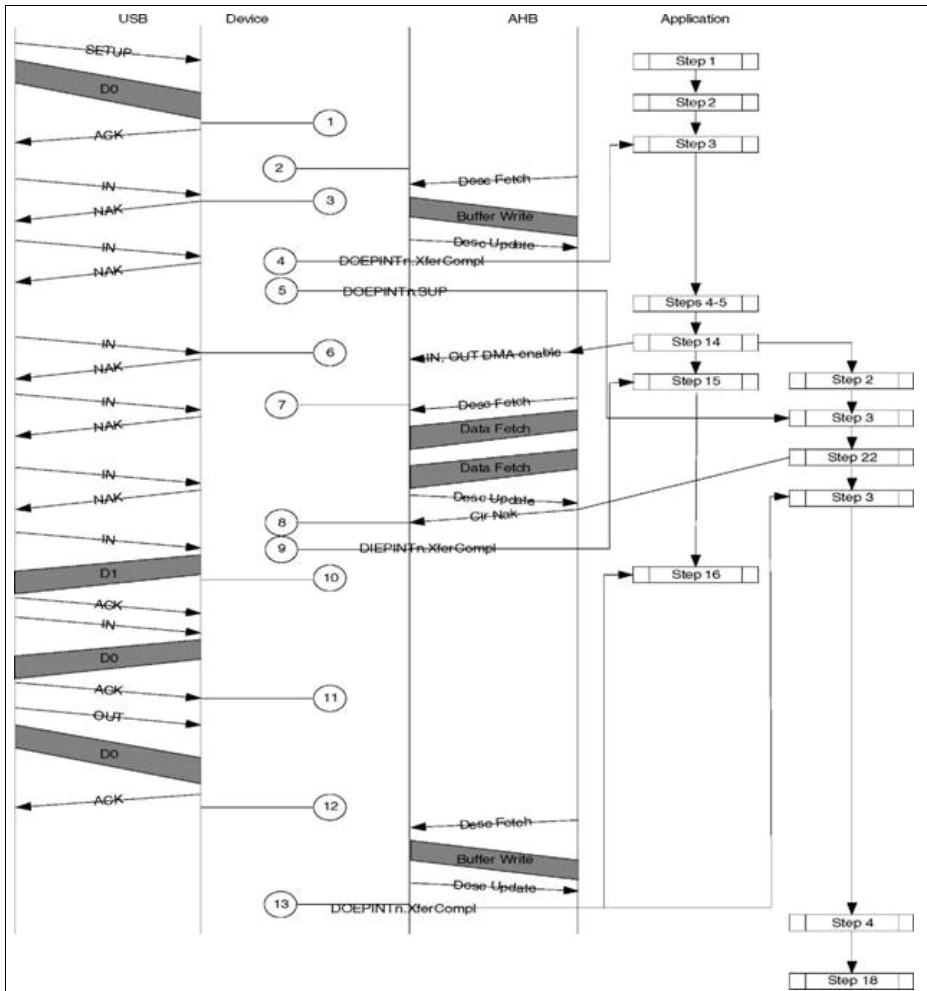

Figure 17-41 Three-Stage Control Read

In this example, it is assumed that the data phase consists of 2 packets, and the application allocates these two packets in a single buffer.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.

Universal Serial Bus (USB)

2. The DMA detects the RxFIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the SETUP packet from the RxFIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the RxFIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the RxFIFO.
6. Data phase IN tokens are NAKed until this point because the NAK has not yet been cleared by the application.
7. The core starts fetching the IN data after the application enables IN DMA (In this example it is assumed that multiple packets are in the same buffer. But it could also be in different buffers). This involves the following steps
 - a) Fetch the descriptor pointed by DIEPDMA.
 - b) Fetch the data into the corresponding Tx FIFO.
 - c) Close the descriptor with DMA_DONE status...
8. The application clears the NAK after receiving the setup complete (DOEPINT.SetUp) interrupt. The application also clears NAK of the OUT End point to accept the status phase.
9. After all the data has been fetched for the descriptor (Step 7), core generates DIEPINT.XferCompl interrupt.
10. The core sends data in response to the IN token for the data phase.
11. The core sends out the last packet of the IN data phase.
12. The core ACKs the status phase.
13. The core generates DOEPINTx.XferCompl interrupt after transferring the data received for the status phase to system memory.

17.11.7.3 Two-Stage Control Transfer

Figure 17-42 displays the core behavior for Two Stage control read transfers.

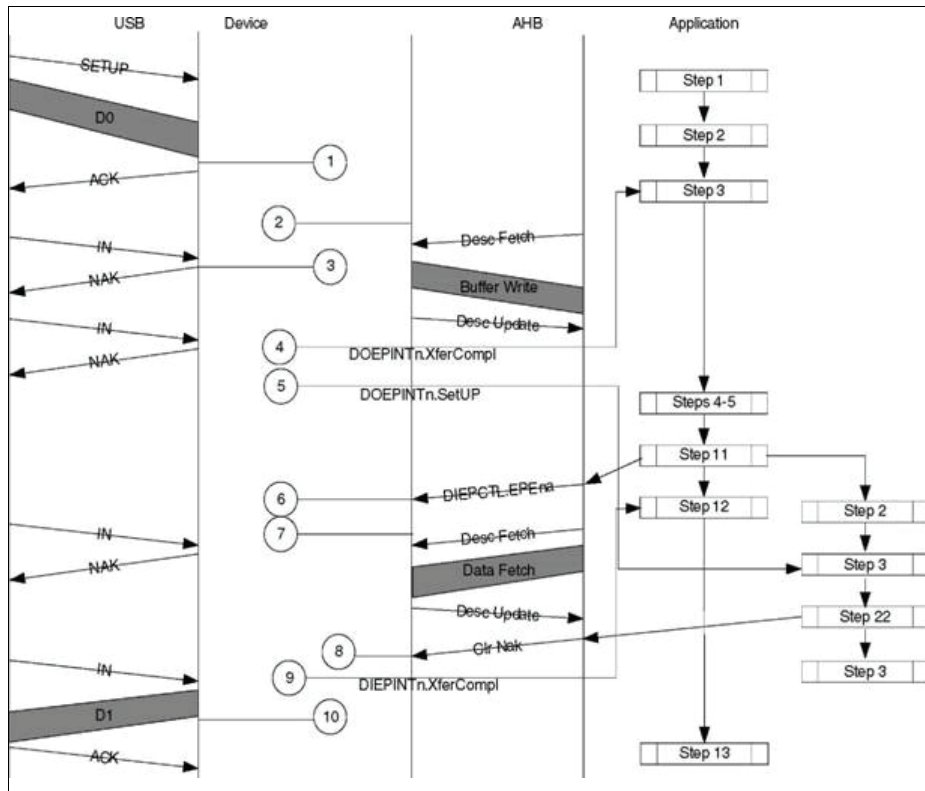

Figure 17-42 Two-Stage Control Transfer

This example shows the core behavior for a Two-Stage Control transfer.

- On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
- The DMA detects the Rx FIFO as non-empty and does the following.
 - Fetch the descriptor pointed by DOEPMA.
 - Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - Close the descriptor with DMA_DONE status.
 - The core receives the status phase IN token, which it NAKs. Core also pushes SETUP_COMPLETE status into the Rx FIFO.

- e) The core generates DOEPINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2)
- f) The core generates DOEPINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
3. Application enables the IN endpoint for status phase.
4. The core starts fetching the descriptor for IN endpoint.
5. Application clears the NAK for IN endpoint after getting the DOEPINTx.SetUp interrupt (Step 4).
6. The core generates DIEPINTx.XferCompl after updating the descriptor after IN data fetch.
7. The core sends out data for the status phase IN token from host.

17.11.7.4 Back to Back SETUP During Control Write

This example shows the core receiving 2 Back to Back SETUP tokens for 3 Three-Stage Control write.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core receives another SETUP, and pushes the data into the Rx FIFO, also sets the NAK.
 - e) The core generates DOEPINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The DMA detects the Rx FIFO as non-empty (because of the 2nd SETUP packet) and does the following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core generates DOEPINT.XferCompl interrupt after having transferred the second SETUP packet into memory (Step 6)
 - e) The core generates DOEPINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
5. Application clears NAK for the data phase, after receiving DOEPINTx.SetUp interrupt.

Universal Serial Bus (USB)

6. The core ACKs the next OUT/Ping token after the NAK has been cleared by the application.
7. The DMA detects the RxFIFO as non-empty (because of the OUT packet) and does the following.
 - a) Fetch the descriptor pointed by DOEPMMA.
 - b) Transfer the SETUP packet from the RxFIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core generates DOEPINT.XferCompl interrupt after having transferred the OUT packet into memory (Step 11) and closing the descriptor.

The remaining steps are similar to Steps 11-18 of **“Application Programming Sequence” on Page 17-164**.

This example shows the core behavior for a Two-Stage Control transfer.

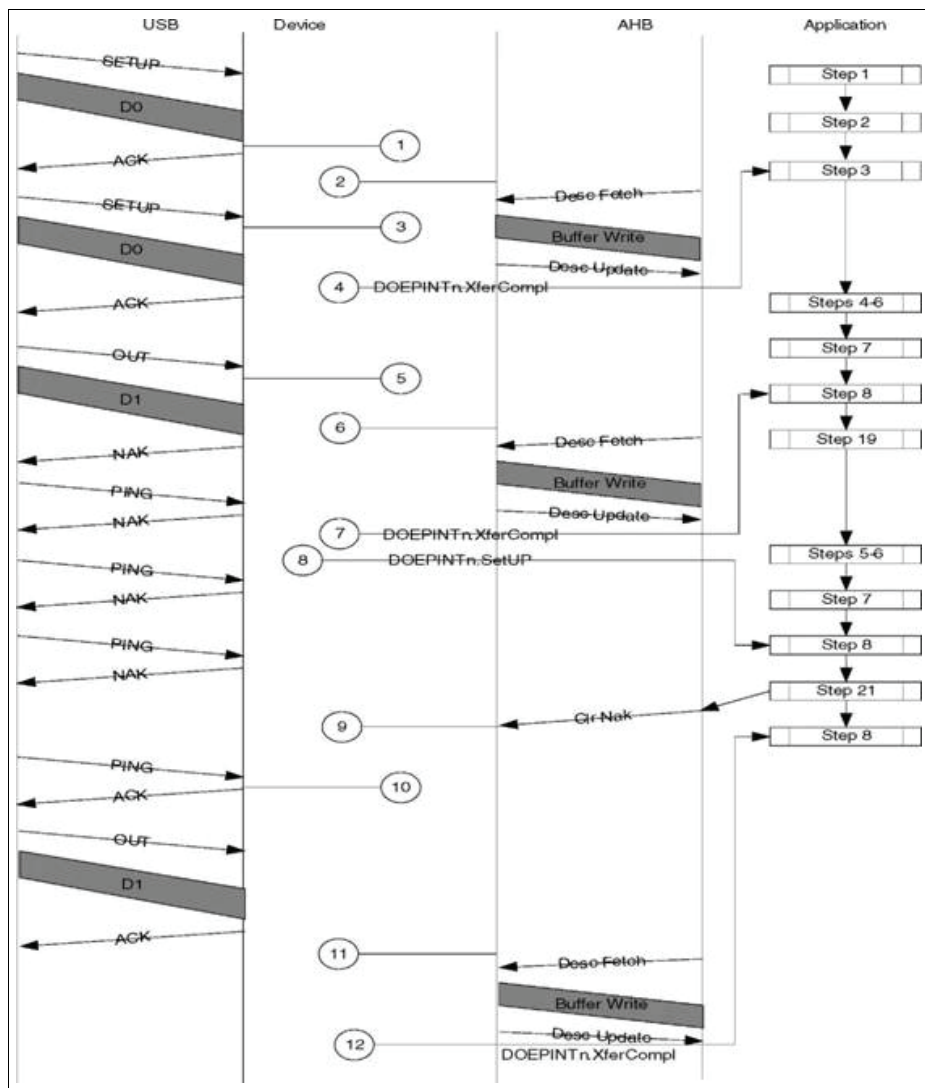

Figure 17-43 Back-to-Back SETUP Packet Handling During Control Write

17.11.7.5 Back-to-Back SETUPS During Control Read

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core receives another SETUP, and pushes the data into the Rx FIFO, also sets the NAK.
3. The core generates DOEPINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
4. Host sends IN token for the data phase which is NAKed by the core, because NAK is set in Step 3. The core pushes SETUP_COMPLETE status into Rx FIFO.
5. After the application has re-enabled the OUT DMA (Application flow Step 2) core detects Rx FIFO as non-empty because of the second SETUP packet and does the following.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core generates DOEPINTx.XferCompl interrupt after having transferred the SETUP packet into memory (Step 6).
 - e) The core starts fetching data for IN endpoint because the IN endpoint was enabled by application in Step 14.
6. On seeing DOEPINTx.XferCompl (Step 7) and finding that it is a SETUP packet, application disables the endpoint in Step 20.
7. The core generates DOEPINTx.SetUP (Setup complete) interrupt after popping the SETUP_COMPLETE status from the Rx FIFO.
8. The core generates endpoint disabled interrupt (as a result of application setting disable bit in step 9)
9. The core generates DIEPINTx.XferCompl after completing the IN data fetch and updating the descriptor.
10. application clears NAK after seeing setup_complete interrupt (generated in Step 10). The flow after this is same as steps 9 - 13 of **“Internal Data Flow” on Page 17-171**

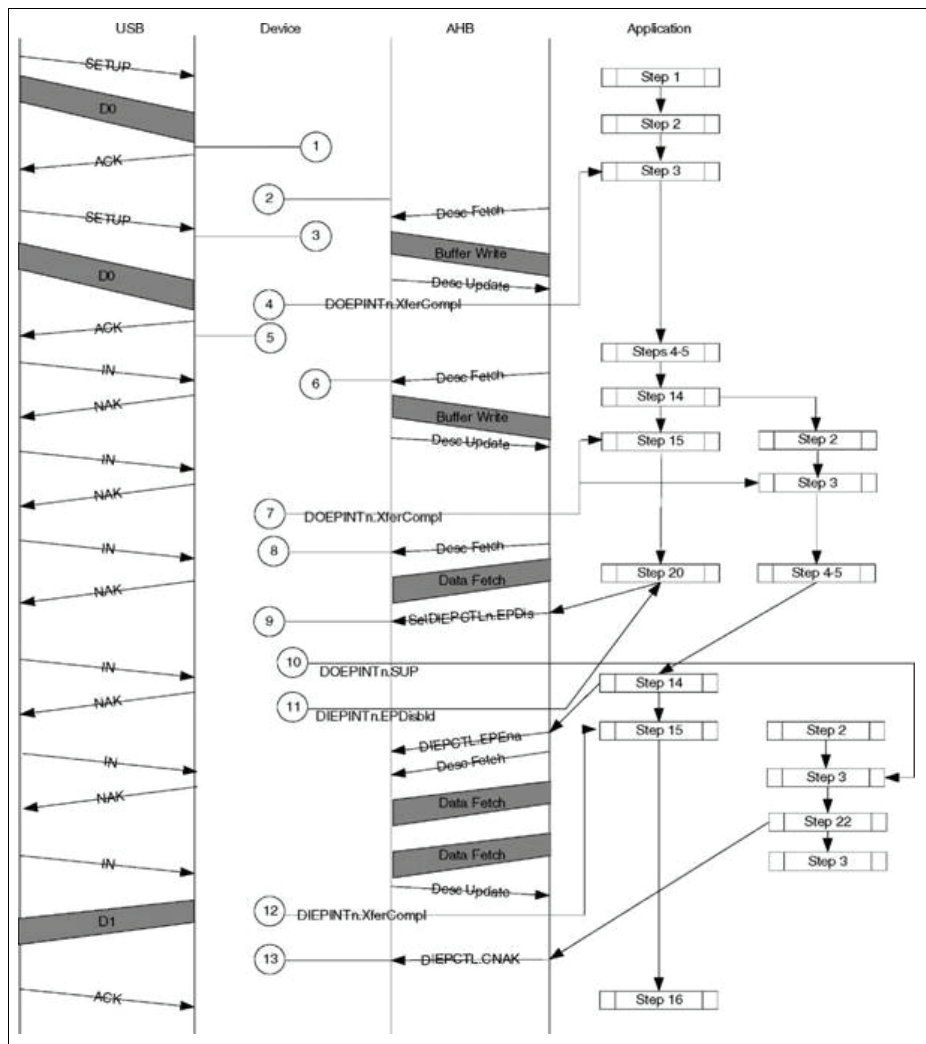

Figure 17-44 Back-to-Back SETUP During Control Read

17.11.7.6 Extra Tokens During Control Write Data Phase

This example assumes a three-stage control write transfer with only WLength field in the SETUP indicating only 1 packet in the data phase. But the host sends an additional OUT packets which the core STALLs.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPInt.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPInt.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. Application clears NAK for the data phase, after receiving DOEPIntX.SetUp interrupt.
7. The core ACKs and the next OUT token because the NAK has been cleared (provided there is enough space in the Rx FIFO).
8. DMA starts transferring the OUT packet to the system memory.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the OUT packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close descriptor with DMA_DONE status.
 - d) The core generates DOEPIntX.XferCompl interrupt after having transferred the OUT packet to the system memory. Since there were only one packet in the data phase, the data phase is complete here.
 - e) The core initially NAK's the extra tokens send by the host, because the core internally sets NAK after each OUT packet for the data phase of control write.
9. Application sets STALL to stall any extra tokens.
10. The core stalls the next OUT/PING token.
11. Host switches to next control transfer, core ACKs the SETUP. This SETUP packet is transferred to the system memory buffer originally allocated for Status phase.
12. The core generates DOEPIntX.XferCompl interrupt after transferring the SETUP packet to the system memory.

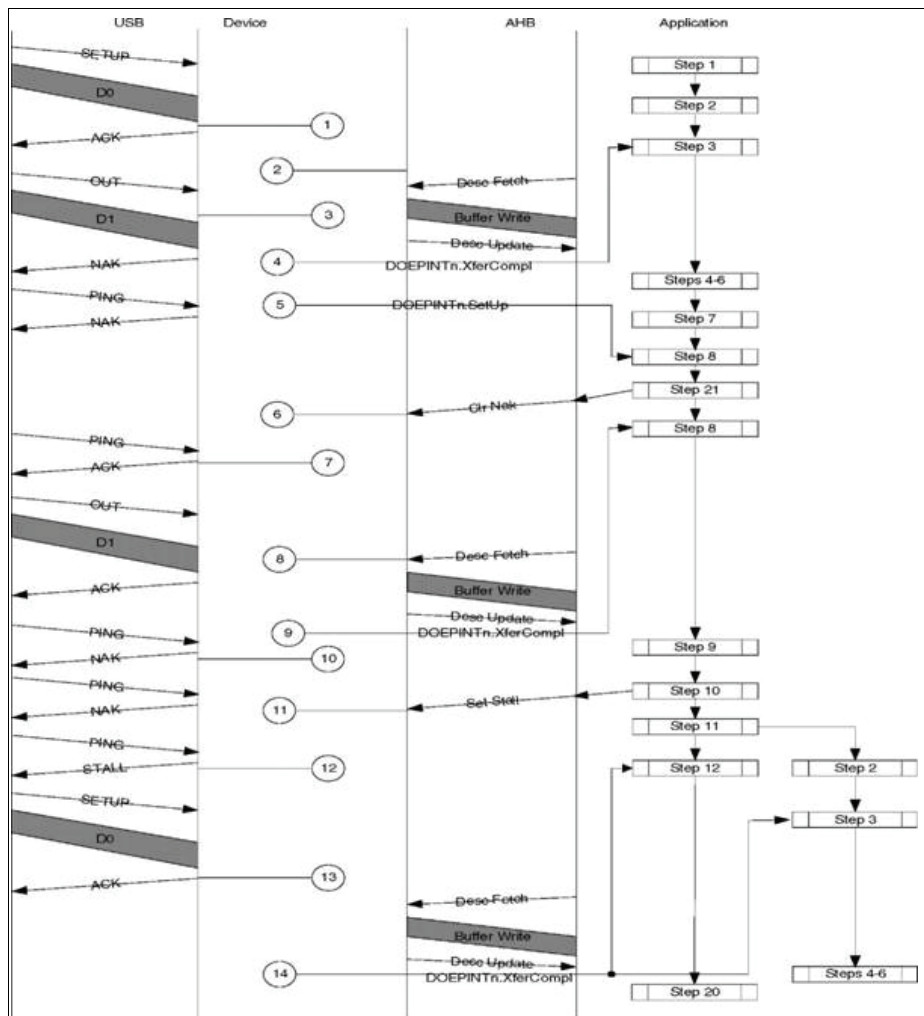

Figure 17-45 Extra Tokens During Control Write Data Phase

17.11.7.7 Extra Tokens During Control Read Data Phase

In this example, it is assumed that the data phase consists of 2 packets, and the application allocates these two packets in a single buffer. After the data phase is complete and the two packets have been transferred, the core sends an extra IN token and then the application sets Stall.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMMA.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPMMA.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPMMA.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. Data phase IN tokens are NAKed until this point because the NAK has not yet been cleared by the application.
7. The core starts fetching the IN data after the application enables IN DMA (In this example it is assumed that multiple packets are in the same buffer. But it could also be in different buffers). This involves the following steps
 - a) Fetch the descriptor pointed by DIEPDMA.
 - b) Fetch the data into the corresponding Tx FIFO.
 - c) Close the descriptor with DMA_DONE status.
8. The application clear the NAK after receiving the setup complete (DOEPMMA.SetUp) interrupt. Set the Stall bit after all the Data has been pushed in the FIFO
9. After all the data has been fetched for the descriptor (Step 7), core generates DIEPDMA.XferCompl interrupt.
10. The core sends data in response to the IN token for the data phase.
11. The core sends out the last packet of the IN data phase.
12. Host sends an extra token.
13. The core Stalls the IN token and also automatically Stalls the Status phase if the Host switches to the Status phase.

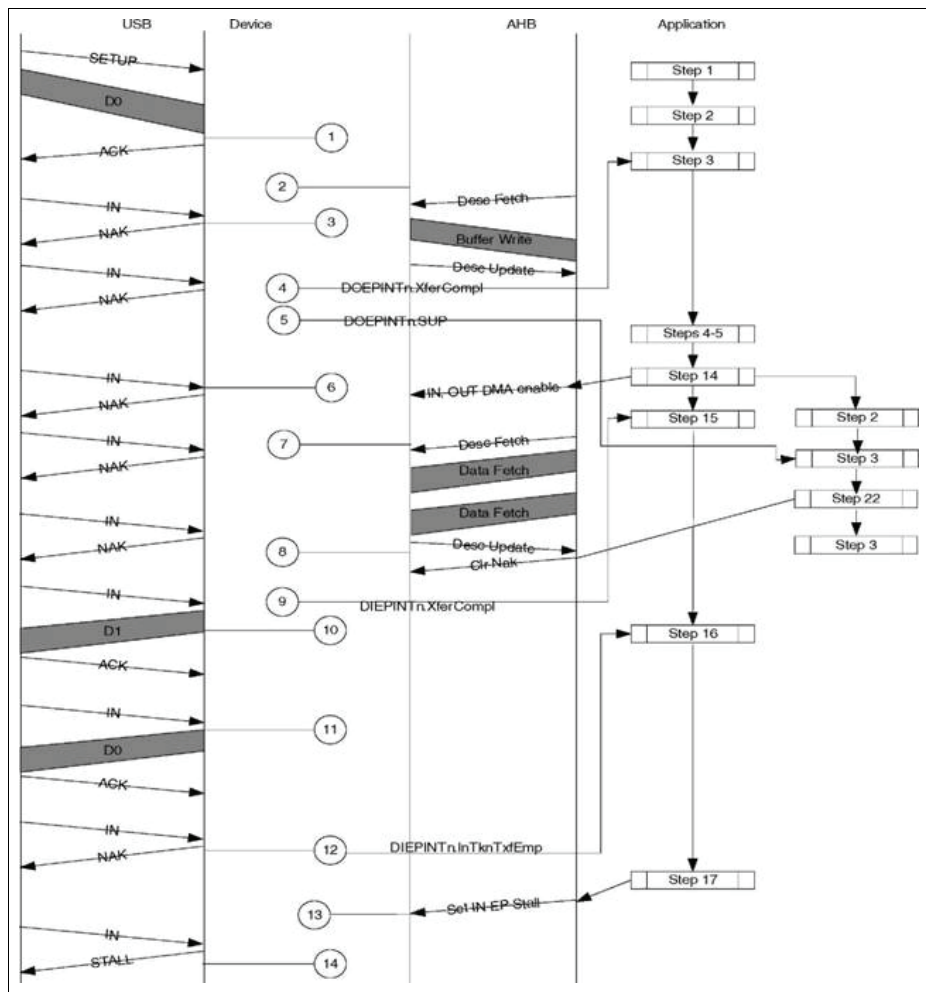

Figure 17-46 Extra IN Tokens During Control Read Data Phase

17.11.7.8 Premature SETUP During Control Write Data Phase

This example shows a Three-Stage Control Write transfer with host sending a premature Control Write SETUP packet during the data phase.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPInt.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPInt.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. The core receives a SETUP packet during the data phase. This is an unexpected SETUP packet. On receiving this SETUP, the SETUP data is pushed into the Rx FIFO and the core again sets NAK on both IN and OUT endpoints of the control endpoint (NAK was already set because of the first SETUP packet received).
7. Application decodes the previous DOEPInt.SetUp interrupt and clears the NAK, unaware of the fact that there is another SETUP packet sitting in the Rx FIFO for the same control endpoint. On seeing this condition, core does not allow clearing of the NAK bit, and masks the clearing of NAK. The core takes this decision based on the fact that a SETUP_COMPLETE status is pending in the RX FIFO.
8. The DMA detects the Rx FIFO as non-empty (because of the unexpected SETUP) and does following
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core NAKs the data phase OUT token because NAK bit clearing by the application did not take effect (as explained in Step 7).
 - e) The core generates DOEPInt.XferCompl interrupt after having transferred the SETUP packet into memory (Step 8).
 - f) The core generates DOEPInt.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status (for the unexpected SETUP packet received) out of the Rx FIFO.
9. Application clears the NAK after decoding the latest SETUP packet. This time, the core does not mask the clearing of the NAK because there are no more SETUP_COMPLETE status sitting in the Rx FIFO.

10. The core ACKs the next OUT/PING token of the data phase.
11. DMA starts transferring the OUT packet to the system memory.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the OUT packet from the RxFIFO to the buffer pointed by the descriptor.
 - c) Close descriptor with DMA_DONE status.
 - d) The core generates DOEPINTx.XferCompl interrupt after having transferred the OUT packet to the system memory.
 - e) The remaining steps are similar to Steps 11-18 of **“Application Programming Sequence” on Page 17-164**

17.11.7.9 Premature SETUP During Control Read Data Phase

In this example, it is assumed that the data phase consists of 2 packets, and the application allocates these two packets in a single buffer. The host switches to a new control read command after having send two IN tokens during the data phase.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMMA.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase IN token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase IN tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPIINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPIINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. Host switches to a new Control transfer by sending a SETUP token. This is the premature SETUP packet. Core sets NAK on both IN and OUT control endpoints.
7. The core fetch the data for IN control endpoint after application enables the IN endpoint.
8. The core push SETUP_COMPLETE status into Rx FIFO on seeing the IN token for data phase.
9. Application clears NAK as a result of DOEPIINT.SetUp (Setup complete) interrupt generated in Step 5. But core masks this clearing of setup_complete interrupt, because there is already one SETUP packet sitting in the Rx FIFO.
10. The core generates DIEPIINTx.XFERCompl after closing the IN endpoint descriptor (for Step 7)
11. The core generates DOEPIINTx.XferCompl after transferring the premature SETUP packet to system memory and closing the descriptor.
12. The core generates SETUP complete interrupt.
13. Application enables IN endpoint DMA for data phase.
14. The core fetches descriptor and data for IN endpoint.
15. Application clears IN endpoint NAK after receiving DOEPIINTx.SetUp (Setup complete) interrupt. This time, the core does not mask the clearing of the Nak because NO SETUP packet is remaining in the Rx FIFO.
16. The core generates DIEPIINTx.XferCompl interrupt after fetching the data and closing the descriptor. The remaining steps are same as steps 11 to 13 of **“Internal Data Flow” on Page 17-171.**

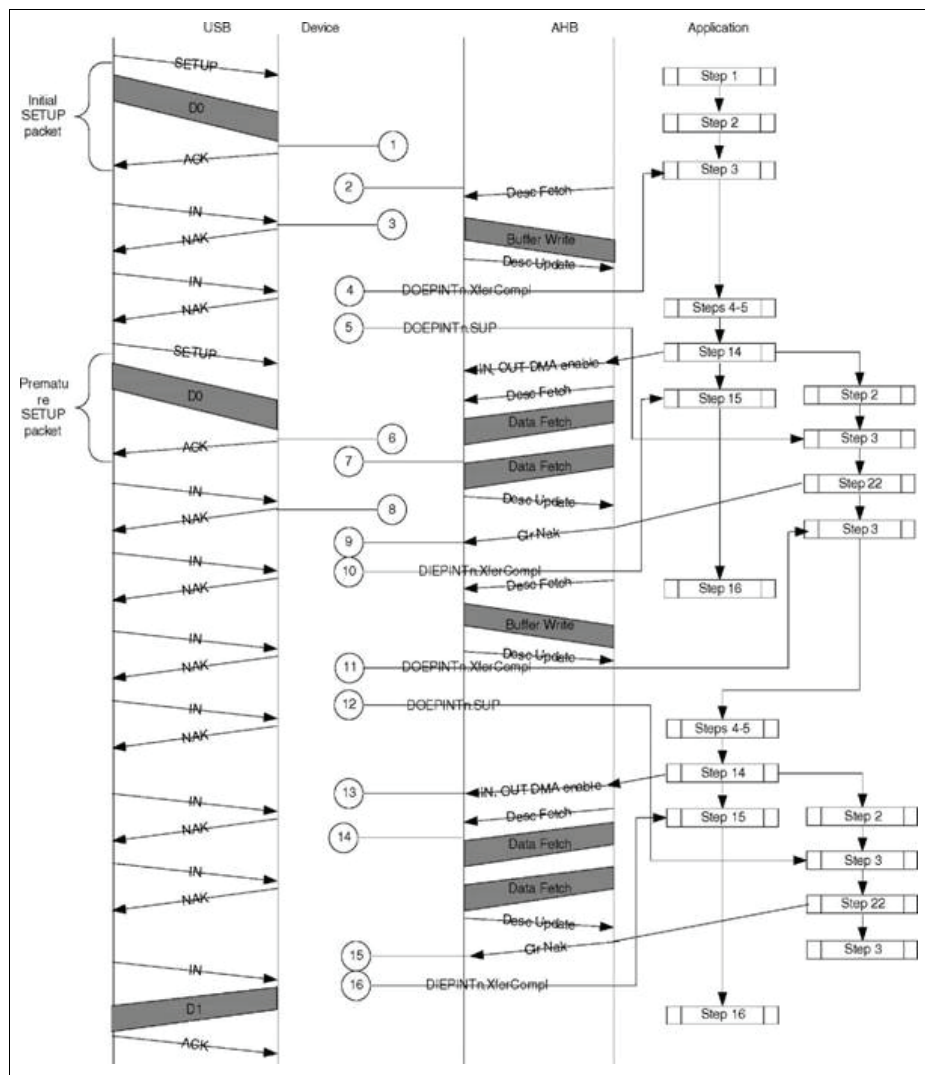

Figure 17-48 Premature SETUP During Control Read Data Phase

17.11.7.10 Premature Status During Control Write

This example assumes a Three-Stage control write transfer with only Wlength field in the SETUP indicating two packets in the data phase. But the host switch to data phase after the first packet of the data phase is complete.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase OUT token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase OUT tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEPINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEPINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. Application clears NAK for the data phase, after receiving DOEPINTx.SetUp interrupt (Step 5).
7. The core ACKs and the next OUT token because the NAK has been cleared (provided there is enough space in the Rx FIFO).
8. DMA sees Tx FIFO non empty and starts transferring the OUT packet to the system memory.
 - a) Fetch the descriptor pointed by DOEPMA.
 - b) Transfer the OUT packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close descriptor with DMA_DONE status.
9. Host switch to status phase (IN token) without completing the data phase.
10. The core generates DOEPINTx.XferComp after closing the descriptor after the data fetch.
11. Application sets up descriptor, enables IN endpoint and clear NAK.
12. The core starts to fetch the descriptor and data for the status phase once application has enabled the IN endpoint.
13. The core generates DIEPINTx.XferCompl after doing the data fetch and the descriptor update (step 12)
14. The core sends data out in response to status phase IN token.

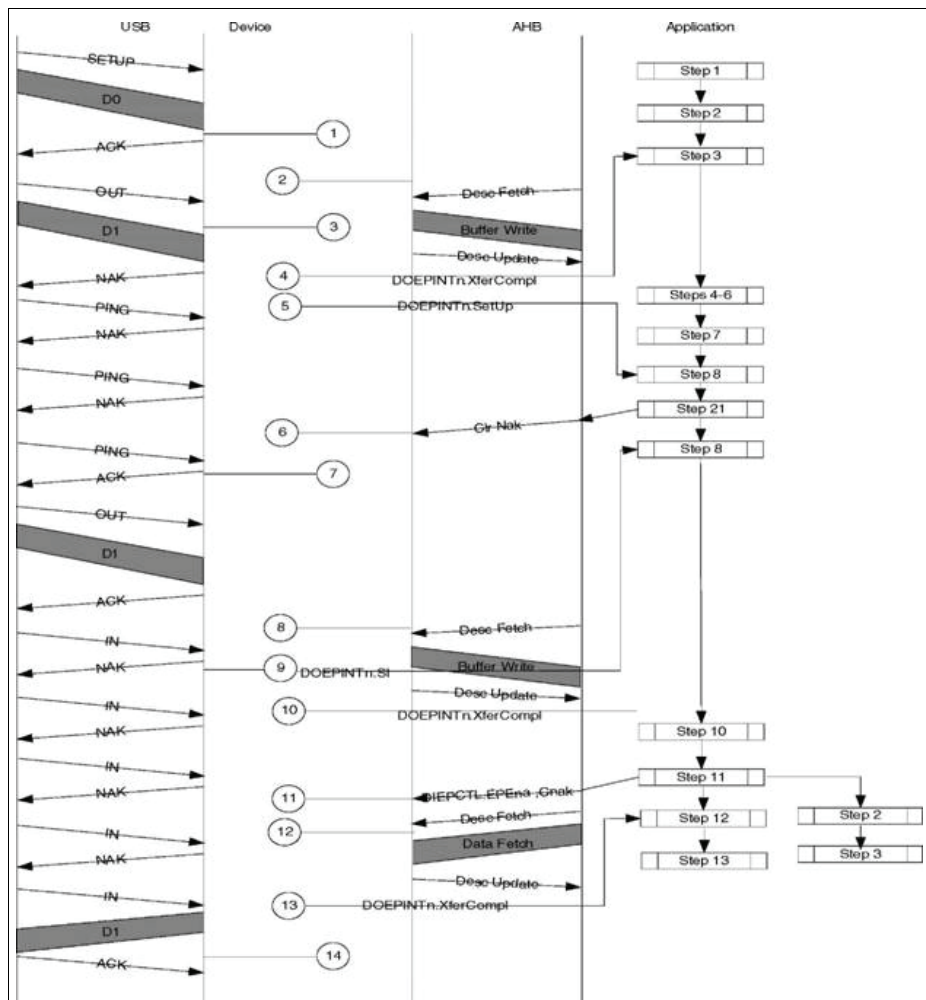

Figure 17-49 Premature Status Phase During Control Write

17.11.7.11 Premature Status During Control Read

In this example, it is assumed that the data phase consists of two packets, and the application allocates these two packets in a single buffer. After one packet in the data phase, host switches to status phase.

1. On receiving SETUP, the data is pushed into the Rx FIFO and the core sets NAK on both IN and OUT endpoint of that control endpoint.
2. The DMA detects the Rx FIFO as non-empty and does the following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
3. On receiving the first data phase IN token after the SETUP, the core push a SETUP_COMPLETE status into the Rx FIFO. Core NAKs the data phase IN tokens because of the NAK set on receiving the SETUP packet.
4. The core generates DOEINT.XferCompl interrupt after having transferred the SETUP packet into memory (Step 2).
5. The core generates DOEINT.SetUp interrupt after the DMA has popped the SETUP_COMPLETE status out of the Rx FIFO.
6. Data phase IN tokens are NAKed until this point because the NAK has not yet been cleared by the application.
7. The core starts fetching the IN data after the application enables IN DMA (In this example it is assumed that multiple packets are in the same buffer. But it could also be in different buffers). This involves the following steps
 - a) Fetch the descriptor pointed by DIEPDMA.
 - b) Fetch the data into the corresponding Tx FIFO.
 - c) Close the descriptor with DMA_DONE status.
8. Application clear the NAK after receiving the setup complete (DOEINT.SetUp) interrupt.
9. After all the data has been fetched for the descriptor (Step 7), core generates DIEPINT.XferCompl interrupt.
10. The core sends data in response to the IN token for the data phase.
11. Host switches to status phase and sends the status phase OUT token. Core ACKs the OUT packet because the NAK has already been cleared.
12. The DMA detects the Rx FIFO as non-empty (because of the status phase data) and does following.
 - a) Fetch the descriptor pointed by DOEPMa.
 - b) Transfer the SETUP packet from the Rx FIFO to the buffer pointed by the descriptor.
 - c) Close the descriptor with DMA_DONE status.
 - d) The core generates DOEINT.XferCompl after transferring the status phase data to system memory and closing the descriptor.

Universal Serial Bus (USB)

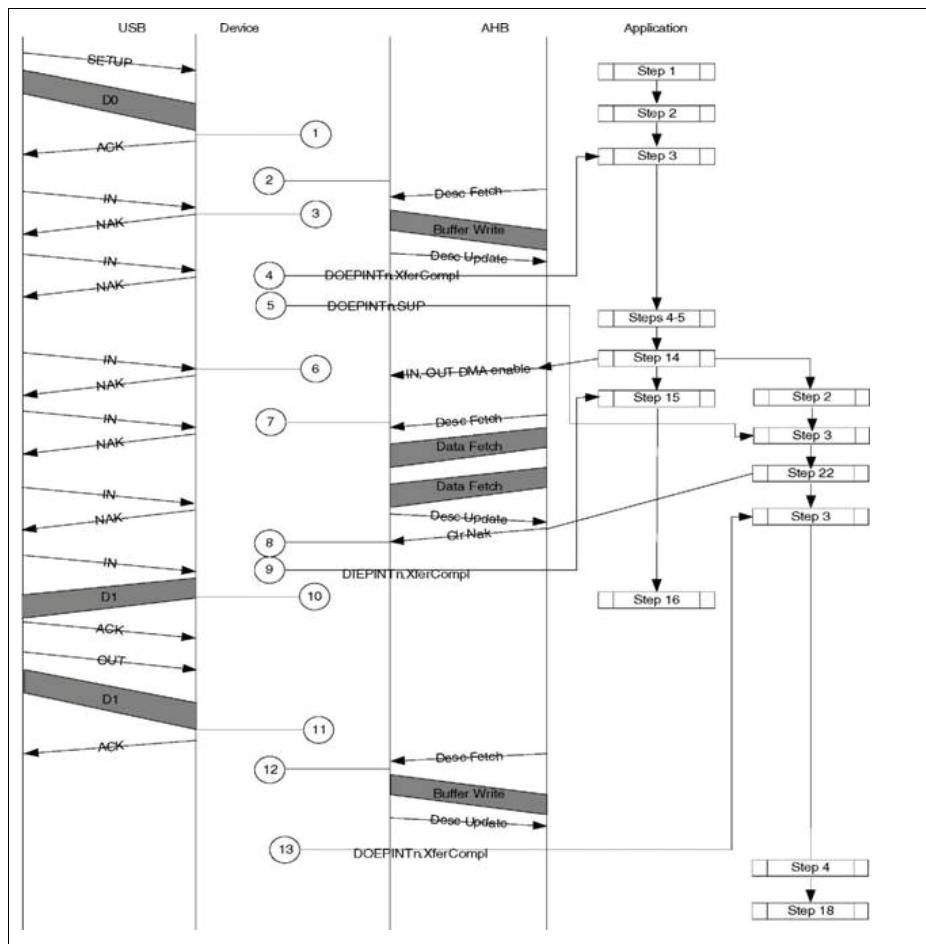

Figure 17-50 Premature Status Phase During Control Read

17.11.7.12 Lost ACK During Last Packet of Control Read

This is similar to the previous section. [Figure 17-51](#) shows this.

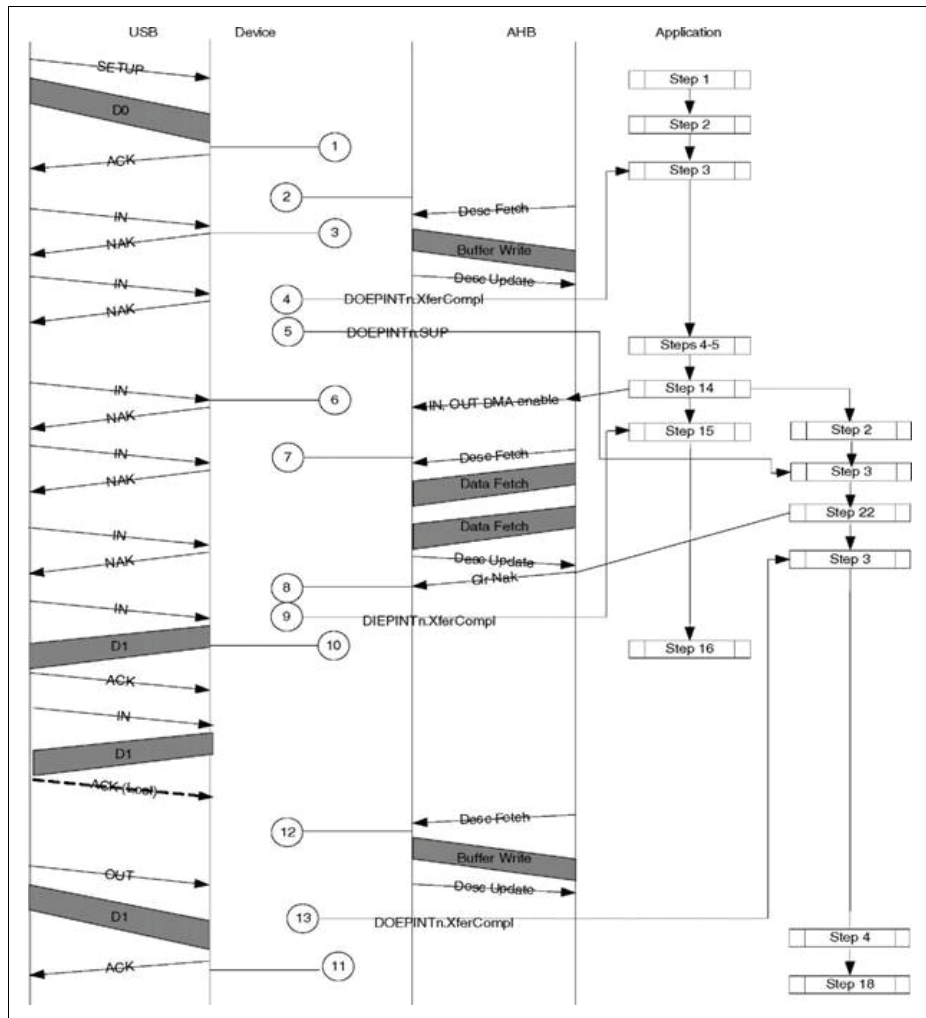

Figure 17-51 Lost ACK During Last Packet of Control Read

17.11.8 Bulk Transfer Handling in Scatter/Gather DMA Mode

17.11.8.1 Bulk IN Transfer in Scatter-Gather DMA Mode

Interrupt usage

The following interrupts are of relevance.

1. DIEPINTx.XferCompl (Transfer complete, based on IOC bit in the descriptor)
2. DIEPINTx.BNA (Buffer Not Available)

Application Programming Sequence

This section describes the application programming sequence for Bulk IN transfer scenarios.

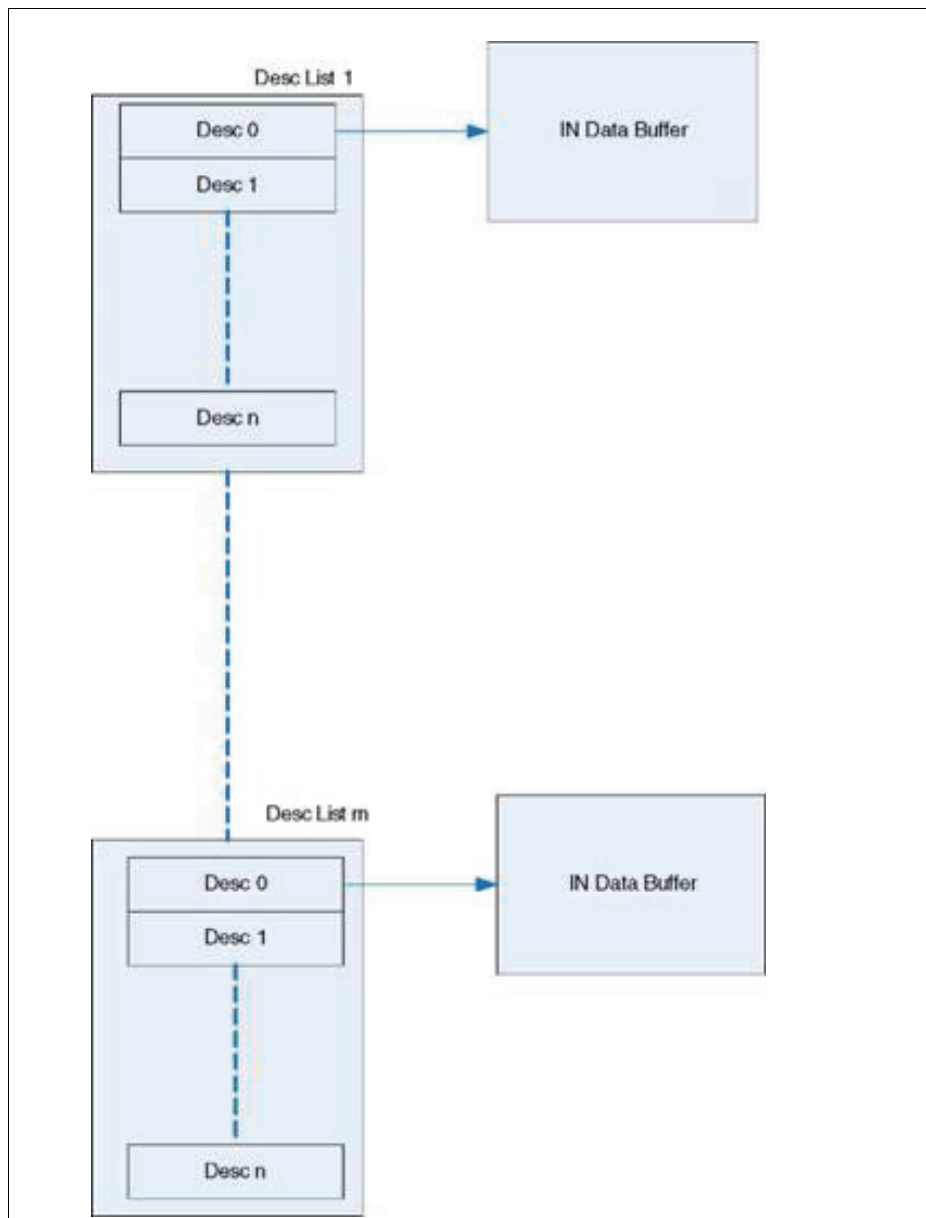

Figure 17-52 IN Descriptor List

Universal Serial Bus (USB)

1. Prepare Descriptor(s):
2. The application creates descriptor list(s) in the system memory pertaining to an Endpoint.
3. Each descriptor list may have up to n descriptors and there may be up to m descriptor lists.
4. Application may choose to set the IOC bit of the corresponding descriptor. If the IOC is set for the last descriptor of the list, the core generates DIEPINTx.XferCompl interrupt after the entire list is processed.
5. Program DIEPDMAx:
 - a) Application programs the base address of the descriptor in the corresponding IN Endpoint DIEPDMAx register.
6. Enable DMA:
 - a) Application programs the corresponding endpoint DIEPCTLx register with the following
 - DIEPCTLx.MPS — Max Packet size of the endpoint
 - DIEPCTLx.CNAK—Set to 1 to clear the NAK
 - DIEPCTLx.EPEna — Set to 1 to enable the DMA for the endpoint.
7. Wait for Interrupt:
 - a) On reception of DIEPINTx.XferCompl, application must check the Buffer status and Tx Status field of the descriptor to ascertain that the descriptor closed normally.

DIEPINTx.BNA interrupt gets generated by the core when it encounters a descriptor in the list whose Buffer Status field is not Host Ready. In this case, the application is suppose to read the DIEPDMAx register to ascertain the address for which the BNA interrupt is asserted to take corrective action.

Internal Flow

Bulk IN Transfers

The core handles Bulk IN transfers internally as functionally depicted in [Figure 17-53](#) (Non ISO IN Descriptor/Data Processing). [Figure 17-54](#) depicts this flow.

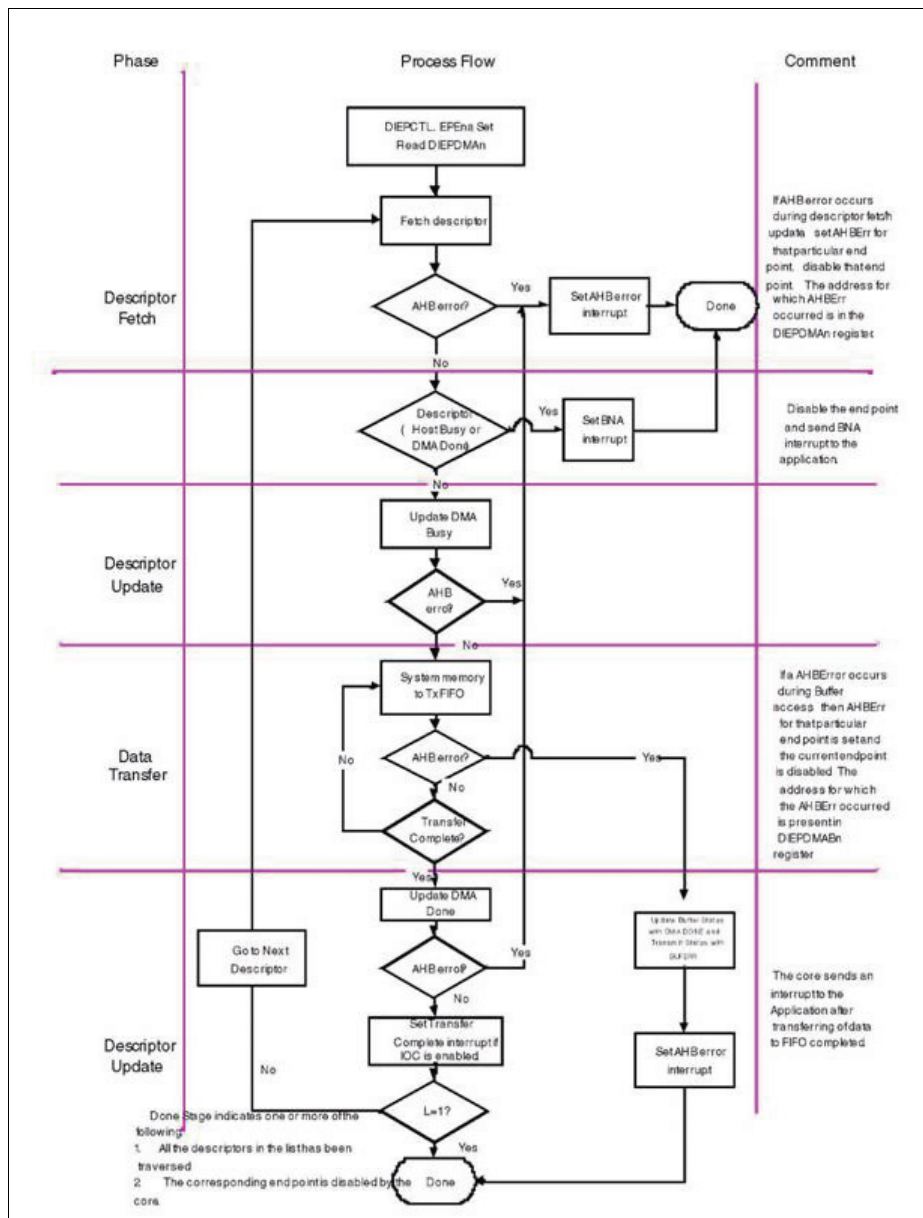

Figure 17-53 Non ISO IN Descriptor/Data Processing

Figure 17-54 Bulk IN Transfers

1. When a BULK IN token is received on an end point before the corresponding DMA is enabled, (DIEPCTLx.EPEna = 0_B), it is NAKed on USB.
2. As a result of application enabling the DMA for the corresponding end point (DIEPCTLx.EPEna=1), the core fetches the descriptor and processes it.
3. The DMA fetches the data from the system memory and populates its internal FIFO with this data.
4. After fetching all the data from a descriptor, the core closes the descriptor with a DMA_DONE status.
5. On reception of BULK IN tokens on USB, data is sent to the USB Host.
6. After the last descriptor in the chain is processed, the core generates DIEPINTx.XferCompl interrupt provided the IOC bit for the last descriptor is set.

17.11.8.2 Bulk OUT Transfer in Scatter-Gather DMA Mode

Interrupt Usage

The following interrupts are of relevance.

1. DOEPINTx.XferCompl (Transfer complete, based on IOC bit in the descriptor)
2. DOEPINTx.BNA (Buffer Not Available)

Application Programming Sequence

This section describes the application programming sequence to take care of Bulk OUT transfer scenarios.

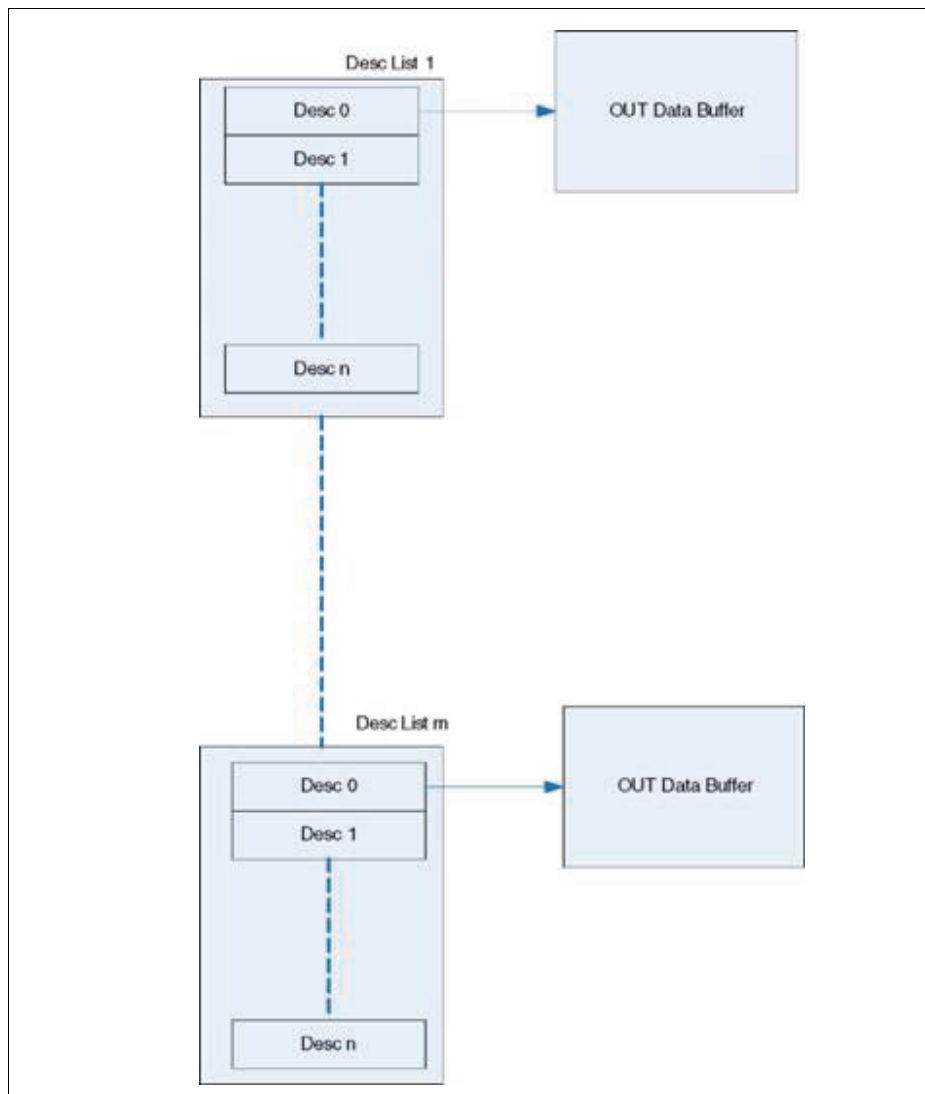

Figure 17-55 OUT Descriptor List

1. Prepare Descriptor(s):
2. The application creates descriptor list(s) in the system memory pertaining to an Endpoint.
3. Each descriptor list may have up to n descriptors and there may be up to m descriptor lists.
4. Application may choose to set the IOC bit of the corresponding descriptor. If the IOC is set for the last descriptor of the list, the core generates DOEPINTx.XferCompl interrupt after the entire list is processed.
 - a) a. Based on L bit and MTRF bit combinations, the core may disable the end point. Refer to **Table 17-9 “OUT Data Memory Structure Values” on Page 17-151** for bit field descriptions.
 - b) If the application programs the NAK bit, the core sets NAK for the endpoint after the descriptor is processed by the DMA. The application must set DIEPCTLn.CNAK to clear the NAK.
5. Program DOEPDMAx:
 - a) Application programs the base address of the descriptor in the corresponding OUT Endpoint DOEPDMAx register.
6. Enable DMA:
 - a) Application programs the corresponding endpoint DOEPCTLx register with the following:
 - DOEPCTL.MPS — Max Packet size of the endpoint
 - DOEPCTL.CNAK—Set to 1 to clear the NAK
 - DOEPCTL.EPEna — Set to 1 to enable the DMA for the endpoint.
7. Wait for Interrupt:
 - a) On reception of DOEPINTx.XferCompl, application must check the Buffer status and Rx Status field of the descriptor to ascertain that the descriptor closed normally.
 - b) On receiving DOEPINTn.BNA interrupt (generated by the core when it encounters a descriptor in the list whose Buffer Status field is not Host Ready), the application must read the DOEPDMA register to ascertain the address for which the BNA interrupt is asserted to take one of the following corrective actions:
 - If the application has programmed DCTL.EnContOnBNA = 1_B, then the application must read the DOEPDMA register, identify which descriptor received BNA status, process the descriptor, and re-enable the endpoint. The core continues to process descriptors from the descriptor which received BNA status.
 - If the application has programmed DCTL.EnContOnBNA = 1_B, then every time the endpoint is disabled, the core automatically sets the NAK for the endpoint, the application must set DIEPCTLn.CNAK = 1 while enabling the endpoint. This ensures that the core does not accept packets when the DMA is disabled for an endpoint.
 - If the application has programmed DCTL.EnContOnBNA = 0_B, then the application must read the DOEPDMA register, identify which descriptor received BNA status, process the descriptor, and re-enable the endpoint. The core

Universal Serial Bus (USB)

continues to process descriptors from the start of the descriptor chain (that is, the descriptor programmed in the DOEPDMA_n register).

Internal Flow

The core handles Bulk OUT transfers internally as depicted in [Figure 17-56](#). [Figure 17-57](#) also diagrams this flow.

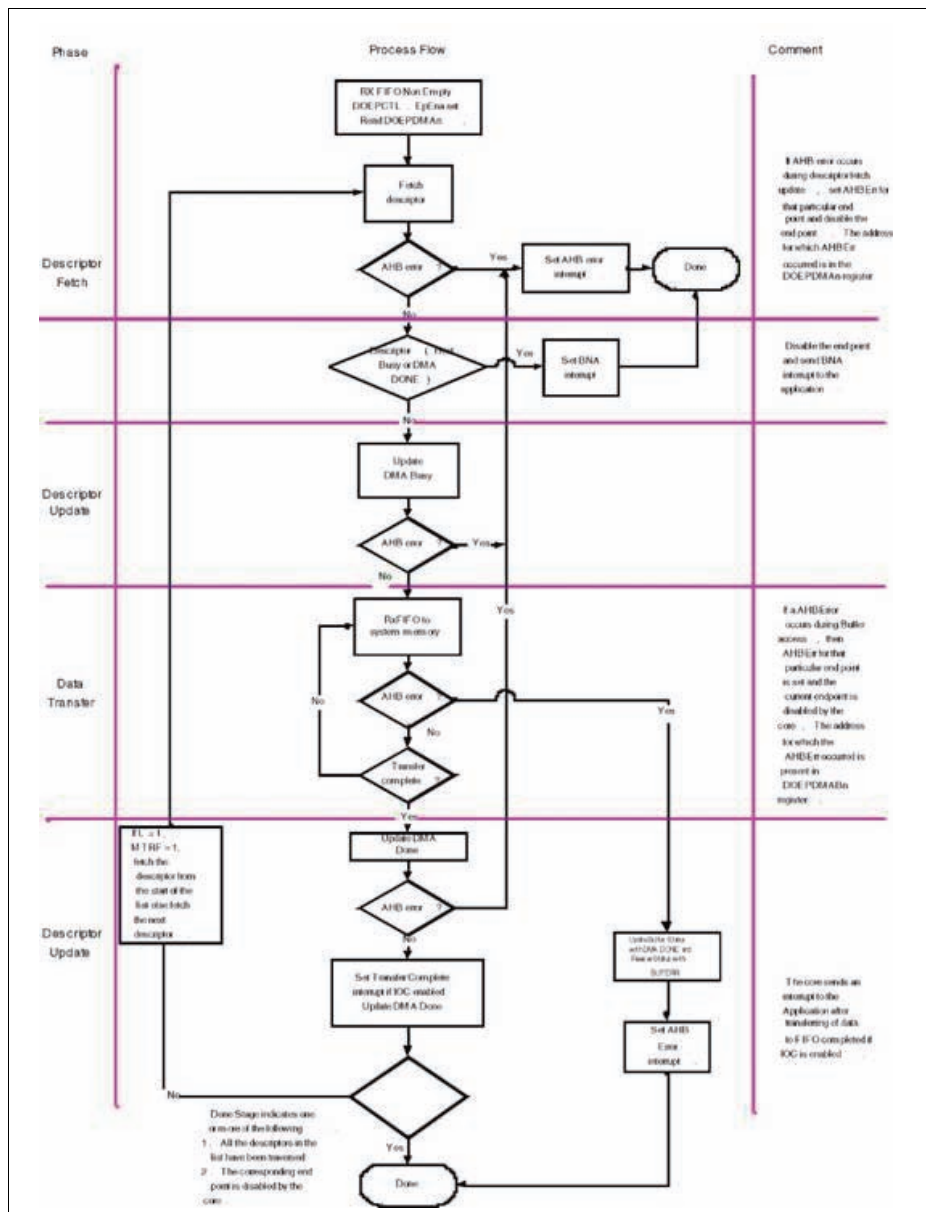

Figure 17-56 Non ISO OUT Descriptor/Data Buffer Processing

Figure 17-57 Bulk OUT Transfers

1. When a BULK OUT token is received on an end point, the core stores the received data internally in a FIFO.
2. As a result of application enabling the DMA for the corresponding end point (DOEPCTLx.EPEna=1), the core fetches the descriptor and processes it.
3. If the descriptor Buffer Status is HOST_READY:
 - a) The DMA transfers the data from the internal FIFO to system memory.
 - b) After transferring all the data from the FIFO, the core closes the descriptor with a DMA_DONE status.
 - c) After the last descriptor in the chain is processed, the core generates DOEPINTn.XferComp1 interrupt provided the IOC bit for the last descriptor is set.
4. If the descriptor Buffer Status is not HOST_READY:
 - a) The DMA generates Buffer Not Available (BNA) interrupt
 - b) After the application re-enables the corresponding endpoint (DOEPCTLn.EPEna=1), the core does the following:
 - Fetches the base descriptor from DOEPDMA n (DCTL.EnContOnBNA = 0_B).
 - Fetches the descriptor that received the BNA interrupt is (DCTL.EnContOnBNA = 1_B).

17.11.9 Interrupt Transfer Handling in Scatter/Gather DMA Mode

17.11.9.1 Interrupt IN Transfer in Scatter/Gather DMA Mode

Application programming for Interrupt IN transfers is as with the Bulk IN transfer sequence. The core handles Interrupt IN transfers internally in the same way it handles Bulk IN transfers

17.11.9.2 Interrupt OUT Transfer in Scatter/Gather DMA Mode

Application programming for Interrupt OUT transfers is as with the Bulk OUT transfer sequence. The core handles Interrupt OUT transfers internally in the same way it handles Bulk OUT Transfers

17.11.10 Isochronous Transfer Handling in Scatter/Gather DMA Mode

17.11.10.1 Isochronous IN Transfer in Scatter/Gather DMA Mode

The application programming for Isochronous IN transfers is in the same manner as Bulk IN transfer sequence.

The following behavior is of importance while working with Isochronous IN end points

$DCTL.IgnrFrmNum = 1_B$

The way the core handles Isochronous IN transfers internally in the same way as it handles Bulk IN Transfers.

$DCTL.IgnrFrmNum = 0_B$

The core closes the descriptor and clears the corresponding fetched data in the FIFO if the USB frame number to which the descriptor belongs is elapsed.

Isochronous Transfers in Scatter/Gather (Descriptor DMA) Mode

This topic includes descriptions of both isochronous IN and OUT transfers

Isochronous IN

In the case of ISO IN After descriptor is fetched, the frame number field M is compared with current USB frame number N.

If the frame number in the fetched descriptor is already elapsed ($M < N$) then the descriptor is closed with status changed to DMA Done.

If the frame number in the fetched descriptor is for future ($N > M+1$) then the descriptor is left untouched. The Core suspends and re-look at this descriptor contents in the next frame.

- If the frame number in the fetched descriptor is for current or next frame ($N=M$ or $M+1$) then the descriptor is further processed as per the flow chart. At the end of data

Universal Serial Bus (USB)

transfer from memory to Tx FIFO the above check must be performed. And if the data fetch finished in the subsequent frame, data must be flushed and descriptor must be closed (DMA Done) with BUFFLUSH status.

- For ISO IN, the application creates a series of descriptors (D,D+1,D+2) for a given periodic end point corresponding to successive frames (N,N+1,N+2).

Note: The series of descriptors does not correspond to the series of frames in the same order.

For example, D and D + 1 may correspond to N, D + 2 may correspond to N + 1 and so on except in the case where the application can create more than one descriptor for the same frame. The core fetches the descriptor and compares the frame/ ^frame number field with the current frame/ ^frame number.

If the fetched descriptor corresponds to a frame which has already elapsed, the core updates the descriptor with DMA Done Buffer status and proceeds to the next descriptor.

If the next descriptor fetched indicates that it corresponds to frame number N or N + 1, it services it. In the process of fetching the descriptors, if the core determines that the descriptor corresponds to a future frame/ ^frame (> N + 1), it does not service the descriptor in that frame/ ^frame. Instead, it moves on to the next periodic endpoint or non-periodic endpoint without disabling the current periodic endpoint. It revisits this endpoint in the next frame/ ^frame and repeats the process.

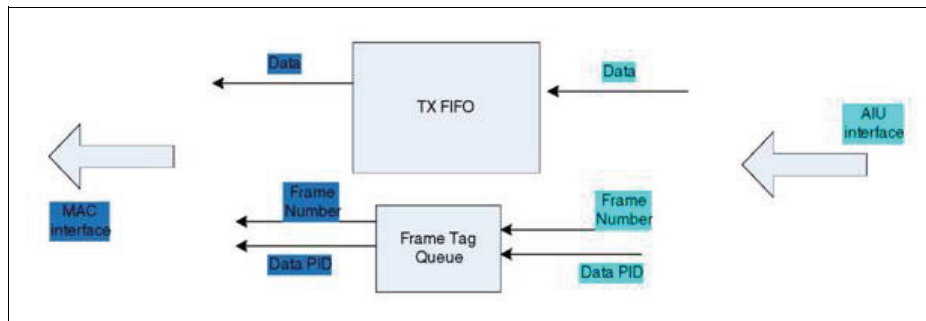

Figure 17-58 ISO IN Data Flow

Application Programming Sequence

This section describes the application programming sequence for Isochronous IN transfer scenarios.

Prepare Descriptor(s)

The application creates descriptor list(s) in the system memory pertaining to an Endpoint.

Universal Serial Bus (USB)

Each descriptor list may have up to n descriptors and there may be up to m descriptor lists.

Application may choose to set the IOC bit of the corresponding descriptor. If the IOC is set for the last descriptor of the list, the core generates DIEPINTx.XferCompl interrupt after the entire list is processed.

1. Program DIEPDMAx:
 - a) Application programs the base address of the descriptor in the corresponding IN Endpoint DIEPDMAx register.
2. Enable DMA:
 - a) Application programs the corresponding endpoint DIEPCTLx register with the following
 - DIEPCTLx.MPS — Max Packet size of the endpoint
 - DIEPCTLx.CNAK—Set to 1 to clear the NAK
 - DIEPCTLx.EPEna — Set to 1 to enable the DMA for the endpoint.
3. Wait for Interrupt:
 - a) On reception of DIEPINTx.XferCompl, application must check the Buffer status and Tx Status field of the descriptor to ascertain that the descriptor closed normally.

DIEPINTx.BNA interrupt gets generated by the core when it encounters a descriptor in the list whose Buffer Status field is not Host Ready. In this case, the application is suppose to read the DIEPDMAx register to ascertain the address for which the BNA interrupt is asserted to take corrective action.

Internal Flow

The core handles isochronous IN transfers internally as functionally depicted in **Figure 17-59**. **Figure 17-60** also diagrams this flow.

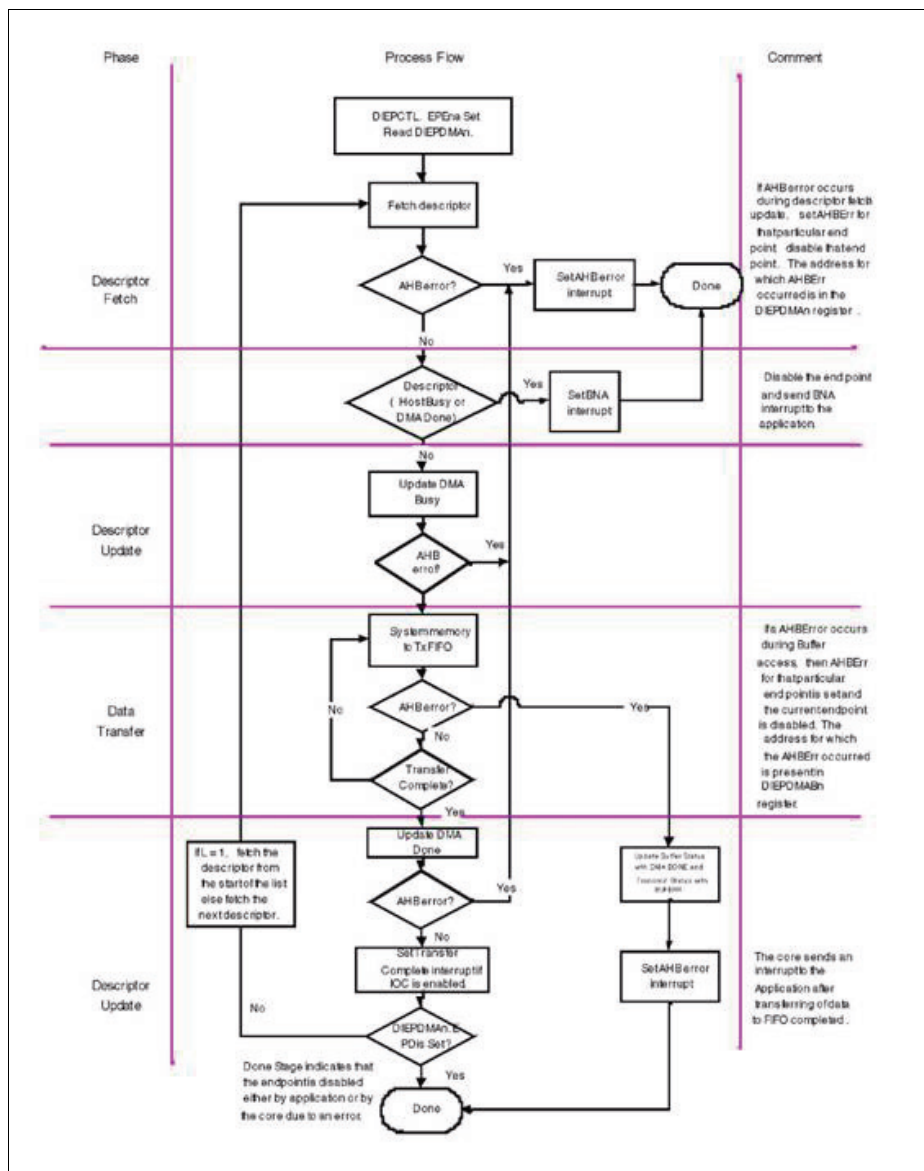

Figure 17-59 ISO IN Descriptor/Data Processing

Figure 17-60 Isochronous IN Transfers

1. When an Isochronous IN token is received on an end point before the corresponding DMA is enabled, ($\text{DIEPCTLx.EPEna} = 0_B$), zero length packet is sent on USB.
2. As a result of application enabling the DMA for the corresponding end point ($\text{DIEPCTLx.EPEna} = 1$), the core fetches the descriptor. If the descriptor belongs to the current or the next USB frame number, the core processes it.
3. The DMA fetches the data pointed by the above descriptor from the system memory and populates its internal FIFO with this data.
4. After fetching all the data, the core closes the descriptor with a `DMA_DONE` status.
5. On reception of Isochronous IN tokens on USB, data is sent to the USB Host.
6. After the last descriptor in the chain is processed, the core generates `DIEPINTx.XferCompl` interrupt provided the IOC bit for the last descriptor is set.
7. When the DMA fetches a descriptor whose USB frame number has been already elapsed, it closes that descriptor with a `DMA_DONE` status without fetching the data for that descriptor.
8. When the DMA fetches a descriptor which has a future USB frame number, it does not service it in the current context. It services it in the future.

17.11.10.2 Isochronous OUT Transfer in Scatter/Gather DMA Mode

The application programming for isochronous out transfers is in the same manner as Bulk OUT transfer sequence, except that the application creates only 1 packet per descriptor for an isochronous OUT endpoint. The core handles isochronous OUT transfers internally in the same way it handles Bulk OUT transfers, and as depicted in [Figure 17-61](#).

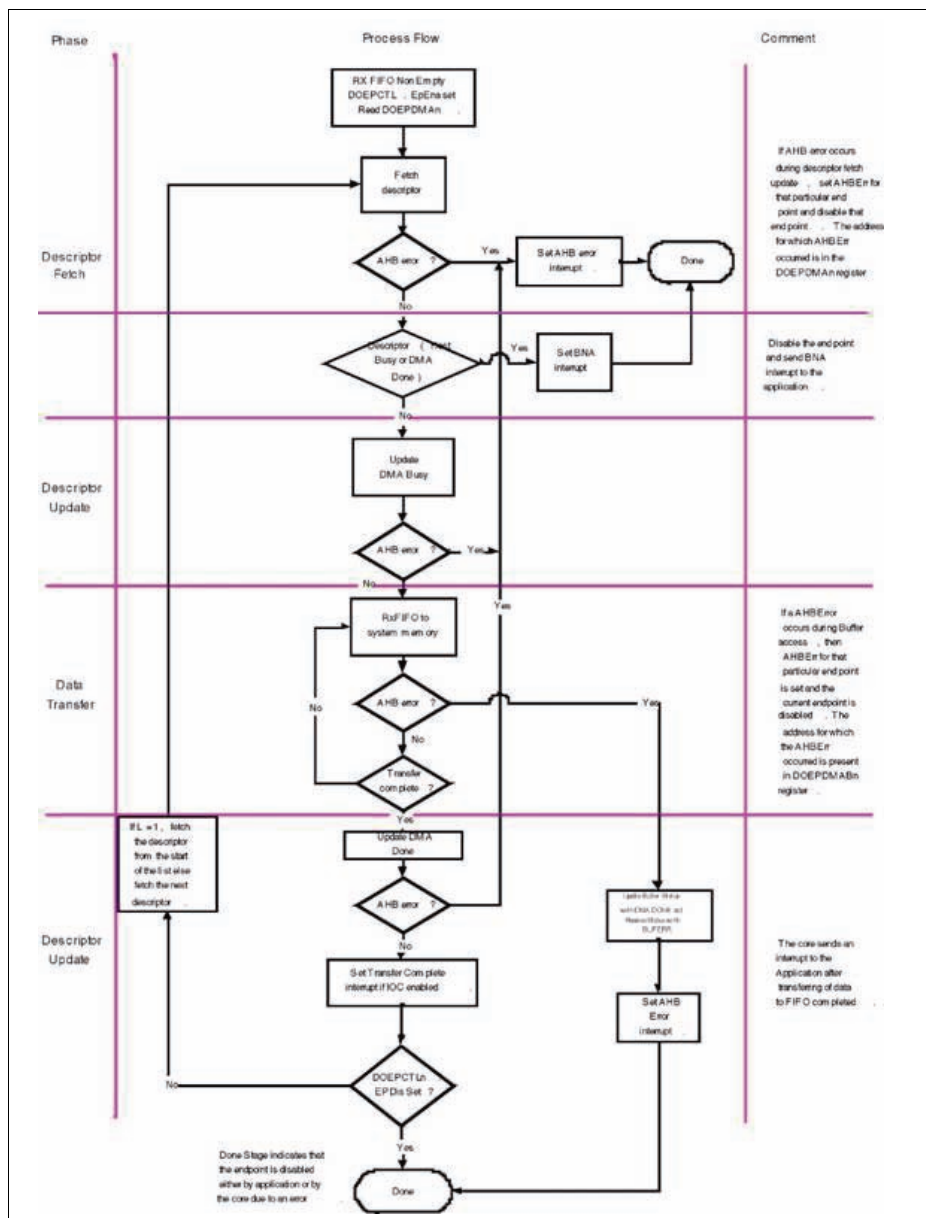

Figure 17-61 Isochronous OUT Descriptor/Data Buffer Processing

Isochronous OUT

For ISO OUT transactions, the core transfers the packets from the Rx FIFO to the system memory and updates the frame number field of the descriptor with the frame number in which the packet was received. The frame number for which data is received is extracted from the Receive Status queue and written back to the descriptor.

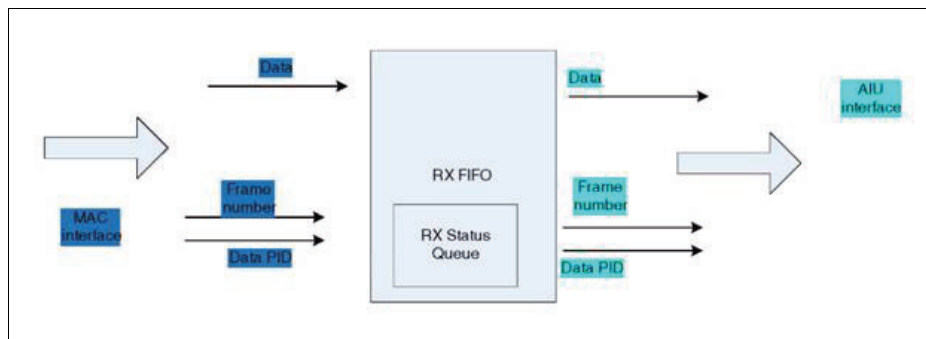

Figure 17-62 ISO Out Data Flow

Note: Incomplete Isochronous Interrupt (GINTSTS.incomplete) is not generated in Scatter/Gather DMA mode. Received isochronous packets are sent unmodified to the application memory, with the corresponding frame number updated in the descriptor status.

17.12 OTG Revision 1.3 Programming Model

This section describes the OTG programming model when the OTG core is configured to support OTG Revision 1.3 of the specification.

The USB core is an OTG device supporting HNP and SRP. When the core is connected to an "A" plug, it is referred to as an A-device. When the core is connected to a "B" plug it is referred to as a B-device. In Host mode, the USB core turns off VBUS to conserve power. SRP is a method by which the B-device signals the A-device to turn on VBUS power. A device must perform both data-line pulsing and VBUS pulsing, but a host can detect either data-line pulsing or VBUS pulsing for SRP. HNP is a method by which the B-device negotiates and switches to host role. In Negotiated mode after HNP, the B-device suspends the bus and reverts to the device role.

17.12.1 A-Device Session Request Protocol

The application must set the SRP-Capable bit in the Core USB Configuration register. This enables the USB core to detect SRP as an A-device.

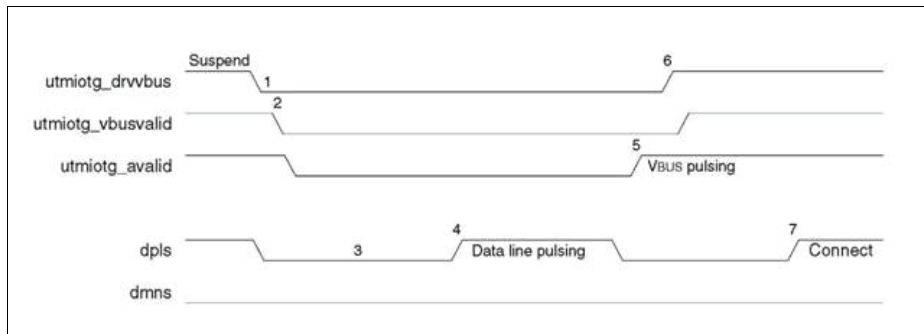

Figure 17-63 A-Device SRP

1. To save power, the application suspends and turns off port power when the bus is idle by writing the port Suspend and Port Power bits in the Host Port Control and Status register.
2. PHY indicates port power off by deasserting the utmi_vbusvalid signal.
3. The device must detect SE0 for at least 2 ms to start SRP when Vbus power is off.
4. To initiate SRP, the device turns on its data line pull-up resistor for 5 to 10 ms. The USB core detects data-line pulsing.
5. The device drives VBUS above the A-device session valid (2.0 V minimum) for VBUS pulsing.
The USB core interrupts the application on detecting SRP. The Session Request Detected bit is set in Global Interrupt Status register (GINTSTS.SessReqInt).
6. The application must service the Session Request Detected interrupt and turn on the Port Power bit by writing the Port Power bit in the Host Port Control and Status register. The PHY indicates port power-on by asserting utmi_vbusvalid signal.
7. When the USB is powered, the device connects, completing the SRP process.

17.12.2 B-Device Session Request Protocol

The application must set the SRP-Capable bit in the Core USB Configuration register. This enables the USB core to initiate SRP as a B-device. SRP is a means by which the USB core can request a new session from the host.

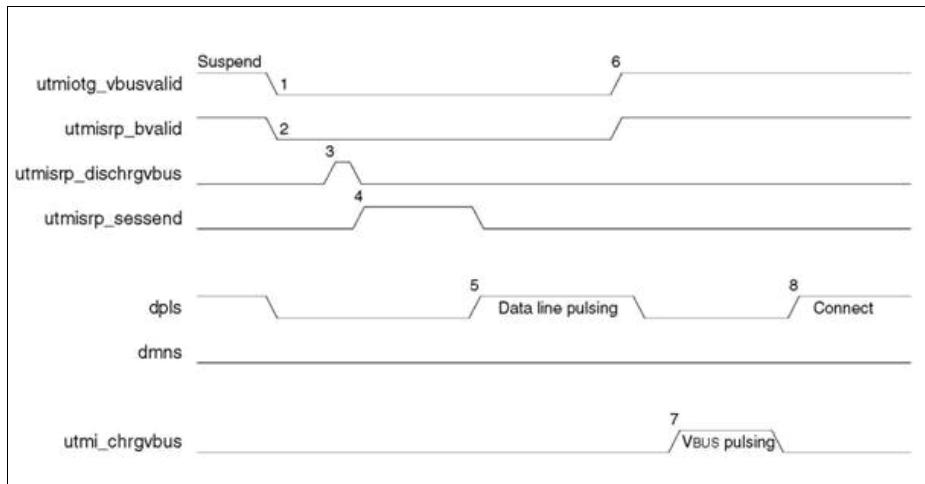

Figure 17-64 B-Device SRP

1. To save power, the host suspends and turns off port power when the bus is idle. PHY indicates port power off by deasserting the utmi_vbusvalid signal. The USB core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the USB core sets the USB Suspend bit in the Core Interrupt register. The PHY indicates the end of the B-device session by deasserting the utmi_bvalid signal.
2. The USB core asserts the utmi_dischrgvbus signal to indicate to the PHY to speed up VBUS discharge.
3. The PHY indicates the session's end by asserting the utmi_sessend signal. This is the initial condition for SRP. The USB core requires 2 ms of SE0 before initiating SRP.
 For a USB 1.1 full-speed serial transceiver, the application must wait until VBUS discharges to 0.2 V after GOTGCTL.BSesVld is deasserted.
4. The application initiates SRP by writing the Session Request bit in the OTG Control and Status register. The USB core performs data-line pulsing followed by VBUS pulsing.
5. The host detects SRP from either the data-line or VBUS pulsing, and turns on VBUS. The PHY indicates VBUS power-on by asserting utmi_vbusvalid.
6. The USB core performs VBUS pulsing by asserting utmi_chrgvbus.
 The host starts a new session by turning on VBUS, indicating SRP success. The USB core interrupts the application by setting the Session Request Success Status Change bit in the OTG Interrupt Status register. The application reads the Session Request Success bit in the OTG Control and Status register.
7. When the USB is powered, the USB core connects, completing the SRP process.

17.12.3 A-Device Host Negotiation Protocol

HNP switches the USB host role from the A-device to the B-device. The application must set the HNP- Capable bit in the Core USB Configuration register to enable the USB core to perform HNP as an A-device.

Figure 17-65 A-Device HNP

1. The USB core sends the B-device a SetFeature b_hnp_enable descriptor to enable HNP support. The B-device's ACK response indicates that the B-device supports HNP. The application must set Host Set HNP Enable bit in the OTG Control and Status register to indicate to the USB core that the B-device supports HNP.
2. When it has finished using the bus, the application suspends by writing the Port Suspend bit in the Host Port Control and Status register.
3. When the B-device observes a USB suspend, it disconnects, indicating the initial condition for HNP. The B-device initiates HNP only when it must switch to the host role; otherwise, the bus continues to be suspended.
The USB core sets the Host Negotiation Detected interrupt in the OTG Interrupt Status register, indicating the start of HNP.
The USB core deasserts the utmiotg_dppulldown and utmiotg_dmpulldown signals to indicate a device role. The PHY enable the D+ pull-up resistor indicates a connect for B-device.
The application must read the Current Mode bit in the OTG Control and Status register to determine Device mode operation.
4. The B-device detects the connection, issues a USB reset, and enumerates the USB core for data traffic.
5. The B-device continues the host role, initiating traffic, and suspends the bus when done.
The USB core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the USB core sets the USB Suspend bit in the Core Interrupt register.

Universal Serial Bus (USB)

6. In Negotiated mode, the USB core detects the suspend, disconnects, and switches back to the host role. The USB core asserts the `utmiotg_dppulldown` and `utmiotg_dmpulldown` signals to indicate its assumption of the host role.
7. The USB core sets the Connector ID Status Change interrupt in the OTG Interrupt Status register. The application must read the connector ID status in the OTG Control and Status register to determine the USB core's operation as an A-device. This indicates the completion of HNP to the application. The application must read the Current Mode bit in the OTG Control and Status register to determine Host mode operation.
8. The B-device connects, completing the HNP process.

17.12.4 B-Device Host Negotiation Protocol

HNP switches the USB host role from B-device to A-device. The application must set the HNP-Capable bit in the Core USB Configuration register to enable the USB core to perform HNP as a B-device.

Figure 17-66 B-Device HNP

1. The A-device sends the SetFeature `b_hnp_enable` descriptor to enable HNP support. The USB core's ACK response indicates that it supports HNP. The application must set the Device HNP Enable bit in the OTG Control and Status register to indicate HNP support.
 The application sets the HNP Request bit in the OTG Control and Status register to indicate to the USB core to initiate HNP.
2. When it has finished using the bus, the A-device suspends by writing the Port Suspend bit in the Host Port Control and Status register.
 The USB core sets the Early Suspend bit in the Core Interrupt register after 3 ms of bus idleness. Following this, the USB core sets the USB Suspend bit in the Core Interrupt register.

Universal Serial Bus (USB)

The USB core disconnects and the A-device detects SE0 on the bus, indicating HNP. The USB core asserts the `utmiotg_dppulldown` and `utmiotg_dmpulldown` signals to indicate its assumption of the host role.

The A-device responds by activating its D+ pull-up resistor within 3 ms of detecting SE0. The USB core detects this as a connect.

The USB core sets the Host Negotiation Success Status Change interrupt in the OTG Interrupt Status register, indicating the HNP status. The application must read the Host Negotiation Success bit in the OTG Control and Status register to determine host negotiation success. The application must read the Current Mode bit in the Core Interrupt register (GINTSTS) to determine Host mode operation.

3. The application sets the reset bit (HPRT.PrtRst) and the USB core issues a USB reset and enumerates the A-device for data traffic
4. The USB core continues the host role of initiating traffic, and when done, suspends the bus by writing the Port Suspend bit in the Host Port Control and Status register.
5. In Negotiated mode, when the A-device detects a suspend, it disconnects and switches back to the host role. The USB core deasserts the `utmiotg_dppulldown` and `utmiotg_dmpulldown` signals to indicate the assumption of the device role.
6. The application must read the Current Mode bit in the Core Interrupt (GINTSTS) register to determine the Host mode operation.
7. The USB core connects, completing the HNP process.

17.13 Clock Gating Programming Model

When the USB is suspended or the session is not valid, the PHY is driven into Suspend mode, and the PHY clock is stopped to reduce power consumption in the PHY and the USB core. The PHY clock is turned off for as long as the core asserts the suspend signal.

To further reduce power consumption, the USB core also supports AHB clock gating. The AHB clock to some of the USB internal modules can be gated by writing to the Gate Hclk bit in the Power and Clock Gating Control register.

The following sections show the procedures to use the clock gating feature.

17.13.1 Host Mode Suspend and Resume With Clock Gating

Sequence of operations:

1. The application sets the Port Suspend bit in the Host Port Control and Signal register, and the core drives a USB suspend.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, the core gates the hclk (`hclk_gated`) to AHB- domain modules other than the BIU.
3. The core remains in Suspend mode.
4. The application clears the Gate hclk and Stop PHY Clock bits, and the PHY clock is generated.

5. The application sets the Port Resume bit, and the core starts driving Resume signaling.
6. The application clears the Port Resume bit after at least 20 ms.
7. The core is in normal operating mode.

Figure 17-67 Host Mode Suspend and Resume With Clock Gating

17.13.2 Host Mode Suspend and Remote Wakeup With Clock Gating

Sequence of operations:

1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
3. The core remains in Suspend mode.
4. The Remote Wakeup signaling from the device is detected. The core deasserts the suspend_n signal to the PHY to generate the PHY clock. The core generates a Remote Wakeup Detected interrupt.
5. The application clears the Gate hclk and Stop PHY Clock bits. The core sets the Port Resume bit.
6. The application clears the Port Resume bit after at least 20 ms.
7. The core is in normal operating mode.

Figure 17-68 Host Mode Suspend and Remote Wakeup With Clock Gating

17.13.3 Host Mode Session End and Start With Clock Gating

Sequence of operations:

1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
2. The application clears the Port Power bit. The core turns off VBUS.
3. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
4. The core remains in Low-Power mode.
5. The application clears the Gate hclk bit and the application clears the Stop PHY Clock bit to start the PHY clock.
6. The application sets the Port Power bit to turn on VBUS.
7. The core detects device connection and drives a USB reset.
8. The core is in normal operating mode.

17.13.4 Host Mode Session End and SRP With Clock Gating

Sequence of operations:

1. The application sets the Port Suspend bit in the Host Port CSR, and the core drives a USB suspend.
2. The application clears the Port Power bit. The core turns off VBUS.

Universal Serial Bus (USB)

3. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
4. The core remains in Low-Power mode.
5. SRP (data line pulsing) from the device is detected. The core deasserts the suspend_n signal to the PHY to generate the PHY clock. An SRP Request Detected interrupt is generated.
6. The application clears the Gate hclk bit and the Stop PHY Clock bit.
7. The core sets the Port Power bit to turn on VBUS.
8. The core detects device connection and drives a USB reset.
9. The core is in normal operating mode.

17.13.5 Device Mode Suspend and Resume With Clock Gating

Sequence of operations:

1. The core detects a USB suspend and generates a Suspend Detected interrupt.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
3. The core remains in Suspend mode.
4. The Resume signaling from the host is detected. The core deasserts the suspend_n signal to the PHY to generate the PHY clock. A Resume Detected interrupt is generated.
5. The application clears the Gate hclk bit and the Stop PHY Clock bit.
6. The host finishes Resume signaling.
7. The core is in normal operating mode.

17.13.6 Device Mode Suspend and Remote Wakeup With Clock Gating

Sequence of operations:

1. The core detects a USB suspend and generates a Suspend Detected interrupt.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, the core gates the hclk (hclk_ctl) to AHB-domain modules other than the BIU.
3. The core remains in Suspend mode.
4. The application clears the Gate hclk bit and the Stop PHY Clock bit.
5. The application sets the Remote Wakeup bit in the Device Control register, the core starts driving Remote Wakeup signaling.
6. The host drives Resume signaling.
7. The core is in normal operating mode.

17.13.7 Device Mode Session End and Start With Clock Gating

Sequence of operations:

1. The core detects a USB suspend, and generates a Suspend Detected interrupt. The host turns off VBUS.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
3. The core remains in Low-Power mode.
4. The new session is detected (bsessvld is high). The core deasserts the suspend_n signal to the PHY to generate the PHY clock. A New Session Detected interrupt is generated.
5. The application clears the Gate hclk and Stop PHY Clock bits.
6. The core detects USB reset.
7. The core is in normal operating mode

17.13.8 Device Mode Session End and SRP With Clock Gating

Sequence of operations:

1. The core detects a USB suspend, and generates a Suspend Detected interrupt. The host turns off VBUS.
2. The application sets the Stop PHY Clock bit in the Power and Clock Gating Control register, the core asserts the suspend_n signal to the PHY, and the PHY clock stops. The application sets the Gate hclk bit in the Power and Clock Gating Control register, and the core gates the hclk (hclk_ctl) to AHB- domain modules other than the BIU.
3. The core remains in Low-Power mode.
4. The application clears the Gate hclk and Stop PHY Clock bits.
5. The application sets the SRP Request bit, and the core drives data line and VBUS pulsing.
6. The host turns on Vbus, detects device connection, and drives a USB reset.
7. The core is in normal operating mode.

17.14 FIFO RAM Allocation

17.14.1 Data FIFO RAM Allocation

The RAM must be allocated among different FIFOs in the core before any transactions can start. The application must follow this procedure every time it changes core FIFO RAM allocation.

The application must allocate data RAM per FIFO based on the following criteria:

Universal Serial Bus (USB)

- AHB's operating frequency
- PHY Clock frequency
- Available AHB bandwidth
- Performance required on the USB

Based on the above criteria, the application must provide a table with RAM sizes for each FIFO in each mode.

USB core shares a single SPRAM between transmit FIFO(s) and receive FIFO.

In DMA mode — The SPRAM is also used for storing some register information:

- **In non Scatter Gather mode** — The Device mode Endpoint DMA address registers (DI/OEPDMA_n) and Host mode Channel DMA registers (HCDMA) are stored in the SPRAM.
- **In Scatter Gather mode** — The Base descriptor address, the Current descriptor address, the current buffer address and the descriptor status quadlet information for each endpoint/channel are stored in the SPRAM.

These register information are stored at the end of the SPRAM after the space allocated for receive and Transmit FIFO. These register space must also be taken into account when allocating the RAM among the different FIFOs.

In Slave mode — No registers are stored in the SPRAM. Therefore no additional space needs to be allocated in the SPRAM for register information.

The following rules apply while calculating how much RAM space must be allocated to store these registers.

Table 17-17 RAM Space Allocation

| Mode | Configuration | RAM Space Allocation |
|------|-------------------------|---|
| Host | Slave mode | No space required |
| | Buffer DMA mode | One location per channel |
| | Scatter/Gather DMA mode | Four locations per channel as follows: <ul style="list-style-type: none"> - Location for storing current descriptor address - Location for storing current buffer address - Location for storing the status quadlet that is used by the List processor - Location for storing the transfer size used by the token request block |

Table 17-17 RAM Space Allocation

| Mode | Configuration | RAM Space Allocation |
|--------|-------------------------|--|
| Device | Slave mode | No space required |
| | Buffer DMA mode | One location per endpoint direction |
| | Scatter/Gather DMA mode | Four locations per endpoint direction as follows: - Location for storing base descriptor address - Location for storing current descriptor addresss - Location for storing current buffer address - Location for storing descriptor status quadlet |

For example in Scatter/Gather DMA mode, if there are five bidirectional endpoints, then the last forty SPRAM locations are reserved for storing these values.

17.14.1.1 Device Mode RAM Allocation

Considerations for allocating data RAM for Device Mode FIFOs are listed here:

1. Receive FIFO RAM Allocation:
 - a) RAM for SETUP Packets: 10 locations must be reserved in the receive FIFO to receive up to n SETUP packets on the control endpoint. The core does not use these locations, which are reserved for SETUP packets, to write any other data.
 - b) One location for Global OUT NAK
 - c) Status information is written to the FIFO along with each received packet. Therefore, a minimum space of $(\text{Largest Packet Size} / 4) + 1$ must be allotted to receive packets. If a high-bandwidth endpoint is enabled, or multiple isochronous endpoints are enabled, then at least two $(\text{Largest Packet Size} / 4) + 1$ spaces must be allotted to receive back-to-back packets. Typically, two $(\text{Largest Packet Size} / 4) + 1$ spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet. If AHB latency is high, enough space must be allocated to receive multiple packets. This is critical to prevent dropping any isochronous packets.
 - d) Along with each endpoint's last packet, transfer complete status information is also pushed to the FIFO. Typically, one location for each OUT endpoint is recommended.
2. Transmit FIFO RAM Allocation:
 - a) The minimum RAM space required for each IN Endpoint Transmit FIFO is the maximum packet size for that particular IN endpoint.
 - b) More space allocated in the transmit IN Endpoint FIFO results in a better performance on the USB and can hide latencies on the AHB.

Table 17-18 FIFO Name - Data RAM Size

| FIFO Name | Data RAM Size |
|-------------------|---|
| Receive data FIFO | rx_fifo_size. This must include RAM for setup packets, OUT endpoint control information and data OUT packets. |
| Transmit FIFO 0 | tx_fifo_size[0] |
| Transmit FIFO 1 | tx_fifo_size[1] |
| Transmit FIFO 2 | tx_fifo_size[2] |
| ... | ... |
| Transmit FIFO i | tx_fifo_size[i] |

With this information, the following registers must be programmed as follows:

1. Receive FIFO Size Register (GRXFSIZ)
GRXFSIZ.Receive FIFO Depth = rx_fifo_size;
2. Device IN Endpoint Transmit FIFO0 Size Register (GNPTXFSIZ)
GNPTXFSIZ.non-periodic Transmit FIFO Depth = tx_fifo_size[0];
GNPTXFSIZ.non-periodic Transmit RAM Start Address = rx_fifo_size;
3. Device IN Endpoint Transmit FIFO#1 Size Register (DIEPTXF1)
DIEPTXF1. Transmit RAM Start Address = GNPTXFSIZ.FIFO0 Transmit RAM Start Address + tx_fifo_size[0];
4. Device IN Endpoint Transmit FIFO#2 Size Register (DIEPTXF2)
DIEPTXF2.Transmit RAM Start Address = DIEPTXF1.Transmit RAM Start Address + tx_fifo_size[1];
5. Device IN Endpoint Transmit FIFO#i Size Register (DIEPTXFi)
DIEPTXFm.Transmit RAM Start Address = DIEPTXFi-1.Transmit RAM Start Address + tx_fifo_size[i-1];
6. The transmit FIFOs and receive FIFO must be flushed after the RAM allocation is done, for the proper functioning of the FIFOs.
 - a) GRSTCTL.TxFNum = 10_H
 - b) GRSTCTL.TxFFlush = 1_B
 - c) GRSTCTL.RxFFlush = 1_B
 - d) The application must wait until the TxFFlush bit and the RxFFlush bits are cleared before performing any operation on the core.

See also [Figure 17-69](#).

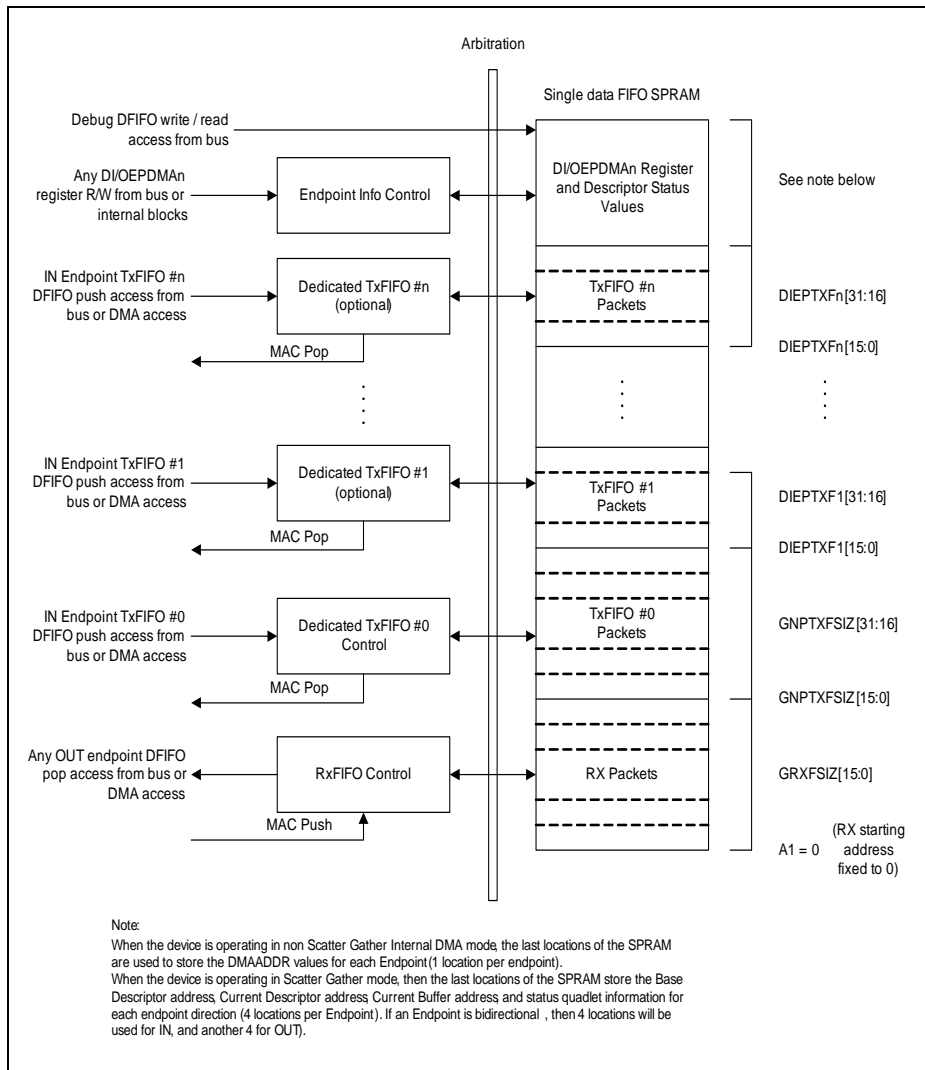

Figure 17-69 Device Mode FIFO Address Mapping

17.14.1.2 Host Mode RAM Allocation

Considerations for allocating data RAM for Host Mode FIFOs are listed here:

Receive FIFO RAM allocation:

Status information is written to the FIFO along with each received packet. Therefore, a minimum space of $(\text{Largest Packet Size} / 4) + 2$ must be allotted to receive packets. If a high-bandwidth channel is enabled, or multiple isochronous channels are enabled, then at least two $(\text{Largest Packet Size} / 4) + 2$ spaces must be allotted to receive back-to-back packets. Typically, two $(\text{Largest Packet Size} / 4) + 2$ spaces are recommended so that when the previous packet is being transferred to AHB, the USB can receive the subsequent packet. If AHB latency is high, enough space must be allocated to receive multiple packets.

Along with each host channel's last packet, information on transfer complete status and channel halted is also pushed to the FIFO. So two locations must be allocated for this.

For handling NAK/NYET in Buffer DMA mode, the application must determine the number of Control/Bulk OUT endpoint data that must fit into the TX_FIFO at the same instant. Based on this, one location each is required for Control/Bulk OUT endpoints.

For example, when the host addresses one Control OUT endpoint and three Bulk OUT endpoints, and all these must fit into the non-periodic TX_FIFO at the same time, then four extra locations are required in the RX FIFO to store the rewind status information for each of these endpoints.

Transmit FIFO RAM allocation

The minimum amount of RAM required for the Host Non-periodic Transmit FIFO is the largest maximum packet size among all supported non-periodic OUT channels.

More space allocated in the Transmit Non-periodic FIFO results in better performance on the USB and can hide AHB latencies. Typically, two Largest Packet Sizes' worth of space is recommended, so that when the current packet is under transfer to the USB, the AHB can get the next packet. If the AHB latency is large, then enough space must be allocated to buffer multiple packets.

The minimum amount of RAM required for Host periodic Transmit FIFO is the largest maximum packet size among all supported periodic OUT channels. If there is at least one High Bandwidth Isochronous OUT endpoint, then the space must be at least two times the maximum packet size of that channel.

Internal Register Storage Space Allocation

When operating in Buffer DMA mode, the DMA address register for each host channel (HCDMAx) is stored in the SPRAM. One location for each channel must be reserved for this.

Universal Serial Bus (USB)

When operating in Scatter/Gather DMA mode, four locations per channel must be reserved.

Table 17-19 FIFO Name - Data RAM Size

| FIFO Name | Data RAM Size |
|----------------------------|-----------------|
| Receive Data FIFO | rx_fifo_size |
| Non-periodic Transmit FIFO | tx_fifo_size[0] |
| IN Endpoint Transmit FIFO | tx_fifo_size[1] |

With this information, the following registers must be programmed:

1. Receive FIFO Size Register (GRXFSIZ)
 - a) GRXFSIZ.RxFDep= rx_fifo_size;
2. Non-periodic Transmit FIFO Size Register (GNPTXFSIZ)
 - a) GNPTXFSIZ.NPTxFDe=tx_fifo_size[0];
 - b) GNPTXFSIZ.NPTxFStAddr = rx_fifo_size;
3. Host Periodic Transmit FIFO Size Register (HPTXFSIZ)
 - a) HPTXFSIZ.PTxFSsize = tx_fifo_size[1];
 - b) HPTXFSIZ.PTxFStAddr= GNPTXFSIZ.NPTxFStAddr + tx_fifo_size[0];
4. The transmit FIFOs and receive FIFO must be flushed after RAM allocation for proper FIFO function.
 - a) GRSTCTL.TxFNum = 10_H
 - b) GRSTCTL.TxFFlush = 1_B
 - c) GRSTCTL.RxFFlush = 1_B
 - d) The application must wait until the TxFFlush bit and the RxFFlush bits are cleared before performing any operation on the core.

See also **Figure 17-70**.

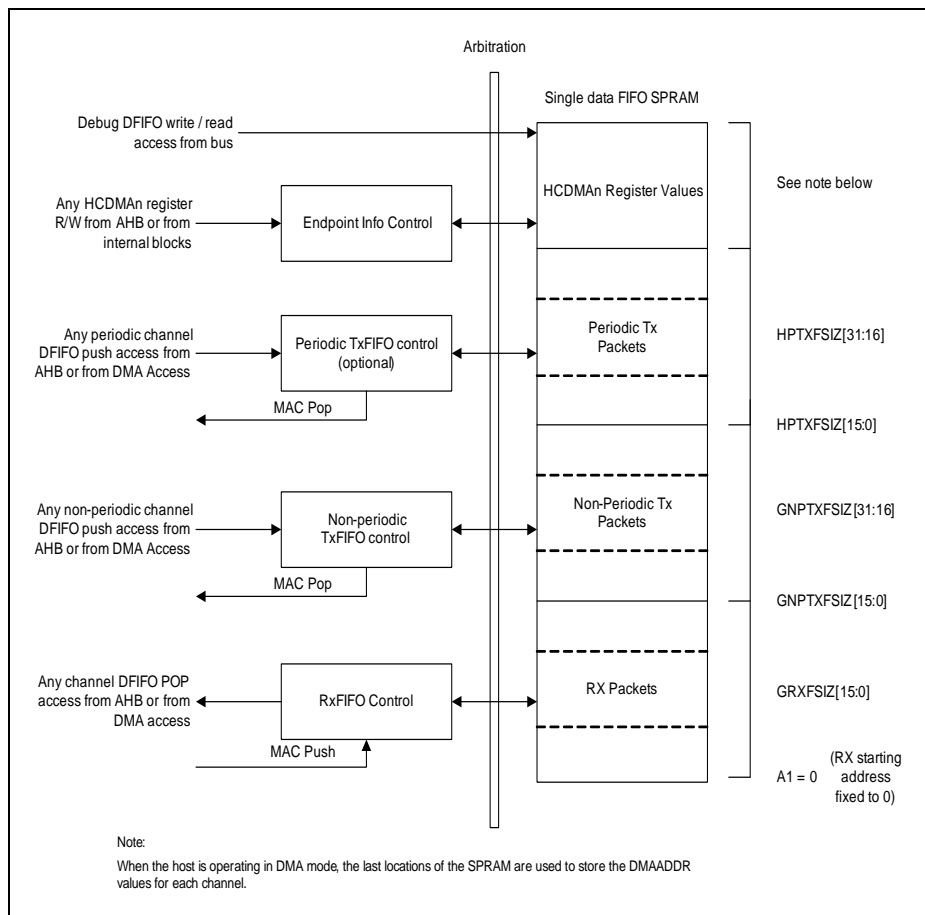

Figure 17-70 Host Mode FIFO Address Mapping

17.14.2 Dynamic FIFO Allocation

The application can change the RAM allocation for each FIFO during the operation of the core.

17.14.2.1 Dynamic FIFO Reallocation in Host Mode

In Host mode, before changing FIFO data RAM allocation, the application must determine the following:

- All channels are disabled
- All FIFOs are empty

Once these conditions are met, the application can reallocate FIFO data RAM as explained in **“Data FIFO RAM Allocation” on Page 17-223**.

After reallocating the FIFO data RAM, the application must flush all FIFOs in the core using the GRSTCTL.Tx FIFO Flush and GRSTCTL.Rx FIFO Flush fields. Flushing is required to reset the pointers in the FIFOs for proper FIFO operation after reallocation. For more information on flushing Tx FIFO, see **Flushing Tx FIFOs in the Core**.

17.14.2.2 Dynamic FIFO Reallocation in Device Mode

Dynamic FIFO re-allocation in device mode occurs when there is Power On Reset or a USB Reset.

In Device mode, before changing FIFO data RAM allocation,

1. The application must determine the following:
 - a) DIEPCTLn/DOEPCTLn.EPEna = 0_B
 - b) DIEPCTLn/DOEPCTLn.NAKSts = 1_B

If the bits are not set as above, follow the procedure in **“Transfer Stop Programming for OUT Endpoints” on Page 17-79** or **“Transfer Stop Programming for IN Endpoints” on Page 17-82** to ensure that all transfers on that endpoint are stopped.
2. Once these conditions are met, the application can reallocate FIFO data RAM as explained in **“Data FIFO RAM Allocation” on Page 17-223**.
3. Flush the Tx FIFO in the core using the GRSTCTL.Tx FIFO field. For more information on flushing Tx FIFO, see **Flushing Tx FIFOs in the Core**.

Note: The GlobalOUTNak process to disable OUT endpoints ensures that the Rx FIFO does not have any data, so an Rx FIFO flush is not required.

17.14.2.3 Flushing Tx FIFOs in the Core

The application can flush all Tx FIFOs in the core using GRSTCTL.Tx FFish as follows:

1. Check that GINTSTS.GINNAkEff=0. If this bit is cleared then set DCTL.SGNPInNak=1.
 NAK Effective interrupt = H indicating that the core is not reading from the FIFO.
2. Wait for GINTSTS.GINNAkEff=1, which indicates the NAK setting has taken effect to all IN endpoints.
3. Poll GRSTCTL.AHBIdle until it is 1.
 AHBIdle = H indicates that the core is not writing anything to the FIFO.
4. Check that GRSTCTL.Tx FFish =0. If it is 0, then write the Tx FIFO number you want to flush to GRSTCTL.TxFNum.
5. Set GRSTCTL.Tx FFish=1 and wait for it to clear.
6. Set the DCTL.GCNPInNak bit.

17.15 Service Request Generation

The USB module provides a single service request output connected to an interrupt node in the Nested Vectored Interrupt Controller (NVIC)

Figure 17-71 displays the USB core interrupt hierarchy.

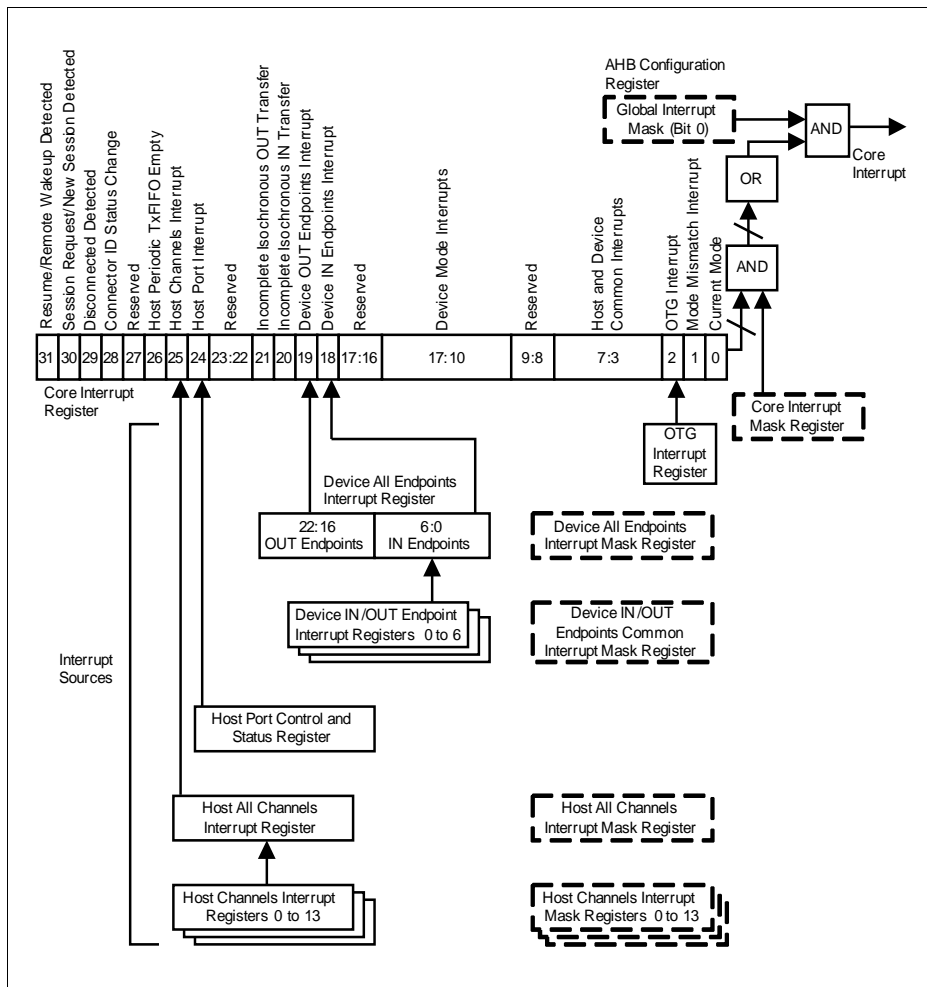

Figure 17-71 Interrupt Hierarchy

The Core Interrupt Handler

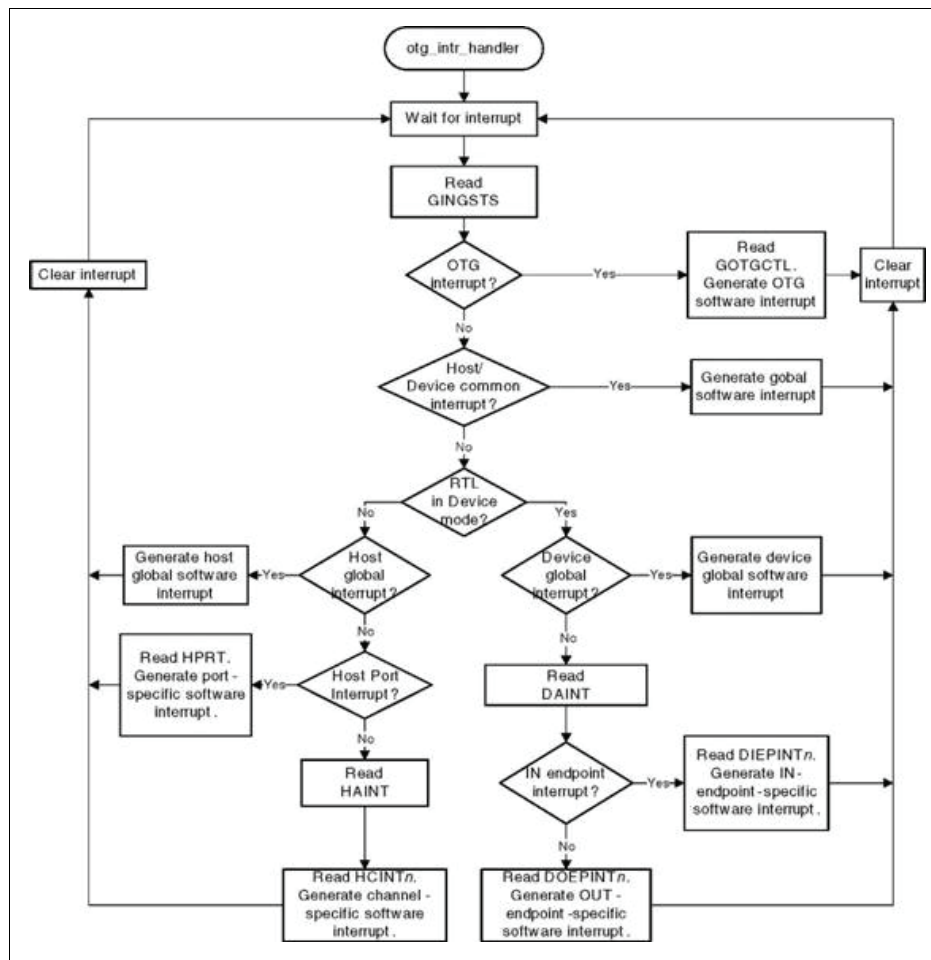

Figure 17-72 Core Interrupt Handler

17.16 Debug Behaviour

The USB module is not affected when the CPU enters HALT mode.

17.17 Power, Reset and Clock

When the USB module is programmed as a host, an external charge pump is required to drive the VBUS.

The module, including all registers, can be reset to its default state by a system reset or a software reset triggered through the setting of corresponding bits in PRSETx registers.

The module has the following input clocks:

- clk_ahbm: the module clock, which is also referred to as hclk in this chapter
- clk_usb: the 48 MHz PHY clock., which is also referred to as phy_clk in this chapter

In addition, the module internally generates:

- hclk_gated: hclk gated for power optimization

17.18 Initialization and System Dependencies

The USB core is held in reset after a start-up from a system or software reset. The USB PHY is also by default in the power-down state. Therefore, the application has to apply the following initialization sequence before programming the USB core:

- Release reset of USB core by writing a 1 to the USBRS bit in SCU_PRCLR2 register
- Enable the 48 MHz PHY clock by configuring the USB PLL in SCU, see clock control section in SCU chapter
- Remove the USB PHY from power-down by writing a 1 to the USBOTGEN and USBPHYPDQ bits in SCU_PWRSET register

17.19 Registers

Register Overview

The application controls the USB core by reading from and writing to the Control and Status Registers (CSRs) through the AHB Slave interface. These registers are 32 bits wide and the addresses are 32-bit block aligned.

Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessed in both Host and Device modes. When the USB core is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis).

When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset.

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 17-20 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| USB0 | 5004 0000 _H | 5007 FFFF _H | |

Figure 17-73 shows the CSR address map. Host and Device mode registers occupy different addresses.

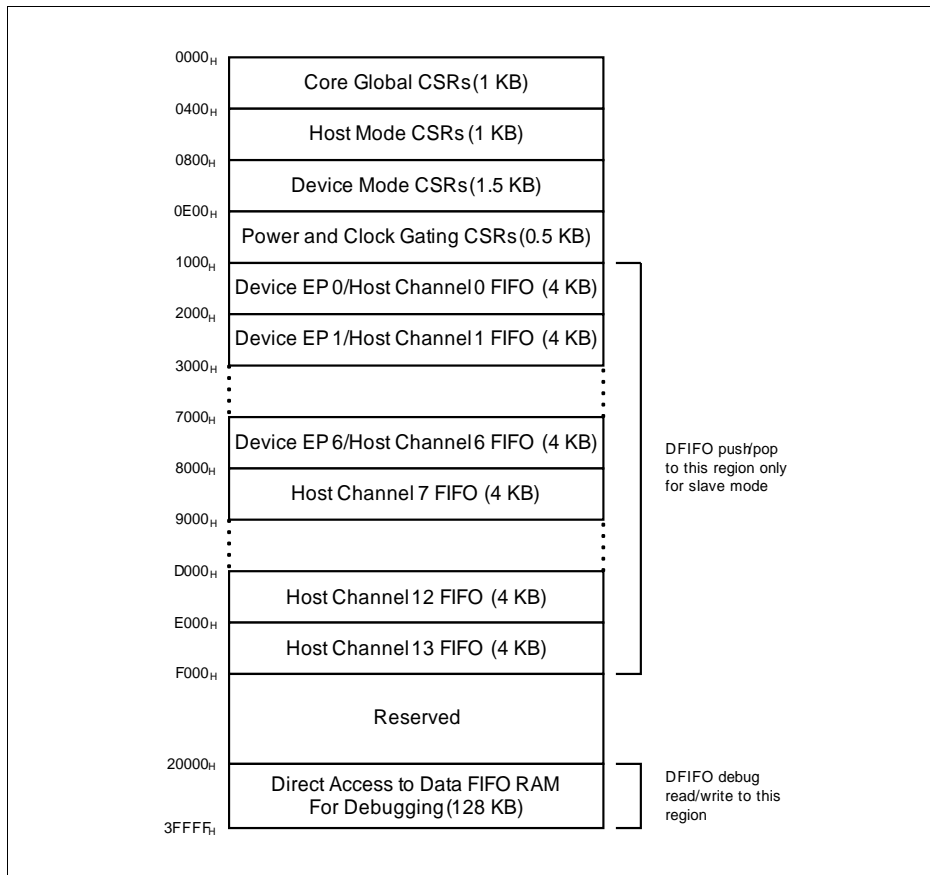

Figure 17-73 CSR Memory Map

The first letter of the register name is a prefix for the register type:

- G: Core Global
- H: Host mode
- D: Device mode

Note: FIFO size and FIFO depth are used interchangeably.

Table 17-21 Register Overview

| Short Name | Description | Offset Addr. | Access Mode | | Description See |

Data FIFO (DFIFO) Access Register Map

These registers, available in both Host and Device modes, are used to read or write the FIFO space for a specific endpoint or a channel, in a given direction. If a host channel is of type IN, the FIFO can only be read on the channel. Similarly, if a host channel is of type OUT, the FIFO can only be written on the channel.

Table 17-22 Data FIFO (DFIFO) Access Register Map

| FIFO Access Register Section | Address Range | Access |
|---|-------------------|--------|
| Device IN Endpoint 0/Host OUT Channel 0: DFIFO Write Access Device OUT Endpoint 0/Host IN Channel 0: DFIFO Read Access | $1000_H - 1FFC_H$ | WO/RO |
| Device IN Endpoint 1/Host OUT Channel 1: DFIFO Write Access Device OUT Endpoint 1/Host IN Channel 1: DFIFO Read Access | $2000_H - 2FFC_H$ | WO/RO |
| ... | ... | ... |

Universal Serial Bus (USB)

Table 17-22 Data FIFO (DFIFO) Access Register Map (cont'd)

| FIFO Access Register Section | Address Range | Access |
|---|----------------------|---------------|
| Device IN Endpoint 6/Host OUT Channel 6: DFIFO Write Access | 7000 _H - | WO/RO |
| Device OUT Endpoint 6/Host IN Channel 6: DFIFO Read Access | 7FFC _H | |
| Host OUT Channel 7: DFIFO Write Access | 8000 _H - | WO/RO |
| Host IN Channel 7: DFIFO Read Access | 8FFC _H | |
| ... | ... | ... |
| Host OUT Channel 13: DFIFO Write Access | E000 _H - | WO/RO |
| Host IN Channel 13: DFIFO Read Access | EFFC _H | |

Access Restriction

Note: The USB registers are accessible only through word accesses. Half-word and byte accesses on USB registers will not generate a bus error. Write to unused address space will not cause an error but be ignored.

17.19.1 Register Description

This section describes Core Global, Device Mode, Host Mode, and Power and Clock Gating CSRs.

Note: Always program Reserved fields with 0s. Treat read values from Reserved fields as unknowns (Xs).

Global Registers

These registers are available in both Host and Device modes, and do not need to be reprogrammed when switching between these modes.

Control and Status Register (GOTGCTL)

The OTG Control and Status register controls the behavior and reflects the status of the OTG function of the core.

Universal Serial Bus (USB)

GOTGCTL

Control and Status Register

(000_H)

Reset Value: 0001 0000_H

| Field | Bits | Type | Description |
|-----------------------|------|------|---|
| SesReqS cs | 0 | rh | Session Request Success The core sets this bit when a session request initiation is successful. 0 _B Session request failure 1 _B Session request success This bit is used in Device only. |
| SesReq | 1 | rw | Session Request The application sets this bit to initiate a session request on the USB. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is set. The core clears this bit when the HstNegSucStsChng bit is cleared. Since the USB 1.1 Full-Speed Serial Transceiver interface is used to initiate the session request, the application must wait until the Vbus discharges to 0.2 V, after the B-Session Valid bit in this register (GOTGCTL.BSesVld) is cleared. 0 _B No session request 1 _B Session request This bit is used in Device only. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------------|------|------|---|
| VbvalidOvEn | 2 | rw | VBUS Valid Override Enable This bit is used to enable/disable the software to override the vbus valid signal using the GOTGCTL.VbvalidOvVal. 0 _B Override is disabled and vbus valid signal from the PHY is used internally by the core. 1 _B Internally vbus valid received from the PHY is overridden with GOTGCTL.VbvalidOvVal. This bit is used in Host only. |
| VbvalidOvVal | 3 | rw | VBUS Valid Override Value This bit is used to set the override value for vbus valid signal when GOTGCTL.VbvalidOvEn is set. 0 _B vbusvalid value is 0 _B when GOTGCTL.VbvalidOvEn = 1 1 _B vbusvalid value is 1 _B when GOTGCTL.VbvalidOvEn = 1 This bit is used in Host only. |
| AvalidOvEn | 4 | rw | A-Peripheral Session Valid Override Enable This bit is used to enable/disable the software to override the Avalid signal using the GOTGCTL.AvalidOvVal. 0 _B Override is disabled and Avalid signal from the PHY is used internally by the core. 1 _B Internally Avalid received from the PHY is overridden with GOTGCTL.AvalidOvVal. This bit is used in Host only. |
| AvalidOvVal | 5 | rw | A-Peripheral Session Valid Override Value This bit is used to set the override value for Avalid signal when GOTGCTL.AvalidOvEn is set. 0 _B Avalid value is 0 _B when GOTGCTL.AvalidOvEn = 1 1 _B Avalid value is 1 _B when GOTGCTL.AvalidOvEn = 1 This bit is used in Host only. |
| BvalidOvEn | 6 | rw | B-Peripheral Session Valid Override Enable This bit is used to enable/disable the software to override the Bvalid signal using the GOTGCTL.BvalidOvVal. 0 _B Override is disabled and Bvalid signal from the PHY is used internally by the core. 1 _B Internally Bvalid received from the PHY is overridden with GOTGCTL.BvalidOvVal. This bit is used in Device only. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------------|------|------|--|
| BvalidOvVal | 7 | rw | B-Peripheral Session Valid Override Value This bit is used to set the override value for Bvalid signal when GOTGCTL.BvalidOvEn is set. 0 _B Bvalid value is 0 _B when GOTGCTL.BvalidOvEn = 1 1 _B Bvalid value is 1 _B when GOTGCTL.BvalidOvEn = 1 This bit is used in Device only. |
| HstNegSs | 8 | rh | Host Negotiation Success The core sets this bit when host negotiation is successful. The core clears this bit when the HNP Request (HNPREq) bit in this register is set. 0 _B Host negotiation failure 1 _B Host negotiation success This bit is used in Device only. |
| HNPREq | 9 | rw | HNP Request The application sets this bit to initiate an HNP request to the connected USB host. The application can clear this bit by writing a 0 when the Host Negotiation Success Status Change bit in the OTG Interrupt register (GOTGINT.HstNegSucStsChng) is set. The core clears this bit when the HstNegSucStsChng bit is cleared. 0 _B No HNP request 1 _B HNP request This bit is used in Device only. |
| HstSetHNPEn | 10 | rw | Host Set HNP Enable The application sets this bit when it has successfully enabled HNP (using the SetFeature.SetHNPEnable command) on the connected device. 0 _B Host Set HNP is not enabled 1 _B Host Set HNP is enabled This bit is used in Host only. |
| DevHNPEn | 11 | rw | Device HNP Enabled The application sets this bit when it successfully receives a SetFeature.SetHNPEnable command from the connected USB host. 0 _B HNP is not enabled in the application 1 _B HNP is enabled in the application This bit is used in Device only. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-----------------|------|------|--|
| ConIDSts | 16 | rh | Connector ID Status Indicates the connector ID status on a connect event. 0 _B The USB core is in A-Device mode 1 _B The USB core is in B-Device mode |
| DbncTime | 17 | rh | Long/Short Debounce Time Indicates the debounce time of a detected connection. 0 _B Long debounce time, used for physical connections (100 ms + 2.5 μs) 1 _B Short debounce time, used for soft connections (2.5 μs) This bit is used in Host only. |
| ASesVld | 18 | rh | A-Session Valid Indicates the Host mode transceiver status. 0 _B A-session is not valid 1 _B A-session is valid <i>Note: If the OTG features (such as SRP and HNP) are not enabled, the read reset value will be 1.</i> This bit is used in Host only. |
| BSesVld | 19 | rh | B-Session Valid Indicates the Device mode transceiver status. 0 _B B-session is not valid. 1 _B B-session is valid. In OTG mode, this bit can be used to determine if the device is connected or disconnected. <i>Note: If the OTG features (such as SRP and HNP) are not enabled, the read reset value will be 1.</i> This bit is used in Device only. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|-------------------------|------|--|
| OTGVer | 20 | rw | OTG Version Indicates the OTG revision. 0 _B OTG Version 1.3. In this version the core supports Data line pulsing and VBus pulsing for SRP. 1 _B OTG Version 2.0. In this version the core supports only Data line pulsing for SRP. <i>Note: XMC4[78]00 supports only OTG Version 1.3. Therefore, the OTGVer bit should always be written with 0.</i> |
| 0 | [15:12] , [31:21] | r | Reserved Read as 0; should be written with 0. |

Interrupt Register (GOTGINT)

The application reads this register whenever there is an OTG interrupt and clears the bits in this register to clear the OTG interrupt.

Note: All bits in this register are set only by hardware and cleared only by a software write of 1 to the bit.

GOTGINT

OTG Interrupt Register

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------------|---|------|--|
| SesEndDet | 2 | rwh | Session End Detected The core sets this bit when the bvalid signal is deasserted. This bit is used in Device only. |
| SesReqSucStsChng | 8 | rwh | Session Request Success Status Change The core sets this bit on the success or failure of a session request. The application must read the Session Request Success bit in the OTG Control and Status register (GOTGCTL.SesReqScs) to check for success or failure. |
| HstNegSucStsChng | 9 | rwh | Host Negotiation Success Status Change The core sets this bit on the success or failure of a USB host negotiation request. The application must read the Host Negotiation Success bit of the OTG Control and Status register (GOTGCTL.HstNegScs) to check for success or failure. |
| HstNegDet | 17 | rwh | Host Negotiation Detected The core sets this bit when it detects a host negotiation request on the USB. |
| ADevTOU Tchg | 18 | rwh | A-Device Timeout Change The core sets this bit to indicate that the A-device has timed out while waiting for the B-device to connect. |
| DbnceDone | 19 | rwh | Debounce Done The core sets this bit when the debounce is completed after the device connect. The application can start driving USB reset after seeing this interrupt. This bit is only valid when the HNP Capable or SRP Capable bit is set in the Core USB Configuration register (GUSBCFG.HNPCap or GUSBCFG.SRPCap, respectively). This bit is used in Host only. |
| 0 | [31:20], [16:10], [7:3], [1:0] | r | Reserved Read as 0; should be written with 0. |

AHB Configuration Register (GAHBCFG)

This register can be used to configure the core after power-on or a change in mode. This register mainly contains AHB system-related configuration parameters. Do not change

Universal Serial Bus (USB)

this register after the initial programming. The application must program this register before starting any transactions on either the AHB or the USB.

| Field | Bits | Type | Description |
|---------|-------|------|---|
| TOutCal | [2:0] | rw | FS Timeout Calibration The number of PHY clocks that the application programs in this field is added to the full-speed interpacket timeout duration in the core to account for any additional delays introduced by the PHY. This can be required, because the delay introduced by the PHY in generating the line state condition can vary from one PHY to another. The USB standard timeout value for full-speed operation is 16 to 18 (inclusive) bit times. The application must program this field based on the speed of enumeration. The number of bit times added per PHY clock is 0.25 bit times |
| PHYSel | 6 | r | USB 1.1 Full-Speed Serial Transceiver Select This bit is always read as 1 to indicate a full-speed transceiver is selected. 0 _B Reserved 1 _B USB 1.1 full-speed serial transceiver |
| SRPCap | 8 | rw | SRP-Capable The application uses this bit to control the USB core SRP capabilities. If the core operates as a non-SRP-capable B-device, it cannot request the connected A-device (host) to activate VBUS and start a session. 0 _B SRP capability is not enabled. 1 _B SRP capability is enabled. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------------|---------|------|--|
| HNPCap | 9 | rw | HNP-Capable The application uses this bit to control the USB core's HNP capabilities. 0 _B HNP capability is not enabled. 1 _B HNP capability is enabled. |
| USBTrdTim | [13:10] | rw | USB Turnaround Time Sets the turnaround time in PHY clocks. Specifies the response time for a MAC request to the Packet FIFO Controller (PFC) to fetch data from the DFIFO (SPRAM). <i>Note: USB turnaround time is critical for certification where long cables and 5-Hubs are used. See "Choosing the Value of GUSBCFG.USBTrdTim" on Page 17-83.</i> This bit is used in Device Only. |
| OtgI2CSel | 16 | rw | UTMIFS Interface Select The application uses this bit to select the USB 1.1 Full-Speed interface. 0 _B UTMI USB 1.1 Full-Speed interface for OTG signals 1 _B Reserved This bit should always be written with 0. |
| TxEndDelay | 28 | rw | Tx End Delay Writing a 1 to this bit enables the TxEndDelay timers in the core as per the section 4.1.5 on Opmode of the USB 2.0 Transceiver Macrocell Interface (UTMI) version 1.05. 0 _B Normal mode 1 _B Introduce Tx end delay timers This bit is used in Device Only. |
| ForceHstMode | 29 | rw | Force Host Mode Writing a 1 to this bit forces the core to host mode irrespective of connected plug. 0 _B Normal Mode 1 _B Force Host Mode After setting the force bit, the application must wait at least 25 ms before the change to take effect. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------------|----------------------------------|------|---|
| ForceDev Mode | 30 | rw | Force Device Mode Writing a 1 to this bit forces the core to device mode irrespective of connected plug. 0 _B Normal Mode 1 _B Force Device Mode After setting the force bit, the application must wait at least 25 ms before the change to take effect. |
| CTP | 31 | rw | Corrupt Tx packet This bit is for debug purposes only. Never set this bit to 1. |
| 0 | [27:17], [15:14], 7, [5:3] | r | Reserved Read as 0; should be written with 0. |

Reset Register (GRSTCTL)

The application uses this register to reset various hardware features inside the core.

GRSTCTL

Reset Register

(010_H)

Reset Value: 1000 0000_H

| | | | | | | | | | | | | | | | |
|-----------------|----------------|----------|----|----|---------------|----|----|----|----|-----------------|-----------------|----------|---------------------|----------|-----------------|

| Field | Bits | Type | Description |
|-------------------|------|------|---|
| CSftRst | 0 | rwh | <p>Core Soft Reset</p> <p>Resets the hclk and phy_clock domains as follows:</p> <ul style="list-style-type: none"> • Clears the interrupts and all the CSR registers except the following register bits: <ul style="list-style-type: none"> – PCGCCTL.GateHclk – GUSBCFG.PHYSel – HCFG.FSLSPclkSel – DCFG.DevSpd – GGPIO • All module state machines (except the AHB Slave Unit) are reset to the IDLE state, and all the transmit FIFOs and the receive FIFO are flushed. • Any transactions on the AHB Master are terminated as soon as possible, after gracefully completing the last data phase of an AHB transfer. Any transactions on the USB are terminated immediately. <p>The application can write to this bit any time it wants to reset the core. This is a self-clearing bit and the core clears this bit after all the necessary logic is reset in the core, which can take several clocks, depending on the current state of the core. Once this bit is cleared software must wait at least 3 PHY clocks before doing any access to the PHY domain (synchronization delay). Software must also must check that bit 31 of this register is 1 (AHB Master is IDLE) before starting any operation.</p> <p>Typically software reset is used during software development.</p> |
| FrmCntrRst | 2 | rwh | <p>Host Frame Counter Reset</p> <p>The application writes this bit to reset the frame number counter inside the core. When the frame counter is reset, the subsequent SOF sent out by the core has a frame number of 0.</p> <p>This bit is used in Host only.</p> <p>This bit is set only by software and cleared only by hardware.</p> |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------|------|------|--|
| RxFFlsh | 4 | rwh | <p>RxFIFO Flush</p> <p>The application can flush the entire RxFIFO using this bit, but must first ensure that the core is not in the middle of a transaction.</p> <p>The application must only write to this bit after checking that the core is neither reading from the RxFIFO nor writing to the RxFIFO.</p> <p>The application must wait until the bit is cleared before performing any other operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.</p> <p>This bit is set only by software and cleared only by hardware.</p> |
| TxFFlsh | 5 | rwh | <p>TxFIFO Flush</p> <p>This bit selectively flushes a single or all transmit FIFOs, but cannot do so if the core is in the midst of a transaction. The application must write this bit only after checking that the core is neither writing to the TxFIFO nor reading from the TxFIFO. Verify using these registers:</p> <ul style="list-style-type: none"> • Read—NAK Effective Interrupt ensures the core is not reading from the FIFO • Write—GRSTCTL.AHBIdle ensures the core is not writing anything to the FIFO. <p>Flushing is normally recommended when FIFOs are re-configured. FIFO flushing is also recommended during device endpoint disable.</p> <p>The application must wait until the core clears this bit before performing any operations. This bit requires 8 clocks (slowest of PHY or AHB clock) to clear.</p> <p>This bit is set only by software and cleared only by hardware.</p> |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------|-------------------|------|--|
| TxFNum | [10:6] | rw | TxFIFO Number This is the FIFO number that must be flushed using the TxFIFO Flush bit. This field must not be changed until the core clears the TxFIFO Flush bit. 00 _H Non-periodic TxFIFO flush in Host mode or Tx FIFO 0 flush in device mode 01 _H Periodic TxFIFO flush in Host mode or Tx FIFO 1 flush in device mode 02 _H Tx FIFO 2 flush in device mode ... _H ... 0F _H Tx FIFO 15 flush in device mode 10 _H Flush all the transmit FIFOs in device or host mode. |
| DMAReq | 30 | r | DMA Request Signal Indicates that the DMA request is in progress. Used for debug. |
| AHBIdle | 31 | r | AHB Master Idle Indicates that the AHB Master State Machine is in the IDLE condition. |
| 0 | [29:11] , 3, 1 | r | Reserved Read as 0; should be written with 0. |

Interrupt Register (GINTSTS)

This register interrupts the application for system-level events in the current mode (Device mode or Host mode). It is shown in [Figure 17-71](#).

Some of the bits in this register are valid only in Host mode, while others are valid in Device mode only. This register also indicates the current mode.

Note: In the GINTSTS register, interrupt status bits with access type 'rwh' are set by hardware. To clear these bits, the application must write 1 into these bits.

The FIFO status interrupts are read only; once software reads from or writes to the FIFO while servicing these interrupts, FIFO interrupt conditions are cleared automatically.

The application must clear the GINTSTS register at initialization before unmasking the interrupt bit to avoid any interrupts generated prior to initialization.

GINTSTS

Interrupt Register [HOSTMODE]

|----------------|------|------|---|
| CurMod | 0 | rh | Current Mode of Operation Indicates the current mode. 0 _B Device mode 1 _B Host mode |
| ModeMis | 1 | rwh | Mode Mismatch Interrupt The core sets this bit when the application is trying to access: <ul style="list-style-type: none"> A Host mode register, when the core is operating in Device mode A Device mode register, when the core is operating in Host mode The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core. |
| OTGInt | 2 | rh | OTG Interrupt The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the GOTGINT register to clear this bit. |
| Sof | 3 | rwh | Start of Frame In Host mode, the core sets this bit to indicate that an SOF is transmitted on the USB. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------------|------|------|---|
| RxFLvl | 4 | rh | RxFIFO Non-Empty Indicates that there is at least one packet pending to be read from the RxFIFO. |
| incomplP | 21 | rwh | Incomplete Periodic Transfer In Host mode , the core sets this interrupt bit when there are incomplete periodic transactions still pending which are scheduled for the current frame. |
| PrtlInt | 24 | rh | Host Port Interrupt The core sets this bit to indicate a change in port status of one of the USB core ports in Host mode. The application must read the Host Port Control and Status (HPRT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the Host Port Control and Status register to clear this bit. |
| HChInt | 25 | rh | Host Channels Interrupt The core sets this bit to indicate that an interrupt is pending on one of the channels of the core (in Host mode). The application must read the Host All Channels Interrupt (HAINT) register to determine the exact number of the channel on which the interrupt occurred, and then read the corresponding Host Channel-n Interrupt (HCINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the HCINTx register to clear this bit. |
| PTxFEmp | 26 | rh | Periodic Tx FIFO Empty This interrupt is asserted when the Periodic Transmit FIFO is either half or completely empty and there is space for at least one entry to be written in the Periodic Request Queue. The half or completely empty status is determined by the Periodic Tx FIFO Empty Level bit in the Core AHB Configuration register (GAHB_CFG.PTxFEmpLvl). |
| ConIDSts Chng | 28 | rwh | Connector ID Status Change This interrupt is asserted when there is a change in connector ID status. |
| DisconnInt | 29 | rwh | Disconnect Detected Interrupt This interrupt is asserted when a device disconnect is detected. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------|---------------------|------|---|

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------|------|------|---|
| CurMod | 0 | rh | Current Mode of Operation Indicates the current mode. 0 _B Device mode 1 _B Host mode |
| ModeMis | 1 | rwh | Mode Mismatch Interrupt The core sets this bit when the application is trying to access: <ul style="list-style-type: none"> A Host mode register, when the core is operating in Device mode A Device mode register, when the core is operating in Host mode The register access is completed on the AHB with an OKAY response, but is ignored by the core internally and does not affect the operation of the core. |
| OTGInt | 2 | rh | OTG Interrupt The core sets this bit to indicate an OTG protocol event. The application must read the OTG Interrupt Status (GOTGINT) register to determine the exact event that caused this interrupt. The application must clear the appropriate status bit in the GOTGINT register to clear this bit. |
| Sof | 3 | rwh | Start of Frame In Device mode, the core sets this bit to indicate that an SOF token has been received on the USB. The application can read the Device Status register to get the current frame number. |
| RxFLvl | 4 | rh | RxFIFO Non-Empty Indicates that there is at least one packet pending to be read from the RxFIFO. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------|------|------|---|
| GINNakEff | 6 | rh | Global IN Non-Periodic NAK Effective Indicates that the Set Global Non-periodic IN NAK bit in the Device Control register (DCTL.SGNPInNak), set by the application, has taken effect in the core. That is, the core has sampled the Global IN NAK bit set by the application. This bit can be cleared by clearing the Clear Global Non-periodic IN NAK bit in the Device Control register (DCTL.CGNPInNak). This interrupt does not necessarily mean that a NAK handshake is sent out on the USB. The STALL bit takes precedence over the NAK bit. |
| GOUTNakEff | 7 | rh | Global OUT NAK Effective Indicates that the Set Global OUT NAK bit in the Device Control register (DCTL.SGOUTNak), set by the application, has taken effect in the core. This bit can be cleared by writing the Clear Global OUT NAK bit in the Device Control register (DCTL.CGOUTNak). |
| ErlySusp | 10 | rwh | Early Suspend The core sets this bit to indicate that an Idle state has been detected on the USB for 3 ms. |
| USBSusp | 11 | rwh | USB Suspend The core sets this bit to indicate that a suspend was detected on the USB. The core enters the Suspended state when there is no activity on the two USB data signals for an extended period of time. |
| USBRst | 12 | rwh | USB Reset The core sets this bit to indicate that a reset is detected on the USB. |
| EnumDone | 13 | rwh | Enumeration Done The core sets this bit to indicate that speed enumeration is complete. The application must read the Device Status (DSTS) register to obtain the enumerated speed. |
| ISOOutDrop | 14 | rwh | Isochronous OUT Packet Dropped Interrupt The core sets this bit when it fails to write an isochronous OUT packet into the RxFIFO because the RxFIFO does not have enough space to accommodate a maximum packet size packet for the isochronous OUT endpoint. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------------|------|------|---|
| EOPF | 15 | rwh | End of Periodic Frame Interrupt Indicates that the period specified in the Periodic Frame Interval field of the Device Configuration register (DCFG.PerFrInt) has been reached in the current frame. |
| IEPInt | 18 | r | IN Endpoints Interrupt The core sets this bit to indicate that an interrupt is pending on one of the IN endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the IN endpoint on which the interrupt occurred, and then read the corresponding Device IN Endpoint-n Interrupt (DIEPINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DIEPINTx register to clear this bit. |
| OEPInt | 19 | r | OUT Endpoints Interrupt The core sets this bit to indicate that an interrupt is pending on one of the OUT endpoints of the core (in Device mode). The application must read the Device All Endpoints Interrupt (DAINT) register to determine the exact number of the OUT endpoint on which the interrupt occurred, and then read the corresponding Device OUT Endpoint-n Interrupt (DOEPINTx) register to determine the exact cause of the interrupt. The application must clear the appropriate status bit in the corresponding DOEPINTx register to clear this bit. |
| incomplS OIN | 20 | rwh | Incomplete Isochronous IN Transfer The core sets this interrupt to indicate that there is at least one isochronous IN endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. <i>Note: This interrupt is not asserted in Scatter/Gather DMA mode.</i> |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------------------|---------------------------------|------|--|
| incomplS OOUT | 21 | rwh | Incomplete Isochronous OUT Transfer In the Device mode, the core sets this interrupt to indicate that there is at least one isochronous OUT endpoint on which the transfer is not completed in the current frame. This interrupt is asserted along with the End of Periodic Frame Interrupt (EOPF) bit in this register. |
| ConIDSts Chng | 28 | rwh | Connector ID Status Change This interrupt is asserted when there is a change in connector ID status. |
| SessReqI nt | 30 | rwh | Session Request/New Session Detected Interrupt In Host mode, this interrupt is asserted when a session request is detected from the device. In Device mode, this interrupt is asserted when the Bvalid signal goes high. |

Interrupt Mask Register (GINTMSK)

This register works with the Interrupt Register ("**Interrupt Register (GINTSTS)**" on [Page 17-256](#)) to interrupt the application. When an interrupt bit is masked, the interrupt associated with that bit is not generated. However, the GINTSTS register bit corresponding to that interrupt is still set.

- Mask interrupt: 0_B
- Unmask interrupt: 1_B

Receive Status Debug Read/Status Read and Pop Registers (GRXSTSR/GRXSTSP)

A read to the Receive Status Debug Read register returns the contents of the top of the Receive FIFO. A read to the Receive Status Read and Pop register additionally pops the top data entry out of the Rx FIFO.

The receive status contents must be interpreted differently in Host and Device modes. The core ignores the receive status pop/read when the receive FIFO is empty and returns a value of 0000'0000_H. The application must only pop the Receive Status FIFO

Universal Serial Bus (USB)

when the Receive FIFO Non-Empty bit of the Core Interrupt register (GINTSTS.RxFLVL) is asserted.

Notes

1. Use of these fields vary based on whether the OTG core is functioning as a host or a device.
2. Do not read this register's reset value before configuring the core because the read value is "X".

|----------------|---------|------|--|
| GDFIFOcfg | [15:0] | rw | GDFIFOcfg This field is for dynamic programming of the DFIFO Size. This value takes effect only when the application programs a non zero value to this register. The value programmed must conform to the guidelines described in “Data FIFO RAM Allocation” on Page 17-223 . The USB core does not have any corrective logic if the FIFO sizes are programmed incorrectly. |
| EPInfoBaseAddr | [31:16] | rw | EPInfoBaseAddr This field provides the start address of the RAM space allocated to store register information in DMA mode. See “Data FIFO RAM Allocation” on Page 17-223 . |

Host Periodic Transmit FIFO Size Register (HPTXFSIZ)

This register holds the size and the memory start address of the Periodic Tx FIFO.

HPTXFSIZ

Host Periodic Transmit FIFO Size Register(100_H)

Reset Value: 0100 012A_H

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| PTxStAddr | [15:0] | rw | Host Periodic Tx FIFO Start Address The power-on reset value of this register is the sum of the Largest Rx Data FIFO Depth and Largest Non-periodic Tx Data FIFO Depth. Programmed values must not exceed the power-on value . |
| PTxFSiz | [31:16] | rw | Host Periodic Tx FIFO Depth This value is in terms of 32-bit words. Minimum value is 16 Maximum value is 256 Programmed values must not exceed the maximum value. |

Device IN Endpoint Transmit FIFO Size Register (DIEPTXF_n)

This register holds the size and memory start address of IN endpoint TxFIFOs implemented in Device mode. Each FIFO holds the data for one IN endpoint. This register is repeated for instantiated IN endpoint FIFOs 1 to 6. For IN endpoint FIFO 0 use GNPTXFSIZ register for programming the size and memory start address.

Note: The reset value of the register serves as a limit value and does not represent the implemented FIFO RAM size. The application must configure these registers in a way that the implemented FIFO RAM size is not exceeded.

DIEPTXF1

Device IN Endpoint 1 Transmit FIFO Size Register(104_H) Reset Value: 0100 012A_H

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| INEPnTxFStAddr | [15:0] | rw | IN Endpoint FIFO_n Transmit RAM Start Address This field contains the memory start address for IN endpoint Transmit FIFO _n (1 < n ≤ 6). Programmed values must not exceed the reset value. |
| INEPnTxFDep | [31:16] | rw | IN Endpoint TxFIFO Depth This value is in terms of 32-bit words. <ul style="list-style-type: none"> Minimum value is 16 Maximum value is 256 Programmed values must not exceed the maximum value. |

Host Mode Registers

These registers affect the operation of the core in the Host mode. Host mode registers must not be accessed in Device mode, as the results are undefined. Host Mode registers can be categorized as follows:

Host Configuration Register (HCFG)

This register configures the core after power-on. Do not make changes to this register after initializing the host.

HCFG

Host Configuration Register (400_H) **Reset Value: 0000 0200_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|-------------|----------|---------|----|----|----|----|----|----------|-------------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | PerSchedEna | FrListEn | DescDMA | 0 | | | | | | | |
| r | | | | | rw | rw | rw | r | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | 1 | 0 | | | | | | FSLSSupp | FSLSPclkSel | |
| r | | | | | | r | r | | | | | | rw | rw | |

| Field | Bits | Type | Description |
|--------------------|-------|------|---|
| FSLSPclkSel | [1:0] | rw | FS PHY Clock Select 01 _B PHY clock is running at 48 MHz Others: Reserved |
| FSLSSupp | 2 | rw | FS-Only Support The application uses this bit to control the core's enumeration speed. Using this bit, the application can make the core enumerate as a FS host, even if the connected device supports HS traffic. Do not make changes to this field after initial programming. 0 _B FS-only, connected device can supports also only FS. 1 _B FS-only, even if the connected device can support HS |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------------|---------|------|---|
| DescDMA | 23 | rw | <p>Enable Scatter/gather DMA in Host mode</p> <p>The application can set this bit during initialization to enable the Scatter/Gather DMA operation.</p> <p><i>Note: This bit must be modified only once after a reset. The following combinations are available for programming:</i></p> <ul style="list-style-type: none"> GAHBCFG.DMAEn=0, HCFG.DescDMA=0 => Slave mode GAHBCFG.DMAEn=0, HCFG.DescDMA=1 => Invalid GAHBCFG.DMAEn=1, HCFG.DescDMA=0 => Buffered DMA mode GAHBCFG.DMAEn=1, HCFG.DescDMA=1 => Scatter/Gather DMA mode <p>In non Scatter/Gather DMA mode, this bit is reserved.</p> |
| FrListEn | [25:24] | rw | <p>Frame List Entries</p> <p>This field is valid only in Scatter/Gather DMA mode. The value in the register specifies the number of entries in the Frame list.</p> <p>00_B 8 Entries 01_B 16 Entries 10_B 32 Entries 11_B 64 Entries</p> <p>In modes other than Scatter/Gather DMA mode, these bits are reserved.</p> |
| PerSched Ena | 26 | rw | <p>Enable Periodic Scheduling</p> <p>Applicable in Scatter/Gather DMA mode only. Enables periodic scheduling within the core. Initially, the bit is reset. The core will not process any periodic channels. As soon as this bit is set, the core will get ready to start scheduling periodic channels and sets HCFG.PerSchedStat. The setting of HCFG.PerSchedStat indicates the core has enabled periodic scheduling. Once HCFG.PerSchedEna is set, the application is not supposed to again reset the bit unless HCFG.PerSchedStat is set. As soon as this bit is reset, the core will get ready to stop scheduling periodic channels and resets HCFG.PerSchedStat.</p> <p>In non Scatter/Gather DMA mode, this bit is reserved.</p> |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------|------------------------------------|------|---|
| 1 | 9 | r | Reserved Read as 1; should be written with 1. |
| 0 | [31:27] , [22:10] , [8:3] | r | Reserved Read as 0; should be written with 0. |

Host Frame Interval Register (HFIR)

This register stores the frame interval information for the current speed to which the USB core has enumerated.

HFIR

Host Frame Interval Register

(404_H)

Reset Value: 0000 EA60_H

| Field | Bits | Type | Description |
|--------------------|---------|------|--|
| FrInt | [15:0] | rw | Frame Interval The value that the application programs to this field specifies the interval between two consecutive SOFs. This field contains the number of PHY clocks that constitute the required frame interval. The default value set in this field for a FS operation when the PHY clock frequency is 60 MHz. The application can write a value to this register only after the Port Enable bit of the Host Port Control and Status register (HPRT.PrtEnaPort) has been set. If no value is programmed, the core calculates the value based on the PHY clock specified in the FS PHY Clock Select field of the Host Configuration register (HCFG.FSLSPckSel). Do not change the value of this field after the initial configuration. <ul style="list-style-type: none"> 1 ms * (PHY clock frequency for FS) |
| HFIRIdC trl | 16 | rw | Reload Control This bit allows dynamic reloading of the HFIR register during runtime. 0 _B HFIR cannot be reloaded dynamically 1 _B HFIR can be dynamically reloaded during runtime This bit needs to be programmed during the initial configuration and its value must not be changed during runtime. |
| 0 | [31:17] | r | Reserved Read as 0; should be written with 0. |

Host Frame Number/Frame Time Remaining Register (HFNUM)

This register indicates the current frame number. It also indicates the time remaining (in terms of the number of PHY clocks) in the current frame.

HFNUM

Host Frame Number/Frame Time Remaining Register

(408_H)
Reset Value: 0000 3FFF_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FrRem | | | | | | | | | | | | | | | | FrNum | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | | rw | | | | | | | | | | | | | | | |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| FrNum | [15:0] | rw | Frame Number This field increments when a new SOF is transmitted on the USB, and is reset to 0 _H when it reaches 3FFF _H . |
| FrRem | [31:16] | r | Frame Time Remaining Indicates the amount of time remaining in the current frame, in terms of PHY clocks. This field decrements on each PHY clock. When it reaches zero, this field is reloaded with the value in the Frame Interval register and a new SOF is transmitted on the USB. |

Host Periodic Transmit FIFO/Queue Status Register (HPTXSTS)

This read-only register contains the free space information for the Periodic Tx FIFO and the Periodic Transmit Request Queue.

HPTXSTS

**Host Periodic Transmit FIFO/
Queue Status Register**

(410_H)

Reset Value: 0008 0100_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|----------------------|---------|------|---|
| PTxFSpC Avail | [15:0] | rw | Periodic Transmit Data FIFO Space Available Indicates the number of free locations available to be written to in the Periodic Tx FIFO. Values are in terms of 32-bit words 0 _H Periodic Tx FIFO is full 1 _H 1 word available 2 _H 2 words available Others: Up to n words can be selected (0 < n < 256); selections greater than n are reserved |
| PTxQSpC Avail | [23:16] | r | Periodic Transmit Request Queue Space Available Indicates the number of free locations available to be written in the Periodic Transmit Request Queue. This queue holds both IN and OUT requests. 0 _H Periodic Transmit Request Queue is full 1 _H 1 location available 2 _H 2 locations available Others: Up to n locations can be selected (0 < n < 8); selections greater than n are reserved |
| PTxQTop | [31:24] | r | Top of the Periodic Transmit Request Queue This indicates the entry in the Periodic Tx Request Queue that is currently being processed by the MAC. This register is used for debugging. Bit [31]: Odd/Even frame 0 _B send in even frame 1 _B send in odd frame Bits [30:27]: Channel/endpoint number Bits [26:25]: Type 00 _B IN/OUT 01 _B Zero-length packet 10 _B Reserved 11 _B Disable channel command Bit [24]: Terminate (last entry for the selected channel/endpoint) |

Host All Channels Interrupt Register (HAINT)

When a significant event occurs on a channel, the Host All Channels Interrupt register interrupts the application using the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt). This is shown in [Figure 17-71 “Interrupt Hierarchy” on](#)

Universal Serial Bus (USB)

Page 17-232. There is one interrupt bit per channel, up to a maximum of 14 bits. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Host Channel- n Interrupt register.

HAINT

Host All Channels Interrupt Register (414_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| HAINT | [13:0] | rh | Channel Interrupts One bit per channel: Bit 0 for Channel 0, bit 13 for Channel 13 |
| 0 | [31:14] | r | Reserved Read as 0; should be written with 0. |

Host All Channels Interrupt Mask Register (HAINTMSK)

The Host All Channel Interrupt Mask register works with the Host All Channel Interrupt register to interrupt the application when an event occurs on a channel. There is one interrupt mask bit per channel, up to a maximum of 14 bits.

- Mask interrupt: 0_B
- Unmask interrupt: 1_B

HAINTMSK

Host All Channels Interrupt Mask Register(418_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|---------|------|--|
| HAINTMSk | [13:0] | rw | Channel Interrupt Mask One bit per channel: Bit 0 for channel 0, bit 13 for channel 13 |
| 0 | [31:14] | r | Reserved Read as 0; should be written with 0. |

Host Frame List Base Address Register (HFLBADDR)

This register holds the starting address of the Frame list information. It is present only in case of Scatter/Gather DMA and used only for Isochronous and Interrupt Channels. The register is implemented in RAM.

HFLBADDR

Host Frame List Base Address Register(41C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------------------|--------|------|--|
| Starting Address | [31:0] | rw | Starting Address The starting address of the Frame list. |

Host Port Control and Status Register (HPRT)

This register is available only in Host mode. Currently, the OTG Host supports only one port.

A single register holds USB port-related information such as USB reset, enable, suspend, resume, connect status, and test mode for each port. It is shown in [Figure 17-71 “Interrupt Hierarchy” on Page 17-232](#). The bits PrtOvrCurrChng, PrtEnChng and PrtConnDet in this register can trigger an interrupt to the application through the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). On a Port Interrupt, the application must read this register and clear the bit that caused the interrupt. For these bits, the application must write a 1 to the bit to clear the interrupt.

HPRT

Host Port Control and Status Register(440_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |
|----|----|----|--------|----------|----|--------|---------|--------|---------------|--------------|-----------|--------|------------|------------|----|

| r | | | rwh | rh | r | rw | rwh | rwh | rwh | r | rwh | rwh | rwh | rh | |

| Field | Bits | Type | Description |
|-------------------|------|------|--|
| PrtConnSts | 0 | rh | Port Connect Status 0 _B No device is attached to the port. 1 _B A device is attached to the port. |
| PrtConnDet | 1 | rwh | Port Connect Detected The core sets this bit when a device connection is detected to trigger an interrupt to the application using the Host Port Interrupt bit of the Core Interrupt register (GINTSTS.PrtInt). This bit is set only by hardware and cleared only by a software write of 1 to the bit. |
| PrtEna | 2 | rwh | Port Enable A port is enabled only by the core after a reset sequence, and is disabled by an overcurrent condition, a disconnect condition, or by the application clearing this bit. The application cannot set this bit by a register write. It can only clear it to disable the port. This bit does not trigger any interrupt to the application. 0 _B Port disabled 1 _B Port enabled |
| PrtEnChng | 3 | rwh | Port Enable/Disable Change The core sets this bit when the status of the Port Enable bit [2] of this register changes. This bit is set only by hardware and cleared only by a software write of 1 to the bit. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------------------|------|------|---|
| PrtOvrCur rAct | 4 | r | Port Overcurrent Active Indicates the overcurrent condition of the port. 0 _B No overcurrent condition 1 _B Overcurrent condition |
| PrtOvrCur rChng | 5 | rwh | Port Overcurrent Change The core sets this bit when the status of the Port Overcurrent Active bit (bit 4) in this register changes. This bit is set only by hardware and cleared only by a software write of 1 to the bit. |
| PrtRes | 6 | rwh | Port Resume The application sets this bit to drive resume signaling on the port. The core continues to drive the resume signal until the application clears this bit. If the core detects a USB remote wakeup sequence, as indicated by the Port Resume/Remote Wakeup Detected Interrupt bit of the Core Interrupt register (GINTSTS.WkUpInt), the core starts driving resume signaling without application intervention and clears this bit when it detects a disconnect condition. The read value of this bit indicates whether the core is currently driving resume signaling. 0 _B No resume driven 1 _B Resume driven This bit can be set and cleared by both hardware and software. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| PrtSusp | 7 | rwh | Port Suspend The application sets this bit to put this port in Suspend mode. The core only stops sending SOFs when this is set. To stop the PHY clock, the application must set the Port Clock Stop bit, which asserts the suspend input pin of the PHY. The read value of this bit reflects the current suspend status of the port. This bit is cleared by the core after a remote wakeup signal is detected or the application sets the Port Reset bit or Port Resume bit in this register or the Resume/Remote WakeupDetected Interrupt bit or Disconnect Detected Interrupt bit in the Core Interrupt register (GINTSTS.WkUpInt or GINTSTS.DisconnInt, respectively). 0 _B Port not in Suspend mode 1 _B Port in Suspend mode This bit is set only by software and cleared only by hardware. |
| PrtRst | 8 | rw | Port Reset When the application sets this bit, a reset sequence is started on this port. The application must time the reset period and clear this bit after the reset sequence is complete. 0 _B Port not in reset 1 _B Port in reset To start a reset on the port, the application must leave this bit set for at least the minimum duration mentioned below, as specified in the USB 2.0 specification, Section 7.1.7.5. The application can leave it set for another 10 ms in addition to the required minimum duration, before clearing the bit, even though there is no maximum limit set by the USB standard. <ul style="list-style-type: none"> Full speed: 10 ms |
| PrtLnSts | [11:10] | rh | Port Line Status Indicates the current logic level USB data lines Bit [10]: Logic level of D+ Bit [11]: Logic level of D- |

Universal Serial Bus (USB)

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| MPS | [10:0] | rw | Maximum Packet Size Indicates the maximum packet size of the associated endpoint. |
| EPNum | [14:11] | rw | Endpoint Number Indicates the endpoint number on the device serving as the data source or sink. |
| EPDir | 15 | rw | Endpoint Direction Indicates whether the transaction is IN or OUT. 0 _B OUT 1 _B IN |
| EPTYPE | [19:18] | rw | Endpoint Type Indicates the transfer type selected. 00 _B Control 01 _B Isochronous 10 _B Bulk 11 _B Interrupt |
| MC_EC | [21:20] | rw | Multi Count / Error Count This field indicates to the host the number of transactions that must be executed per frame for this periodic endpoint. For non periodic transfers, this field is used only in DMA mode, and specifies the number packets to be fetched for this channel before the internal DMA engine changes arbitration. 00 _B Reserved. This field yields undefined results. 01 _B 1 transaction 10 _B 2 transactions to be issued for this endpoint per frame 11 _B 3 transactions to be issued for this endpoint per frame |
| DevAddr | [28:22] | rw | Device Address This field selects the specific device serving as the data source or sink. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| OddFrm | 29 | rw | Odd Frame This field is set (reset) by the application to indicate that the OTG host must perform a transfer in an odd frame. This field is applicable for only periodic (isochronous and interrupt) transactions. 0 _B Even frame 1 _B Odd frame This field is not applicable for Scatter/Gather DMA mode and need not be programmed by the application and is ignored by the core. |
| ChDis | 30 | rwh | Channel Disable The application sets this bit to stop transmitting/receiving data on a channel, even before the transfer for that channel is complete. The application must wait for the Channel Disabled interrupt before treating the channel as disabled. This bit can be set by software and can be cleared by both hardware and software. |
| ChEna | 31 | rwh | Channel Enable 0 _B Scatter/Gather mode enabled: Indicates that the descriptor structure is not yet ready. Scatter/Gather mode disabled: Channel disabled 1 _B Scatter/Gather mode enabled: Indicates that the descriptor structure and data buffer with data is setup and this channel can access the descriptor. Scatter/Gather mode disabled: Channel enabled This bit is set only by software and cleared only by hardware. |
| 0 | [17:16] | r | Reserved Read as 0; should be written with 0. |

Host Channel-n Interrupt Register (HCINTx)

This register indicates the status of a channel with respect to USB- and AHB-related events. It is shown in **Figure 17-71 “Interrupt Hierarchy” on Page 17-232**. The application must read this register when the Host Channels Interrupt bit of the Core Interrupt register (GINTSTS.HChInt) is set. Before the application can read this register, it must first read the Host All Channels Interrupt (HAINT) register to get the exact channel number for the Host Channel-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the HAINT and GINTSTS registers.

Universal Serial Bus (USB)

Note: All bits of the access type 'rwh' in this register are set only by hardware and cleared only by a software write of 1 to the bits.

HCINTx (x=0-13)

Host Channel-x Interrupt Register(508_H + x*20_H)

Reset Value: 0000 0000_H

| r | | rw | | r | | | | | | | | | | | | | | rw | | | | | | | | rw | | | | | | | |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------------|-------------|------|---|
| SCHED_I NFO | [7:0] | rw | Schedule information This field should be written with 1111'1111 _B for a FS Host. |
| NTD | [15:8] | rw | Number of Transfer Descriptors (Non Isochronous) This value is in terms of number of descriptors. Maximum number of descriptor that can be present in the list is 64. The values can be from 0 to 63. 0 _D : 1 descriptor ... _D : ... 63 _D : 64 descriptors This field indicates the total number of descriptors present in that list. The core will wrap around after servicing NTD number of descriptors for that list. (Isochronous) This field indicates the number of descriptors present in that list frame The possible values are 1 _D : 2 descriptors 3 _D : 4 descriptors 7 _D : 8 descriptors 15 _D : 16 descriptors 31 _D : 32 descriptors 63 _D : 64 descriptors |
| Pid | [30:29] | rw | PID The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer. 00 _B DATA0 01 _B DATA2 10 _B DATA1 11 _B MDATA (non-control) |
| 0 | 31, [28:16] | r | Reserved Read as 0; should be written with 0. |

Host Channel-n Transfer Size Register (HCTSIZx)

In **Buffer DMA Mode**, HCTSIZx is defined as follows:

HCTSIZx (x=0-13)

Host Channel-x Transfer Size Register [BUFFERMODE]

($510_H + x \cdot 20_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|---------|------|--|
| XferSize | [18:0] | rw | Transfer Size For an OUT, this field is the number of data bytes the host sends during the transfer. For an IN, this field is the buffer size that the application has reserved for the transfer. The application is expected to program this field as an integer multiple of the maximum packet size for IN transactions (periodic and non-periodic). |
| PktCnt | [28:19] | rw | Packet Count This field is programmed by the application with the expected number of packets to be transmitted (OUT) or received (IN). The host decrements this count on every successful transmission or reception of an OUT/IN packet. Once this count reaches zero, the application is interrupted to indicate normal completion. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|------------|---------|------|--|
| Pid | [30:29] | rw | PID The application programs this field with the type of PID to use for the initial transaction. The host maintains this field for the rest of the transfer. 00 _B DATA0 01 _B DATA2 10 _B DATA1 11 _B MDATA (non-control)/SETUP (control) |
| 0 | 31 | r | Reserved Read as 0; should be written with 0. |

Host Channel-n DMA Address Register (HCDMAx)

This register is used by the OTG host in DMA mode to maintain the current buffer pointer for IN/OUT transactions. The starting DMA address must be DWORD-aligned. The HCDMAx register description depends on the selected DMA mode.

In **Buffer DMA Mode**, HCDMAx is defined as follows:

HCDMAx (x=0-13)

Host Channel-x DMA Address Register [BUFFERMODE]

$$(514_H + x \cdot 20_H)$$

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| DMAAddr | [31:0] | rw | DMA Address This field holds the start address in the external memory from which the data for the endpoint must be fetched or to which it must be stored. This register is incremented on every AHB transaction. |

In **Scatter/Gather DMA Mode**, HCDMAx is defined as follows:

HCDMA_x (x=0-13)

Host Channel-x DMA Address Register [SCATGATHER]

(514_H + x*20_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DMAAddr | | | | | | | | | | | | | | | | | | | | | | | | CTD | | | | 0 | | | |
| rw | | | | | | | | | | | | | | | | | | | | | | | | rw | | | | r | | | |

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| CTD | [8:3] | rw | Current Transfer Desc: Non Isochronous: This value is in terms of number of descriptors. The values can be from 0 to 63. 0_D 1 descriptor \dots_D ... 63_D 64 descriptors This field indicates the current descriptor processed in the list. This field is updated both by application and the core. For example, if the application enables the channel after programming CTD=5, then the core will start processing the 6th descriptor. The address is obtained by adding a value of (8 bytes*5=) 40 to DMAAddr. Isochronous: For isochronous transfers, the bits are [N-1:3]. CTD for isochronous is based on the current frame value. Need to be set to zero by application. |
| DMAAddr | [31:9] | rw | DMA Address Non-Isochronous: This field holds the start address of the 512 bytes page. The first descriptor in the list should be located in this address. The first descriptor may be or may not be ready. The core starts processing the list from the CTD value. Isochronous: For isochronous transfers, the bits are [31:N]. This field holds the address of the $2*(nTD+1)$ bytes of locations in which the isochronous descriptors are present where N is based on nTD as listed below: $nTD=1 \Rightarrow N=4$ $nTD=3 \Rightarrow N=5$ $nTD=7 \Rightarrow N=6$ $nTD=15 \Rightarrow N=7$ $nTD=31 \Rightarrow N=8$ $nTD=63 \Rightarrow N=9$ <i>Note: For Scatter/Gather DMA mode, this address is the start of the page address where the descriptor list is located.</i> |
| 0 | [2:0] | r | Reserved Read as 0; should be written with 0. |

Host Channel-n DMA Buffer Address Register (HCDMABx)

This register is present only in case of Scatter/Gather DMA. It is implemented in RAM. This register holds the current buffer address.

HCDMABx (x=0-13)

Host Channel-x DMA Buffer Address Register($51C_H + x \cdot 20_H$)

Reset Value:

0000 0000_H

| Field | Bits | Type | Description |
|-----------------------|--------|------|---|
| Buffer_Address | [31:0] | r | Buffer Address Holds the current buffer address. This register is updated as and when the data transfer for the corresponding end point is in progress. Reset: "X" if not programmed as the register is in SPRAM |

Device Mode Registers

These registers are visible only in Device mode and must not be accessed in Host mode, as the results are unknown. Some of them affect all the endpoints uniformly, while others affect only a specific endpoint. Device Mode registers fall into two categories:

Device Logical IN Endpoint-Specific Registers

One set of endpoint registers is instantiated per logical endpoint. A logical endpoint is unidirectional: it can be either IN or OUT. To represent a bidirectional endpoint, two logical endpoints are required, one for the IN direction and the other for the OUT direction. This is also true for control endpoints.

The registers and register fields described in this section can pertain to IN or OUT endpoints, or both, or specific endpoint types as noted.

Device Configuration Register (DCFG)

This register configures the core in Device mode after power-on or after certain control commands or enumeration. Do not make changes to this register after initial programming.

DCFG

Device Configuration Register

(800_H)

Reset Value: 0820 0000_H

| | | | | | | | | | | | | | | | |

| rw | rw | | r | w | w | w | w | | | r | | rh | rh | rw | rw |

| Field | Bits | Type | Description |
|------------------------|------|------|---|
| RmtWkUp Sig | 0 | rw | Remote Wakeup Signaling When the application sets this bit, the core initiates remote signaling to wake the USB host. The application must set this bit to instruct the core to exit the Suspend state. As specified in the USB 2.0 specification, the application must clear this bit 1 to15 ms after setting it. |
| SftDiscon | 1 | rw | Soft Disconnect The application uses this bit to signal the USB core to do a soft disconnect. As long as this bit is set, the host does not see that the device is connected, and the device does not receive signals on the USB. The core stays in the disconnected state until the application clears this bit. The minimum duration for which the core must keep this bit set is specified in Table 17-23 . 0 _B Normal operation. When this bit is cleared after a soft disconnect, the core drives a device connect event to the USB host. When the device is reconnected, the USB host restarts device enumeration. 1 _B The core drives a device disconnect event to the USB host. |

| Field | Bits | Type | Description |
|-------------------------|------|------|---|
| GNPINNa kSts | 2 | rh | Global Non-periodic IN NAK Status 0 _B A handshake is sent out based on the data availability in the transmit FIFO. 1 _B A NAK handshake is sent out on all non-periodic IN endpoints, irrespective of the data availability in the transmit FIFO. |
| GOUTNa kSts | 3 | rh | Global OUT NAK Status 0 _B A handshake is sent based on the FIFO Status and the NAK and STALL bit settings. 1 _B No data is written to the RxFIFO, irrespective of space availability. Sends a NAK handshake on all packets, except on SETUP transactions. All isochronous OUT packets are dropped. |
| SGNPInN ak | 7 | w | Set Global Non-periodic IN NAK A write to this field sets the Global Non-periodic IN NAK. The application uses this bit to send a NAK handshake on all non-periodic IN endpoints. The core can also set this bit when a timeout condition is detected on a non-periodic endpoint in shared FIFO operation. The application must set this bit only after making sure that the Global IN NAK Effective bit in the Core Interrupt Register (GINTSTS.GINNakEff) is cleared. |
| CGNPInN ak | 8 | w | Clear Global Non-periodic IN NAK A write to this field clears the Global Non-periodic IN NAK. |
| SGOUTNa k | 9 | w | Set Global OUT NAK A write to this field sets the Global OUT NAK. The application uses this bit to send a NAK handshake on all OUT endpoints. The application must set this bit only after making sure that the Global OUT NAK Effective bit in the Core Interrupt Register (GINTSTS.GOUTNakEff) is cleared. |
| CGOUTN ak | 10 | w | Clear Global OUT NAK A write to this field clears the Global OUT NAK. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------|---------|------|---|
| GMC | [14:13] | rw | Global Multi Count GMC must be programmed only once after initialization. Applicable only for Scatter/Gather DMA mode. This indicates the number of packets to be serviced for that end point before moving to the next end point. It is only for non-periodic end points. 00 _B Invalid. 01 _B 1 packet. 10 _B 2 packets. 11 _B 3 packets. When Scatter/Gather DMA mode is disabled, this field is reserved. and reads 00 _B . |
| IgnrFrmNum | 15 | rw | Ignore frame number for isochronous endpoints in case of Scatter/Gather DMA <i>Note: When this bit is enabled, there must be only one packet per descriptor.</i> In Scatter/Gather DMA mode, when this bit is enabled, the packets are not flushed when an ISOC IN token is received for an elapsed frame. When Scatter/Gather DMA mode is disabled, this field is used by the application to enable periodic transfer interrupt. The application can program periodic endpoint transfers for multiple frames. 0 _B Scatter/Gather enabled: The core transmits the packets only in the frame number in which they are intended to be transmitted. Scatter/Gather disabled: Periodic transfer interrupt feature is disabled; the application must program transfers for periodic endpoints every frame 1 _B Scatter/Gather enabled: The core ignores the frame number, sending packets immediately as the packets are ready. Scatter/Gather disabled: Periodic transfer interrupt feature is enabled; the application can program transfers for multiple frames for periodic endpoints. In non-Scatter/Gather DMA mode, the application receives transfer complete interrupt after transfers for multiple frames are completed. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------------|------------------------------------|------|--|
| NakOnBble | 16 | rw | Set NAK automatically on babble The core sets NAK automatically for the endpoint on which babble is received. |
| EnContOnBNA | 17 | rw | Enable continue on BNA This bit enables the core to continue on BNA for Bulk OUT endpoints. With this feature enabled, when a Bulk OUT endpoint receives a BNA interrupt the core starts processing the descriptor that caused the BNA interrupt after the endpoint re-enables the endpoint. 0 _B After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the DOEPDMA descriptor. 1 _B After receiving BNA interrupt, the core disables the endpoint. When the endpoint is re-enabled by the application, the core starts processing from the descriptor that received the BNA interrupt. |

Device All Endpoints Interrupt Register (DAINT)

When a significant event occurs on an endpoint, a Device All Endpoints Interrupt register interrupts the application using the Device OUT Endpoints Interrupt bit or Device IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively). This is shown in **Figure 17-71 “Interrupt Hierarchy” on Page 17-232**. There is one interrupt bit per endpoint, up to a maximum of 7 bits for OUT endpoints and 7 bits for IN endpoints. For a bidirectional endpoint, the corresponding IN and OUT interrupt bits are used. Bits in this register are set and cleared when the application sets and clears bits in the corresponding Device Endpoint-n Interrupt register (DIEPINTx/DOEPINTx).

DAINT

Device All Endpoints Interrupt Register(818_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|---------|------|---|

| r | r | | | | | | | | | | | | rw | | |

| Field | Bits | Type | Description |
|--------------------------|---------|------|---|
| MPS | [1:0] | rw | Maximum Packet Size Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. 00 _B 64 bytes 01 _B 32 bytes 10 _B 16 bytes 11 _B 8 bytes |
| USBActE P | 15 | r | USB Active Endpoint This bit is always set to 1, indicating that control endpoint 0 is always active in all configurations and interfaces. |
| NAKSts | 17 | rh | NAK Status Indicates the following: 0 _B The core is transmitting non-NAK handshakes based on the FIFO status 1 _B The core is transmitting NAK handshakes on this endpoint. When this bit is set, either by the application or core, the core stops transmitting data, even if there is data available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. |
| EPT ype | [19:18] | r | Endpoint Type Hardcoded to 00 _B for control. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| Stall | 21 | rwh | STALL Handshake The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. This bit is set only by software and cleared only by hardware. |
| TxFNum | [25:22] | rw | TxFIFO Number <ul style="list-style-type: none"> This value is set to the FIFO number that is assigned to IN Endpoint 0. |
| CNAK | 26 | w | Clear NAK A write to this bit clears the NAK bit for the endpoint. |
| SNAK | 27 | w | Set NAK A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for an endpoint after a SETUP packet is received on that endpoint. |
| EPDis | 30 | rwh | Endpoint Disable The application sets this bit to stop transmitting data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled Interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. This bit is set only by software and cleared only by hardware. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------|-------------------------|------|---|
| EPEna | 31 | rwh | Endpoint Enable <ul style="list-style-type: none"> When Scatter/Gather DMA mode is enabled, for IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. When Scatter/Gather DMA mode is disabled—such as in buffer-pointer based DMA mode—this bit indicates that data is ready to be transmitted on the endpoint. The core clears this bit before setting the following interrupts on this endpoint: <ul style="list-style-type: none"> Endpoint Disabled Transfer Completed This bit is set only by software and cleared only by hardware. |

| USB ActE P | | | | | | | 0 | | | | | | | MPS | |
| r | | | | | | | r | | | | | | | | r |

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| MPS | [1:0] | r | Maximum Packet Size The maximum packet size for control OUT endpoint 0 is the same as what is programmed in control IN Endpoint 0. 00 _B 64 bytes 01 _B 32 bytes 10 _B 16 bytes 11 _B 8 bytes |
| USBActEP | 15 | r | USB Active Endpoint This bit is always set to 1, indicating that a control endpoint 0 is always active in all configurations and interfaces. |
| NAKSts | 17 | rh | NAK Status Indicates the following: 0 _B The core is transmitting non-NAK handshakes based on the FIFO status. 1 _B The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit, the core stops receiving data, even if there is space in the Rx FIFO to accommodate the incoming packet. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. |
| EPTYPE | [19:18] | r | Endpoint Type Hardcoded to 00 for control. |
| Snp | 20 | rw | Snoop Mode This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. |
| Stall | 21 | rwh | STALL Handshake The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. This bit is set only by software and cleared only by hardware. |
| CNAK | 26 | w | Clear NAK A write to this bit clears the NAK bit for the endpoint. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|--------------|------------------------------------|------|---|
| SNAK | 27 | w | Set NAK A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set bit on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. |
| EPDis | 30 | r | Endpoint Disable The application cannot disable control OUT endpoint 0. |
| EPEna | 31 | rwh | Endpoint Enable When Scatter/Gather DMA mode is enabled, for OUT endpoints this bit indicates that the descriptor structure and data buffer to receive data is setup. <ul style="list-style-type: none"> When Scatter/Gather DMA mode is disabled—(such as for buffer-pointer based DMA mode)—this bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears this bit before setting any of the following interrupts on this endpoint: <ul style="list-style-type: none"> SETUP Phase Done Endpoint Disabled Transfer Completed <i>Note: In DMA mode, this bit must be set for the core to transfer SETUP data packets into memory.</i> This bit is set only by software and cleared only by hardware. |
| 0 | [29:28], [25:22], 16, [14:2] | r | Reserved Read as 0; should be written with 0. |

Device Endpoint-n Control Register (DIEPCTLx/DOEPCTLx)

The application uses this register to control the behavior of each logical endpoint other than endpoint 0.

Note: The fields of the DIEPCTLx/DOEPCTLx register change, depending on interrupt/bulk or isochronous/control endpoint.

Universal Serial Bus (USB)

DIEPCTLx (x=1-6)

| USB ActE P | 0 | | | | MPS | | | | | | | | | | |
| rwh | r | | | | rw | | | | | | | | | | |

| Field | Bits | Type | Description |
|-----------------|-------------|-------------|--|
| MPS | [10:0] | rw | Maximum Packet Size Applies to IN and OUT endpoints. The application must program this field with the maximum packet size for the current logical endpoint. This value is in bytes. |
| USBActEP | 15 | rwh | USB Active Endpoint Applies to IN and OUT endpoints. Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. This bit is set only by software and can be cleared by hardware or a software write of 0 to the bit. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|------|------|--|
| DPID | 16 | rh | Endpoint Data PID Applies to interrupt/bulk IN and OUT endpoints only. Contains the PID of the packet to be received or transmitted on this endpoint. The application must program the PID of the first packet to be received or transmitted on this endpoint, after the endpoint is activated. The applications use the SetD1PID and SetD0PID fields of this register to program either DATA0 or DATA1 PID. 0_B DATA0 1_B DATA1 This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. |
| NAKSts | 17 | rh | NAK Status Applies to IN and OUT endpoints. Indicates the following: 0_B The core is transmitting non-NAK handshakes based on the FIFO status. 1_B The core is transmitting NAK handshakes on this endpoint. When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet. For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO. For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| EPTYPE | [19:18] | rw | Endpoint Type Applies to IN and OUT endpoints. This is the transfer type supported by this logical endpoint. 00 _B Control 01 _B Isochronous 10 _B Bulk 11 _B Interrupt |
| SnP | 20 | rw | Snoop Mode Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. |
| STALL | 21 | rw | STALL Handshake Applies to non-control, non-isochronous IN and OUT endpoints only. The application sets this bit to stall all tokens from the USB host to this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Only the application can clear this bit, never the core. |
| TxFNum | [25:22] | rw | TxFIFO Number These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints. |
| CNAK | 26 | w | Clear NAK Applies to IN and OUT endpoints. A write to this bit clears the NAK bit for the endpoint. |
| SNACK | 27 | w | Set NAK Applies to IN and OUT endpoints. A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-----------------|------|------|--|
| SetD0PID | 28 | w | Set DATA0 PID Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA0. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. |
| SetD1PID | 29 | w | 29 Set DATA1 PID Applies to interrupt/bulk IN and OUT endpoints only. Writing to this field sets the Endpoint Data PID (DPID) field in this register to DATA1. This field is applicable both for Scatter/Gather DMA mode and non-Scatter/Gather DMA mode. |
| EPDis | 30 | rwh | Endpoint Disable Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. This bit is set only by software and cleared only by hardware. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| EPEna | 31 | rwh | Endpoint Enable Applies to IN and OUT endpoints. <ul style="list-style-type: none"> When Scatter/Gather DMA mode is enabled, For IN endpoints this bit indicates that the descriptor structure and data buffer with data ready to transmit is setup. For OUT endpoint it indicates that the descriptor structure and data buffer to receive data is setup. When Scatter/Gather DMA mode is enabled—such as for buffer-pointer based DMA mode: <ul style="list-style-type: none"> For IN endpoints, this bit indicates that data is ready to be transmitted on the endpoint. For OUT endpoints, this bit indicates that the application has allocated the memory to start receiving data from the USB. The core clears this bit before setting any of the following interrupts on this endpoint: <ul style="list-style-type: none"> SETUP Phase Done Endpoint Disabled Transfer Completed <p><i>Note: For control endpoints in DMA mode, this bit must be set to be able to transfer SETUP data packets in memory.</i></p> <p>This bit is set only by software and cleared only by hardware.</p> |

| USBActEP | 15 | rwh | USB Active Endpoint Applies to IN and OUT endpoints. Indicates whether this endpoint is active in the current configuration and interface. The core clears this bit for all endpoints (other than EP 0) after detecting a USB reset. After receiving the SetConfiguration and SetInterface commands, the application must program endpoint registers accordingly and set this bit. This bit is set only by software and can be cleared by hardware or a software write of 0 to the bit. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|----------|------|------|---|
| EO_FrNum | 16 | rh | <p>Even/Odd Frame</p> <p>Applies to isochronous IN and OUT endpoints only. In non-Scatter/Gather DMA mode, the bit Indicates the frame number in which the core transmits/receives isochronous data for this endpoint. The application must program the even/odd frame number in which it intends to transmit/receive isochronous data for this endpoint using the SetEvnFr and SetOddFr fields in this register.</p> <p>0_B Even frame 1_B Odd rame</p> <p>When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is provided in the transmit descriptor structure. The frame in which data is received is updated in receive descriptor structure.</p> |
| NAKSts | 17 | rh | <p>NAK Status</p> <p>Applies to IN and OUT endpoints. Indicates the following:</p> <p>0_B The core is transmitting non-NAK handshakes based on the FIFO status. 1_B The core is transmitting NAK handshakes on this endpoint.</p> <p>When either the application or the core sets this bit: The core stops receiving any data on an OUT endpoint, even if there is space in the RxFIFO to accommodate the incoming packet.</p> <p>For non-isochronous IN endpoints: The core stops transmitting any data on an IN endpoint, even if there data is available in the TxFIFO.</p> <p>For isochronous IN endpoints: The core sends out a zero-length data packet, even if there data is available in the TxFIFO.</p> <p>Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake.</p> |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| EPTYPE | [19:18] | rw | Endpoint Type Applies to IN and OUT endpoints. This is the transfer type supported by this logical endpoint. 00 _B Control 01 _B Isochronous 10 _B Bulk 11 _B Interrupt |
| Snp | 20 | rw | Snoop Mode Applies to OUT endpoints only. This bit configures the endpoint to Snoop mode. In Snoop mode, the core does not check the correctness of OUT packets before transferring them to application memory. |
| Stall | 21 | rwh | STALL Handshake Applies to control endpoints only. The application can only set this bit, and the core clears it, when a SETUP token is received for this endpoint. If a NAK bit, Global Non-periodic IN NAK, or Global OUT NAK is set along with this bit, the STALL bit takes priority. Irrespective of this bit's setting, the core always responds to SETUP data packets with an ACK handshake. This bit is set only by software and cleared only by hardware. |
| TxFNum | [25:22] | rw | TxFIFO Number These bits specify the FIFO number associated with this endpoint. Each active IN endpoint must be programmed to a separate FIFO number. This field is valid only for IN endpoints. |
| CNAK | 26 | w | Clear NAK Applies to IN and OUT endpoints. A write to this bit clears the NAK bit for the endpoint. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|------------------|------|------|--|
| SNAK | 27 | w | Set NAK Applies to IN and OUT endpoints. A write to this bit sets the NAK bit for the endpoint. Using this bit, the application can control the transmission of NAK handshakes on an endpoint. The core can also set this bit for OUT endpoints on a Transfer Completed interrupt, or after a SETUP is received on the endpoint. |
| SetEvenFr | 28 | w | In non-Scatter/Gather DMA mode: Set Even frame Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EO_FrNum) field to even frame. When Scatter/Gather DMA mode is enabled, this field is reserved. The frame number in which to send data is in the transmit descriptor structure. The frame in which to receive data is updated in receive descriptor structure. |
| SetOddFr | 29 | w | Set Odd frame Applies to isochronous IN and OUT endpoints only. Writing to this field sets the Even/Odd frame (EO_FrNum) field to odd frame. This field is not applicable for Scatter/Gather DMA mode. |
| EPDis | 30 | rwh | Endpoint Disable Applies to IN and OUT endpoints. The application sets this bit to stop transmitting/receiving data on an endpoint, even before the transfer for that endpoint is complete. The application must wait for the Endpoint Disabled interrupt before treating the endpoint as disabled. The core clears this bit before setting the Endpoint Disabled interrupt. The application must set this bit only if Endpoint Enable is already set for this endpoint. This bit is set only by software and cleared only by hardware. |

Universal Serial Bus (USB)

Device Endpoint-n Interrupt Register (DIEPINTx/DOEPINTx)

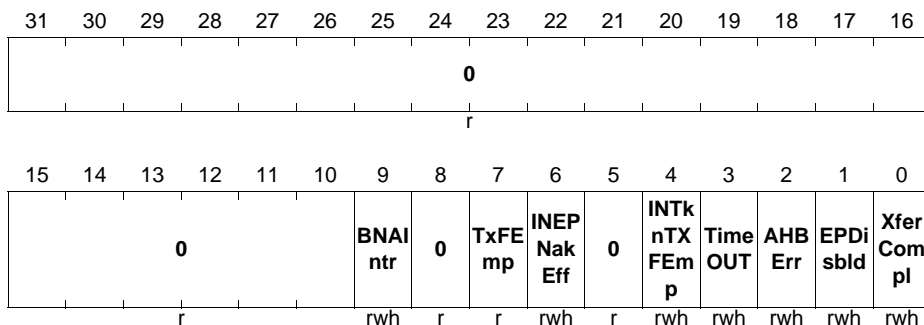

This register indicates the status of an endpoint with respect to USB- and AHB-related events. It is shown in **Figure 17-71 “Interrupt Hierarchy” on Page 17-232**. The application must read this register when the OUT Endpoints Interrupt bit or IN Endpoints Interrupt bit of the Core Interrupt register (GINTSTS.OEPInt or GINTSTS.IEPInt, respectively) is set. Before the application can read this register, it must first read the Device All Endpoints Interrupt (DAINT) register to get the exact endpoint number for the Device Endpoint-n Interrupt register. The application must clear the appropriate bit in this register to clear the corresponding bits in the DAINT and GINTSTS registers.

Note: In the DIEPINTx/DOEPINTx registers, status bits with access type ‘rwh’ are set by hardware. To clear these bits, the application must write 1 into these bits.

DIEPINTx (x=0-6)

Device Endpoint-x Interrupt Register (908_H + x*20_H)

Reset Value: 0000 0080_H

| Field | Bits | Type | Description |
|------------------|------|------|--|
| XferCompl | 0 | rwh | Transfer Completed Interrupt Applies to IN and OUT endpoints. <ul style="list-style-type: none"> When Scatter/Gather DMA mode is enabled For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. |
| EPDisbld | 1 | rwh | Endpoint Disabled Interrupt Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. |
| AHBErr | 2 | rwh | AHB Error Applies to IN and OUT endpoints. This is generated only in DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------------|---------------|------|--|
| TimeOUT | 3 | rwh | Timeout Condition <ul style="list-style-type: none"> Applies only to Control IN endpoints. In Scatter/Gather DMA mode, the TimeOUT interrupt is not asserted. Indicates that the core has detected a timeout condition on the USB for the last IN token on this endpoint. |
| INTknTXF Emp | 4 | rwh | IN Token Received When Tx FIFO is Empty <p>Indicates that an IN token was received when the associated Tx FIFO (periodic/non-periodic) was empty. This interrupt is asserted on the endpoint for which the IN token was received.</p> |
| INEPNakeff | 6 | rwh | IN Endpoint NAK Effective <p>Applies to periodic IN endpoints only. This bit can be cleared when the application clears the IN endpoint NAK by writing to DIEPCTLx.CNAK. This interrupt indicates that the core has sampled the NAK bit set (either by the application or by the core). The interrupt indicates that the IN endpoint NAK bit set by the application has taken effect in the core. This interrupt does not guarantee that a NAK handshake is sent on the USB. A STALL bit takes priority over a NAK bit. This bit is applicable only when the endpoint is enabled.</p> |
| TxFEmp | 7 | r | Transmit FIFO Empty <p>This bit is valid only for IN Endpoints. This interrupt is asserted when the Tx FIFO for this endpoint is either half or completely empty. The half or completely empty status is determined by the Tx FIFO Empty Level bit in the Core AHB Configuration register (GAHB_CFG.NPTxFEmpLvl).</p> |
| BNAIntr | 9 | rwh | BNA (Buffer Not Available) Interrupt <p>The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done. This bit is valid only when Scatter/Gather DMA mode is enabled.</p> |
| 0 | [31:10], 8, 5 | r | Reserved <p>Read as 0; should be written with 0.</p> |

DOEPINTx (x=0-6)

Device Endpoint-x Interrupt Register (B08_H + x*20_H)

| r | rwh | rwh | rwh | rwh | r | rwh | r | | rw | rwh | rwh | rwh | rwh | rwh | rwh |

| Field | Bits | Type | Description |
|------------------|------|------|--|
| XferCompl | 0 | rwh | Transfer Completed Interrupt Applies to IN and OUT endpoints. <ul style="list-style-type: none"> When Scatter/Gather DMA mode is enabled For IN endpoint this field indicates that the requested data from the descriptor is moved from external system memory to internal FIFO. For OUT endpoint this field indicates that the requested data from the internal FIFO is moved to external system memory. This interrupt is generated only when the corresponding endpoint descriptor is closed, and the IOC bit for the corresponding descriptor is set. When Scatter/Gather DMA mode is disabled, this field indicates that the programmed transfer is complete on the AHB as well as on the USB, for this endpoint. |
| EPDisblld | 1 | rwh | Endpoint Disabled Interrupt Applies to IN and OUT endpoints. This bit indicates that the endpoint is disabled per the application's request. |
| AHBErr | 2 | rwh | AHB Error Applies to IN and OUT endpoints. This is generated only in DMA mode when there is an AHB error during an AHB read/write. The application can read the corresponding endpoint DMA address register to get the error address. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|-------------------------|------|------|--|
| SetUp | 3 | rwh | SETUP Phase Done Applies to control OUT endpoints only. Indicates that the SETUP phase for the control endpoint is complete and no more back-to-back SETUP packets were received for the current control transfer. On this interrupt, the application can decode the received SETUP data packet. |
| OUTTknE Pdis | 4 | rwh | OUT Token Received When Endpoint Disabled Indicates that an OUT token was received when the endpoint was not yet enabled. This interrupt is asserted on the endpoint for which the OUT token was received. |
| StsPhseR cvd | 5 | rwh | Status Phase Received For Control Write This interrupt is valid only for Control OUT endpoints and only in Scatter Gather DMA mode. This interrupt is generated only after the core has transferred all the data that the host has sent during the data phase of a control write transfer, to the system memory buffer. The interrupt indicates to the application that the host has switched from data phase to the status phase of a Control Write transfer. The application can use this interrupt to ACK or STALL the Status phase, after it has decoded the data phase. This is applicable only in case of Scatter Gather DMA mode. |
| Back2Back kSETup | 6 | rw | Back-to-Back SETUP Packets Received Applies to Control OUT endpoints only. This bit indicates that the core has received more than three back-to-back SETUP packets for this particular endpoint. For information about handling this interrupt, see “Handling More Than Three Back-to-Back SETUP Packets” on Page 17-97 . |
| BNAIntr | 9 | rwh | BNA (Buffer Not Available) Interrupt The core generates this interrupt when the descriptor accessed is not ready for the Core to process, such as Host busy or DMA done This bit is valid only when Scatter/Gather DMA mode is enabled. |

Universal Serial Bus (USB)

| Field | Bits | Type | Description |
|---------------------------|---------------------------|------|--|
| PktDrpSts | 11 | rwh | Packet Dropped Status This bit indicates to the application that an ISOC OUT packet has been dropped. This bit does not have an associated mask bit and does not generate an interrupt. This bit is valid in non Scatter/Gather DMA mode when periodic transfer interrupt feature is selected. |
| BbleErrInt rpt | 12 | rwh | BbleErr (Babble Error) interrupt The core generates this interrupt when babble is received for the endpoint. |
| NAKIntrpt | 13 | rwh | NAK interrupt The core generates this interrupt when a NAK is transmitted or received by the device. In case of isochronous IN endpoints the interrupt gets generated when a zero length packet is transmitted due to unavailability of data in the TXFIFO. |
| NYETIntr pt | 14 | rwh | NYET interrupt The core generates this interrupt when a NYET response is transmitted for a non isochronous OUT endpoint. |
| 0 | [31:15] , 10, [8:7] | r | Reserved Read as 0; should be written with 0. |

Device Endpoint 0 Transfer Size Register (DIEPTSIZ0/DOEPTSIZ0)

The application must modify this register before enabling endpoint 0. Once endpoint 0 is enabled using Endpoint Enable bit of the Device Control Endpoint 0 Control registers (DIEPCTL0.EPENA/DOEPCTL0.EPENA), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Non-zero endpoints use the registers for endpoints 1-6.

When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros.

DIEPTSIZE0

Device IN Endpoint 0 Transfer Size Register(910_H)

Reset Value: 0000 0000_H

|-----------------|---------------------|------|--|
| XferSize | [6:0] | rw | Transfer Size Indicates the transfer size in bytes for endpoint 0. The core interrupts the application only after it has exhausted the transfer size amount of data. The transfer size can be set to the maximum packet size of the endpoint, to be interrupted at the end of each packet. The core decrements this field every time a packet is read from the RxFIFO and written to the external memory. |
| PktCnt | [20:19] | rw | Packet Count This field is decremented to zero after a packet is written into the RxFIFO. |
| SUPCnt | [30:29] | rw | SETUP Packet Count This field specifies the number of back-to-back SETUP data packets the endpoint can receive. 01 _B 1 packet 10 _B 2 packets 11 _B 3 packets |
| 0 | 31, [28:21], [18:7] | r | Reserved Read as 0; should be written with 0. |

Device Endpoint-n Transfer Size Register (DIEPTSIZx/DOEPTSIZx)

The application must modify this register before enabling the endpoint. Once the endpoint is enabled using Endpoint Enable bit of the Device Endpoint-n Control registers (DIEPCTLx.EPEna/DOEPCTLx.EPEna), the core modifies this register. The application can only read this register once the core has cleared the Endpoint Enable bit.

Universal Serial Bus (USB)

This register is used only for endpoints other than Endpoint 0.

Note: When Scatter/Gather DMA mode is enabled, this register must not be programmed by the application. If the application reads this register when Scatter/Gather DMA mode is enabled, the core returns all zeros

| USB0.DRIVEVBUS | O | P0.1 P3.2 | Drive VBUS signal |

18 Universal Serial Interface Channel (USIC)

The **Universal Serial Interface Channel** module (USIC) is a flexible interface module covering several serial communication protocols. A USIC module contains two independent communication channels named USICx_CH0 and USICx_CH1, with x being the number of the USIC module (e.g. channel 0 of USIC module 0 is referenced as USIC0_CH0). The user can program during run-time which protocol will be handled by each communication channel and which pins are used.

| RSR | Receive Shift Register |
| SCLK | Shift Clock |
| TSR | Transmit Shift Register |

18.1 Overview

This section gives an overview about the feature set of the USIC.

18.1.1 Features

Each USIC channel can be individually configured to match the application needs, e.g. the protocol can be selected or changed during run time without the need for a reset. The following protocols are supported:

- **UART** (ASC, asynchronous serial channel)
 - Module capability: receiver/transmitter with max. baud rate $f_{\text{PERIPH}} / 4$
 - Wide baud rate range down to single-digit baud rates
 - Number of data bits per data frame: 1 to 63
 - MSB or LSB first

Universal Serial Interface Channel (USIC)

- **LIN** Support by hardware (Local Interconnect Network)
 - Data transfers based on ASC protocol
 - Baud rate detection possible by built-in capture event of baud rate generator
 - Checksum generation under software control for higher flexibility
- **SSC/SPI** (synchronous serial channel with or without slave select lines)
 - Standard, Dual and Quad SPI format supported
 - Module capability: maximum baud rate $f_{\text{PERIPH}} / 2$, limited by loop delay
 - Number of data bits per data frame 1 to 63, more with explicit stop condition
 - Parity bit generation supported
 - MSB or LSB first
- **IIC** (Inter-IC Bus)
 - Application baud rate 100 kbit/s to 400 kbit/s
 - 7-bit and 10-bit addressing supported
 - Full master and slave device capability
- **IIS** (infotainment audio bus)
 - Module capability: maximum baud rate $f_{\text{PERIPH}} / 2$

Note: The real baud rates that can be achieved in a real application depend on the operating frequency of the device, timing parameters as described in the Data Sheet, signal delays on the PCB and timings of the peer device.

In addition to the flexible choice of the communication protocol, the USIC structure has been designed to reduce the system load (CPU load) allowing efficient data handling. The following aspects have been considered:

- **Data buffer capability**
 The standard buffer capability includes a double word buffer for receive data and a single word buffer for transmit data. This allows longer CPU reaction times (e.g. interrupt latency).
- **Additional FIFO buffer capability**
 In addition to the standard buffer capability, the received data and the data to be transmitted can be buffered in a FIFO buffer structure. The size of the receive and the transmit FIFO buffer can be programmed independently. Depending on the application needs, a total buffer capability of 64 data words can be assigned to the receive and transmit FIFO buffers of a USIC module (the two channels of the USIC module share the 64 data word buffer).
 In addition to the FIFO buffer, a bypass mechanism allows the introduction of high-priority data without flushing the FIFO buffer.
- **Transmit control information**
 For each data word to be transmitted, a 5-bit transmit control information has been added to automatically control some transmission parameters, such as word length, frame length, or the slave select control for the SPI protocol. The transmit control information is generated automatically by analyzing the address where the user software has written the data word to be transmitted (32 input locations = $2^5 = 5$ bit transmit control information).

Universal Serial Interface Channel (USIC)

This feature allows individual handling of each data word, e.g. the transmit control information associated to the data words stored in a transmit FIFO can automatically modify the slave select outputs to select different communication targets (slave devices) without CPU load. Alternatively, it can be used to control the frame length.

- **Flexible frame length control**

The number of bits to be transferred within a data frame is independent of the data word length and can be handled in two different ways. The first option allows automatic generation of frames up to 63 bits with a known length. The second option supports longer frames (even unlimited length) or frames with a dynamically controlled length.

- **Interrupt capability**

The events of each USIC channel can be individually routed to one of 6 service request outputs SR[5:0] available for each USIC module, depending on the application needs. Furthermore, specific start and end of frame indications are supported in addition to protocol-specific events.

- **Flexible interface routing**

Each USIC channel offers the choice between several possible input and output pins connections for the communications signals. This allows a flexible assignment of USIC signals to pins that can be changed without resetting the device.

- **Input conditioning**

Each input signal is handled by a programmable input conditioning stage with programmable filtering and synchronization capability.

- **Baud rate generation**

Each USIC channel contains its own baud rate generator. The baud rate generation can be based either on the internal module clock or on an external frequency input. This structure allows data transfers with a frequency that can not be generated internally, e.g. to synchronize several communication partners.

- **Transfer trigger capability**

In master mode, data transfers can be triggered by events generated outside the USIC module, e.g. by an input pin or a timer unit (transmit data validation). This feature allows time base related data transmission.

- **Debugger support**

The USIC offers specific addresses to read out received data without interaction with the FIFO buffer mechanism. This feature allows debugger accesses without the risk of a corrupted receive data sequence.

To reach a desired baud rate, two criteria have to be respected, the module capability and the application environment. The module capability is defined with respect to the module's input clock frequency, being the base for the module operation. Although the module's capability being much higher (depending on the module clock and the number of module clock cycles needed to represent a data bit), the reachable baud rate is generally limited by the application environment. In most cases, the application

Universal Serial Interface Channel (USIC)

environment limits the maximum reachable baud rate due to driver delays, signal propagation times, or due to EMI reasons.

Note: Depending on the selected additional functions (such as digital filters, input synchronization stages, sample point adjustment, data structure, etc.), the maximum reachable baud rate can be limited. Please also take care about additional delays, such as (internal or external) propagation delays and driver delays (e.g. for collision detection in ASC mode, for IIC, etc.).

Universal Serial Interface Channel (USIC)

A block diagram of the USIC module/channel structure is shown in **Figure 18-1**.

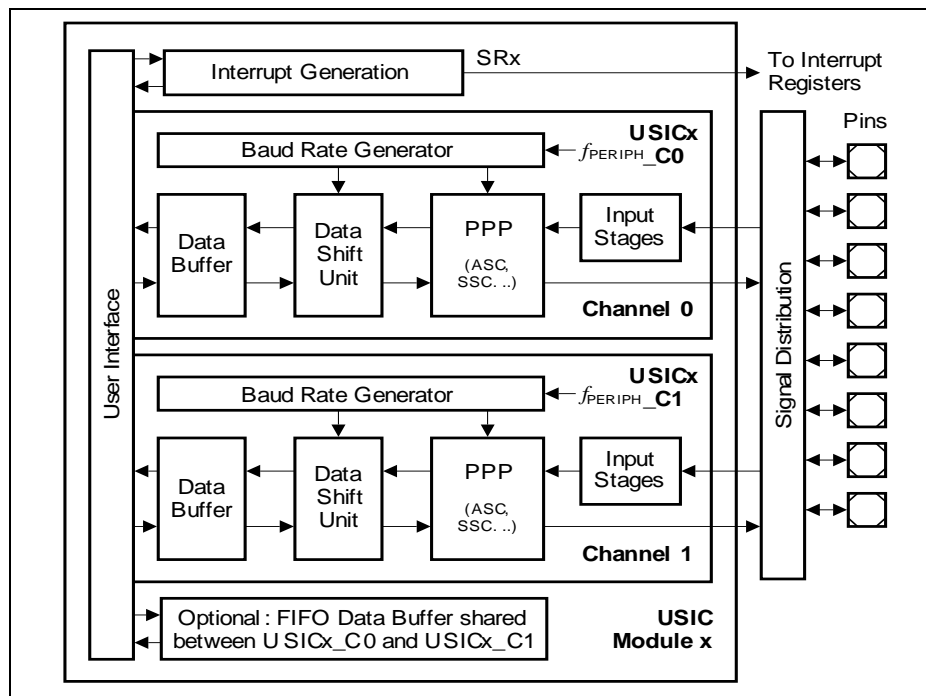

Figure 18-1 USIC Module/Channel Structure

18.2 Operating the USIC

This section describes how to operate the USIC communication channel.

18.2.1 USIC Structure Overview

This section introduces the USIC structure.

18.2.1.1 Channel Structure

The USIC module contains two independent communication channels, with a structure as shown in [Figure 18-1](#).

The data shift unit and the data buffering of each channel support full-duplex data transfers. The protocol-specific actions are handled by the protocol pre-processors (PPP). In order to simplify data handling, an additional FIFO data buffer is optionally available for each USIC module to store transmit and receive data for each channel.

Due to the independent channel control and baud rate generation, the communication protocol, baud rate and the data format can be independently programmed for each communication channel.

18.2.1.2 Input Stages

For each protocol, the number of input signals used depends on the selected protocol. Each input signal is handled by an input stage (called DX_n, where n=0-5) for signal conditioning, such as input selection, polarity control, or a digital input filter. They can be classified according to their meaning for the protocols, see [Table 18-2](#).

The inputs marked as “optional” are not needed for the standard function of a protocol and may be used for enhancements. The descriptions of protocol-specific items are given in the related protocol chapters. For the external frequency input, please refer to the baud rate generator section, and for the transmit data validation, to the data handling section.

Universal Serial Interface Channel (USIC)
Table 18-2 Input Signals for Different Protocols

| Selected Protocol | Shift Data Input(s) (handled by DX0, DX3, DX4 and DX5)¹⁾ | Shift Clock Input (handled by DX1) | Shift Control Input (handled by DX2) |
|---|--|--|--|
| ASC, LIN | RXD | optional: external frequency input or TXD collision detection | optional: transmit data validation |
| Standard SSC, SPI (Master) | DIN0 (MRST, MISO) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Standard SSC, SPI (Slave) | DIN0 (MTSR, MOSI) | SCLKIN | SELIN |
| Dual- SSC, SPI (Master) | DIN[1:0] (MRST[1:0], MISO[1:0]) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Dual- SSC, SPI (Slave) | DIN[1:0] (MTSR[1:0], MOSI[1:0]) | SCLKIN | SELIN |
| Quad- SSC, SPI (Master) | DIN[3:0] (MRST[3:0], MISO[3:0]) | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| Quad- SSC, SPI (Slave) | DIN[3:0] (MTSR[3:0], MOSI[3:0]) | SCLKIN | SELIN |
| IIC | SDA | SCL | optional: transmit data validation |
| IIS (Master) | DIN0 | optional: external frequency input or delay compensation | optional: transmit data validation or delay compensation |
| IIS (Slave) | DIN0 | SCLKIN | WAIN |

1) ASC, IIC, IIS and standard SSC protocols use only DX0 as the shift data input.

Universal Serial Interface Channel (USIC)

Note: To allow a certain flexibility in assigning required USIC input functions to port pins of the device, each input stage can select the desired input location among several possibilities.

The available USIC signals and their port locations are listed in the interconnects section, see [Page 18-227](#).

18.2.1.3 Output Signals

For each protocol, up to 14 protocol-related output signals are available. The number of actually used outputs depends on the selected protocol. They can be classified according to their meaning for the protocols, see [Table 18-3](#).

The outputs marked as “optional” are not needed for the standard function of a protocol and may be used for enhancements. The descriptions of protocol-specific items are given in the related protocol chapters. The MCLKOUT output signal has a stable frequency relation to the shift clock output (the frequency of MCLKOUT can be higher than for SCLKOUT) for synchronization purposes of a slave device to a master device. If the baud rate generator is not needed for a specific protocol (e.g. in SSC slave mode), the SCLKOUT and MCLKOUT signals can be used as clock outputs with 50% duty cycle with a frequency that can be independent from the communication baud rate.

Table 18-3 Output Signals for Different Protocols

| Selected Protocol | Shift Data Output(s) DOUT[3:0]¹⁾ | Shift Clock Output SCLKOUT | Shift Control Outputs SELO[7:0] | Master Clock Output MCLKOUT |
|-----------------------------------|--|---------------------------------------|--|--|
| ASC, LIN | TXD | not used | not used | optional: master time base |
| Standard SSC, SPI (Master) | DOUT0 (MTSR, MOSI) | master shift clock | slave select, chip select | optional: master time base |
| Standard SSC, SPI (Slave) | DOUT0 (MRST, MISO) | optional: independent clock output | not used | optional: independent clock output |
| Dual-SSC, SPI (Master) | DOUT[1:0] (MTSR[1:0], MOSI[1:0]) | master shift clock | slave select, chip select | optional: master time base |
| Dual-SSC, SPI (Slave) | DOUT[1:0] (MRST[1:0], MISO[1:0]) | optional: independent clock output | not used | optional: independent clock output |

Universal Serial Interface Channel (USIC)
Table 18-3 Output Signals for Different Protocols (cont'd)

| Selected Protocol | Shift Data Output(s) DOUT[3:0]¹⁾ | Shift Clock Output SCLKOUT | Shift Control Outputs SELO[7:0] | Master Clock Output MCLKOUT |
|-------------------------------|--|---|--|--|
| Quad-SSC, SPI (Master) | DOUT[3:0] (MSTR[3:0], MOSI[3:0]) | master shift clock | slave select, chip select | optional: master time base |
| Quad-SSC, SPI (Slave) | DOUT[3:0] (MRST[3:0], MISO[3:0]) | optional: independent clock output | not used | optional: independent clock output |
| IIC | SDA | SCL | not used | optional: master time base |
| IIS (master) | DOUT0 | master shift clock | WA | optional: master time base |
| IIS (slave) | DOUT0 | optional: independent clock output | not used | optional: independent clock output |

1) ASC, IIC, IIS and standard SSC protocols use only DOUT0 as the shift data output.

Note: To allow a certain flexibility in assigning required USIC output functions to port pins of the device, most output signals are made available on several port pins. The port control itself defines pin-by-pin which signal is used as output signal for a port pin (see port chapter). The available USIC signals and their port locations are listed in the interconnects section, see [Page 18-227](#).

18.2.1.4 Baud Rate Generator

Each USIC Channel contains a baud rate generator structured as shown in [Figure 18-2](#). It is based on coupled divider stages, providing the frequencies needed for the different protocols. It contains:

- A fractional divider to generate the input frequency $f_{PIN} = f_{FD}$ for baud rate generation based on the internal system frequency f_{PERIPH} .
- The DX1 input to generate the input frequency $f_{PIN} = f_{DX1}$ for baud rate generation based on an external signal.
- Two protocol-related counters: the divider mode counter to provide the master clock signal MCLK, the shift clock signal SCLK, and other protocol-related signals; and the capture mode timer for time interval measurement, e.g. baud rate detection.
- A time quanta counter associated to the protocol pre-processor defining protocol-specific timings, such shift control signals or bit timings, based on the input frequency f_{CTQIN} .

Universal Serial Interface Channel (USIC)

- The output signals MCLKOUT and SCLKOUT of the protocol-related divider that can be made available on pins. In order to adapt to different applications, some output characteristics of these signals can be configured.
 For device-specific details about availability of USIC signals on pins please refer to the interconnects section.

Figure 18-2 Baud Rate Generator

18.2.1.5 Channel Events and Interrupts

The notification of the user about events occurring during data traffic and data handling is based on:

- Data transfer events related to the transmission or reception of a data word, independent of the selected protocol.
- Protocol-specific events depending on the selected protocol.
- Data buffer events related to data handling by the optional FIFO data buffers.

18.2.1.6 Data Shifting and Handling

The data handling of the USIC module is based on an independent data shift unit (DSU) and a buffer structure that is similar for the supported protocols. The data shift and buffer registers are 16-bit wide (maximum data word length), but several data words can be concatenated to achieve longer data frames. The DSU inputs are the shift data (handled by input stage DX0, DX3, DX4 and DX5), the shift clock (handled by the input stage DX1), and the shift control (handled by the input stage DX2). The signal DOUT[3:0] represents the shift data outputs.

Universal Serial Interface Channel (USIC)

Figure 18-3 Principle of Data Buffering

The principle of data handling comprises:

- A transmitter with transmit shift registers (TSR and TSR[3:0]) in the DSU and a transmit data buffer (TBUF). A data validation scheme allows triggering and gating of data transfers by external events under certain conditions.
- A receiver with two alternating sets of receive shift registers (RSR0[3:0] and RSR1[3:0]) in the DSU and a double receive buffer structure (RBUF0, RBUF1). The alternating receive shift registers support the reception of data streams and data frames longer than one data word.
- A user interface to handle data, interrupts, and status and control information.

Basic Data Buffer Structure

The read access to received data and the write access of data to be transmitted can be handled by a basic data buffer structure.

The received data stored in the receiver buffers RBUF0/RBUF1 can be read directly from these registers. In this case, the user has to take care about the reception sequence to read these registers in the correct order. To simplify the use of the receive buffer structure, register RBUF has been introduced. A read action from this register delivers the data word received first (oldest data) to respect the reception sequence. With a read access from at least the low byte of RBUF, the data is automatically declared to be no longer new and the next received data word becomes visible in RBUF and can be read out next.

Universal Serial Interface Channel (USIC)

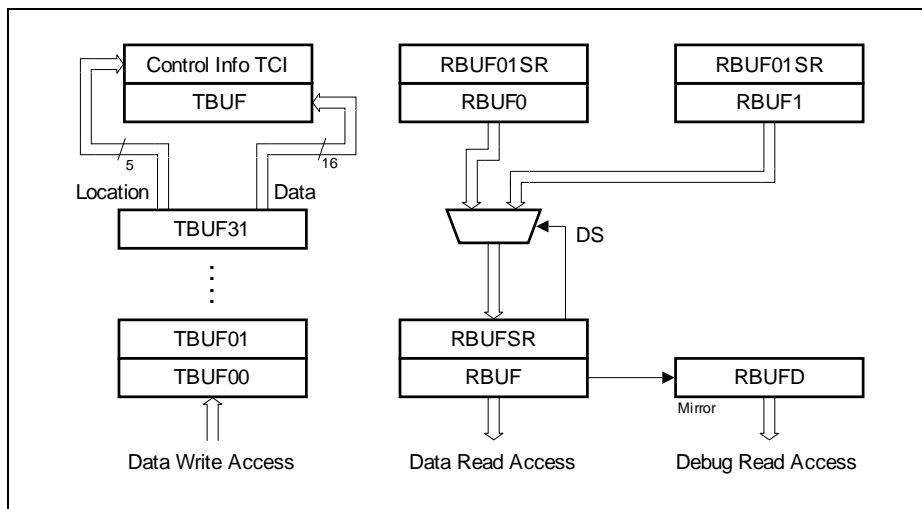

Figure 18-4 Data Access Structure without additional Data Buffer

It is recommended to read the received data words by accesses to RBUF and to avoid handling of RBUF0 and RBUF1. The USIC module also supports the use of debug accesses to receive data words. Debugger read accesses should not disturb the receive data sequence and, as a consequence, should not target RBUF. Therefore, register RBUFD has been introduced. It contains the same value as RBUF, but a read access from RBUFD does not change the status of the data (same data can be read several times). In addition to the received data, some additional status information about each received data word is available in the receiver buffer status register RBUF01SR (related to data in RBUF0 and RBUF1) and RBUFSR (related to data in RBUF).

Transmit data can be loaded to TBUF by software by writing to the transmit buffer input locations TBUF_x ($x = 00-31$), consisting of 32 consecutive addresses. The data written to one of these input locations is stored in the transmit buffer TBUF. Additionally, the address of the written location is evaluated and can be used for additional control purposes. This 5-bit wide information (named **Transmit Control Information TCI**) can be used for different purposes in different protocols.

FIFO Buffer Structure

To allow easier data setup and handling, an additional data buffering mechanism can be optionally supported. The data buffer is based on the first-in-first-out principle (FIFO) that ensures that the sequence of transferred data words is respected.

If a FIFO buffer structure is used, the data handling scheme (data with associated control information) is similar to the one without FIFO. The additional FIFO buffer can be

Universal Serial Interface Channel (USIC)

independently enabled/disabled for transmission and reception (e.g. if data FIFO buffers are available for a specific USIC channel, it is possible to configure the transmit data path without and the receive data path with FIFO buffering).

The transmit FIFO buffer is addressed by using 32 consecutive address locations for INx instead of TBUFx (x=00-31) regardless of the FIFO depth. The 32 addresses are used to store the 5-bit TCI (together with the written data) associated with each FIFO entry.

The receive FIFO can be read out at two independent addresses, OUTR and OUTDR instead of RBUF and RBUFD. A read from the OUTR location triggers the next data packet to be available for the next read (general FIFO mechanism). In order to allow non-intrusive debugging (without risk of data loss), a second address location (OUTDR) has been introduced. A read at this location delivers the same value as OUTR, but without modifying the FIFO contents.

The transmit FIFO also has the capability to bypass the data stream and to load bypass data to TBUF. This can be used to generate high-priority messages or to send an emergency message if the transmit FIFO runs empty. The transmission control of the FIFO buffer can also use the transfer trigger and transfer gating scheme of the transmission logic for data validation (e.g. to trigger data transfers by events).

Note: The available size of a FIFO data buffer for a USIC channel depends on the specific device. Please refer to the implementation chapter for details about available FIFO buffer capability.

Universal Serial Interface Channel (USIC)

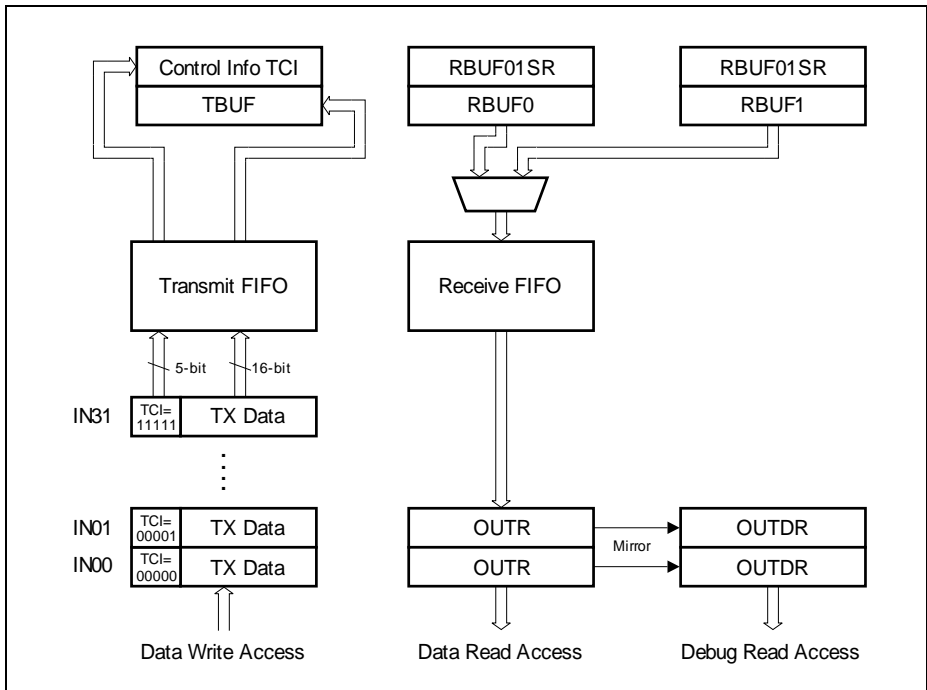

Figure 18-5 Data Access Structure with FIFO

18.2.2 Operating the USIC Communication Channel

This section describes how to operate a USIC communication channel, including protocol control and status, mode control and interrupt handling. The following aspects have to be taken into account:

- Enable the USIC module for operation and configure the behavior for the different device operation modes (see [Page 18-16](#)).
- Configure the pinning (refer to description in the corresponding protocol section).
- Configure the data structure (shift direction, word length, frame length, polarity, etc.).
- Configure the data buffer structure of the optional FIFO buffer area. A FIFO buffer can only be enabled if the related bit in register CCFG is set.
- Select a protocol by CCR.MODE. A protocol can only be selected if the related bit in register CCFG is set.

18.2.2.1 Protocol Control and Status

The protocol-related control and status information are located in the protocol control register PCR and in the protocol status register PSR. These registers are shared between the available protocols. As a consequence, the meaning of the bit positions in these registers is different within the protocols.

Use of PCR Bits

The signification of the bits in register PCR is indicated by the protocol-related alias names for the different protocols.

- PCR for the ASC protocol (see [Page 18-66](#))
- PCR for the SSC protocol (see [Page 18-98](#))
- PCR for the IIC protocol (see [Page 18-129](#))
- PCR for the IIS protocol (see [Page 18-147](#))

Use of PSR Flags

The signification of the flags in register PSR is indicated by the protocol-related alias names for the different protocols.

- PSR flags for the ASC protocol (see [Page 18-69](#))
- PSR flags for the SSC protocol (see [Page 18-102](#))
- PSR flags for the IIC protocol (see [Page 18-132](#))
- PSR flags for the IIS protocol (see [Page 18-150](#))

18.2.2.2 Mode Control

The mode control concept for system control tasks, such as suspend request for debugging, allows to program the module behavior under different device operating conditions. The behavior of a communication channel can be programmed for each of the device operating modes (normal operation, suspend mode). Therefore, each communication channel has an associated kernel state configuration register KSCFG defining its behavior in the following operating modes:

- **Normal operation:**
 This operating mode is the default operating mode when no suspend request is pending. The module clock is not switched off and the USIC registers can be read or written. The channel behavior is defined by KSCFG.NOMCFG.
- **Suspend mode:**
 This operating mode is requested when a suspend request is pending in the device. The module clock is not switched off and the USIC registers can be read or written. The channel behavior is defined by KSCFG.SUMCFG.

The four kernel modes defined by the register KSCFG are shown in [Table 18-4](#).

Table 18-4 USIC Communication Channel Behavior

| Kernel Mode | Channel Behavior | KSCFG. NOMCFG |
|-------------|---|------------------|
| Run mode 0 | Channel operation as specified, no impact on data transfer | 00 _B |
| Run mode 1 | | 01 _B |
| Stop mode 0 | Explicit stop condition as described in the protocol chapters | 10 _B |
| Stop mode 1 | | 11 _B |

Generally, bit field KSCFG.NOMCFG should be configured for run mode 0 as default setting for standard operation. If a communication channel should not react to a suspend request (and to continue its operation as in normal mode), bit field KSCFG.SUMCFG has to be configured with the same value as KSCFG.NOMCFG. If the communication channel should show a different behavior and stop operation when a specific stop condition is reached, the code for stop mode 0 or stop mode 1 have to be written to KSCFG.SUMCFG.

The stop conditions are defined for the selected protocol (see mode control description in the protocol section).

Note: The stop mode selection strongly depends on the application needs and it is very unlikely that different stop modes are required in parallel in the same application. As a result, only one stop mode type (either 0 or 1) should be used in the bit fields in register KSCFG. Do not mix stop mode 0 and stop mode 1 and avoid transitions

Universal Serial Interface Channel (USIC)

from stop mode 0 to stop mode 1 (or vice versa) for the same communication channel.

18.2.2.3 General Channel Events and Interrupts

The general event and interrupt structure is shown in [Figure 18-6](#). If a defined condition is met, an event is detected and an event indication flag becomes automatically set. The flag stays set until it is cleared by software. If enabled, an interrupt can be generated if an event is detected. The actual status of the event indication flag has no influence on the interrupt generation. As a consequence, the event indication flag does not need to be cleared to generate further interrupts.

Additionally, the service request output SRx of the USIC channel that becomes activated in case of an event condition can be selected by an interrupt node pointer. This structure allows to assign events to interrupts, e.g. depending on the application, several events can share the same interrupt routine (several events activate the same SRx output) or can be handled individually (only one event activates one SRx output).

The SRx outputs are connected to interrupt control registers to handle the CPU reaction to the service requests. This assignment is described in the implementation section on [Page 18-153](#).

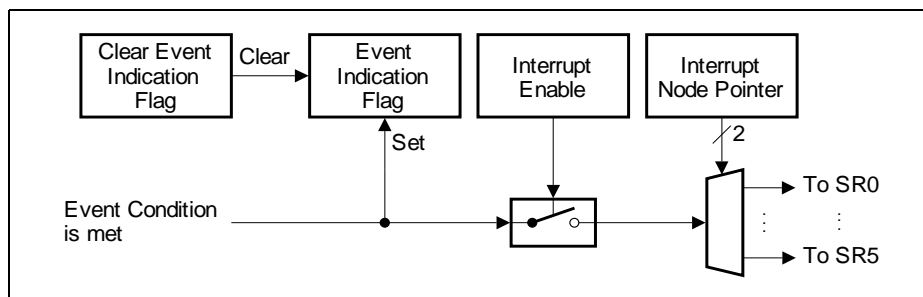

Figure 18-6 General Event and Interrupt Structure

18.2.2.4 Data Transfer Events and Interrupts

The data transfer events are based on the transmission or reception of a data word. The related indication flags are located in register PSR. All events can be individually enabled for interrupt generation.

- **Receive event to indicate that a data word has been received:**
 If a new received word becomes available in the receive buffer RBUF0 or RBUF1, either a receive event or an alternative receive event occurs.
 The receive event occurs if bit RBUFSR.PERR = 0. It is indicated by flag PSR.RIF and, if enabled, leads to receive interrupt.
- **Receiver start event to indicate that a data word reception has started:**
 When the receive clock edge that shifts in the first bit of a new data word is detected and reception is enabled, a receiver start event occurs. It is indicated by flag PSR.RSIF and, if enabled, leads to transmit buffer interrupt.
 In full duplex mode, this event follows half a shift clock cycle after the transmit buffer event and indicates when the shift control settings are internally “frozen” for the current data word reception and a new setting can be programmed.
 In SSC and IIS mode, the transmit data valid flag TCSR.TDV is cleared in single shot mode with the receiver start event.
- **Alternative receive event to indicate that a specific data word has been received:**
 If a new received word becomes available in the receive buffer RBUF0 or RBUF1, either a receive event or an alternative receive event occurs.
 The alternative receive event occurs if bit RBUFSR.PERR = 1. It is indicated by flag PSR.AIF and, if enabled, leads to alternative receive interrupt.
 Depending on the selected protocol, bit RBUFSR.PERR is set to indicate a parity error in ASC mode, the reception of the first byte of a new frame in IIC mode, and the WA information about right/left channel in IIS mode. In SSC mode, it is used as indication if the received word is the first data word, and is set if first and reset if not.
- **Transmit shift event to indicate that a data word has been transmitted:**
 A transmit shift event occurs with the last shift clock edge of a data word. It is indicated by flag PSR.TSIF and, if enabled, leads to transmit shift interrupt.
- **Transmit buffer event to indicate that a data word transmission has been started:**
 When a data word from the transmit buffer TBUF has been loaded to the shift register and a new data word can be written to TBUF, a transmit buffer event occurs. This happens with the transmit clock edge that shifts out the first bit of a new data word and transmission is enabled. It is indicated by flag PSR.TBIF and, if enabled, leads to transmit buffer interrupt.
 This event also indicates when the shift control settings (word length, shift direction, etc.) are internally “frozen” for the current data word transmission.
 In ASC and IIC mode, the transmit data valid flag TCSR.TDV is cleared in single shot mode with the transmit buffer event.
- **Data lost event to indicate a loss of the oldest received data word:**
 If the data word available in register RBUF (oldest data word from RBUF0 or RBUF1)

Universal Serial Interface Channel (USIC)

has not been read out before it becomes overwritten with new incoming data, this event occurs. It is indicated by flag PSR.DLIF and, if enabled, leads to a protocol interrupt.

Table 18-5 shows the registers, bits and bit fields indicating the data transfer events and controlling the interrupts of a USIC channel.

Table 18-5 Data Transfer Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|---------------------------|-----------------|-----------------------|----------------------|------------------------|
| Standard receive event | PSR.RIF | PSCR.CRIF | CCR.RIEN | INPR.RINP |
| Receive start event | PSR.RSIF | PSCR.CRSIF | CCR.RSIEN | INPR.TBINP |
| Alternative receive event | PSR.AIF | PSCR.CAIF | CCR.AIEN | INPR.AINP |
| Transmit shift event | PSR.TSIF | PSCR.CTSIF | CCR.TSIEN | INPR.TSINP |
| Transmit buffer event | PSR.TBIF | PSCR.CTBIF | CCR.TBIEN | INPR.TBINP |
| Data lost event | PSR.DLIF | PSCR.CDLIF | CCR.DLIEN | INPR.PINP |

Figure 18-7 shows the two transmit events and interrupts.

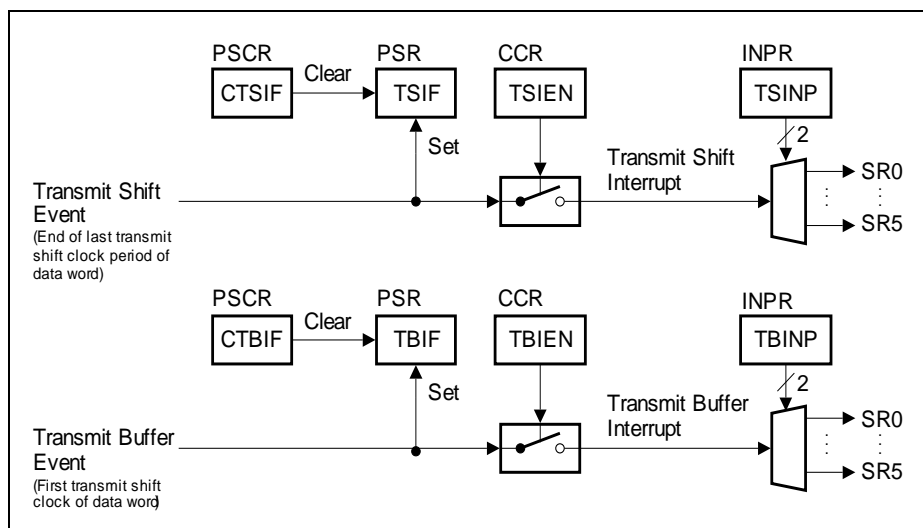

Figure 18-7 Transmit Events and Interrupts

Universal Serial Interface Channel (USIC)

Figure 18-8 shows the receive events and interrupts.

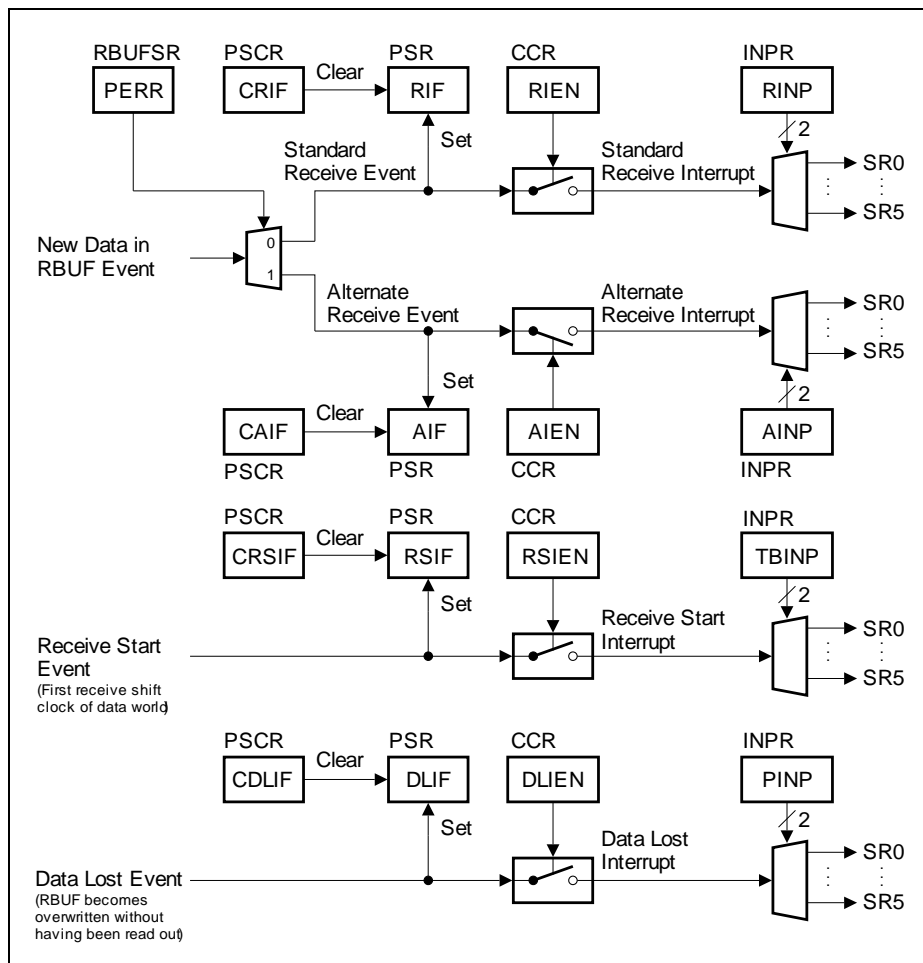

Figure 18-8 Receive Events and Interrupts

18.2.2.5 Baud Rate Generator Event and Interrupt

The baud rate generator event is based on the capture mode timer reaching its maximum value. It is indicated by flag PSR.BRGIF and, if enabled, leads to a protocol interrupt.

Universal Serial Interface Channel (USIC)

Table 18-6 shows the registers, bits and bit fields indicating the baud rate generator event and controlling the interrupt of a USIC channel.

Table 18-6 Baud Rate Generator Event and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|---------------------------|-----------------|-----------------------|----------------------|------------------------|
| Baud rate generator event | PSR. BRGIF | PSCR. CBRGIF | CCR. BRGIEN | INPR.PINP |

Figure 18-9 shows the baud rate generator event and interrupt.

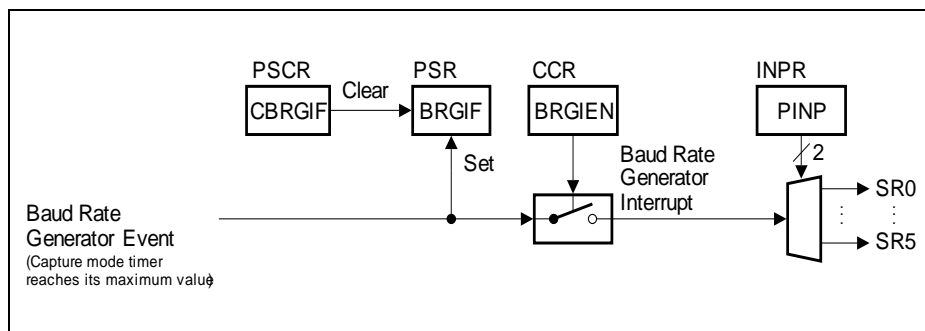

Figure 18-9 Baud Rate Generator Event and Interrupt

18.2.2.6 Protocol-specific Events and Interrupts

These events are related to protocol-specific actions that are described in the corresponding protocol chapters. The related indication flags are located in register PSR. All events can be individually enabled for the generation of the common protocol interrupt.

- Protocol-specific events in ASC mode:
Synchronization break, data collision on the transmit line, receiver noise, format error in stop bits, receiver frame finished, transmitter frame finished
- Protocol-specific events in SSC mode:
MSLS event (start-end of frame in master mode), DX2T event (start/end of frame in slave mode), both based on slave select signals, parity error
- Protocol-specific events in IIC mode:
Wrong transmit code (error in frame sequence), start condition received, repeated start condition received, stop condition received, non-acknowledge received, arbitration lost, slave read request, other general errors
- Protocol-specific events in IIS mode:
DX2T event (change on WA line), WA falling edge or rising edge detected, WA generation finished

Table 18-7 Protocol-specific Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|--------------------------------------|-----------------|-----------------------|------------------------------|------------------------|
| Protocol-specific events in ASC mode | PSR.ST[8:2] | PSCR.CST[8:2] | PCR.CTR[7:3] | INPR.PINP |
| Protocol-specific events in SSC mode | PSR.ST[3:2] | PSCR.CST[3:2] | PCR.CTR[15:14] | INPR.PINP |
| Protocol-specific events in IIC mode | PSR.ST[8:1] | PSCR.CST[8:1] | PCR.CTR[24:18] | INPR.PINP |
| Protocol-specific events in IIS mode | PSR.ST[6:3] | PSCR.CST[6:3] | PCR.CTR[6:4], PCR.CTR[15] | INPR.PINP |

18.2.3 Operating the Input Stages

All input stages offer the same feature set. They are used for all protocols, because the signal conditioning can be adapted in a very flexible way and the digital filters can be switched on and off separately.

18.2.3.1 General Input Structure

There are generally two types of input stages, one for the data input stages DX0, DX[5:3] and the other for non-data input stages DX[2:1], as shown in [Figure 18-10](#) and [Figure 18-11](#). The difference is that for the data input stages, the input signal can be additionally selected from the port signal HWINn if hardware port control is enabled through CCR.HPCEN bit. All other enable/disable functions and selections are controlled independently for each input stage by bits in the registers DXnCR.

The desired input signal can be selected among the input lines DXnA to DXnG and a permanent 1-level by programming bit field DSEL (for the data input stages, hardware port control must be disabled for DSEL to take effect). Please refer to the interconnects section ([Section 18.12](#)) for the device-specific input signal assignment. Bit DPOL allows a polarity inversion of the selected input signal to adapt the input signal polarity to the internal polarity of the data shift unit and the protocol state machine. For some protocols, the input signals can be directly forwarded to the data shift unit for the data transfers (DSEN = 0, INSW = 1) without any further signal conditioning. In this case, the data path does not contain any delay due to synchronization or filtering.

In the case of noise on the input signals, there is the possibility to synchronize the input signal (signal DXnS is synchronized to f_{PERIPH}) and additionally to enable a digital noise filter in the signal path. The synchronized input signal (and optionally filtered if DFEN = 1) is taken into account by DSEN = 1. Please note that the synchronization leads to a delay in the signal path of 2-3 times the period of f_{PERIPH} .

Figure 18-10 Input Conditioning for DX0 and DX[5:3]

Universal Serial Interface Channel (USIC)

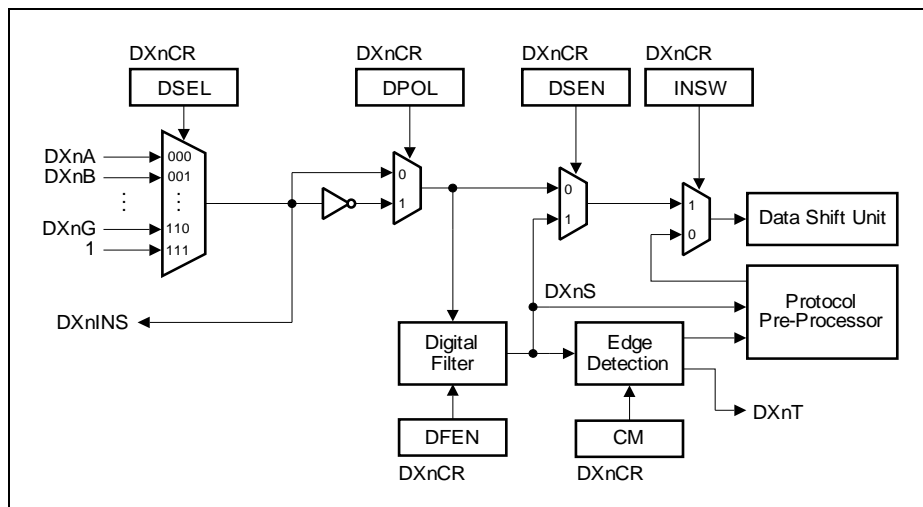

Figure 18-11 Input Conditioning for DX[2:1]

If the input signals are handled by a protocol pre-processor, the data shift unit is directly connected to the protocol pre-processor by INSW = 0. The protocol pre-processor is connected to the synchronized input signal DXnS and, depending on the selected protocol, also evaluates the edges.

To support delay compensation in SSC and IIS protocols, the DX1 input stage additionally allows the receive shift clock to be controlled independently from the transmit shift clock through the bit DCEN. When DCEN = 0, the shift clock source is selected by INSW and is the same for both receive and transmit. When DCEN = 1, the receive shift clock is derived from the selected input line as shown in [Figure 18-12](#).

Figure 18-12 Delay Compensation Enable in DX1

18.2.3.2 Digital Filter

The digital filter can be enabled to reduce noise on the input signals. Before being filtered, the input signal becomes synchronized to f_{PERIPH} . If the filter is disabled, signal DXnS corresponds to the synchronized input signal. If the filter is enabled, pulses shorter than one filter sampling period are suppressed in signal DXnS. After an edge of the synchronized input signal, signal DXnS changes to the new value if two consecutive samples of the new value have been detected.

In order to adapt the filter sampling period to different applications, it can be programmed. The first possibility is the system frequency f_{PERIPH} . Longer pulses can be suppressed if the fractional divider output frequency f_{FD} is selected. This frequency is programmable in a wide range and can also be used to determine the baud rate of the data transfers.

In addition to the synchronization delay of 2-3 periods of f_{PERIPH} , an enabled filter adds a delay of up to two filter sampling periods between the selected input and signal DXnS.

18.2.3.3 Edge Detection

The synchronized (and optionally filtered) signal DXnS can be used as input to the data shift unit and is also an input to the selected protocol pre-processor. If the protocol pre-processor does not use the DXnS signal for protocol-specific handling, DXnS can be

Universal Serial Interface Channel (USIC)

used for other tasks, e.g. to control data transmissions in master mode (a data word can be tagged valid for transmission, see chapter about data buffering).

A programmable edge detection indicates that the desired event has occurred by activating the trigger signal DXnT (introducing a delay of one period of f_{PERIPH} before a reaction to this event can take place).

18.2.3.4 Selected Input Monitoring

The selected input signal of each input stage has been made available with the signals DXnINS. These signals can be used in the system to trigger other actions, e.g. to generate interrupts.

18.2.3.5 Loop Back Mode

The USIC transmitter output signals can be connected to the corresponding receiver inputs of the same communication channel in loop back mode. Therefore, the input "G" of the input stages that are needed for the selected protocol have to be selected. In this case, drivers for ASC, SSC, and IIS can be evaluated on-chip without the connections to port pins. Data transferred by the transmitter can be received by the receiver as if it would have been sent by another communication partner.

18.2.4 Operating the Baud Rate Generator

The following blocks can be configured to operate the baud rate generator, see also [Figure 18-2](#).

18.2.4.1 Fractional Divider

The fractional divider generates its output frequency f_{FD} by either dividing the input frequency f_{PERIPH} by an integer factor n or by multiplication of $n/1024$. It has two operating modes:

- Normal divider mode ($\text{FDR.DM} = 01_{\text{B}}$):
In this mode, the output frequency f_{FD} is derived from the input clock f_{PERIPH} by an integer division by a value between 1 and 1024. The division is based on a counter FDR.RESULT that is incremented by 1 with f_{PERIPH} . After reaching the value 3FF_{H} , the counter is loaded with FDR.STEP and then continues counting. In order to achieve $f_{\text{FD}} = f_{\text{PERIPH}}$, the value of STEP has to be programmed with 3FF_{H} .
The output frequency in normal divider mode is defined by the equation:

(18.1)

$$f_{\text{FD}} = f_{\text{PERIPH}} \times \frac{1}{n} \quad \text{with } n = 1024 - \text{STEP}$$

Universal Serial Interface Channel (USIC)

- Fractional divider mode (FDR.DM = 10_B):

In this mode, the output frequency f_{FD} is derived from the input clock f_{PERIPH} by a fractional multiplication of $n/1024$ for a value of n between 0 and 1023. In general, the fractional divider mode allows to program the average output clock frequency with a finer granularity than in normal divider mode. Please note that in fractional divider mode f_{FD} can have a maximum period jitter of one f_{PERIPH} period. This jitter is not accumulated over several cycles.

The frequency f_{FD} is generated by an addition of FDR.STEP to FDR.RESULT with f_{PERIPH} . The frequency f_{FD} is based on the overflow of the addition result over $3FF_H$. The output frequency in fractional divider mode is defined by the equation:

(18.2)

$$f_{FD} = f_{PERIPH} \times \frac{n}{1024} \quad \text{with } n = \text{STEP}$$

The output frequency f_{FD} of the fractional divider is selected for baud rate generation by BRG.CLKSEL = 00_B.

18.2.4.2 External Frequency Input

The baud rate can be generated referring to an external frequency input (instead of to f_{PERIPH}) if in the selected protocol the input stage DX1 is not needed (DX1CTR.INSW = 0). In this case, an external frequency input signal at the DX1 input stage can be synchronized and sampled with the system frequency f_{PERIPH} . It can be optionally filtered by the digital filter in the input stage. This feature allows data transfers with frequencies that can not be generated by the device itself, e.g. for specific audio frequencies.

If BRG.CLKSEL = 10_B, the trigger signal DX1T determines f_{DX1} . In this mode, either the rising edge, the falling edge, or both edges of the input signal can be used for baud rate generation, depending on the configuration of the DX1T trigger event by bit field DX1CTR.CM. The signal MCLK toggles with each trigger event of DX1T.

If BRG.CLKSEL = 11_B, the rising edges of the input signal can be used for baud rate generation. The signal MCLK represents the synchronized input signal DX1S.

Both, the high time and the low time of external input signal must each have a length of minimum 2 periods of f_{PERIPH} to be used for baud rate generation.

18.2.4.3 Divider Mode Counter

The divider mode counter is used for an integer division delivering the output frequency f_{PDIV} . Additionally, two divider stages with a fixed division by 2 provide the output signals MCLK and SCLK with 50% duty cycle. If the fractional divider mode is used, the maximum fractional jitter of 1 period of f_{PERIPH} can also appear in these signals. The output frequencies of this divider is controlled by register BRG.

Universal Serial Interface Channel (USIC)

In order to define a frequency ratio between the master clock MCLK and the shift clock SCLK, the divider stage for MCLK is located in front of the divider by PDIV+1, whereas the divider stage for SCLK is located at the output of this divider.

$$f_{\text{MCLK}} = \frac{f_{\text{PIN}}}{2} \quad (18.3)$$

$$f_{\text{SCLK}} = \frac{f_{\text{PDIV}}}{2} \quad (18.4)$$

In the case that the master clock is used as reference for external devices (e.g. for IIS components) and a fixed phase relation to SCLK and other timing signals is required, it is recommended to use the MCLK signal as input for the PDIV divider. If the MCLK signal is not used or a fixed phase relation is not necessary, the faster frequency f_{PIN} can be selected as input frequency.

$$\begin{aligned} f_{\text{PDIV}} &= f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} & \text{if } \text{PPPEN} = 0 \\ f_{\text{PDIV}} &= f_{\text{MCLK}} \times \frac{1}{\text{PDIV} + 1} & \text{if } \text{PPPEN} = 1 \end{aligned} \quad (18.5)$$

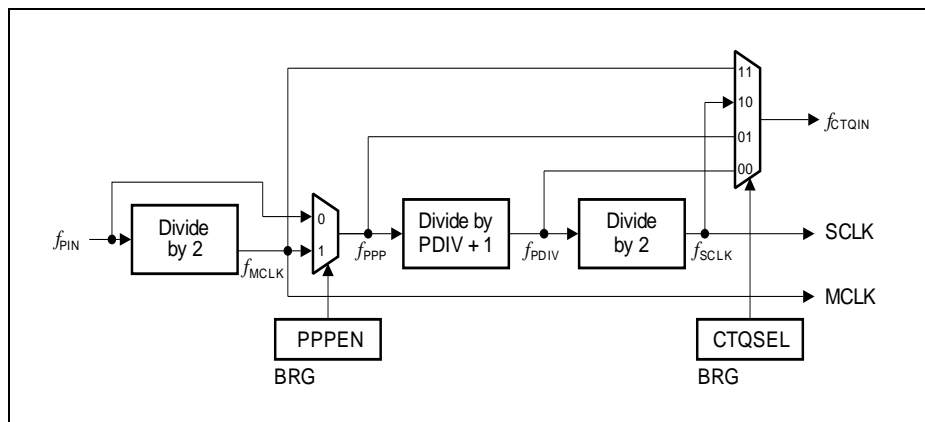

Figure 18-13 Divider Mode Counter

18.2.4.4 Capture Mode Timer

The capture mode timer is used for time interval measurement and is enabled by $\text{BRG.TMEN} = 1$. The timer works independently from the divider mode counter. Therefore, any serial data reception or transmission can continue while the timer is performing timing measurements. The timer counts f_{PPP} periods and stops counting

Universal Serial Interface Channel (USIC)

when it reaches its maximum value. Additionally, a baud rate generator interrupt event is generated (bit PSR.BRGIF becomes set).

If an event is indicated by DX0T or DX1T, the actual timer value is captured into bit field CMTR.CTV and the timer restarts from 0. Additionally, a transmit shift interrupt event is generated (bit PSR.TSIF becomes set).

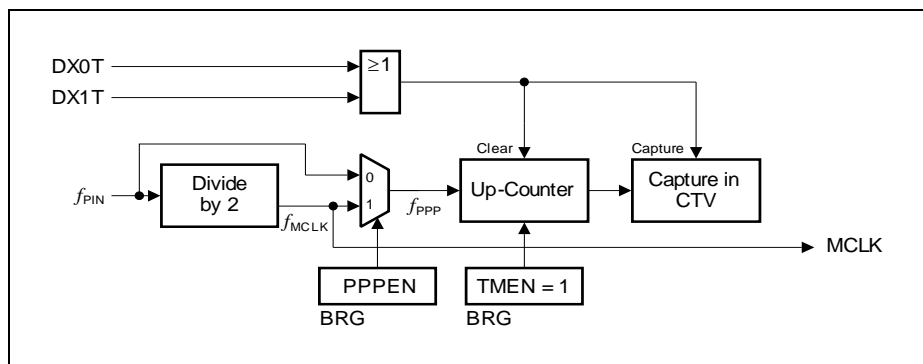

Figure 18-14 Protocol-Related Counter (Capture Mode)

The capture mode timer can be used to measure the baud rate in slave mode before starting or during data transfers, e.g. to measure the time between two edges of a data signal (by DX0T) or of a shift clock signal (by DX1T). The conditions to activate the DXnT trigger signals can be configured in each input stage.

18.2.4.5 Time Quanta Counter

The time quanta counter CTQ associated to the protocol pre-processor allows to generate time intervals for protocol-specific purposes. The length of a time quantum t_q is given by the selected input frequency f_{CTQIN} and the programmed pre-divider value.

The meaning of the time quanta depend on the selected protocol, please refer to the corresponding chapters for more protocol-specific information.

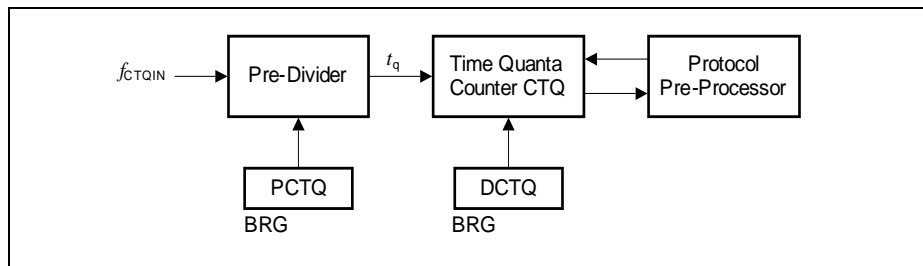

Figure 18-15 Time Quanta Counter

18.2.4.6 Master and Shift Clock Output Configuration

The master clock output signal MCLKOUT available at the corresponding output pin can be configured in polarity. The MCLK signal can be generated for each protocol in order to provide a kind of higher frequency time base compared to the shift clock.

The configuration mechanism of the master clock output signal MCLKOUT ensures that no shortened pulses can occur. Each MCLK period consists of two phases, an active phase, followed by a passive phase. The polarity of the MCLKOUT signal during the active phase is defined by the inverted level of bit BRG.MCLKCFG, evaluated at the start of the active phase. The polarity of the MCLKOUT signal during the passive phase is defined by bit BRG.MCLKCFG, evaluated at the start of the passive phase. If bit BRG.MCLKCFG is programmed with another value, the change is taken into account with the next change between the phases. This mechanism ensures that no shorter pulses than the length of a phase occur at the MCLKOUT output. In the example shown in [Figure 18-16](#), the value of BRG.MCLKCFG is changed from 0 to 1 during the passive phase of MCLK period 2.

The generation of the MCLKOUT signal is enabled/disabled by the protocol pre-processor, based on bit PCR.MCLK. After this bit has become set, signal MCLKOUT is generated with the next active phase of the MCLK period. If PCR.MCLK = 0 (MCLKOUT generation disabled), the level for the passive phase is also applied for active phase.

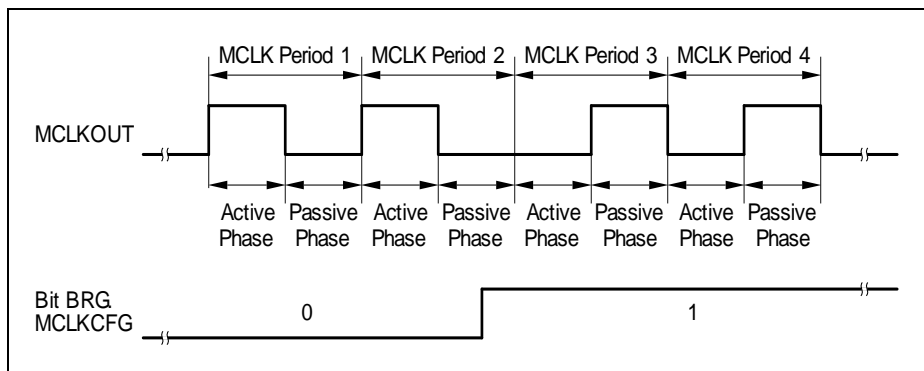

Figure 18-16 Master Clock Output Configuration

The shift clock output signal SCLKOUT available at the corresponding output pin can be configured in polarity and additionally, a delay of one period of f_{PDIV} (= half SCLK period) can be introduced. The delay allows to adapt the order of the shift clock edges to the application requirements. If the delay is used, it has to be taken into account for the calculation of the signal propagation times and loop delays.

The mechanism for the polarity control of the SCLKOUT signal is similar to the one for MCLKOUT, but based on bit field BRG.SCLKCFG. The generation of the SCLKOUT

Universal Serial Interface Channel (USIC)

signal is enabled/disabled by the protocol pre-processor. Depending on the selected protocol, the protocol pre-processor can control the generation of the SCLKOUT signal independently of the divider chain, e.g. for protocols without the need of a shift clock available at a pin, the SCLKOUT generation is disabled.

18.2.5 Operating the Transmit Data Path

The transmit data path is based on 16-bit wide transmit shift registers (TSR and TSR[3:0]) and a transmit buffer TBUF. The data transfer parameters like data word length, data frame length, or the shift direction are controlled commonly for transmission and reception by the shift control register SCTR. The transmit control and status register TCSR controls the transmit data handling and monitors the transmit status.

A change of the value of the data shift output signal DOUTx only happens at the corresponding edge of the shift clock input signal. The level of the last data bit of a data word/frame is held constant at DOUTx until the next data word begins with the next corresponding edge of the shift clock.

18.2.5.1 Transmit Buffering

The transmit shift registers can not be directly accessed by software, because they are automatically updated with the value stored in the transmit buffer TBUF if a currently transmitted data word is finished and new data is valid for transmission. Data words can be loaded directly into TBUF by writing to one of the transmit buffer input locations TBUFx (see [Page 18-33](#)) or, optionally, by a FIFO buffer stage (see [Page 18-39](#)).

Figure 18-17 Transmit Data Path

18.2.5.2 Transmit Data Shift Mode

The transmit shift data can be selected to be shifted out one, two or four bits at a time through the corresponding number of output lines. This option allows the USIC to support protocols such as the Dual- and Quad-SSC. The selection is done through the bit field DSM in the shift control register SCTR.

Note: The bit field SCTR.DSM controls the data shift mode for both the transmit and receive paths to allow the transmission and reception of data through one to four data lines.

For the shift mode with two or four parallel data outputs, the data word and frame length must be in multiples of two or four respectively. The number of data shifts required to output a specific data word or data frame length is thus reduced by the factor of the number of parallel data output lines. For example, to transmit a 16-bit data word through four output lines, only four shifts are required.

Universal Serial Interface Channel (USIC)

Depending on the shift mode, different transmit shift registers with different bit composition are used as shown in **Table 18-8**. Note that the 'n' in the table denotes the shift number less one, i.e. for the first data shift $n = 0$, the second data shift $n = 1$ and continues until the total number of shifts less one is reached.

For all transmit shift registers, whether the first bit shifted out is the MSB or LSB depends on the setting of SCTR.SDIR.

Table 18-8 Transmit Shift Register Composition

| Transmit Shift Registers | Single Data Output (SCTR.DSM = 00 _B) | Two Data Outputs (SCTR.DSM = 10 _B) | Four Data Outputs (SCTR.DSM = 11 _B) |
|--------------------------|--|--|---|
| TSR | All data bits | Not used | Not used |
| TSR0 | Not used | Bit $n*2$ | Bit $n*4$ |
| TSR1 | Not used | Bit $n*2 + 1$ | Bit $n*4 + 1$ |
| TSR2 | Not used | Not used | Bit $n*4 + 2$ |
| TSR3 | Not used | Not used | Bit $n*4 + 3$ |

18.2.5.3 Transmit Control Information

The transmit control information TCI is a 5-bit value derived from the address x of the written TBUFx or INx input location. For example, writing to TBUF31 generates a TCI of 11111_B.

The TCI can be used as an additional control parameter for data transfers to dynamically change the data word length, the data frame length, or other protocol-specific functions (for more details about this topic, please refer to the corresponding protocol chapters). The way how the TCI is used in different applications can be programmed by the bits WLEMD, FLEMD, SELMD, WAMD and HPCMD in register TCSR. Please note that not all possible settings lead to useful system behavior.

- Word length control:
If TCSR.WLEMD = 1, bit field SCTR.WLE is updated with TCI[3:0] if a transmit buffer input location TBUFx is written. This function can be used in all protocols to dynamically change the data word length between 1 and 16 data bits per data word. Additionally, bit TCSR.EOF is updated with TCI[4]. This function can be used in SSC master mode to control the slave select generation to finish data frames. It is recommended to program TCSR.FLEMD = TCSR.SELMD = TCSR.WAMD = TCSR.HPCMD = 0.
- Frame length control:
If TCSR.FLEMD = 1, bit field SCTR.FLE[4:0] is updated with TCI[4:0] and SCTR.FLE[5] becomes 0 if a transmit buffer input location TBUFx is written. This function can be used in all protocols to dynamically change the data frame length

Universal Serial Interface Channel (USIC)

between 1 and 32 data bits per data frame. It is recommended to program $TCSR.SELMD = TCSR.WLEMD = TCSR.WAMD = TCSR.HPCMD = 0$.

- **Select output control:**
If $TCSR.SELMD = 1$, bit field $PCR.CTR[20:16]$ is updated with $TCI[4:0]$ and $PCR.CTR[23:21]$ becomes 0 if a transmit buffer input location $TBUFx$ is written. This function can be used in SSC master mode to define the targeted slave device(s). It is recommended to program $TCSR.WLEMD = TCSR.FLEMD = TCSR.WAMD = TCSR.HPCMD = 0$.
- **Word address control:**
If $TCSR.WAMD = 1$, bit $TCSR.WA$ is updated with $TCI[4]$ if a transmit buffer input location $TBUFx$ is written. This function can be used in IIS mode to define if the data word is transmitted on the right or the left channel. It is recommended to program $TCSR.WLEMD = TCSR.FLEMD = TCSR.SELMD = TCSR.HPCMD = 0$.
- **Hardware Port control:**
If $TCSR.HPCMD = 1$, bit field $SCTR.DSM$ is updated with $TCI[1:0]$ if a transmit buffer input location $TBUFx$ is written. This function can be used in SSC protocols to dynamically change the number of data input and output lines to set up for standard, dual and quad SSC formats.
Additionally, bit $TCSR.HPCDIR$ is updated with $TCI[2]$. This function can be used in SSC protocols to control the pin(s) direction when the hardware port control function is enabled through $CCR.HPCEN = 1$. It is recommended to program $TCSR.FLEMD = TCSR.WLEMD = TCSR.SELMD = TCSR.WAMD = 0$.

18.2.5.4 Transmit Data Validation

The data word in the transmit buffer $TBUF$ can be tagged valid or invalid for transmission by bit $TCSR.TDV$ (transmit data valid). A combination of data flow related and event related criteria define whether the data word is considered valid for transmission. A data validation logic checks the start conditions for each data word. Depending on the result of the check, the transmit shift register is loaded with different values, according to the following rules:

- If a USIC channel is the communication master (it defines the start of each data word transfer), a data word transfer can only be started with valid data in the transmit buffer $TBUF$. In this case, the transmit shift register is loaded with the content of $TBUF$, that is not changed due to this action.
- If a USIC channel is a communication slave (it can not define the start itself, but has to react), a data word transfer requested by the communication master has to be started independently of the status of the data word in $TBUF$. If a data word transfer is requested and started by the master, the transmit shift register is loaded at the first corresponding shift clock edge either with the data word in $TBUF$ (if it is valid for transmission) or with the level defined by bit $SCTR.PDL$ (if the content of $TBUF$ has not been valid at the transmission start). In both cases, the content of $TBUF$ is not changed.

Universal Serial Interface Channel (USIC)

The control and status bits for the data validation are located in register TCSR. The data validation is based on the logic blocks shown in **Figure 18-18**.

Figure 18-18 Transmit Data Validation

- A transfer gating logic enables or disables the data word transfer from TBUF under software or under hardware control. If the input stage DX2 is not needed for data shifting, signal DX2S can be used for gating purposes. The transfer gating logic is controlled by bit field TCSR.TDEN.
- A transfer trigger logic supports data word transfers related to events, e.g. timer based or related to an input pin. If the input stage DX2 is not needed for data shifting, signal DX2T can be used for trigger purposes. The transfer trigger logic is controlled by bit TCSR.TDVTR and the occurrence of a trigger event is indicated by bit TCSR.TE. For example, this can be used for triggering the data transfer upon receiving the Clear to Send (CTS) signal at DX2 in the RS-232 protocol.
- A data validation logic combining the inputs from the gating logic, the triggering logic and DSU signals. A transmission of the data word located in TBUF can only be started if the gating enables the start, bit TCSR.TDV = 1, and bit TCSR.TE = 1. The content of the transmit buffer TBUF should not be overwritten with new data while it is valid for transmission and a new transmission can start. If the content of TBUF has to be changed, it is recommended to clear bit TCSR.TDV by writing $\text{FMR.MTDV} = 10_{\text{B}}$ before updating the data. Bit TCSR.TDV becomes automatically set when TBUF is updated with new data. Another possibility are the interrupts TBI (for ASC and IIC) or RSI (for SSC and IIS) indicating that a transmission has started. While a transmission is in progress, TBUF can be loaded with new data. In this case the user has to take care that an update of the TBUF content takes place before a new transmission starts.

With this structure, the following data transfer functionality can be achieved:

Universal Serial Interface Channel (USIC)

- If bit TCSR.TDSSM = 0, the content of the transmit buffer TBUF is always considered as valid for transmission. The transfer trigger mechanism can be used to start the transfer of the same data word based on the selected event (e.g. on a timer base or an edge at a pin) to realize a kind of life-sign mechanism. Furthermore, in slave mode, it is ensured that always a correct data word is transmitted instead of the passive data level.
- Bit TCSR.TDSSM = 1 has to be programmed to allow word-by-word data transmission with a kind of single-shot mechanism. After each transmission start, a new data word has to be loaded into the transmit buffer TBUF, either by software write actions to one of the transmit buffer input locations TBUFx or by an optional data buffer (e.g. FIFO buffer). To avoid that data words are sent out several times or to allow data handling with an additional data buffer (e.g. FIFO), bit TCSR.TDSSM has to be 1.
- Bit TCSR.TDV becoming automatically set when a new data word is loaded into the transmit buffer TBUF, a transmission start can be requested by a write action of the data to be transmitted to at least the low byte of one of the transmit buffer input locations TBUFx. The additional information TCI can be used to control the data word length or other parameters independently for each data word by a single write access.
- Bit field FMR.MTDV allows software driven modification (set or clear) of bit TCSR.TDV. Together with the gating control bit field TCSR.TDEN, the user can set up the transmit data word without starting the transmission. A possible program sequence could be: clear TCSR.TDEN = 00_B, write data to TBUFx, clear TCSR.TDV by writing FMR.MTDV = 10_B, re-enable the gating with TCSR.TDEN = 01_B and then set TCSR.TDV under software control by writing FMR.MTDV = 01_B.

18.2.6 Operating the Receive Data Path

The receive data path is based on two sets of 16-bit wide receive shift registers RSR0[3:0] and RSR1[3:0] and a receive buffer for each of the set (RBUF0 and RBUF1). The data transfer parameters like data word length, data frame length, or the shift direction are controlled commonly for transmission and reception by the shift control registers.

Register RBUF01SR monitors the status of RBUF0 and RBUF1.

18.2.6.1 Receive Buffering

The receive shift registers cannot be directly accessed by software, but their contents are automatically loaded into the receive buffer registers RBUF0 (or RBUF1 respectively) if a complete data word has been received or the frame is finished. The received data words in RBUF0 or RBUF1 can be read out in the correct order directly from register RBUF or, optionally, from a FIFO buffer stage (see [Page 18-39](#)).

Figure 18-19 Receive Data Path

18.2.6.2 Receive Data Shift Mode

Receive data can be selected to be shifted in one, two or four bits at a time through the corresponding number of input stages and data input lines. This option allows the USIC to support protocols such as the Dual- and Quad-SSC. The selection is done through the bit field DSM in the shift control register SCTR.

Note: The bit field SCTR.DSM controls the data shift mode for both the transmit and receive paths to allow the transmission and reception of data through one to four data lines.

For the shift mode with two or four parallel data inputs, the data word and frame length must be in multiples of two or four respectively. The number of data shifts required to input a specific data word or data frame length is thus reduced by the factor of the

Universal Serial Interface Channel (USIC)

number of parallel data input lines. For example, to receive a 16-bit data word through four input lines, only four shifts are required.

Depending on the shift mode, different receive shift registers with different bit composition are used as shown in [Table 18-8](#). Note that the 'n' in the table denotes the shift number less one, i.e. for the first data shift $n = 0$, the second data shift $n = 1$ and continues until the total number of shifts less one is reached.

For all receive shift registers, whether the first bit shifted in is the MSB or LSB depends on the setting of SCTR.SDIR.

Table 18-9 Receive Shift Register Composition

| Receive Shift Registers | Input stage used | Single Data Input (SCTR.DSM = 00 _B) | Two Data Inputs (SCTR.DSM = 10 _B) | Four Data Inputs (SCTR.DSM = 11 _B) |
|-------------------------|------------------|---|---|--|
| RSR _x 0 | DX0 | All data bits | Bit $n*2$ | Bit $n*4$ |
| RSR _x 1 | DX3 | Not used | Bit $n*2 + 1$ | Bit $n*4 + 1$ |
| RSR _x 2 | DX4 | Not used | Not used | Bit $n*4 + 2$ |
| RSR _x 3 | DX5 | Not used | Not used | Bit $n*4 + 3$ |

18.2.6.3 Baud Rate Constraints

The following baud rate constraints have to be respected to ensure correct data reception and buffering. The user has to take care about these restrictions when selecting the baud rate and the data word length with respect to the module clock frequency f_{PERIPH} .

- A received data word in a receiver shift registers RSR_x[3:0] must be held constant for at least 4 periods of f_{PERIPH} in order to ensure correct loading of the related receiver buffer register RBUF_x.
- The shift control signal has to be constant inactive for at least 5 periods of f_{PERIPH} between two consecutive frames in order to correctly detect the end of a frame.
- The shift control signal has to be constant active for at least 1 period of f_{PERIPH} in order to correctly detect a frame (shortest frame).
- A minimum setup and hold time of the shift control signal with respect to the shift clock signal has to be ensured.

18.2.7 Hardware Port Control

Hardware port control is intended for SSC protocols with half-duplex configurations, where a single port pin is used for both input and output data functions, to control the pin direction through a dedicated hardware interface. All settings in Pn_IOCRy.PC_x, except for the input pull device selection and output driver type (open drain or push-pull), are overruled by the hardware port control.

Universal Serial Interface Channel (USIC)

Input pull device selection is done through the Pn_IOCry.PCx as before, while the output driver is fixed to push-pull-only in this mode.

One, two or four port pins can be selected with the hardware port control to support SSC protocols with multiple bi-directional data lines, such as dual- and quad-SSC. This selection and the enable/disable of the hardware port control is done through CCR.HPCEN. The direction of all selected pins is controlled through a single bit SCTR.HPCDIR.

SCTR.HPCDIR is automatically shadowed with the start of each data word to prevent changing of the pin direction in the middle of a data word transfer.

18.2.8 Operating the FIFO Data Buffer

The FIFO data buffers of a USIC module are built in a similar way, with transmit buffer and receive buffer capability for each channel. Depending on the device, the amount of available FIFO buffer area can vary. In the XMC4[78]00, totally 64 buffer entries can be distributed among the transmit or receive FIFO buffers of both channels of the USIC module.

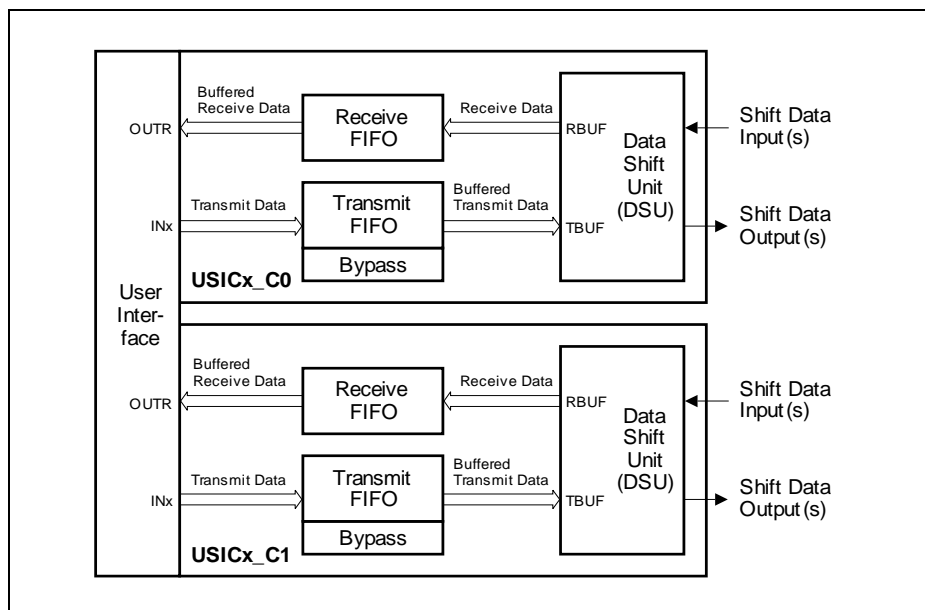

Figure 18-20 FIFO Buffer Overview

In order to operate the FIFO data buffers, the following issues have to be considered:

Universal Serial Interface Channel (USIC)

- FIFO buffer available and selected:
 The transmit FIFO buffer and the bypass structure are only available if CCFG.TB = 1, whereas the receive FIFO buffer is only available if CCFG.RB = 1.
 It is recommended to configure all buffer parameters while there is no data traffic for this USIC channel and the FIFO mechanism is disabled by TBCTR.SIZE = 0 (for transmit buffer) or RBCTR.SIZE = 0 (for receive buffer). The allocation of a buffer area by writing TBCTR or RBCTR has to be done while the corresponding FIFO buffer is disabled. The FIFO buffer interrupt control bits can be modified independently of data traffic.
- FIFO buffer setup:
 The total amount of available FIFO buffer entries limits the length of the transmit and receive buffers for each USIC channel.
- Bypass setup:
 In addition to the transmit FIFO buffer, a bypass can be configured as described on [Page 18-50](#).

18.2.8.1 FIFO Buffer Partitioning

If available, the FIFO buffer area consists of a defined number of FIFO buffer entries, each containing a data part and the associated control information (RCI for receive data, TCI for transmit data). One FIFO buffer entry represents the finest granularity that can be allocated to a receive FIFO buffer or a transmit FIFO buffer. All available FIFO buffer entries of a USIC module are located one after the other in the FIFO buffer area. The overall counting starts with FIFO entry 0, followed by 1, 2, etc.

For each USIC module, a certain number of FIFO entries is available, that can be allocated to the channels of the same USIC module. It is not possible to assign FIFO buffer area to USIC channels that are not located within the same USIC module.

For each USIC channel, the size of the transmit and the receive FIFO buffer can be chosen independently. For example, it is possible to allocate the full amount of available FIFO entries as transmit buffer for one USIC channel. Some possible scenarios of FIFO buffer partitioning are shown in [Figure 18-21](#).

Each FIFO buffer consists of a set of consecutive FIFO entries. The size of a FIFO data buffer can only be programmed as a power of 2, starting with 2 entries, then 4 entries, then 8 entries, etc. A FIFO data buffer can only start at a FIFO entry aligned to its size. For example, a FIFO buffer containing n entries can only start with FIFO entry 0, n , $2*n$, $3*n$, etc. and consists of the FIFO entries $[x*n, (x+1)*n-1]$, with x being an integer number (incl. 0). It is not possible to have “holes” with unused FIFO entries within a FIFO buffer, whereas there can be unused FIFO entries between two FIFO buffers.

Universal Serial Interface Channel (USIC)

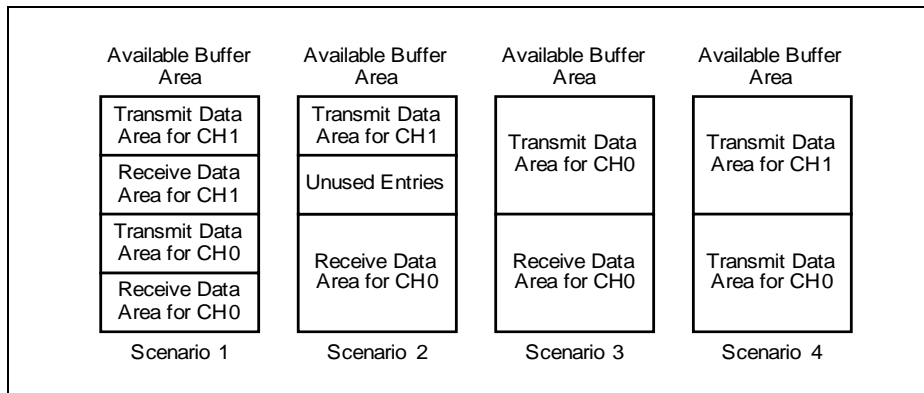

Figure 18-21 FIFO Buffer Partitioning

The data storage inside the FIFO buffers is based on pointers, that are internally updated whenever the data contents of the FIFO buffers have been modified. This happens automatically when new data is put into a FIFO buffer or the oldest data is taken from a FIFO buffer. As a consequence, the user program does not need to modify the pointers for data handling. Only during the initialization phase, the start entry of a FIFO buffer has to be defined by writing the number of the first FIFO buffer entry in the FIFO buffer to the corresponding bit field DPTR in register RBCTR (for a receive FIFO buffer) or TBCTR (for a transmit FIFO buffer) while the related bit field RBCTR.SIZE=0 (or TBCTR.SIZE = 0, respectively). The assignment of buffer entries to a FIFO buffer (regarding to size and pointers) must not be changed by software while the related USIC channel is taking part in data traffic.

18.2.8.2 Transmit Buffer Events and Interrupts

The transmit FIFO buffer mechanism detects the following events, that can lead to interrupts (if enabled):

- Standard transmit buffer event
- Transmit buffer error event

Standard Transmit Buffer Event

The standard transmit buffer event is triggered by the filling level of the transmit buffer (given by TRBSR.TBFLVL) exceeding (TBCTR.LOF = 1) or falling below (TBCTR.LOF = 0)¹⁾ a programmed limit (TBCTR.LIMIT).

¹⁾ If the standard transmit buffer event is used to indicate that new data has to be written to one of the INx locations, TBCTR.LOF = 0 should be programmed.

Universal Serial Interface Channel (USIC)

If the event trigger with TRBSR.STBT feature is disabled (TBCTR.STBTEN = 0), the trigger of the standard transmit buffer event is based on the transition of the fill level from equal to below or above the limit, not the fact of being below or above.

If TBCTR.STBTEN = 1, the transition of the fill level below or above the programmed limit additionally sets TRBSR.STBT. This bit triggers also the standard transmit buffer event whenever there is a transfer data to TBUF event or write data to INx event, depending on TBCTR.LOF setting.

The way TRBSR.STBT is cleared depends on the trigger mode (selected by TBCTR.STBTM). If TBCTR.STBTM = 0, TRBSR.STBT is cleared by hardware when the buffer fill level equals the programmed limit again (TRBSR.TBFLVL = TBCTR.LIMIT). If TBCTR.STBTM = 1, TRBSR.STBT is cleared by hardware when the buffer fill level equals the buffer size (TRBSR.TBFLVL = TBCTR.SIZE).

Note: The flag TRBSR.STBI is set only when the transmit buffer fill level exceeds or falls below the programmed limit (depending on TBCTR.LOF setting). Standard transmit buffer events triggered by TRBSR.STBT does not set the flag.

Figure 18-22 shows examples of the standard transmit buffer event with the different TBCTR.STBTEN and TBCTR.STBTM settings. These examples are meant to illustrate the hardware behaviour and might not always represent real application use cases.

Universal Serial Interface Channel (USIC)

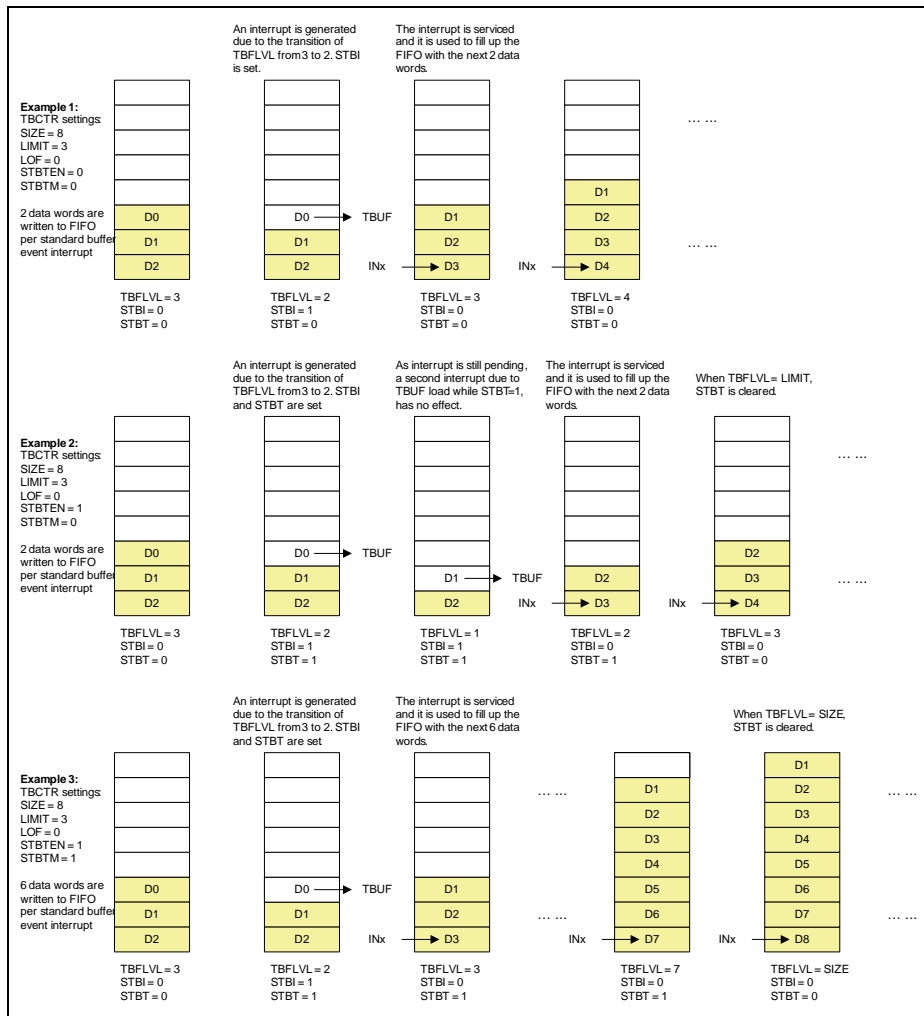

Figure 18-22 Standard Transmit Buffer Event Examples

Transmit Buffer Error Event

The transmit buffer error event is triggered when software has written to a full buffer. The written value is ignored.

Transmit Buffer Events and Interrupt Handling

Figure 18-23 shows the transmit buffer events and interrupts.

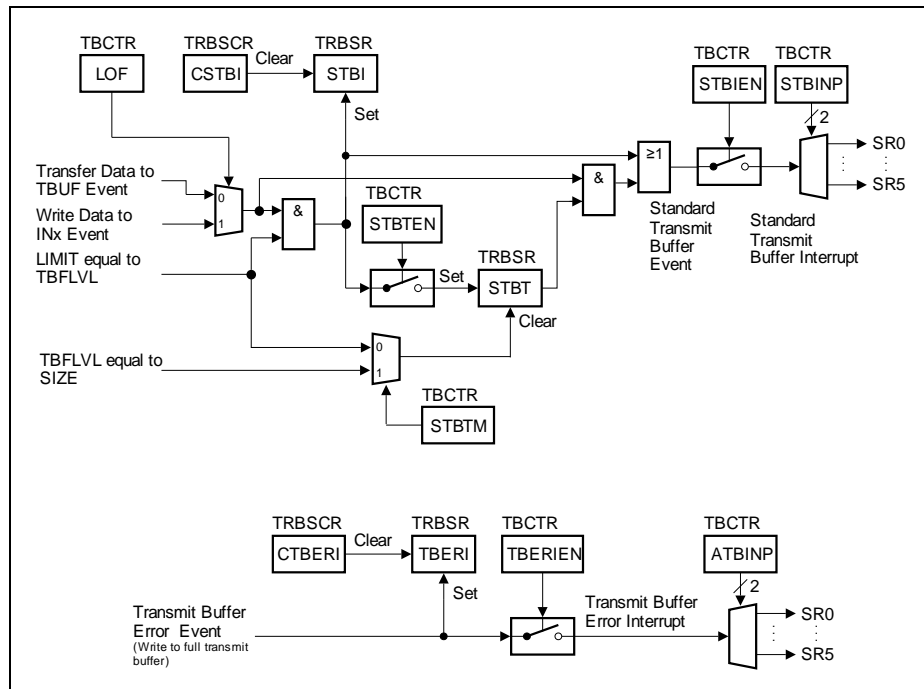

Figure 18-23 Transmit Buffer Events

Table 18-10 shows the registers, bits and bit fields to indicate the transmit buffer events and to control the interrupts related to the transmit FIFO buffers of a USIC channel.

Table 18-10 Transmit Buffer Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|--------------------------------|-----------------|-----------------------|----------------------|------------------------|
| Standard transmit buffer event | TRBSR. STBI | TRBSR. CSTBI | TBCTR. STBIEN | TBCTR. STBINP |
| | TRBSR. STBT | Cleared by hardware | | |
| Transmit buffer error event | TRBSR. TBERI | TRBSR. CTBERI | TBCTR. TBERIEN | TBCTR. ATBINP |

18.2.8.3 Receive Buffer Events and Interrupts

The receive FIFO buffer mechanism detects the following events, that can lead to an interrupt (if enabled):

- Standard receive buffer event
- Alternative receive buffer event
- Receive buffer error event

The standard receive buffer event and the alternative receive buffer event can be programmed to two different modes, one referring to the filling level of the receive buffer, the other one related to a bit position in the receive control information RCI of the data word that becomes available in OUTR.

If the interrupt generation refers to the filling level of the receive FIFO buffer, only the standard receive buffer event is used, whereas the alternative receive buffer event is not used. This mode can be selected to indicate that a certain amount of data has been received, without regarding the content of the associated RCI.

If the interrupt generation refers to RCI, the filling level is not taken into account. Each time a new data word becomes available in OUTR, an event is detected. If bit RCI[4] = 0, a standard receive buffer event is signaled, otherwise an alternative receive buffer device (RCI[4] = 1). Depending on the selected protocol and the setting of RBCTR.RCIM, the value of RCI[4] can hold different information that can be used for protocol-specific interrupt handling (see protocol sections for more details).

Standard Receive Buffer Event in Filling Level Mode

In filling level mode (RBCTR.RNM = 0), the standard receive buffer event is triggered by the filling level of the receive buffer (given by TRBSR.RBFLVL) exceeding (RBCTR.LOF = 1) or falling below (RBCTR.LOF = 0) a programmed limit (RBCTR.LIMIT).¹⁾

If the event trigger with bit TRBSR.SRBT feature is disabled (RBCTR.SRBTEN = 0), the trigger of the standard receive buffer event is based on the transition of the fill level from equal to below or above the limit, not the fact of being below or above.

If RBCTR.SRBTEN = 1, the transition of the fill level below or above the programmed limit additionally sets the bit TRBSR.SRBT. This bit also triggers the standard receive buffer event each time there is a data read out event or new data received event, depending on RBCTR.LOF setting.

The way TRBSR.SRBT is cleared depends on the trigger mode (selected by RBCTR.SRBTM). If RBCTR.SRBTM = 0, TRBSR.SRBT is cleared by hardware when the buffer fill level equals the programmed limit again (TRBSR.RBFLVL =

¹⁾ If the standard receive buffer event is used to indicate that new data has to be read from OUTR, RBCTR.LOF = 1 should be programmed.

Universal Serial Interface Channel (USIC)

RBCTR.LIMIT). If RBCTR.SRBTM = 1, TRBSR.SRBT is cleared by hardware when the buffer fill level equals 0 (TRBSR.RBFLVL = 0).

Note: The flag TRBSR.SRBI is set only when the receive buffer fill level exceeds or falls below the programmed limit (depending on RBCTR.LOF setting). Standard receive buffer events triggered by TRBSR.SRBT does not set the flag.

Universal Serial Interface Channel (USIC)

Standard and Alternate Receive Buffer Events in RCI Mode

In RCI mode ($RBCTR.RNM = 1$), the standard receive buffer event is triggered when the OUTR stage is updated with a new data value with $RCI[4] = 0$.

If the OUTR stage is updated with a new data value with $RCI[4] = 1$, an alternate receive buffer event is triggered instead.

Receive Buffer Error Event

The receive buffer error event is triggered if the software reads from an empty buffer, regardless of $RBCTR.RNM$ value. The read data is invalid.

Receive Buffer Events and Interrupt Handling

Figure 18-25 shows the receiver buffer events and interrupts in filling level mode.

Figure 18-25 Receiver Buffer Events in Filling Level Mode

Universal Serial Interface Channel (USIC)

Figure 18-26 shows the receiver buffer events and interrupts in RCI mode.

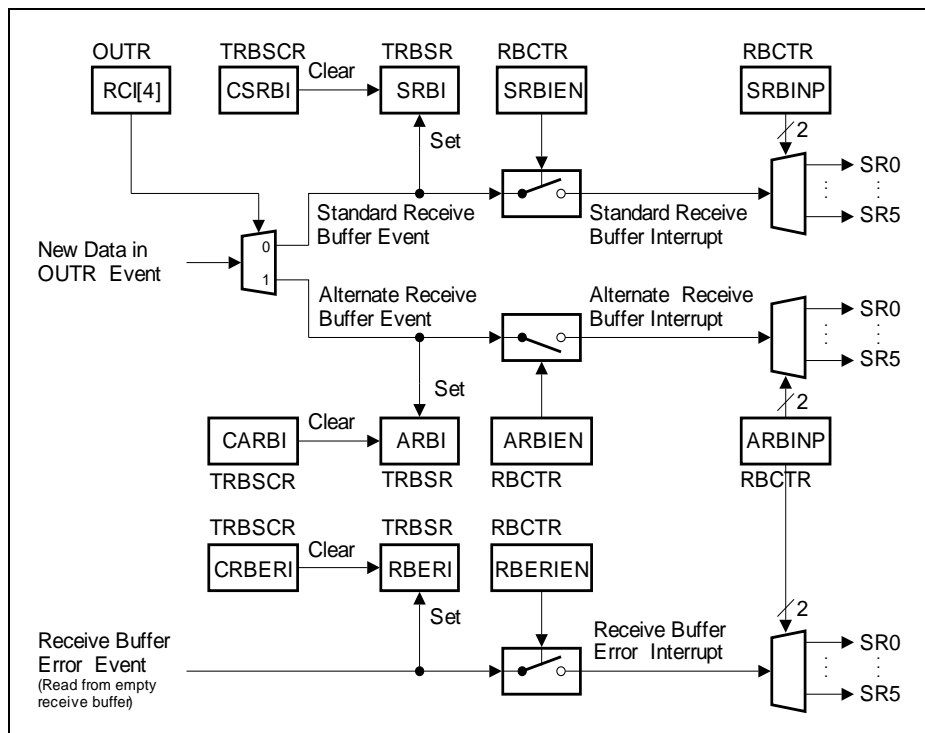

Figure 18-26 Receiver Buffer Events in RCI Mode

Table 18-11 shows the registers, bits and bit fields to indicate the receive buffer events and to control the interrupts related to the receive FIFO buffers of a USIC channel.

Table 18-11 Receive Buffer Events and Interrupt Handling

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|-------------------------------|-----------------|-----------------------|----------------------|------------------------|
| Standard receive buffer event | TRBSR. SRBI | TRBSCR. CSRBI | RBCTR. SRBIEN | RBCTR. SRBINP |
| | TRBSR. SRBT | Cleared by hardware | | |

Universal Serial Interface Channel (USIC)

Table 18-11 Receive Buffer Events and Interrupt Handling (cont'd)

| Event | Indication Flag | Indication cleared by | Interrupt enabled by | SRx Output selected by |
|----------------------------------|-----------------|-----------------------|----------------------|------------------------|
| Alternative receive buffer event | TRBSR. ARBI | TRBSCR. CARBI | RBCTR. ARBIEIN | RBCTR. ARBINP |
| Receive buffer error event | TRBSR. RBERI | TRBSCR. CRBERI | RBCTR. RBERIEN | RBCTR. ARBINTXDP |

18.2.8.4 FIFO Buffer Bypass

The data bypass mechanism is part of the transmit FIFO control block. It allows to introduce a data word in the data stream without modifying the transmit FIFO buffer contents, e.g. to send a high-priority message. The bypass structure consists of a bypass data word of maximum 16 bits in register BYP and some associated control information in register BYPCR. For example, these bits define the word length of the bypass data word and configure a transfer trigger and gating mechanism similar to the one for the transmit buffer TBUF.

The bypass data word can be tagged valid or invalid for transmission by bit BYRCR.BDV (bypass data valid). A combination of data flow related and event related criteria define whether the bypass data word is considered valid for transmission. A data validation logic checks the start conditions for this data word. Depending on the result of the check, the transmit buffer register TBUF is loaded with different values, according to the following rules:

- Data from the transmit FIFO buffer or the bypass data can only be transferred to TBUF if TCSR.TDV = 0 (TBUF is empty).
- Bypass data can only be transferred to TBUF if the bypass is enabled by BYPCR.BDEN or the selecting gating condition is met.
- If the bypass data is valid for transmission and has either a higher transmit priority than the FIFO data or if the transmit FIFO is empty, the bypass data is transferred to TBUF.
- If the bypass data is valid for transmission and has a lower transmit priority than the FIFO buffer that contains valid data, the oldest transmit FIFO data is transferred to TBUF.
- If the bypass data is not valid for transmission and the FIFO buffer contains valid data, the oldest FIFO data is transferred to TBUF.
- If neither the bypass data is valid for transmission nor the transmit FIFO buffer contains valid data, TBUF is unchanged.

The bypass data validation is based on the logic blocks shown in [Figure 18-27](#).

- A transfer gating logic enables or disables the bypass data word transfer to TBUF under software or under hardware control. If the input stage DX2 is not needed for

Universal Serial Interface Channel (USIC)

data shifting, signal DX2S can be used for gating purposes. The transfer gating logic is controlled by bit BYPCR.BDEN.

- A transfer trigger logic supports data word transfers related to events, e.g. timer based or related to an input pin. If the input stage DX2 is not needed for data shifting, signal DX2T can be used for trigger purposes. The transfer trigger logic is controlled by bit BYPCR.BDVTR.
- A bypass data validation logic combining the inputs from the gating logic, the triggering logic and TCSR.TDV.

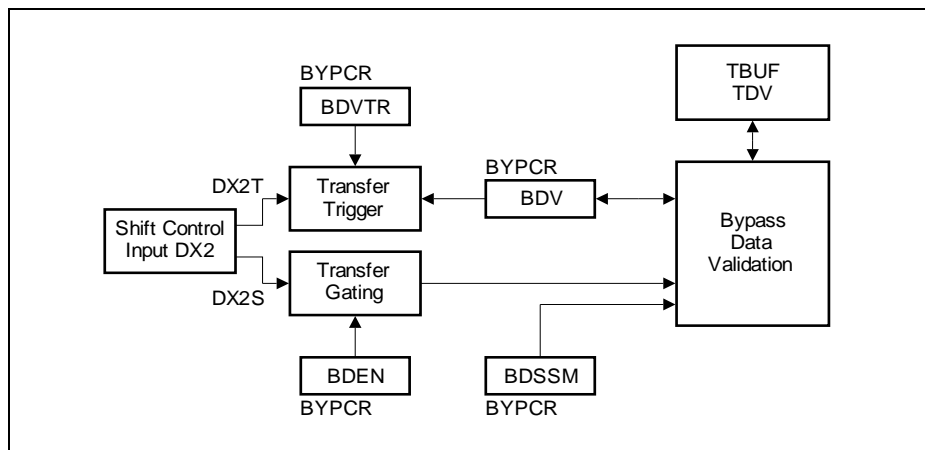

Figure 18-27 Bypass Data Validation

With this structure, the following bypass data transfer functionality can be achieved:

- Bit BYPCR.BDSSM = 1 has to be programmed for a single-shot mechanism. After each transfer of the bypass data word to TBUF, the bypass data word has to be tagged valid again. This can be achieved either by writing a new bypass data word to BYP or by DX2T if BDVTR = 1 (e.g. trigger on a timer base or an edge at a pin).
- Bit BYPCR.BDSSM = 0 has to be programmed if the bypass data is permanently valid for transmission (e.g. as alternative data if the data FIFO runs empty).

18.2.8.5 FIFO Access Constraints

The data in the shared FIFO buffer area is accessed by the hardware mechanisms for data transfer of each communication channel (for transmission and reception) and by software to read out received data or to write data to be transmitted. As a consequence, the data delivery rate can be limited by the FIFO mechanism. Each access by hardware to the FIFO buffer area has priority over a software access, that is delayed in case of an access collision.

In order to avoid data loss and stalling of the CPU due to delayed software accesses, the

Universal Serial Interface Channel (USIC)

baud rate, the word length and the software access mechanism have to be taken into account. Each access to the FIFO data buffer area by software or by hardware takes one period of f_{PERIPH} . Especially a continuous flow of very short, consecutive data words can lead to an access limitation.

18.2.8.6 Handling of FIFO Transmit Control Information

In addition to the transmit data, the transmit control information TCI can be transferred from the transmit FIFO or bypass structure to the USIC channel. Depending on the selected protocol and the enabled update mechanism, some settings of the USIC channel parameters can be modified. The modifications are based on the TCI of the FIFO data word loaded to TBUF or by the bypass control information if the bypass data is loaded into TBUF.

- TCSR.SELMD = 1: update of PCR.CTR[20:16] by FIFO TCI or BYPCR.BSELO with additional clear of PCR.CTR[23:21]
- TCSR.WLEMD = 1: update of SCTR.WLE and TCSR.EOF by FIFO TCI or BYPCR.BWLE (if the WLE information is overwritten by TCI or BWLE, the user has to take care that FLE is set accordingly)
- TCSR.FLEMD = 1: update of SCTR.FLE[4:0] by FIFO TCI or BYPCR.BWLE with additional clear of SCTR.FLE[5]
- TCSR.HPCMD = 1: update of SCTR.DSM and SCTR.HPCDIR by FIFO TCI or BYPCR.BHPC
- TCSR.WAMD = 1: update of TCSR.WA by FIFO TCI[4]

See [Section 18.2.5.3](#) for more details on TCI.

Universal Serial Interface Channel (USIC)

Figure 18-28 TCI Handling with FIFO / Bypass

Universal Serial Interface Channel (USIC)

18.3 Asynchronous Serial Channel (ASC = UART)

The asynchronous serial channel ASC covers the reception and the transmission of asynchronous data frames and provides a hardware LIN support. The receiver and transmitter being independent, frames can start at different points in time for transmission and reception. The ASC mode is selected by $CCR.MODE = 0010_B$ with $CCFG.ASC = 1$ (ASC mode available).

18.3.1 Signal Description

An ASC connection is characterized by the use of a single connection line between a transmitter and a receiver. The receiver input RXD signal is handled by the input stage DX0.

Figure 18-29 ASC Signal Connections for Full-Duplex Communication

For full-duplex communication, an independent communication line is needed for each transfer direction. **Figure 18-29** shows an example with a point-to-point full-duplex connection between two communication partners ASC A and ASC B.

For half-duplex or multi-transmitter communication, a single communication line is shared between the communication partners. **Figure 18-30** shows an example with a point-to-point half-duplex connection between ASC A and ASC B. In this case, the user has to take care that only one transmitter is active at a time. In order to support transmitter collision detection, the input stage DX1 can be used to monitor the level of the transmit line and to check if the line is in the idle state or if a collision occurred. There are two possibilities to connect the receiver input DIN0 to the transmitter output

Universal Serial Interface Channel (USIC)

DOUT0. Communication partner ASC A uses an internal connection with only the transmit pin TXD, that is delivering its input value as RXD to the DX0 input stage for reception and to DX1 to check for transmitter collisions. Communication partner ASC B uses an external connection between the two pins TXD and RXD.

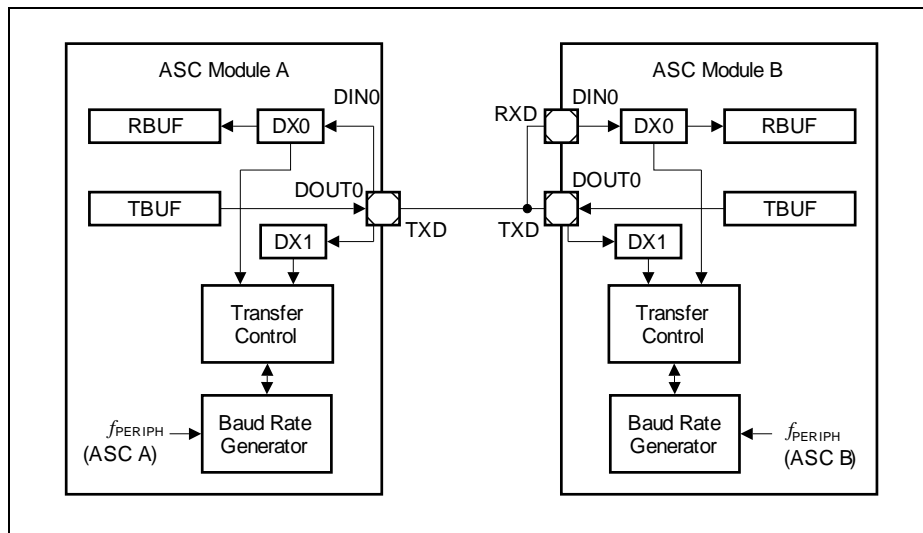

Figure 18-30 ASC Signal Connections for Half-Duplex Communication

18.3.2 Frame Format

A standard ASC frame is shown in [Figure 18-31](#). It consists of:

- An idle time with the signal level 1.
- One start of frame bit (SOF) with the signal level 0.
- A data field containing a programmable number of data bits (1-63).
- A parity bit (P), programmable for either even or odd parity. It is optionally possible to handle frames without parity bit.
- One or two stop bits with the signal level 1.

Figure 18-31 Standard ASC Frame Format

The protocol specific bits (SOF, P, STOP) are automatically handled by the ASC protocol state machine and do not appear in the data flow via the receive and transmit buffers.

18.3.2.1 Idle Time

The receiver and the transmitter independently check the respective data input lines (DX0, DX1) for being idle. The idle detection ensures that an SOF bit of a recently enabled ASC module does not collide with an already running frame of another ASC module.

In order to start the idle detection, the user software has to clear bits PSR.RXIDLE and/or PSR.TXIDLE, e.g. before selecting the ASC mode or during operation. If a bit is cleared by software while a data transfer is in progress, the currently running frame transfer is finished normally before starting the idle detection again. Frame reception is only possible if PSR.RXIDLE = 1 and frame transmission is only possible if PSR.TXIDLE = 1. The duration of the idle detection depends on the setting of bit PCR.IDM. In the case that a collision is not possible, the duration can be shortened and the bus can be declared as being idle by setting PCR.IDM = 0.

In the case that the complete idle detection is enabled by PCR.IDM = 1, the data input of DX0 is considered as idle (PSR.RXIDLE becomes set) if a certain number of consecutive passive bit times has been detected. The same scheme applies for the transmitter's data input of DX1. Here, bit PSR.TXIDLE becomes set if the idle condition of this input signal has been detected.

The duration of the complete idle detection is given by the number of programmed data bits per frame plus 2 (in the case without parity) or plus 3 (in the case with parity). The counting of consecutive bit times with 1 level restarts from the beginning each time an edge is found, after leaving a stop mode or if ASC mode becomes enabled.

If the idle detection bits PSR.RXIDLE and/or TXIDLE are cleared by software, the counting scheme is not stopped (no re-start from the beginning). As a result, the cleared bit(s) can become set immediately again if the respective input line still meets the idle criterion.

Please note that the idle time check is based on bit times, so the maximum time can be up to 1 bit time more than programmed value (but not less).

18.3.2.2 Start Bit Detection

The receiver input signal DIN0 (selected signal of input stage DX0) is checked for a falling edge. An SOF bit is detected when a falling edge occurs while the receiver is idle or after the sampling point of the last stop bit. To increase noise immunity, the SOF bit timing starts with the first falling edge that is detected. If the sampled bit value of the SOF is 1, the previous falling edge is considered to be due to noise and the receiver is considered to be idle again.

18.3.2.3 Data Field

The length of the data field (number of data bits) can be programmed by bit field SCTR.FLE. It can vary between 1 and 63 data bits, corresponding to values of SCTR.FLE = 0 to 62 (the value of 63 is reserved and must not be programmed in ASC mode).

The data field can consist of several data words, e.g. a transfer of 12 data bits can be composed of two 8-bit words, with the 12 bits being split into 8-bits of the first word and 4 bits of the second word. The user software has to take care that the transmit data is available in-time, once a frame has been started. If the transmit buffer runs empty during a running data frame, the passive data level (SCTR.PDL) is sent out.

The shift direction can be programmed by SCTR.SDIR. The standard setting for ASC frames with LSB first is achieved with the default setting SDIR = 0.

18.3.2.4 Parity Bit

The ASC allows parity generation for transmission and parity check for reception on frame base. The type of parity can be selected by bit field CCR.PM, common for transmission and reception (no parity, even or odd parity). If the parity handling is disabled, the ASC frame does not contain any parity bit. For consistency reasons, all communication partners have to be programmed to the same parity mode.

After the last data bit of the data field, the transmitter automatically sends out its calculated parity bit if parity generation has been enabled. The receiver interprets this bit as received parity and compares it to its internally calculated one. The received parity bit value and the result of the parity check are monitored in the receiver buffer status registers, RBUFSR and RBUF01SR, as receiver buffer status information. These registers contain bits to monitor a protocol-related argument (PAR) and protocol-related error indication (PERR).

18.3.2.5 Stop Bit(s)

Each ASC frame is completed by 1 or 2 of stop bits with the signal level 1 (same level as the idle level). The number of stop bits is programmable by bit PSR.STPB. A new start bit can be transferred directly after the last stop bit.

18.3.3 Operating the ASC

In order to operate the ASC protocol, the following issues have to be considered:

- **Select ASC mode:**
 It is recommended to configure all parameters of the ASC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 01_B$ has to be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the ASC mode can be enabled by $CCR.MODE = 0010_B$ afterwards.
- **Pin connections:**
 Establish a connection of input stage DX0 with the selected receive data input pin (signal DIN0) with $DX0CR.INSW = 0$ and configure a transmit data output pin (signal DOUT0). For collision or idle detection of the transmitter, the input stage DX1 has to be connected to the selected transmit output pin, also with $DX1CR.INSW = 0$. Additionally, program $DX2CR.INSW = 0$.
 Due to the handling of the input data stream by the synchronous protocol handler, the propagation delay of the synchronization in the input stage has to be considered.
 Note that the step to enable the alternate output port functions should only be done after the ASC mode is enabled, to avoid unintended spikes on the output.
- **Bit timing configuration:**
 The desired baud rate setting has to be selected, comprising the fractional divider, the baud rate generator and the bit timing. Please note that not all feature combinations can be supported by the application at the same time, e.g. due to propagation delays. For example, the length of a frame is limited by the frequency difference of the transmitter and the receiver device. Furthermore, in order to use the average of samples ($SMD = 1$), the sampling point has to be chosen to respect the signal settling and data propagation times.
- **Data format configuration:**
 The word length, the frame length, and the shift direction have to be set up according to the application requirements by programming the register SCTR. If required by the application, the data input and output signals can be inverted.
 Additionally, the parity mode has to be configured ($CCR.PM$).

18.3.3.1 Bit Timing

In ASC mode, each bit (incl. protocol bits) is divided into time quanta in order to provide granularity in the sub-bit range to adjust the sample point to the application requirements. The number of time quanta per bit is defined by bit fields $BRG.DCTQ$ and the length of a time quantum is given by $BRG.PCTQ$.

In the example given in [Figure 18-32](#), one bit time is composed of 16 time quanta ($BRG.DCTQ = 15$). It is not recommended to program less than 4 time quanta per bit time.

Universal Serial Interface Channel (USIC)

Bit field PCR.SP determines the position of the sampling point for the bit value. The value of PCR.SP must not be set to a value greater than BRG.DCTQ. It is possible to sample the bit value only once per bit time or to take the average of samples. Depending on bit PCR.SMD, either the current input value is directly sampled as bit value, or a majority decision over the input values sampled at the latest three time quanta is taken into account. The standard ASC bit timing consists of 16 time quanta with sampling after 8 or 9 time quanta with majority decision.

The bit timing setup (number of time quanta and the sampling point definition) is common for the transmitter and the receiver. Due to independent bit timing blocks, the receiver and the transmitter can be in different time quanta or bit positions inside their frames. The transmission of a frame is aligned to the time quanta generation.

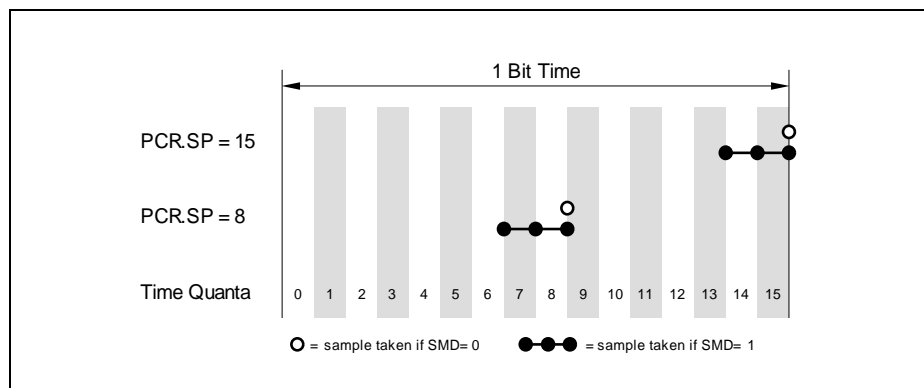

Figure 18-32 ASC Bit Timing

The sample point setting has to be adjusted carefully if collision or idle detection is enabled (via DX1 input signal), because the driver delay and some external delays have to be taken into account. The sample point for the transmit line has to be set to a value where the bit level is stable enough to be evaluated.

If the sample point is located late in the bit time, the signal itself has more time to become stable, but the robustness against differences in the clock frequency of transmitter and receiver decreases.

18.3.3.2 Baud Rate Generation

The baud rate f_{ASC} in ASC mode depends on the number of time quanta per bit time and their timing. The baud rate setting should only be changed while the transmitter and the receiver are idle. The bits in register BRG define the baud rate setting:

- **BRG.CTQSEL**
to define the input frequency f_{CTQIN} for the time quanta generation

Universal Serial Interface Channel (USIC)

- **BRG.PCTQ**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4)
- **BRG.DCTQ**
to define the number of time quanta per bit time

The standard setting is given by $\text{CTQSEL} = 00_{\text{B}}$ ($f_{\text{CTQIN}} = f_{\text{PDIV}}$) and $\text{PPPEN} = 0$ ($f_{\text{PPP}} = f_{\text{PIN}}$). Under these conditions, the baud rate is given by:

$$f_{\text{ASC}} = f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \times \frac{1}{\text{DCTQ} + 1} \quad (18.6)$$

In order to generate slower frequencies, two additional divide-by-2 stages can be selected by $\text{CTQSEL} = 10_{\text{B}}$ ($f_{\text{CTQIN}} = f_{\text{SCLK}}$) and $\text{PPPEN} = 1$ ($f_{\text{PPP}} = f_{\text{MCLK}}$), leading to:

$$f_{\text{ASC}} = \frac{f_{\text{PIN}}}{2 \times 2} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \times \frac{1}{\text{DCTQ} + 1} \quad (18.7)$$

18.3.3.3 Noise Detection

The ASC receiver permanently checks the data input line of the DX0 stage for noise (the check is independent from the setting of bit PCR.SMD). Bit PSR.RNS (receiver noise) becomes set if the three input samples of the majority decision are not identical at the sample point for the bit value. The information about receiver noise gets accumulated over several bits in bit PSR.RNS (it has to be cleared by software) and can trigger a protocol interrupt each time noise is detected if enabled by PCR.RNIEN .

18.3.3.4 Collision Detection

In some applications, such as data transfer over a single data line shared by several sending devices (see [Figure 18-30](#)), several transmitters have the possibility to send on the same data output line TXD. In order to avoid collisions of transmitters being active at the same time or to allow a kind of arbitration, a collision detection has been implemented.

The data value read at the TXD input at the DX1 stage and the transmitted data bit value are compared after the sampling of each bit value. If enabled by $\text{PCR.CDEN} = 1$ and a bit sent is not equal to the bit read back, a collision is detected and bit PSR.COL is set. If enabled, bit $\text{PSR.COL} = 1$ disables the transmitter (the data output lines become 1) and generates a protocol interrupt. The content of the transmit shift register is considered as invalid, so the transmit buffer has to be programmed again.

18.3.3.5 Pulse Shaping

For some applications, the 0 level of transmitted bits with the bit value 0 is not applied at the transmit output during the complete bit time. Instead of driving the original 0 level,

Universal Serial Interface Channel (USIC)

only a 0 pulse is generated and the remaining time quanta of the bit time are driven with 1 level. The length of a bit time is not changed by the pulse shaping, only the signalling is changed.

In the standard ASC signalling scheme, the 0 level is signalled during the complete bit time with bit value 0 (ensured by programming $\text{PCR.PL} = 000_B$). In the case $\text{PCR.PL} > 000_B$, the transmit output signal becomes 0 for the number of time quanta defined by PCR.PL . In order to support correct reception with pulse shaping by the transmitter, the sample point has to be adjusted in the receiver according to the applied pulse length.

Figure 18-33 Transmitter Pulse Length Control

Figure 18-34 shows an example for the transmission of an 8-bit data word with LSB first and one stop bit (e.g. like for IrDA). The polarity of the transmit output signal has been inverted by $\text{SCTR.DOCFG} = 01_B$.

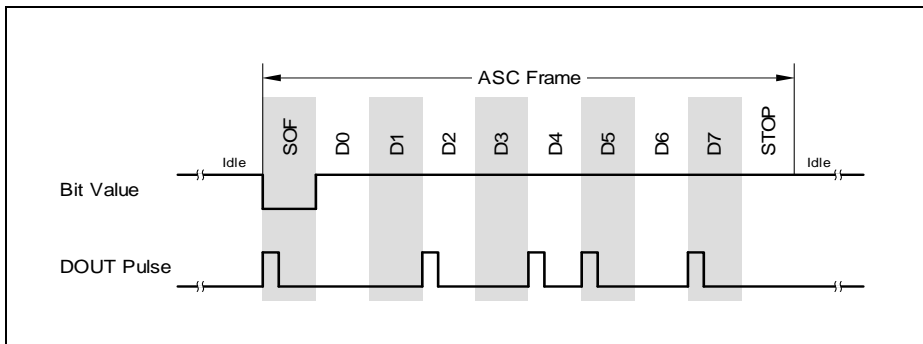

Figure 18-34 Pulse Output Example

18.3.3.6 Automatic Shadow Mechanism

The contents of the protocol control register PCR, as well as bit field SCTR.FLE are internally kept constant while a data frame is transferred by an automatic shadow mechanism (shadowing takes place with each frame start). The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame.

Bit fields SCTR.WLE and SCTR.SDIR are shadowed automatically with the start of each data word. As a result, a data frame can consist of data words with a different length. It is recommended to change SCTR.SDIR only when no data frame is running to avoid interference between hardware and software.

Please note that the starting point of a data word can be different for a transmitter and a receiver. In order to ensure correct handling, it is recommended to modify SCTR.WLE only while transmitter and receiver are both idle. If the transmitter and the receiver are referring to the same data signal (e.g. in a LIN bus system), SCTR.WLE can be modified while a data transfer is in progress after the RSI event has been detected.

18.3.3.7 End of Frame Control

The number of bits per ASC frame is defined by bit field SCTR.FLE. In order to support different frame length settings for consecutively transmitted frames, this bit field can be modified by hardware. The automatic update mechanism is enabled by TCSR.FLEMD = 1 (in this case, bits TCSR.WLEMD, SELMD, WAMD and HPCMD have to be written with 0).

If enabled, the transmit control information TCI automatically overwrites the bit field TCSR.FLEMD when the ASC frame is started (leading to frames with 1 to 32 data bits). The TCI value represents the written address location of TBUFxx (without additional data

Universal Serial Interface Channel (USIC)

buffer) or INxx (with additional data buffer). With this mechanism, an ASC with 8 data bits is generated by writing a data word to TBUF07 (IN07, respectively).

18.3.3.8 Mode Control Behavior

In ASC mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0:
Bit PSR.TXIDLE is cleared. A new transmission is not started. A current transmission is finished normally. Bit PSR.RXIDLE is not modified. Reception is still possible. When leaving stop mode 0, bit TXIDLE is set according to PCR.IDM.
- Stop Mode 1:
Bit PSR.TXIDLE is cleared. A new transmission is not started. A current transmission is finished normally. Bit PSR.RXIDLE is cleared. A new reception is not possible. A current reception is finished normally. When leaving stop mode 1, bits TXIDLE and RXIDLE are set according to PCR.IDM.

18.3.3.9 Disabling ASC Mode

In order to switch off ASC mode without any data corruption, the receiver and the transmitter have to be both idle. This is ensured by requesting Stop Mode 1 in register KSCFG. After waiting for the end of the frame, the ASC mode can be disabled.

18.3.3.10 Protocol Interrupt Events

The following protocol-related events are generated in ASC mode and can lead to a protocol interrupt. The collision detection and the transmitter frame finished events are related to the transmitter, whereas the receiver events are given by the synchronization break detection, the receiver noise detection, the format error checks and the end of the received frame.

Please note that the bits in register PSR are not automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- Collision detection:
This interrupt indicates that the transmitted value (DOUT0) does not match with the input value of the DX1 input stage at the sample point of a bit. For more details refer to [Page 18-60](#).
- Transmitter frame finished:
This interrupt indicates that the transmitter has completely finished a frame. Bit PSR.TFF becomes set at the end of the last stop bit. The DOUT0 signal assignment to port pins can be changed while no transmission is in progress.
- Receiver frame finished:
This interrupt indicates that the receiver has completely finished a frame. Bit

Universal Serial Interface Channel (USIC)

PSR.RFF becomes set at the end of the last stop bit. The DIN0 signal assignment to port pins can be changed while no reception is in progress.

- Synchronization break detection:
This interrupt can be used in LIN networks to indicate the reception of the synchronization break symbol (at the beginning of a LIN frame).
- Receiver noise detection:
This interrupt indicates that the input value at the sample point of a bit and at the two time quanta before are not identical.
- Format error:
The bit value of the stop bit(s) is defined as 1 level for the ASC protocol. A format error is signalled if the sampled bit value of a stop bit is 0.

18.3.3.11 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to ASC frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word. This is the earliest point in time when a new data word can be written to TBUF.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.
- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the sample point of the first data bit of a data word.
- Receiver interrupt RI and alternative interrupt AI:
Bit PSR.RIF is set after the sampling point of the last data bit of a data word if this data word is not directly followed by a parity bit (parity generation disabled or not the last word of a data frame).
If the data word is directly followed by a parity bit (last data word of a data frame and parity generation enabled), bit PSR.RIF is set after the sampling point of the parity bit if no parity error has been detected. If a parity error has been detected, bit PSR.AIF is set instead of bit PSR.RIF.
The first data word of a data frame is indicated by RBUFSR.SOF = 1 for the received word.
Bit PSR.RIF is set for a receiver interrupt RI with WA = 0. Bit PSR.AIF is set for a alternative interrupt AI with WA = 1.

18.3.3.12 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

18.3.3.13 Protocol-Related Argument and Error

The protocol-related argument (RBUFSR.PAR) and the protocol-related error (RBUFSR.PERR) are two flags that are assigned to each received data word in the corresponding receiver buffer status registers.

In ASC mode, the received parity bit is monitored by the protocol-related argument and the result of the parity check by the protocol-related error indication (0 = received parity bit equal to calculated parity value). This information being elaborated only for the last received data word of each data frame, both bit positions are 0 for data words that are not the last data word of a data frame or if the parity generation is disabled.

18.3.3.14 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 11_B in ASC mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[0] = 1, a parity error is indicated by OUTR.RCI[4] = 1, and the received parity bit value is given by OUTR.RCI[3].

The standard receive buffer event and the alternative receive buffer event can be used for the following operations in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that has been received without parity error.
- An alternative receive buffer event indicates that a data word can be read from OUTR that has been received with parity error.

18.3.3.15 Sync-Break Detection

The receiver permanently checks the DIN0 signal for a certain number of consecutive bit times with 0 level. The number is given by the number of programmed bits per frame (SCTR.FLE) plus 2 (in the case without parity) or plus 3 (in the case with parity). If a 0 level is detected at a sample point of a bit after this event has been found, bit PSR.SBD is set and additionally, a protocol interrupt can be generated (if enabled by PCR.SBIEN = 1). The counting restarts from 0 each time a falling edge is found at input DIN0. This feature can be used for the detection of a synchronization break for slave devices in a LIN bus system (the master does not check for sync break).

For example, in a configuration for 8 data bits without parity generation, bit PCR.SBD is set after at the next sample point at 0 level after 10 complete bit times have elapsed (representing the sample point of the 11th bit time since the first falling edge).

18.3.3.16 Transfer Status Indication

The receiver status can be monitored by flag PSR[9] = BUSY if bit PCR.CTR[16] (receiver status enable RSTEN) is set. In this case, bit BUSY is set during a complete frame reception from the beginning of the start of frame bit to the end of the last stop bit.

Universal Serial Interface Channel (USIC)

The transmitter status can be monitored by flag PSR[9] = BUSY if bit PCR.CTR[17] (transmitter status enable TSTEN) is set. In this case, bit BUSY is set during a complete frame reception from the beginning of the start of frame bit to the end of the last stop bit. If both bits RSTEN and TSTEN are set, flag BUSY indicates the logical OR-combination of the receiver and the transmitter status. If both bits are cleared, flag BUSY is not modified depending on the transfer status (status changes are ignored).

18.3.4 ASC Protocol Registers

In ASC mode, the registers PCR and PSR handle ASC related information.

18.3.4.1 ASC Protocol Control Register

In ASC mode, the PCR register bits or bit fields are defined as described in this section.

PCR

Protocol Control Register [ASC Mode]

(3C_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

| | rw | | | | rw | | | rw | rw | rw | rw | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|--|
| SMD | 0 | rw | Sample Mode This bit field defines the sample mode of the ASC receiver. The selected data input signal can be sampled only once per bit time or three times (in consecutive time quanta). When sampling three times, the bit value shifted in the receiver shift register is given by a majority decision among the three sampled values. 0 _B Only one sample is taken per bit time. The current input value is sampled. 1 _B Three samples are taken per bit time and a majority decision is made. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| STPB | 1 | rw | Stop Bits This bit defines the number of stop bits in an ASC frame. 0 _B The number of stop bits is 1. 1 _B The number of stop bits is 2. |
| IDM | 2 | rw | Idle Detection Mode This bit defines if the idle detection is switched off or based on the frame length. 0 _B The bus idle detection is switched off and bits PSR.TXIDLE and PSR.RXIDLE are set automatically to enable data transfers without checking the inputs before. 1 _B The bus is considered as idle after a number of consecutive passive bit times defined by SCTR.FLE plus 2 (in the case without parity bit) or plus 3 (in the case with parity bit). |
| SBIEN | 3 | rw | Synchronization Break Interrupt Enable This bit enables the generation of a protocol interrupt if a synchronization break is detected. The automatic detection is always active, so bit SBD can be set independently of SBIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| CDEN | 4 | rw | Collision Detection Enable This bit enables the reaction of a transmitter to the collision detection. 0 _B The collision detection is disabled. 1 _B If a collision is detected, the transmitter stops its data transmission, outputs a 1, sets bit PSR.COL and generates a protocol interrupt. In order to allow data transmission again, PSR.COL has to be cleared by software. |
| RNIEN | 5 | rw | Receiver Noise Detection Interrupt Enable This bit enables the generation of a protocol interrupt if receiver noise is detected. The automatic detection is always active, so bit PSR.RNS can be set independently of PCR.RNIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| FEIEN | 6 | rw | Format Error Interrupt Enable This bit enables the generation of a protocol interrupt if a format error is detected. The automatic detection is always active, so bits PSR.FER0/FER1 can be set independently of PCR.FEIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| FFIEN | 7 | rw | Frame Finished Interrupt Enable This bit enables the generation of a protocol interrupt if the receiver or the transmitter reach the end of a frame. The automatic detection is always active, so bits PSR.RFF or PSR.TFF can be set independently of PCR.FFIEN. 0 _B The interrupt generation is disabled. 1 _B The interrupt generation is enabled. |
| SP | [12:8] | rw | Sample Point This bit field defines the sample point of the bit value. The sample point must not be located outside the programmed bit timing ($PCR.SP \leq BRG.DCTQ$). |
| PL | [15:13] | rw | Pulse Length This bit field defines the length of a 0 data bit, counted in time quanta, starting with the time quantum 0 of each bit time. Each bit value that is a 0 can lead to a 0 pulse that is shorter than a bit time, e.g. for IrDA applications. The length of a bit time is not changed by PL, only the length of the 0 at the output signal. The pulse length must not be longer than the programmed bit timing ($PCR.PL \leq BRG.DCTQ$). This bit field is only taken into account by the transmitter and is ignored by the receiver. 000 _B The pulse length is equal to the bit length (no shortened 0). 001 _B The pulse length of a 0 bit is 2 time quanta. 010 _B The pulse length of a 0 bit is 3 time quanta. ... 111 _B The pulse length of a 0 bit is 8 time quanta. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| RSTEN | 16 | rw | Receiver Status Enable This bit enables the modification of flag PSR[9] = BUSY according to the receiver status. 0 _B Flag PSR[9] is not modified depending on the receiver status. 1 _B Flag PSR[9] is set during the complete reception of a frame. |
| TSTEN | 17 | rw | Transmitter Status Enable This bit enables the modification of flag PSR[9] = BUSY according to the transmitter status. 0 _B Flag PSR[9] is not modified depending on the transmitter status. 1 _B Flag PSR[9] is set during the complete transmission of a frame. |
| MCLK | 31 | rw | Master Clock Enable This bit enables the generation of the master clock MCLK. 0 _B The MCLK generation is disabled and the MCLK signal is 0. 1 _B The MCLK generation is enabled. |
| 0 | [30:18] | r | Reserved Returns 0 if read; should be written with 0. |

18.3.4.2 ASC Protocol Status Register

In ASC mode, the PSR register bits or bit fields are defined as described in this section. The bits and bit fields in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. The PSR flags should be cleared by software before enabling a new protocol.

| Field | Bits | Type | Description |
|---------------|------|------|---|
| TXIDLE | 0 | rwh | Transmission Idle This bit shows if the transmit line (DX1) has been idle. A frame transmission can only be started if TXIDLE is set. 0 _B The transmitter line has not yet been idle. 1 _B The transmitter line has been idle and frame transmission is possible. |
| RXIDLE | 1 | rwh | Reception Idle This bit shows if the receive line (DX0) has been idle. A frame reception can only be started if RXIDLE is set. 0 _B The receiver line has not yet been idle. 1 _B The receiver line has been idle and frame reception is possible. |
| SBD | 2 | rwh | Synchronization Break Detected¹⁾ This bit is set if a programmed number of consecutive bit values with level 0 has been detected (called synchronization break, e.g. in a LIN bus system). 0 _B A synchronization break has not yet been detected. 1 _B A synchronization break has been detected. |
| COL | 3 | rwh | Collision Detected¹⁾ This bit is set if a collision has been detected (with PCR.CDEN = 1). 0 _B A collision has not yet been detected and frame transmission is possible. 1 _B A collision has been detected and frame transmission is not possible. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|------|------|---|
| RNS | 4 | rwh | Receiver Noise Detected¹⁾ This bit is set if receiver noise has been detected. 0 _B Receiver noise has not been detected. 1 _B Receiver noise has been detected. |
| FER0 | 5 | rwh | Format Error in Stop Bit 0¹⁾ This bit is set if a 0 has been sampled in the stop bit 0 (called format error 0). 0 _B A format error 0 has not been detected. 1 _B A format error 0 has been detected. |
| FER1 | 6 | rwh | Format Error in Stop Bit 1¹⁾ This bit is set if a 0 has been sampled in the stop bit 1 (called format error 1). 0 _B A format error 1 has not been detected. 1 _B A format error 1 has been detected. |
| RFF | 7 | rwh | Receive Frame Finished¹⁾ This bit is set if the receiver has finished the last stop bit. 0 _B The received frame is not yet finished. 1 _B The received frame is finished. |
| TFF | 8 | rwh | Transmitter Frame Finished¹⁾ This bit is set if the transmitter has finished the last stop bit. 0 _B The transmitter frame is not yet finished. 1 _B The transmitter frame is finished. |
| BUSY | 9 | r | Transfer Status BUSY This bit indicates the receiver status (if PCR.RSTEN = 1) or the transmitter status (if PCR.TSTEN = 1) or the logical OR combination of both (if PCR.RSTEN = PCR.TSTEN = 1). 0 _B A data transfer does not take place. 1 _B A data transfer currently takes place. |
| RSIF | 10 | rwh | Receiver Start Indication Flag 0 _B A receiver start event has not occurred. 1 _B A receiver start event has occurred. |
| DLIF | 11 | rwh | Data Lost Indication Flag 0 _B A data lost event has not occurred. 1 _B A data lost event has occurred. |
| TSIF | 12 | rwh | Transmit Shift Indication Flag 0 _B A transmit shift event has not occurred. 1 _B A transmit shift event has occurred. |

Universal Serial Interface Channel (USIC)

| RIF | 14 | rwh | Receive Indication Flag 0_B A receive event has not occurred. 1_B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0_B An alternative receive event has not occurred. 1_B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0_B A baud rate generator event has not occurred. 1_B A baud rate generator event has occurred. |
| 0 | [31:17]] | r | Reserved Returns 0 if read; should be written with 0. |

1) This status bit can generate a protocol interrupt (see [Page 18-22](#)). The general interrupt status flags are described in the general interrupt chapter.

18.3.5 Hardware LIN Support

In order to support the LIN protocol, bit TCSR.FLEMD = 1 should be set for the master. For slave devices, it can be cleared and the fixed number of 8 data bits has to be set (SCTR.FLE = 7_H). For both, master and slave devices, the parity generation has to be switched off (CCR.PM = 00_B) and transfers take place with LSB first (SCTR.SDIR = 0) and 1 stop bit (PCR.STPB = 0).

The Local Interconnect Network (LIN) data exchange protocol contains several symbols that can all be handled in ASC mode. Each single LIN symbol represents a complete ASC frame. The LIN bus is a master-slave bus system with a single master and multiple slaves (for the exact definition please refer to the official LIN specification).

A complete LIN frame contains the following symbols:

- Synchronization break:

The master sends a synchronization break to signal the beginning of a new frame. It contains at least 13 consecutive bit times at 0 level, followed by at least one bit time at 1 level (corresponding to 1 stop bit). Therefore, TBUF11 if the transmit buffer is used, (or IN11 if the FIFO buffer is used) has to be written with 0 (leading to a frame with SOF followed by 12 data bits at 0 level).

A slave device shall detect 11 consecutive bit times at 0 level, which done by the synchronization break detection. Bit PSR.SBD is set if such an event is detected and a protocol interrupt can be generated. Additionally, the received data value of 0 appears in the receive buffer and a format error is signaled.

Universal Serial Interface Channel (USIC)

If the baud rate of the slave has to be adapted to the master, the baud rate measurement has to be enabled for falling edges by setting $\text{BRG.TMEN} = 1$, $\text{DX0CR.CM} = 10_{\text{H}}$ and $\text{DX1CR.CM} = 00_{\text{H}}$ before the next symbol starts.

- Synchronization byte:
The master sends this symbol after writing the data value 55_{H} to TBUF07 (or IN07). A slave device can either receive this symbol without any further action (and can discard it) or it can use the falling edges for baud rate measurement. Bit $\text{PSR.TSIF} = 1$ (with optionally the corresponding interrupt) indicates the detection of a falling edge and the capturing of the elapsed time since the last falling edge in CMTR.CTV . Valid captured values can be read out after the second, third, fourth and fifth activation of TSIF. After the fifth activation of TSIF within this symbol, the baud rate detection can be disabled ($\text{BRG.TMEN} = 0$) and BRG.PDIV can be programmed with the captured CMTR.CTV value divided by twice the number of time quanta per bit (assuming $\text{BRG.PCTQ} = 00_{\text{B}}$).
- Other symbols:
The other symbols of a LIN frame can be handled with ASC data frames without specific actions.

If LIN frames should be sent out on a frame base by the LIN master, the input DX2 can be connected to external timers to trigger the transmit actions (e.g. the synchronization break symbol has been prepared but is started if a trigger occurs). Please note that during the baud rate measurement of the ASC receiver, the ASC transmitter of the same USIC channel can still perform a transmission.

18.4 Synchronous Serial Channel (SSC)

The synchronous serial channel SSC covers the data transfer function of an SPI-like module. It can handle reception and transmission of synchronous data frames between a device operating in master mode and at least one device in slave mode. Besides the standard SSC protocol consisting of one input and one output data line, SSC protocols with two (Dual-SSC) or four (Quad-SSC) input/output data lines are also supported. The SSC mode is selected by $CCR.MODE = 0001_B$ with $CCFG.SSC = 1$ (SSC mode is available).

18.4.1 Signal Description

A synchronous SSC data transfer is characterized by a simultaneous transfer of a shift clock signal together with the transmit and/or receive data signal(s) to determine when the data is valid (definition of transmit and sample point).

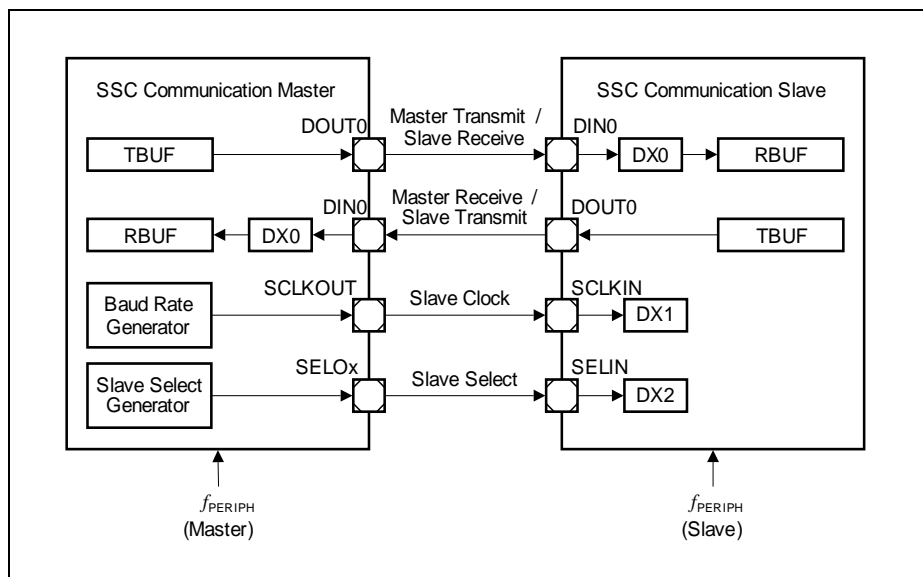

Figure 18-35 SSC Signals for Standard Full-Duplex Communication

In order to explicitly indicate the start and the end of a data transfer and to address more than one slave devices individually, the SSC module supports the handling of slave select signals. They are optional and are not necessarily needed for SSC data transfers. The SSC module supports up to 8 different slave select output signals for master mode operation (named $SELOx$, with $x = 0-7$) and 1 slave select input $SELIN$ for slave mode. In most applications, the slave select signals are active low.

Universal Serial Interface Channel (USIC)

A device operating in master mode controls the start and end of a data frame, as well as the generation of the shift clock and slave select signals. This comprises the baud rate setting for the shift clock and the delays between the shift clock and the slave select output signals. If several SSC modules are connected together, there can be only one SSC master at a time, but several slaves. Slave devices receive the shift clock and optionally a slave select signal(s). For the programming of the input stages DXn please refer to [Page 18-22](#).

Table 18-12 SSC Communication Signals

| SSC Mode | Receive Data | Transmit Data | Shift Clock | Slave Select(s) |
|---------------------|---|--------------------------------------|---------------------------------|--------------------------------|
| Standard SSC Master | MRST ¹⁾ , input DIN0, handled by DX0 | MTSR ²⁾ , Output DOUT0 | Output SCLKOUT | Output(s) SELOx |
| Standard SSC Slave | MTSR, input DIN0, handled by DX0 | MRST, Output DOUT0 | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |
| Dual-SSC Master | MRST[1:0], input DIN[1:0], handled by DX0 and DX3 | MTSR[1:0], Output DOUT[1:0] | Output SCLKOUT | Output(s) SELOx |
| Dual-SSC Slave | MTSR[1:0], input DIN[1:0], handled by DX0 and DX3 | MRST[1:0], Output DOUT[1:0] | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |
| Quad-SSC Master | MRST[3:0], input DIN[3:0], handled by DX0, DX3, DX4 and DX5 | MTSR[3:0], Output DOUT[3:0] | Output SCLKOUT | Output(s) SELOx |
| Quad-SSC Slave | MTSR[3:0], input DIN[3:0], handled by DX0, DX3, DX4 and DX5 | MRST[3:0], Output DOUT[3:0] | Input SCLKIN, handled by DX1 | input SELIN, handled by DX2 |

1) MRST = master receive slave transmit, also known as MISO = master in slave out

2) MTSR = master transmit slave receive, also known as MOSI = master out slave in

Universal Serial Interface Channel (USIC)

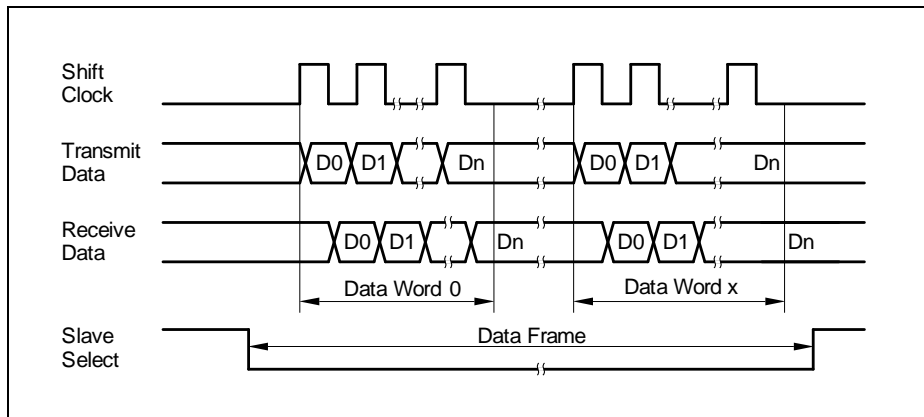

Figure 18-36 4-Wire SSC Standard Communication Signals

18.4.1.1 Transmit and Receive Data Signals

In standard SSC half-duplex mode, a single data line is used, either for data transfer from the master to a slave or from a slave to the master. In this case, MRST and MTSR are connected together, one signal as input, the other one as output, depending on the data direction. The user software has to take care about the data direction to avoid data collision (e.g. by preparing dummy data of all 1s for transmission in case of a wired AND connection with open-drain drivers, by enabling/disabling push/pull output drivers or by switching pin direction with hardware port control enabled). In full-duplex mode, data transfers take place in parallel between the master device and a slave device via two independent data signals MTSR and MRST, as shown in [Figure 18-35](#).

The receive data input signal DIN0 is handled by the input stage DX0. In master mode (referring to MRST) as well as in slave mode (referring to MTSR), the data input signal DIN0 is taken from an input pin. The signal polarity of DOUT0 (data output) with respect to the data bit value can be configured in block DOCFG (data output configuration) by bit field SCTR.DOCFG.

Figure 18-37 SSC Data Signals

Universal Serial Interface Channel (USIC)

For dual- and quad-SSC modes that require multiple input and output data lines to be used, additional input stages, DINx and DOUTx signals need to be set up.

18.4.1.2 Shift Clock Signals

The shift clock signal is handled by the input stage DX1. In slave mode, the signal SCLKIN is received from an external master, so the DX1 stage has to be connected to an input pin. The input stage can invert the received input signal to adapt to the polarity of SCLKIN to the function of the data shift unit (data transmission on rising edges, data reception on falling edges).

In master mode, the shift clock is generated by the internal baud rate generator. The output signal SCLK of the baud rate generator is taken as shift clock input for the data shift unit. The internal signal SCLK is made available for external slave devices by signal SCLKOUT. For complete closed loop delay compensation in a slave mode, SCLKOUT can also take the transmit shift clock from the input stage DX1. The selection is done through the bit BRG.SCLKOSEL. See [Section 18.4.6.3](#).

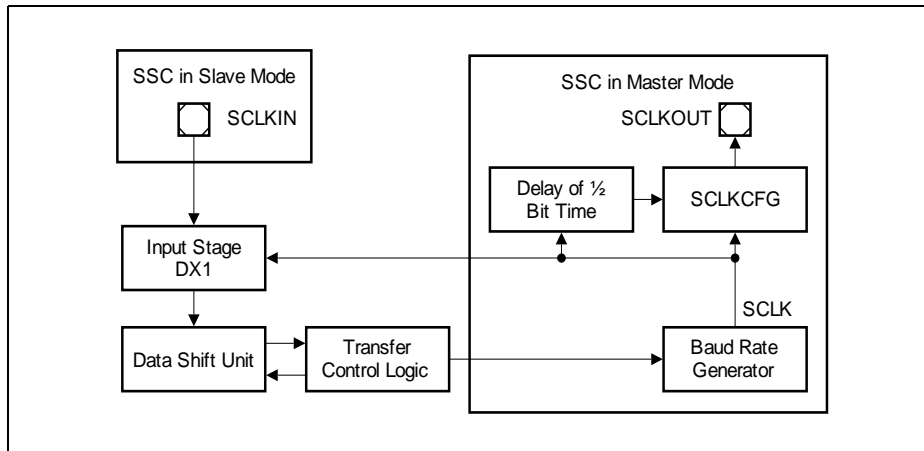

Figure 18-38 SSC Shift Clock Signals

Due to the multitude of different SSC applications, in master mode, there are different ways to configure the shift clock output signal SCLKOUT with respect to SCLK. This is done in the block SCLKCFG (shift clock configuration) by bit field BRG.SCLKCFG, allowing 4 possible settings, as shown in [Figure 18-39](#).

- No delay, no polarity inversion (SCLKCFG = 00_b, SCLKOUT equals SCLK):
 The inactive level of SCLKOUT is 0, while no data frame is transferred. The first data bit of a new data frame is transmitted with the first rising edge of SCLKOUT and the first data bit is received in with the first falling edge of SCLKOUT. The last data bit of a data frame is transmitted with the last rising clock edge of SCLKOUT and the last

Universal Serial Interface Channel (USIC)

data bit is received in with the last falling edge of SCLKOUT. This setting can be used in master and in slave mode. It corresponds to the behavior of the internal data shift unit.

- No delay, polarity inversion (SCLKCFG = 01_B):
 The inactive level of SCLKOUT is 1, while no data frame is transferred. The first data bit of a new data frame is transmitted with the first falling clock edge of SCLKOUT and the first data bit is received with the first rising edge of SCLKOUT. The last data bit of a data frame is transmitted with the last falling edge of SCLKOUT and the last data bit is received with the last rising edge of SCLKOUT.
 This setting can be used in master and in slave mode. For slave mode, bit field DX1CR.DPOL = 1_B has to be programmed.
- SCLKOUT is delayed by 1/2 shift clock period, no polarity inversion (SCLKCFG = 10_B):
 The inactive level of SCLKOUT is 0, while no data frame is transferred.
 The first data bit of a new data frame is transmitted 1/2 shift clock period before the first rising clock edge of SCLKOUT. Due to the delay, the next data bits seem to be transmitted with the falling edges of SCLKOUT. The last data bit of a data frame is transmitted 1/2 period of SCLKOUT before the last rising clock edge of SCLKOUT. The first data bit is received 1/2 shift clock period before the first falling edge of SCLKOUT. Due to the delay, the next data bits seem to be received with the rising edges of SCLKOUT. The last data bit is received 1/2 period of SCLKOUT before the last falling clock edge of SCLKOUT.
 This setting can be used only in master mode and not in slave mode (the connected slave has to provide the first data bit before the first SCLKOUT edge, e.g. as soon as it is addressed by its slave select).
- SCLKOUT is delayed by 1/2 shift clock period, polarity inversion (SCLKCFG = 11_B):
 The inactive level of SCLKOUT is 1, while no data frame is transferred.
 The first data bit of a new data frame is transmitted 1/2 shift clock period before the first falling clock edge of SCLKOUT. Due to the delay, the next data bits seem to be transmitted with the rising edges of SCLKOUT. The last data bit of a data frame is transmitted 1/2 period of SCLKOUT before the last falling clock edge of SCLKOUT. The first data bit is received 1/2 shift clock period before the first rising edge of SCLKOUT. Due to the delay, the next data bits seem to be received with the falling edges of SCLKOUT. The last data bit is received 1/2 period of SCLKOUT before the last rising clock edge of SCLKOUT.
 This setting can be used only in master mode and not in slave mode (the connected slave has to provide the first data bit before the first SCLKOUT edge, e.g. as soon as it is addressed by its slave select).

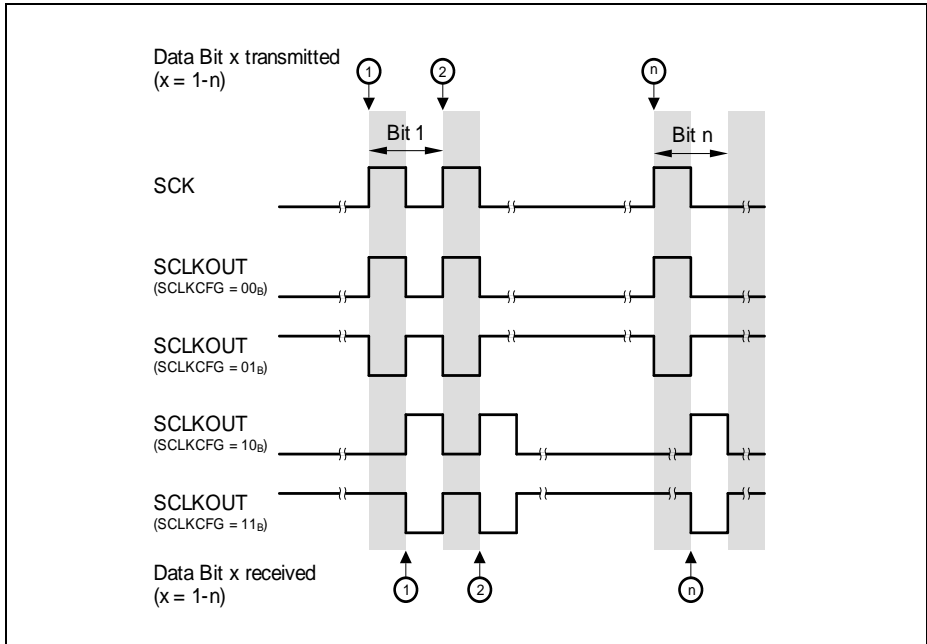

Figure 18-39 SCLKOUT Configuration in SSC Master Mode

Note: If a configuration with delay is selected and a slave select line is used, the slave select delays have to be set up accordingly.

In SSC slave mode, the bit PCR.SLPSEL can be used to configure the clock phase of the data shift.

- When SLPSEL = 0_B, the slave SSC transmits data bits with each leading edge of the selected shift clock input (SCLKIN) and receives data bits with each trailing edge of SCLKIN
- When SLPSEL = 1_B, the slave SSC transmits the first data bit once the selected slave select input (SELIN) becomes active. If SELIN is not used, the DX2 stage has to deliver a 1-level to the data shift unit to shift out the first bit. Subsequent data bits are then transmitted with each trailing edge of SCLKIN. The SSC slave receives all data bits with each leading edge of SCLKIN.

For both settings, the clock polarity is determined by bit 0 of SCLKCFG.

Universal Serial Interface Channel (USIC)

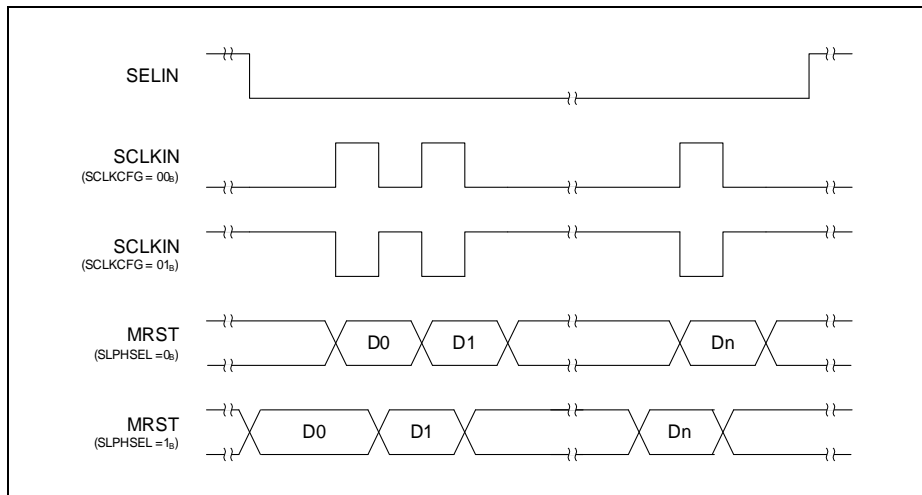

Figure 18-40 SLPHSEL Configuration in SSC Slave Mode

18.4.1.3 Slave Select Signals

The slave select signal is handled by the input stage DX2. In slave mode, the input signal SELIN is received from an external master via an input pin. The input stage can invert the received input signal to adapt the polarity of signal SELIN to the function of the data shift unit (the module internal signals are considered as high active, so a data transfer is only possible while the slave select input of the data shift unit is at 1-level, otherwise, shift clock pulses are ignored and do not lead to data transfers). If an input signal SELIN is low active, it should be inverted in the DX2 input stage.

In master mode, a master slave select signal MSLS is generated by the internal slave select generator. In order to address different external slave devices independently, the internal MSLS signal is made available externally via up to 8 SELOx output signals that can be configured by the block SELCFG (select configuration).

Universal Serial Interface Channel (USIC)

Figure 18-41 SSC Slave Select Signals

The control of the SELCFG block is based on protocol specific bits and bit fields in the protocol control register PCR. For the generation of the MSLS signal please refer to [Section 18.4.3.2](#).

- PCR.SELCTR to chose between direct and coded select mode
- PCR.SELINV to invert the SELOx outputs
- PCR.SELO[7:0] as individual value for each SELOx line

The SELCFG block supports the following configurations of the SELOx output signals:

- Direct Select Mode (SELCTR = 1):
 Each SELOx line (with $x = 0-7$) can be directly connected to an external slave device. If bit x in bit field SELO is 0, the SELOx output is permanently inactive. A SELOx output becomes active while the internal signal MSLS is active (see [Section 18.4.3.2](#)) and bit x in bit field SELO is 1. Several external slave devices can be addressed in parallel if more than one bit in bit field SELO are set during a data frame. The number of external slave devices that can be addressed individually is limited to the number of available SELOx outputs.
- Coded Select Mode (SELCTR = 0):
 The SELOx lines (with $x = 1-7$) can be used as addresses for an external address decoder to increase the number of external slave devices. These lines only change with the start of a new data frame and have no other relation to MSLS. Signal SELO0 can be used as enable signal for the external address decoder. It is active while MSLS is active (during a data frame) and bit 0 in bit field SELO is 1. Furthermore, in coded select mode, this output line is delayed by one cycle of f_{PERIPH} compared to MSLS to allow the other SELOx lines to stabilize before enabling the address decoder.

18.4.2 Operating the SSC

This chapter contains SSC issues, that are of general interest and not directly linked to either master mode or slave mode.

18.4.2.1 Automatic Shadow Mechanism

The contents of the baud rate control register BRG, bit fields SCTR.FLE as well as the protocol control register PCR are internally kept constant while a data frame is transferred (= while MSLS is active) by an automatic shadow mechanism. The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame.

Bit fields SCTR.WLE, SCTR.DSM, SCTR.HPCDIR and SCTR.SDIR are shadowed automatically with the start of each data word. As a result, a data frame can consist of data words with a different length, or data words that are transmitted or received through different number of data lines. It is recommended to change SCTR.SDIR only when no data frame is running to avoid interference between hardware and software.

Please note that the starting point of a data word are different for a transmitter (first bit transmitted) and a receiver (first bit received). In order to ensure correct handling, it is recommended to refer to the receive start interrupt RSI before modifying SCTR.WLE. If TCSR.WLEMD = 1, it is recommended to update TCSR and TBUFxx after the receiver start interrupt has been generated.

18.4.2.2 Mode Control Behavior

In SSC mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0/1:
The content of the transmit buffer is considered as not valid for transmission. Although being considered as 0, bit TCSR.TDV it is not modified by the stop mode condition.
In master mode, a currently running word transfer is finished normally, but no new data word is started (the stop condition is not considered as end-of-frame condition). In slave mode, a currently running word transfer is finished normally. Passive data will be sent out instead of a valid data word if a data word transfer is started by the external master while the slave device is in stop mode. In order to avoid passive slave transmit data, it is recommended not to program stop mode for an SSC slave device if the master device does not respect the slave device's stop mode.

18.4.2.3 Disabling SSC Mode

In order to disable SSC mode without any data corruption, the receiver and the transmitter have to be both idle. This is ensured by requesting Stop Mode 1 in register KSCFG. After Stop Mode 1 has been acknowledged by KSCFG.2 = 1, the SSC mode can be disabled.

18.4.2.4 Data Frame Control

An SSC data frame can consist of several consecutive data words that may be separated by an inter-word delay. Without inter-word delay, the data words seem to form a longer data word, being equivalent to a data frame. The length of the data words are most commonly identical within a data frame, but may also differ from one word to another. The data word length information (defined by SCTR.WLE) is evaluated for each new data word, whereas the frame length information (defined by SCTR.FLE) is evaluated at the beginning at each start of a new frame.

The length of an SSC data frame can be defined in two different ways:

- By the number of bits per frame:
If the number of bits per data frame is defined (frame length FLE), a slave select signal is not necessarily required to indicate the start and the end of a data frame.
If the programmed number of bits per frame is reached within a data word, the frame is considered as finished and remaining data bits in the last data word are ignored and are not transferred.
This method can be applied for data frames with up to 63 data bits.
- By the slave select signal:
If the number of bits per data frame is not known, the start/end information of a data frame is given by a slave select signal. If a deactivation of the slave select signal is detected within a data word, the frame is considered as finished and remaining data bits in the last data word are ignored and are not transferred.
This method has to be applied for frames with more than 63 data bits (programming limit of FLE). The advantage of slave select signals is the clearly defined start and end condition of data frames in a data stream. Furthermore, slave select signals allow to address slave devices individually.

18.4.2.5 Parity Mode

The SSC allows parity generation for transmission and parity check for reception on frame base. The type of parity can be selected by bit field CCR.PM, common for transmission and reception (no parity, even or odd parity). If the parity handling is disabled, the SSC frame does not contain any parity bit. For consistency reasons, all communication partners have to be programmed to the same parity mode.

Universal Serial Interface Channel (USIC)

If parity generation has been enabled, the transmitter automatically extends the clock by one cycle after the last data word of the data frame, and sends out its calculated parity bit in this cycle.

Figure 18-42 shows how a parity bit is added to the transmitted data bits of a frame. The number of the transmitted bits of a complete frame with parity is always one more than that without parity. The parity bit is transmitted as the last bit of a frame, following the data bits, independent of the shift direction (SCTR.SDIR).

Note: For dual and quad SSC protocols, the parity bit will be transmitted and received only on DOUT0 and DX0 respectively in the extended clock cycle.

Figure 18-42 Data Frames without/with Parity

Universal Serial Interface Channel (USIC)

Similarly, after the receiver receives the last word of a data frame as defined by FLE, it expects an additional one clock cycle, which will contain the parity bit. The receiver interprets this bit as received parity and separates it from the received data. The received parity bit value is instead monitored in the protocol-related argument (PAR) of the receiver buffer status registers as receiver buffer status information. The receiver compares the bit to its internally calculated parity and the result of the parity check is indicated by the flag PSR.PARERR. The parity error event generates a protocol interrupt if PCR.PARIEN = 1.

Parity bit generation and detection is not supported for the following cases:

- When frame length is 64 data bits or greater, i.e. $FLE = 63_H$;
- When in slave mode, the end of frame occurs before the number of data bits defined by FLE is reached.
- When in slave mode, the content of the TBUF is not valid at the transmission start. In this case, the slave outputs the level defined by SCTR.PDL including for the parity bit. This might result in the detection of a parity error at the master.

18.4.2.6 Transfer Mode

In SSC mode, bit field SCTR.TRM = 01_B has to be programmed to allow data transfers. Setting SCTR.TRM = 00_B disables and stops the data transfer immediately.

18.4.2.7 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to SSC frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.
- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the reception of the first data bit of a data word.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Receiver interrupt RI:
The reception of the second, third, and all subsequent words in a multi-word frame is always indicated by RBUFSR.SOF = 0. Bit PSR.RIF is set after the reception of the last data bit of a data word if RBUFSR.SOF = 0.
Bit RBUFSR.SOF indicates whether the received data word has been the first data word of a multi-word frame or some subsequent word. In SSC mode, it decides if alternative interrupt or receive interrupt is generated.
- Alternative interrupt AI:
The reception of the first word in a frame is always indicated by RBUFSR.SOF = 1. This is true both in case of reception of multi-word frames and single-word frames. In SSC mode, this results in setting PSR.AIF.

18.4.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

18.4.2.9 Protocol-Related Argument and Error

The protocol-related argument (RBUFSR.PAR) and the protocol-related error (RBUFSR.PERR) are two flags that are assigned to each received data word in the corresponding receiver buffer status registers.

In SSC mode, the received parity bit is monitored by the protocol-related argument. The received start of frame indication is monitored by the protocol-related error indication (0 = received word is not the first word of a frame, 1 = received word is the first word of a new frame).

Note: For SSC, the parity error event indication bit is located in the PSR register.

18.4.2.10 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 01_B in SSC mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[4] = 1, and the word length of the received data is given by OUTR.RCI[3:0].

The standard receive buffer event and the alternative receive buffer event can be used for the following operation in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that has not been the first word of a data frame.
- An alternative receive buffer event indicates that the first data word of a new data frame can be read from OUTR.

18.4.2.11 Multi-IO SSC Protocols

The SSC implements the following three features to support multiple data input/output SSC protocols, such as the dual- and quad-SSC:

1. Data Shift Mode ([Section 18.2.5.2](#))
Configures the data for transmission and reception using one, two or four data lines in parallel, through the bit field SCTR.DSM.
2. Hardware Port Control ([Section 18.2.7](#))
Sets up a dedicated hardware interface to control the direction of the pins overlaid with both DINx and DOUTx functions, through the bit SCTR.HPCDIR.
3. Transmit Control Information ([Section 18.2.5.3](#))
Allows the dynamic control of both the shift mode and pin direction during data transfers by writing to SCTR.DSM and SCTR.HPCDIR with TCI.

Universal Serial Interface Channel (USIC)

Figure 18-43 shows an example of a Quad-SSC protocol, which requires the master SSC to first transmit a command byte (to request a quad output read from the slave) and a dummy byte through a single data line. At the end of the dummy byte, both master and slave SSC switches to quad data lines, and with the roles of transmitter and receiver reversed. The master SSC then receives the data four bits per shift clock from the slave through the MRST[3:0] lines.

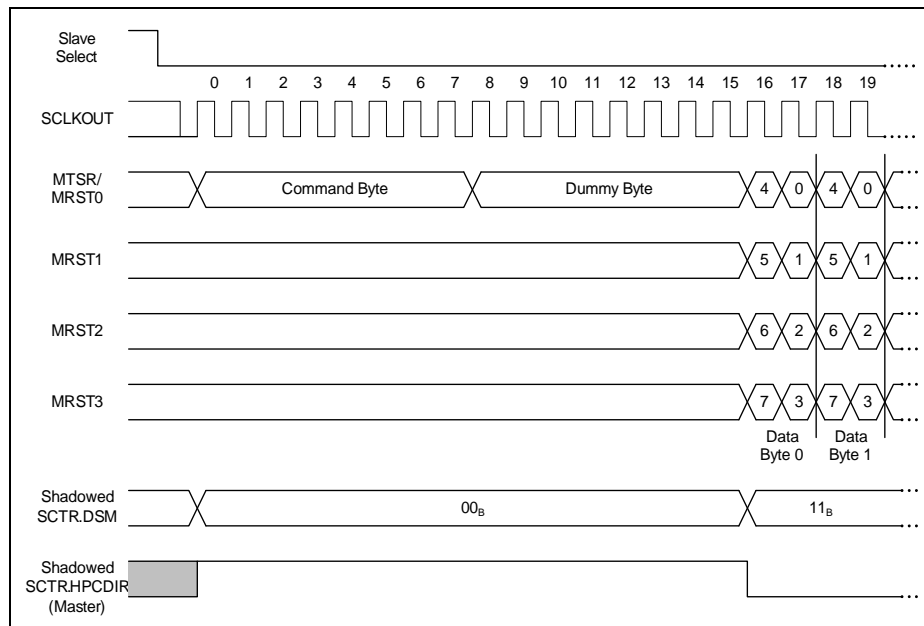

Figure 18-43 Quad-SSC Example

To work with the quad-SSC protocol in the given example, the following issues have to be additionally considered on top of those defined in [Section 18.4.3](#) and [Section 18.4.4](#):

- During the initialization phase:
 - Set CCR.HPCEN to 11_B to enable the dedicated hardware interface to the DX0/DOUT0, DX3/DOUT1, DX4/DOUT2 and DX5/DOUT3 pins.
 - Set TCSR.[4:0] to 10_H to enable hardware port control in TC1
- To start the data transfer:
 - For the master SSC, write the command and dummy bytes into TBUF04 to select a single data line in output mode and initiate the data transfer.
 - For the slave SSC, dummy data can be preloaded into TBUF00 to select a single data line in input mode.
- To switch to quad data lines and pin direction:

Universal Serial Interface Channel (USIC)

- For the master SSC, write subsequent dummy data to TBUF03 to select quad data lines in input mode to read in valid slave data.
- For the slave SSC, write valid data to TBUF07 for transmission through quad data lines in output mode.

Note: If DOUT[1:0] or DOUT[3:0] pins are already enabled with CCR.HPCEN but SCTR.DSM does not use all pins, the unused DOUTx pins output the passive data level defined by SCTR.PDL.

Figure 18-44 shows the connections for the Quad-SSC example.

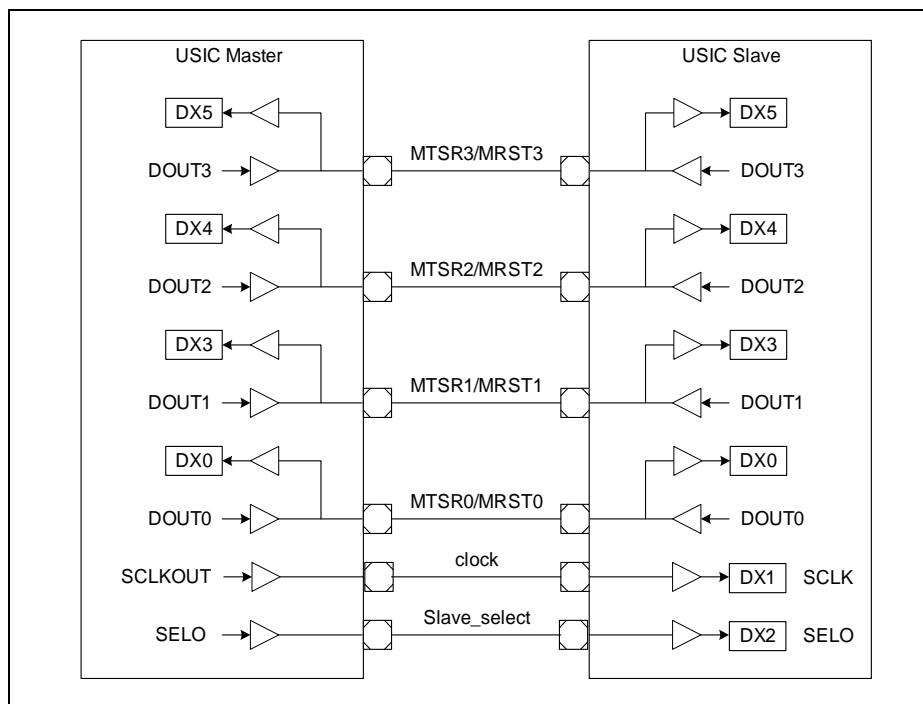

Figure 18-44 Connections for Quad-SSC Example

18.4.3 Operating the SSC in Master Mode

In order to operate the SSC in master mode, the following issues have to be considered:

- **Select SSC mode:**
It is recommended to configure all parameters of the SSC that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 01_B has to be programmed. The configuration of the input stages has to be done while

Universal Serial Interface Channel (USIC)

CCR.MODE = 0000_B to avoid unintended edges of the input signals and the SSC mode can be enabled by CCR.MODE = 0001_B afterwards.

- Pin connections:
Establish a connection of the input stage (DX0, DX3, DX4, DX5) with the selected receive data input pin (DIN[3:0]) with DXnCR.INSW = 1 and configure the transmit data output pin (DOUT[3:0]). One, two or four such connections may be needed depending on the protocol. For half-duplex configurations, hardware port control can be also used to establish the required connections.
- Baud rate generation:
The desired baud rate setting has to be selected, comprising the fractional divider and the baud rate generator. Bit DX1CR.INSW = 0 has to be programmed to use the baud rate generator output SCLK directly as input for the data shift unit. Configure a shift clock output pin (signal SCLKOUT).
- Slave select generation:
The slave select delay generation has to be enabled by setting PCR.MSLSEN = 1 and the programming of the time quanta counter setting. Bit DX2CR.INSW = 0 has to be programmed to use the slave select generator output MSLS as input for the data shift unit. Configure slave select output pins (signals SELOx) if needed.
- Data format configuration:
The word length, the frame length, the shift direction and shift mode have to be set up according to the application requirements by programming the register SCTR.

Note: The USIC can only receive in master mode if it is transmitting, because the master frame handling refers to bit TDV of the transmitter part.

Note: The step to enable the alternate output port functions should only be done after the SSC mode is enabled, to avoid unintended spikes on the output.

18.4.3.1 Baud Rate Generation

The baud rate (determining the length of one data bit) of the SSC is defined by the frequency of the SCLK signal (one period of f_{SCLK} represents one data bit). The SSC baud rate generation does not imply any time quanta counter.

In a standard SSC application, the phase relation between the optional MCLK output signal and SCLK is not relevant and can be disabled (BRG.PPPEN = 0). In this case, the SCLK signal directly derives from the protocol input frequency f_{PIN} . In the exceptional case that a fixed phase relation between the MCLK signal and SCLK is required (e.g. when using MCLK as clock reference for external devices), the additional divider by 2 stage has to be taken into account (BRG.PPPEN = 1).

Universal Serial Interface Channel (USIC)

The adjustable divider factor is defined by bit field BRG.PDIV.

$$f_{\text{SCLK}} = \frac{f_{\text{PIN}}}{2} \times \frac{1}{\text{PDIV} + 1} \quad \text{if } \text{PPPEN} = 0$$

$$f_{\text{SCLK}} = \frac{f_{\text{PIN}}}{2 \times 2} \times \frac{1}{\text{PDIV} + 1} \quad \text{if } \text{PPPEN} = 1$$
(18.8)

18.4.3.2 MSLS Generation

The slave select signals indicate the start and the end of a data frame and are also used by the communication master to individually select the desired slave device. A slave select output of the communication master becomes active a programmable time before a data part of the frame is started (leading delay T_{id}), necessary to prepare the slave device for the following communication. After the transfer of a data part of the frame, it becomes inactive again a programmable time after the end of the last bit (trailing delay T_{id}) to respect the slave hold time requirements. If data frames are transferred back-to-back one after the other, the minimum time between the deactivation of the slave select and the next activation of a slave select is programmable (next-frame delay T_{nf}). If a data frame consists of more than one data word, an optional delay between the data words can also be programmed (inter-word delay T_{iw}).

Figure 18-45 MSLS Generation in SSC Master Mode

In SSC master mode, the slave select delays are defined as follows:

Universal Serial Interface Channel (USIC)

- **Leading delay T_{ld} :**
The leading delay starts if valid data is available for transmission. The internal signal MSLS becomes active with the start of the leading delay. The first shift clock edge (rising edge) of SCLK is generated by the baud rate generator after the leading delay has elapsed.
- **Trailing delay T_{td}**
The trailing delay starts at the end of the last SCLK cycle of a data frame. The internal signal MSLS becomes inactive with the end of the trailing delay.
- **Inter-word delay T_{iw} :**
This delay is optional and can be enabled/disabled by PCR.TIWEN. If the inter-word delay is disabled (TIWEN = 0), the last data bit of a data word is directly followed by the first data bit of the next data word of the same data frame. If enabled (TIWEN = 1), the inter-word delay starts at the end of the last SCLK cycle of a data word. The first SCLK cycle of the following data word of the same data frame is started when the inter-word delay has elapsed. During this time, no shift clock pulses are generated and signal MSLS stays active. The communication partner has time to “digest” the previous data word or to prepare for the next one.
- **Next-frame delay T_{nf} :**
The next-frame delay starts at the end of the trailing delay. During this time, no shift clock pulses are generated and signal MSLS stays inactive. A frame is considered as finished after the next-frame delay has elapsed.

18.4.3.3 Automatic Slave Select Update

If the number of bits per SSC frame and the word length are defined by bit fields SCTR.FLE and SCTR.WLE, the transmit control information TCI can be used to update the slave select setting PCR.CTR[23:16] to control the SELOx select outputs. The automatic update mechanism is enabled by TCSR.SELMD = 1 (bits TCSR.WLEMD, FLEMD, and WAMD have to be cleared). In this case, the TCI of the first data word of a frame defines the slave select setting of the complete frame due to the automatic shadow mechanism (see [Page 18-62](#)).

18.4.3.4 Slave Select Delay Generation

The slave select delay generation is based on time quanta. The length of a time quantum (defined by the period of the f_{CTQIN}) and the number of time quanta per delay can be programmed.

In standard SSC applications, the leading delay T_{ld} and the trailing delay T_{td} are mainly used to ensure stability on the input and output lines as well as to respect setup and hold times of the input stages. These two delays have the same length (in most cases shorter than a bit time) and can be programmed with the same set of bit fields.

- **BRG.CTQSEL**
to define the input frequency f_{CTQIN} for the time quanta generation for T_{ld} and T_{td}
- **BRG.PCTQ**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4) for T_{ld} and T_{td}
- **BRG.DCTQ**
to define the number of time quanta for the delay generation for T_{ld} and T_{td}

The inter-word delay T_{iw} and the next-frame delay T_{nf} are used to handle received data or to prepare data for the next word or frame. These two delays have the same length (in most cases in the bit time range) and can be programmed with a second, independent set of bit fields.

- **PCR.CTQSEL1**
to define the input frequency f_{CTQIN} for the time quanta generation for T_{nf} and T_{iw}
- **PCR.PCTQ1**
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4) for T_{nf} and T_{iw}
- **PCR.DCTQ1**
to define the number of time quanta for the delay generation for T_{nf} and T_{iw}
- **PCR.TIWEN**
to enable/disable the inter-word delay T_{iw}

Each delay depends on the length of a time quantum and the programmed number of time quanta given by the bit fields CTQSEL/CTQSEL1, PCTQ/DCTQ and PCTQ1/DCTQ1 (the coding of CTQSEL1 is similar to CTQSEL, etc.). To provide a high flexibility in programming the delay length, the input frequencies can be selected between several possibilities (e.g. based on bit times or on the faster inputs of the protocol-related divider). The delay times are defined as follows:

$$T_{ld} = T_{td} = \frac{(PCTQ + 1) \times (DCTQ + 1)}{f_{CTQIN}} \quad (18.9)$$

$$T_{iw} = T_{nf} = \frac{(PCTQ1 + 1) \times (DCTQ1 + 1)}{f_{CTQIN}}$$

18.4.3.5 Protocol Interrupt Events

The following protocol-related events generated in SSC mode and can lead to a protocol interrupt. They are related to the start and the end of a data frame. After the start of a data frame a new setting could be programmed for the next data frame and after the end of a data frame the SSC connections to pins can be changed.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **MSLS Interrupt:**
This interrupt indicates in master mode (MSLS generation enabled) that a data frame has started (activation of MSLS) and has been finished (deactivation of MSLS). Any change of the internal MSLS signal sets bit PSR.MSLSEV and additionally, a protocol interrupt can be generated if PCR.MSLSIEN = 1. The actual state of the internal MSLS signal can be read out at PSR.MSLS to take appropriate actions when this interrupt has been detected.
- **DX2T Interrupt:**
This interrupt monitors edges of the input signal of the DX2 stage (although this signal is not used as slave select input for data transfers).
A programmable edge detection for the DX2 input signal sets bit PSR.DX2TEV and additionally, a protocol interrupt can be generated if PCR.DX2TIEN = 1. The actual state of the selected input signal can be read out at PSR.DX2S to take appropriate actions when this interrupt has been detected.
- **Parity Error Interrupt:**
This interrupt indicates that there is a mismatch in the received parity bit (in RBUFSR.PAR) with the calculated parity bit of the last received word of a data frame.

18.4.3.6 End-of-Frame Control

The information about the frame length is required for the MSLS generator of the master device. In addition to the mechanism based on the number of bits per frame (selected with $SCTR.FLE < 63$), the following alternative mechanisms for end of frame handling are supported. It is recommended to set $SCTR.FLE = 63$ (if several end of frame mechanisms are activated in parallel, the first end condition being found finishes the frame).

- **Software-based start of frame indication TCSR.SOF:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit SOF is set, a valid content of TBUF is considered as first word of a new frame. Bit SOF has to be set before the content of TBUF is transferred to the transmit shift register, so it is recommended to write it before writing data to TBUF. A current data word transfer is finished completely and the slave select delays T_{td} and T_{nf} are applied before starting a new data frame with T_{td} and the content of TBUF. For software-handling of bit SOF, bit $TCSR.WLEMD = 0$ has to be programmed. In this case, all $TBUF[31:0]$ address locations show an identical behavior (TCI not taken into account for data handling).
- **Software-based end of frame indication TCSR.EOF:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit EOF is set, a valid content of TBUF is considered as last word of a new frame. Bit EOF has to be set before the content of TBUF is transferred to the transmit shift register, so it is recommended to write it before writing data to TBUF. The data word in TBUF is sent out completely and the slave select delays T_{td} and T_{nf} are applied. A new data frame can start with T_{td} with the next valid TBUF value. For software-handling of bit EOF, bit $TCSR.WLEMD = 0$ has to be programmed. In this case, all $TBUF[31:0]$ address locations show an identical behavior (TCI not taken into account for data handling).
- **Software-based address related end of frame handling:**
 This mechanism can be used if software handles the TBUF data without data FIFO. If bit $TCSR.WLEMD = 1$, the address of the written $TBUF[31:0]$ is used as transmit control information $TCI[4:0]$ to update $SCTR.WLE (= TCI[3:0])$ and $TCSR.EOF (= TCI[4])$ for each data word. The written $TBUF[31:0]$ address location defines the word length and the end of a frame (locations $TBUF[31:16]$ lead to a frame end). For example, writing transmit data to $TBUF[07]$ results in a data word of 8-bit length without finishing the frame, whereas writing transmit data to $TBUF[31]$ leads to a data word length of 16 bits, followed by T_{td} , the deactivation of MSLS and T_{nf} . If $TCSR.WLEMD = 1$, bits $TCSR.EOF$ and SOF , as well as $SCTR.WLE$ must not be written by software after writing data to a TBUF location. Furthermore, it is recommended to clear bits $TCSR.SELMD$, $FLEMD$ and $WAMD$.
- **FIFO-based address related end of frame handling:**
 This mechanism can be used if a data FIFO is used to store the transmit data. The general behavior is similar to the software-based address related end of frame

Universal Serial Interface Channel (USIC)

handling, except that transmit data is not written to the locations TBUF[31:0], but to the FIFO input locations IN[31:0] instead. In this case, software must not write to any of the TBUF locations.

- TBUF related end of frame handling:
If bit PCR.FEM = 0, an end of frame is assumed if the transmit buffer TBUF does not contain valid transmit data at the end of a data word transmission (TCSR.TDV = 0 or in Stop Mode). In this case, the software has to take care that TBUF does not run empty during a data frame in Run Mode. If bit PCR.FEM = 1, signal MSLS stays active while the transmit buffer is waiting for new data (TCSR.TDV = 1 again) or until Stop Mode is left.
- Explicit end of frame by software:
The software can explicitly stop a frame by clearing bit PSR.MSLS by writing a 1 to the related bit position in register PSCR. This write action immediately clears bit PSR.MSLS, whereas the internal MSLS signal becomes inactive after finishing a currently running word transfer and respecting the slave select delays T_{id} and T_{nf} .

18.4.4 Operating the SSC in Slave Mode

In order to operate the SSC in slave mode, the following issues have to be considered:

- **Select SSC mode:**
It is recommended to configure all parameters of the SSC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 01_B$ has to be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the SSC mode can be enabled afterwards by $CCR.MODE = 0001_B$.
- **Pin connections:**
Establish the connection of the input stage (DX0, DX3, DX4, DX5) with the selected receive data input pin (DIN[3:0]) with $DXnCR.INSW = 1$ and configure the transmit data output pin (DOUT[3:0]). One, two or four such connections may be needed depending on the protocol. For half-duplex configurations, hardware port control can be also used to establish the required connections.
Establish a connection of input stage DX1 with the selected shift clock input pin (signal SCLKIN) with $DX1CR.INSW = 1$.
Establish a connection of input stage DX2 with the selected slave select input pin (signal SELIN) with $DX2CR.INSW = 1$. If no slave select input signal is used, the DX2 stage has to deliver a 1-level to the data shift unit to allow data reception and transmission. If a slave device is not selected (DX2 stage delivers a 0 to the data shift unit) and a shift clock pulse are received, the incoming data is not received and the DOUTx signal outputs the passive data level defined by $SCTR.PDL$.
Note that the step to enable the alternate output port functions should only be done after the SSC mode is enabled, to avoid unintended spikes on the output.
- **Baud rate generation:**
The baud rate generator is not needed and can be switched off by the fractional divider.
- **Data format configuration:**
If required, the shift mode can be set up for reception and/or transmission of two or four data bits at one time by programming the register $SCTR$.
- **Slave select generation:**
The slave select delay generation is not needed and can be switched off. The bits and bit fields $MSLSEN$, $SELCTR$, $SELINV$, $CTQSEL1$, $PCTQ1$, $DCTQ1$, $MSLSIEN$, $SELO[7:0]$, and $TIWEN$ in register PCR are not necessary and can be programmed to 0.

18.4.4.1 Protocol Interrupts

The following protocol-related events generated in SSC mode and can lead to a protocol interrupt. They are related to the start and the end of a data frame. After the start of a data frame a new setting could be programmed for the next data frame and after the end of a data frame the SSC connections to pins can be changed.

Universal Serial Interface Channel (USIC)

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **MSLS event:**
The MSLS generation being switched off, this event is not available.
- **DX2T event:**
The slave select input signal SELIN is handled by the DX2 stage and the edges of the selected signal can generate a protocol interrupt. This interrupt allows to indicate that a data frame has started and/or that a data frame has been completely finished. A programmable edge detection for the DX2 input signal activates DX2T, sets bit PSR.DX2TEV and additionally, a protocol interrupt can be generated if PCR.DX2TIEN = 1. The actual state of the selected input signal can be read out at PSR.DX2S to take appropriate actions when this interrupt has been detected.
- **Parity Error Interrupt:**
This interrupt indicates that there is a mismatch in the received parity bit (in RBUFSR.PAR) with the calculated parity bit of the last received word of a data frame.

18.4.4.2 End-of-Frame Control

In slave mode, the following possibilities exist to determine the frame length. The slave device either has to refer to an external slave select signal, or to the number of received data bits.

- **Frame length known in advance by the slave device, no slave select:**
In this case bit field SCTR.FLE can be programmed to the known value (if it does not exceed 63 bits). A currently running data word transfer is considered as finished if the programmed frame length is reached.
- **Frame length not known by the slave, no slave select:**
In this case, the slave device's software has to decide on data word base if a frame is finished. Bit field SCTR.FLE can be either programmed to the word length SCTR.WLE, or to its maximum value to disable the slave internal frame length evaluation by counting received bits.
- **Slave device addressed via slave select signal SELIN:**
If the slave device is addressed by a slave select signal delivered by the communication master, the frame start and end information are given by this signal. In this case, bit field SCTR.FLE should be programmed to its maximum value to disable the slave internal frame length evaluation.

Universal Serial Interface Channel (USIC)

18.4.5 SSC Protocol Registers

In SSC mode, the registers PCR and PSR handle SSC related information.

18.4.5.1 SSC Protocol Control Registers

In SSC mode, the PCR register bits or bit fields are defined as described in this section.

PCR

Protocol Control Register [SSC Mode]

| rw | rw | rw | rw | | | | rw | | rw | | rw | rw | rw | rw | |

| Field | Bits | Type | Description |
|--------|------|------|---|
| MSLSEN | 0 | rw | MSLS Enable This bit enables/disables the generation of the master slave select signal MSLS. If the SSC is a transfer slave, the SLS information is read from a pin and the internal generation is not needed. If the SSC is a transfer master, it has to provide the MSLS signal. 0 _B The MSLS generation is disabled (MSLS = 0). This is the setting for SSC slave mode. 1 _B The MSLS generation is enabled. This is the setting for SSC master mode. |
| SELCTR | 1 | rw | Select Control This bit selects the operating mode for the SELO[7:0] outputs. 0 _B The coded select mode is enabled. 1 _B The direct select mode is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| SELINV | 2 | rw | Select Inversion This bit defines if the polarity of the SELO[7:0] outputs in relation to the master slave select signal MSLS. 0_B The SELO outputs have the same polarity as the MSLS signal (active high). 1_B The SELO outputs have the inverted polarity to the MSLS signal (active low). |
| FEM | 3 | rw | Frame End Mode This bit defines if a transmit buffer content that is not valid for transmission is considered as an end of frame condition for the slave select generation. 0_B The current data frame is considered as finished when the last bit of a data word has been sent out and the transmit buffer TBUF does not contain new data ($TDV = 0$). 1_B The MSLS signal is kept active also while no new data is available and no other end of frame condition is reached. In this case, the software can accept delays in delivering the data without automatic deactivation of MSLS in multi-word data frames. |
| CTQSEL1 | [5:4] | rw | Input Frequency Selection This bit field defines the input frequency f_{CTQIN} for the generation of the slave select delays T_{iw} and T_{nf} . 00_B $f_{CTQIN} = f_{PDIV}$ 01_B $f_{CTQIN} = f_{PPP}$ 10_B $f_{CTQIN} = f_{SCLK}$ 11_B $f_{CTQIN} = f_{MCLK}$ |
| PCTQ1 | [7:6] | rw | Divider Factor PCTQ1 for T_{iw} and T_{nf} This bit field represents the divider factor PCTQ1 (range = 0 - 3) for the generation of the inter-word delay and the next-frame delay. $T_{iw} = T_{nf} = 1/f_{CTQIN} \times (PCTQ1 + 1) \times (DCTQ1 + 1)$ |
| DCTQ1 | [12:8] | rw | Divider Factor DCTQ1 for T_{iw} and T_{nf} This bit field represents the divider factor DCTQ1 (range = 0 - 31) for the generation of the inter-word delay and the next-frame delay. $T_{iw} = T_{nf} = 1/f_{CTQIN} \times (PCTQ1 + 1) \times (DCTQ1 + 1)$ |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| PARIEN | 13 | rw | Parity Error Interrupt Enable This bit enables/disables the generation of a protocol interrupt with the detection of a parity error. 0_B A protocol interrupt is not generated with the detection of a parity error. 1_B A protocol interrupt is generated with the detection of a parity error. |
| MSLSIEN | 14 | rw | MSLS Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the state of the MSLS signal changes (indicated by $PSR.MSLSEV = 1$). 0_B A protocol interrupt is not generated if a change of signal MSLS is detected. 1_B A protocol interrupt is generated if a change of signal MSLS is detected. |
| DX2TIEN | 15 | rw | DX2T Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the DX2T signal becomes activated (indicated by $PSR.DX2TEV = 1$). 0_B A protocol interrupt is not generated if DX2T is activated. 1_B A protocol interrupt is generated if DX2T is activated. |
| SELO | [23:16] | rw | Select Output This bit field defines the setting of the SELO[7:0] output lines. 0_B The corresponding SELOx line cannot be activated. 1_B The corresponding SELOx line can be activated (according to the mode selected by SELCTR). |
| TIWEN | 24 | rw | Enable Inter-Word Delay T_{iw} This bit enables/disables the inter-word delay T_{iw} after the transmission of a data word. 0_B No delay between data words of the same frame. 1_B The inter-word delay T_{iw} is enabled and introduced between data words of the same frame. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| SLPHSEL | 25 | rw | Slave Mode Clock Phase Select This bit selects the clock phase for the data shifting in slave mode. 0_B Data bits are shifted out with the leading edge of the shift clock signal and latched in with the trailing edge. 1_B The first data bit is shifted out when the data shift unit receives a low to high transition from the DX2 stage. Subsequent bits are shifted out with the trailing edge of the shift clock signal. Data bits are always latched in with the leading edge. |
| MCLK | 31 | rw | Master Clock Enable This bit enables/disables the generation of the master clock output signal MCLK, independent from master or slave mode. 0_B The MCLK generation is disabled and output MCLK = 0. 1_B The MCLK generation is enabled. |
| 0 | [30:26] | rw | Reserved Returns 0 if read; should be written with 0. |

Universal Serial Interface Channel (USIC)

18.4.5.2 SSC Protocol Status Register

In SSC mode, the PSR register bits or bit fields are defined as described in this section. The bits and bit fields in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. The PSR flags should be cleared by software before enabling a new protocol.

| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | [9:5], [31:17] | r | Reserved Returns 0 if read; not modified in SSC mode. |

1) This status bit can generate a protocol interrupt in SSC mode (see [Page 18-22](#)). The general interrupt status flags are described in the general interrupt chapter.

18.4.6 SSC Timing Considerations

The input and output signals have to respect certain timings in order to ensure correct data reception and transmission. In addition to module internal timings (due to input filters, reaction times on events, etc.), also the timings from the input pin via the input stage (T_{in}) to the module and from the module via the output driver stage to the pin (T_{out}), as well as the signal propagation on the wires (T_{prop}) have to be taken into account.

Please note that there might be additional delays in the DXn input stages, because the digital filter and the synchronization stages lead to systematic delays, that have to be considered if these functions are used.

18.4.6.1 Closed-loop Delay

A system-inherent limiting factor for the baud rate of an SSC connection is the closed-loop delay. In a typical application setup, a communication master device is connected to a slave device in full-duplex mode with independent lines for transmit and receive data. In a general case, all transmitters refer to one shift clock edge for transmission and all receivers refer to the other shift clock edge for reception. The master device's SSC module sends out the transmit data, the shift clock and optionally the slave select signal. Therefore, the baud rate generation (BRG) and slave select generation (SSG) are part of the master device. The frame control is similar for SSC modules in master and slave mode, the main difference is the fact which module generates the shift clock and optionally, the slave select signals.

Figure 18-46 SSC Closed-loop Delay

Universal Serial Interface Channel (USIC)

The signal path between the SSC modules of the master and the slave device includes the master's output driver, the wiring to the slave device and the slave device's input stage. With the received shift clock edges, the slave device receives the master's transmit data and transmits its own data back to the master device, passing by a similar signal path in the other direction. The master module receives the slave's transmit data related to its internal shift clock edges. In order to ensure correct data reception in the master device, the slave's transmit data has to be stable (respecting setup and hold times) as master receive data with the next shift clock edge of the master (generally 1/2 shift clock period). To avoid data corruption, the accumulated delays of the input and output stages, the signal propagation on the wiring and the reaction times of the transmitter/receiver have to be carefully considered, especially at high baud rates.

In the given example, the time between the generation of the shift clock signal and the evaluation of the receive data by the master SSC module is given by the sum of $T_{\text{out_master}} + 2 \times T_{\text{prop}} + T_{\text{in_slave}} + T_{\text{out_slave}} + T_{\text{in_master}}$ + module reaction times + input setup times.

The input path is characterized by an input delay depending mainly on the input stage characteristics of the pads. The output path delay is determined by the output driver delay and its slew rate, the external load and current capability of the driver. The device specific values for the input/output driver are given in the Data Sheet.

Universal Serial Interface Channel (USIC)

Figure 18-47 describes graphically the closed-loop delay and the effect of two delay compensation options discussed in [Section 18.4.6.2](#) and [Section 18.4.6.3](#).

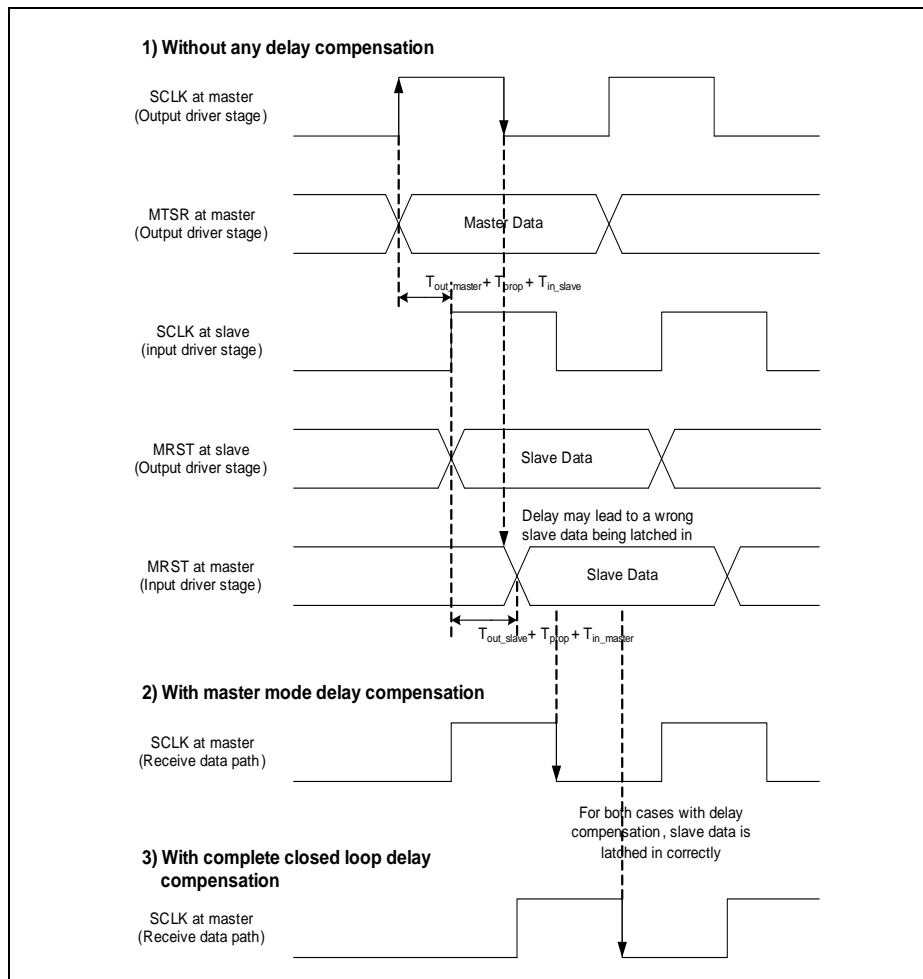

Figure 18-47 SSC Closed-loop Delay Timing Waveform

18.4.6.2 Delay Compensation in Master Mode

A higher baud rate can be reached by delay compensation in master mode. This compensation is possible if (at least) the shift clock pin is bidirectional.

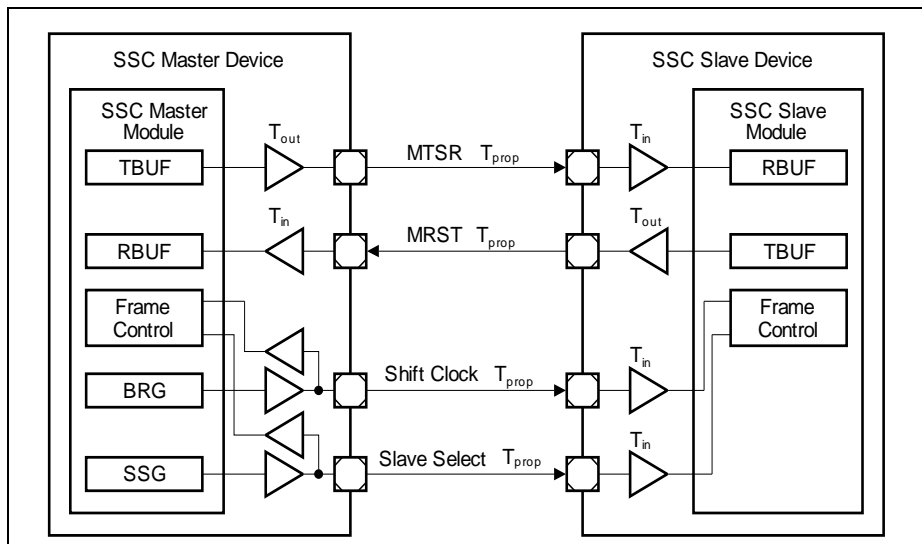

Figure 18-48 SSC Master Mode with Delay Compensation

If the receive shift clock signal in master mode is directly taken from the input function in parallel to the output signal, the output delay of the master device's shift clock output is compensated and only the difference between the input delays of the master and the slave devices have to be taken into account instead of the complete master's output delay and the slave's input delay of the shift clock path. The delay compensation is enabled with $DX1CR.DCEN = 1$ while $DX1CR.INSW = 0$ (transmit shift clock is taken from the baud-rate generator).

In the given example, the time between the evaluation of the shift clock signal and the receive data by the master SSC module is reduced by $T_{in_master} + T_{out_master}$.

Although being a master mode, the shift clock input and optionally the slave select signal are not directly connected internally to the data shift unit, but are taken as external signals from input pins. The delay compensation does not lead to additional pins for the SSC communication if the shift clock output pin (slave select output pin, respectively) is/are bidirectional. In this case, the input signal is decoupled from other internal signals, because it is related to the signal level at the pin itself.

18.4.6.3 Complete Closed-loop Delay Compensation

Alternatively, the complete closed-loop delay can be compensated by using one additional pin on both the SSC master and slave devices for the SSC communication.

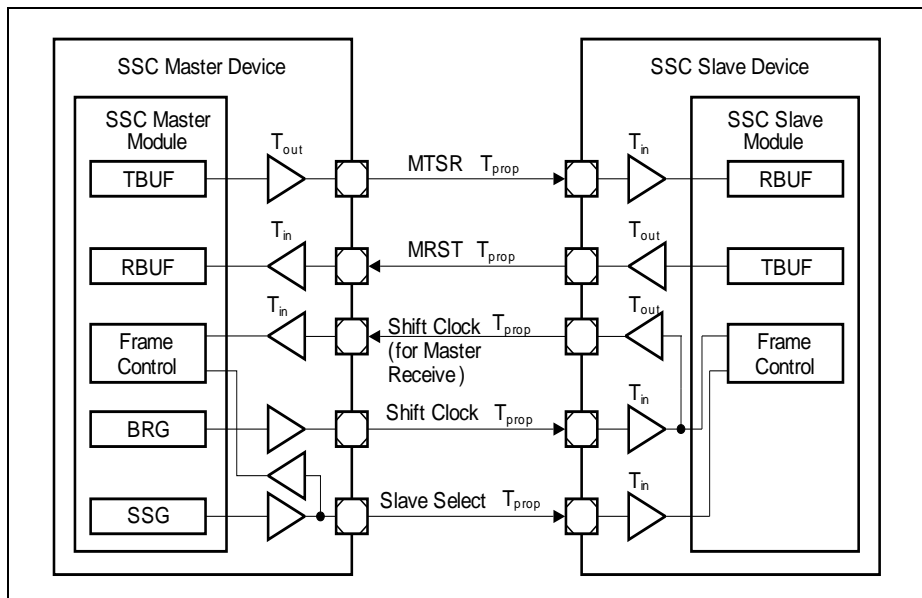

Figure 18-49 SSC Complete Closed-loop Delay Compensation

The principle behind this delay compensation method is to have the slave feedback the shift clock back to the master, which uses it as the receive shift clock. By going through a complete closed-loop signal path, the receive shift clock is thus fully compensated.

The slave has to setup the SCLKOUT pin function to output the shift clock by setting the bit BRG.SCLKOSEL to 1, while the master has to setup the DX1 pin function to receive the shift clock from the slave and enable the delay compensation with DX1CR.DCEN = 1 and DX1CR.INSW = 0.

18.5 Inter-IC Bus Protocol (IIC)

The IIC protocol of the USIC refers to the IIC bus specification [20]. Contrary to that specification, the USIC device assumes rise/fall times of the bus signals of max. 300 ns in all modes. Please refer to the pad characteristics in the AC/DC chapter for the driver capability. CBUS mode and HS mode are not supported.

The IIC mode is selected by $CCR.MODE = 0100_B$ with $CCFG.IIC = 1$ (IIC mode available).

18.5.1 Introduction

USIC IIC Features:

- Two-wire interface, with one line for shift clock transfer and synchronization (shift clock SCL), the other one for the data transfer (shift data SDA)
- Communication in standard mode (100 kBit/s) or in fast mode (up to 400 kBit/s)
- Support of 7-bit addressing, as well as 10-bit addressing
- Master mode operation, where the IIC controls the bus transactions and provides the clock signal.
- Slave mode operation, where an external master controls the bus transactions and provides the clock signal.
- Multi-master mode operation, where several masters can be connected to the bus and bus arbitration can take place, i.e. the IIC module can be master or slave. The master/slave operation of an IIC bus participant can change from frame to frame.
- Efficient frame handling (low software effort), also allowing DMA transfers
- Powerful interrupt handling due to multitude of indication flags
- Compensation support for input delays

18.5.1.1 Signal Description

An IIC connection is characterized by two wires (SDA and SCL). The output drivers for these signals must have open-drain characteristics to allow the wired-AND connection of all SDA lines together and all SCL lines together to form the IIC bus system. Due to this structure, a high level driven by an output stage does not necessarily lead immediately to a high level at the corresponding input. Therefore, each SDA or SCL connection has to be input and output at the same time, because the input function always monitors the level of the signal, also while sending.

- Shift data SDA: input handled by DX0 stage, output signal DOUT0
- Shift clock SCL: input handled by DX1 stage, output signal SCLKOUT

Figure 18-29 shows a connection of two IIC bus participants (modules IIC A and IIC B) using the USIC. In this example, the pin assignment of module IIC A shows separate pins for the input and output signals for SDA and SCL. This assignment can be used if the application does not provide pins having DOUT0 and a DX0 stage input for the same pin

Universal Serial Interface Channel (USIC)

(similar for SCLKOUT and DX1). The pin assignment of module IIC B shows the connection of DOUT0 and a DX0 input at the same pin, also for SCLKOUT and a DX1 input.

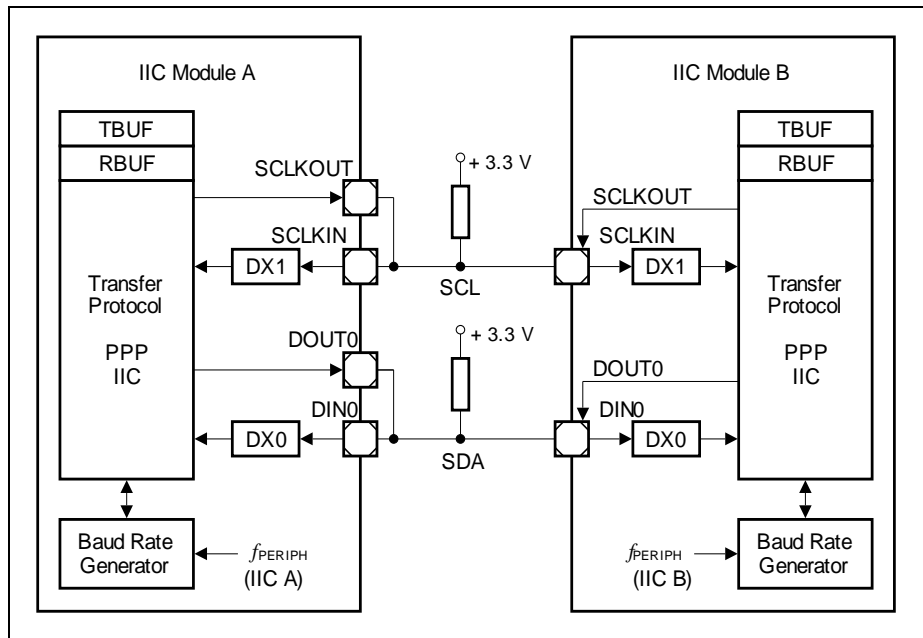

Figure 18-50 IIC Signal Connections

18.5.1.2 Symbols

A symbol is a sequence of edges on the lines SDA and SCL. Symbols contain 10 or 25 time quanta t_q , depending on the selected baud rate. The baud rate generator determines the length of the time quanta t_q , the sequence of edges in a symbol is handled by the IIC protocol pre-processor, and the sequence of symbols can be programmed by the user according to the application needs.

The following symbols are defined:

- Bus idle:
SDA and SCL are high. No data transfer takes place currently.
- Data bit symbol:
SDA stable during the high phase of SCL. SDA then represents the transferred bit value. There is one clock pulse on SCL for each transferred bit of data. During data transfers SDA may only change while SCL is low.

Universal Serial Interface Channel (USIC)

- **Start symbol:**
Signal SDA being high followed by a falling edge of SDA while SCL is high indicates a start condition. This start condition initiates a data transfer over the IIC bus after the bus has been idle.
- **Repeated start symbol:**
This start condition initiates a data transfer over the bus after a data symbol when the bus has not been idle. Therefore, SDA is set high and SCL low, followed by a start symbol.
- **Stop symbol:**
A rising edge on SDA while SCL is high indicates a stop condition. This stop condition terminates a data transfer to release the bus to idle state. Between a start condition and a stop condition an arbitrary number of bytes may be transferred.

18.5.1.3 Frame Format

Data is transferred by the 2-line IIC bus (SDA, SCL) using a protocol that ensures reliable and efficient transfers. The sender of a (data) byte receives and checks the value of the following acknowledge field. The IIC being a wired-AND bus system, a 0 of at least one device leads to a 0 on the bus, which is received by all devices.

A data word consists of 8 data bit symbols for the data value, followed by another data bit symbol for the acknowledge bit. The data word can be interpreted as address information (after a start symbol) or as transferred data (after the address).

In order to be able to receive an acknowledge signal, the sender of the data bits has to release the SDA line by sending a 1 as acknowledge value. Depending on the internal state of the receiver, the acknowledge bit is either sent active or passive.

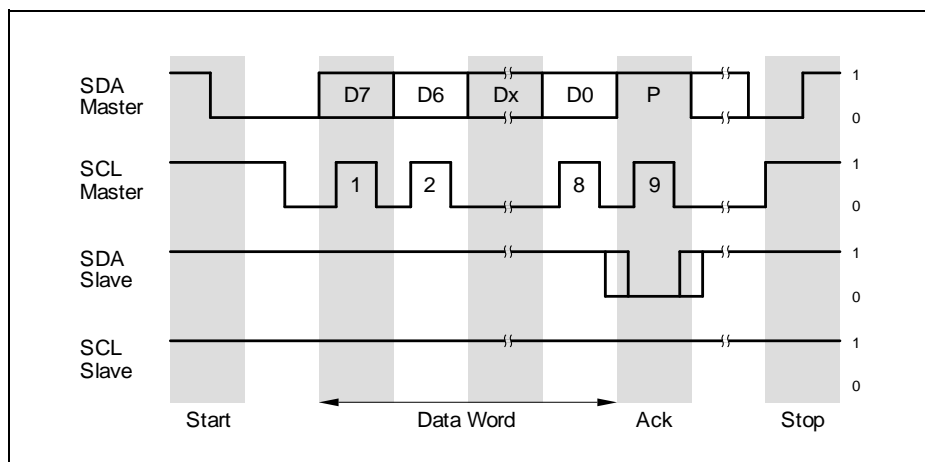

Figure 18-51 IIC Frame Example (simplified)

18.5.2 Operating the IIC

In order to operate the IIC protocol, the following issues have to be considered:

- **Select IIC mode:**
It is recommended to configure all parameters of the IIC that do not change during run time while $CCR.MODE = 0000_B$. Bit field $SCTR.TRM = 11_B$ should be programmed. The configuration of the input stages has to be done while $CCR.MODE = 0000_B$ to avoid unintended edges of the input signals and the IIC mode can be enabled by $CCR.MODE = 0100_B$ afterwards.
- **Pin connections:**
Establish a connection of input stage DX0 (with $DX0CR.DPOL = 0$) to the selected shift data pin SDA (signal DIN0) with $DX0CR.INSW = 0$ and configure the transmit data output signal DOUT0 (with $SCTR.DOCFG = 00_B$) to the same pin. If available, this can be the same pin for input and output, or connect the selected input pin and the output pin to form the SDA line.
The same mechanism applies for the shift clock line SCL. Here, signal SCLKOUT (with $BRG.SCLKCFG = 00_B$) and an input of the DX1 stage have to be connected (with $DX1CR.DPOL = 0$).
The input stage DX2 is not used for the IIC protocol.
If the digital input filters are enabled in the DX0/1 stages, their delays have to be taken into account for correct calculation of the signal timings.
The pins used for SDA and SCL have to be set to open-drain mode to support the wired-AND structure of the IIC bus lines.
Note that the step to enable the alternate output port functions should only be done after the IIC mode is enabled, to avoid unintended spikes on the output.
- **Bit timing configuration:**
In standard mode (100 kBit/s) a minimum module frequency of 2 MHz is necessary, whereas in fast mode (400 kBit/s) a minimum of 10 MHz is required. Additionally, if the digital filter stage should be used to eliminate spikes up to 50 ns, a filter frequency of 20 MHz is necessary.
There could be an uncertainty in the SCL high phase timing of maximum $1/f_{PPP}$ if another IIC participant lengthens the SCL low phase on the bus.
More details are given in [Section 18.5.3](#).
- **Data format configuration:**
The data format has to be configured for 8 data bits ($SCTR.WLE = 7$), unlimited data flow ($SCTR.FLE = 3F_H$), and MSB shifted first ($SCTR.SDIR = 1$). The parity generation has to be disabled ($CCR.PM = 00_B$).
- **General hints:**
The IIC slave module becomes active (for reception or transmission) if it is selected by the address sent by the master. In the case that the slave sends data to the master, it uses the transmit path. So a master must not request to read data from the slave address defined for its own channel in order to avoid collisions.
The built-in error detection mechanisms are only activated while the IIC module is

taking part in IIC bus traffic.

If the slave can not deal with too high frequencies, it can lengthen the low phase of the SCL signal.

For data transfers according to the IIC specification, the shift data line SDA shall only change while SCL = 0 (defined by IIC bus specification).

18.5.2.1 Transmission Chain

The IIC bus protocol requiring a kind of in-bit-response during the arbitration phase and while a slave is transmitting, the resulting loop delay of the transmission chain can limit the reachable maximal baud rate, strongly depending on the bus characteristics (bus load, module frequency, etc.).

Figure 18-50 shows the general signal path and the delays in the case of a slave transmission. The shift clock SCL is generated by the master device, output on the wire, then it passes through the input stage and the input filter. Now, the edges can be detected and the SDA data signal can be generated accordingly. The SDA signal passes through the output stage and the wire to the master receiver part. There, it passes through the input stage and the input filter before it is sampled.

This complete loop has to be finished (including all settling times to obtain stable signal levels) before the SCL signal changes again. The delays in this path have to be taken into account for the calculation of the baud rate as a function of f_{PERIPH} and f_{PPP} .

18.5.2.2 Byte Stretching

If a device is selected as transceiver and should transmit a data byte but the transmit buffer TBUF does not contain valid data to be transmitted, the device ties down SCL = 0 at the end of the previous acknowledge bit. The waiting period is finished if new valid data has been detected in TBUF.

18.5.2.3 Master Arbitration

During the address and data transmission, the master transmitter checks at the rising edge of SCL for each data bit if the value it is sending is equal to the value read on the SDA line. If yes, the next data bit values can be 0. If this is not the case (transmitted value = 1, value read = 0), the master has lost the transmit arbitration. This is indicated by status flag PSR.ARL and can generate a protocol interrupt if enabled by PCR.ARLIEN.

When the transmit arbitration has been lost, the software has to initialize the complete frame again, starting with the first address byte together with the start condition for a new master transmit attempt. Arbitration also takes place for the ACK bit.

18.5.2.4 Non-Acknowledge and Error Conditions

In case of a non-acknowledge or an error, the TCSR.TDV flag remains set, but no further transmission will take place. User software must invalidate the transmit buffer and disable transmissions (by writing FMRL.MTDV = 10_B), before configuring the transmission (by writing TBUF) again with appropriate values to react on the previous event. In the case the FIFO data buffer is used, additionally the FIFO buffer needs to be flushed and filled again.

18.5.2.5 Mode Control Behavior

In multi-master mode, only run mode 0 and stop mode 0 are supported, the other modes must not be programmed.

- **Run Mode 0:**
Behavior as programmed. If TCSR.TDV = 0 (no new valid TBUF entry found) when a new TBUF entry needs to be processed, the IIC module waits for TDV becoming set to continue operation.
- **Run Mode 1:**
Behavior as programmed. If in master mode, TCSR.TDV = 0 (no new valid TBUF entry found) when a new TBUF entry needs to be processed, the IIC module sends a stop condition to finish the frame. In slave mode, no difference to run mode 0.
- **Stop Mode 0:**
Bit TCSR.TDV is internally considered as 0 (the bit itself is not modified by the stop mode). A currently running word is finished normally, but no new word is started in case of master mode (wait for TDV active).
Bit TDV being considered as 0 for master and slave, the slave will force a wait state on the bus if read by an external master, too.
Additionally, it is not possible to force the generation of a STOP condition out of the wait state. The reason is, that a master read transfer must be finished with a not-acknowledged followed by a STOP condition to allow the slave to release his SDA line. Otherwise the slave may force the SDA line to 0 (first data bit of next byte) making it impossible to generate the STOP condition (rising edge on SDA).
To continue operation, the mode must be switched to run mode 0
- **Stop Mode 1:**
Same as stop mode 0, but additionally, a master sends a STOP condition to finish the frame.
If stop mode 1 is requested for a master device after the first byte of a 10 bit address, a stop condition will be sent out. In this case, a slave device will issue an error interrupt.

18.5.2.6 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to IIC frame handling. As the data input and output pins are the same in IIC protocol, a IIC transmitter also receives the

Universal Serial Interface Channel (USIC)

output data at its input pin. However, no receive related interrupts will be generated in this case.

- **Transmit buffer event:**
 The transmit buffer event indication flag PSR.TBIF is set when the content of the transmit buffer TBUF has been loaded to the transmit shift register, indicating that the action requested by the TBUF entry has started.
 With this event, bit TCSR.TDV is cleared. This interrupt can be used to write the next TBUF entry while the last one is in progress (handled by the transmitter part).
- **Receive event:**
 This receive event indication flag PSR.RIF indicates that a new data byte has been written to the receive buffer RBUF0/1 (except for the first data byte of a new frame, that is indicated by an alternative receive interrupt). The flag becomes set when the data byte is received (after the falling edge of SCL). This interrupt can be used to read out the received data while a new data byte can be in progress (handled by the receiver part).
- **Alternate receive event:**
 The alternative receive event indication flag AIF is based on bit RBUFSR[9] (same as RBUF[9]), indicating that the received data word has been the first data word of a new data frame.
- **Transmit shift event:**
 The transmit shift event indication flag TSIF is set after the start of the last data bit of a data byte.
- **Receive start event:**
 The receive start event indication flag RSIF is set after the sample point of the first data bit of a data byte.

Note: The transmit shift and receive start events can be ignored if the application does not require them during the IIC data transfer.

18.5.2.7 IIC Protocol Interrupt Events

The following protocol-related events are generated in IIC mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- start condition received at a correct position in a frame (PSR.SCR)
- repeated start condition received at a correct position in a frame (PSR.RSCR)
- stop condition transferred at a correct position in a frame (PSR.PCR)
- master arbitration lost (PSR.ARL)
- slave read requested (PSR.SRR)
- acknowledge received (PSR.ACK)
- non-acknowledge received (PSR.NACK)
- start condition not at the expected position in a frame (PSR.ERR)

Universal Serial Interface Channel (USIC)

- stop condition not at the expected position in a frame (PSR.ERR)
- as slave, 10-bit address interrupted by a stop condition after the first address byte (PSR.ERR)
- TDF slave code in master mode (PSR.WTDF)
- TDF master code in slave mode (PSR.WTDF)
- Reserved TDF code found (PSR.WDTF)
- Start condition code during a running frame in master mode (PSR.WTDF)
- Data byte transmission code after transfer direction has been changed to reception (master read) in master mode (PSR.WTDF)

If a wrong TDF code is found in TBUF, the error event is active until the TDF value is either corrected or invalidated. If the related interrupt is enabled, the interrupt handler should check PSR.WDTF first and correct or invalidate TBUF, before dealing with the other possible interrupt events.

18.5.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

18.5.2.9 Receiver Address Acknowledge

After a (repeated) start condition, the master sends a slave address to identify the target device of the communication. The start address can comprise one or two address bytes (for 7 bit or for 10 bit addressing schemes). After an address byte, a slave sensitive to the transmitted address has to acknowledge the reception.

Therefore, the slave's address can be programmed in the device, where it is compared to the received address. In case of a match, the slave answers with an acknowledge (SDA = 0). Slaves that are not targeted answer with a non-acknowledge (SDA = 1).

In addition to the match of the programmed address, another address byte value has to be answered with an acknowledge if the slave is capable to handle the corresponding requests. The address byte 00_H indicates a general call address, that can be acknowledged. The value 01_H stands for a start byte generation, that is not acknowledged

In order to allow selective acknowledges for the different values of the address byte(s), the following control mechanism is implemented:

- The address byte 00_H is acknowledged if bit PCR.ACK00 is set.
- The address byte 01_H is not acknowledged.
- The first 7 bits of a received first address byte are compared to the programmed slave address (PCR.SLAD[15:9]). If these bits match, the slave sends an acknowledge. In addition to this, if the slave address is programmed to 1111 0XX_B, the slave device waits for a second address byte and compares it also to PCR.SLAD[7:0] and sends an acknowledge accordingly to cover the 10 bit addressing mode. The user has to

Universal Serial Interface Channel (USIC)

take care about reserved addresses (refer to IIC specification for more detailed description). Only the address 1111 0XX₆ is supported.

Under each of these conditions, bit PSR.SLSEL will be set when the addressing delivered a match. This bit is cleared automatically by a (repeated) start condition.

18.5.2.10 Receiver Handling

A selected slave receiver always acknowledges a received data byte. If the receive buffers RBUF0/1 are already full and can not accept more data, the respective register is overwritten (PSR.DLI becomes set in this case and a protocol interrupt can be generated).

An address reception also uses the registers RBUF0/1 to store the address before checking if the device is selected. The received addresses do not set RDV0/1, so the addresses are not handled like received data.

18.5.2.11 Receiver Status Information

In addition to the received data byte, some IIC protocol related information is stored in the 16-bit data word of the receive buffer. The received data byte is available at the bit positions RBUF[7:0], whereas the additional information is monitored at the bit positions RBUF[12:8]. This structure allows to identify the meaning of each received data byte without reading additional registers, also when using a FIFO data buffer.

- RBUF[8]:
Value of the received acknowledge bit. This information is also available in RBUF[8] as protocol argument.
- RBUF[9]:
A 1 at this bit position indicates that after a (repeated) start condition followed by the address reception the first data byte of a new frame has been received. A 0 at this bit position indicates further data bytes. This information is also available in RBUF[9], allowing different interrupt routines for the address and data handling.
- RBUF[10]:
A 0 at this bit position indicates that the data byte has been received when the device has been in slave mode, whereas a 1 indicates a reception in master mode.
- RBUF[11]:
A 1 at this bit position indicates an incomplete/erroneous data byte in the receive buffer caused by a wrong position of a START or STOP condition in the frame. The bit is not identical to the frame error status bit in PSR, because the bit in the PSR has to be cleared by software ("sticky" bit), whereas RBUF[11] is evaluated data byte by data byte. If RBUF[11] = 0, the received data byte has been correct, independent of former errors.
- RBUF[12]:
A 0 at this bit position indicates that the programmed address has been received. A 1 indicates a general call address.

18.5.3 Symbol Timing

The symbol timing of the IIC is determined by the master stimulating the shift clock line SCL. It is different in each of the modes.

- 100 kBaud standard mode (PCR.STIM = 0):
The symbol timing is based on 10 time quanta t_q per symbol. A minimum module clock frequency $f_{\text{PERIPH}} = 2 \text{ MHz}$ is required.
- 400 kBaud fast mode (PCR.STIM = 1):
The symbol timing is based on 25 time quanta t_q per symbol. A minimum module clock frequency $f_{\text{PERIPH}} = 10 \text{ MHz}$ is required.

The baud rate setting should only be changed while the transmitter and the receiver are idle or CCR.MODE = 0. The bits in register BRG define the length of a time quantum t_q that is given by one period of f_{PCTQ} .

- BRG.CTQSEL
to define the input frequency f_{CTQIN} for the time quanta generation
- BRG.PCTQ
to define the length of a time quantum (division of f_{CTQIN} by 1, 2, 3, or 4)
- BRG.DCTQ
to define the number of time quanta per symbol (number of $t_q = \text{DCTQ} + 1$)

The standard setting is given by CTQSEL = 00_B ($f_{\text{CTQIN}} = f_{\text{PDIV}}$) and PPPEN = 0 ($f_{\text{PPP}} = f_{\text{IN}}$). Under these conditions, the frequency f_{PCTQ} is given by:

$$f_{\text{PCTQ}} = f_{\text{PIN}} \times \frac{1}{\text{PDIV} + 1} \times \frac{1}{\text{PCTQ} + 1} \quad (18.10)$$

To respect the specified SDA hold time of 300 ns for standard mode and fast mode after a falling edge of signal SCL, a hold delay t_{HDEL} has been introduced. It also prevents an erroneous detection of a start or a stop condition. The length of this delay can be programmed by bit field PCR.HDEL. Taking into account the input sampling and output update, bit field HDEL can be programmed according to:

(18.11)

$$\begin{aligned} \text{HDEL} &\geq 300 \text{ ns} \times f_{\text{PPP}} - \left(3 \times \frac{f_{\text{PPP}}}{f_{\text{PERIPH}}} \right) + 1 && \text{with digital filter and HDELmin} = 2 \\ \text{HDEL} &\geq 300 \text{ ns} \times f_{\text{PPP}} - \left(3 \times \frac{f_{\text{PPP}}}{f_{\text{PERIPH}}} \right) + 2 && \text{without digital filter and HDELmin} = 1 \end{aligned}$$

If the digital input filter is used, HDEL compensates the filter delay of 2 filter periods (f_{PPP} should be used) in case of a spike on the input signal. This ensures that a data bit on the SDA line changing just before the rising edge or behind the falling edge of SCL will not be treated as a start or stop condition.

18.5.3.1 Start Symbol

Figure 18-52 shows the general start symbol timing.

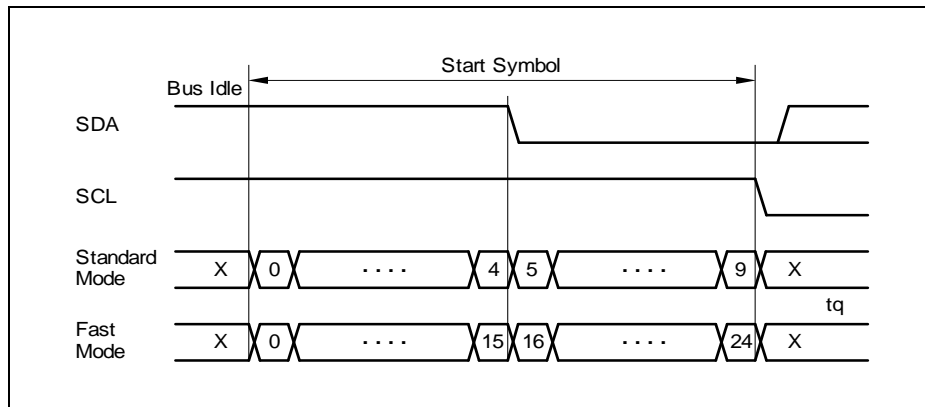

Figure 18-52 Start Symbol Timing

18.5.3.2 Repeated Start Symbol

During the first part of a repeated start symbol, an SCL low value is driven for the specified number of time quanta. Then a high value is output. After the detection of a rising edge at the SCL input, a normal start symbol is generated, as shown in **Figure 18-53**.

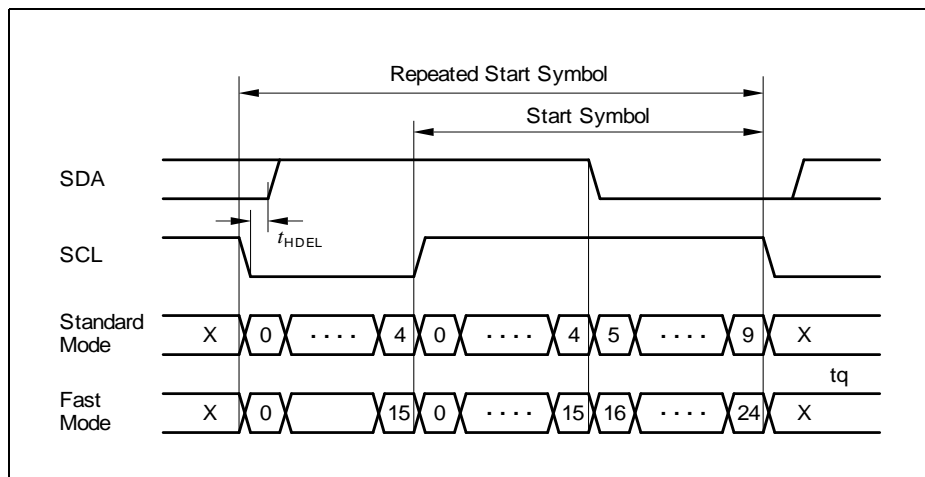

Figure 18-53 Repeated Start Symbol Timing

18.5.3.3 Stop Symbol

Figure 18-54 shows the stop symbol timing.

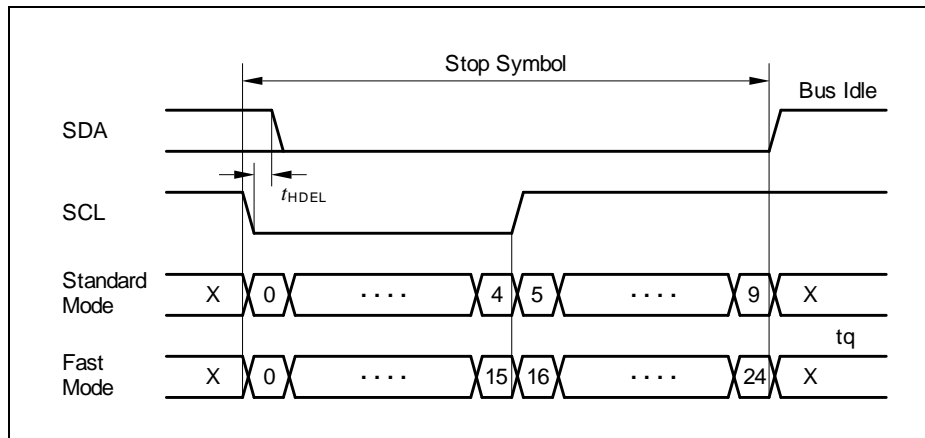

Figure 18-54 Stop Symbol Timing

18.5.3.4 Data Bit Symbol

Figure 18-55 shows the general data bit symbol timing.

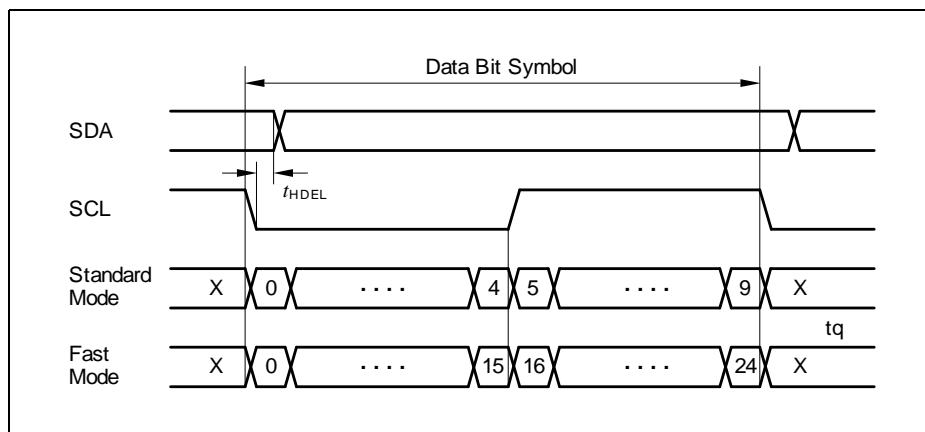

Figure 18-55 Data Bit Symbol

Output SDA changes after the time t_{HDEL} defined by PCR.HDEL has elapsed if a falling edge is detected at the SCL input to respect the SDA hold time. The value of PCR.HDEL allows compensation of the delay of the SCL input path (sampling, filtering).

Universal Serial Interface Channel (USIC)

In the case of an acknowledge transmission, the USIC IIC waits for the receiver indicating that a complete byte has been received. This adds an additional delay of 3 periods of f_{PERIPH} to the path. The minimum module input frequency has to be selected properly to ensure the SDA setup time to SCL rising edge.

18.5.4 Data Flow Handling

The handling of the data flow and the sequence of the symbols in an IIC frame is controlled by the IIC transmitter part of the USIC communication channel. The IIC bus protocol is byte-oriented, whereas a USIC data buffer word can contain up to 16 data bits. In addition to the data byte to be transmitted (located at TBUF[7:0]), bit field TDF (transmit data format) to control the IIC sequence is located at the bit positions TBUF[10:8]. The TDF code defines for each data byte how it should be transmitted (IIC master or IIC slave), and controls the transmission of (repeated) start and stop symbols. This structure allows the definition of a complete IIC frame for an IIC master device only by writing to TBUFx or by using a FIFO data buffer mechanism, because no other control registers have to be accessed. Alternatively, polling of the ACK and NACK bits in PSR register can be performed, and the next data byte is transmitted only after an ACK is received.

If a wrong or unexpected TDF code is encountered (e.g. due to a software error during setup of the transmit buffer), a stop condition will be sent out by the master. This leads to an abort of the currently running frame. A slave module waits for a valid TDF code and sets SCL = 0. The software then has to invalidate the unexpected TDF code and write a valid one.

Please note that during an arbitration phase in multi-master bus systems an unpredictable bus behavior may occur due to an unexpected stop condition.

18.5.4.1 Transmit Data Formats

The following transmit data formats are available in master mode:

Table 18-13 Master Transmit Data Formats

| TDF Code | Description |
|------------------|---|
| 000 _B | Send data byte as master This format is used to transmit a data byte from the master to a slave. The transmitter sends its data byte (TBUF[7:0]), receives and checks the acknowledge bit sent by the slave. |
| 010 _B | Receive data byte and send acknowledge This format is used by the master to read a data byte from a slave. The master acknowledges the transfer with a 0-level to continue the transfer. The content of TBUF[7:0] is ignored. |

Universal Serial Interface Channel (USIC)

Table 18-13 Master Transmit Data Formats (cont'd)

| TDF Code | Description |
|------------------|--|
| 011 _B | Receive data byte and send not-acknowledge This format is used by the master to read a data byte from a slave. The master does not acknowledge the transfer with a 1-level to finish the transfer. The content of TBUF[7:0] is ignored. |
| 100 _B | Send start condition If TBUF contains this entry while the bus is idle, a start condition will be generated. The content of TBUF[7:0] is taken as first address byte for the transmission (bits TBUF[7:1] are the address, the LSB is the read/write control). |
| 101 _B | Send repeated start condition If TBUF contains this entry and SCL = 0 and a byte transfer is not in progress, a repeated start condition will be sent out if the device is the current master. The current master is defined as the device that has set the start condition (and also won the master arbitration) for the current message. The content of TBUF[7:0] is taken as first address byte for the transmission (bits TBUF[7:1] are the address, the LSB is the read/write control). |
| 110 _B | Send stop condition If the current master has finished its last byte transfer (including acknowledge), it sends a stop condition if this format is in TBUF. The content of TBUF[7:0] is ignored. |
| 111 _B | Reserved This code must not be programmed. No additional action except releasing the TBUF entry and setting the error bit in PSR (that can lead to a protocol interrupt). |

The following transmit data format is available in slave mode (the symbols in a frame are controlled by the master and the slave only has to send data if it has been “asked” by the master):

Table 18-14 Slave Transmit Data Format

| TDF Code | Description |
|------------------|--|
| 001 _B | Send data byte as slave This format is used to transmit a data byte from a slave to the master. The transmitter sends its data byte (TBUF[7:0]) plus the acknowledge bit as a 1. |

18.5.4.2 Valid Master Transmit Data Formats

Due to the IIC frame format definitions, only some specific sequences of TDF codes are possible and valid. If the USIC IIC module detects a wrong TDF code in a running frame, the transfer is aborted and flag PCR.WTDF is set. Additionally, an interrupt can be generated if enabled by the user. In case of a wrong TDF code, the frame will be aborted immediately with a STOP condition if the USIC IIC master still owns the SDA line. But if the accessed slave owns the SDA line (read transfer), the master must perform a dummy read with a non-acknowledge so that the slave releases the SDA line before a STOP condition can be sent. The received data byte of the dummy read will be stored in RBUF0/1, but RDV0/1 will not be set. Therefore the dummy read will not generate a receive interrupt and the data byte will not be stored into the receive FIFO.

If the transfer direction has changed in the current frame (master read access), the transmit data request (TDF = 000_B) is not possible and won't be accepted (leading to a wrong TDF Code indication).

Table 18-15 Valid TDF Codes Overview

| Frame Position | Valid TDF Codes |
|--|--|
| First TDF code (master idle) | Start (100 _B) |
| Read transfer: second TDF code (after start or repeated start) | Receive with acknowledge (010 _B) or receive with not-acknowledge (011 _B) |
| Write transfer: second TDF code (after start or repeated start) | Transmit (000 _B), repeated start (101 _B), or stop (110 _B) |
| Read transfer: third and subsequent TDF code after acknowledge | Receive with acknowledge (010 _B) or receive with not-acknowledge (011 _B) |
| Read transfer: third and subsequent TDF code after not-acknowledge | Repeated start (101 _B) or stop (110 _B) |
| Write transfer: third and subsequent TDF code | Transmit (000 _B), repeated start (101 _B), or stop (110 _B) |

- First TDF code:
A master transfer starts with the TDF start code (100_B). All other codes are ignored, but no WTDF error will be indicated.
- TDF code after a start (100_B) or repeated start code (101_B) in case of a read access:
If a master-read transfer is started (determined by the LSB of the address byte = 1), the transfer direction of SDA changes and the slave will actively drive the data line. In this case, only the codes 010_B and 011_B are valid. To abort the transfer in case of a wrong code, a dummy read must be performed by the master before the STOP condition can be generated.

Universal Serial Interface Channel (USIC)

- TDF code after a start (100_B) or repeated start code (101_B) in case of a write access:
If a master-write transfer is started (determined by the LSB of the address byte = 0), the master still owns the SDA line. In this case, the transmit (000_B), repeated start (101_B) and stop (110_B) codes are valid. The other codes are considered as wrong. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- TDF code of the third and subsequent command in case of a read access with acknowledged previous data byte:
If a master-read transfer is started (determined by the LSB of the address byte), the transfer direction of SDA changes and the slave will actively drive the data line. To force the slave to release the SDA line, the master has to not-acknowledge a byte transfer. In this case, only the receive codes 010_B and 011_B are valid. To abort the transfer in case of a wrong code, a dummy read must be performed by the master before the STOP condition can be generated.
- TDF code of the third and subsequent command in case of a read access with a not-acknowledged previous data byte:
If a master-read transfer is started (determined by the LSB of the address byte), the transfer direction of SDA changes and the slave will actively drive the data line. To force the slave to release the SDA line, the master has to not-acknowledge a byte transfer. In this case, only the restart (101_B) and stop code (110_B) are valid. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- TDF code of the third and subsequent command in case of a write access:
If a master-write transfer is started (determined by the LSB of the address byte), the master still owns the SDA line. In this case, the transmit (000_B), repeated start (101_B) and stop (110_B) codes are valid. The other codes are considered as wrong. To abort the transfer in case of a wrong code, the STOP condition is generated immediately.
- After a master device has received a non-acknowledge from a slave device, a stop condition will be sent out automatically, except if the following TDF code requests a repeated start condition. In this case, the TDF code is taken into account, whereas all other TDF codes are ignored.

Universal Serial Interface Channel (USIC)

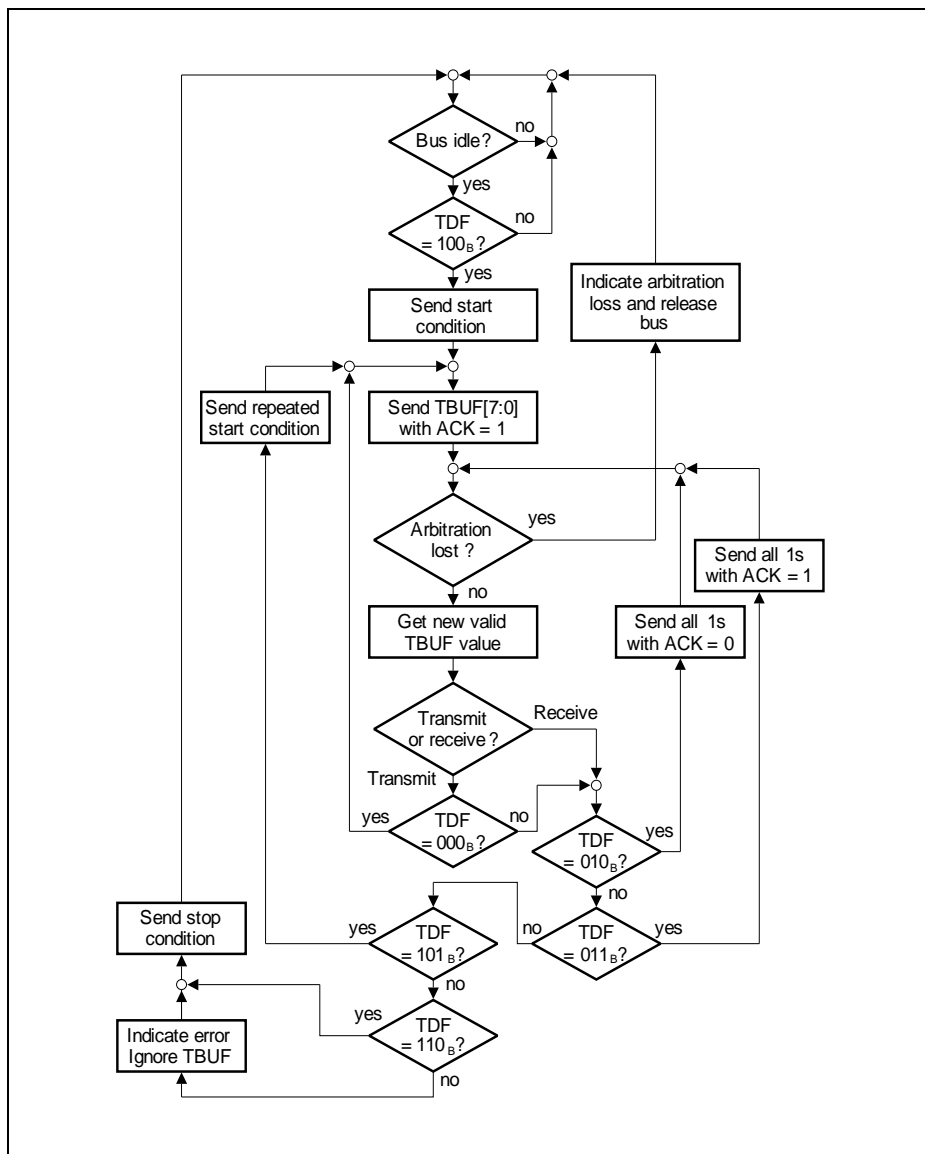

Figure 18-56 IIC Master Transmission

18.5.4.3 Master Transmit/Receive Modes

In master transmit mode, the IIC sends a number of data bytes to a slave receiver. The TDF code sequence for the master transmit mode is shown in [Table 18-16](#).

Table 18-16 TDF Code Sequence for Master Transmit

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|------------------------------------|------------------------------|--------------------------------|---|--|
| 1st code | 100 _B | Slave address + write bit | Send START condition, slave address and write bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 000 _B | Data or 2nd slave address byte | Send data or 2nd slave address byte | TBIF: Next word can be written to TBUF |
| Subsequent codes for data transmit | 000 _B | Data | Send data | TBIF: Next word can be written to TBUF |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

In master receive mode, the IIC receives a number of data bytes from a slave transmitter. The TDF code sequence for the master receive 7-bit and 10-bit addressing modes are shown in [Table 18-17](#) and [Table 18-18](#).

Universal Serial Interface Channel (USIC)
Table 18-17 TDF Code Sequence for Master Receive (7-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|-----------------------------------|------------------------------|--------------------------|--|--|
| 1st code | 100 _B | Slave address + read bit | Send START condition, slave address and read bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF AIF: First data received can be read |
| Subsequent codes for data receive | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF RIF: Subsequent data received can be read |
| Code for last data to be received | 011 _B | Don't care | Receive data and send NACK bit | TBIF: Next word can be written to TBUF RIF: Last data received can be read |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

Table 18-18 TDF Code Sequence for Master Receive (10-bit Addressing Mode)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|--------------------------|------------------------------|--------------------------------------|--|--|
| 1st code | 100 _B | Slave address (1st byte) + write bit | Send START condition, slave address (1st byte) and write bit | SCR: Indicates a START condition is detected TBIF: Next word can be written to TBUF |
| 2nd code | 000 _B | Slave address (2nd byte) | Send address (2nd byte) | TBIF: Next word can be written to TBUF |

Universal Serial Interface Channel (USIC)
Table 18-18 TDF Code Sequence for Master Receive (10-bit Addressing Mode)
 (cont'd)

| TDF Code Sequence | TBUF[10:8] (TDF Code) | TBUF[7:0] | IIC Response | Interrupt Events |
|-----------------------------------|------------------------------|------------------------------|--|--|
| 3rd code | 101 _B | 1st slave address + read bit | Send repeated START condition, slave address (1st byte) and read bit | RSCR: Indicates a repeated START condition is detected TBIF: Next word can be written to TBUF |
| 4th code | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF AIF: First data received can be read |
| Subsequent codes for data receive | 010 _B | Don't care | Receive data and send ACK bit | TBIF: Next word can be written to TBUF RIF: Subsequent data received can be read |
| Code for last data to be received | 011 _B | Don't care | Receive data and send NACK bit | TBIF: Next word can be written to TBUF RIF: Last data received from slave can be read |
| Last code | 110 _B | Don't care | Send STOP condition | PCR: Indicates a STOP condition is detected |

Figure 18-57 shows the interrupt events during the master transmit-slave receive and master receive/slave transmit sequences.

Universal Serial Interface Channel (USIC)

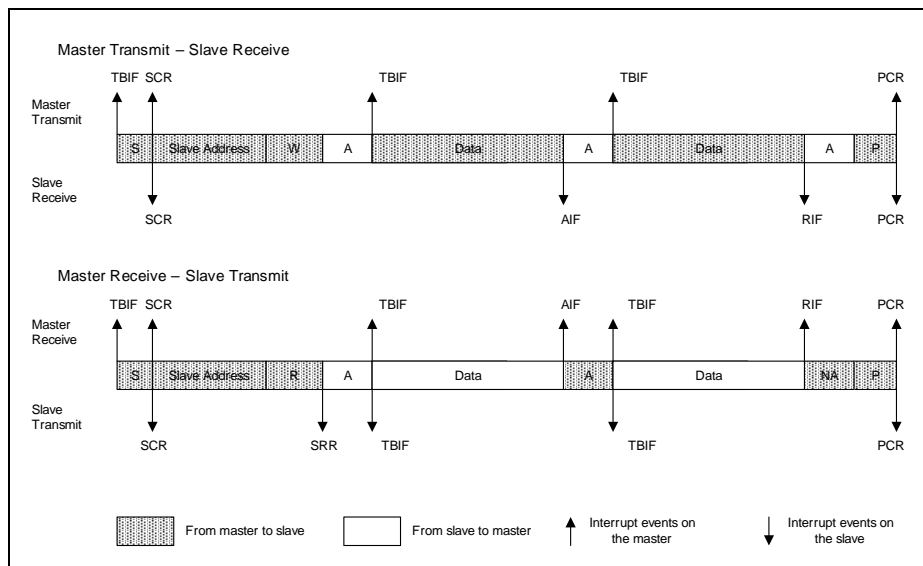

Figure 18-57 Interrupt Events on Data Transfers

18.5.4.4 Slave Transmit/Receive Modes

In slave receive mode, no TDF code needs to be written and data reception is indicated by the alternate receive (AIF) or receive (RIF) events.

In slave transmit mode, upon receiving its own slave address or general call address if this option is enabled, a slave read request event (SRR) will be triggered. The slave IIC then writes the TDF code 001_B and the requested data to TBUF to transmit the data to the master. The slave does not check if the master reply with an ACK or NACK to the transmitted data.

In both cases, the data transfer is terminated by the master sending a STOP condition, which is indicated by a PCR event. See also [Figure 18-57](#).

18.5.5 IIC Protocol Registers

In IIC mode, the registers PCR and PSR handle IIC related information.

18.5.5.1 IIC Protocol Control Registers

In IIC mode, the PCR register bits or bit fields are defined as described in this section.

Universal Serial Interface Channel (USIC)

| SLAD | | | | | | | | | | | | | | | |
| rw | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| SLAD | [15:0] | rw | Slave Address This bit field contains the programmed slave address. The corresponding bits in the first received address byte are compared to the bits SLAD[15:9] to check for address match. If SLAD[15:11] = 11110 _B , then the second address byte is also compared to SLAD[7:0]. |
| ACK00 | 16 | rw | Acknowledge 00_H This bit defines if a slave device should be sensitive to the slave address 00 _H . 0 _B The slave device is not sensitive to this address. 1 _B The slave device is sensitive to this address. |
| STIM | 17 | rw | Symbol Timing This bit defines how many time quanta are used in a symbol. 0 _B A symbol contains 10 time quanta. The timing is adapted for standard mode (100 kBaud). 1 _B A symbol contains 25 time quanta. The timing is adapted for fast mode (400 kBaud). |
| SCRIEN | 18 | rw | Start Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a start condition is detected. 0 _B The start condition interrupt is disabled. 1 _B The start condition interrupt is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|------|------|--|
| RSCRIEN | 19 | rw | Repeated Start Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a repeated start condition is detected. 0 _B The repeated start condition interrupt is disabled. 1 _B The repeated start condition interrupt is enabled. |
| PCRIEN | 20 | rw | Stop Condition Received Interrupt Enable This bit enables the generation of a protocol interrupt if a stop condition is detected. 0 _B The stop condition interrupt is disabled. 1 _B The stop condition interrupt is enabled. |
| NACKIEN | 21 | rw | Non-Acknowledge Interrupt Enable This bit enables the generation of a protocol interrupt if a non-acknowledge is detected by a master. 0 _B The non-acknowledge interrupt is disabled. 1 _B The non-acknowledge interrupt is enabled. |
| ARLIEN | 22 | rw | Arbitration Lost Interrupt Enable This bit enables the generation of a protocol interrupt if an arbitration lost event is detected. 0 _B The arbitration lost interrupt is disabled. 1 _B The arbitration lost interrupt is enabled. |
| SRRIEN | 23 | rw | Slave Read Request Interrupt Enable This bit enables the generation of a protocol interrupt if a slave read request is detected. 0 _B The slave read request interrupt is disabled. 1 _B The slave read request interrupt is enabled. |
| ERRIEN | 24 | rw | Error Interrupt Enable This bit enables the generation of a protocol interrupt if an IIC error condition is detected (indicated by PSR.ERR or PSR.WTDF). 0 _B The error interrupt is disabled. 1 _B The error interrupt is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| SACKDIS | 25 | rw | Slave Acknowledge Disable This bit disables the generation of an active acknowledge signal for a slave device (active acknowledge = 0 level). Once set by software, it is automatically cleared with each (repeated) start condition. If this bit is set after a byte has been received (indicated by an interrupt) but before the next acknowledge bit has started, the next acknowledge bit will be sent with passive level. This would indicate that the receiver does not accept more bytes. As a result, a minimum of 2 bytes will be received if the first receive interrupt is used to set this bit. 0 _B The generation of an active slave acknowledge is enabled (slave acknowledge with 0 level = more bytes can be received). 1 _B The generation of an active slave acknowledge is disabled (slave acknowledge with 1 level = reception stopped). |
| HDEL | [29:26] | rw | Hardware Delay This bit field defines the delay used to compensate the internal treatment of the SCL signal (see Page 18-118) in order to respect the SDA hold time specified for the IIC protocol. |
| ACKIEN | 30 | rw | Acknowledge Interrupt Enable This bit enables the generation of a protocol interrupt if an acknowledge is detected by a master. 0 _B The acknowledge interrupt is disabled. 1 _B The acknowledge interrupt is enabled. |
| MCLK | 31 | rw | Master Clock Enable This bit enables generation of the master clock MCLK (not directly used for IIC protocol, can be used as general frequency output). 0 _B The MCLK generation is disabled and MCLK is 0. 1 _B The MCLK generation is enabled. |

18.5.5.2 IIC Protocol Status Register

The following PSR status bits or bit fields are available in IIC mode. Please note that the bits in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag,

Universal Serial Interface Channel (USIC)

but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol.

PSR

| Field | Bits | Type | Description |
|--------------|------|------|--|
| SLSEL | 0 | rwh | Slave Select This bit indicates that this device has been selected as slave. 0 _B The device is not selected as slave. 1 _B The device is selected as slave. |
| WTDF | 1 | rwh | Wrong TDF Code Found¹⁾ This bit indicates that an unexpected/wrong TDF code has been found. A protocol interrupt can be generated if PCR.ERRIEN = 1. 0 _B A wrong TDF code has not been found. 1 _B A wrong TDF code has been found. |
| SCR | 2 | rwh | Start Condition Received¹⁾ This bit indicates that a start condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.SCRIEN = 1. 0 _B A start condition has not yet been detected. 1 _B A start condition has been detected. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|------|------|--|
| RSCR | 3 | rwh | Repeated Start Condition Received¹⁾ This bit indicates that a repeated start condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.RSCRIEN = 1. 0 _B A repeated start condition has not yet been detected. 1 _B A repeated start condition has been detected. |
| PCR | 4 | rwh | Stop Condition Received¹⁾ This bit indicates that a stop condition has been detected on the IIC bus lines. A protocol interrupt can be generated if PCR.PCRIEN = 1. 0 _B A stop condition has not yet been detected. 1 _B A stop condition has been detected. |
| NACK | 5 | rwh | Non-Acknowledge Received¹⁾ This bit indicates that a non-acknowledge has been received in master mode. This bit is not set in slave mode. A protocol interrupt can be generated if PCR.NACKIEN = 1. 0 _B A non-acknowledge has not been received. 1 _B A non-acknowledge has been received. |
| ARL | 6 | rwh | Arbitration Lost¹⁾ This bit indicates that an arbitration has been lost. A protocol interrupt can be generated if PCR.ARLIEN = 1. 0 _B An arbitration has not been lost. 1 _B An arbitration has been lost. |
| SRR | 7 | rwh | Slave Read Request¹⁾ This bit indicates that a slave read request has been detected. It becomes active to request the first data byte to be made available in the transmit buffer. For further consecutive data bytes, the transmit buffer issues more interrupts. For the end of the transfer, the master transmitter sends a stop condition. A protocol interrupt can be generated if PCR.SRRIEN = 1. 0 _B A slave read request has not been detected. 1 _B A slave read request has been detected. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| ERR | 8 | rwh | Error¹⁾ This bit indicates that an IIC error (frame format or TDF code) has been detected. A protocol interrupt can be generated if PCR.ERRIEN = 1. 0 _B An IIC error has not been detected. 1 _B An IIC error has been detected. |
| ACK | 9 | rwh | Acknowledge Received¹⁾ This bit indicates that an acknowledge has been received in master mode. This bit is not set in slave mode. A protocol interrupt can be generated if PCR.ACKIEN = 1. 0 _B An acknowledge has not been received. 1 _B An acknowledge has been received. |
| RSIF | 10 | rwh | Receiver Start Indication Flag 0 _B A receiver start event has not occurred. 1 _B A receiver start event has occurred. |
| DLIF | 11 | rwh | Data Lost Indication Flag 0 _B A data lost event has not occurred. 1 _B A data lost event has occurred. |
| TSIF | 12 | rwh | Transmit Shift Indication Flag 0 _B A transmit shift event has not occurred. 1 _B A transmit shift event has occurred. |
| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0 _B A transmit buffer event has not occurred. 1 _B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0 _B A receive event has not occurred. 1 _B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | [31:17] | r | Reserved Returns 0 if read; not modified in IIC mode. |

1) This status bit can generate a protocol interrupt (see [Page 18-22](#)). The general interrupt status flags are described in the general interrupt chapter.

18.6 Inter-IC Sound Bus Protocol (IIS)

This chapter describes how the USIC module handles the IIS protocol. This serial protocol can handle reception and transmission of synchronous data frames between a device operating in master mode and a device in slave mode. An IIS connection based on a USIC communication channel supports half-duplex and full-duplex data transfers. The IIS mode is selected by $CCR.MODE = 0011_B$ with $CCFG.IIS = 1$ (IIS mode is available).

18.6.1 Introduction

The IIS protocol is a synchronous serial communication protocol mainly for audio and infotainment applications [21].

18.6.1.1 Signal Description

A connection between an IIS master and an IIS slave is based on the following signals:

- A shift clock signal SCK, generated by the transfer master. It is permanently generated while an IIS connection is established, also while no valid data bits are transferred.
- A word address signal WA (also named WS), generated by the transfer master. It indicates the beginning of a new data word and the targeted audio channel (e.g. left/right). The word address output signal WA is available on all SELOx outputs if the WA generation is enabled (by $PCR.WAGEN = 1$ for the transfer master). The WA signal changes synchronously to the falling edges of the shift clock.
- If the transmitter is the IIS master device, it generates a master transmit slave receive data signal. The data changes synchronously to the falling edges of the shift clock.
- If the transmitter is the IIS slave device, it generates a master receive slave transmit data signal. The data changes synchronously to the falling edges of the shift clock.

The transmitter part and the receiver part of the USIC communication channel can be used together to establish a full-duplex data connection between an IIS master and a slave device.

Table 18-19 IIS IO Signals

| IIS Mode | Receive Data | Transmit Data | Shift Clock | Word Address |
|-----------------|-------------------------------|----------------------|---------------------------------|--------------------------------|
| Master | Input DIN0, handled by DX0 | Output DOUT0 | Output SCLKOUT | Output(s) SELOx |
| Slave | Input DIN0, handled by DX0 | Output DOUT0 | Input SCLKIN, handled by DX1 | Input SELIN, handled by DX2 |

Universal Serial Interface Channel (USIC)

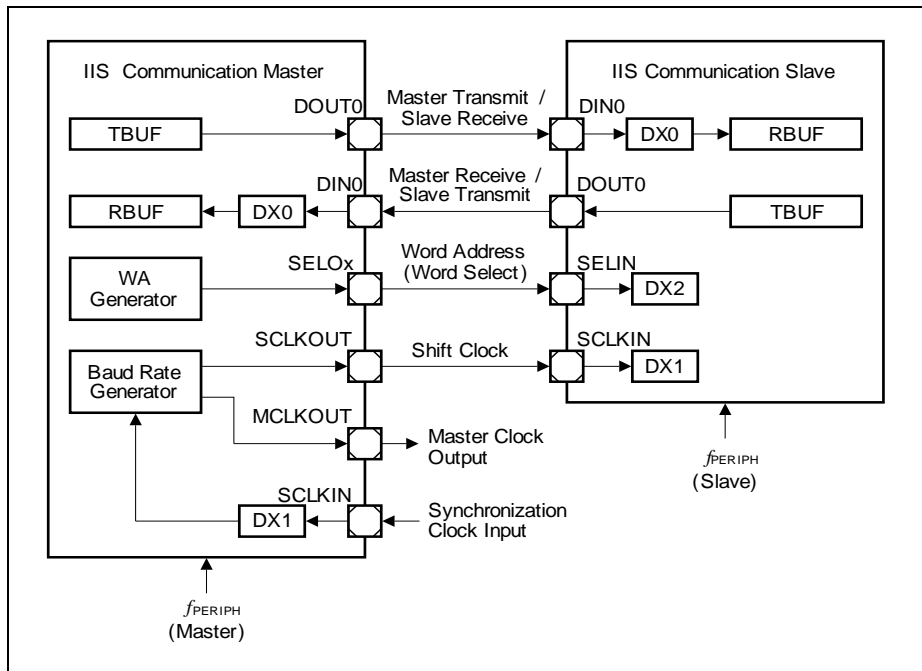

Figure 18-58 IIS Signals

Two additional signals are available for the USIC IIS communication master:

- A master clock output signal **MCLKOUT** with a fixed phase relation to the shift clock to support oversampling for audio components. It can also be used as master clock output of a communication network with synchronized IIS connections.
- A synchronization clock input **SCLKIN** for synchronization of the shift clock generation to an external frequency to support audio frequencies that can not be directly derived from the system clock f_{PERIPH} of the communication master. It can be used as master clock input of a communication network with synchronized IIS connections.

18.6.1.2 Protocol Overview

An IIS connection supports transfers for two different data frames via the same data line, e.g. a data frames for the left audio channel and a data frame for the right audio channel. The word address signal **WA** is used to distinguish between the different data frames. Each data frame can consist of several data words.

Universal Serial Interface Channel (USIC)

In a USIC communication channel, data words are tagged for being transmitted for the left or for the right channel. Also the received data words contain a tag identifying the WA state when the data has been received.

Figure 18-59 Protocol Overview

18.6.1.3 Transfer Delay

The transfer delay feature allows the transfer of data (transmission and reception) with a programmable delay (counted in shift clock periods).

Figure 18-60 Transfer Delay for IIS

18.6.1.4 Connection of External Audio Components

The IIS signals can be used to communicate with external audio devices (such as Codecs) or other audio data sources/destinations.

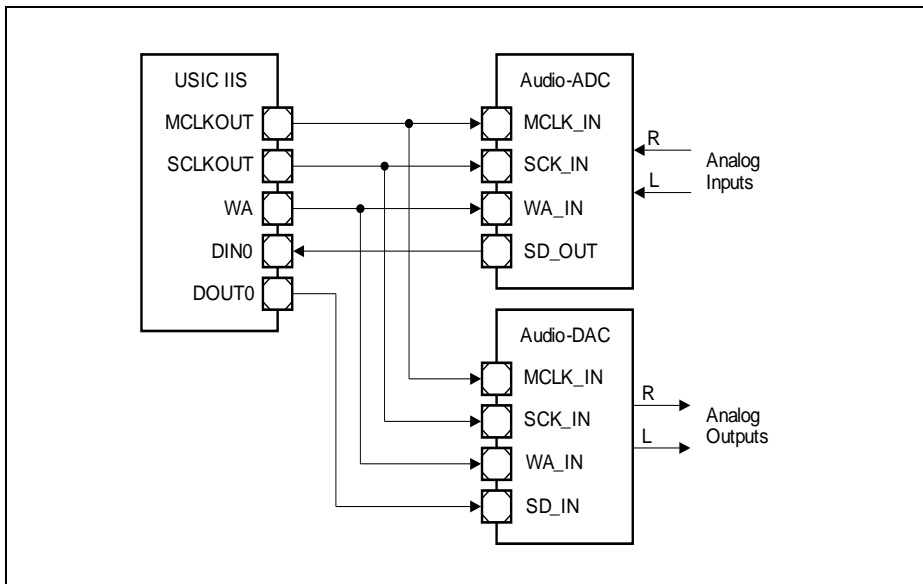

Figure 18-61 Connection of External Audio Devices

In some applications, especially for Audio-ADCs or Audio-DACs, a master clock signal is required with a fixed phase relation to the shift clock signal. The frequency of MCLKOUT is a multiple of the shift frequency SCLKOUT. This factor defines the oversampling factor of the external device (commonly used values: 256 or 384).

18.6.2 Operating the IIS

This chapter contains IIS issues, that are of general interest and not directly linked to master mode or slave mode.

18.6.2.1 Frame Length and Word Length Configuration

After each change of the WA signal, a complete data frame is intended to be transferred (frame length \leq system word length). The number of data bits transferred after a change of signal WA is defined by SCTR.FLE. A data frame can consist of several data words with a data word length defined by SCTR.WLE. The changes of signal WA define the system word length as the number of SCLK cycles between two changes of WA (number of bits available for the right channel and same number available for the left channel).

If the system word length is longer than the frame length defined by SCTR.FLE, the additional bits are transmitted with passive data level (SCTR.PDL). If the system word

Universal Serial Interface Channel (USIC)

length is smaller than the device frame length, not all LSBs of the transmit data can be transferred.

It is recommended to program bits WLEMD, FLEMD and SELMD in register TCSR to 0.

18.6.2.2 Automatic Shadow Mechanism

The baud rate and shift control setting are internally kept constant while a data frame is transferred by an automatic shadow mechanism. The registers can be programmed all the time with new settings that are taken into account for the next data frame. During a data frame, the applied (shadowed) setting is not changed, although new values have been written after the start of the data frame. The setting is internally “frozen” with the start of each data frame.

Although this shadow mechanism being implemented, it is recommended to change the baud rate and shift control setting only while the IIS protocol is switched off.

18.6.2.3 Mode Control Behavior

In IIS mode, the following kernel modes are supported:

- Run Mode 0/1:
Behavior as programmed, no impact on data transfers.
- Stop Mode 0/1:
Bit PCR.WAGEN is internally considered as 0 (the bit itself is not changed). If WAGEN = 1, the WA generation is stopped, but PSR.END is not set. The complete data frame is finished before entering stop mode, including a possible delay due to PCR.TDEL.
When leaving a stop mode with WAGEN = 1, the WA generation starts from the beginning.

18.6.2.4 Transfer Delay

The transfer delay can be used to synchronize a data transfer to an event (e.g. a change of the WA signal). This event has to be synchronously generated to the falling edge of the shift clock SCK (like the change of the transmit data), because the input signal for the event is directly sampled in the receiver (as a result, the transmitter can use the detection information with its next edge).

Event signals that are asynchronous to the shift clock while the shift clock is running must not be used. In the example in [Figure 18-60](#), the event (change of signal WA) is generated by the transfer master and as a result, is synchronous to the shift clock SCK. With the rising edge of SCK, signal WA is sampled and checked for a change. If a change is detected, a transfer delay counter TDC is automatically loaded with its programmable reload value (PCR.TDEL), otherwise it is decremented with each rising edge of SCK until it reaches 0, where it stops. The transfer itself is started if the value of TDC has become 0. This can happen under two conditions:

Universal Serial Interface Channel (USIC)

- TDC is reloaded with a PCR.TDEL = 0 when the event is detected
- TDC has reached 0 while counting down

The transfer delay counter is internal to the IIS protocol pre-processor and can not be observed by software. The transfer delay in SCK cycles is given by PCR.TDEL+1.

In the example in [Figure 18-62](#), the reload value PCR.TDEL for TDC is 0. When the samples taken on receiver side show the change of the WA signal, the counter TDC is reloaded. If the reload value is 0, the data transfer starts with 1 shift clock cycle delay compared to the change of WA.

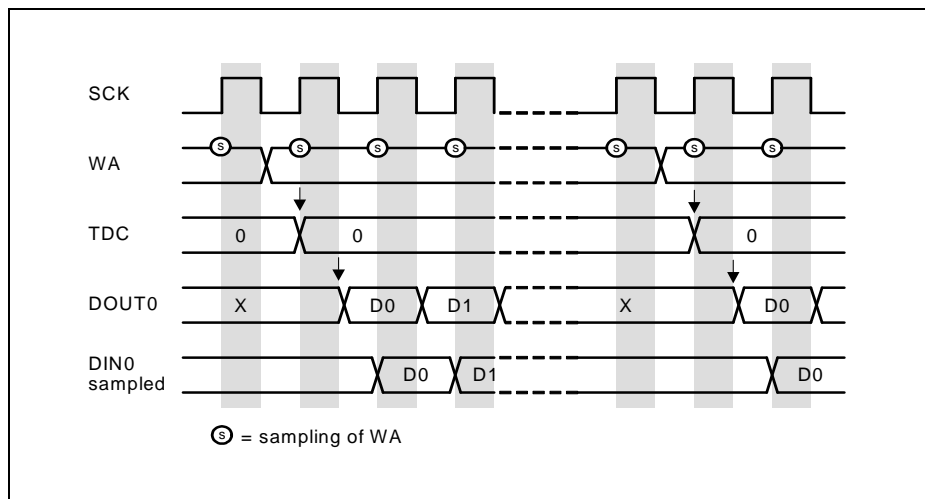

Figure 18-62 Transfer Delay with Delay 1

The ideal case without any transfer delay is shown in [Figure 18-63](#). The WA signal changes and the data output value become valid at the same time. This implies that the transmitter “knows” in advance that the event signal will change with the next rising edge of TCLK. This is achieved by delaying the data transmission after the previously detected WA change the system word length minus 1.

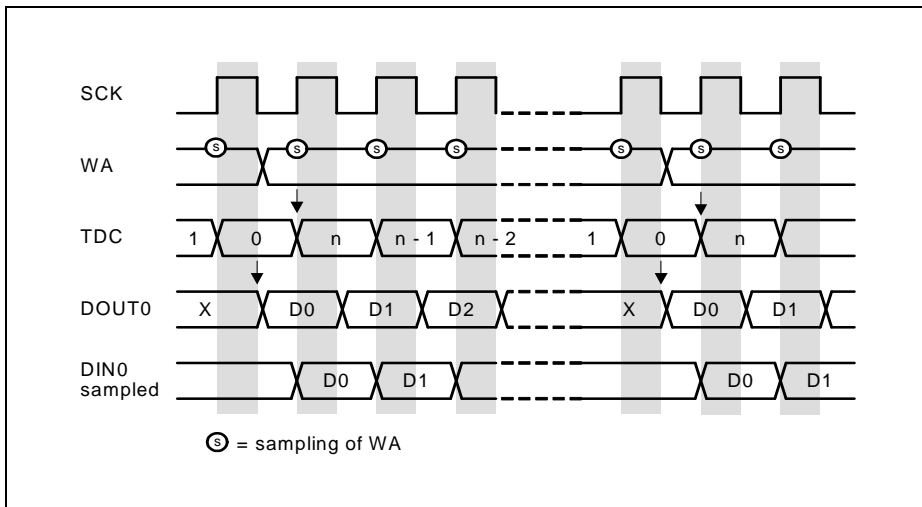

Figure 18-63 No Transfer Delay

If the end of the transfer delay is detected simultaneously to change of WA, the transfer is started and the delay counter is reloaded with PCR.TDEL. This allows to run the USIC as IIS device without any delay. In this case, internally the delay from the previous event elapses just at the moment when a new event occurs. If PCR.TDEL is set to a value bigger than the system word length, no transfer takes place.

18.6.2.5 Parity Mode

Parity generation is not supported in IIS mode and bit field CCR.PM = 00_B has to be programmed.

18.6.2.6 Transfer Mode

In IIS mode, bit field SCTR.TRM = 11_B has to be programmed to allow data transfers. Setting SCTR.TRM = 00_B disables and stops the data transfer immediately.

18.6.2.7 Data Transfer Interrupt Handling

The data transfer interrupts indicate events related to IIS frame handling.

- Transmit buffer interrupt TBI:
Bit PSR.TBIF is set after the start of first data bit of a data word.
- Transmit shift interrupt TSI:
Bit PSR.TSIF is set after the start of the last data bit of a data word.

Universal Serial Interface Channel (USIC)

- Receiver start interrupt RSI:
Bit PSR.RSIF is set after the reception of the first data bit of a data word.
With this event, bit TCSR.TDV is cleared and new data can be loaded to the transmit buffer.
- Receiver interrupt RI and alternative interrupt AI:
Bit PSR.RIF is set at after the reception of the last data bit of a data word with WA = 0.
Bit RBUF SR.SOF indicates whether the received data word has been the first data word of a new data frame.
Bit PSR.AIF is set at after the reception of the last data bit of a data word with WA = 1.
Bit RBUF SR.SOF indicates whether the received data word has been the first data word of a new data frame.

18.6.2.8 Baud Rate Generator Interrupt Handling

The baud rate generator interrupt indicate that the capture mode timer has reached its maximum value. With this event, the bit PSR.BRGIF is set.

18.6.2.9 Protocol-Related Argument and Error

In order to distinguish between data words received for the left or the right channel, the IIS protocol pre-processor samples the level of the WA input (just after the WA transition) and propagates it as protocol-related error (although it is not an error, but an indication) to the receive buffer status register at the bit position RBUF SR[9]. This bit position defines if either a standard receive interrupt (if RBUF SR[9] = 0) or an alternative receive interrupt (if RBUF SR[9] = 1) becomes activated when a new data word has been received. Incoming data can be handled by different interrupts or DMA mechanisms for the left and the right channel if the corresponding events are directed to different interrupt nodes. Flag PAR is always 0.

18.6.2.10 Transmit Data Handling

The IIS protocol pre-processor allows to distinguish between the left and the right channel for data transmission. Therefore, bit TCSR.WA indicates on which channel the data in the buffer will be transmitted. If TCSR.WA = 0, the data will be transmitted after a falling edge of WA. If TCSR.WA = 1, the data will be transmitted after a rising edge of WA. The WA value sampled after the WA transition is considered to distinguish between both channels (referring to PSR.WA).

Bit TCSR.WA can be automatically updated by the transmit control information TCI[4] for each data word if TCSR.WAMD = 1. In this case, data written to TBUF[15:0] (or IN[15:0] if a FIFO data buffer is used) is considered as left channel data, whereas data written to TBUF[31:16] (or IN[31:16] if a FIFO data buffer is used) is considered as right channel data.

18.6.2.11 Receive Buffer Handling

If a receive FIFO buffer is available (CCFG.RB = 1) and enabled for data handling (RBCTR.SIZE > 0), it is recommended to set RBCTR.RCIM = 11_B in IIS mode. This leads to an indication that the data word has been the first data word of a new data frame if bit OUTR.RCI[0] = 1, and the channel indication by the sampled WA value is given by OUTR.RCI[4].

The standard receive buffer event and the alternative receive buffer event can be used for the following operation in RCI mode (RBCTR.RNM = 1):

- A standard receive buffer event indicates that a data word can be read from OUTR that belongs to a data frame started when WA = 0.
- An alternative receive buffer event indicates that a data word can be read from OUTR that belongs to a data frame started when WA = 1.

18.6.2.12 Loop-Delay Compensation

The synchronous signaling mechanism of the IIS protocol being similar to the one of the SSC protocol, the closed-loop delay has to be taken into account for the application setup. In IIS mode, loop-delay compensation in master mode is also possible to achieve higher baud rates.

Please refer to the more detailed description in the SSC chapter.

18.6.3 Operating the IIS in Master Mode

In order to operate the IIS in master mode, the following issues have to be considered:

- Select IIS mode:
It is recommended to configure all parameters of the IIS that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 11_B has to be programmed. The configuration of the input stages has to be done while CCR.MODE = 0000_B to avoid unintended edges of the input signals and the IIS mode can be enabled by CCR.MODE = 0011_B afterwards.
- Pin connection for data transfer:
Establish a connection of input stage DX0 with the selected receive data input pin (DIN0) with DX0CR.INSW = 1. Configure a transmit data output pin (DOUT0) for a transmitter.
The data shift unit allowing full-duplex data transfers based on the same WA signal, the values delivered by the DX0 stage are considered as data bits (receive function can not be disabled independently from the transmitter). To receive IIS data, the transmitter does not necessarily need to be configured (no assignment of DOUT0 signal to a pin).
- Baud rate generation:
The desired baud rate setting has to be selected, comprising the fractional divider

Universal Serial Interface Channel (USIC)

and the baud rate generator. Bit DX1CR.INSW = 0 has to be programmed to use the baud rate generator output SCLK directly as input for the data shift unit.

- **Word address WA generation:**
 The WA generation has to be enabled by setting PCR.WAGEN = 1 and the programming of the number of shift clock cycles between the changes of WA. Bit DX2CR.INSW = 0 has to be programmed to use the WA generator as input for the data shift unit. Configure WA output pin for signal SELOx if needed.
- **Data format configuration:**
 The word length, the frame length, and the shift direction have to be set up according to the application requirements by programming the register SCTR. Generally, the MSB is shifted first (SCTR.SDIR = 1).
 Bit TCSR.WAMD can be set to use the transmit control information TCI[4] to distinguish the data words for transmission while WA = 0 or while WA = 1.

Note: The step to enable the alternate output port functions should only be done after the IIS mode is enabled, to avoid unintended spikes on the output.

18.6.3.1 Baud Rate Generation

The baud rate is defined by the frequency of the SCLK signal (one period of f_{SCLK} represents one data bit).

If the fractional divider mode is used to generate f_{PIN} , there can be an uncertainty of one period of f_{PERIPH} for f_{PIN} . This uncertainty does not accumulate over several SCLK cycles. As a consequence, the average frequency is reached, whereas the duty cycle of 50% of the SCLK and MCLK signals can vary by one period of f_{PERIPH} .

In IIS applications, where the phase relation between the optional MCLK output signal and SCLK is not relevant, SCLK can be based on the frequency f_{PIN} (BRG.PPPEN = 0). In the case that a fixed phase relation between the MCLK signal and SCLK is required (e.g. when using MCLK as clock reference for external devices), the additional divider by 2 stage has to be taken into account (BRG.PPPEN = 1). This division is due to the fact that signal MCLK toggles with each cycle of f_{PIN} . Signal SCLK is then based on signal MCLK, see [Figure 18-64](#).

The adjustable integer divider factor is defined by bit field BRG.PDIV.

$$\begin{aligned}
 f_{SCLK} &= \frac{f_{PIN}}{2} \times \frac{1}{PDIV + 1} & \text{if } PPPEN = 0 \\
 f_{SCLK} &= \frac{f_{PIN}}{2 \times 2} \times \frac{1}{PDIV + 1} & \text{if } PPPEN = 1
 \end{aligned}
 \tag{18.12}$$

Note: In the IIS protocol, the master (unit generating the shift clock and the WA signal) changes the status of its data and WA output line with the falling edge of SCK. The slave transmitter also has to transmit on falling edges. The sampling of the received data is done with the rising edges of SCLK. The input stage DX1 and the

Universal Serial Interface Channel (USIC)

SCLKOUT have to be programmed to invert the shift clock signal to fit to the internal signals.

18.6.3.2 WA Generation

The word address (or word select) line WA regularly toggles after N cycles of signal SCLK. The time between the changes of WA is called system word length and can be programmed by using the following bit fields.

In IIS master mode, the system word length is defined by:

- BRG.CTQSEL = 10_B
to base the WA toggling on SCLK
- BRG.PCTQ
to define the number N of SCLK cycles per system word length
- BRG.DCTQ
to define the number N of SCLK cycles per system word length

$$N = (PCTQ + 1) \times (DCTQ + 1) \quad (18.13)$$

18.6.3.3 Master Clock Output

The master clock signal MCLK can be generated by the master of the IIS transfer (BRG.PPPEN = 1). It is used especially to connect external Codec devices. It can be configured by bit BRG.MCLKCFG in its polarity to become the output signal MCLKOUT.

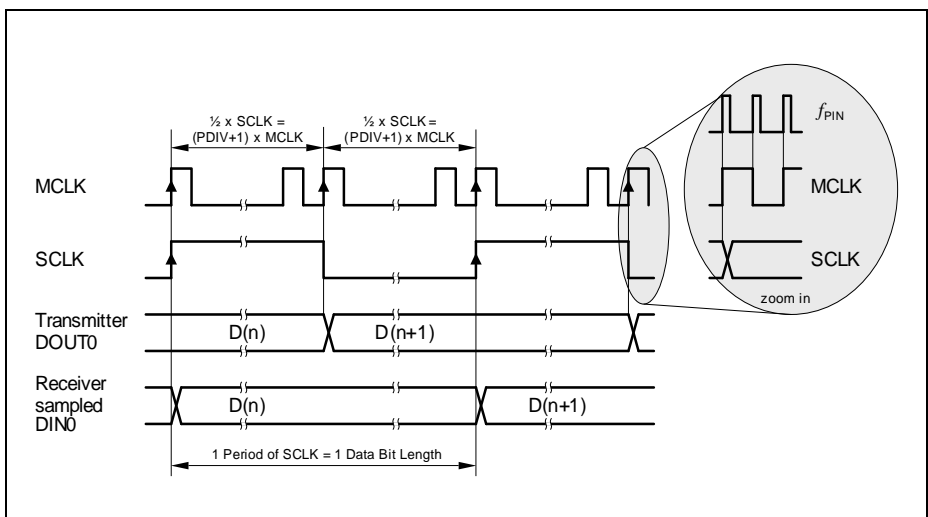

Figure 18-64 MCLK and SCLK for IIS

18.6.3.4 Protocol Interrupt Events

The following protocol-related events are generated in IIS mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- **WA rising/falling edge events:**
The WA generation block indicates two events that are monitored in register PSR. Flag PSR.WAFE is set with the falling edge, flag PSR.WARE with the rising edge of the WA signal. A protocol interrupt can be generated if PCR.WAFEIEN = 1 for the falling edge, similar for PCR.WAREIEN = 1 for a rising edge.
- **WA end event:**
The WA generation block also indicates when it has stopped the WA generation after it has been disabled by writing PCR.WAGEN = 0. A protocol interrupt can be generated if PCR.ENDIEN = 1.
- **DX2T event:**
An activation of the trigger signal DX2T is indicated by PSR.DX2TEV = 1 and can generate a protocol interrupt if PCR.DX2TIEN = 1. This event can be evaluated instead of the WA rising/falling events if a delay compensation like in SSC mode (for details, refer to corresponding SSC section) is used.

18.6.4 Operating the IIS in Slave Mode

In order to operate the IIS in slave mode, the following issues have to be considered:

- **Select IIS mode:**
It is recommended to configure all parameters of the IIS that do not change during run time while CCR.MODE = 0000_B. Bit field SCTR.TRM = 11_B has to be programmed. The configuration of the input stages has to be done while CCR.MODE = 0000_B to avoid unintended edges of the input signals and the IIS mode can be enabled by CCR.MODE = 0011_B afterwards.
- **Pin connection for data transfer:**
Establish a connection of input stage DX0 with the selected receive data input pin (DIN0) with DX0CR.INSW = 1. Configure a transmit data output pin (DOUT0) for a transmitter.
The data shift unit allowing full-duplex data transfers based on the same WA signal, the values delivered by the DX0 stage are considered as data bits (receive function can not be disabled independently from the transmitter). To receive IIS data, the transmitter does not necessarily need to be configured (no assignment of DOUT0 signal to a pin).
Note that the step to enable the alternate output port functions should only be done after the IIS mode is enabled, to avoid unintended spikes on the output.

Universal Serial Interface Channel (USIC)

- Pin connection for shift clock:
Establish a connection of input stage DX1 with the selected shift clock input pin (SCLKIN) with DX1CR.INSW = 1 and with inverted polarity (DX1CR.DPOL = 1).
- Pin connection for WA input:
Establish a connection of input stage DX2 with the WA input pin (SELIN) with DX2CR.INSW = 1.
- Baud rate generation:
The baud rate generator is not needed and can be switched off by the fractional divider.
- WA generation:
The WA generation is not needed and can be switched off (PCR.WAGEN = 0).

18.6.4.1 Protocol Events and Interrupts

The following protocol-related event is generated in IIS mode and can lead to a protocol interrupt.

Please note that the bits in register PSR are not all automatically cleared by hardware and have to be cleared by software in order to monitor new incoming events.

- WA rising/falling/end events:
The WA generation being switched off, these events are not available.
- DX2T event:
An activation of the trigger signal DX2T is indicated by PSR.DX2TEV = 1 and can generate a protocol interrupt if PCR.DX2TIEN = 1.

18.6.5 IIS Protocol Registers

In IIS mode, the registers PCR and PSR handle IIS related information.

18.6.5.1 IIS Protocol Control Registers

In IIS mode, the PCR register bits or bit fields are defined as described in this section.

Universal Serial Interface Channel (USIC)

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|------|------|---|
| SELINV | 2 | rw | Select Inversion This bit defines if the polarity of the SELOx outputs in relation to the internally generated word address signal WA. 0 _B The SELOx outputs have the same polarity as the WA signal. 1 _B The SELOx outputs have the inverted polarity to the WA signal. |
| WAFEIEN | 4 | rw | WA Falling Edge Interrupt Enable This bit enables/disables the activation of a protocol interrupt when a falling edge of WA has been generated. 0 _B A protocol interrupt is not activated if a falling edge of WA is generated. 1 _B A protocol interrupt is activated if a falling edge of WA is generated. |
| WAREIEN | 5 | rw | WA Rising Edge Interrupt Enable This bit enables/disables the activation of a protocol interrupt when a rising edge of WA has been generated. 0 _B A protocol interrupt is not activated if a rising edge of WA is generated. 1 _B A protocol interrupt is activated if a rising edge of WA is generated. |
| ENDIEN | 6 | rw | END Interrupt Enable This bit enables/disables the activation of a protocol interrupt when the WA generation stops after clearing PCR.WAGEN (complete system word length is processed before stopping). 0 _B A protocol interrupt is not activated. 1 _B A protocol interrupt is activated. |
| DX2TIEN | 15 | rw | DX2T Interrupt Enable This bit enables/disables the generation of a protocol interrupt if the DX2T signal becomes activated (indicated by PSR.DX2TEV = 1). 0 _B A protocol interrupt is not generated if DX2T is active. 1 _B A protocol interrupt is generated if DX2T is active. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|--------------------|------|--|
| TDEL | [21:16] | rw | Transfer Delay This bit field defines the transfer delay when an event is detected. If bit field TDEL = 0, the additional delay functionality is switched off and a delay of one shift clock cycle is introduced. |
| MCLK | 31 | rw | Master Clock Enable This bit enables generation of the master clock MCLK (not directly used for IIC protocol, can be used as general frequency output). 0 _B The MCLK generation is disabled and MCLK is 0. 1 _B The MCLK generation is enabled. |
| 0 | 3, [14:7], [30:22] | rw | Reserved Returns 0 if read; should be written with 0; |

18.6.5.2 IIS Protocol Status Register

The following PSR status bits or bit fields are available in IIS mode. Please note that the bits in register PSR are not cleared by hardware.

The flags in the PSR register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol.

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|------|------|--|
| WA | 0 | rwh | Word Address This bit indicates the status of the WA input signal, sampled after a transition of WA has been detected. This information is forwarded to the corresponding bit position RBUFSTR[9] to distinguish between data received for the right and the left channel. 0 _B WA has been sampled 0. 1 _B WA has been sampled 1. |
| DX2S | 1 | rwh | DX2S Status This bit indicates the current status of the DX2S signal, which is used as word address signal WA. 0 _B DX2S is 0. 1 _B DX2S is 1. |
| DX2TEV | 3 | rwh | DX2T Event Detected¹⁾ This bit indicates that the DX2T signal has been activated. In IIS slave mode, an activation of DX2T generates a protocol interrupt if PCR.DX2TIEN = 1. 0 _B The DX2T signal has not been activated. 1 _B The DX2T signal has been activated. |
| WAFE | 4 | rwh | WA Falling Edge Event¹⁾ This bit indicates that a falling edge of the WA output signal has been generated. This event generates a protocol interrupt if PCR.WAFEIEN = 1. 0 _B A WA falling edge has not been generated. 1 _B A WA falling edge has been generated. |
| WARE | 5 | rwh | WA Rising Edge Event¹⁾ This bit indicates that a rising edge of the WA output signal has been generated. This event generates a protocol interrupt if PCR.WAREIEN = 1. 0 _B A WA rising edge has not been generated. 1 _B A WA rising edge has been generated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|----------------------|------|---|
| END | 6 | rwh | WA Generation End¹⁾ This bit indicates that the WA generation has ended after clearing PCR.WAGEN. This bit should be cleared by software before clearing WAGEN. 0 _B The WA generation has not yet ended (if it is running and WAGEN has been cleared). 1 _B The WA generation has ended (if it has been running). |
| RSIF | 10 | rwh | Receiver Start Indication Flag 0 _B A receiver start event has not occurred. 1 _B A receiver start event has occurred. |
| DLIF | 11 | rwh | Data Lost Indication Flag 0 _B A data lost event has not occurred. 1 _B A data lost event has occurred. |
| TSIF | 12 | rwh | Transmit Shift Indication Flag 0 _B A transmit shift event has not occurred. 1 _B A transmit shift event has occurred. |
| TBIF | 13 | rwh | Transmit Buffer Indication Flag 0 _B A transmit buffer event has not occurred. 1 _B A transmit buffer event has occurred. |
| RIF | 14 | rwh | Receive Indication Flag 0 _B A receive event has not occurred. 1 _B A receive event has occurred. |
| AIF | 15 | rwh | Alternative Receive Indication Flag 0 _B An alternative receive event has not occurred. 1 _B An alternative receive event has occurred. |
| BRGIF | 16 | rwh | Baud Rate Generator Indication Flag 0 _B A baud rate generator event has not occurred. 1 _B A baud rate generator event has occurred. |
| 0 | 2, [9:7], [31:17] | r | Reserved Returns 0 if read; not modified in IIS mode. |

1) This status bit can generate a protocol interrupt (see [Page 18-22](#)). The general interrupt status flags are described in the general interrupt chapter.

18.7 Service Request Generation

The USIC module provides 6 service request outputs SR[5:0] to be shared between two channels. The service request outputs SR[5:0] are connected to interrupt nodes in the Nested Vectored Interrupt Controller (NVIC). Additionally, the first 2 outputs, SR[1:0], are also connected to the General Purpose DMA (GPDMA) via the DMA Line Router (DLR). An exception is USIC2 module, which has the first 4 outputs, SR[3:0] connected. For details of the interrupt node and DMA line assignments, refer to the respective chapter in the specification.

Each USIC communication channel can be connected to up to 6 service request handlers (connected to USICx.SR[5:0], though 3 or 4 are normally used, e.g. one for transmission, one for reception, one or two for protocol or error handling, or for the alternative receive events).

18.8 Debug Behaviour

Each USIC communication channel can be pre-configured to enter one of four kernel modes, when the program execution of the CPU is halted by the debugger.

Refer to [Section 18.2.2.2](#) for details.

18.9 Power, Reset and Clock

The USIC module is located in the core power domain. The module, including all registers other than the bit field KSCFG.SUMCFG, can be reset to its default state by a system reset or a software reset triggered through the setting of corresponding bits in PRSETx registers. The bit field KSCFG.SUMCFG is reset to its default value only by a debug reset.

The USIC module is clocked by the Peripheral Bus clock (f_{PERIPH}). If the module clock is disabled by KSCFG.MODEN = 0, the module cannot be accessed by read or write operations (except register KSCFG that can always be accessed).

18.10 Initialization and System Dependencies

The USIC module is held in reset after a start-up from a system or software reset. Therefore, the application has to apply the following initialization sequence before operating the USIC module:

- Release reset of USIC module by writing a 1 to the USICxRS bit in SCU_PRCLR0 or SCU_PRCLR1 registers
- Enable the module by writing 1s to the MODEN and BPMODEN bits in KSCFG register.

Universal Serial Interface Channel (USIC)

18.11 Registers

Table 18-20 shows all registers which are required for programming a USIC channel, as well as the FIFO buffer. It summarizes the USIC communication channel registers and defines the relative addresses and the reset values.

Please note that all registers can be accessed with any access width (8-bit, 16-bit, 32-bit), independent of the described width.

All USIC registers (except bit field KSCFG.SUMCFG) are always reset by a system reset. Bit field KSCFG.SUMCFG is reset by a debug reset.

Note: The register bits marked “w” always deliver 0 when read. They are used to modify flip-flops in other registers or to trigger internal actions.

Figure 18-65 shows the register types of the USIC module registers and channel registers. In a specific microcontroller, module registers of USIC module “x” are marked by the module prefix “USICx_”. Channel registers of USIC module “x” are marked by the channel prefix “USICx_CH0_” and “USICx_CH1_”.

18.11.1 Address Map

The registers of the USIC communication channel are available at the following base addresses. The exact register address is given by the relative address of the register (given in [Table 18-20](#)) plus the channel base address (given in [Table 18-21](#)).

Table 18-21 Registers Address Space

| Module | Base Address | End Address | Note |
|-----------|-----------------------|-----------------------|------|
| USIC0_CH0 | 40030000 _H | 400301FF _H | – |
| USIC0_CH1 | 40030200 _H | 400303FF _H | – |
| USIC1_CH0 | 48020000 _H | 480201FF _H | – |
| USIC1_CH1 | 48020200 _H | 480203FF _H | – |
| USIC2_CH0 | 48024000 _H | 480241FF _H | – |
| USIC2_CH1 | 48024200 _H | 480243FF _H | – |

Universal Serial Interface Channel (USIC)
Table 18-22 FIFO and Reserved Address Space

| Module | Base Address | End Address | Note |
|----------|-----------------------|-----------------------|--|
| USIC0 | 40030400 _H | 400307FF _H | USIC0 RAM area, shared between USIC0_CH0 and USIC0_CH1 |
| reserved | 40030800 _H | 40033FFF _H | This address range is reserved |
| USIC1 | 48020400 _H | 480207FF _H | USIC1 RAM area, shared between USIC1_CH0 and USIC1_CH1 |
| reserved | 48020800 _H | 48023FFF _H | This address range is reserved |
| USIC2 | 48024400 _H | 480247FF _H | USIC2 RAM area, shared between USIC2_CH0 and USIC2_CH1 |
| reserved | 48024800 _H | 48027FFF _H | This address range is reserved |

18.11.2 Module Identification Registers

The module identification registers indicate the function and the design step of the USIC modules.

Universal Serial Interface Channel (USIC)

USIC0_ID

Module Identification Register

(4003 0008_H)

Reset Value: 00AA C0XX_H

USIC1_ID

Module Identification Register

(4802 0008_H)

Reset Value: 00AA C0XX_H

USIC2_ID

Module Identification Register

(4802 4008_H)

Reset Value: 00AA C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the revision number. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the USIC module identification number (00AA _H = USIC). |

18.11.3 Channel Control and Configuration Registers

18.11.3.1 Channel Control Register

The channel control register contains the enable/disable bits for hardware port control and interrupt generation on channel events, the control of the parity generation and the protocol selection of a USIC channel.

FDR can be written only with a privilege mode access.

Universal Serial Interface Channel (USIC)

CCR

Channel Control Register

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| MODE | [3:0] | rw | <p>Operating Mode</p> <p>This bit field selects the protocol for this USIC channel. Selecting a protocol that is not available (see register CCFG) or a reserved combination disables the USIC channel. When switching between two protocols, the USIC channel has to be disabled before selecting a new protocol. In this case, registers PCR and PSR have to be cleared or updated by software.</p> <p>0_H The USIC channel is disabled. All protocol-related state machines are set to an idle state.</p> <p>1_H The SSC (SPI) protocol is selected.</p> <p>2_H The ASC (SCI, UART) protocol is selected.</p> <p>3_H The IIS protocol is selected.</p> <p>4_H The IIC protocol is selected.</p> <p>Other bit combinations are reserved.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|-------|------|---|
| HPCEN | [7:6] | rw | Hardware Port Control Enable This bit enables the hardware port control for the specified set of DX[3:0] and DOUT[3:0] pins. 00 _B The hardware port control is disabled. 01 _B The hardware port control is enabled for DX0 and DOUT0. 10 _B The hardware port control is enabled for DX3, DX0 and DOUT[1:0]. 11 _B The hardware port control is enabled for DX0, DX[5:3] and DOUT[3:0]. <i>Note: The hardware port control feature is useful only for SSC protocols in half-duplex configurations, such as dual- and quad-SSC. For all other protocols HPCEN must always be written with 00_B.</i> |
| PM | [9:8] | rw | Parity Mode This bit field defines the parity generation of the sampled input values. 00 _B The parity generation is disabled. 01 _B Reserved 10 _B Even parity is selected (parity bit = 1 on odd number of 1s in data, parity bit = 0 on even number of 1s in data). 11 _B Odd parity is selected (parity bit = 0 on odd number of 1s in data, parity bit = 1 on even number of 1s in data). |
| RSIEN | 10 | rw | Receiver Start Interrupt Enable This bit enables the interrupt generation in case of a receiver start event. 0 _B The receiver start interrupt is disabled. 1 _B The receiver start interrupt is enabled. In case of a receiver start event, the service request output SRx indicated by INPR.TBINP is activated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| DLIEN | 11 | rw | Data Lost Interrupt Enable This bit enables the interrupt generation in case of a data lost event (data received in RBUFx while RDVx = 1). 0 _B The data lost interrupt is disabled. 1 _B The data lost interrupt is enabled. In case of a data lost event, the service request output SRx indicated by INPR.PINP is activated. |
| TSIEN | 12 | rw | Transmit Shift Interrupt Enable This bit enables the interrupt generation in case of a transmit shift event. 0 _B The transmit shift interrupt is disabled. 1 _B The transmit shift interrupt is enabled. In case of a transmit shift interrupt event, the service request output SRx indicated by INPR.TSINP is activated. |
| TBIEN | 13 | rw | Transmit Buffer Interrupt Enable This bit enables the interrupt generation in case of a transmit buffer event. 0 _B The transmit buffer interrupt is disabled. 1 _B The transmit buffer interrupt is enabled. In case of a transmit buffer event, the service request output SRx indicated by INPR.TBINP is activated. |
| RIEN | 14 | rw | Receive Interrupt Enable This bit enables the interrupt generation in case of a receive event. 0 _B The receive interrupt is disabled. 1 _B The receive interrupt is enabled. In case of a receive event, the service request output SRx indicated by INPR.RINP is activated. |
| AIEN | 15 | rw | Alternative Receive Interrupt Enable This bit enables the interrupt generation in case of a alternative receive event. 0 _B The alternative receive interrupt is disabled. 1 _B The alternative receive interrupt is enabled. In case of an alternative receive event, the service request output SRx indicated by INPR.AINP is activated. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------------------|------|---|
| BRGIEN | 16 | rw | Baud Rate Generator Interrupt Enable This bit enables the interrupt generation in case of a baud rate generator event. 0 _B The baud rate generator interrupt is disabled. 1 _B The baud rate generator interrupt is enabled. In case of a baud rate generator event, the service request output SRx indicated by INPR.PINP is activated. |
| 0 | [5:4], [31:17] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

18.11.3.2 Channel Configuration Register

The channel configuration register contains indicates the functionality that is available in the USIC channel.

CCFG

Channel Configuration Register

| r | | | | w | r | rw | | w | r | rw | | r | w | rw | |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|----------------|-------|------|---|
| MODEN | 0 | rw | Module Enable This bit enables the module kernel clock and the module functionality. 0_B The module is switched off immediately (without respecting a stop condition). It does not react on mode control actions and the module clock is switched off. The module does not react on read accesses and ignores write accesses (except to KSCFG). 1_B The module is switched on and can operate. After writing 1 to MODEN, it is recommended to read register KSCFG to avoid pipeline effects in the control block before accessing other USIC registers. |
| BPMODEN | 1 | w | Bit Protection for MODEN This bit enables the write access to the bit MODEN. It always reads 0. 0_B MODEN is not changed. 1_B MODEN is updated with the written value. |
| NOMCFG | [5:4] | rw | Normal Operation Mode Configuration This bit field defines the kernel mode applied in normal operation mode. 00_B Run mode 0 is selected. 01_B Run mode 1 is selected. 10_B Stop mode 0 is selected. 11_B Stop mode 1 is selected. |
| BPNOM | 7 | w | Bit Protection for NOMCFG This bit enables the write access to the bit field NOMCFG. It always reads 0. 0_B NOMCFG is not changed. 1_B NOMCFG is updated with the written value. |
| SUMCFG | [9:8] | rw | Suspend Mode Configuration This bit field defines the kernel mode applied in suspend mode. Coding like NOMCFG. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|-----------------------------|------|--|
| BPSUM | 11 | w | Bit Protection for SUMCFG This bit enables the write access to the bit field SUMCFG. It always reads 0. 0 _B SUMCFG is not changed. 1 _B SUMCFG is updated with the written value. |
| 0 | [3:2], 6, 10, [31:12] | r | Reserved Read as 0; should be written with 0. Bit 2 can read as 1 after BootROM exit (but can be ignored). |

Universal Serial Interface Channel (USIC)

18.11.3.4 Interrupt Node Pointer Register

The interrupt node pointer register defines the service request output SRx that is activated if the corresponding event occurs and interrupt generation is enabled.

INPR

Interrupt Node Pointer Register (18_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|----|------|----|----|------|----|----|-------|----|----|-------|----|----|------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | PINP | | |
| r | | | | | | | | | | | | | rw | | |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TSINP | [2:0] | rw | Transmit Shift Interrupt Node Pointer This bit field defines which service request output SRx becomes activated in case of a transmit shift interrupt. 000 _B Output SR0 becomes activated. 001 _B Output SR1 becomes activated. 010 _B Output SR2 becomes activated. 011 _B Output SR3 becomes activated. 100 _B Output SR4 becomes activated. 101 _B Output SR5 becomes activated. <i>Note: All other settings of the bit field are reserved.</i> |
| TBINP | [6:4] | rw | Transmit Buffer Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a transmit buffer interrupt or a receive start interrupt. Coding like TSINP. |
| RINP | [10:8] | rw | Receive Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a receive interrupt. Coding like TSINP. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|-----------------------|------|--|
| AINP | [14:12] | rw | Alternative Receive Interrupt Node Pointer This bit field defines which service request output SRx will be activated in case of a alternative receive interrupt. Coding like TSINP. |
| PINP | [18:16] | rw | Protocol Interrupt Node Pointer This bit field defines which service request output SRx becomes activated in case of a protocol interrupt. Coding like TSINP. |
| 0 | 3, 7, 11, 15, [31:19] | r | Reserved Read as 0; should be written with 0. |

18.11.4 Protocol Related Registers

18.11.4.1 Protocol Control Registers

The bits in the protocol control register define protocol-specific functions. They have to be configured by software before enabling a new protocol. Only the bits used for the selected protocol are taken into account, whereas the other bit positions always read as 0. The protocol-specific meaning is described in the related protocol section.

Universal Serial Interface Channel (USIC)

18.11.4.2 Protocol Status Register

The flags in the protocol status register can be cleared by writing a 1 to the corresponding bit position in register PSCR. Writing a 1 to a bit position in PSR sets the corresponding flag, but does not lead to further actions (no interrupt generation). Writing a 0 has no effect. These flags should be cleared by software before enabling a new protocol. The protocol-specific meaning is described in the related protocol section.

PSR

18.11.5 Input Stage Register

18.11.5.1 Input Control Registers

The input control registers contain the bits to define the characteristics of the input stages (input stage DX0 is controlled by register DX0CR, etc.).

Universal Serial Interface Channel (USIC)

DX0CR

Input Control Register 0 (1C_H) **Reset Value: 0000 0000_H**

DX2CR

Input Control Register 2 (24_H) **Reset Value: 0000 0000_H**

DX3CR

Input Control Register 3 (28_H) **Reset Value: 0000 0000_H**

DX4CR

Input Control Register 4 (2C_H) **Reset Value: 0000 0000_H**

DX5CR

Input Control Register 5 (30_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|-------|------|---|
| DSEL | [2:0] | rw | Data Selection for Input Signal This bit field defines the input data signal for the corresponding input line for protocol pre-processor. The selection can be made from the input vector DXn[G:A]. 000 _B The data input DXnA is selected. 001 _B The data input DXnB is selected. 010 _B The data input DXnC is selected. 011 _B The data input DXnD is selected. 100 _B The data input DXnE is selected. 101 _B The data input DXnF is selected. 110 _B The data input DXnG is selected. 111 _B The data input is always 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| INSW | 4 | rw | Input Switch This bit defines if the data shift unit input is derived from the input data path DXn or from the selected protocol pre-processors. 0_B The input of the data shift unit is controlled by the protocol pre-processor. 1_B The input of the data shift unit is connected to the selected data input line. This setting is used if the signals are directly derived from an input pin without treatment by the protocol pre-processor. |
| DFEN | 5 | rw | Digital Filter Enable This bit enables/disables the digital filter for signal DXnS. 0_B The input signal is not digitally filtered. 1_B The input signal is digitally filtered. |
| DSEN | 6 | rw | Data Synchronization Enable This bit selects if the asynchronous input signal or the synchronized (and optionally filtered) signal DXnS can be used as input for the data shift unit. 0_B The un-synchronized signal can be taken as input for the data shift unit. 1_B The synchronized signal can be taken as input for the data shift unit. |
| DPOL | 8 | rw | Data Polarity for DXn This bit defines the signal polarity of the input signal. 0_B The input signal is not inverted. 1_B The input signal is inverted. |
| SFSEL | 9 | rw | Sampling Frequency Selection This bit defines the sampling frequency of the digital filter for the synchronized signal DXnS. 0_B The sampling frequency is f_{PERIPH} . 1_B The sampling frequency is f_{FD} . |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|------------------------|------|---|
| CM | [11:10] | rw | Combination Mode This bit field selects which edge of the synchronized (and optionally filtered) signal DXnS activates the trigger output DXnT of the input stage. 00 _B The trigger activation is disabled. 01 _B A rising edge activates DXnT. 10 _B A falling edge activates DXnT. 11 _B Both edges activate DXnT. |
| DXS | 15 | rh | Synchronized Data Value This bit indicates the value of the synchronized (and optionally filtered) input signal. 0 _B The current value of DXnS is 0. 1 _B The current value of DXnS is 1. |
| 0 | 3, 7, [14:12], [31:16] | r | Reserved Read as 0; should be written with 0. |

| rw | | r | | | | rw | | | | | | | | | |

| Field | Bits | Type | Description |
|-------|---------|------|---|
| STEP | [9:0] | rw | Step Value In normal divider mode STEP contains the reload value for RESULT after RESULT has reached 3FF _H . In fractional divider mode STEP defines the value added to RESULT with each input clock cycle. |
| DM | [15:14] | rw | Divider Mode This bit fields defines the functionality of the fractional divider block. 00 _B The divider is switched off, $f_{FD} = 0$. 01 _B Normal divider mode selected. 10 _B Fractional divider mode selected. 11 _B The divider is switched off, $f_{FD} = 0$. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|---------------------|------|--|
| RESULT | [25:16] | rh | Result Value In normal divider mode this bit field is updated with f_{PERIPH} according to: $\text{RESULT} = \text{RESULT} + 1$ In fractional divider mode this bit field is updated with f_{PERIPH} according to: $\text{RESULT} = \text{RESULT} + \text{STEP}$ If bit field DM is written with 01_{B} or 10_{B} , RESULT is loaded with a start value of 3FF_{H} . |
| 0 | [31:30] | rw | Reserved for Future Use Must be written with 0 to allow correct fractional divider operation. |
| 0 | [13:10], [29:26] | r | Reserved Read as 0; should be written with 0. |

18.11.6.2 Baud Rate Generator Register

The protocol-related counters for baud rate generation and timing measurement are controlled by the register BRG.

FDR can be written only with a privilege mode access.

BRG

Baud Rate Generator Register (14_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|----------------|-------------|----------------|----------------|----------|----|-------------|----|---------------|----|----------|--------------|-------------|----------|---------------|----|

| SCLKCFG | | MCLKCFG | SCLKSEL | 0 | | PDIV | | | | | | | | | |
| rw | | rw | rw | r | | rw | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | DCTQ | | | | | PCTQ | | CTQSEL | | 0 | PPPEN | TMEN | 0 | CLKSEL | |
| r | rw | | | | | rw | | rw | | r | rw | rw | r | rw | |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| CLKSEL | [1:0] | rw | Clock Selection This bit field defines the input frequency f_{PIN} 00 _B The fractional divider frequency f_{FD} is selected. 01 _B Reserved, no action 10 _B The trigger signal DX1T defines f_{PIN} . Signal MCLK toggles with f_{PIN} . 11 _B Signal MCLK corresponds to the DX1S signal and the frequency f_{PIN} is derived from the rising edges of DX1S. |
| TMEN | 3 | rw | Timing Measurement Enable This bit enables the timing measurement of the capture mode timer. 0 _B Timing measurement is disabled: The trigger signals DX0T and DX1T are ignored. 1 _B Timing measurement is enabled: The 10-bit counter is incremented by 1 with f_{PPP} and stops counting when reaching its maximum value. If one of the trigger signals DX0T or DX1T become active, the counter value is captured into bit field CTV, the counter is cleared and a transmit shift event is generated. |
| PPPEN | 4 | rw | Enable 2:1 Divider for f_{PPP} This bit defines the input frequency f_{PPP} . 0 _B The 2:1 divider for f_{PPP} is disabled. $f_{PPP} = f_{PIN}$ 1 _B The 2:1 divider for f_{PPP} is enabled. $f_{PPP} = f_{MCLK} = f_{PIN} / 2$. |
| CTQSEL | [7:6] | rw | Input Selection for CTQ This bit defines the length of a time quantum for the protocol pre-processor. 00 _B $f_{CTQIN} = f_{PDIV}$ 01 _B $f_{CTQIN} = f_{PPP}$ 10 _B $f_{CTQIN} = f_{SCLK}$ 11 _B $f_{CTQIN} = f_{MCLK}$ |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-----------------|-------------------|------|--|
| PCTQ | [9:8] | rw | Pre-Divider for Time Quanta Counter This bit field defines length of a time quantum t_q for the time quanta counter in the protocol pre-processor. $t_q = (PCTQ + 1) / f_{CTQIN}$ |
| DCTQ | [14:10] | rw | Denominator for Time Quanta Counter This bit field defines the number of time quanta t_q taken into account by the time quanta counter in the protocol pre-processor. |
| PDIV | [25:16] | rw | Divider Mode: Divider Factor to Generate f_{PDIV} This bit field defines the ratio between the input frequency f_{PPP} and the divider frequency f_{PDIV} . |
| SCLKOSEL | 28 | rw | Shift Clock Output Select This bit field selects the input source for the SCLKOUT signal. 0_B SCLK from the baud rate generator is selected as the SCLKOUT input source. 1_B The transmit shift clock from DX1 input stage is selected as the SCLKOUT input source. <i>Note: The setting SCLKOSEL = 1 is used only when complete closed loop delay compensation is required for a slave SSC/IIS. The default setting of SCLKOSEL = 0 should be always used for all other cases.</i> |
| MCLKCFG | 29 | rw | Master Clock Configuration This bit field defines the level of the passive phase of the MCLKOUT signal. 0_B The passive level is 0. 1_B The passive level is 1. |
| SCLKCFG | [31:30] | rw | Shift Clock Output Configuration This bit field defines the level of the passive phase of the SCLKOUT signal and enables/disables a delay of half of a SCLK period. 00_B The passive level is 0 and the delay is disabled. 01_B The passive level is 1 and the delay is disabled. 10_B The passive level is 0 and the delay is enabled. 11_B The passive level is 1 and the delay is enabled. |
| 0 | 2, 5, 15, [27:26] | r | Reserved Read as 0; should be written with 0. |

18.11.6.3 Capture Mode Timer Register

The captured timer value is provided by the register CMTR.

CMTR

Capture Mode Timer Register

(44_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| CTV | [9:0] | rwh | Captured Timer Value The value of the counter is captured into this bit field if one of the trigger signals DX0T or DX1T are activated by the corresponding input stage. |
| 0 | [31:10] | r | Reserved Read as 0; should be written with 0. |

18.11.7 Transfer Control and Status Registers

18.11.7.1 Shift Control Register

The data shift unit is controlled by the register SCTR. The values in this register are applied for data transmission and reception.

Please note that the shift control settings SDIR, WLE, FLE, DSM and HPCDIR are shared between transmitter and receiver. They are internally “frozen” for a each data word transfer in the transmitter with the first transmit shift clock edge and with the first receive shift clock edge in the receiver. The software has to take care that updates of these bit fields by software are done coherently (e.g. refer to the receiver start event indication PSR.RSIF).

Universal Serial Interface Channel (USIC)

SCTR

Shift Control Register

| 0 | | | | | | TRM | | DOCFG | | 0 | HPC DIR | DSM | | PDL | SDIR |
| r | | | | | | rw | | rw | | r | rw | rw | | rw | rw |

| Field | Bits | Type | Description |
|-------------|------|------|--|
| SDIR | 0 | rw | Shift Direction This bit defines the shift direction of the data words for transmission and reception. 0 _B Shift LSB first. The first data bit of a data word is located at bit position 0. 1 _B Shift MSB first. The first data bit of a data word is located at the bit position given by bit field SCTR.WLE. |
| PDL | 1 | rw | Passive Data Level This bit defines the output level at the shift data output signal when no data is available for transmission. The PDL level is output with the first relevant transmit shift clock edge of a data word. 0 _B The passive data level is 0. 1 _B The passive data level is 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| DSM | [3:2] | rw | Data Shift Mode This bit field describes how the receive and transmit data is shifted in and out. 00 _B Receive and transmit data is shifted in and out one bit at a time through DX0 and DOUT0. 01 _B Reserved. 10 _B Receive and transmit data is shifted in and out two bits at a time through two input stages (DX0 and DX3) and DOUT[1:0] respectively. 11 _B Receive and transmit data is shifted in and out four bits at a time through four input stages (DX0, DX[5:3]) and DOUT[3:0] respectively. <i>Note: Dual- and Quad-output modes are used only by the SSC protocol. For all other protocols DSM must always be written with 00_B.</i> |
| HPCDIR | 4 | rw | Port Control Direction This bit defines the direction of the port pin(s) which allows hardware pin control (CCR.PCEN = 1). 0 _B The pin(s) with hardware pin control enabled are selected to be in input mode. 1 _B The pin(s) with hardware pin control enabled are selected to be in output mode. |
| DOCFG | [7:6] | rw | Data Output Configuration This bit defines the relation between the internal shift data value and the data output signal DOUTx. X0 _B DOUTx = shift data value X1 _B DOUTx = inverted shift data value |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|---------|------|--|
| TRM | [9:8] | rw | Transmission Mode This bit field describes how the shift control signal is interpreted by the DSU. Data transfers are only possible while the shift control signal is active. 00 _B The shift control signal is considered as inactive and data frame transfers are not possible. 01 _B The shift control signal is considered active if it is at 1-level. This is the setting to be programmed to allow data transfers. 10 _B The shift control signal is considered active if it is at 0-level. It is recommended to avoid this setting and to use the inversion in the DX2 stage in case of a low-active signal. 11 _B The shift control signal is considered active without referring to the actual signal level. Data frame transfer is possible after each edge of the signal. |
| FLE | [21:16] | rwh | Frame Length This bit field defines how many bits are transferred within a data frame. A data frame can consist of several concatenated data words. If TCSR.FLEMD = 1, the value can be updated automatically by the data handler. |
| WLE | [27:24] | rwh | Word Length This bit field defines the data word length (amount of bits that are transferred in each data word) for reception and transmission. The data word is always right-aligned in the data buffer at the bit positions [WLE down to 0]. If TCSR.WLEMD = 1, the value can be updated automatically by the data handler. 0 _H The data word contains 1 data bit located at bit position 0. 1 _H The data word contains 2 data bits located at bit positions [1:0]. ... E _H The data word contains 15 data bits located at bit positions [14:0]. F _H The data word contains 16 data bits located at bit positions [15:0]. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |

| Field | Bits | Type | Description |
|--------------|------|------|--|
| WLEMD | 0 | rw | WLE Mode This bit enables the data handler to automatically update the bit field SCTR.WLE by the transmit control information TCI[3:0] and bit TCSR.EOF by TCI[4] (see Page 18-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer. 0 _B The automatic update of SCTR.WLE and TCSR.EOF is disabled. 1 _B The automatic update of SCTR.WLE and TCSR.EOF is enabled. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| SELMD | 1 | rw | <p>Select Mode</p> <p>This bit can be used mainly for the SSC protocol. It enables the data handler to automatically update bit field PCR.CTR[20:16] by the transmit control information TCI[4:0] and clear bit field PCR.CTR[23:21] (see Page 18-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of PCR.CTR[23:16] is disabled.</p> <p>1_B The automatic update of PCR.CTR[23:16] is disabled.</p> |
| FLEMD | 2 | rw | <p>FLE Mode</p> <p>This bit enables the data handler to automatically update bits SCTR.FLE[4:0] by the transmit control information TCI[4:0] and to clear bit SCTR.FLE[5] (see Page 18-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of FLE is disabled.</p> <p>1_B The automatic update of FLE is enabled.</p> |
| WAMD | 3 | rw | <p>WA Mode</p> <p>This bit can be used mainly for the IIS protocol. It enables the data handler to automatically update bit TCSR.WA by the transmit control information TCI[4] (see Page 18-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of bit WA is disabled.</p> <p>1_B The automatic update of bit WA is enabled.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| HPCMD | 4 | rw | <p>Hardware Port Control Mode</p> <p>This bit can be used mainly for the dual and quad SSC protocol. It enables the data handler to automatically update bit SCTR.DSM by the transmit control information TCI[1:0] and bit SCTR.HPCDIR by TCI[2] (see Page 18-33). If enabled, an automatic update takes place when new data is loaded to register TBUF, either by writing to one of the transmit buffer input locations TBUFx or by an optional data buffer.</p> <p>0_B The automatic update of bits SCTR.DSM and SCTR.HPCDIR is disabled.</p> <p>1_B The automatic update of bits SCTR.DSM and SCTR.HPCDIR is enabled.</p> |
| SOF | 5 | rwh | <p>Start Of Frame</p> <p>This bit is only taken into account for the SSC protocol, otherwise it is ignored. It indicates that the data word in TBUF is considered as the first word of a new SSC frame if it is valid for transmission (TCSR.TDV = 1). This bit becomes cleared when the TBUF data word is transferred to the transmit shift register.</p> <p>0_B The data word in TBUF is not considered as first word of a frame.</p> <p>1_B The data word in TBUF is considered as first word of a frame. A currently running frame is finished and MSLS becomes deactivated (respecting the programmed delays).</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------|------|------|--|
| EOF | 6 | rwh | <p>End Of Frame</p> <p>This bit is only taken into account for the SSC protocol, otherwise it is ignored. It can be modified automatically by the data handler if bit WLEMD = 1. It indicates that the data word in TBUF is considered as the last word of an SSC frame. If it is the last word, the MSLS signal becomes inactive after the transfer, respecting the programmed delays. This bit becomes cleared when the TBUF data word is transferred to the transmit shift register.</p> <p>0_B The data word in TBUF is not considered as last word of an SSC frame.</p> <p>1_B The data word in TBUF is considered as last word of an SSC frame.</p> |
| TDV | 7 | rh | <p>Transmit Data Valid</p> <p>This bit indicates that the data word in the transmit buffer TBUF can be considered as valid for transmission. The TBUF data word can only be sent out if TDV = 1. It is automatically set when data is moved to TBUF (by writing to one of the transmit buffer input locations TBUFx, or optionally, by the bypass or FIFO mechanism).</p> <p>0_B The data word in TBUF is not valid for transmission.</p> <p>1_B The data word in TBUF is valid for transmission and a transmission start is possible. New data should not be written to a TBUFx input location while TDV = 1.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| TDSSM | 8 | rw | TBUF Data Single Shot Mode This bit defines if the data word TBUF data is considered as permanently valid or if the data should only be transferred once. 0 _B The data word in TBUF is not considered as invalid after it has been loaded into the transmit shift register. The loading of the TBUF data into the shift register does not clear TDV. 1 _B The data word in TBUF is considered as invalid after it has been loaded into the shift register. In ASC and IIC mode, TDV is cleared with the TBI event, whereas in SSC and IIS mode, it is cleared with the RSI event. TDSSM = 1 has to be programmed if an optional data buffer is used. |
| TDEN | [11:10] | rw | TBUF Data Enable This bit field controls the gating of the transmission start of the data word in the transmit buffer TBUF. 00 _B A transmission start of the data word in TBUF is disabled. If a transmission is started, the passive data level is sent out. 01 _B A transmission of the data word in TBUF can be started if TDV = 1. 10 _B A transmission of the data word in TBUF can be started if TDV = 1 while DX2S = 0. 11 _B A transmission of the data word in TBUF can be started if TDV = 1 while DX2S = 1. |
| TDVTR | 12 | rw | TBUF Data Valid Trigger This bit enables the transfer trigger unit to set bit TCSR.TE if the trigger signal DX2T becomes active for event driven transfer starts, e.g. timer-based or depending on an event at an input pin. Bit TDVTR has to be 0 for protocols where the input stage DX2 is used for data shifting. 0 _B Bit TCSR.TE is permanently set. 1 _B Bit TCSR.TE is set if DX2T becomes active while TDV = 1. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|------|------|--|
| WA | 13 | rwh | <p>Word Address</p> <p>This bit is only taken into account for the IIS protocol, otherwise it is ignored. It can be modified automatically by the data handler if bit WAMD = 1. Bit WA defines for which channel the data stored in TBUF will be transmitted.</p> <p>0_B The data word in TBUF will be transmitted after a falling edge of WA has been detected (referring to PSR.WA).</p> <p>1_B The data word in TBUF will be transmitted after a rising edge of WA has been detected (referring to PSR.WA).</p> |
| TSOF | 24 | rh | <p>Transmitted Start Of Frame</p> <p>This bit indicates if the latest start of a data word transmission has taken place for the first data word of a new data frame. This bit is updated with the transmission start of each data word.</p> <p>0_B The latest data word transmission has not been started for the first word of a data frame.</p> <p>1_B The latest data word transmission has been started for the first word of a data frame.</p> |
| TV | 26 | rh | <p>Transmission Valid</p> <p>This bit represents the transmit buffer underflow and indicates if the latest start of a data word transmission has taken place with a valid data word from the transmit buffer TBUF. This bit is updated with the transmission start of each data word.</p> <p>0_B The latest start of a data word transmission has taken place while no valid data was available. As a result, the transmission of a data words with passive level (SCTR.PDL) has been started.</p> <p>1_B The latest start of a data word transmission has taken place with valid data from TBUF.</p> |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|------------|-------------------------|------|---|
| TVC | 27 | rh | Transmission Valid Cumulated This bit cumulates the transmit buffer underflow indication TV. It is cleared automatically together with bit TV and has to be set by writing FMR.ATVC = 1. 0_B Since TVC has been set, at least one data buffer underflow condition has occurred. 1_B Since TVC has been set, no data buffer underflow condition has occurred. |
| TE | 28 | rh | Trigger Event If the transfer trigger mechanism is enabled, this bit indicates that a trigger event has been detected (DX2T = 1) while TCSR.TDV = 1. If the event trigger mechanism is disabled, the bit TE is permanently set. It is cleared by writing FMR.MTDV = 10_B or when the data word located in TBUF is loaded into the shift register. 0_B The trigger event has not yet been detected. A transmission of the data word in TBUF can not be started. 1_B The trigger event has been detected (or the trigger mechanism is switched off) and a transmission of the data word in TBUF can be started. |
| 0 | 9, [23:14], 25, [31:29] | r | Reserved Read as 0; should be written with 0. |

18.11.7.3 Flag Modification Registers

The flag modification register FMR allows the modification of control and status flags related to data handling by using only write accesses. Read accesses to FMR always deliver 0 at all bit positions.

Additionally, the service request outputs of this USIC channel can be activated by software (the activation is triggered by the write access and is deactivated automatically).

Universal Serial Interface Channel (USIC)

FMR

Flag Modification Register

|-------|-------|------|---|
| MTDV | [1:0] | w | Modify Transmit Data Valid Writing to this bit field can modify bits TCSR.TDV and TCSR.TE to control the start of a data word transmission by software. 00 _B No action. 01 _B Bit TDV is set, TE is unchanged. 10 _B Bits TDV and TE are cleared. 11 _B Reserved |
| ATVC | 4 | w | Activate Bit TVC Writing to this bit can set bit TCSR.TVC to start a new cumulation of the transmit buffer underflow condition. 0 _B No action. 1 _B Bit TCSR.TVC is set. |
| CRDV0 | 14 | w | Clear Bits RDV for RBUF0 Writing 1 to this bit clears bits RBUF01SR.RDV00 and RBUF01SR.RDV10 to declare the received data in RBUF0 as no longer valid (to emulate a read action). 0 _B No action. 1 _B Bits RBUF01SR.RDV00 and RBUF01SR.RDV10 are cleared. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|---|------------------------|------|---|
| CRDV1 | 15 | w | Clear Bit RDV for RBUF1 Writing 1 to this bit clears bits RBUF01SR.RDV01 and RBUF01SR.RDV11 to declare the received data in RBUF1 as no longer valid (to emulate a read action). 0 _B No action. 1 _B Bits RBUF01SR.RDV01 and RBUF01SR.RDV11 are cleared. |
| SIO0, SIO1, SIO2, SIO3, SIO4, SIO5 | 16, 17, 18, 19, 20, 21 | w | Set Interrupt Output SRx Writing a 1 to this bit field activates the service request output SRx of this USIC channel. It has no impact on service request outputs of other USIC channels. 0 _B No action. 1 _B The service request output SRx is activated. |
| 0 | [3:2], [13:5], [31:22] | r | Reserved Read as 0; should be written with 0. |

18.11.8 Data Buffer Registers

18.11.8.1 Transmit Buffer Locations

The 32 independent data input locations TBUF00 to TBUF31 are address locations that can be used as data entry locations for the transmit buffer. Data written to one of these locations will appear in a common register TBUF. Additionally, the 5 bit coding of the number [31:0] of the addressed data input location represents the transmit control information TCI (please refer to the protocol sections for more details).

The internal transmit buffer register TBUF contains the data that will be loaded to the transmit shift register for the next transmission of a data word. It can be read out at all TBUF00 to TBUF31 addresses.

Universal Serial Interface Channel (USIC)

TBUF_x (x = 00-31)

Transmit Buffer Input Location x ($80_H + x \cdot 4$) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|---------|------|---|
| TDATA | [15:0] | rwh | Transmit Data This bit field contains the data to be transmitted (read view). A data write action to at least the low byte of TDATA sets TCSR.TDV. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

18.11.8.2 Receive Buffer Registers RBUF0, RBUF1

The receive buffer register RBUF0 contains the data received from RSR0[3:0]. A read action does not change the status of the receive data from “not yet read = valid” to “already read = not valid”.

RBUF0

Receiver Buffer Register 0 ($5C_H$) **Reset Value: 0000 0000_H**

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| DSR0 | [15:0] | rh | Data of Shift Registers 0[3:0] |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

The receive buffer register RBUF1 contains the data received from RSR1[3:0]. A read action does not change the status of the receive data from “not yet read = valid” to “already read = not valid”.

RBUF1

Receiver Buffer Register 1

(60_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| DSR1 | [15:0] | rh | Data of Shift Registers 1[3:0] |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

The receive buffer status register RBUF01SR provides the status of the data in receive buffers RBUF0 and RBUF1.

Universal Serial Interface Channel (USIC)

RBUF01SR

Receiver Buffer 01 Status Register (64_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|-------|------|---|
| WLEN0 | [3:0] | rh | Received Data Word Length in RBUF0 This bit field indicates how many bits have been received within the last data word stored in RBUF0. This number indicates how many data bits have to be considered as receive data, whereas the other bits in RBUF0 have been cleared automatically. The received bits are always right-aligned. For all protocol modes besides dual and quad SSC, Received data word length = WLEN0 + 1 For dual SSC mode, Received data word length = WLEN0 + 2 For quad SSC mode, Received data word length = WLEN0 + 4 |
| SOF0 | 6 | rh | Start of Frame in RBUF0 This bit indicates whether the data word in RBUF0 has been the first data word of a data frame. 0 _B The data in RBUF0 has not been the first data word of a data frame. 1 _B The data in RBUF0 has been the first data word of a data frame. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| PAR0 | 8 | rh | Protocol-Related Argument in RBUF0 This bit indicates the value of the protocol-related argument. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF0. The meaning of this bit is described in the corresponding protocol chapter. |
| PERR0 | 9 | rh | Protocol-related Error in RBUF0 This bit indicates if the value of the protocol-related argument meets an expected value. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF0. The meaning of this bit is described in the corresponding protocol chapter. 0 _B The received protocol-related argument PAR matches the expected value. The reception of the data word sets bit PSR.RIF and can generate a receive interrupt. 1 _B The received protocol-related argument PAR does not match the expected value. The reception of the data word sets bit PSR.AIF and can generate an alternative receive interrupt. |
| RDV00 | 13 | rh | Receive Data Valid in RBUF0 This bit indicates the status of the data content of register RBUF0. This bit is identical to bit RBUF01SR.RDV10 and allows consisting reading of information for the receive buffer registers. It is set when a new data word is stored in RBUF0 and automatically cleared if it is read out via RBUF. 0 _B Register RBUF0 does not contain data that has not yet been read out. 1 _B Register RBUF0 contains data that has not yet been read out. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| RDV01 | 14 | rh | Receive Data Valid in RBUF1 This bit indicates the status of the data content of register RBUF1. This bit is identical to bit RBUF01SR.RDV11 and allows consisting reading of information for the receive buffer registers. It is set when a new data word is stored in RBUF1 and automatically cleared if it is read out via RBUF. 0 _B Register RBUF1 does not contain data that has not yet been read out. 1 _B Register RBUF1 contains data that has not yet been read out. |
| DS0 | 15 | rh | Data Source This bit indicates which receive buffer register (RBUF0 or RBUF1) is currently visible in registers RBUF(D) and in RBUFSR for the associated status information. It indicates which buffer contains the oldest data (the data that has been received first). This bit is identical to bit RBUF01SR.DS1 and allows consisting reading of information for the receive buffer registers. 0 _B The register RBUF contains the data of RBUF0 (same for associated status information). 1 _B The register RBUF contains the data of RBUF1 (same for associated status information). |
| WLEN1 | [19:16] | rh | Received Data Word Length in RBUF1 This bit field indicates how many bits have been received within the last data word stored in RBUF1. This number indicates how many data bits have to be considered as receive data, whereas the other bits in RBUF1 have been cleared automatically. The received bits are always right-aligned. For all protocol modes besides dual and quad SSC, Received data word length = WLEN1 + 1 For dual SSC mode, Received data word length = WLEN1 + 2 For quad SSC mode, Received data word length = WLEN1 + 4 |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| SOF1 | 22 | rh | Start of Frame in RBUF1 This bit indicates whether the data word in RBUF1 has been the first data word of a data frame. 0 _B The data in RBUF1 has not been the first data word of a data frame. 1 _B The data in RBUF1 has been the first data word of a data frame. |
| PAR1 | 24 | rh | Protocol-Related Argument in RBUF1 This bit indicates the value of the protocol-related argument. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF1. The meaning of this bit is described in the corresponding protocol chapter. |
| PERR1 | 25 | rh | Protocol-related Error in RBUF1 This bit indicates if the value of the protocol-related argument meets an expected value. This value is elaborated depending on the selected protocol and adds additional information to the data word in RBUF1. The meaning of this bit is described in the corresponding protocol chapter. 0 _B The received protocol-related argument PAR matches the expected value. The reception of the data word sets bit PSR.RIF and can generate a receive interrupt. 1 _B The received protocol-related argument PAR does not match the expected value. The reception of the data word sets bit PSR.AIF and can generate an alternative receive interrupt. |
| RDV10 | 29 | rh | Receive Data Valid in RBUF0 This bit indicates the status of the data content of register RBUF0. This bit is identical to bit RBUF01SR.RDV00 and allows consistent reading of information for the receive buffer registers. 0 _B Register RBUF0 does not contain data that has not yet been read out. 1 _B Register RBUF0 contains data that has not yet been read out. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---|------|--|
| RDV11 | 30 | rh | Receive Data Valid in RBUF1 This bit indicates the status of the data content of register RBUF1. This bit is identical to bit RBUF01SR.RDV01 and allows consisting reading of information for the receive buffer registers. 0 _B Register RBUF1 does not contain data that has not yet been read out. 1 _B Register RBUF1 contains data that has not yet been read out. |
| DS1 | 31 | rh | Data Source This bit indicates which receive buffer register (RBUF0 or RBUF1) is currently visible in registers RBUF(D) and in RBUF SR for the associated status information. It indicates which buffer contains the oldest data (the data that has been received first). This bit is identical to bit RBUF01SR.DS0 and allows consisting reading of information for the receive buffer registers. 0 _B The register RBUF contains the data of RBUF0 (same for associated status information). 1 _B The register RBUF contains the data of RBUF1 (same for associated status information). |
| 0 | [5:4], 7, [12:10], [21:20], 23, [28:26] | r | Reserved Read as 0; should be written with 0. |

18.11.8.3 Receive Buffer Registers RBUF, RBUFD, RBUFSR

The receiver buffer register RBUF shows the content of the either RBUF0 or RBUF1, depending on the order of reception. Always the oldest data (the data word that has been received first) from both receive buffers can be read from RBUF. It is recommended to read out the received data from RBUF instead of RBUF0/1. With a read access of at least the low byte of RBUF, the status of the receive data is automatically changed from “not yet read = valid” to “already read = not valid”, the content of RBUF becomes updated, and the next received data word becomes visible in RBUF.

Universal Serial Interface Channel (USIC)

RBUF

Receiver Buffer Register

(54_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DSR | [15:0] | rh | Received Data This bit field monitors the content of either RBUF0 or RBUF1, depending on the reception sequence. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

If a debugger should be used to monitor the received data, the automatic update mechanism has to be de-activated to guaranty data consistency. Therefore, the receiver buffer register for debugging RBUFD is available. It is similar to RBUF, but without the automatic update mechanism by a read action. So a debugger (or other monitoring function) can read RBUFD without disturbing the receive sequence.

RBUFD

Receiver Buffer Register for Debugger(58_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DSR | [15:0] | rh | Data from Shift Register Same as RBUF.DSR, but without releasing the buffer after a read action. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

The receive buffer status register RBUF01SR provides the status of the data in receive buffers RBUF and RBUFD. If bits RBUF01SR.DS0 (or RBUF01SR.DS1) are 0, the lower 16-bit content of RBUF01SR is monitored in RBUF01SR, otherwise the upper 16-bit content of RBUF01SR is shown.

| BDV | 0 | BPRI | BDV | BDEN | 0 | BDS | SM | 0 | | | | BWLE | | | |
| rh | r | rw | rw | rw | r | rw | | r | | | | rw | | | |

| Field | Bits | Type | Description |
|--------------|-------|------|--|
| BWLE | [3:0] | rw | Bypass Word Length This bit field defines the word length of the bypass data. The word length is given by BWLE + 1 with the data word being right-aligned in the data buffer at the bit positions [BWLE down to 0]. The bypass data word is always considered as an own frame with the length of BWLE. Same coding as SCTR.WLE. |
| BDSSM | 8 | rw | Bypass Data Single Shot Mode This bit defines if the bypass data is considered as permanently valid or if the bypass data is only transferred once (single shot mode). 0 _B The bypass data is still considered as valid after it has been loaded into TBUF. The loading of the data into TBUF does not clear BDV. 1 _B The bypass data is considered as invalid after it has been loaded into TBUF. The loading of the data into TBUF clears BDV. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| BDEN | [11:10] | rw | Bypass Data Enable This bit field defines if and how the transfer of bypass data to TBUF is enabled. 00 _B The transfer of bypass data is disabled. 01 _B The transfer of bypass data to TBUF is possible. Bypass data will be transferred to TBUF according to its priority if BDV = 1. 10 _B Gated bypass data transfer is enabled. Bypass data will be transferred to TBUF according to its priority if BDV = 1 and while DX2S = 0. 11 _B Gated bypass data transfer is enabled. Bypass data will be transferred to TBUF according to its priority if BDV = 1 and while DX2S = 1. |
| BDVTR | 12 | rw | Bypass Data Valid Trigger This bit enables the bypass data for being tagged valid when DX2T is active (for time framing or time-out purposes). 0 _B Bit BDV is not influenced by DX2T. 1 _B Bit BDV is set if DX2T is active. |
| BPRIO | 13 | rw | Bypass Priority This bit defines the priority between the bypass data and the transmit FIFO data. 0 _B The transmit FIFO data has a higher priority than the bypass data. 1 _B The bypass data has a higher priority than the transmit FIFO data. |
| BDV | 15 | rh | Bypass Data Valid This bit defines if the bypass data is valid for a transfer to TBUF. This bit is set automatically by a write access to at least the low-byte of register BYP. It can be cleared by software by writing TRBSCR.CBDV. 0 _B The bypass data is not valid. 1 _B The bypass data is valid. |
| BSELO | [20:16] | rw | Bypass Select Outputs This bit field contains the value that is written to PCR.CTR[20:16] if bypass data is transferred to TBUF while TCSR.SELMD = 1. In the SSC protocol, this bit field can be used to define which SELOx output line will be activated when bypass data is transmitted. |

Universal Serial Interface Channel (USIC)

| Field | Bits | Type | Description |
|-------------|-----------------------|------|--|
| BHPC | [23:21] | rw | Bypass Hardware Port Control This bit field contains the value that is written to SCTR[4:2] if bypass data is transferred to TBUF while TCSR.HPCMD = 1. In the SSC protocol, this bit field can be used to define the data shift mode and if hardware port control is enabled through CCR.HPCEN = 1, the pin direction when bypass data is transmitted. |
| 0 | [7:4], 9, 14, [31:24] | r | Reserved Read as 0; should be written with 0. |

18.11.9.2 General FIFO Buffer Control Registers

The transmit and receive FIFO status information of USICx_CHy is given in registers USICx_CHy.TRBSR.

The bits related to the transmitter buffer in this register can only be written if the transmit buffer functionality is enabled by CCFG.TB = 1, otherwise write accesses are ignored. A similar behavior applies for the bits related to the receive buffer referring to CCFG.RB = 1.

The interrupt flags (event flags) in the transmit and receive FIFO status register TRBSR can be cleared by writing a 1 to the corresponding bit position in register TRBSCR, whereas writing a 0 has no effect on these bits. Writing a 1 by software to SRBI, RBERI, ARBI, STBI, or TBERI sets the corresponding bit to simulate the detection of a transmit/receive buffer event, but without activating any service request output (therefore, see FMR.SIOx).

Bits TBUS and RBUS have been implemented for testing purposes. They can be ignored by data handling software. Please note that a read action can deliver either a 0 or a 1 for these bits. It is recommended to treat them as "don't care".

| RBERIEN | 31 | rw | Receive Buffer Error Interrupt Enable This bit enables/disables the generation of a receive buffer error interrupt in case of a receive buffer error event (the software reads from an empty receive buffer). 0_B The receive buffer error interrupt generation is disabled. 1_B The receive buffer error interrupt generation is enabled. |
| 0 | [7:6] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

18.11.9.5 FIFO Buffer Data Registers

The 32 independent data input locations IN00 to IN31 are addresses that can be used as data entry locations for the transmit FIFO buffer. Data written to one of these locations will be stored in the transmit buffer FIFO. Additionally, the 5-bit coding of the number [31:0] of the addressed data input location represents the transmit control information TCI.

If the FIFO is already full and new data is written to it, the write access is ignored and a transmit buffer error event is signaled.

INx (x = 00-31)

Transmit FIFO Buffer Input Location x

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| TDATA | [15:0] | w | Transmit Data This bit field contains the data to be transmitted (write view), read actions deliver 0. A write action to at least the low byte of TDATA triggers the data storage in the FIFO. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

The receiver FIFO buffer output register OUTR shows the oldest received data word in the FIFO buffer and contains the receiver control information RCI containing the information selected by RBCTR.RCIM. A read action from this address location delivers the received data. With a read access of at least the low byte, the data is declared to be read and the next entry becomes visible. Write accesses to OUTR are ignored.

OUTR

Receiver Buffer Output Register

(11C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|---|
| DSR | [15:0] | rh | Received Data This bit field monitors the content of the oldest data word in the receive FIFO. Reading at least the low byte releases the buffer entry currently shown in DSR. |
| RCI | [20:16] | rh | Receiver Control Information This bit field monitors the receiver control information associated to DSR. The bit structure of RCI depends on bit field RBCTR.RCIM. |
| 0 | [31:21] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

If a debugger should be used to monitor the received data in the FIFO buffer, the FIFO mechanism must not be activated in order to guaranty data consistency. Therefore, a second address set is available, named OUTDR (D like debugger), having the same bit fields like the original buffer output register OUTR, but without the FIFO mechanism. A debugger can read here (in order to monitor the receive data flow) without the risk of data corruption. Write accesses to OUTDR are ignored.

OUTDR

Receiver Buffer Output Register L for Debugger

(120_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DSR | [15:0] | rh | Data from Shift Register Same as OUTR.DSR, but without releasing the buffer after a read action. |
| RCI | [20:16] | rh | Receive Control Information from Shift Register Same as OUTR.RCI. |
| 0 | [31:21] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

18.11.9.6 FIFO Buffer Pointer Registers

The pointers for FIFO handling of the transmit and receive FIFO buffers are located in register TRBPTR. The pointers are automatically handled by the FIFO buffer mechanism and do not need to be modified by software. As a consequence, these registers can only be read by software (e.g. for verification purposes), whereas write accesses are ignored.

TRBPTR

Transmit/Receive Buffer Pointer Register

(110_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|---|------|---|
| TDIPTR | [5:0] | rh | Transmitter Data Input Pointer This bit field indicates the buffer entry that will be used for the next transmit data coming from the INx addresses. |
| TDOPTR | [13:8] | rh | Transmitter Data Output Pointer This bit field indicates the buffer entry that will be used for the next transmit data to be output to TBUF. |
| RDIPTR | [21:16] | rh | Receiver Data Input Pointer This bit field indicates the buffer entry that will be used for the next receive data coming from RBUF. |
| RDOPTR | [29:24] | rh | Receiver Data Output Pointer This bit field indicates the buffer entry that will be used for the next receive data to be output at the OUT(D)R addresses. |
| 0 | [7:6], [15:14], [23:22], [31:30] | r | Reserved Read as 0; should be written with 0. |

Universal Serial Interface Channel (USIC)

18.12 Interconnects

The XMC4[78]00 device contains three USIC modules (USIC0, USIC1 and USIC2) with 2 communication channels each.

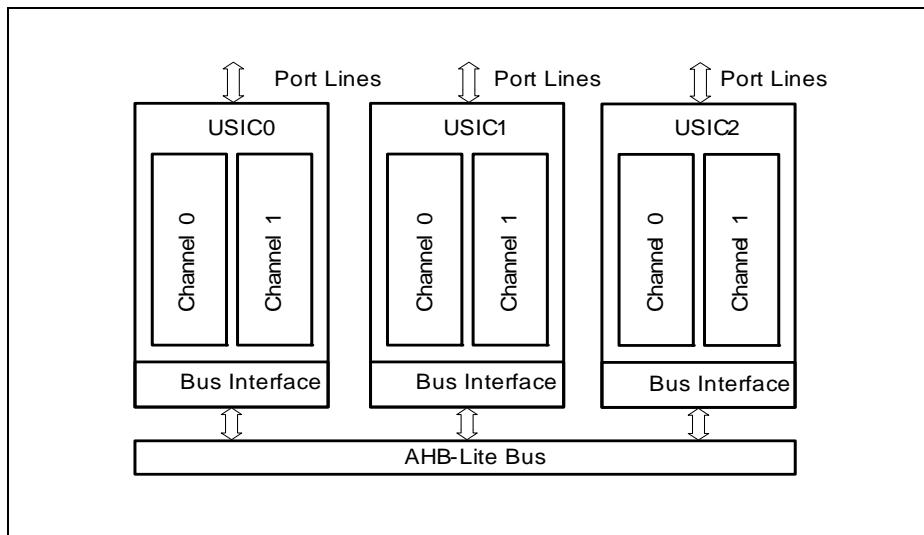

Figure 18-66 USIC Module Structure in XMC4[78]00

Figure 18-67 shows the I/O lines of one USIC channel. The tables in this section define the pin assignments and internal connections of the USIC channels I/O lines in the XMC4[78]00 device. Naming convention: USICx_CHy refers to USIC module x channel y.

The meaning of these pins with respect to each protocol is described in the protocols' respective chapters and summarized in [Table 18-2](#) and [Table 18-3](#).

Universal Serial Interface Channel (USIC)

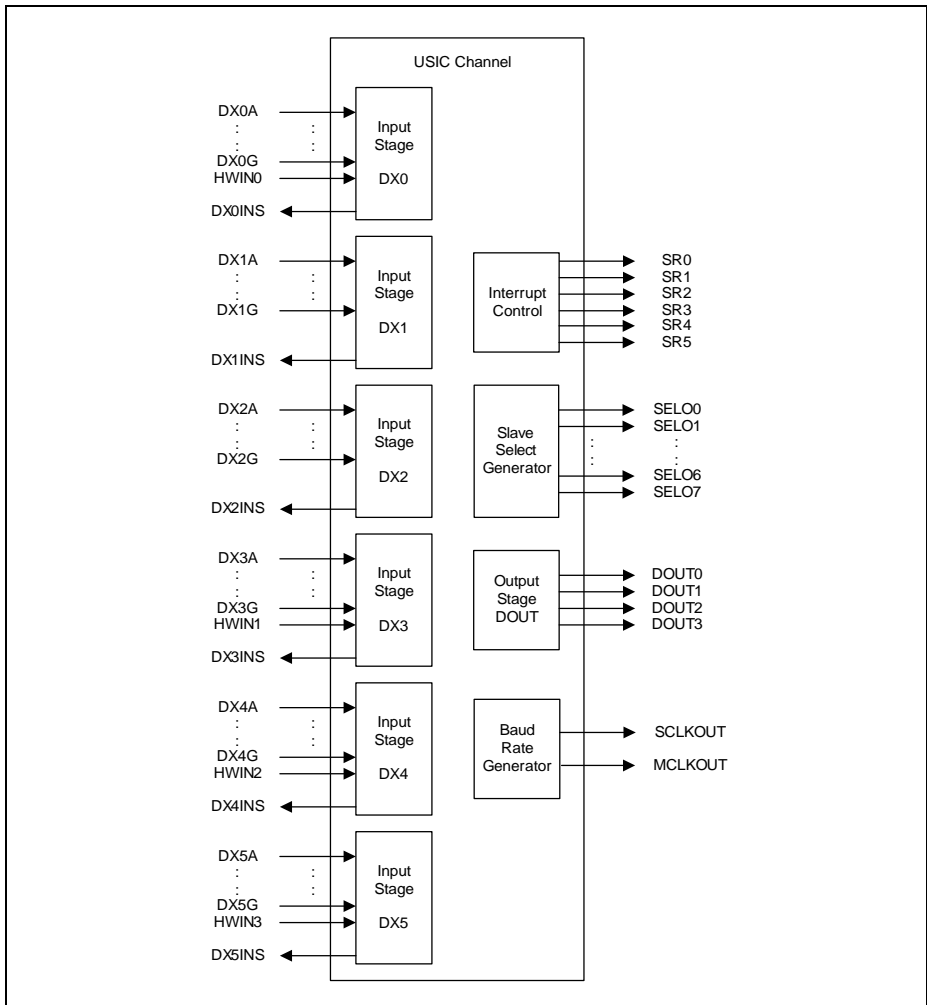

Figure 18-67 USIC Channel I/O Lines

The service request outputs SR[5:0] of one USIC channel is combined with those of the other channel with the module. Therefore, only 6 service request outputs are available per module.

18.12.1 USIC Module 0 Interconnects

The interconnects of USIC module 0 is grouped into the following categories:

Universal Serial Interface Channel (USIC)

- **USIC Module 0 Channel 0 Interconnects (Table 18-23)**
- **USIC Module 0 Channel 1 Interconnects (Table 18-24)**
- **USIC Module 0 Module Interconnects (Table 18-25)**

Table 18-23 USIC Module 0 Channel 0 Interconnects

18.12.3 USIC Module 2 Interconnects

The interconnects of USIC module 2 is grouped into the following three categories:

- **USIC Module 2 Channel 0 Interconnects (Table 18-29)**
- **USIC Module 2 Channel 1 Interconnects (Table 18-30)**
- **USIC Module 2 Module Interconnects (Table 18-31)**

19 Controller Area Network Controller (MultiCAN+)

This chapter describes the MultiCAN+ controller of the XMC4[78]00. It contains the following sections:

- CAN basics (see [Page 19-2](#))
- Overview of the CAN Module in the XMC4[78]00 (see [Page 19-10](#))
- Functional description of the MultiCAN+ Kernel (see [Page 19-13](#))
- MultiCAN+ Kernel register description (see [Page 19-57](#))
- XMC4[78]00 implementation-specific details (port connections and control, interrupt control, address decoding, clock control, see [Page 19-113](#)).

Table 19-1 Fixed Module Constants

| Constant | Description |
|---|---|
| n_objects | Number of Message Objects available. |
| n_interrupts | Number of Interrupt Output Lines available. |
| n_pendings n_pendingregs | Number of Message Pending Bits available. There are n_pendings/32 message pending registers. |
| n_lists | Number of Lists available for allocation of Message Objects. |
| n_nodes | Number of CAN Nodes available As each CAN node has its own list in addition to the list of un-allocated elements, the relation n_nodes < n_lists is true. |

19.1 CAN Basics

CAN is an asynchronous serial bus system with one logical bus line. It has an open, linear bus structure with equal bus participants called nodes. A CAN bus consists of two or more nodes.

The bus logic corresponds to a “wired-AND” mechanism. Recessive bits (equivalent to the logic 1 level) are overwritten by dominant bits (logic 0 level). As long as no bus node is sending a dominant bit, the bus is in the recessive state. In this state, a dominant bit from any bus node generates a dominant bus state. The maximum CAN bus speed is, by definition, 1 Mbit/s. This speed limits the CAN bus to a length of up to 40 m. For bus lengths longer than 40 m, the bus speed must be reduced.

The binary data of a CAN frame is coded in NRZ code (Non-Return-to-Zero). To ensure re-synchronization of all bus nodes, bit stuffing is used. This means that during the transmission of a message, a maximum of five consecutive bits can have the same polarity. Whenever five consecutive bits of the same polarity have been transmitted, the transmitter will insert one additional bit (stuff bit) of the opposite polarity into the bit stream before transmitting further bits. The receiver also checks the number of bits with the same polarity and removes the stuff bits from the bit stream (= destuffing).

19.1.1 Addressing and Bus Arbitration

In the CAN protocol, address information is defined in the identifier field of a message. The identifier indicates the contents of the message and its priority. The lower the binary value of the identifier, the higher is the priority of the message.

For bus arbitration, CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) is used. If bus node A attempts to transmit a message across the network, it first checks that the bus is in the idle state (“Carrier Sense”) i.e. no node is currently transmitting. If this is the case (and no other node wishes to start a transmission at the same moment), node A becomes the bus master and sends its message. All other nodes switch to receive mode during the first transmitted bit (Start-Of-Frame bit). After correct reception of the message (acknowledged by each node), each bus node checks the message identifier and stores the message, if required. Otherwise, the message is discarded.

If two or more bus nodes start their transmission at the same time (“Multiple Access”), bus collision of the messages is avoided by bit-wise arbitration (“Collision Detection / Non-Destructive Arbitration” together with the “Wired-AND” mechanism, dominant bits override recessive bits). Each node that sends also reads back the bus level. When a recessive bit is sent but a dominant one is read back, bus arbitration is lost and the transmitting node switches to receive mode. This condition occurs for example when the message identifier of a competing node has a lower binary value and therefore sends a message with a higher priority. In this way, the bus node with the highest priority message wins arbitration without losing time by having to repeat the message. Other nodes that lost arbitration will automatically try to repeat their transmission once the bus

Controller Area Network Controller (MultiCAN+)

returns to idle state. Therefore, the same identifier can be sent in a Data Frame only by one node in the system. There must not be more than one node programmed to send Data Frames with the same identifier.

Standard message identifier has a length of 11 bits. CAN specification 2.0B extended the message identifier lengths to 29 bits, i.e. the extended identifier. Both frame formats are part of the ISO 11898-1. The identifier is available for Classical CAN.

19.1.2 CAN Frame Types

There are three types of CAN frames:

- Data Frames
- Remote Frames
- Error Frames

A Data Frame for Classical CAN contains a Data Field of 0 to 8 bytes in length. A Remote Frame contains no Data Field and is typically generated as a request for data (e.g. from a sensor). Data and Remote Frames can use an 11-bit "Standard" identifier or a 29-bit "Extended" identifier. An Error Frame can be generated by any node that detects a CAN bus error.

19.1.2.1 Data Frames

There are two types of Data Frames defined (see [Figure 19-1](#)):

- 11bit ID Data Frame
- 29bit ID Data Frame

11-bit Data Frame (Classical CAN Format)

A Data Frame begins with the Start-Of-Frame bit (SOF = dominant level) for hard synchronization of all nodes. The SOF is followed by the Arbitration Field consisting of 12 bits, the 11-bit identifier (reflecting the contents and priority of the message), and the RTR (Remote Transmission Request for Classical CAN) bit. With RTR at dominant level, the frame is marked as Data Frame. With RTR at recessive level, the frame is defined as a Remote Frame.

The next field is the Control Field consisting of 6 bits. The first bit of this field is the IDE (Identifier Extension) bit and is at dominant level for the Standard Data Frame. The following bit is reserved and defined as a dominant bit. The remaining 4 bits of the Control Field are the Data Length Code (DLC) that specifies the number of bytes in the Data Field. The Data Field can be 0 to 8 bytes wide. The Cyclic Redundancy (CRC) Field that follows the data bytes is used to detect possible transmission errors. It consists of a 15-bit CRC sequence completed by a recessive CRC delimiter bit.

The final field is the Acknowledge Field. During the ACK Slot, the transmitting node sends out a recessive bit. Any node that has received an error free frame acknowledges

Controller Area Network Controller (MultiCAN+)

the correct reception of the frame by sending back a dominant bit, regardless of whether or not the node is configured to accept that specific message. This behavior assigns the CAN protocol to the “in-bit-response” group of protocols. The recessive ACK delimiter bit, which must not be overwritten by a dominant bit, completes the Acknowledge Field.

Seven recessive End-of-Frame (EOF) bits finish the Data Frame. Between any two consecutive frames, the bus must remain in the recessive state for at least 3 bit times (called Inter Frame Space). If after the Inter Frame Space, no other nodes attempt to transmit the bus remains in idle state with a recessive level.

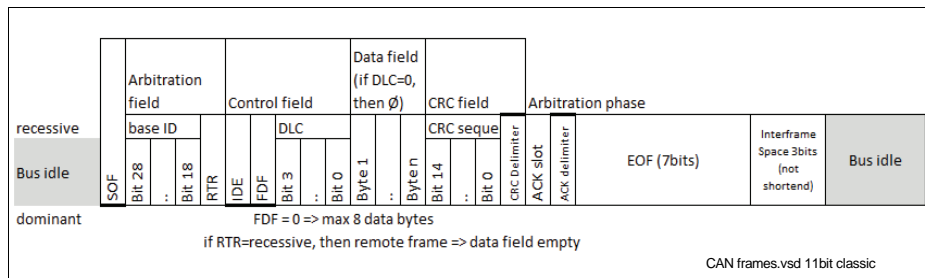

Figure 19-1 Classical 11-bit ID CAN Data Frame

Extended Data Frame (Classical CAN Format)

In the Extended CAN Data Frame, the message identifier of the standard frame has been extended to 29-bit. A split of the extended identifier into two parts, an 11-bit least significant section (as in classical CAN frame) and an 18-bit most significant section, ensures that the Identifier Extension bit (IDE) can remain at the same bit position in both standard and extended frames.

In the Extended CAN Data Frame, the SOF bit is followed by the 32-bit Arbitration Field. The first 11 bits are the least significant bits of the 29-bit Identifier (“Base-ID”). These 11 bits are followed by the recessive Substitute Remote Request (SRR) bit. The SRR is further followed by the recessive IDE bit, which indicates the frame to be an Extended CAN frame. If arbitration remains unresolved after transmission of the first 11 bits of the identifier, and if one of the nodes involved in arbitration is sending a classical CAN frame, then the CAN frame will win arbitration due to the assertion of its dominant IDE bit. Therefore, the SRR bit in an Extended CAN frame is recessive to allow the assertion of a dominant RTR bit by a node that is sending a CAN Remote Frame. The SRR and IDE bits are followed by the remaining 18 bits of the extended identifier and the RTR bit.

Control field and frame termination is identical to the Classical Data Frame.

Controller Area Network Controller (MultiCAN+)

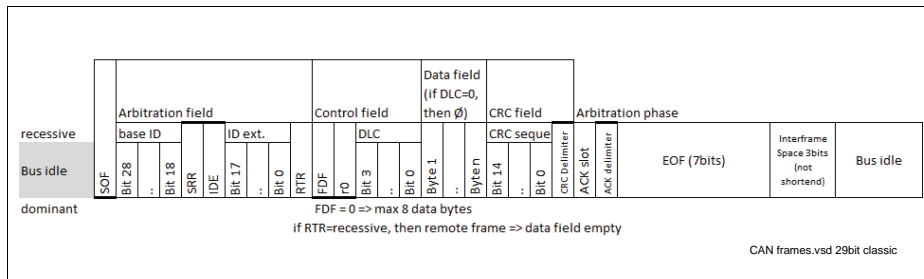

Figure 19-2 29 bit ID CAN Data Frame

19.1.2.2 Remote Frames

Normally, data transmission is performed on an autonomous basis with the data source node (e.g. a sensor) sending out a Data Frame. It is also possible, however, for a destination node (or nodes) to request the data from the source. For this purpose, the destination node sends a Remote Frame with an identifier that matches the identifier of the required Data Frame. The appropriate data source node will then send a Data Frame as a response to this remote request.

There are 2 differences between a Remote Frame and a Data Frame.

- The RTR bit is in the recessive state in a Remote Frame.
- There is no Data Field in a Remote Frame.

If a Data Frame and a Remote Frame with the same identifier are transmitted at the same time, the Data Frame wins arbitration due to the dominant RTR bit following the identifier. In this way, the node that transmitted the Remote Frame receives the requested data immediately.

19.1.2.3 Error Frames

An Error Frame is generated by any node that detects a bus error. An Error Frame consists of two fields, an Error Flag field followed by an Error Delimiter field. The Error Delimiter Field consists of 8 recessive bits and allows the bus nodes to restart bus communications after an error. There are, however, two forms of Error Flag fields. The form of the Error Flag field depends on the error status of the node that detects the error.

When an error-active node detects a bus error, the node generates an Error Frame with an active-error flag. The error-active flag is composed of six consecutive dominant bits that actively violate the bit-stuffing rule. All other stations recognize a bit-stuffing error and generate Error Frames themselves. The resulting Error Flag field on the CAN bus therefore consists of six to twelve consecutive dominant bits (generated by one or more nodes). The Error Delimiter field completes the Error Frame. After completion of the

Controller Area Network Controller (MultiCAN+)

Error Frame, bus activity returns to normal and the interrupted node attempts to re-send the aborted message.

If an error-passive node detects a bus error, the node transmits an error-passive flag followed, again, by the Error Delimiter field. The error-passive flag consists of six consecutive recessive bits, and therefore the Error Frame (for an error-passive node) consists of 14 recessive bits (i.e. no dominant bits). Therefore, the transmission of an Error Frame by an error-passive node will not affect any other node on the network, unless the bus error is detected by the node that is actually transmitting (i.e. the bus master). If the bus master node generates an error-passive flag, this may cause other nodes to generate Error Frames due to the resulting bit-stuffing violation. After transmission of an Error Frame an error-passive node must wait for 6 consecutive recessive bits on the bus before attempting to rejoin bus communications.

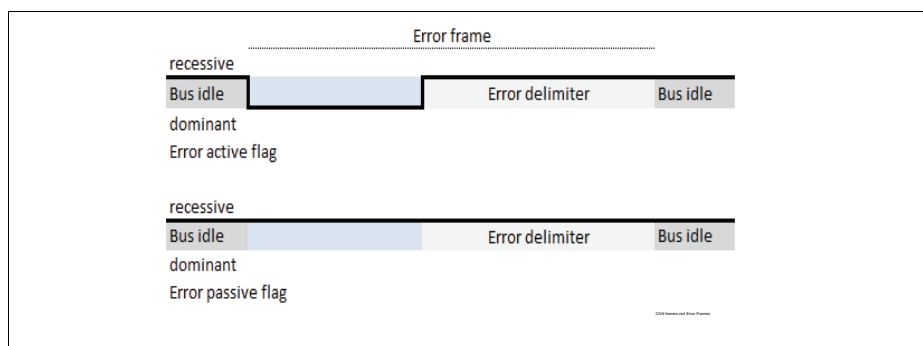

Figure 19-3 CAN Error Frames

19.1.3 The Nominal Bit Time

One bit cell (this means one high or low pulse of the NRZ code) is composed by four segments. Each segment is an integer multiple of Time Quanta t_Q . The Time Quanta is the smallest discrete timing resolution used by a CAN node. The nominal bit time definition with its segments is shown in [Figure 19-4](#).

Controller Area Network Controller (MultiCAN+)

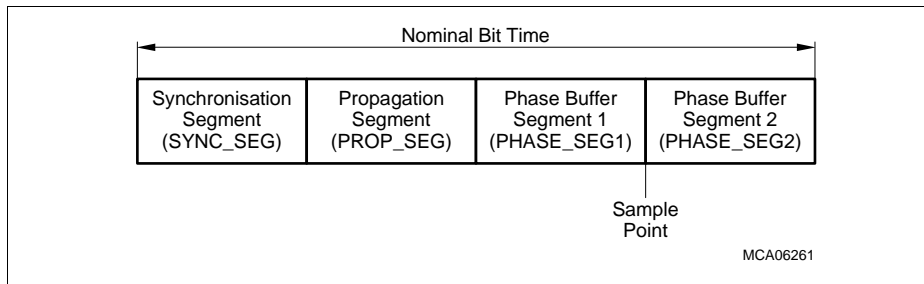

Figure 19-4 Partition of Nominal Bit Time

The Synchronization Segment (SYNC_SEG) is used to synchronize the various bus nodes. If there is a bit state change between the previous bit and the current bit, then the bus state change is expected to occur within this segment. The length of this segment is always $1 t_Q$.

The Propagation Segment (PROP_SEG) is used to compensate for signal delays across the network. These delays are caused by signal propagation delay on the bus line and through the electronic interface circuits of the bus nodes.

The Phase Segments 1 and 2 (PHASE_SEG1, PHASE_SEG2) are used to compensate for edge phase errors. These segments can be lengthened or shortened by re-synchronization. PHASE_SEG2 is reserved for calculation of the subsequent bit level, and is $\geq 2 t_Q$. At the sample point, the bus level is read and interpreted as the value of the bit cell. It occurs at the end of PHASE_SEG1.

The total number of t_Q in a bit time is between 8 and 25.

As a result of re-synchronization, PHASE_SEG1 can be lengthened or PHASE_SEG2 can be shortened. The amount of lengthening or shortening the phase buffer segments has an upper limit given by the re-synchronization jump width. The re-synchronization jump width may be between 1 and $4 t_Q$, but it may not be longer than PHASE_SEG1.

19.1.4 Error Detection and Error Handling

The CAN protocol has sophisticated error detection mechanisms. The following errors can be detected:

- **Cyclic Redundancy Check (CRC) Error**

With the CRC, the transmitter calculates special check bits for the bit sequence from the start of a frame until the end of the Data Field. This CRC sequence is transmitted in the CRC Field. The receiving node also calculates the CRC sequence using the same formula, and performs a comparison to the received sequence. If a mismatch is detected, a CRC error has occurred and an Error Frame is generated. The message is repeated.

Controller Area Network Controller (MultiCAN+)

- **Acknowledge Error**

In the Acknowledge Field of a message, the transmitter checks whether a dominant bit is read during the Acknowledge Slot (that is sent out as a recessive bit). If not, no other node has received the frame correctly, an Acknowledge Error has occurred, and the message must be repeated. No Error Frame is generated.

- **Form Error**

If a transmitter detects a dominant bit in one of the four segments End of Frame, Interframe Space, Acknowledge Delimiter, or CRC Delimiter, a Form Error has occurred, and an Error Frame is generated. The message is repeated.

- **Bit Error**

A Bit Error occurs if a) a transmitter sends a dominant bit and detects a recessive bit or b) if the transmitter sends a recessive bit and detects a dominant bit when monitoring the actual bus level and comparing it to the just transmitted bit. In case b), no error occurs during the Arbitration Field (ID, RTR, IDE) and the Acknowledge Slot.

- **Stuff Error**

If between Start of Frame and CRC Delimiter, six consecutive bits with the same polarity are detected, the bit-stuffing rule has been violated. A stuff error occurs and an Error Frame is generated. The message is repeated.

Detected errors are made public to all other nodes via Error Frames (except Acknowledge Errors). The transmission of the erroneous message is aborted and the frame is repeated as soon as possible. Furthermore, each CAN node is in one of the three error states (error-active, error-passive or bus-off) according to the value of the internal error counters. The error-active state is the usual state where the bus node can transmit messages and active-error frames (made of dominant bits) without any restrictions. In the error-passive state, messages and passive-error frames (made of recessive bits) may be transmitted. The bus-off state makes it temporarily impossible for the node to participate in the bus communication. During this state, messages can be neither received nor transmitted.

Basic CAN, Full CAN

There is one more CAN characteristic that is related to the interface of a CAN module (controller) and the host CPU: Basic-CAN and Full-CAN functionality.

In Basic-CAN devices, only basic functions of the protocol are implemented in hardware, such as the generation and the check of the bit stream. The decision, whether a received message has to be stored or not (acceptance filtering), and the complete message management must be done by software.

Full-CAN devices (this is the case for the MultiCAN+ controller as implemented in XMC4[78]00) manage the whole bus protocol in hardware, including the acceptance filtering and message management. Full-CAN devices contain message objects that handle autonomously the identifier, the data, the direction (receive or transmit) and the information of CAN operation. During the initialization of the device, the host CPU

Controller Area Network Controller (MultiCAN+)

determines which messages are to be sent and which are to be received. The host CPU is informed by interrupt if the identifier of a received message matches with one of the programmed (receive-) message objects. The CPU load of Full-CAN devices is greatly reduced. When using Full-CAN devices, high baud rates and high bus loads with many messages can be handled.

Normally, the CAN device also provides only one transmit buffer and one or two receive buffers. Therefore, the host CPU load is quite high when using Basic-CAN modules. The main advantage of Basic-CAN is a reduced chip size leading to low costs of these devices.

Controller Area Network Controller (MultiCAN+)

19.2 Overview

The MultiCAN+ module provides a communication interface which is fully compliant with CAN specification V2.0B (active), providing communications at up to 1 Mbit/s in Classical CAN (ISO 11898-1:2003(E) mode).

The MultiCAN+ module for the XMC4[78]00 consists of 1 module (i.e MultiCAN with 6 CAN nodes), representing 6 serial communication interfaces. Each CAN node communicates over two pins (TXD and RXD). The device ports which are used for TXD and RXD may be individually configured within the PORTS block. Several port configuration options are available to provide application-specific flexibility.

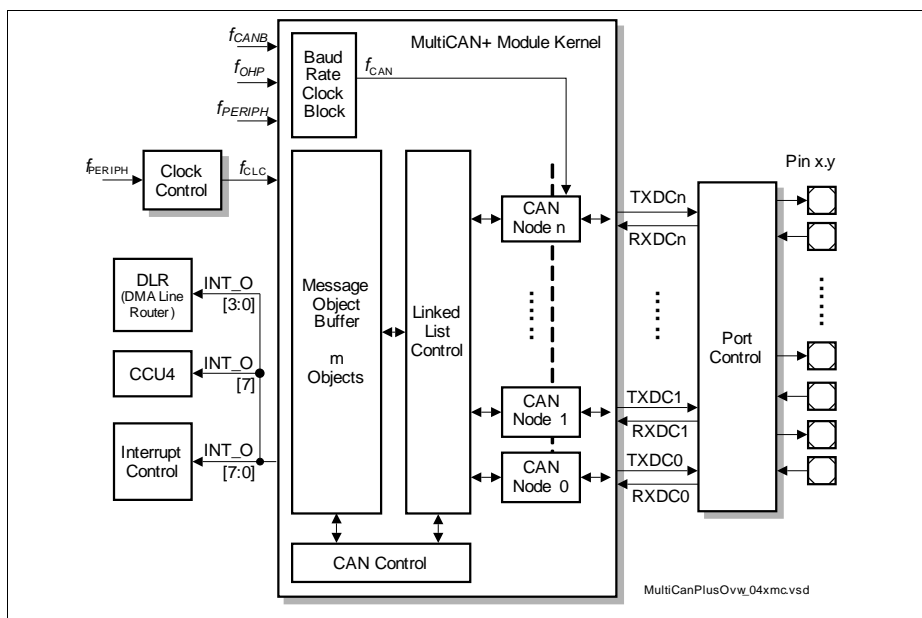

Figure 19-5 Overview of the MultiCAN+ Module. The module has 6 nodes and 256 objects. XMC4800

The MultiCAN+ module contains 6 independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

All CAN nodes share a common set of 256 message objects. Each message object can be individually allocated to one of the CAN nodes. Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

Controller Area Network Controller (MultiCAN+)

The message objects are organized in double-chained linked lists, where each CAN node has its own list of message objects. A CAN node stores frames only into message objects that are allocated to the message object list of the CAN node, and it transmits only messages belonging to this message object list. A powerful, command-driven list controller performs all message object list operations.

The bit timings for the CAN nodes are derived from the module timer clock (f_{CAN}) and are programmable up to a data rate of 1 Mbit/s. External bus transceivers are connected to a CAN node via a pair of receive and transmit pins.

19.2.1 Features List

The MultiCAN+ module provides the following features:

- Compliant with ISO 11898 and SAE J 1939
- CAN functionality according to CAN specification V2.0 B active
- Dedicated control registers for each CAN node
- Data transfer rates up to 1 Mbit/s
- Support for asynchronous clock sources for baud rate generation by providing separate frequency domain and input:
 - System frequency clock f_{CLC}
 - Direct oscillator clock (e.g. from ceramic resonator)
- Flexible and powerful message transfer control and error handling capabilities
- Advanced CAN bus bit timing analysis and baud rate detection for each CAN node via a frame counter
- Full-CAN functionality: A set of 256 message objects can be individually
 - Allocated (assigned) to any CAN node
 - Configured as transmit or receive object
 - Setup to handle frames with 11-bit or 29-bit identifier
 - Identified by a timestamp via a frame counter
 - Configured to remote monitoring mode
- Advanced Acceptance Filtering
 - Each message object provides an individual acceptance mask to filter incoming frames
 - A message object can be configured to accept standard or extended frames or to accept both standard and extended frames
 - Message objects can be grouped into different priority classes for transmission and reception
 - The selection of the message to be transmitted first can be based on frame identifier, IDE bit and RTR bit according to CAN arbitration rules, or on its order in the list
- Advanced CAN node features
 - Analyzer Mode supports monitoring of bus traffic without actively participating on the bus
 - Internal Loop-Back Mode is available for test purposes

Controller Area Network Controller (MultiCAN+)

- Data transmission from a node can be stopped without affecting reception
- Programmable minimum delay between two consecutive messages
- Advanced message object functionality
 - Message objects can be combined to build FIFO message buffers of arbitrary size, limited only by the total number of message objects
 - Message objects can be linked to form a gateway that automatically transfers frames between 2 different CAN buses. A single gateway can link any two CAN nodes. An arbitrary number of gateways can be defined
- Advanced data management
 - The message objects are organized in double-chained lists
 - List reorganizations can be performed at any time, even during full operation of the CAN nodes
 - A powerful, command-driven list controller manages the organization of the list structure and ensures consistency of the list
 - Message FIFOs are based on the list structure and can easily be scaled in size during CAN operation
- Advanced interrupt handling
 - Message interrupts, node interrupts can be generated
 - Interrupt requests can be routed individually to one of the 8 interrupt output lines
 - Message post-processing notifications can be combined flexibly into a dedicated register field of 256 notification bits

Controller Area Network Controller (MultiCAN+)

19.3 MultiCAN+ Kernel Functional Description

This section describes the functionality of the MultiCAN+ module.

19.3.1 Module Structure

Figure 19-6 shows the general structure of the MultiCAN+ module.

Figure 19-6 MultiCAN+ Block Diagram

CAN Nodes

Each CAN node consists of several sub-units.

- **Bitstream Processor**

The Bitstream Processor performs data, remote, error and overload frame processing according to the ISO 11898 standard. This includes conversion between the serial data stream and the input/output registers.

- **Bit Timing Unit**

The Bit Timing Unit determines the length of a bit time and the location of the sample point according to the user settings, taking into account propagation delays and phase shift errors. The Bit Timing Unit also performs resynchronization.

Controller Area Network Controller (MultiCAN+)

- **Error Handling Unit**

The Error Handling Unit manages the receive and transmit error counter. Depending on the contents of both counters, the CAN node is set into an error-active, error passive or bus-off state.

- **Node Control Unit**

The Node Control Unit coordinates the operation of the CAN node:

- Enable/disable CAN transfer of the node
- Enable/disable and generate node-specific events that lead to an interrupt request (CAN bus errors, successful frame transfers etc.)
- Administration of the frame counter

- **Interrupt Control Unit**

The Interrupt Control Unit in the CAN node controls the interrupt generation for the different conditions that can occur in the CAN node.

Message Controller

The Message Controller handles the exchange of CAN frames between the CAN nodes and the message objects that are stored in the Message RAM. The Message Controller performs several functions:

- Receive acceptance filtering to determine the correct message object for storing of a received CAN frame
- Transmit acceptance filtering to determine the message object to be transmitted first, individually for each CAN node
- Transfer contents between message objects and the CAN nodes, taking into account the status/control bits of the message objects
- Handling of the FIFO buffering and gateway functionality
- Aggregation of message-pending notification bits

List Controller

The List Controller performs all operations that lead to a modification of the double-chained message object lists. Only the list controller is allowed to modify the list structure. The allocation/deallocation or reallocation of a message object can be requested via a user command interface (command panel). The list controller state machine then performs the requested command autonomously.

Interrupt Control

The general interrupt structure is shown in **Figure 19-7**. The interrupt event can trigger the interrupt generation. The interrupt pulse is generated independently of the interrupt flag in the interrupt status register. The interrupt flag can be reset by software by writing a 0 to it.

Controller Area Network Controller (MultiCAN+)

If enabled by the related interrupt enable bit in the interrupt enable register, an interrupt pulse can be generated at one of the 8 interrupt output lines INT_Om of the MultiCAN+ module. If more than one interrupt source is connected to the same interrupt node pointer (in the interrupt node pointer register), the requests are combined to one common line.

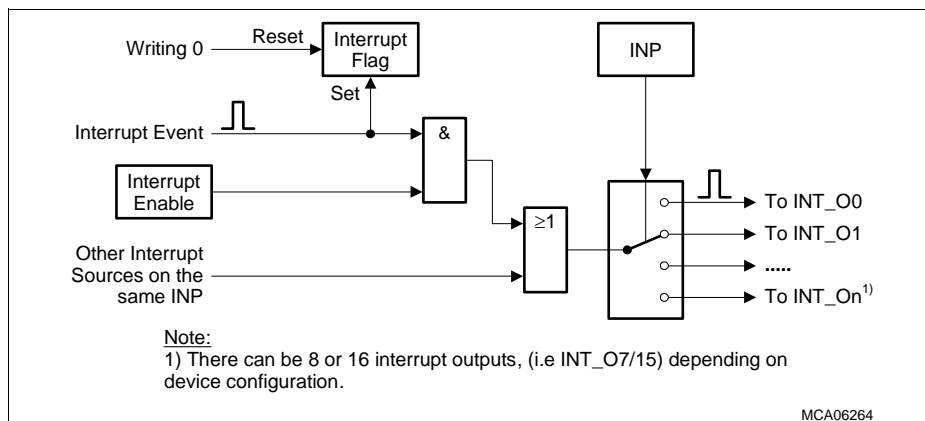

Figure 19-7 General Interrupt Structure

19.3.2 Clock Control

The CAN module timer clock f_{CAN} of the functional blocks of the MultiCAN+ module is derived from the synchronous clock source. The Fractional Divider is used to generate f_{CAN} used for bit timing calculation. The frequency of f_{CAN} is identical for all CAN nodes. The register file operates with the module control clock f_{CLC} . See also **“MultiCAN+ Clock Generation” on Page 19-16**.

The output clock f_{CAN} of the Fractional Divider is based on the clock f_A , but only every nth clock pulse is taken.

Controller Area Network Controller (MultiCAN+)

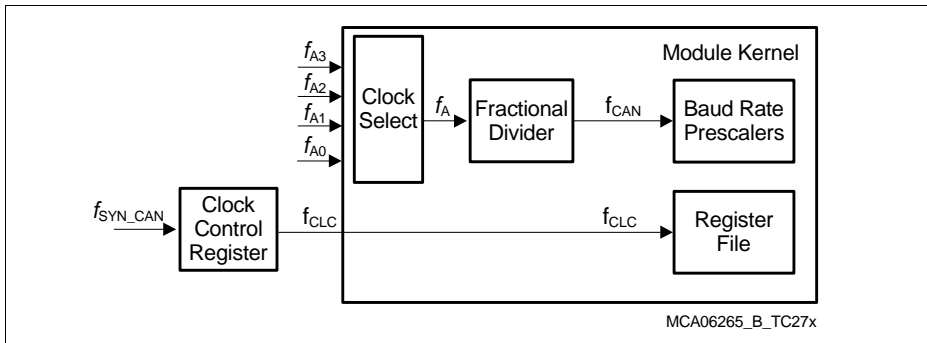

Figure 19-8 MultiCAN+ Clock Generation

The f_{SYN_CAN} is identical to f_{PERIPH} . f_{Ai} is the asynchronous clock input.

Table 19-2 indicates the minimum operating frequencies in MHz for f_{CLC} that are required for a baud rate of 1 Mbit/s for the active CAN nodes. If a lower baud rate is desired, the values can be scaled linearly (e.g. for a maximum of 500 kbit/s, 50% of the indicated value are required).

The values imply that the CPU (or DMA) executes maximum accesses to the MultiCAN+ module. The values may contain rounding effects.

Controller Area Network Controller (MultiCAN+)

Table 19-2 Minimum Operating Frequencies¹⁾ [MHz]

| Number of allocated message objects MO ²⁾ , | Number of Active CAN Nodes | | | | |
|--|----------------------------|----|----|----|----|
| | 1 | 2 | 3 | 4 | 5 |
| 16 MO | 12 | 19 | 26 | 33 | 40 |
| 32 MO | 15 | 23 | 30 | 37 | 44 |
| 64 MO | 21 | 28 | 37 | 46 | 53 |
| 128 MO | 40 | 45 | 50 | 55 | 61 |
| 256 MO | 72 | 77 | 82 | 88 | 93 |

1) In the case of 15 time quanta, the minimum operating frequency required is 15 MHz.

2) Only those message objects have to be taken into account that are allocated to a CAN node. The unallocated message objects have no influence on the minimum operating frequency.

The baud rate generation of the MultiCAN+ being based on f_A , this frequency has to be chosen carefully to allow correct CAN bit timing. The required value of f_A is given by an integer multiple (n) of the CAN baud rate multiplied by the number of time quanta per CAN bit time. For example, to reach 1 Mbit/s with 20 tq per bit time, possible values of f_A are given by formula $[n \times 20]$ MHz, with n being an integer value, starting at 1.

It is not advised to use fractional divider mode.

Additionally, for correct operation of the MultiCAN, the following conditions have to be fulfilled,

$$\text{Baudrate}_{\max} = [(8 \times T_{\text{CAN}}) + (8 \times T_{\text{CLC}}) + (4 \times \text{No. of active CAN nodes} \times T_{\text{CLC}})] \quad (19.1)$$

also

$$\text{NBTR.SJW} < \text{NBTR.TSEG1}$$

As an example, when $f_{\text{CLC}} = 10$ MHz, $f_{\text{CAN}} = 20$ MHz, No of active CAN nodes =2,
 $\text{Baudrate}_{\max} = [(8 \times 50 \text{ ns}) + (8 \times 100 \text{ ns}) + (4 \times 2 \times 100 \text{ ns})] = 2000 \text{ ns} = 500 \text{ kBaud}$

Table 19-3 below illustrates the minimum CAN module timer clock f_{CAN} and Module Control Clock f_{CLC} that's required to support a baudrate generation of 500 kBaud. If a higher baudrate is desired, the values need to be calculated as per **Equation (19.1)**.

Table 19-3 Minimum Operating Frequencies [MHz] required for 500kBaud

| No. of active CAN nodes | $f_{\text{CAN}} = f_{\text{CLC}}$ (MHz) | $f_{\text{CAN}} \neq f_{\text{CLC}}$ (MHz) | |
|-------------------------|--|---|------------------|
| | | f_{CAN} | f_{CLC} |

Controller Area Network Controller (MultiCAN+)

**Table 19-3 Minimum Operating Frequencies [MHz] required for 500kBaud
(cont'd)**

| | | | |
|---|----|----|----|
| 1 | 10 | 16 | 8 |
| | | 20 | 8 |
| | | 24 | 8 |
| | | 80 | 7 |
| 2 | 12 | 16 | 11 |
| | | 20 | 10 |
| | | 24 | 10 |
| | | 80 | 9 |
| 3 | 14 | 16 | 14 |
| | | 20 | 13 |
| | | 24 | 12 |
| | | 80 | 11 |

19.3.3 Port Input Control

It is possible to select the input lines for the RXDCx inputs for the CAN nodes. The selected input is connected to the CAN node and is also available to wake-up the system. More details are defined in [Section 19.6.4.2](#) on [Page 19-120](#).

19.3.4 CAN Node Control

Each CAN node may be configured and run independently of the other CAN node. Each CAN node is equipped with its own node control logic to configure the global behavior and to provide status information.

Note: In the following descriptions, index “x” stands for the node number and index “n” represents the message object number.

Configuration Mode is activated when bit NCRx.CCE is set to 1. This mode allows CAN bit timing parameters and the error counter registers to be modified.

CAN Analyzer Mode

CAN Analyzer Mode is activated when bit NCRx.CALM is set to 1. In this operation mode, Data And Remote Frames are monitored without active participation in any CAN transfer (CAN transmit pin is held on recessive level). Incoming Remote Frames are stored in a corresponding transmit message object, while arriving data frames are saved in a matching receive message object.

In CAN Analyzer Mode, the entire configuration information of the valid (including ACK) received frame is stored in the corresponding message object, and can be evaluated by the CPU to determine their identifier, IDE bit information and data length code (ID and DLC optionally if the Remote Monitoring Mode is active, bit MOFCRn.RMM = 1). Incoming frames are not acknowledged, and no Error Frames are generated. If CAN Analyzer Mode is enabled, Remote Frames are not responded to by the corresponding Data Frame, and Data Frames cannot be transmitted by setting the transmit request bit MOSTATn.TXRQ. Receive interrupts are generated in CAN Analyzer Mode (if enabled) for all error free received frames.

The node-specific interrupt configuration is also defined by the Node Control Logic via the NCRx register bits TRIE, ALIE and LECIE:

- If control bit TRIE is set to 1, a transfer interrupt is generated when the NSRx register has been updated (after each successfully completed message transfer).
- If control bit ALIE is set to 1, an alert interrupt is generated when a “bus-off” condition has been recognized or the Error Warning Level has been exceeded or under-run. Additionally, list or object errors lead to this type of interrupt.
- If control bit LECIE is set to 1, a last error code interrupt is generated when an error code > 0 is written into bit field NSRx.LEC by hardware.

Setting bit TXDIS in register NCRx stops the transmit activity of this node without affecting reception; bit CANDIS disables the node completely.

The Node x Status Register NSRx provides an overview about the current state of the respective CAN node x, comprising information about CAN transfers, CAN node status, and error conditions.

Controller Area Network Controller (MultiCAN+)

The CAN frame counter can be used to check the transfer sequence of message objects or to obtain information about the instant a frame has been transmitted or received from the associated CAN bus. CAN frame counting is performed by a 16-bit counter, controlled by register NFCRx. Bit fields NFCRx.CFMODE and NFCRx.CFSEL determine the operation mode and the trigger event incrementing the frame counter.

19.3.4.1 Bit Timing Unit

According to the ISO 11898 standard, a CAN bit time is subdivided into different segments (**Figure 19-9**). Each segment consists of multiples of a time quantum t_q . The magnitude of t_q is adjusted by Node x Bit Timing Register bit fields NBTRx.BRP and NBTRx.DIV8, both controlling the baud rate prescaler (register NBTRx is described on **Page 19-84**). The baud rate prescaler is driven by the module timer clock f_{CAN} (generation and control of f_{CAN} is described on **Page 19-115**).

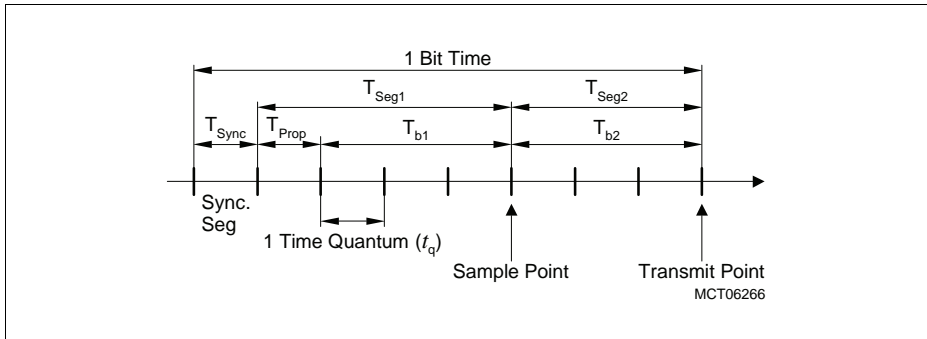

Figure 19-9 CAN Bus Bit Timing Standard

The Synchronization Segment (T_{Sync}) allows phase synchronization between transmitter and receiver time base. The Synchronization Segment length is always one t_q . The Propagation Time Segment (T_{Prop}) takes into account the physical propagation delay in the transmitter output driver on the CAN bus line and in the transceiver circuit. For a working collision detection mechanism, T_{Prop} must be two times the sum of all propagation delay quantities rounded up to a multiple of t_q . The phase buffer segments 1 and 2 (T_{b1} , T_{b2}) before and after the signal sample point are used to compensate for a mismatch between transmitter and receiver clock phases detected in the synchronization segment.

The maximum number of time quanta allowed for re-synchronization is defined by bit field NBTRx.SJW. The Propagation Time Segment and the Phase Buffer Segment 1 are combined to parameter T_{Seg1} , which is defined by the value NBTRx.TSEG1. A minimum of 3 time quanta is demanded by the ISO standard. Parameter T_{Seg2} , which is defined by the value of NBTRx.TSEG2, covers the Phase Buffer Segment 2. A minimum of 2 time

Controller Area Network Controller (MultiCAN+)

quanta is demanded by the ISO standard. According to ISO standard, a CAN bit time, calculated as the sum of T_{Sync} , T_{Seg1} and T_{Seg2} , must not fall below 8 time quanta.

Calculation of the bit time:

$$\begin{aligned}
 t_q &= (\text{BRP} + 1) / f_{\text{CAN}} && \text{if DIV8} = 0 \\
 &= 8 \times (\text{BRP} + 1) / f_{\text{CAN}} && \text{if DIV8} = 1 \\
 T_{\text{Sync}} &= 1 \times t_q \\
 T_{\text{Seg1}} &= (\text{TSEG1} + 1) \times t_q && (\text{min. } 3 t_q) \\
 T_{\text{Seg2}} &= (\text{TSEG2} + 1) \times t_q && (\text{min. } 2 t_q) \\
 \text{bit time} &= T_{\text{Sync}} + T_{\text{Seg1}} + T_{\text{Seg2}} && (\text{min. } 8 t_q)
 \end{aligned}$$

To compensate phase shifts between clocks of different CAN controllers, the CAN controller must synchronize on any edge from the recessive to the dominant bus level. The hard synchronization is enabled (at the start of frame), the bit time is restarted at the synchronization segment. Otherwise, the re-synchronization jump width T_{SJW} defines the maximum number of time quanta, a bit time may be shortened or lengthened by one re-synchronization. The value of SJW is defined by bit field NBTRx.SJW.

$$\begin{aligned}
 T_{\text{SJW}} &= (\text{SJW} + 1) \times t_q \\
 T_{\text{Seg1}} &\geq T_{\text{SJW}} + T_{\text{prop}} \\
 T_{\text{Seg2}} &\geq T_{\text{SJW}}
 \end{aligned}$$

The maximum relative tolerance for f_{CAN} depends on the Phase Buffer Segments, re-synchronization jump width and the bit time.

$$\begin{aligned}
 df_{\text{CAN}} &\leq \min(T_{b1}, T_{b2}) / [2 \times (13 \times \text{bit time} - T_{b2})] && \text{AND} \\
 df_{\text{CAN}} &\leq T_{\text{SJW}} / 20 \times \text{bit time}
 \end{aligned}$$

A valid CAN bit timing must be written to the CAN Node Bit Timing Register NBTR before resetting the INIT bit in the Node Control Register, i.e. before enabling the operation of the CAN node.

The Node Bit Timing Register may be written only if bit CCE (Configuration Change Enable) is set in the corresponding Node Control Register.

19.3.4.2 Bitstream Processor

Based on the message objects in the message buffer, the Bitstream Processor generates the remote and Data Frames to be transmitted via the CAN bus. It controls the

Controller Area Network Controller (MultiCAN+)

CRC generator and adds the checksum information to the new remote or Data Frame. After including the SOF bit and the EOF field, the Bitstream Processor starts the CAN bus arbitration procedure and continues with the frame transmission when the bus was found in idle state. While the data transmission is running, the Bitstream Processor continuously monitors the I/O line. If (outside the CAN bus arbitration phase or the acknowledge slot) a mismatch is detected between the voltage level on the I/O line and the logic state of the bit currently sent out by the transmit shift register, a CAN LEC error interrupt request is generated, and the error code is indicated by the Node x Status Register bit field NSRx.LEC.

The data consistency of an incoming frame is verified by checking the associated CRC field. When an error has been detected, a CAN LEC error interrupt request is generated and the associated error code is presented in the Node x Status Register NSRx. Furthermore, an Error Frame is generated and transmitted on the CAN bus. After decomposing a faultless frame into identifier and data portion, the received information is transferred to the message buffer executing remote and Data Frame handling, interrupt generation and status processing.

19.3.4.3 Error Handling Unit

The Error Handling Unit of a CAN node x is responsible for the fault confinement of the CAN device. Its two counters, the Receive Error Counter REC and the Transmit Error Counter TEC (bit fields of the Node x Error Counter Register NECNTx, see [Page 19-86](#)) are incremented and decremented by commands from the Bitstream Processor. If the Bitstream Processor itself detects an error while a transmit operation is running, the Transmit Error Counter is incremented by 8. An increment of 1 is used when the error condition was reported by an external CAN node via an Error Frame generation. For error analysis, the transfer direction of the disturbed message and the node that recognizes the transfer error are indicated for the respective CAN node x in register NECNTx. Depending on the values of the error counters, the CAN node is set into error-active, error-passive, or bus-off state.

The CAN node is in error-active state if both error counters are below the error-passive limit of 128. The CAN node is in error-passive state, if at least one of the error counters is equal to or greater than 128.

The bus-off state is activated if the Transmit Error Counter is equal to or greater than the bus-off limit of 256. This state is reported for CAN node x by the Node x Status Register flag NSRx.BOFF. The device remains in this state, until the “bus-off” recovery sequence is finished. Additionally, Node x Status Register flag NSRx.EWRN is set when at least one of the error counters is equal to or greater than the error warning limit defined by the Node x Error Count Register bit field NECNTx.EWRNLVL. Bit NSRx.EWRN is reset if both error counters fall below the error warning limit again (see [Page 19-75](#)).

19.3.4.4 CAN Frame Counter

Each CAN node is equipped with a frame counter that counts transmitted/received CAN frames or obtains information about the time when a frame has been started to transmit or be received by the CAN node. CAN frame counting/bit time counting is performed by a 16-bit counter that is controlled by Node x Frame Counter Register NFCRx (see [Page 19-87](#)). Bit field NFCRx.CFSEL determines the operation mode of the frame counter:

- **Frame Count Mode:**
After the successful transmission and/or reception of a CAN frame, the frame counter is copied into the CFCVAL bit field of the MOIPRn register of the message object involved in the transfer. Afterwards, the frame counter is incremented.
- **Time Stamp Mode:**
The frame counter is incremented (internally) with the beginning of a new bit time. Its value is permanently sampled in the CFC field while the bus is idle. The value sampled just before the SOF bit of a new frame is detected is written to the corresponding message object. When the treatment of a message object is finished, the sampling continues.
- **Bit Timing Mode:**
Used for baud rate detection and analysis of the bit timing ([Chapter 19.3.6.3](#)).
- **Error Count Mode:**
The frame counter is incremented when an error frame is received or an error is detected by the node (001_B to 110_B) (see [Table 19-9](#) for [Encoding of the LEC Bit field](#)). If the NFCRx.CFCIE interrupt bit is enabled, the NFCRx.CFCOV overflow flag will be set when the frame counter overflows. Configuration of CFSEL has no influence.

19.3.4.5 CAN Node Interrupts

Each CAN node has four hardware triggered interrupt request types that are able to generate an interrupt request upon:

- The successful transmission or reception of a frame
- A CAN protocol error with a last error code
- An alert condition: Transmit/receive error counters reach the warning limit, bus-off state changes, a List Length Error occurs, or a List Object Error occurs
- An overflow of the frame counter

Besides the hardware generated interrupts, software initiated interrupts can be generated using the Module Interrupt Trigger Register MITR. Writing a 1 to bit n of bit field MITR.IT generates an interrupt request signal on the corresponding interrupt output line INT_On. When writing MITR.IT more than one bit can be set resulting in activation of multiple INT_On interrupt output lines at the same time. See also [“Interrupt Control” on Page 19-122](#) for further processing of the CAN node interrupts.

Controller Area Network Controller (MultiCAN+)

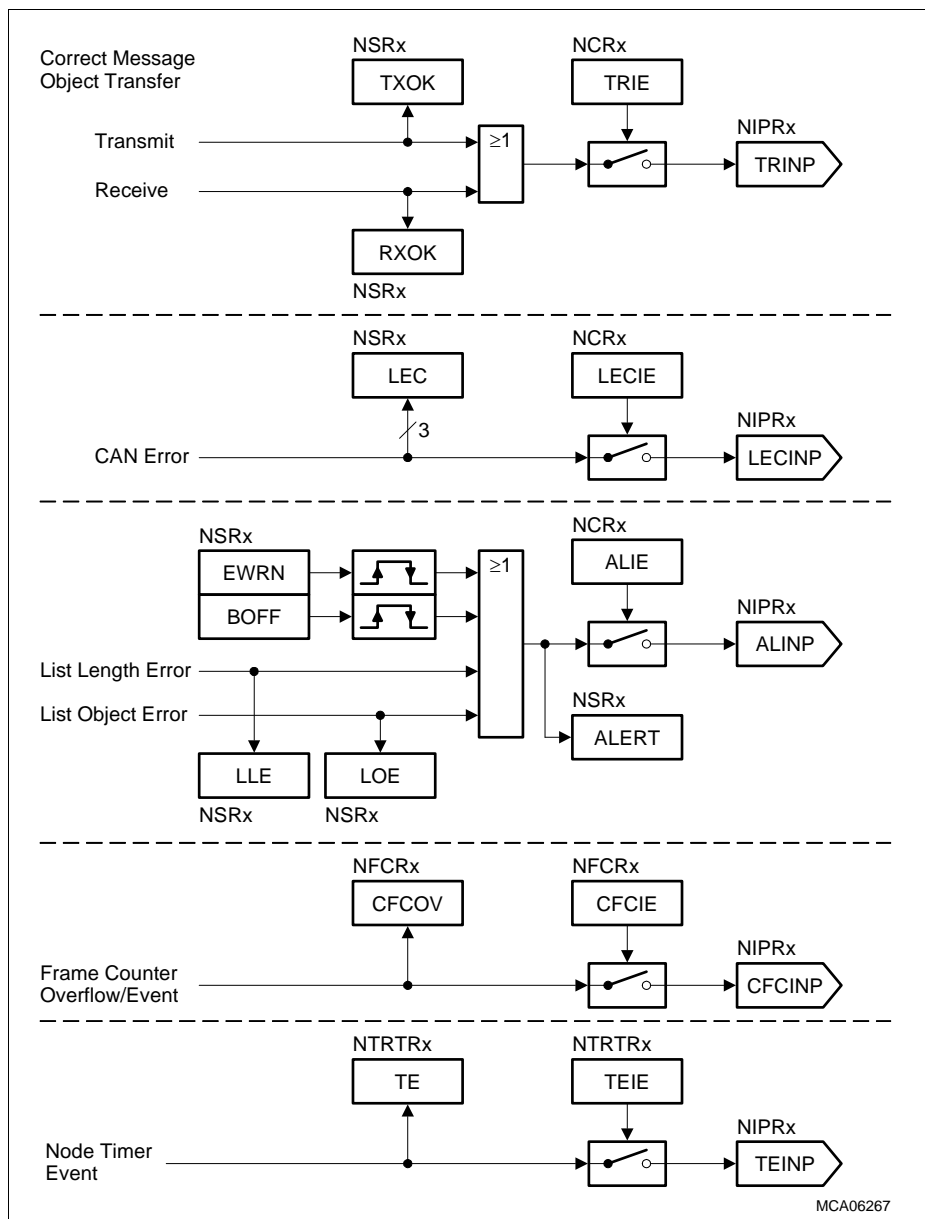

Figure 19-10 CAN Node Interrupts

19.3.5 Message Object List Structure

This section describes the structure of the message object lists in the MultiCAN+ module.

19.3.5.1 Basics

The message objects of the MultiCAN+ module are organized in double-chained lists, where each message object has a pointer to the previous message object in the list as well as a pointer to the next message object in the list. The MultiCAN+ module provides 16 lists. Each message object is allocated to one of these lists. In the example in **Figure 19-11**, the three message objects (3, 5, and 16) are allocated to the list with index 2 (List Register LIST2).

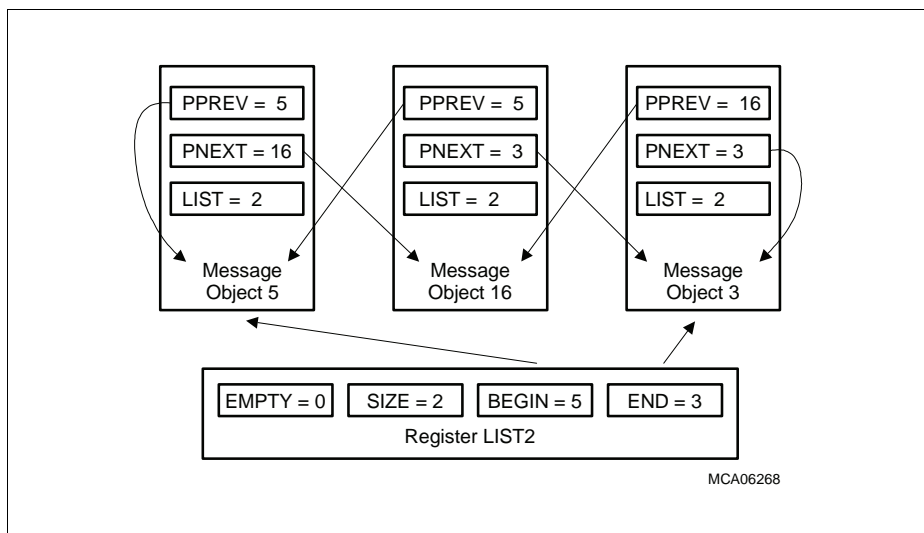

Figure 19-11 Example Allocation of Message Objects to a List

Bit field BEGIN in the List Register (for definition, see [Page 19-70](#)) points to the first element in the list (object 5 in the example), and bit field END points to the last element in the list (object 3 in the example). The number of elements in the list is indicated by bit field SIZE of the List Register (SIZE = number of list elements - 1, thus SIZE = 2 for the 3 elements in the example). The EMPTY bit of the List Register indicates whether or not a list is empty (EMPTY = 0 in the example, because list 2 is not empty).

Each message object *n* has a pointer PNEXT in its Message Object *n* Status Register MOSTAT_{*n*} (see [Page 19-95](#)) that points to the next message object in the list, and a pointer PPREV that points to the previous message object in the list. PPREV of the first message object points to the message object itself because the first message object has

Controller Area Network Controller (MultiCAN+)

no predecessor (in the example message object 5 is the first message object in the list, indicated by PPREV = 5). PNEXT of the last message object also points to the message object itself because the last message object has no successor (in the example, object 3 is the last message object in the list, indicated by PNEXT = 3).

Bit field MOSTATn.LIST indicates the list index number to which the message object is currently allocated to. The message objects of the example are allocated to list 2. Therefore, all LIST bit fields for the message objects assigned to list 2 are set to LIST = 2.

19.3.5.2 List of Unallocated Elements

The list with list index 0 has a special meaning: it is the list of all unallocated elements. An element is called unallocated if it belongs to list 0 (MOSTATn.LIST = 0). It is called allocated if it belongs to a list with an index not equal to 0 (MOSTATn.LIST > 0).

After reset, all message objects are unallocated. This means that they are assigned to the list of unallocated elements with MOSTATn.LIST = 0. After this initial allocation of the message objects caused by reset, the list of all unallocated message objects is ordered by message number (predecessor of message object n is object n-1, successor of object n is object n+1).

19.3.5.3 Connection to the CAN Nodes

Each CAN node is linked to one unique list of message objects. A CAN node performs message transfer only with the message objects that are allocated to the list of the CAN node. This is illustrated in [Figure 19-12](#). Frames that are received on a CAN node may only be stored in one of the message objects that belongs to the CAN node; frames to be transmitted on a CAN node are selected only from the message objects that are allocated to that node, as indicated by the vertical arrows.

There are more lists (16) than CAN nodes (6). This means that some lists are not linked to one of the CAN nodes. A message object that is allocated to one of these unlinked lists cannot receive messages directly from a CAN node and it may not transmit messages.

FIFO and gateway mechanisms refer to message numbers and not directly to a specific list. The user must take care that the message objects targeted by FIFO/gateway belong to the desired list. The mechanisms make it possible to work with lists that do not belong to the CAN node.

Controller Area Network Controller (MultiCAN+)

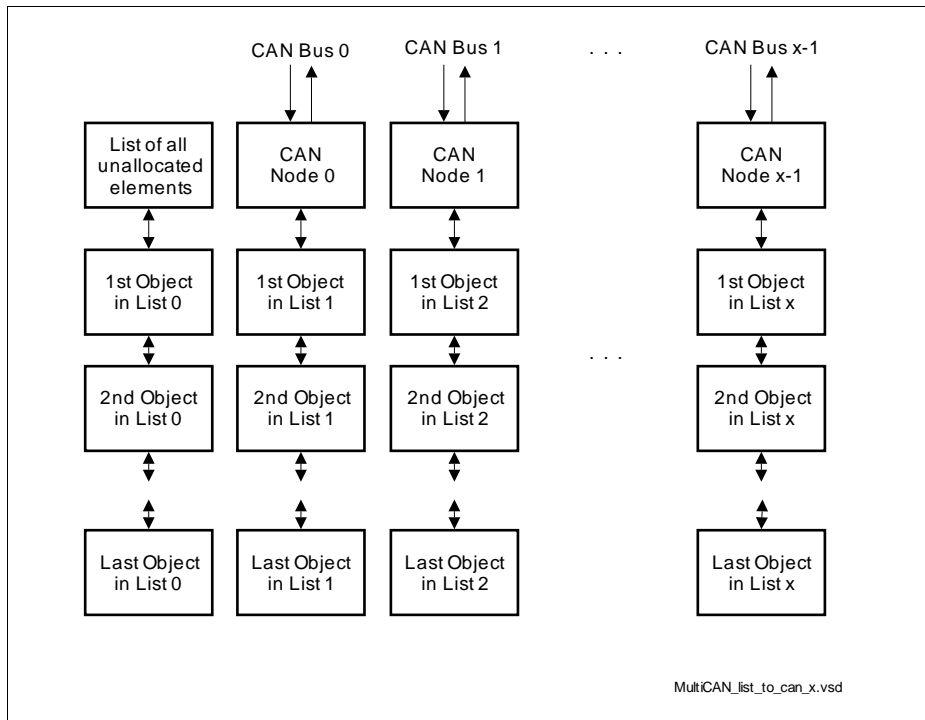

Figure 19-12 Message Objects Linked to CAN Nodes

19.3.5.4 List Command Panel

The list structure cannot be modified directly by write accesses to the LIST registers and the PPREV, PNEXT and LIST bit fields in the Message Object Status Registers, as they are read only. The list structure is managed by and limited to the list controller inside the MultiCAN+ module. The list controller is controlled via a command panel allowing the user to issue list allocation commands to the list controller. The list controller has two main purposes:

1. Ensure that all operations that modify the list structure result in a consistent list structure.
2. Present maximum ease of use and flexibility to the user.

The list controller and the associated command panel allows the programmer to concentrate on the final properties of the list, which are characterized by the allocation of message objects to a CAN node, and the ordering relation between objects that are allocated to the same list. The process of list (re-)building is done in the list controller.

Controller Area Network Controller (MultiCAN+)

Table 19-4 gives an overview on the available panel commands while **Table 19-8** on **Page 19-64** describes the panel commands in more detail.

Table 19-4 Panel Commands Overview

| Command Name | Description |
|------------------------------|--|
| No Operation | No new command is started. |
| Initialize Lists | Run the initialization sequence to reset the CTRL and LIST field of all message objects. |
| Static Allocate | Allocate message object to a list. |
| Dynamic Allocate | Allocate the first message object of the list of unallocated objects to the selected list. |
| Static Insert Before | Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. |
| Dynamic Insert Before | Insert a new message object before a given destination object. |
| Static Insert Behind | Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. |
| Dynamic Insert Behind | Insert a new message object behind a given destination object. |

A panel command is started by writing the respective command code into the Panel Control Register bit field PANCTR.PANCMD (see **Page 19-63**). The corresponding command arguments must be written into bit fields PANCTR.PANAR1 and PANCTR.PANAR2 before writing the command code, or latest along with the command code in a single 32-bit write access to the Panel Control Register.

With the write operation of a valid command code, the PANCTR.BUSY flag is set and further write accesses to the Panel Control Register are ignored. The BUSY flag remains active and the control panel remains locked until the execution of the requested command has been completed. After a reset and resetting the CLC.DISR (see **Page 19-117**) register, the list controller builds up list 0. Afterwards the BUSY bit is set, dependent on core speed this might be visible. During list controller initialization, BUSY is set and other accesses to the CAN RAM are forbidden. The CAN RAM can be accessed again when BUSY becomes inactive.

Note: The CAN RAM is automatically initialized after enabling the clocks of the module, by the list controller in order to ensure correct list pointers in each message object. The operation is indicated by automatically setting the BUSY bit. The end of this CAN RAM initialization is indicated by bit PANCTR.BUSY becoming inactive. It is

Controller Area Network Controller (MultiCAN+)

advised to initialize some registers within the CAN controller before polling the PANCTR.BUSY the first time.

In case of a dynamic allocation command that takes an element from the list of unallocated objects, the PANCTR.RBUSY bit is also set along with the BUSY bit (RBUSY = BUSY = 1). This indicates that bit fields PANAR1 and PANAR2 are going to be updated by the list controller in the following way:

1. The message number of the message object taken from the list of unallocated elements is written to PANAR1.
2. If ERR (bit 7 of PANAR2) is set to 1, the list of unallocated elements was empty and the command is aborted. If ERR is 0, the list was not empty and the command will be performed successfully.

The results of a dynamic allocation command are written before the list controller starts the actual allocation process. As soon as the results are available, RBUSY becomes inactive (RBUSY = 0) again, while BUSY still remains active until completion of the command. This allows the user to set up the new message object while it is still in the process of list allocation. The access to message objects is not limited during ongoing list operations. However, any access to a register resource located inside the RAM delays the ongoing allocation process by one access cycle.

As soon as the command is finished, the BUSY flag becomes inactive (BUSY = 0) and write accesses to the Panel Control Register are enabled again. Also, the "No Operation" command code is automatically written to the PANCTR.PANCMD field. A new command may be started any time when BUSY = 0.

All fields of the Panel Control Register PANCTR except BUSY and RBUSY may be written by the user. This makes it possible to save and restore the Panel Control Register if the Command Panel is used within independent (mutually interruptible) interrupt service routines. If this is the case, any task that uses the Command Panel and that may interrupt another task that also uses the Command Panel should poll the BUSY flag until it becomes inactive and save the whole PANCTR register to a memory location before issuing a command. At the end of the interrupt service routine, the task should restore PANCTR from the memory location.

Before a message object that is allocated to the list of an active CAN node shall be moved to another list or to another position within the same list, bit MOSTATn.MSGVAL ("Message Valid") of message object n must be cleared.

19.3.6 CAN Node Analyzer Mode

The chapter describes the CAN node analyzer capabilities of the MultiCAN+ module.

19.3.6.1 Analyzer Mode

The CAN Analyzer Mode makes it possible to monitor the CAN traffic for each CAN node individually without affecting the logical state of the CAN bus. The CAN Analyzer Mode for CAN node x is selected by setting Node x Control Register bit NCRx.CALM.

In CAN Analyzer Mode, the transmit pin of a CAN node is held at a recessive level permanently. The CAN node may receive frames (Data, Remote, and Error Frames) but is not allowed to transmit. Received Data/Remote Frames are not acknowledged (i.e. acknowledge slot is sent recessive) but will be received and stored in matching message objects as long as there is any other node that acknowledges the frame. The complete message object functionality is available, but no transmit request will be executed.

19.3.6.2 Loop-Back Mode

The MultiCAN+ module provides a Loop-Back Mode to enable an in-system test of the MultiCAN+ module as well as the development of CAN driver software without access to an external CAN bus.

The loop-back feature consists of an internal CAN bus (inside the MultiCAN+ module) and a bus select switch for each CAN node (see [Figure 19-13](#)). With the switch, each CAN node can be connected either to the internal CAN bus (Loop-Back Mode activated) or the external CAN bus, respectively to transmit and receive pins (normal operation). The CAN bus that is not currently selected is driven recessive; this means the transmit pin is held at 1, and the receive pin is ignored by the CAN nodes that are in Loop-Back Mode.

The Loop-Back Mode is selected for CAN node x by setting the Node x Port Control Register bit NPCRx.LBM. All CAN nodes that are in Loop-Back Mode may communicate together via the internal CAN bus without affecting the normal operation of the other CAN nodes that are not in Loop-Back Mode.

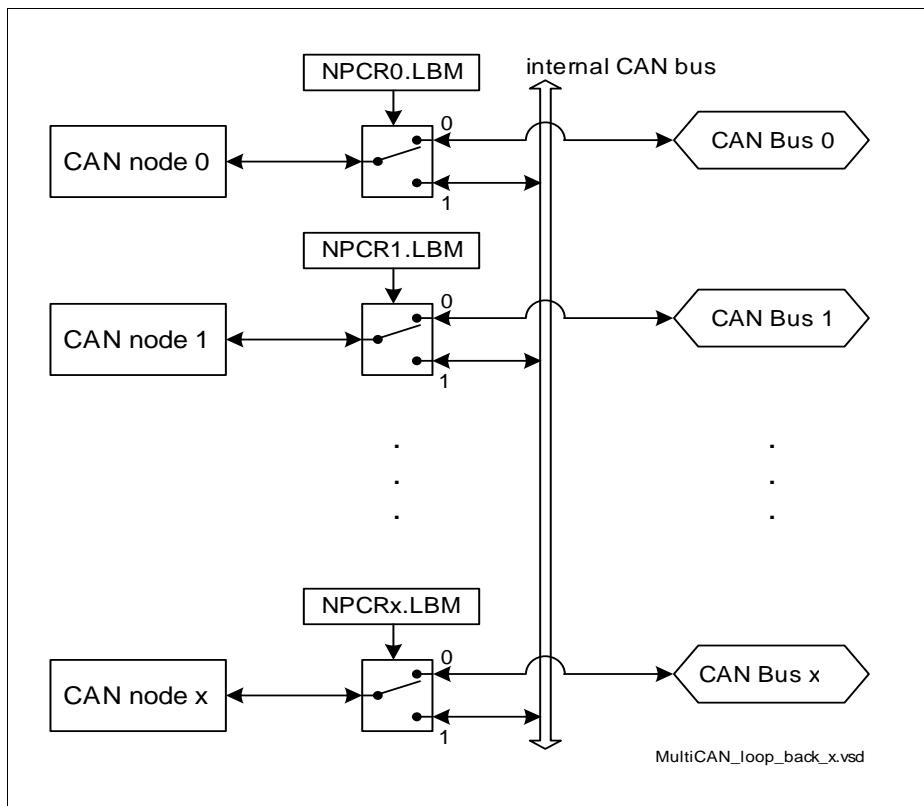

Figure 19-13 Loop-Back Mode

19.3.6.3 Bit Timing Analysis

Detailed analysis of the bit timing can be performed for each CAN node using the analysis modes of the CAN frame counter. The bit timing analysis functionality of the frame counter may be used for automatic detection of the CAN baud rate, as well as to analyze the timing of the CAN network.

Bit timing analysis for CAN node x is selected when bit field $NFCRx.CFMODE = 10_B$. Bit timing analysis does not affect the operation of the CAN node.

The bit timing measurement results are written into the $NFCRx.CFC$ bit field. Whenever $NFCRx.CFC$ is updated in bit timing analysis mode, bit $NFCRx.CFCOV$ is also set to indicate the CFC update event. The value of $NFCRx.CFC$ is valid one module cycle later when $NFCRx.CFCOV$ is set. If $NFCRx.CFCIE$ is set, an interrupt request can be generated (see [Figure 19-10](#)).

Automatic Baud Rate Detection

For automatic baud rate detection, the time between the observation of subsequent dominant edges on the CAN bus must be measured. This measurement is automatically performed if bit field $\text{NFCRx.CFSEL} = 000_{\text{B}}$. With each dominant edge monitored on the CAN receive input line, the time (measured in f_{CLC} clock cycles) between this edge and the most recent dominant edge is stored in the NFCRx.CFC bit field.

Synchronization Analysis

The bit time synchronization is monitored if $\text{NFCRx.CFSEL} = 010_{\text{B}}$. The time between the first dominant edge and the sample point is measured and stored in the NFCRx.CFC bit field. The bit timing synchronization offset may be derived from this time as the first edge after the sample point triggers synchronization and there is only one synchronization between consecutive sample points.

Synchronization analysis can be used, for example, for fine tuning of the baud rate during reception of the first CAN frame with the measured baud rate.

Driver Delay Measurement

The delay between a transmitted edge and the corresponding received edge is measured when $\text{NFCRx.CFSEL} = 011_{\text{B}}$ (dominant to dominant) and $\text{NFCRx.CFSEL} = 100_{\text{B}}$ (recessive to recessive). These delays indicate the time needed to represent a new bit value on the physical implementation of the CAN bus.

19.3.7 Message Acceptance Filtering

The chapter describes the Message Acceptance Filtering capabilities of the MultiCAN+ module.

19.3.7.1 Receive Acceptance Filtering

When a CAN frame is received by a CAN node, a unique message object is determined in which the received frame is stored after successful frame reception. A message object is qualified for reception of a frame if the following six conditions are met.

- The message object is allocated to the message object list of the CAN node by which the frame is received.
- Bit MOSTATn.MSGVAL in the Message Object Status Register (see [Page 19-95](#)) is set.
- Bit MOSTATn.RXEN is set.
- Bit MOSTATn.DIR is equal to bit RTR of the received frame.
 If bit $\text{MOSTATn.DIR} = 1$ (transmit object), the message object accepts only Remote Frames. If bit $\text{MOSTATn.DIR} = 0$ (receive object), the message object accepts only Data Frames.

Controller Area Network Controller (MultiCAN+)

- If bit MOAMRn.MIDE = 1, the IDE bit of the received frame becomes evaluated in the following way: If MOARn.IDE = 1, the IDE bit of the received frame must be set (indicates extended identifier). If MOARn.IDE = 0, the IDE bit of the received frame must be cleared (indicates standard identifier).
If bit MOAMRn.MIDE = 0, the IDE bit of the received frame is “don't care”. In this case, message objects with standard and extended frames are accepted.
- The identifier of the received frame matches the identifier stored in the Arbitration Register of the message object as qualified by the acceptance mask in the MOAMRn register. This means that each bit of the received message object identifier is equal to the bit field MOARn.ID, except those bits for which the corresponding acceptance mask bits in bit field MOAMRn.AM are cleared. These identifier bits are “don't care” for reception. **Figure 19-14** illustrates this receive message identifier check.

Among all messages that fulfill all six qualifying criteria the message object with the highest receive priority wins receive acceptance filtering and becomes selected to store the received frame. All other message objects lose receive acceptance filtering.

The following priority scheme is defined for the message objects:

A message object a (MOa) has higher receive priority than a message object b (MOb) if the following two conditions are fulfilled (see **Page 19-109**):

- MOa has a higher priority class than MOb. This means, the 2-bit priority bit field MOARa.PRI must be equal or less than bit field MOARb.PRI.
- If both message objects have the same priority class (MOARa.PRI = MOARb.PRI), MOb is a list successor of MOa. This means that MOb can be reached by means of successively stepping forward in the list, starting from a.

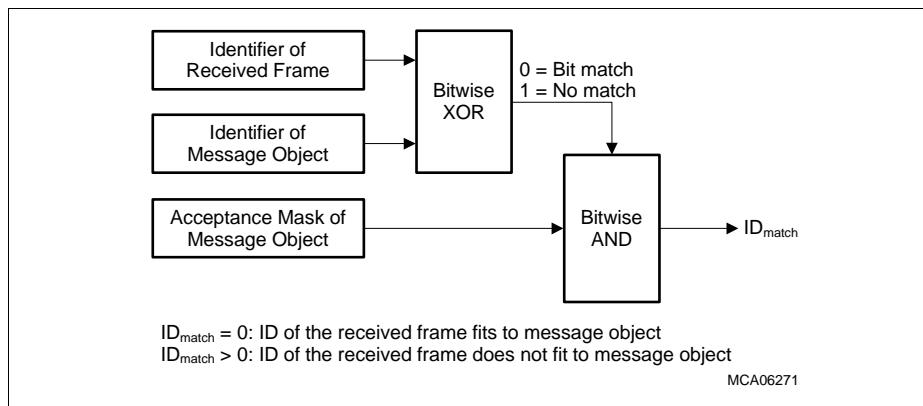

Figure 19-14 Received Message Identifier Acceptance Check

19.3.7.2 Transmit Acceptance Filtering

A message is requested for transmission by setting a transmit request in the message object that holds the message. If more than one message object have a valid transmit request for the same CAN node, one of these message objects is chosen for transmission, because only a single message object can be transmitted at one time on a CAN bus.

A message object is qualified for transmission on a CAN node if the following four conditions are met (see also [Figure 19-15](#)).

1. The message object is allocated to the message object list of the CAN node.
2. Bit MOSTATn.MSGVAL is set.
3. Bit MOSTATn.TXRQ is set.
4. Bit MOSTATn.TXEN0 and MOSTATn.TXEN1 are set.

A priority scheme determines which one of all qualifying message objects is transmitted first. It is assumed that message object a (MOa) and message object b (MOb) are two message objects qualified for transmission. MOb is a list successor of MOa. For both message objects, CAN messages CANa and CANb are defined (identifier, IDE, and RTR are taken from the message-specific bit fields and bits MOARn.ID, MOARn.IDE and MOSTATn.DIR).

If both message objects belong to the same priority class (identical PRI bit field in register MOARn), MOa has a higher transmit priority than MOb if one of the following conditions is fulfilled.

- $PRI = 10_B$ and CAN message MOa has higher or equal priority than CAN message MOb with respect to CAN arbitration rules (see [Table 19-14](#) on [Page 19-110](#)).
- $PRI = 01_B$ or $PRI = 11_B$ (priority by list order).
- $PRI = 00_B$ is reserved and makes the message object to have no function.

The message object that is qualified for transmission and has highest transmit priority wins the transmit acceptance filtering, and will be transmitted first. All other message objects lose the current transmit acceptance filtering round. They get a new chance in subsequent acceptance filtering rounds.

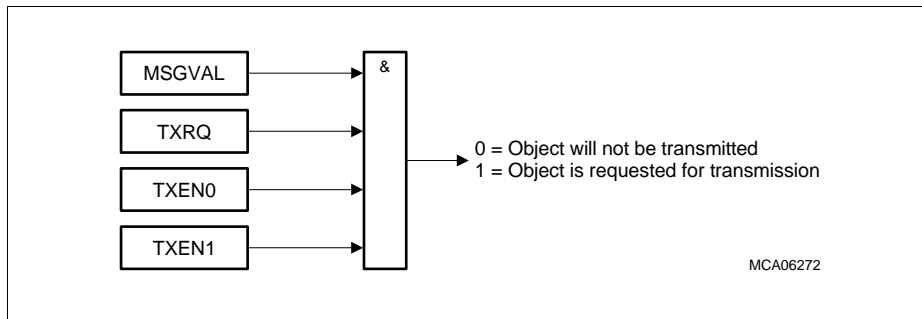

Figure 19-15 Effective Transmit Request of Message Object

19.3.8 Message Postprocessing

After a message object has successfully received or transmitted a frame, the CPU can be notified to perform a postprocessing on the message object. The postprocessing of the MultiCAN+ module consists of two elements:

1. Message interrupts to trigger postprocessing.
2. Message pending registers to collect pending message interrupts into a common structure for postprocessing.

19.3.8.1 Message Object Interrupts

When the storage of a received frame into a message object or the successful transmission of a frame is completed, a message interrupt can be issued. For each message object, a transmit and a receive interrupt can be generated and routed to one of the sixteen CAN interrupt output lines (see [Figure 19-16](#)). A receive interrupt occurs also after a frame storage event that has been induced by a FIFO or a gateway action. The status bits TXPND and RXPND in the Message Object n Status Register are always set after a successful transmission/reception, whether or not the respective message interrupt is enabled.

A third FIFO full interrupt condition of a message object is provided. If bit field MOFCRn.OVIE (Overflow Interrupt Enable) is set, the FIFO full interrupt will be activated depending on the actual message object type.

In case of a Receive FIFO Base Object (MOFCRn.MMC = 0001_B), the FIFO full interrupt is routed to the interrupt output line INT_Om as defined by the transmit interrupt node pointer MOIPRn.TXINP.

In case of a Transmit FIFO Base Object (MOFCRn.MMC = 0010_B), the FIFO full interrupt becomes routed to the interrupt output line INT_Om as defined by the receive interrupt node pointer MOIPRn.RXINP.

Controller Area Network Controller (MultiCAN+)

See also **“Interrupt Control” on Page 19-122** for further processing of the message object interrupts.

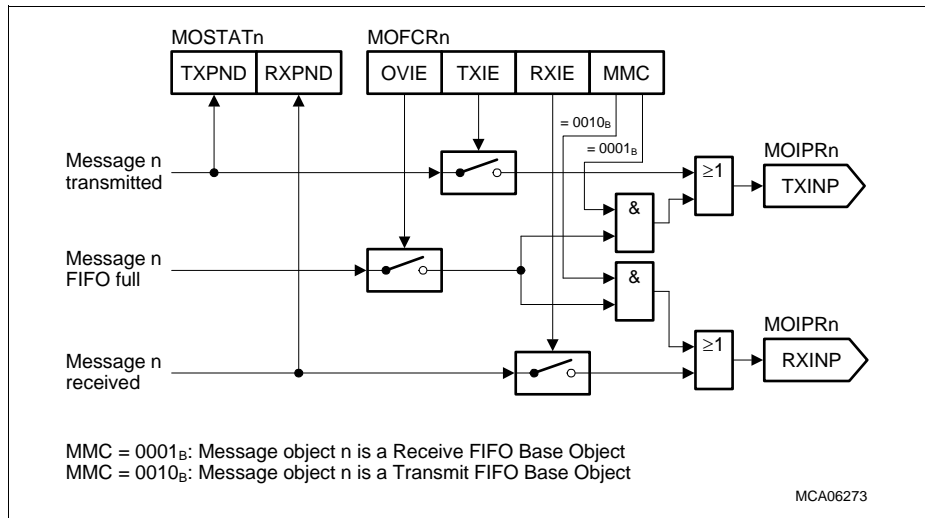

Figure 19-16 Message Interrupt Request Routing

19.3.8.2 Pending Messages

When a message interrupt request is generated, a message pending bit is set in one of the Message Pending Registers. There are 8 Message Pending Registers, MSPNDk (k = 0-7) with 32 pending bits available each. The general [Figure 19-17](#) shows the allocation of the message pending bits in case that the maximum possible number of eight Message Pending Registers are implemented and available on the chip.

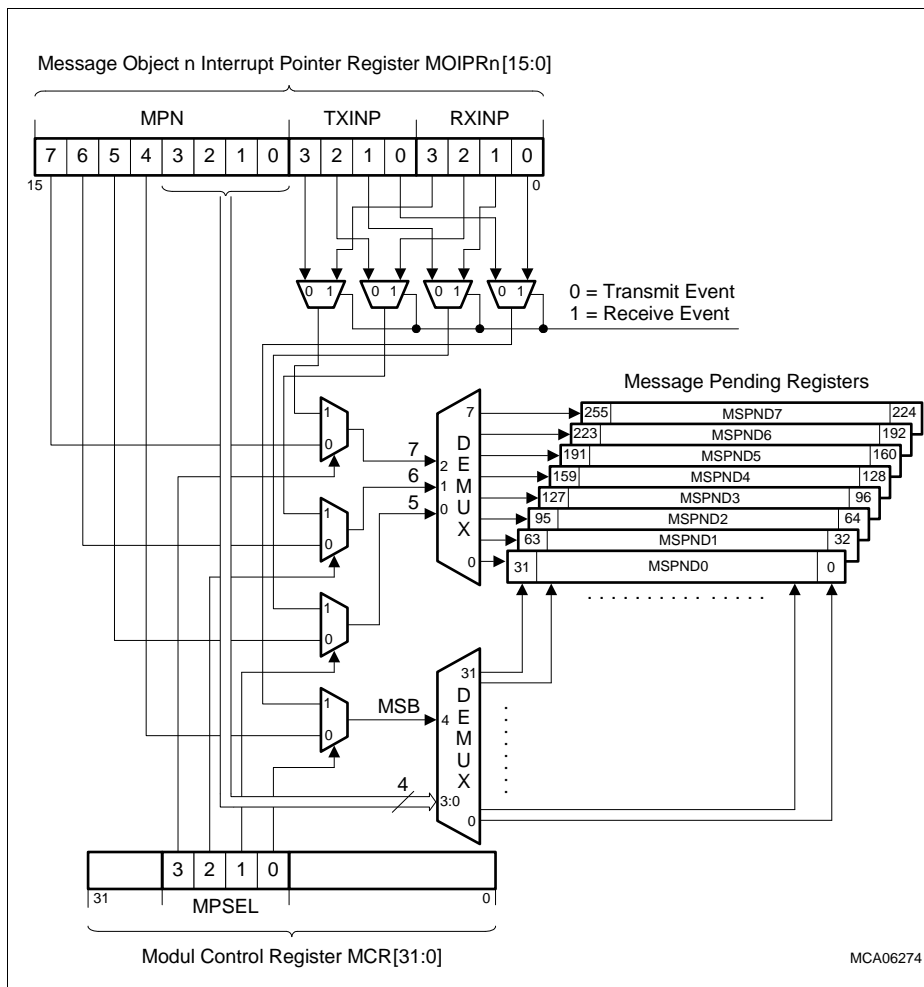

Figure 19-17 Message Pending Bit Allocation

Controller Area Network Controller (MultiCAN+)

The location of a pending bit is defined by two demultiplexers selecting the number k of the MSPND k registers (3-bit demux), and the bit location within the corresponding MSPND k register (5-bit demux).

Allocation Case 1

In this allocation case, bit field MCR.MPSEL = 0000_B (see [Page 19-67](#)). The location selection consists of 2 parts:

- The upper three bits of MOIPR n .MPN (MPN[7:5]) select the number k of a Message Pending Register MSPND k in which the pending bit will be set.
- The lower five bits of MOIPR n .MPN (MPN[4:0]) select the bit position (0-31) in MSPND k for the pending bit to be set.

Allocation Case 2

In this allocation case, bit field MCR.MPSEL is taken into account for pending bit allocation. Bit field MCR.MPSEL makes it possible to include the interrupt request node pointer for reception (MOIPR n .RXINP) or transmission (MOIPR n .TXINP) for pending bit allocation in such a way that different target locations for the pending bits are used in receive and transmit case. If MPSEL = 1111_B, the location selection operates in the following way:

- At a transmit event, the upper 3 bits of TXINP determine the number k of a Message Pending Register MSPND k in which the pending bit will be set. At a receive event, the upper 3 bits of RXINP determine the number k .
- The bit position (0-31) in MSPND k for the pending bit to be set is selected by the lowest bit of TXINP or RXINP (selects between low and high half-word of MSPND k) and the four least significant bits of MPN.

General Hints

The Message Pending Registers MSPND k can be written by software. Bits that are written with 1 are left unchanged, and bits which are written with 0 are cleared. This makes it possible to clear individual MSPND k bits with a single register write access. Therefore, access conflicts are avoided when the MultiCAN+ module (hardware) sets another pending bit at the same time when software writes to the register.

Each Message Pending Register MSPND k is associated with a Message Index Register MSID k (see [Page 19-73](#)) which indicates the lowest bit position of all set (1) bits in Message Pending Register k . The MSID k register is a read-only register that is updated immediately when a value in the corresponding Message Pending Register k is changed by software or hardware.

19.3.9 Message Object Data Handling

This chapter describes the handling capabilities for the Message Object Data of the MultiCAN+ module.

19.3.9.1 Frame Reception

After the reception of a message, it is stored in a message object according to the scheme shown in **Figure 19-18**. The MultiCAN+ module not only copies the received data into the message object, and it provides advanced features to enable consistent data exchange between MultiCAN+ and CPU.

MSGVAL

Bit MSGVAL (Message Valid) in the Message Object n Status Register MOSTATn is the main switch of the message object. During the frame reception, information is stored in the message object only when MSGVAL = 1. If bit MSGVAL is reset by the CPU, the MultiCAN+ module stops all ongoing write accesses to the message object. Now the message object can be re-configured by the CPU with subsequent write accesses to it without being disturbed by the MultiCAN+.

RTSEL

When the CPU re-configures a message object during CAN operation (for example, clears MSGVAL, modifies the message object and sets MSGVAL again), the following scenario can occur:

1. The message object wins receive acceptance filtering.
2. The CPU clears MSGVAL to re-configure the message object.
3. The CPU sets MSGVAL again after re-configuration.
4. The end of the received frame is reached. As MSGVAL is set, the received data is stored in the message object, a message interrupt request is generated, gateway and FIFO actions are processed, etc.

After the re-configuration of the message object (after step 3 above) the storage of further received data may be undesirable. This can be achieved through bit MOSTATn.RTSEL (Receive/Transmit Selected) that makes it possible to disconnect a message object from an ongoing frame reception.

When a message object wins the receive acceptance filtering, its RTSEL bit is set by the MultiCAN+ module to indicate an upcoming frame delivery. The MultiCAN+ module checks RTSEL whether it is set on successful frame reception to verify that the object is still ready for receiving the frame. The received frame is then stored in the message object (along with all subsequent actions such as message interrupts, FIFO & gateway actions, flag updates) only if RTSEL = 1.

When a message object is invalidated during CAN operation (resetting bit MSGVAL), RTSEL should be cleared before setting MSGVAL again (latest with the same write

Controller Area Network Controller (MultiCAN+)

access that sets MSGVAL) to prevent the storage of a frame that belongs to the old context of the message object. Therefore, a message object re-configuration should consist of the following steps:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL bit and set MSGVAL again

RXEN

Bit MOSTATn.RXEN enables a message object for frame reception. A message object can receive CAN messages from the CAN bus only if RXEN = 1. The MultiCAN+ module evaluates RXEN only during receive acceptance filtering. After receive acceptance filtering, RXEN is ignored and has no further influence on the actual storage of a received message in a message object.

Bit RXEN enables the “soft phase out” of a message object: after clearing RXEN, a currently received CAN message for which the message object has won acceptance filtering is still stored in the message object but for subsequent messages the message object no longer wins receive acceptance filtering.

RXUPD, NEWDAT and MSGLST

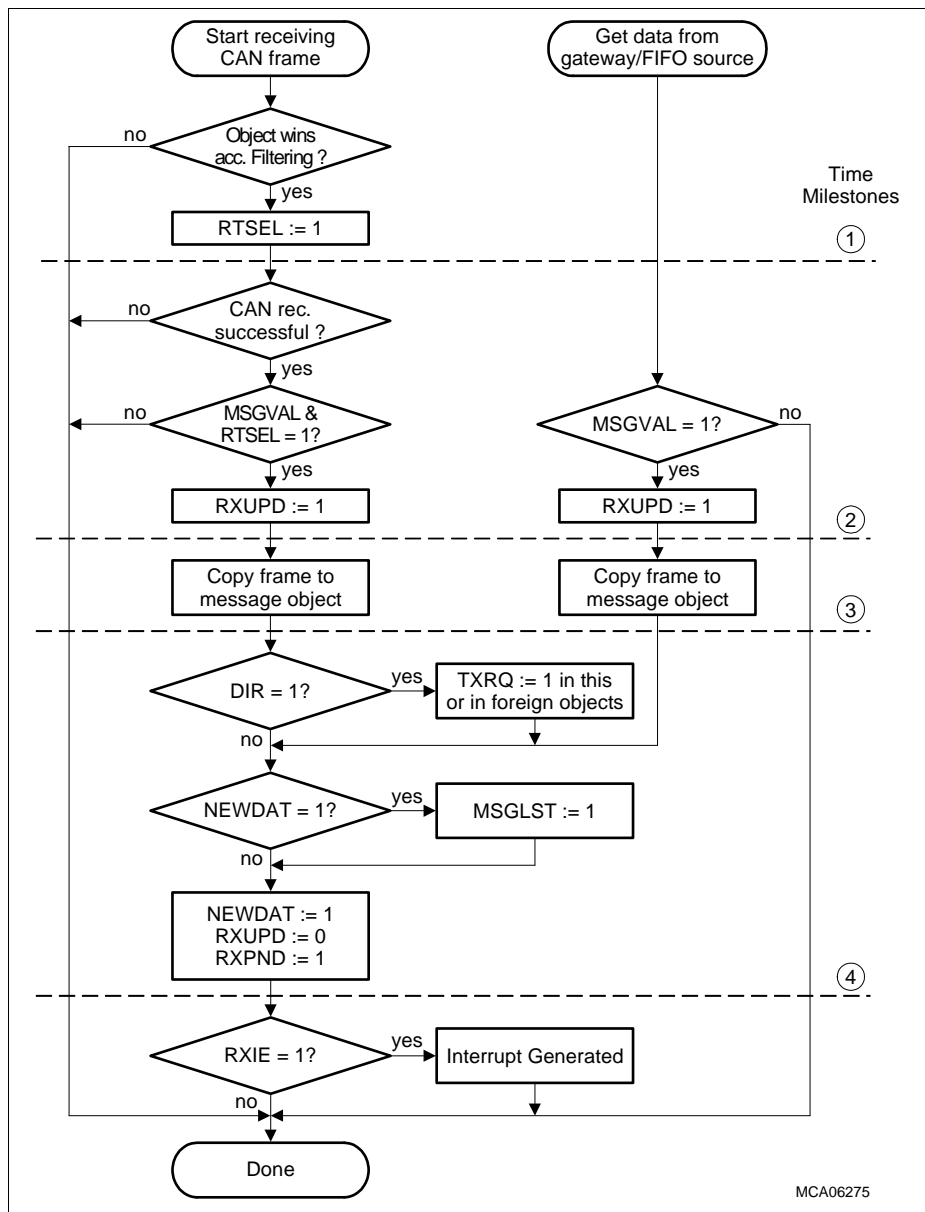

An ongoing frame storage process is indicated by the RXUPD (Receive Updating) flag in the MOSTATn register. RXUPD is set with the start and cleared with the end of a message object update, which consists of frame storage as well as flag updates.

After storing the received frame (identifier, IDE bit, DLC; including the Data Field for Data Frames), the NEWDAT (New Data) bit of the message object is set. If NEWDAT was already set before it becomes set again, bit MSGLST (Message Lost) is set to indicate a data loss condition.

The RXUPD and NEWDAT flags can help to read consistent frame data from the message object during an ongoing CAN operation. The following steps are recommended to be executed:

1. Clear NEWDAT bit.
2. Read message content (identifier, data etc.) from the message object.
3. Check that both, NEWDAT and RXUPD, are cleared. If this is not the case, go back to step 1.
4. When step 3 was successful, the message object contents is consistent and has not been updated by the MultiCAN+ module while reading.

Bits RXUPD, NEWDAT and MSGLST have the same behavior for the reception of Data as well as Remote Frames.

MCA06275

Figure 19-18 Reception of a Message Object

19.3.9.2 Frame Transmission

The process of a message object transmission is shown in [Figure 19-19](#). Along with the copy of the message object content to be transmitted (identifier, IDE bit, RTR = DIR bit, DLC, including the Data Field for Data Frames) into the internal transmit buffer of the assigned CAN node, several status flags are also served and monitored to control consistent data handling.

The transmission process of a message object starting after the transmit acceptance filtering is identical for Remote and Data Frames.

MSGVAL, TXRQ, TXEN0, TXEN1

A message can only be transmitted if all four bits in registers MOSTATn, MSGVAL (Message Valid), TXRQ (Transmit Request), TXEN0 (Transmit Enable 0), TXEN1 (Transmit Enable 1) are set as shown in [Figure 19-15](#). Although these bits are equivalent with respect to the transmission process, they have different semantics:

Table 19-5 Message Transmission Bit Definitions

| Bit | Description |
|---------------|---|
| MSGVAL | Message Valid This is the main switch bit of the message object. |
| TXRQ | Transmit Request This is the standard transmit request bit. This bit must be set whenever a message object should be transmitted. TXRQ is cleared by hardware at the end of a successful transmission, except when there is new data (indicated by NEWDAT = 1) to be transmitted. When bit MOFCRn.STT ("Single Transmit Trial") is set, TXRQ becomes already cleared when the contents of the message object are copied into the transmit frame buffer of the CAN node. A received remote request (after a Remote Frame reception) sets bit TXRQ to request the transmission of the requested data frame. |
| TXEN0 | Transmit Enable 0 This bit can be temporarily cleared by software to suppress the transmission of this message object when it writes new content to the Data Field. This avoids transmission of inconsistent frames that consist of a mixture of old and new data. Remote requests are still accepted when TXEN0 = 0, but transmission of the Data Frame is suspended until transmission is re-enabled by software (setting TXEN0). |

Controller Area Network Controller (MultiCAN+)

Table 19-5 Message Transmission Bit Definitions (cont'd)

| Bit | Description |
|--------------|---|
| TXEN1 | Transmit Enable 1 This bit is used in transmit FIFOs to select the message object that is transmit active within the FIFO structure. For message objects that are not transmit FIFO elements, TXEN1 can either be set permanently to 1 or can be used as a second independent transmission enable bit. |

RTSEL

When a message object has been identified to be transmitted next after transmission acceptance filtering, bit MOSTATn.RTSEL (Receive/Transmit Selected) is set.

When the message object is copied into the internal transmit buffer, bit RTSEL is checked, and the message is transmitted only if RTSEL = 1. After the successful transmission of the message, bit RTSEL is checked again and the message postprocessing is only executed if RTSEL = 1.

For a complete re-configuration of a valid message object, the following steps should be executed:

1. Clear MSGVAL bit
2. Re-configure the message object while MSGVAL = 0
3. Clear RTSEL and set MSGVAL

Clearing of RTSEL ensures that the message object is disconnected from an ongoing/scheduled transmission and no message object processing (copying message to transmit buffer including clearing NEWDAT, clearing TXRQ, time stamp update, message interrupt, etc.) within the old context of the object can occur after the message object becomes valid again, but within a new context.

NEWDAT

When the contents of a message object have been transferred to the internal transmit buffer of the CAN node, bit MOSTATn.NEWDAT (New Data) is cleared by hardware to indicate that the transmit message object data is no longer new.

When the transmission of the frame is successful and NEWDAT is still cleared (if no new data has been copied into the message object meanwhile), TXRQ (Transmit Request) is cleared automatically by hardware.

If, however, the NEWDAT bit has been set again by the software (because a new frame should be transmitted), TXRQ is not cleared to enable the transmission of the new data.

Controller Area Network Controller (MultiCAN+)

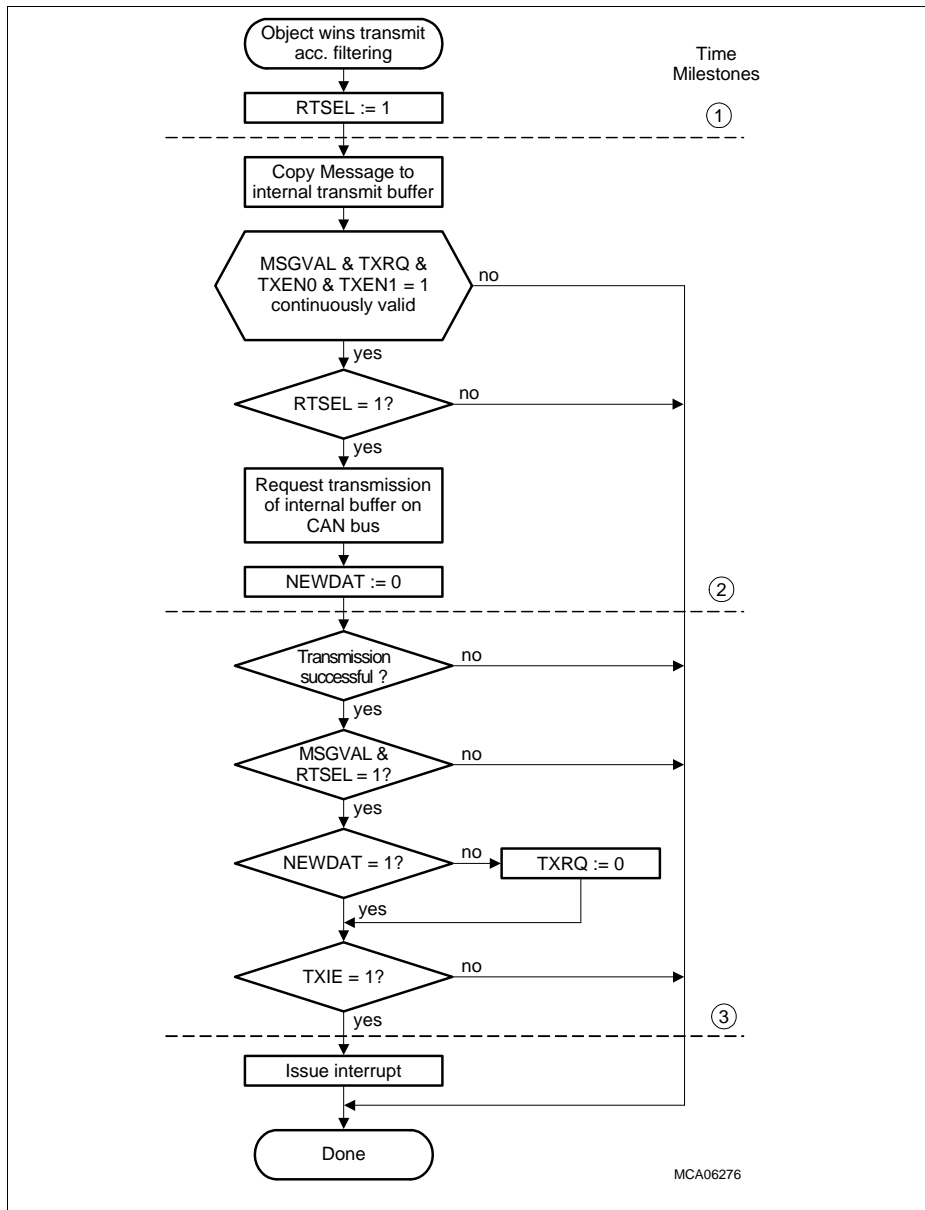

Figure 19-19 Transmission of a Message Object

19.3.10 Message Object Functionality

This chapter describes the functionality of the Message Objects in the MultiCAN+ module.

19.3.10.1 Standard Message Object

A message object is selected as standard message object when bit field MOFCRn.MMC = 0000_B (see [Page 19-87](#)). The standard message object can transmit and receive CAN frames according to the basic rules described in the previous sections. Additional services such as Single Data Transfer Mode or Single Transmit Trial (see following sections) are available and can be individually selected.

19.3.10.2 Single Data Transfer Mode

Single Data Transfer Mode is a useful feature in order to broadcast data over the CAN bus without unintended duplication of information. Single Data Transfer Mode is selected via bit MOFCRn.SDT.

Message Reception

When a received message stored in a message object is overwritten by a new received message, the contents of the first message are lost and replaced with the contents of the new received message (indicated by MSGLST = 1).

If SDT is set (Single Data Transfer Mode activated), bit MSGVAL of the message object is automatically cleared by hardware after the storage of a received Data or Remote Frame. This prevents the reception of further messages.

Message Transmission

When a message object receives a series of multiple remote requests, it transmits several Data Frames in response to the remote requests. If the data within the message object has not been updated in the time between the transmissions, the same data can be sent more than once on the CAN bus.

In Single Data Transfer Mode (SDT = 1), this is avoided because MSGVAL is automatically cleared after the successful transmission of a Data or Remote Frame.

19.3.10.3 Single Transmit Trial

If the bit STT in the message object function register is set (STT = 1), the transmission request is cleared (TXRQ = 0) when the frame contents of the message object have been copied to the internal transmit buffer of the CAN node. Thus, the transmission of the message object is not tried again when it fails due to CAN bus errors.

19.3.10.4 Message Object FIFO Structure

In case of high CPU load it may be difficult to process a series of CAN frames in time. This may happen if multiple messages are received or must be transmitted in short time.

Therefore, a FIFO buffer structure is available to avoid loss of incoming messages and to minimize the setup time for outgoing messages. The FIFO structure can also be used to automate the reception or transmission of a series of CAN messages and to generate a single message interrupt when the whole CAN frame series is done.

There can be several FIFOs in parallel. The number of FIFOs and their size are limited only by the number of available message objects. A FIFO can be installed, resized and de-installed at any time, even during CAN operation.

The basic structure of a FIFO is shown in [Figure 19-20](#). A FIFO consists of one base object and n slave objects. The slave objects are chained together in a list structure (similar as in message object lists). The base object may be allocated to any list. Although [Figure 19-20](#) shows the base object as a separate part beside the slave objects, it is also possible to integrate the base object at any place into the chain of slave objects. This means that the base object is slave object, too (not possible for gateways). The absolute object numbers of the message objects have no impact on the operation of the FIFO.

The base object does not need to be allocated to the same list as the slave objects. Only the slave object must be allocated to a common list (as they are chained together). Several pointers (BOT, CUR and TOP) that are located in the Message Object n FIFO/Gateway Pointer Register MOFGPRn link the base object to the slave objects, regardless whether the base object is allocated to the same or to another **list** than the slave objects.

The smallest FIFO would be a single message object which is both, FIFO base and FIFO slave (not very useful). The biggest possible FIFO structure would include all message objects of the MultiCAN+ module. Any FIFO sizes between these limits are possible.

In the FIFO base object, the FIFO boundaries are defined. Bit field MOFGPRn.BOT of the base object points to (includes the number of) the bottom slave object in the FIFO structure. The MOFGPRn.TOP bit field points to (includes the number of) the top slave object in the FIFO structure. The MOFGPRn.CUR bit field points to (includes the number of) the slave object that is actually selected by the MultiCAN+ module for message transfer. When a message transfer takes place with this object, CUR is set to the next message object in the list structure of the slave objects (CUR = PNEXT of current object). If CUR was equal to TOP (top of the FIFO reached), the next update of CUR will result in CUR = BOT (wrap-around from the top to the bottom of the FIFO). This scheme represents a circular FIFO structure where the bit fields BOT and TOP establish the link from the last to the first element.

Bit field MOFGPRn.SEL of the base object can be used for monitoring purposes. It makes it possible to define a slave object within the list at which a message interrupt is

Controller Area Network Controller (MultiCAN+)

generated whenever the CUR pointer reaches the value of the SEL pointer. Thus SEL makes it possible to detect the end of a predefined message transfer series or to issue a warning interrupt when the FIFO becomes full.

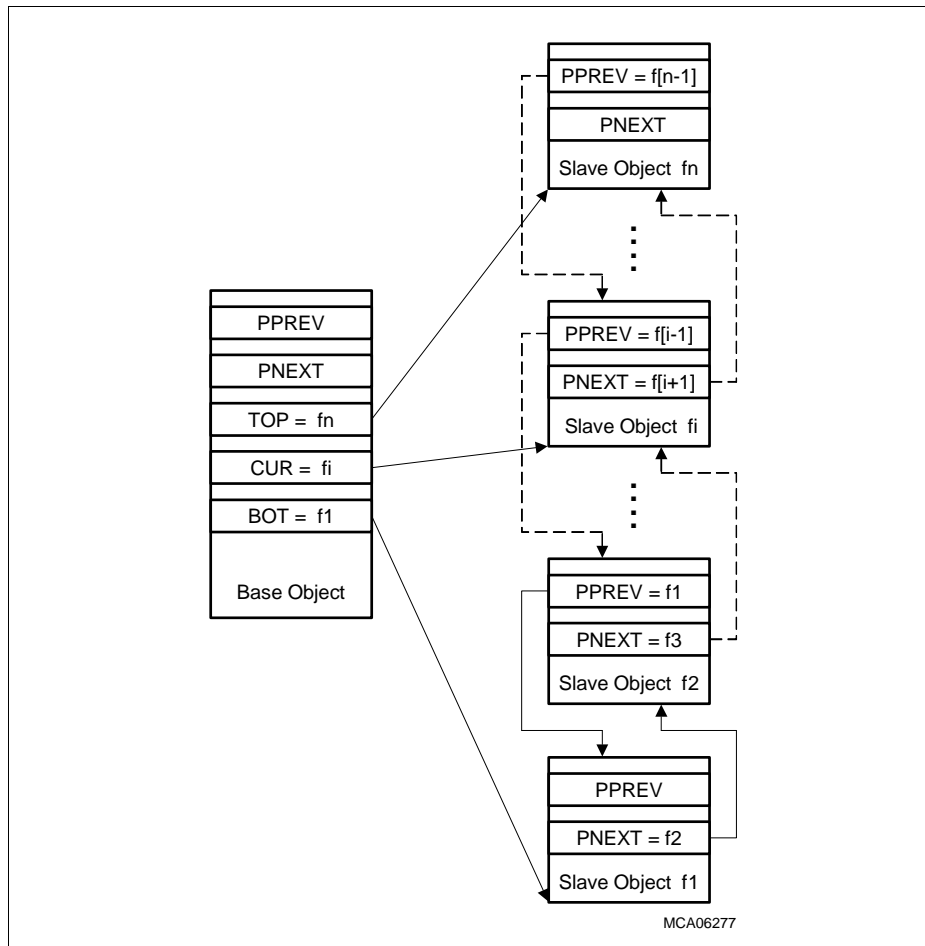

Figure 19-20 FIFO Structure with FIFO Base Object and n FIFO Slave Objects

19.3.10.5 Receive FIFO

The Receive FIFO structure is used to buffer incoming (received) Remote or Data Frames.

A Receive FIFO is selected by setting MOFCRn.MMC = 0001_B in the FIFO base object. This MMC code automatically designates a message object as FIFO base object. The message modes of the FIFO slave objects are not relevant for the operation of the Receive FIFO.

When the FIFO base object receives a frame from the CAN node it belongs to, the frame is not stored in the base object itself but in the message object that is selected by the base object's MOFGPRn.CUR pointer. This message object receives the CAN message as if it is the direct receiver of the message. However, MOFCRn.MMC = 0000_B is implicitly assumed for the FIFO slave object, and a standard message delivery is performed. The actual message mode (MMC setting) of the FIFO slave object is ignored. For the slave object, no acceptance filtering takes place that checks the received frame for a match with the identifier, IDE bit, and DIR bit.

With the reception of a CAN frame, the current pointer CUR of the base object is set to the number of the next message object in the FIFO structure. This message object will then be used to store the next incoming message.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer MOFGPRn.CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. This interrupt request is generated on interrupt node TXINP of the base object immediately after the storage of the received frame in the slave object. Transmit interrupts are still generated if TXIE is set.

A CAN message is stored in FIFO base and slave object only if MSGVAL = 1.

In order to avoid direct reception of a message by a slave message object, as if it was an independent message object and not a part of a FIFO, the bit RXEN of each slave object must be cleared. The setting of the bit RXEN is "don't care" only if the slave object is located in a list not assigned to a CAN node.

19.3.10.6 Transmit FIFO

The Transmit FIFO structure is used to buffer a series of Data or Remote Frames that must be transmitted. A transmit FIFO consists of one base message object and one or more slave message objects.

A Transmit FIFO is selected by setting MOFCRn.MMC = 0010_B in the FIFO base object. Unlike the Receive FIFO, slave objects assigned to the Transmit FIFO must explicitly set their bit fields MOFCRn.MMC = 0011_B. The CUR pointer in all slave objects must point back to the Transmit FIFO Base Object (to be initialized by software).

The MOSTATn.TXEN1 bits (Transmit Enable 1) of all message objects except the one which is selected by the CUR pointer of the base object must be cleared by software.

Controller Area Network Controller (MultiCAN+)

TXEN1 of the message (slave) object selected by CUR must be set. CUR (of the base object) may be initialized to any FIFO slave object.

When tagging the message objects of the FIFO as valid to start the operation of the FIFO, then the base object must be tagged valid (MSGVAL = 1) first.

Before a Transmit FIFO becomes de-installed during operation, its slave objects must be tagged invalid (MSGVAL = 0).

The Transmit FIFO uses the TXEN1 bit in the Message Object Status Register of all FIFO elements to select the actual message for transmission. Transmit acceptance filtering evaluates TXEN1 for each message object and a message object can win transmit acceptance filtering only if its TXEN1 bit is set. When a FIFO object has transmitted a message, the hardware clears its TXEN1 bit in addition to standard transmit postprocessing (clear TXRQ, transmit interrupt etc.), and moves the CUR pointer in the next FIFO base object to be transmitted. TXEN1 is set automatically (by hardware) in the next message object. Thus, TXEN1 moves along the Transmit FIFO structure as a token that selects the active element.

If bit field MOFCRn.OVIE ("Overflow Interrupt Enable") of the FIFO base object is set and the current pointer CUR becomes equal to MOFGPRn.SEL, a FIFO overflow interrupt request is generated. The interrupt request is generated on interrupt node RXINP of the base object after postprocessing of the received frame. Receive interrupts are still generated for the Transmit FIFO base object if bit RXIE is set.

19.3.10.7 Gateway Mode

The Gateway Mode makes it possible to establish an automatic information transfer between two independent CAN buses without CPU interaction.

The Gateway Mode operates on message object level. In Gateway mode, information is transferred between two message objects, resulting in an information transfer between the two CAN nodes to which the message objects are allocated. A gateway may be established with any pair of CAN nodes, and there can be as many gateways as there are message objects available to build the gateway structure.

Gateway Mode is selected by setting MOFCRs.MMC = 0100_B for the gateway source object s. The gateway destination object d is selected by the MOFGPRs.CUR=d pointer of the source object. The gateway destination object only needs to be valid (its MSGVAL = 1). All other settings are not relevant for the information transfer from the source object to the destination object.

Gateway source object behaves as a standard message object with the difference that some additional actions are performed by the MultiCAN+ module when a CAN frame has been received and stored in the source object (see [Figure 19-21](#)):

1. If bit MOFCRs.DLCC is set, the data length code MOFCRs.DLC is copied from the gateway source object to the gateway destination object.

Controller Area Network Controller (MultiCAN+)

2. If bit MOFCRs.IDC is set, the identifier MOARs.ID and the identifier extension MOARs.IDE are copied from the gateway source object to the gateway destination object.
3. If bit MOFCRs.DATC is set, the data bytes stored in the two data registers MODATALs and MODATAHs are copied from the gateway source object to the gateway destination object. All 8 data bytes are copied, even if MOFCRs.DLC indicates less than 8 data bytes.
4. If bit MOFCRs.GDFS is set, the transmit request flag MOSTATd.TXRQ is set in the gateway destination object.
5. The receive pending bit MOSTATd.RXPND and the new data bit MOSTATd.NEWDAT are set in the gateway destination object.
6. A message interrupt request is generated for the gateway destination object if its MOSTATd.RXIE is set.
7. The current object pointer MOFGPRs.CUR of the gateway source object is moved to the next destination object according to the FIFO rules as described on [Page 19-46](#). A gateway with a single (static) destination object is obtained by setting MOFGPRs.TOP = MOFGPRs.BOT = MOFGPRs.CUR = destination object.

The link from the gateway source object to the gateway destination object works in the same way as the link from a FIFO base to a FIFO slave. This means that a gateway with an integrated destination FIFO may be created; in [Figure 19-20](#), the object on the left is the gateway source object and the message object on the right side is the gateway destination objects.

The gateway operates equivalent for the reception of data frames (source object is receive object, i.e. DIR = 0) as well as for the reception of Remote Frames (source object is transmit object).

Controller Area Network Controller (MultiCAN+)

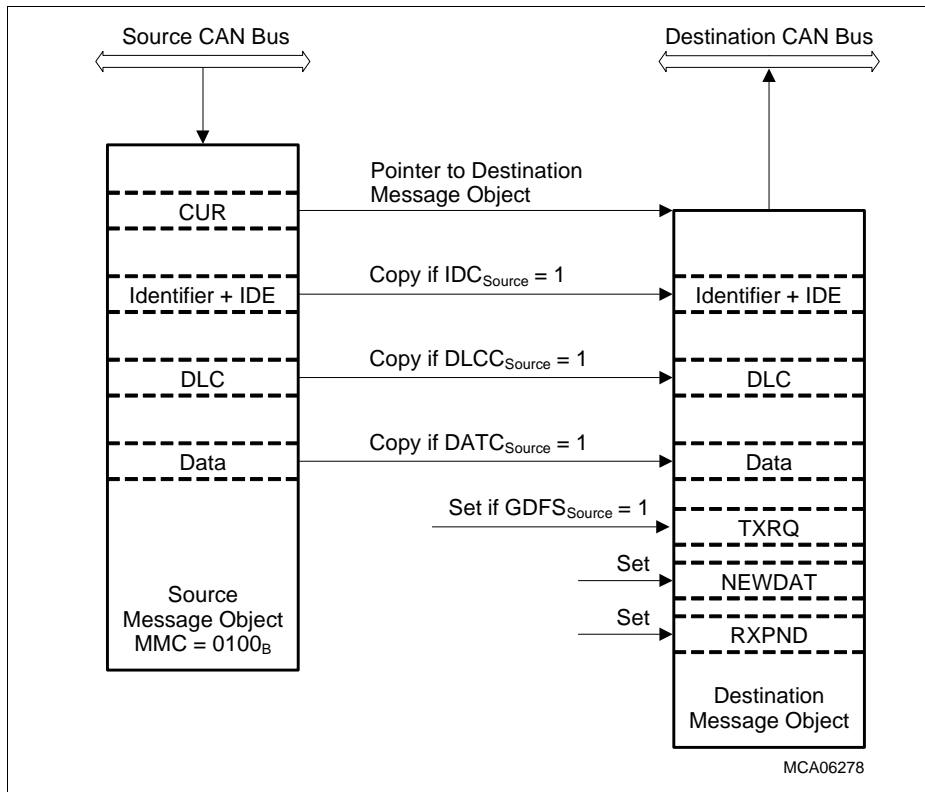

Figure 19-21 Gateway Transfer from Source to Destination

19.3.10.8 Foreign Remote Requests

When a Remote Frame has been received on a CAN node and is stored in a message object, a transmit request is set to trigger the answer (transmission of a Data Frame) to the request or to automatically issue a secondary request. If the Foreign Remote Request Enable bit MOFCRn.FRREN is cleared in the message object in which the remote request is stored, MOSTATn.TXRQ is set in the same message object.

If bit FRREN is set (FRREN = 1: foreign remote request enabled), TXRQ is set in the message object that is referenced by pointer MOFGPRn.CUR. The value of CUR is, however, not changed by this feature.

Although the foreign remote request feature works independently of the selected message mode, it is especially useful for gateways to issue a remote request on the source bus of a gateway after the reception of a remote request on the gateway destination bus. According to the setting of FRREN in the gateway destination object, there are two capabilities to handle remote requests that appear on the destination side (assuming that the source object is a receive object and the destination is a transmit object, i.e. $DIR_{source} = 0$ and $DIR_{destination} = 1$):

FRREN = 0 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway destination object.
3. A Data Frame with the current data stored in the destination object is transmitted on the destination bus.

FRREN = 1 in the Gateway Destination Object

1. A Remote Frame is received by gateway destination object.
2. TXRQ is set automatically in the gateway source object (must be referenced by CUR pointer of the destination object).
3. A remote request is transmitted by the source object (which is a receive object) on the source CAN bus.
4. The receiver of the remote request responds with a Data Frame on the source bus.
5. The Data Frame is stored in the source object.
6. The Data Frame is copied to the destination object (gateway action).
7. TXRQ is set in the destination object (assuming $GDFS_{source} = 1$).
8. The new data stored in the destination object is transmitted on the destination bus, in response to the initial remote request on the destination bus.

19.4 Use Case Example MultiCAN+

This section explains the core functionality of the MultiCAN+ module with a code example. The example realizes sending a CAN message via internal CAN-bus from node 0 to node 1.

The MultiCAN+ module for the XMC4[78]00 consists of module (i.e MultiCAN with 6 CAN nodes), representing serial communication interfaces. Each CAN node can either be connected to a port or to the internal CAN bus (see [Figure 19-24](#)). So a maximum of 6 CAN channels can be realized with the MultiCAN+ module (For more information and further functions see [Section 19.2](#)).

All CAN nodes share a common set of 256 message objects. A message object function like a container for a specific CAN message; both transmitting and receiving of CAN messages can be realized. The message objects are organized in double-chained lists, each list is dedicated to a certain CAN node (list 1 is node 0, list 2 is node 1, etc.). After a reset, all message objects are unallocated and therefore assigned to list 0, this list does not belong to a CAN node. During initialization it is possible to allocate the message objects individually to certain CAN node lists. Each allocated message object can be set up with all necessary information like the message ID etc. (see chapter 26.2 and following for further explanations of the CAN module).

In the use case example CAN node 0 will send a CAN message via internal CAN bus to CAN node 1. The transmitting message object (MO) will be MO 0 and the receiving message object will be MO 1. As soon as the CAN frame successfully receives at MO 1 a receive interrupt will occur. The initialization process follows the following order:

1. Load global MultiCAN+ module registers
2. Initialize the CAN nodes
3. Allocate the message objects to the CAN nodes
4. Initialize the message objects
5. Start the CAN nodes
6. Start transmit request for CAN message from node 0 to node 1.
7. Receive message at node 1, Rx interrupt occurs.

Step description to initialize the MultiCAN+ module:

(Line 2) enable control of the module, in clock control register CLC ([CLC](#)).

(Line 3) read back (dummy variable has to be defined). The reading process ensures that the write process from line 2 is done.

(Line 4) load fractional divider to $f_{CAN} = f_{PERIPH}$ (see also 26.3.2 Clock Control ([Fractional Divider](#)), f_{PERIPH} see [MCR](#)).

(Line 5) read back (dummy variable to be defined).

(Line 6) set clk source to f_{PERIPH} in module control register MCR([MCR](#)).

Controller Area Network Controller (MultiCAN+)

Note: The reconfiguration of the clk source must be done by two writes and a certain delay between these. See MCR for more details.

(Line 7) The setting of protection CCE[6] and INIT[0] activates the initialization and configuration mode for CAN node 0. This is necessary for the upcoming changes in CAN node 0. (see also node configuration register NCRn (**CAN_NCRx (x = 0-5)**))

(Line 8) This example uses the internal loop-back mode, so this line connects CAN node 0 to the internal CAN Bus. (see also Figure 26-13(**Figure 19-13**) and node port control register NPCR(**CAN_NPCRx (x = 0-5)**))

(Line 9) The CAN bit time is subdivided into different segments. (see also 26.3.6.1 Bit Timing Unit(**Bit Timing Unit**)). Assuming $f_{CAN} = 100$ MHz this line then sets the baudrate to 500 kBaud and the sample point to 80% in the node bit timing register NBTR (**CAN_NBTRx (x = 0-5)**).

(Line 10 - 12) same as line 7 - 9 but with node 1.

(Line 13) The allocation of the message objects to certain CAN node lists function via a list command panel. The panel control register PANCTR(**PANCTR**) can only be written if both busy flags are reset. Therefore this while loop waits until the register is ready.

(Line 14) This line allocates message object 0 to list 1 (belongs to CAN node 0).

(Line 15) see line 13.

(Line 16) This line allocates message object 1 to list 2 (belongs to CAN node 0).

(Line 17) Initialize MO 0 in the message object register MOCTR(**CAN_MOCTRz (z = 0-254)**) as transmit MO by setting bits [27:25]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 18) this line sets the message data length of MO 0 to 8 bytes.(see also message object function control register MOFCR (**CAN_MOFCRn (n = 0-255)**)).

(Line 19) the message ID of MO 0 gets set to standard message (11 bit length) with a message ID of FF_H in the Message object arbitration register MOAR (**CAN_MOARn (n = 0-255)**).

(Line 20) Initialize MO 1 in the message object register MOCTR as receive MO by setting bit RXEN[23]. Set also MSGVAL[21], that's the main switch bit of the MO.

(Line 21) the receive interrupt gets enabled in the message object function control register MOFCR .

(Line 22) same as Line 19 but for MO 1. The same message ID is necessary to receive CAN messages from the bus with this specific ID.

(Line 23) the Rx interrupt gets connected to the CAN interrupt output line 1.(see also MOIPR(**CAN_MOIPRn (n = 0-255)**))

(Line 24) This line enables the Rx interrupt in the service request control register SRC_CANINT1 and sets the interrupt priority to CAN_SR1INT (1...255)

(Line 25) This function sets the interrupt priority of the receive interrupt.

Controller Area Network Controller (MultiCAN+)

(Line 26) The 4 lower data bytes are getting loaded in the MODATAL(**CAN_MODATALn (n = 0-255)**) register. the data itself is here just an example.

(Line 27) The 4 higher data bytes are getting loaded in the MODATAH(**CAN_MODATAHn (n = 0-255)**) register. (just an data example as well)

(Line 28) This line resets INIT[0] and CCE[6] bit in the node control register from node 0. The node is now synchronizing itself to the bus.

(Line 29) same as line 28, but with node 1.

(Line 30) The NEWDATA bit gets set in the MOCTR register, this should always be done after a write process in the data registers from line 26/27. The transmit request bit TXRQ gets set, this starts the transmission of the CAN message. The RTSEL gets reset to ensure the transmission.

(Line 31) If the message is received the MOCTR.NEWDAT[19] bit in the receive MO 1 is set. This line just waits for the reception. The occurrence of the Rx interrupt can also be used as a proof that the message arrived.

(Line 32/33) Access the data bytes without clearing NEWDAT.

Note: The Rx ISR function prototype would be: void CAN1_Rx_irq (void); here could be your ISR code;

Note: Line 1 does not apply for ARM products, therefore this line does not exist.

Initialization of the MultiCAN+ module:

```
// Load global MultiCAN+ registers:
(2)  CAN_CLC = 0x000;           // enable module control
(3)  dummy = CAN_CLC;           //read to check the made changes

19.5 MultiCAN+ Kernel Registers

This section describes the kernel registers of the MultiCAN+ module. All MultiCAN+ kernel register names described in this section are also referenced in other parts of the XMC4[78]00 Reference Manual by the module name prefix "CAN_".

MultiCAN+ Kernel Register Overview

The MultiCAN+ Kernel include three blocks of registers:

- Global Module Registers
- Node Registers, for each CAN node x
- Message Object Registers, for each message object n

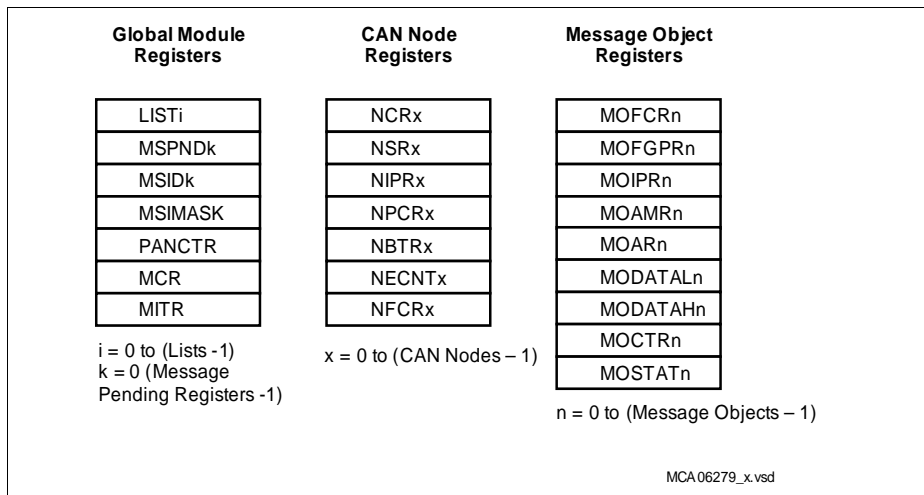

Figure 19-22 MultiCAN+ Kernel Registers

The registers of the MultiCAN+ module kernel are listed below.

Table 19-6 Registers Address Space - MultiCAN+ Kernel Registers

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| CAN | 4801 4000 _H | 4801 7FFF _H | - |

Controller Area Network Controller (MultiCAN+)

1) The absolute register address is calculated as follows:

Module Base Address ([Table 19-6](#)) + Offset Address (shown in this column)

Further, the following ranges for parameters i, k, x, and n are valid: i = 0-15, k = 0-7, x = 0-5, n = 0-255.

2) Accesses to empty addresses: nBE

Controller Area Network Controller (MultiCAN+)

Figure 19-23

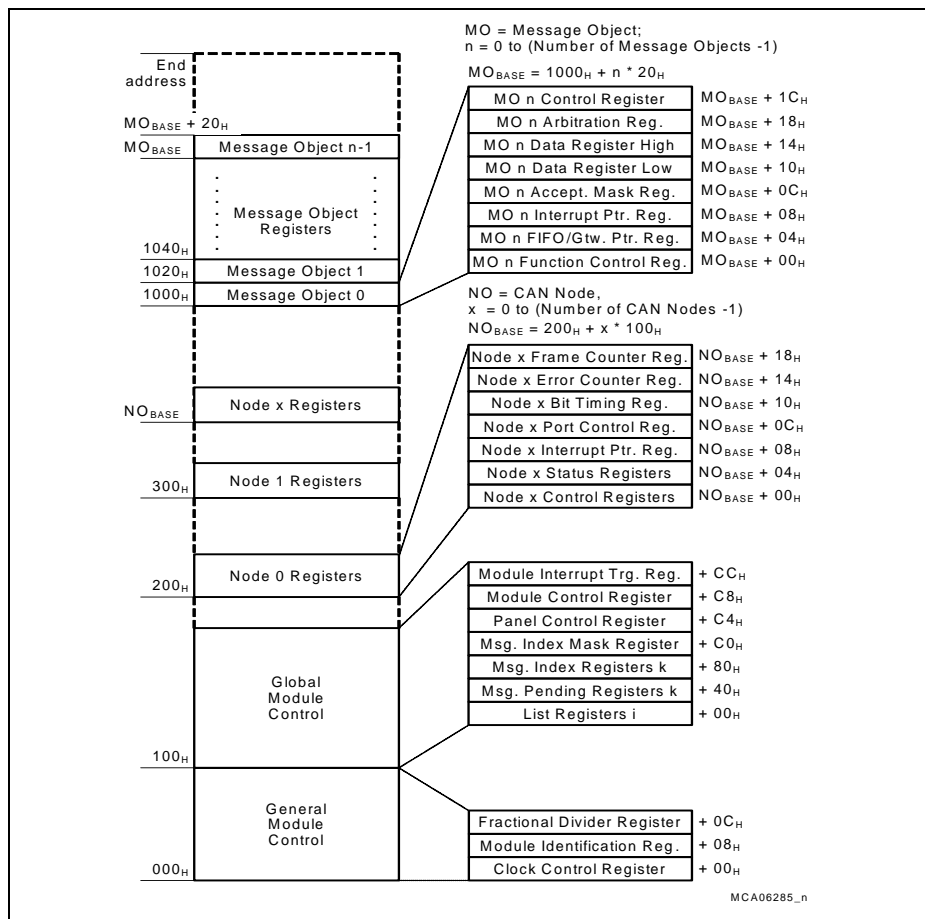

Figure 19-23 MultiCAN+ Register Address Map XMC

19.5.1 Global Module Registers

All list operations such as allocation, de-allocation and relocation of message objects within the list structure are performed via the Command Panel. It is not possible to modify the list structure directly by software by writing to the message objects and the LIST registers.

Module Identification Register.

Controller Area Network Controller (MultiCAN+)

ID

Module Identification Register

(008_H)

Reset Value: 00B5 C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the revision number. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type C0 _H Define the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the MultiCAN+ module identification number (=00B5H) |

Controller Area Network Controller (MultiCAN+)

The Panel Control Register PANCTR is used to start a new command by writing the command arguments and the command code into its bit fields.

PANCTR

Panel Control Register

(1C4_H)

Reset Value: 0000 0301_H

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| PANCMD | [7:0] | rwh | Panel Command This bit field is used to start a new command by writing a panel command code into it. At the end of a panel command, the NOP (no operation) command code is automatically written into PANCMD. The coding of PANCMD is defined in Table 19-8 . |
| BUSY | 8 | rh | Panel Busy Flag 0 _B Panel has finished command and is ready to accept a new command. 1 _B Panel operation is in progress. Initial list controller initialization must be finalized, when INIT bit is reset. |
| RBUSY | 9 | rh | Result Busy Flag 0 _B No update of PANAR1 and PANAR2 is scheduled by the list controller. 1 _B A list command is running (BUSY = 1) that will write results to PANAR1 and PANAR2, but the results are not yet available. |
| PANAR1 | [23:16] | rwh | Panel Argument 1 See Table 19-8 . |
| PANAR2 | [31:24] | rwh | Panel Argument 2 See Table 19-8 . |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [15:10] | r | Reserved Read as 0; should be written with 0. |

Panel Commands

A panel operation consists of a command code (PANCMD) and up to two panel arguments (PANAR1, PANAR2). Commands that have a return value deliver it to the PANAR1 bit field. Commands that return an error flag deliver it to bit 31 of the Panel Control Register, this means bit 7 of PANAR2.

Table 19-8 Panel Commands

| PANCMD | PANAR2 | PANAR1 | Command Description |
|-----------------|--|--------|---|
| 00 _H | — | — | No Operation Writing 00 _H to PANCMD has no effect. No new command is started. |
| 01 _H | Result: Bit 7: ERR Bit 6-0: undefined | — | Initialize Lists Run the initialization sequence to reset the CTRL and LIST fields of all message objects. List registers LIST[7:0] are set to their reset values. This results in the de-allocation of all message objects. The initialization command requires that bits NCRx.INIT and NCRx.CCE are set for all CAN nodes. Bit 7 of PANAR2 (ERR) reports the success of the operation: 0 _B Initialization was successful 1 _B Not all NCRx.INIT and NCRx.CCE bits are set. Therefore, no initialization is performed. The initialize lists command is automatically performed with each reset of the MultiCAN+ module, but with the exception that all message object registers are reset, too. |

Controller Area Network Controller (MultiCAN+)

Table 19-8 Panel Commands (cont'd)

| PANCMD | PANAR2 | PANAR1 | Command Description |
|-----------------|--|---|--|
| 02 _H | Argument: List Index | Argument: Message Object Number | Static Allocate Allocate message object to a list. The message object is removed from the list that it currently belongs to, and appended to the end of the list, given by PANAR2. This command is also used to deallocate a message object. In this case, the target list is the list of unallocated elements (PANAR2 = 0). |
| 03 _H | Argument: List Index Result: Bit 7: ERR Bit 6-0: undefined | Result: Message Object Number | Dynamic Allocate Allocate the first message object of the list of unallocated objects to the selected list. The message object is appended to the end of the list. The message number of the message object is returned in PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty. |
| 04 _H | Argument: Destination Object Number | Argument: Source Object Number | Static Insert Before Remove a message object (source object) from the list that it currently belongs to, and insert it before a given destination object into the list structure of the destination object. The source object thus becomes the predecessor of the destination object. |

Controller Area Network Controller (MultiCAN+)

Table 19-8 Panel Commands (cont'd)

| PANCMD | PANAR2 | PANAR1 | Command Description |
|-----------------------------------|---|--|---|
| 05 _H | Argument: Destination Object Number Result: Bit 7: ERR Bit 6-0: undefined | Result: Object Number of inserted object | Dynamic Insert Before Insert a new message object before a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as a result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty. |
| 06 _H | Argument: Destination Object Number | Argument: Source Object Number | Static Insert Behind Remove a message object (source object) from the list that it currently belongs to, and insert it behind a given destination object into the list structure of the destination object. The source object thus becomes the successor of the destination object. |
| 07 _H | Argument: Destination Object Number Result: Bit 7: ERR Bit 6-0: undefined | Result: Object Number of inserted object | Dynamic Insert Behind Insert a new message object behind a given destination object. The new object is taken from the list of unallocated elements (the first element is chosen). The number of the new object is delivered as result to PANAR1. An ERR bit (bit 7 of PANAR2) reports the success of the operation: 0 _B Success. 1 _B The operation has not been performed because the list of unallocated elements was empty. |
| 08 _H - FF _H | — | — | Reserved |

Controller Area Network Controller (MultiCAN+)

The Module Control Register MCR contains basic settings that determine the operation of the MultiCAN+ module.

The write access to the lowest byte of the MCR register is possible only if the CCE bits of all CAN nodes are set (NCRx.CCE bits). The NCRx.INIT bits will be automatically set when the lowest byte of the MCR register is written, independent of the setting of the CCE bits. The INIT bits have to be reset by software in order to activate the CAN nodes.

The reconfiguration of the clock source has to be done by using two writes: first a write of zero to the CLKSEL bit field, and then a second write defining the new clock source. Between the first and the second write a delay of $4 / f_A + 2 / f_{CAN}$ number of cycles must be inserted by software, where f_A is the frequency being switched off with the first write. Exception: in case that f_{PERIPH} is selected as the baud rate logic clock (MCR.CLKSEL = 1), no delay cycles between the writes are necessary. In both cases, simply using one write defining the new clock source is not allowed.

Note: If the baud rate logic is supplied from an unstable clock source, or no clock at all, the CAN functionality is not guaranteed.

MCR

Module Control Register

(1C8_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|-------|------|---|
| CLKSEL | [3:0] | rw | Baud Rate Logic Clock Select 0000 _B No clock supplied 0001 _B f_{PERIPH} 0010 _B f_{OHP} 0100 _B not allowed 1000 _B hard wired to 0 ... _B not allowed |
| 0 | 8 | rw | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|------------------------------|------|---|
| MPSEL | [15:12] | rw | Message Pending Selector Bit field MPSEL makes it possible to select the bit position of the message pending bit after a message reception/transmission by a mixture of the MOIPRn register bit fields RXINP, TXINP, and MPN. Selection details are given in Figure 19-17 on Page 19-37 . |
| 0 | [31:16], [11:9], [7:4] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Interrupt Trigger Register ITR is used to trigger interrupt requests on each interrupt output line by software.

MITR

Module Interrupt Trigger Register

(1CC_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| IT | [7:0] | w | Interrupt Trigger Writing a 1 to IT[m] (m = 0-7) generates an interrupt request on interrupt output line INT_O[m]. Writing a 0 to IT[m] has no effect. Bit field IT is always read as 0. Multiple interrupt requests can be generated with a single write operation to MITR by writing a 1 to several bit positions of IT. All 16 interrupts are existing, even if the interrupt request unit is not connected. |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

List Pointer and List Register

Each CAN node has a list that determines the allocated message objects. Additionally, a list of all unallocated objects is available. Furthermore, general purpose lists are available which are not associated to a CAN node. The List Registers are assigned in the following way:

- LIST0 provides the list of all unallocated objects
- LIST1 provides the list for CAN node 0
- LIST2 provides the list for CAN node 1
- ...
- LIST $\underline{6}$ provides the list for CAN node $\underline{5}$

LIST0

List Register 0 (100_H) **Reset Value: 00FF FF00_H**

LIST \underline{n} ($\underline{n} = 1-15$)

List Register \underline{n} (100_H+ \underline{n} *4_H) **Reset Value: 0100 0000_H**

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| BEGIN | [7:0] | rh | List Begin BEGIN indicates the number of the first message object in list i. |
| END | [15:8] | rh | List End END indicates the number of the last message object in list i. |
| SIZE | [23:16] | rh | List Size SIZE indicates the number of elements in the list i. SIZE = number of list elements - 1 SIZE = 0 indicates that list i is empty. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| EMPTY | 24 | rh | List Empty Indication 0_B At least one message object is allocated to list i. 1_B No message object is allocated to the list i. List i is empty. |
| 0 | [31:25] | r | Reserved Read as 0. |

Controller Area Network Controller (MultiCAN+)

Message Notifications

When a message object n generates an interrupt request upon the transmission or reception of a message, then the request is routed to the interrupt output line selected by the bit field MOIPR n .TXINP or MOIPR n .RXINP of the message object n . As there are more message objects than interrupt output lines, an interrupt routine typically processes requests from more than one message object. Therefore, a priority selection mechanism is implemented in the MultiCAN+ module to select the highest priority object within a collection of message objects.

The Message Pending Register MSPND k contains the pending interrupt notification of list i .

MSPND k ($k = 0-7$)

Message Pending Register k **($140_H + k * 4_H$)** **Reset Value: 0000 0000 $_H$**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PND | [31:0] | rwh | Message Pending When a message interrupt occurs, the message object sets a bit in one of the MSPND register, where the bit position is given by the MPN[4:0] field of the IPR register of the message object. The register selection n is given by the higher bits of MPN. The register bits can be cleared by software (write 0). Writing a 1 has no effect. |

Controller Area Network Controller (MultiCAN+)

Each Message Pending Register has a Message Index Register MSIDk associated with it. The Message Index Register shows the active (set) pending bit with lowest bit position within groups of pending bits.

MSIDk (k = 0-7)

Message Index Register k $(180_H + k \cdot 4_H)$ **Reset Value: 0000 0020_H**

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| INDEX | [5:0] | rh | Message Pending Index The value of INDEX is given by the bit position i of the pending bit of MSPNDk with the following properties: <ol style="list-style-type: none"> MSPNDk[i] & IM[i] = 1 i = 0 or MSPNDk[i-1:0] & IM[i-1:0] = 0 If no bit of MSPNDk satisfies these conditions then INDEX reads 100000 _B . Thus INDEX shows the position of the first pending bit of MSPNDk, in which only those bits of MSPNDk that are selected in the Message Index Mask Register are taken into account. |
| 0 | [31:6] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Message Index Mask Register MSIMASK selects individual bits for the calculation of the Message Pending Index. The Message Index Mask Register is used commonly for all Message Pending registers and their associated Message Index registers.

MSIMASK

Message Index Mask Register (1C0_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| IM | [31:0] | rw | Message Index Mask Only those bits in MSPNDk for which the corresponding Index Mask bits are set contribute to the calculation of the Message Index. |

19.5.2 CAN Node Registers

The CAN node registers are built in for each CAN node of the MultiCAN+ module. They contain information that is directly related to the operation of the CAN nodes and are shared among the nodes.

The Node Control Register contains basic settings that determine the operation of the CAN node.

Controller Area Network Controller (MultiCAN+)

CAN_NCRx (x = 0-5)

Node x Control Register

(200_H+x*100_H)

Reset Value: 0000 0041_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----------|-----|-----------|------------|------|-----------|------|------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | | 0 | | | | 0 | 0 | CAL M | CCE | TXDI S | CAN DIS | ALIE | LECI E | TRIE | INIT |
| r | | r | | | r | r | rw | rw | rw | rw | rw | rw | rw | rw | rwh |

| Field | Bits | Type | Description |
|-------|------|------|--|
| INIT | 0 | rwh | <p>Node Initialization</p> <p>0_B Resetting bit INIT enables the participation of the node in the CAN traffic. If the CAN node is in the bus-off state, the ongoing bus-off recovery (which does not depend on the INIT bit) is continued. With the end of the bus-off recovery sequence the CAN node is allowed to take part in the CAN traffic. If the CAN node is not in the bus-off state, a sequence of 11 consecutive recessive bits must be detected before the node is allowed to take part in the CAN traffic.</p> <p>1_B Setting this bit terminates the participation of this node in the CAN traffic. Any ongoing frame transfer is cancelled and the transmit line goes recessive. If the CAN node is in the bus-off state, then the running bus-off recovery sequence is continued. If the INIT bit is still set after the successful completion of the bus-off recovery sequence, i.e. after detecting 128 sequences of 11 consecutive recessive bits (11 × 1), then the CAN node leaves the bus-off state but remains inactive as long as INIT remains set.</p> <p>Bit INIT is automatically set when the CAN node enters the bus-off state (see Page 19-22).</p> |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|---------------|------|------|---|
| TRIE | 1 | rw | Transfer Interrupt Enable TRIE enables the transfer interrupt of CAN node x. This interrupt is generated after the successful reception or transmission of a CAN frame in node x. 0 _B Transfer interrupt is disabled. 1 _B Transfer interrupt is enabled. Bit field NIPRx.TRINP selects the interrupt output line which becomes activated at this type of interrupt. |
| LECIE | 2 | rw | LEC Indicated Error Interrupt Enable LECIE enables the last error code interrupt of CAN node x. This interrupt is generated with each hardware update of bit field NSRx.LEC with LEC > 0 (CAN protocol error). 0 _B Last error code interrupt is disabled. 1 _B Last error code interrupt is enabled. Bit field NIPRx.LECINP selects the interrupt output line which becomes activated at this type of interrupt. |
| ALIE | 3 | rw | Alert Interrupt Enable ALIE enables the alert interrupt of CAN node x. This interrupt is generated by any one of the following events: <ul style="list-style-type: none"> • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE 0 _B Alert interrupt is disabled. 1 _B Alert interrupt is enabled. Bit field NIPRx.ALINP selects the interrupt output line which becomes activated at this type of interrupt. |
| CANDIS | 4 | rw | CAN Disable Setting this bit disables the CAN node. The CAN node first waits until it is bus-idle or bus-off. Then bit NCRx.INIT is automatically set, and an alert interrupt is generated if bit ALIE is set. |
| TXDIS | 5 | rw | Transmit Disable Setting this bit disables the transmission on CAN node x as soon as bus-idle is reached. Reception and bits in MOSTATn, e.g. TXRQ, will not be influenced. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| CCE | 6 | rw | Configuration Change Enable 0_B The Bit Timing Register, the Port Control Register, and the Error Counter Register may only be read. All attempts to modify them are ignored. 1_B The Bit Timing Register, the Port Control Register, and the Error Counter Register may be read and written. |
| CALM | 7 | rw | CAN Analyzer Mode If this bit is set, then the CAN node operates in Analyzer Mode. This means that messages may be received, but not transmitted. No acknowledge is sent on the CAN bus upon frame reception. Active-error flags are sent recessive instead of dominant. The transmit line is continuously held at recessive (1) level. Bit CALM can be written only while bit INIT is set. |
| 0 | 8 | rw | Reserved Read as 0; should be written with 0. |
| 0 | [31:9] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

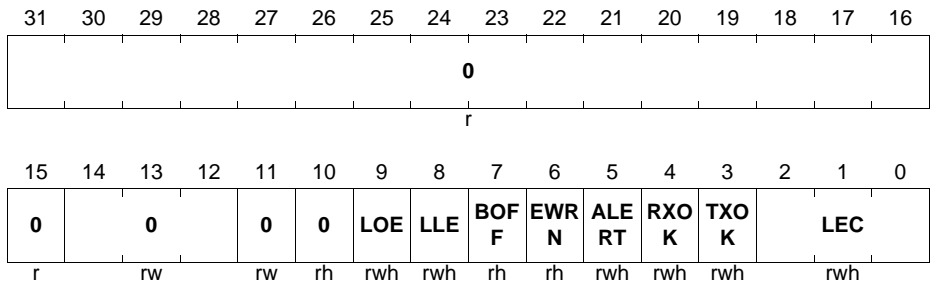

The Node Status Register NSRx reports errors as well as successfully transferred CAN frames.

CAN_NSRx (x = 0-5)

Node x Status Register

(204_H+x*100_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|-------|------|---|
| LEC | [2:0] | rwh | Last Error Code This bit field indicates the type of the last (most recent) CAN error. The encoding of this bit field is described in Table 19-9 . |
| TXOK | 3 | rwh | Message Transmitted Successfully 0 _B No successful transmission since last (most recent) flag reset. 1 _B A message has been transmitted successfully (error-free and acknowledged by at least another node). TXOK must be reset by software (write 0). Writing 1 has no effect. |
| RXOK | 4 | rwh | Message Received Successfully 0 _B No successful reception since last (most recent) flag reset. 1 _B A message has been received successfully. RXOK must be reset by software (write 0). Writing 1 has no effect. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| ALERT | 5 | rwh | Alert Warning The ALERT bit is set upon the occurrence of one of the following events (the same events which also trigger an alert interrupt if ALIE is set): <ul style="list-style-type: none"> • A change of bit NSRx.BOFF • A change of bit NSRx.EWRN • A List Length Error, which also sets bit NSRx.LLE • A List Object Error, which also sets bit NSRx.LOE ALERT must be reset by software (write 0). Writing 1 has no effect. |
| EWRN | 6 | rh | Error Warning Status 0 _B No warning limit exceeded. 1 _B One of the error counters REC or TEC reached the warning limit EWRNLVL. |
| BOFF | 7 | rh | Bus-off Status 0 _B CAN controller is not in the bus-off state. 1 _B CAN controller is in the bus-off state. |
| LLE | 8 | rwh | List Length Error 0 _B No List Length Error since last (most recent) flag reset. 1 _B A List Length Error has been detected during message acceptance filtering. The number of elements in the list that belongs to this CAN node differs from the list SIZE given in the list termination pointer. LLE must be reset by software (write 0). Writing 1 has no effect. |
| LOE | 9 | rwh | List Object Error 0 _B No List Object Error since last (most recent) flag reset. 1 _B A List Object Error has been detected during message acceptance filtering. A message object with wrong LIST index entry in the Message Object Status Register has been detected. LOE must be reset by software (write 0). Writing 1 has no effect. |
| 0 | 10 | rh | Reserved |

| 0 | [31:11] | r | Reserved Read as 0; should be written with 0. |

Encoding of the LEC Bit field

Table 19-9 Encoding of the LEC Bit field

| LEC Value | Signification |
|------------------|--|
| 000 _B | No Error: No error was detected for the last (most recent) message on the CAN bus. |
| 001 _B | Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed. |
| 010 _B | Form Error: A fixed format part of a received frame has the wrong format. |
| 011 _B | Ack Error: The transmitted message was not acknowledged by another node. |
| 100 _B | Bit1 Error: During a message transmission, the CAN node tried to send a recessive level (1) outside the arbitration field and the acknowledge slot, but the monitored bus value was dominant. |
| 101 _B | Bit0 Error: Two different conditions are signaled by this code: <ol style="list-style-type: none"> 1. During transmission of a message (or acknowledge bit, active-error flag, overload flag), the CAN node tried to send a dominant level (0), but the monitored bus value was recessive. 2. During bus-off recovery, this code is set each time a sequence of 11 recessive bits has been monitored. The CPU may use this code as indication that the bus is not continuously disturbed. |
| 110 _B | CRC Error: The CRC checksum of the received message was incorrect. |
| 111 _B | CPU write to LEC: Whenever the CPU writes the value 111 to LEC, it takes the value 111. Whenever the CPU writes another value to LEC, the written LEC value is ignored. |

Controller Area Network Controller (MultiCAN+)

The four interrupt pointers in the Node Interrupt Pointer Register NIPRx select one out of the sixteen interrupt outputs individually for each type of CAN node interrupt. See also [Page 19-23](#) for more CAN node interrupt details.

CAN_NIPRx (x = 0-5)

Node x Interrupt Pointer Register (208_H+x*100_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|-------|------|---|
| ALINP | [3:0] | rw | Alert Interrupt Node Pointer ALINP selects the interrupt output line INT_Om (m = 0-7) for an alert interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected. |
| LECINP | [7:4] | rw | Last Error Code Interrupt Node Pointer LECINP selects the interrupt output line INT_Om (m = 0-7) for an LEC interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| TRINP | [11:8] | rw | Transfer OK Interrupt Node Pointer TRINP selects the interrupt output line INT_Om (m = 0-7) for a transfer OK interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected. |
| CFCINP | [15:12] | rw | Frame Counter Interrupt Node Pointer CFCINP selects the interrupt output line INT_Om (m = 0-7) for a frame counter overflow interrupt of CAN Node x. 0000 _B Interrupt output line INT_O0 is selected. 0001 _B Interrupt output line INT_O1 is selected. ... 1110 _B Interrupt output line INT_O14 is selected. 1111 _B Interrupt output line INT_O15 is selected. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Node Port Control Register NPCRx configures the CAN bus transmit/receive ports. NPCRx can be written only if bit NCRx.CCE is set.

CAN_NPCRx (x = 0-5)

Node x Port Control Register (20C_H+x*100_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------|------------------|------|--|
| RXSEL | [2:0] | rw | Receive Select RXSEL selects one out of 8 possible receive inputs. The CAN receive signal is performed only through the selected input. <i>Note: In XMC4[78]00, only specific combinations of RXSEL are available (see also “Node Receive Input Selection” on Page 19-120 for description and the page before for RXSEL selections).</i> |
| LBM | 8 | rw | Loop-Back Mode 0 _B Loop-Back Mode is disabled. 1 _B Loop-Back Mode is enabled. This node is connected to an internal (virtual) loop-back CAN bus. All CAN nodes which are in Loop-Back Mode are connected to this virtual CAN bus so that they can communicate with each other internally. The external transmit line is forced recessive in Loop-Back Mode. |
| 0 | [7:3], [31:9] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Node Bit Timing Register NBTRx contains all parameters to set up the bit timing for the CAN transfer. NBTRx can be written only if bit NCRx.CCE is set.

CAN_NBTRx (x = 0-5)
Node x Bit Timing Register
(210_H + x*100_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| BRP | [5:0] | rw | Baud Rate Prescaler The duration of one time quantum is given by (BRP + 1) clock cycles if DIV8 = 0. The duration of one time quantum is given by 8 × (BRP + 1) clock cycles if DIV8 = 1. |
| SJW | [7:6] | rw | (Re) Synchronization Jump Width (SJW + 1) time quanta are allowed for re-synchronization. |
| TSEG1 | [11:8] | rw | Time Segment Before Sample Point (TSEG1 + 1) time quanta is the user-defined nominal time between the end of the synchronization segment and the sample point. It includes the propagation segment, which takes into account signal propagation delays. The time segment may be lengthened due to re-synchronization. Valid values for TSEG1 are 2 to 15. |
| TSEG2 | [14:12] | rw | Time Segment After Sample Point (TSEG2 + 1) time quanta is the user-defined nominal time between the sample point and the start of the next synchronization segment. It may be shortened due to re-synchronization. Valid values for TSEG2 are 1 to 7. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| DIV8 | 15 | rw | Divide Prescaler Clock by 8 0_B A time quantum lasts (BRP+1) clock cycles. 1_B A time quantum lasts $8 \times (BRP+1)$ clock cycles. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Node Error Counter Register NECNTx contains the CAN receive and transmit error counter as well as some additional bits to ease error analysis. NECNTx can be written only if bit NCRx.CCE is set.

CAN_NECNTx (x = 0-5)

Node x Error Counter Register (214_H+x*100_H)

Reset Value: 0060 0000_H

| Field | Bits | Type | Description |
|---------|---------|------|---|
| REC | [7:0] | rwh | Receive Error Counter Bit field REC contains the value of the receive error counter of CAN node x. |
| TEC | [15:8] | rwh | Transmit Error Counter Bit field TEC contains the value of the transmit error counter of CAN node x. |
| EWRNLVL | [23:16] | rw | Error Warning Level Bit field EWRNLVL determines the threshold value (warning level, default 96) to be reached in order to set the corresponding error warning bit EWRN. |
| LETD | 24 | rh | Last Error Transfer Direction 0 _B The last error occurred while the CAN node x was receiver (REC has been incremented). 1 _B The last error occurred while the CAN node x was transmitter (TEC has been incremented). |
| LEINC | 25 | rh | Last Error Increment 0 _B The last error led to an error counter increment of 1. 1 _B The last error led to an error counter increment of 8. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [31:26] | r | Reserved Read as 0; should be written with 0. |

The Node Frame Counter Register NFCRx contains the actual value of the frame counter as well as control and status bits of the frame counter.

CAN_NFCRx (x = 0-5)

Node x Frame Counter Register ($218_H + x \cdot 100_H$)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

| CFC | | | | | | | | | | | | | | | |
| rwh | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|------------|--------|------|--|
| CFC | [15:0] | rwh | CAN Frame Counter In Frame Count Mode (CFMOD = 00 _B), this bit field contains the frame count value. In Time Stamp Mode (CFMOD = 01 _B), this bit field contains the captured bit time count value, captured with the start of a new frame. In all Bit Timing Analysis Modes ¹⁾ (CFMOD = 10 _B), CFC always displays the number of f_{CLC} clock cycles (measurement result) minus 1. Example: a CFC value of 34 in measurement mode CFSEL = 000 _B means that 35 f_{CLC} clock cycles have been elapsed between the most recent two dominant edges on the receive input. In Error Count Mode (CFMOD = 11 _B), this bit field contains the total amount of error frames received or error detected by the node. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| CFSEL | [18:16] | rw | <p>CAN Frame Count Selection</p> <p>This bit field selects the function of the frame counter for the chosen frame count mode.</p> <p>Frame Count Mode</p> <p>Bit 0</p> <p>If Bit 0 of CFSEL is set, then CFC is incremented each time a foreign frame (i.e. a frame not matching to a message object) has been received on the CAN bus.</p> <p>Bit 1</p> <p>If Bit 1 of CFSEL is set, then CFC is incremented each time a frame matching to a message object has been received on the CAN bus.</p> <p>Bit 2</p> <p>If Bit 2 of CFSEL is set, then CFC is incremented each time a frame has been transmitted successfully by the node.</p> <p>Time Stamp Mode</p> <p>The frame counter is incremented (internally) at the beginning of a new bit time. The value is sampled during the SOF bit of a new frame. The sampled value is visible in the CFC field.</p> <p>Bit Timing Mode</p> <p>The available bit timing measurement modes are shown in Table 19-10. If CFCIE is set, then an interrupt on request node x (where x is the CAN node number) is generated with a CFC update.</p> <p>Error Count Mode</p> <p>The frame counter is incremented when an error frame is received or an error is detected by the node. (001_B to 110_B) (see Table 19-9 for Encoding of the LEC Bit field). The configuration is don't care, in this mode.</p> |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|----------------|------|---|
| CFMOD | [20:19] | rw | CAN Frame Counter Mode This bit field determines the operation mode of the frame counter. 00 _B Frame Count Mode: The frame counter is incremented upon the reception and transmission of frames. 01 _B Time Stamp Mode: The frame counter is used to count bit times. 10 _B Bit Timing Mode: The frame counter is used for analysis of the bit timing. 11 _B Error Count Mode: The frame counter is used for counting when an error frame is received or an error is detected by the node. |
| CFCIE | 22 | rw | CAN Frame Count Interrupt Enable CFCIE enables the CAN frame counter overflow interrupt of CAN node x. 0 _B CAN frame counter overflow interrupt is disabled. 1 _B CAN frame counter overflow interrupt is enabled. Bit field NIPRx.CFCINP selects the interrupt output line that is activated at this type of interrupt. |
| CFCOV | 23 | rwh | CAN Frame Counter Overflow Flag Flag CFCOV is set upon a frame counter overflow (transition from FFFF _H to 0000 _H). In bit timing analysis mode, CFCOV is set upon an update of CFC. An interrupt request is generated if CFCIE = 1. 0 _B No overflow has occurred since last flag reset. 1 _B An overflow has occurred since last flag reset. CFCOV must be reset by software. |
| 0 | 21, [31:24] | r | Reserved Read as 0; should be written with 0. |

1) The value of NFCRx.CFC is valid one module cycle later when NFCRx.CFCOV is set.

Bit Timing Analysis Modes
Table 19-10 Bit Timing Analysis Modes (CFMOD = 10)

| CFSEL | Measurement |
|------------------|---|
| 000 _B | Whenever a dominant edge (transition from 1 to 0) is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC. |
| 001 _B | Whenever a recessive edge (transition from 0 to 1) is monitored on the receive input the time (measured in clock cycles) between this edge and the most recent dominant edge is stored in CFC. |
| 010 _B | Whenever a dominant edge is received as a result of a transmitted dominant edge, the time (clock cycles) between both edges is stored in CFC. |
| 011 _B | Whenever a recessive edge is received as a result of a transmitted recessive edge, the time (clock cycles) between both edges is stored in CFC. |
| 100 _B | Whenever a dominant edge that qualifies for synchronization is monitored on the receive input, the time (measured in clock cycles) between this edge and the most recent sample point is stored in CFC. |
| 101 _B | With each sample point, the time (measured in clock cycles) between the start of the new bit time and the start of the previous bit time is stored in CFC[11:0]. Additional information is written to CFC[15:12] at each sample point: CFC[15]: Transmit value of actual bit time CFC[14]: Receive sample value of actual bit time CFC[13:12]: CAN bus information (see Table 19-11) |
| 110 _B | Reserved, do not use this combination. |
| 111 _B | Reserved, do not use this combination. |

Table 19-11 CAN Bus State Information

| CFC[13:12] | CAN Bus State |
|-------------------|--|
| 00 _B | NoBit The CAN bus is idle, performs bit (de-) stuffing or is in one of the following frame segments: SOF, SRR, CRC, delimiters, first 6 EOF bits, IFS. |
| 01 _B | NewBit This code represents the first bit of a new frame segment. The current bit is the first bit in one of the following frame segments: Bit 10 (MSB) of standard ID (transmit only), RTR, reserved bits, IDE, DLC(MSB), bit 7 (MSB) in each data byte and the first bit of the ID extension. |
| 10 _B | Bit This code represents a bit inside a frame segment with a length of more than one bit (not the first bit of those frame segments that is indicated by NewBit). The current bit is processed within one of the following frame segments: ID bits (except first bit of standard ID for transmission and first bit of ID extension), DLC (3 LSB) and bits 6-0 in each data byte. |
| 11 _B | Done The current bit is in one of the following frame segments: Acknowledge slot, last bit of EOF, active/passive-error frame, overload frame. Two or more directly consecutive Done codes signal an Error Frame. |

Controller Area Network Controller (MultiCAN+)

19.5.3 Message Object Registers

The Message Object Control Register MOCTR_n and the Message Object Status Register MOSTAT_n are located at the same address offset within a message object address block (offset address 1C_H). The MOCTR_n is a write-only register that makes it possible to set/reset CAN transfer related control bits through software. Therefore the reset value is written as 0_H, even though the read part of the register has a different reset value.

CAN_MOCTR_z (z = 0-254)

Message Object z Control Register(101C_H+z*20_H)

Reset Value: 00000000_H

CAN_MOCTR255

Message Object 255 Control Register(2FFC_H)

Reset Value: 00000000_H

|------------------------------|-----------------|------------------------|
| Write 1 | Write 0 | Reset element |
| | No write | |
| Write 0 | Write 1 | Set element |
| No write | | |

1) The parameter "y" stands for the second part of the bit name ("RXPND", "TXPND", ... up to "DIR").

Controller Area Network Controller (MultiCAN+)

The MOSTATn is a read-only register that indicates message object list status information such as the number of the current message object predecessor and successor message object, as well as the list number to which the message object is assigned.

CAN_MOSTAT0

Message Object 0 Status Register (101C_H)

Reset Value: 0100 0000_H

CAN_MOSTATn (n = 1-254)

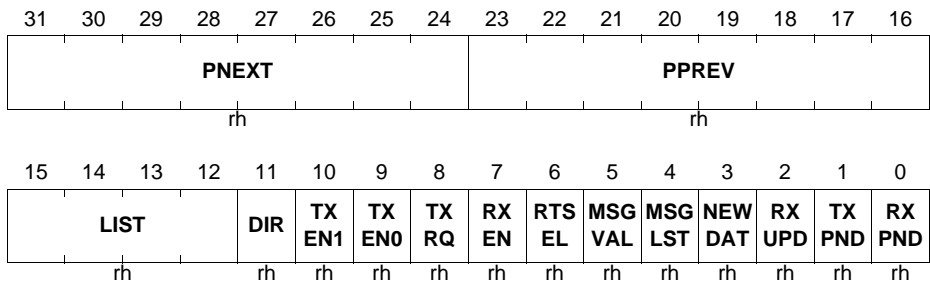

Message Object n Status Register(101C_H+n*20_H)

Reset Value: ((n+1)*01000000_H)+((n-1)*00010000_H)

CAN_MOSTAT255

Message Object 255 Status Register (2FFC_H)

Reset Value: FFFE0000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| RXPND | 0 | rh | Receive Pending 0 _B No CAN message has been received. 1 _B A CAN message has been received by the message object n, either directly or via gateway copy action. RXPND is set by hardware and must be reset by software. |
| TXPND | 1 | rh | Transmit Pending 0 _B No CAN message has been transmitted. 1 _B A CAN message from message object n has been transmitted successfully over the CAN bus. TXPND is set by hardware and must be reset by software. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|---------------|------|------|---|
| RXUPD | 2 | rh | Receive Updating 0_B No receive update ongoing. 1_B Message identifier, DLC, and data of the message object are currently updated. |
| NEWDAT | 3 | rh | New Data 0_B No update of the message object n since last flag reset. 1_B Message object n has been updated. NEWDAT is set by hardware after a received CAN frame has been stored in message object n. NEWDAT is cleared by hardware when a CAN transmission of message object n has been started. NEWDAT should be set by software after the new transmit data has been stored in message object n to prevent the automatic reset of TXRQ at the end of an ongoing transmission. |
| MSGLST | 4 | rh | Message Lost 0_B No CAN message is lost. 1_B A CAN message is lost because NEWDAT has become set again when it has already been set. |
| MSGVAL | 5 | rh | Message Valid 0_B Message object n is not valid. 1_B Message object n is valid. Only a valid message object takes part in CAN transfers. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------|------|------|--|
| RTSEL | 6 | rh | <p>Receive/Transmit Selected</p> <p>0_B Message object n is not selected for receive or transmit operation.</p> <p>1_B Message object n is selected for receive or transmit operation.</p> <p>Frame Reception: RTSEL is set by hardware when message object n has been identified for storage of a CAN frame that is currently received. Before a received frame becomes finally stored in message object n, a check is performed to determine if RTSEL is set. Thus the CPU can suppress a scheduled frame delivery to this message object n by clearing RTSEL by software.</p> <p>Frame Transmission: RTSEL is set by hardware when message object n has been identified to be transmitted next. A check is performed to determine if RTSEL is still set before message object n is actually set up for transmission and bit NEWDAT is cleared. It is also checked that RTSEL is still set before its message object n is verified due to the successful transmission of a frame. RTSEL needs to be checked only when the context of message object n changes, and a conflict with an ongoing frame transfer shall be avoided. In all other cases, RTSEL can be ignored. RTSEL has no impact on message acceptance filtering. RTSEL is not cleared by hardware.</p> |
| RXEN | 7 | rh | <p>Receive Enable</p> <p>0_B Message object n is not enabled for frame reception.</p> <p>1_B Message object n is enabled for frame reception.</p> <p>RXEN is evaluated for receive acceptance filtering only.</p> |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| TXRQ | 8 | rh | Transmit Request 0 _B No transmission of message object n is requested. 1 _B Transmission of message object n on the CAN bus is requested. The transmit request becomes valid only if TXRQ, TXEN0, TXEN1 and MSGVAL are set. TXRQ is set by hardware if a matching Remote Frame has been received correctly. TXRQ is reset by hardware if message object n has been transmitted successfully and NEWDAT is not set again by software. |
| TXEN0 | 9 | rh | Transmit Enable 0 0 _B Message object n is not enabled for frame transmission. 1 _B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. The user may clear TXEN0 in order to inhibit the transmission of a message that is currently updated, or to disable automatic response of Remote Frames. |
| TXEN1 | 10 | rh | Transmit Enable 1 0 _B Message object n is not enabled for frame transmission. 1 _B Message object n is enabled for frame transmission. Message object n can be transmitted only if both bits, TXEN0 and TXEN1, are set. TXEN1 is used by the MultiCAN+ module for selecting the active message object in the Transmit FIFOs. |

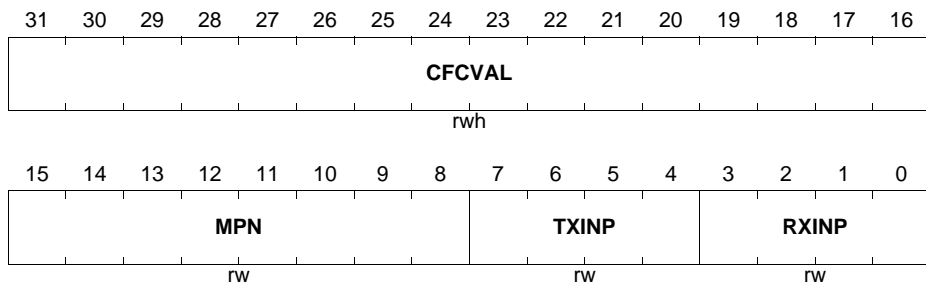

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| DIR | 11 | rh | Message Direction 0_B Receive Object selected: With TXRQ = 1, a Remote Frame with the identifier of message object n is scheduled for transmission. On reception of a Data Frame with matching identifier, the message is stored in message object n. 1_B Transmit Object selected: If TXRQ = 1, message object n is scheduled for transmission of a Data Frame. On reception of a Remote Frame with matching identifier, bit TXRQ is set. |
| LIST | [15:12] | rh | List Allocation LIST indicates the number of the message list to which message object n is allocated. LIST is updated by hardware when the list allocation of the object is modified by a panel command. |
| PPREV | [23:16] | rh | Pointer to Previous Message Object PPREV holds the message object number of the previous message object in a message list structure. |
| PNEXT | [31:24] | rh | Pointer to Next Message Object PNEXT holds the message object number of the next message object in a message list structure. |

Table 19-13 MOSTATn Reset Values

| Message Object | PNEXT | PPREV | Reset Value |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------------|------|------|---|
| GDFS | 8 | rw | Gateway Data Frame Send 0 _B TXRQ is unchanged in the destination object. 1 _B TXRQ is set in the gateway destination object after the internal transfer from the gateway source to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes. |
| IDC | 9 | rw | Identifier Copy 0 _B The identifier of the gateway source object is not copied. 1 _B The identifier of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes. |
| DLCC | 10 | rw | Data Length Code Copy 0 _B Data length code is not copied. 1 _B Data length code of the gateway source object (after storing the received frame in the source) is copied to the gateway destination object. Applicable only to a gateway source object; ignored in other nodes. |
| DATC | 11 | rw | Data Copy 0 _B Data fields are not copied. 1 _B Data fields in registers MODATALn and MODATAHn of the gateway source object (after storing the received frame in the source) are copied to the gateway destination. Applicable only to a gateway source object; ignored in other nodes. |
| RXIE | 16 | rw | Receive Interrupt Enable RXIE enables the message receive interrupt of message object n. This interrupt is generated after reception of a CAN message (independent of whether the CAN message is received directly or indirectly via a gateway action). 0 _B Message receive interrupt is disabled. 1 _B Message receive interrupt is enabled. Bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| TXIE | 17 | rw | Transmit Interrupt Enable TXIE enables the message transmit interrupt of message object n. This interrupt is generated after the transmission of a CAN message. 0 _B Message transmit interrupt is disabled. 1 _B Message transmit interrupt is enabled. Bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. |
| OVIE | 18 | rw | Overflow Interrupt Enable OVIE enables the FIFO full interrupt of message object n. This interrupt is generated when the pointer to the current message object (CUR) reaches the value of SEL in the FIFO/Gateway Pointer Register. 0 _B FIFO full interrupt is disabled. 1 _B FIFO full interrupt is enabled. If message object n is a Receive FIFO base object, bit field MOIPRn.TXINP selects the interrupt output line which becomes activated at this type of interrupt. If message object n is a Transmit FIFO base object, bit field MOIPRn.RXINP selects the interrupt output line which becomes activated at this type of interrupt. For all other message object modes, bit OVIE has no effect. |
| FRREN | 20 | rw | Foreign Remote Request Enable Specifies whether the TXRQ bit is set in message object n or in a foreign message object referenced by the pointer CUR. 0 _B TXRQ of message object n is set on reception of a matching Remote Frame. 1 _B TXRQ of the message object referenced by the pointer CUR is set on reception of a matching Remote Frame. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|------------|----------------------------|------|--|
| RMM | 21 | rw | Transmit Object Remote Monitoring 0_B Remote monitoring is disabled: Identifier, IDE bit, and DLC of message object n remain unchanged upon the reception of a matching Remote Frame. 1_B Remote monitoring is enabled: Identifier, IDE bit, and DLC of a matching Remote Frame are copied to transmit object n in order to monitor incoming Remote Frames. Bit RMM applies only to transmit objects and has no effect on receive objects. |
| SDT | 22 | rw | Single Data Transfer If SDT = 1 and message object n is not a FIFO base object, then MSGVAL is reset when this object has taken part in a successful data transfer (receive or transmit). If SDT = 1 and message object n is a FIFO base object, then MSGVAL is reset when the pointer to the current object CUR reaches the value of SEL in the FIFO/Gateway Pointer Register. With SDT = 0, bit MSGVAL is not affected. |
| STT | 23 | rw | Single Transmit Trial If this bit is set, then TXRQ is cleared on transmission start of message object n. Thus, no transmission retry is performed in case of transmission failure. |
| DLC | [27:24] | rwh | Data Length Code Bit field determines the number of data bytes for message object n. A value of DLC > 8 results in a data length of 8 data bytes. If a frame with DLC > 8 is received, the received value is stored in the message object. |
| 0 | 5, 7, [15:12], 19, [31:28] | rw | Reserved Read as 0 after reset; value last written is read back; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

The Message Object FIFO/Gateway Pointer register MOFGPRn contains a set of message object link pointers that are used for FIFO and gateway operations.

CAN_MOFGPRn (n = 0-255)

Message Object n FIFO/Gateway Pointer Register

(1004_H + n * 20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|---------|------|---|
| BOT | [7:0] | rw | Bottom Pointer Bit field BOT points to the first element in a FIFO structure. |
| TOP | [15:8] | rw | Top Pointer Bit field TOP points to the last element in a FIFO structure. |
| CUR | [23:16] | rwh | Current Object Pointer Bit field CUR points to the actual target object within a FIFO/Gateway structure. After a FIFO/gateway operation CUR is updated with the message number of the next message object in the list structure (given by PNEXT of the Message Object Status Register) until it reaches the FIFO top element (given by TOP) when it is reset to the bottom element (given by BOT). |
| SEL | [31:24] | rw | Object Select Pointer Bit field SEL is the second (software) pointer to complement the hardware pointer CUR in the FIFO structure. SEL is used for monitoring purposes (FIFO interrupt generation). |

Controller Area Network Controller (MultiCAN+)

Message Object n Acceptance Mask Register MOAMRn contains the mask bits for the acceptance filtering of the message object n.

CAN_MOAMRn (n = 0-255)

Message Object n Acceptance Mask Register

(100C_H+n*20_H)

Reset Value: 3FFF FFFF_H

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| AM | [28:0] | rw | Acceptance Mask for Message Identifier Bit field AM is the 29-bit mask for filtering incoming messages with standard identifiers (AM[28:18]) or extended identifiers (AM[28:0]). For standard identifiers, bits AM[17:0] are "don't care". |
| MIDE | 29 | rw | Acceptance Mask Bit for Message IDE Bit 0 _B Message object n accepts the reception of both, standard and extended frames. 1 _B Message object n receives frames only with matching IDE bit. |
| 0 | [31:30] | rw | Reserved Read as 0 after reset; value last written is read back; should be written with 0. |

Controller Area Network Controller (MultiCAN+)

Message Object n Arbitration Register MOARn contains the CAN identifier of the message object.

CAN_MOARn (n = 0-255)

Message Object n Arbitration Register

(1018_H+n*20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| ID | [28:0] | rwh | CAN Identifier of Message Object n Identifier of a standard message (ID[28:18]) or an extended message (ID[28:0]). For standard identifiers, bits ID[17:0] are “don’t care”. |
| IDE | 29 | rwh | Identifier Extension Bit of Message Object n 0 _B Message object n handles standard frames with 11-bit identifier. 1 _B Message object n handles extended frames with 29-bit identifier. |

Controller Area Network Controller (MultiCAN+)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| PRI | [31:30] | rw | <p>Priority Class</p> <p>PRI assigns one of the four priority classes 0, 1, 2, 3 to message object n. A lower PRI number defines a higher priority. Message objects with lower PRI value always win acceptance filtering for frame reception and transmission over message objects with higher PRI value. Acceptance filtering based on identifier/mask and list position is performed only between message objects of the same priority class. PRI also determines the acceptance filtering method for transmission:</p> <p>00_B Reserved.</p> <p>01_B Transmit acceptance filtering is based on the list order. This means that message object n is considered for transmission only if there is no other message object with valid transmit request (MSGVAL & TXEN0 & TXEN1 = 1) somewhere before this object in the list.</p> <p>10_B Transmit acceptance filtering is based on the CAN identifier. This means, message object n is considered for transmission only if there is no other message object with higher priority identifier + IDE + DIR (with respect to CAN arbitration rules) somewhere in the list (see Table 19-14).</p> <p>11_B Transmit acceptance filtering is based on the list order (as PRI = 01_B).</p> |

Controller Area Network Controller (MultiCAN+)

Transmit Priority of Msg. Objects based on CAN Arbitration Rules

Table 19-14 Transmit Priority of Msg. Objects Based on CAN Arbitration Rules

| Settings of Arbitrarily Chosen Message Objects A and B, (A has higher transmit priority than B) | Comment |
|--|--|
| A.MOAR[28:18] < B.MOAR[28:18] (11-bit standard identifier of A less than 11-bit standard identifier of B) | Messages with lower standard identifier have higher priority than messages with higher standard identifier. MOAR[28] is the most significant bit (MSB) of the standard identifier. MOAR[18] is the least significant bit of the standard identifier. |
| A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = 0 (send Standard Frame) B.MOAR.IDE = 1 (send Extended Frame) | Standard Frames have higher transmit priority than Extended Frames with equal standard identifier. |
| A.MOAR[28:18] = B.MOAR[28:18] A.MOAR.IDE = B.MOAR.IDE = 0 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Frame) | Standard Data Frames have higher transmit priority than standard Remote Frames with equal identifier. |
| A.MOAR[28:0] = B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 A.MOSTAT.DIR = 1 (send Data Frame) B.MOSTAT.DIR = 0 (send Remote Frame) | Extended Data Frames have higher transmit priority than Extended Remote Frames with equal identifier. |
| A.MOAR[28:0] < B.MOAR[28:0] A.MOAR.IDE = B.MOAR.IDE = 1 (29-bit identifier) | Extended Frames with lower identifier have higher transmit priority than Extended Frames with higher identifier. MOAR[28] is the most significant bit (MSB) of the overall identifier (standard identifier MOAR[28:18] and identifier extension MOAR[17:0]). MOAR[0] is the least significant bit (LSB) of the overall identifier. |

Controller Area Network Controller (MultiCAN+)

Message Object n Data Register Low MODATALn contains the lowest four data bytes of message object n. Unused data bytes are set to zero upon reception and ignored for transmission.

Controller Area Network Controller (MultiCAN+)

19.6 MultiCAN+ Module Implementation

This section describes CAN module interfaces with the clock control, port connections, interrupt control, and address decoding.

19.6.1 Interfaces of the MultiCAN+ Module

Figure 19-24 shows the XMC4[78]00 specific implementation details and interconnections of the MultiCAN+ module. The I/O lines of the MultiCAN+ module (two I/O lines of each CAN node) are connected to the Ports listed in **Table 19-16**. The MultiCAN+ module is also supplied by clock control, interrupt control, and address decoding logic. MultiCAN+ interrupts can be directed to the DMA, CPU, CCU4 modules which are able to trigger DMA transfers and CCU4, CPU operations.

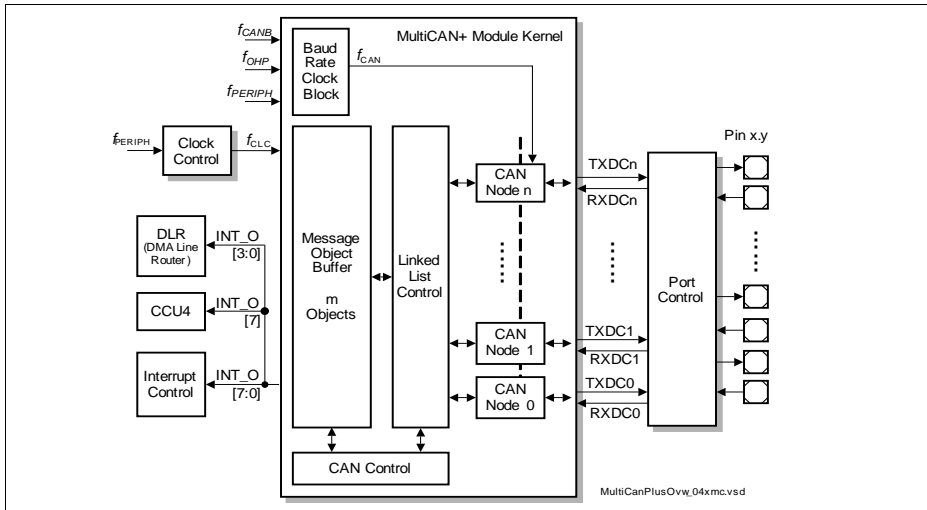

Figure 19-24 MultiCAN+ Module Implementation and Interconnections with $n := 5$ and $m := 256$ for XMC4800

Controller Area Network Controller (MultiCAN+)

19.6.2 MultiCAN+ Module External Registers

The registers listed in [Figure 19-25](#) are not included in the MultiCAN+ module kernel, some registers must be programmed for proper operation of the MultiCAN+ module.

Figure 19-25 CAN Implementation-specific Special Function Registers

Table 19-15 MultiCAN+ Module External Registers

| Short Name | Description | Offset Addr | Access Mode | | Reset Class | Description see |

| FDR | Fractional Divider Register | 00C _H | U, PV | PV, | Appli- cation Reset | Page 19-11 8 |

19.6.3 Module Clock Generation

This chapter describes the way the module gets its clock.

19.6.3.1 Clock Selection

The bit timing machine and the rest of the MultiCAN+ module are separate frequency domains and can be driven by separate independent frequencies. The bit timing unit can be driven by the AHB bus clock or with the direct oscillator clock, and the rest of the chip is driven only by the AHB bus clock.

The purpose of supplying the bit timing unit with a direct oscillator clock is to avoid the clock jitter added by the PLL, necessary when the chip is driven by a low cost ceramic resonator instead of a high precision quartz crystal.

Selecting the clock source for the bit timing unit is done by programming the bit-field MCR.CLKSEL.

Enabling and disabling the clock of the module by using CLC.DISR affects always both frequency domains, so that when f_{CLC} is switched off, f_A is also switched off.

19.6.3.2 Fractional Divider

As shown in **Figure 19-26**, the clock signals for the MultiCAN+ module are generated and controlled by a clock control unit. This clock generation unit is responsible for the enable/disable control, the clock frequency adjustment, and the debug clock control. This unit includes two registers:

- CAN_CLC: generation of the module control clock f_{CLC}
- CAN_FDR: frequency control of the module timer clock f_{CAN}

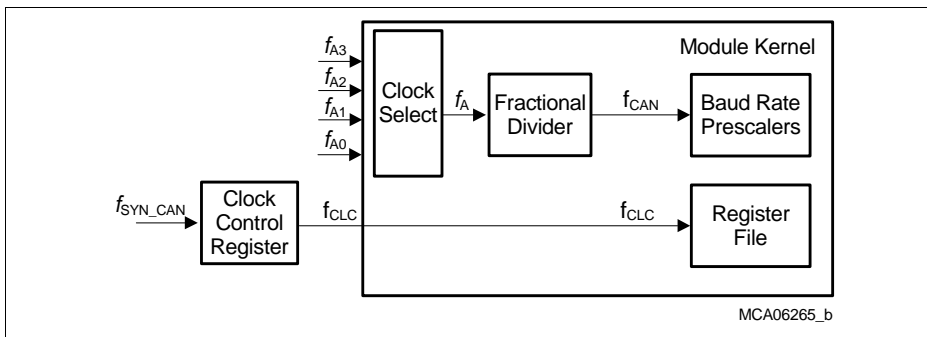

Figure 19-26 MultiCAN+ Module Clock Generation

The f_{SYN_CAN} is identical to f_{PERIPH} .

Controller Area Network Controller (MultiCAN+)

The module control clock f_{CLC} is used inside the MultiCAN+ module for control purposes such as clocking of control logic and register operations. The frequency of f_{CLC} is identical to the system clock frequency f_{PERIPH} . The clock control register CAN_CLC makes it possible to enable/disable f_{CLC} under certain conditions.

The module timer clock f_{CAN} is used inside the MultiCAN+ module as input clock for all timing relevant operations (e.g. bit timing). The settings in the CAN_FDR register determine the frequency of the module timer clock f_{CAN} according the following two formulas:

$$f_{CAN} = f_A \times \frac{1}{n} \quad \text{with } n = 1024 - \text{CAN_FDR.STEP} \quad (19.2)$$

$$f_{CAN} = f_A \times \frac{n}{1024} \quad \text{with } n = 0-1023 \quad (19.3)$$

Equation (19.2) applies to normal divider mode (CAN_FDR.DM = 01_B) of the fractional divider. **Equation (19.3)** applies to fractional divider mode (CAN_FDR.DM = 10_B).

Note: The CAN module is disabled after reset. In general, after reset, the module control clock f_{CLC} must be switched on (writing to register CAN_CLC) before the frequency of the module timer clock f_{CAN} is defined (writing to register CAN_FDR).

Controller Area Network Controller (MultiCAN+)

CAN Clock Control Register

The Clock Control Register CLC allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. The description below shows the clock control register functionality which is implemented in the BPI for the module. CLC controls the f_{CAN} module clock signal.

CLC

CAN Clock Control Register

(000_H)

Reset Value: 0000 0003_H

| Field | Bits | Type | Description |
|-------------|--------------|------|---|
| DISR | 0 | rw | Module Disable Request Bit Used for enable/disable control of the module. Note that no register access is possible to any register while module is disabled. |
| DISS | 1 | rh | Module Disable Status Bit Bit indicates the current status of the module. |
| EDIS | 3 | rw | Sleep Mode Enable Control Used to control module's sleep mode. |
| 0 | [31:4], 2 | r | Reserved Read as 0; should be written with 0. |

Note: The number of module clock cycles (wait states) which are required by the kernel to execute a read or write access depends on the selected CLC clock frequency.

The fractional divider register allows the programmer to control the clock rate of the module timer clock f_{CAN} .

Controller Area Network Controller (MultiCAN+)

FDR

CAN Fractional Divider Register

(00C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|---------------------|------|--|
| STEP | [9:0] | rw | Step Value Reload or addition value for the result. |
| DM | [15:14] | rw | Divider Mode This bit field selects normal divider mode, fractional divider mode, and off-state. |
| 0 | [13:10], [31:16] | r | Reserved Read as 0; should be written with 0. |

Controller Area Network Controller (MultiCAN+)
19.6.4 Port and I/O Line Control

The interconnections between the MultiCAN+ module and the port I/O lines are controlled in the port logic. Additionally to the port input selection, the following port control operations must be executed:

- Input/output function selection (IOCR registers)
- Pad driver characteristics selection for the outputs (PDR registers)

19.6.4.1 Input/Output Function Selection in Ports

The port input/output control registers contain the bit fields that select the digital output and input driver characteristics such as pull-up/down devices, port direction (input/output), open-drain, and alternate output selections. The I/O lines for the MultiCAN+ module are controlled by the port input/output control registers, which are described in the datasheet. In case of discrepancies between datasheet and CAN chapter, the description in the datasheet is correct.

Table 19-16 shows the corresponding pins, sorted by node. Even though the table is pair wise, it is possible to select a different pairing for RXD and TXD. In addition the RXSEL value to be programmed for the Receive Pins is part of this table. For more information on RXSEL please see **Chapter 19.6.4.2**.

Table 19-16 MultiCAN+ I/O Control Selection and Setup for XMC4800

19.6.4.2 Node Receive Input Selection

Additionally to the I/O control selection, as defined in the datasheet, the selection of a CAN node's receive input line requires that bit field RXSEL in its node port control register NPCR_x must be set according to [Table 19-16](#). Values for NPCR_x.RXSEL other than those of the table mentioned above will result in a recessive receive input for node x. As a hint A results in 0_H, B in 1_H until H resulting in the value of 7_H.

This feature allows, for example, a CAN node which operates in analyzer mode to monitor the receive operations of its neighbor CAN node.

19.6.4.3 Connections to Interrupt Router Inputs

The interrupt output lines INT_O0-7 are connected to the Interrupt Router module, see [Table 19-17](#).

Table 19-17 Interrupt Router Inputs

| Interrupt Router Input | Connected to CAN Interrupt Output |
|------------------------|-----------------------------------|
| SRC_CANINT0 | INT_O0 |
| SRC_CANINT1 | INT_O1 |
| SRC_CANINT2 | INT_O2 |
| SRC_CANINT3 | INT_O3 |
| SRC_CANINT4 | INT_O4 |
| SRC_CANINT5 | INT_O5 |
| SRC_CANINT6 | INT_O6 |
| SRC_CANINT7 | INT_O7 |

19.6.4.4 Connections to Capcom4 Inputs

The interrupt output line INT_O7 of MultiCAN+ is connected to the CAPCOM4, see [Table 19-18](#).

Table 19-18 General Timer Module Inputs

| CCU4 Input | Connected to CAN Interrupt Output |
|--------------------------|-----------------------------------|
| Timer input (CCU40.IN0H) | INT_O7 |
| Timer input (CCU41.IN0H) | |
| Timer input (CCU42.IN2G) | |
| Timer input (CCU43.IN1G) | |

19.6.4.5 Connections to USIC Inputs

The internal signal CAN1INS is connected to the USIC module, see [Table 19-19](#).

Table 19-19 CAN-to-USIC Connections

| USIC Input | Connected to CAN Internal Signal |
|------------|----------------------------------|
| U1C1_DX0E | CAN1INS |

19.6.5 Interrupt Control

The interrupt control logic in the MultiCAN+ module uses an interrupt compressing scheme that allows high flexibility in interrupt processing. There are hardware and software interrupt sources available:

- CAN node interrupts:
 - Five different interrupt sources for each of the 6 CAN nodes = $5 * \underline{6}$ interrupt sources
- Message object interrupts:
 - Two interrupt source for each message object = $2 * \underline{256}$ interrupt sources
- One register (MITR) to initiate 16 interrupts via software

Each of the hardware initiated interrupt sources is controlled by a 4-bit interrupt pointer that directs the interrupt source to one of the 8 interrupt outputs INT_Om ($m = 0\text{--}7$). This makes it possible to connect more than one interrupt source (between one and all) to one interrupt output line. The interrupt wiring matrix shown in **Figure 19-28** is built up according to the following rules:

- Each output of the 4-bit interrupt pointer demultiplexer is connected to exactly one OR-gate input of the INT_Om line. The number “m” of the corresponding selected INT_Om interrupt output line is defined by the interrupt pointer value.
- Each INT_Om output line has an input OR gate which is connected to all interrupt pointer demultiplexer outputs which are selected by an identical 4-bit pointer value.

Analog Frontend Peripherals

20 Versatile Analog-to-Digital Converter (VADC)

The XMC4[78]00 provides a series of analog input channels connected to a cluster of Analog/Digital Converters using the Successive Approximation Register (SAR) principle to convert analog input values (voltages) to discrete digital values.

The number of analog input channels and ADCs depends on the chosen product type (please refer to **“Product-Specific Configuration” on Page 20-133**).

Table 20-1 Abbreviations used in ADC chapter

| | |
|------------------|---|
| ADC | Analog to Digital Converter |
| DMA | Direct Memory Access (controller) |
| DNL | Differential Non-Linearity (error) |
| INL | Integral Non-Linearity (error) |
| LSB _n | Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2 ⁿ equally distributed steps) |
| SCU | System Control Unit of the device |
| TUE | Total Unadjusted Error |

20.1 Overview

Each converter of the ADC cluster can operate independent of the others, controlled by a dedicated set of registers and triggered by a dedicated group request source. The results of each channel can be stored in a dedicated channel-specific result register or in a group-specific result register.

A background request source can access all analog input channels that are not assigned to any group request source. These conversions are executed with low priority. The background request source can, therefore, be regarded as an additional background converter.

The Versatile Analog to Digital Converter module (VADC) of the XMC4[78]00 comprises a set of converter blocks that can be operated either independently or via a common request source that emulates a background converter. Each converter block is equipped with a dedicated input multiplexer and dedicated request sources, which together build separate groups.

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

Versatile Analog-to-Digital Converter (VADC)

The basic module clock f_{ADC} is connected to the system clock signal f_{PERIPH} .

Feature List

The following features describe the functionality of the ADC cluster:

- Nominal analog supply voltage 3.3 V
- Input voltage range from 0 V up to analog supply voltage
- Standard (V_{AREF}) and alternate (CH0) reference voltage source selectable for each channel to support ratiometric measurements and different signal scales
- Up to 4 independent converters with up to 8 analog input channels
- External analog multiplexer control, including adjusted sample time and scan support
- Conversion speed and sample time adjustable to adapt to sensors and reference
- Conversion time below 1 μs (depending on result width and sample time)
- Flexible source selection and arbitration
 - Programmable arbitrary conversion sequence (single or repeated)
 - Configurable auto scan conversion (single or repeated) on each converter
 - Configurable auto scan conversion (single or repeated) in the background (all converters)
 - Conversions triggered by software, timer events, or external events
 - Cancel-inject-restart mode for reduced conversion delay on priority channels
- Powerful result handling
 - Selectable result width of 8/10/12 bits
 - Fast Compare Mode
 - Independent result registers
 - Configurable limit checking against programmable border values
 - Data rate reduction through adding a selectable number of conversion results
 - FIR/IIR filter with selectable coefficients
- Flexible service request generation based on selectable events
- Built-in safety features
 - Broken wire detection with programmable default levels
 - Multiplexer test mode to verify signal path integrity
- Support of suspend and power saving modes

Note: Additional functions are available from the out of range comparator (see description in the SCU).

Versatile Analog-to-Digital Converter (VADC)

Table 20-2 VADC Applications

| Use Case VADC | Application |
|---|---------------------------------|
| Automatic scheduling of complex conversion sequences, including prioritization of time-critical conversions | Motor control, Power conversion |
| Effective result handling for bursts of high-speed conversions | Highly dynamic input signals |
| Synchronous sampling of up to 4 input signals | Multi-phase current measurement |

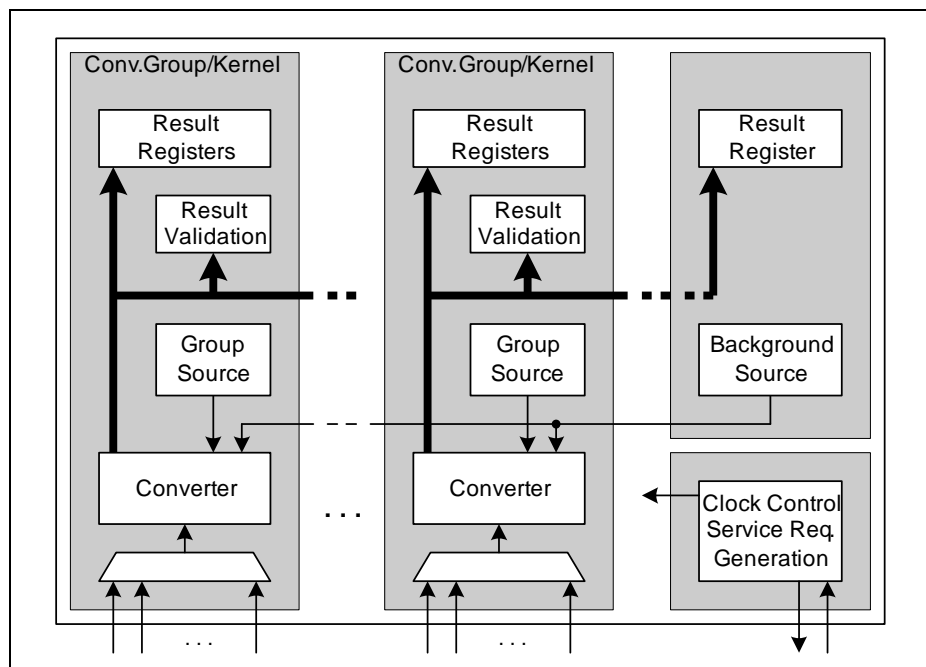

Figure 20-1 ADC Structure Overview

Versatile Analog-to-Digital Converter (VADC)**Conversion Modes and Request Sources**

Analog/Digital conversions can be requested by several request sources (2 group request sources and the background request source) and can be executed in several conversion modes. The request sources can be enabled concurrently with configurable priorities.

- **Fixed Channel Conversion (single or continuous)**

A specific channel source requests conversions of one selectable channel (once or repeatedly)

- **Auto Scan Conversion (single or continuous)**

A channel scan source (request source 1 or 2) requests auto scan conversions of a configurable linear sequence of all available channels (once or repeatedly)

- **Channel Sequence Conversion (single or continuous)**

A queued source (request source 0) requests a sequence of conversions of up to 8 arbitrarily selectable channels (once or repeatedly)

The conversion modes can be used concurrently by the available request sources, i.e. conversions in different modes can be enabled at the same time. Each source can be enabled separately and can be triggered by external events, such as edges of PWM or timer signals, or pin transitions.

Request Source Control

Because all request sources can be enabled at the same time, an arbiter resolves concurrent conversion requests from different sources. Each source can be triggered by external signals, by on-chip signals, or by software.

Requests with higher priority can either cancel a running lower-priority conversion (cancel-inject-repeat mode) or be converted immediately after the currently running conversion (wait-for-start mode). If the target result register has not been read, a conversion can be deferred (wait-for-read mode).

Certain channels can also be synchronized with other ADC kernels, so several signals can be converted in parallel.

Versatile Analog-to-Digital Converter (VADC)

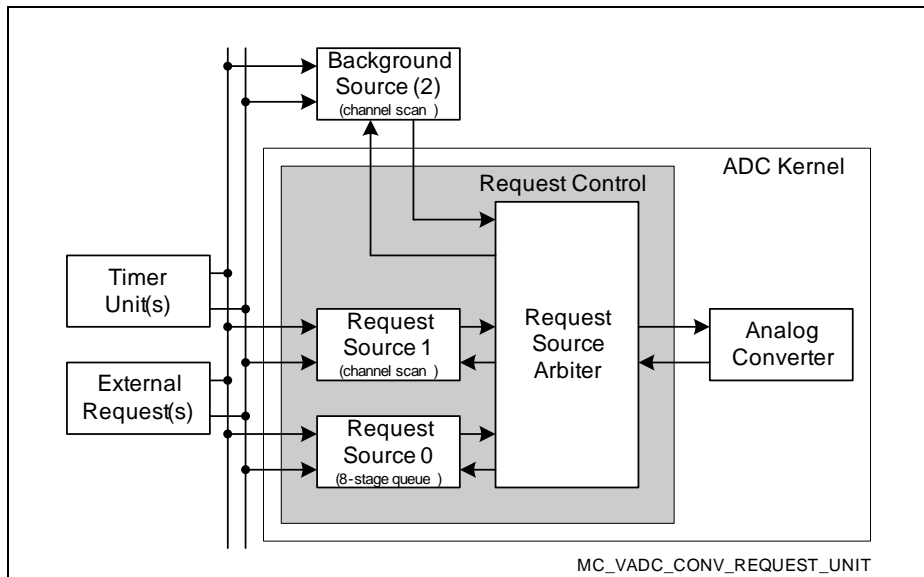

Figure 20-3 Conversion Request Unit

Input Channel Selection

The analog input multiplexer selects one of the available analog inputs (CH0 - CHx¹⁾) to be converted. Three sources can select a linear sequence, an arbitrary sequence, or a specific channel. The priorities of these sources can be configured.

Additional external analog multiplexers can be controlled automatically, if more separate input channels are required than are built in.

Note: Not all analog input channels are necessarily available in all packages, due to pin limitations. Please refer to the implementation description in [Section 20.14](#).

Conversion Control

Conversion parameters, such as sample phase duration, reference voltage, or result resolution can be configured for 4 input classes (2 group-specific classes, 2 global classes). Each channel can be individually assigned to one of these input classes.

The input channels can, thus, be adjusted to the type of sensor (or other analog sources) connected to the ADC.

¹⁾ The availability of input channels depends on the package of the used product type. A summary can be found in [Section 20.14.2](#).

Versatile Analog-to-Digital Converter (VADC)

This unit also controls the built-in multiplexer and external analog multiplexers, if selected.

Analog/Digital Converter

The selected input channel is converted to a digital value by first sampling the voltage on the selected input and then generating the selected number of result bits.

For 12-bit conversions, post-calibration is executed after converting the channel.

For broken wire detection (see [Section 20.10.1](#)), the converter network can be preloaded before sampling the selected input channel.

Result Handling

The conversion results of each analog input channel can be directed to one of 16 group-specific result registers and one global result register to be stored there. A result register can be used by a group of channels or by a single channel.

The wait-for-read mode avoids data loss due to result overwrite by blocking a conversion until the previous result has been read.

Data reduction (e.g. for digital anti-aliasing filtering) can automatically add up to 4 conversion results before issuing a service request.

Alternatively, an FIR or IIR filter can be enabled that preprocesses the conversion results before sending them to the result register.

Also, result registers can be concatenated to build FIFO structures that store a number of conversion results without overwriting previous data. This increases the allowed CPU latency for retrieving conversion data from the ADC.

Service Request Generation

Several ADC events can issue service requests to CPU or DMA:

- **Source events** indicate the completion of a conversion sequence in the corresponding request source. This event can be used to trigger the setup of a new sequence.
- **Channel events** indicate the completion of a conversion for a certain channel. This can be combined with limit checking, so interrupt are generated only if the result is within a defined range of values.
- **Result events** indicate the availability of new result data in the corresponding result register. If data reduction mode is active, events are generated only after a complete accumulation sequence.

Each event can be assigned to one of eight service request nodes. This allows grouping the requests according to the requirements of the application.

Versatile Analog-to-Digital Converter (VADC)**Safety Features**

Safety-aware applications are supported with mechanisms that help to ensure the integrity of a signal path.

Broken-wire-detection (BWD) preloads the converter network with a selectable level before sampling the input channel. The result will then reflect the preload value if the input signal is no more connected. If buffer capacitors are used, a certain number of conversions may be required to reach the failure indication level.

Pull Down Diagnostics (PDD) connects an additional strong pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper connection of a signal source (sensor) to the multiplexer.

Multiplexer Diagnostics (MD) connects a weak pull-up or pull-down device to an input channel. A subsequent conversion can then confirm the expected modified signal level. This allows to check the proper operation of the multiplexer.

Note: These pull-up/pull-down devices are controlled via the port logic.

Converter Diagnostics (CD) connects an alternate signal to the converter. A subsequent conversion can then confirm the proper operation of the converter.

Versatile Analog-to-Digital Converter (VADC)

20.3 Configuration of General Functions

While many parameters can be selected individually for each channel, source, or group, some adjustments are valid for the whole ADC cluster:

- Clock control
- Kernel synchronization
- External multiplexer control
- Test functions

20.3.1 General Clocking Scheme and Control

The A/D Converters of the XMC4[78]00 are supplied with a global clock signal from the system f_{ADC} . Two clock signals are derived from this input and are distributed to all converters. The global configuration register defines common clock bases for all converters of the cluster. This ensures deterministic behavior of converters that shall operate in parallel.

The analog converter clock f_{ADC_I} determines the performance of the converters and must be selected to comply with the specification given in the Data Sheet.

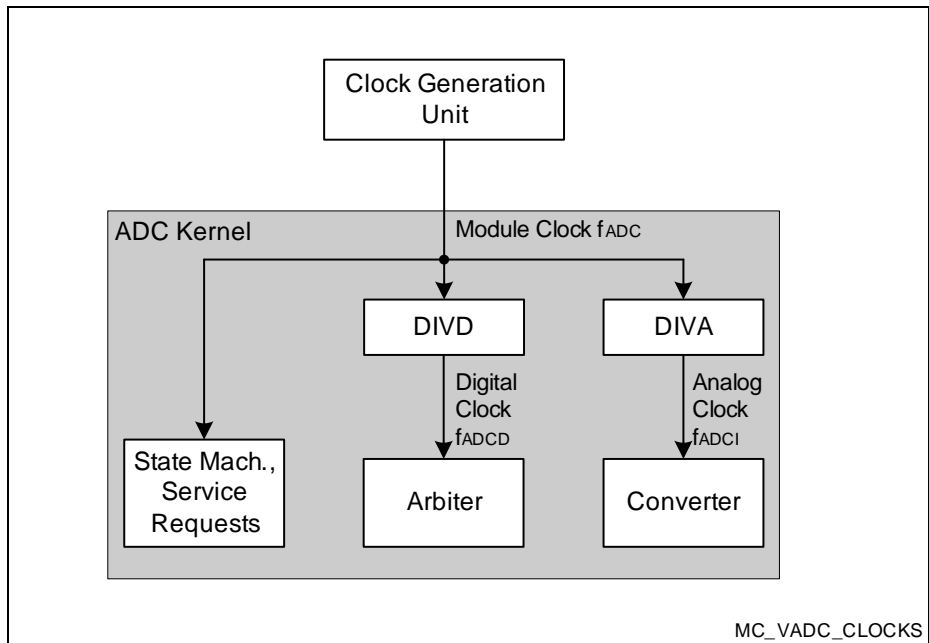

Figure 20-4 Clock Signal Summary

20.3.2 Priority Channel Assignment

Each channel of a group can be assigned to this group's request sources and is then regarded as a priority channel. An assigned priority channel can only be converted by its own group's request sources. A not assigned channel can also be converted by the background request source.

20.4 Module Activation and Power Saving

The analog converter of the ADC draws a permanent current during its operation. It can be deactivated between conversions to reduce the consumed overall energy.

The operating mode is determined by bitfield **GxARBCFG (x = 0 - 3)**.ANONS:

- **ANONS = 11_B: Normal Operation**
The converter is active, conversions are started immediately.
Requires no wakeup time.
- **ANONS = 10_B or 01_B: Reserved**
- **ANONS = 00_B: Converter switched Off** (default after reset)
The converter is switched off. Furthermore, digital logic blocks are set to their initial state. If the arbiter is currently running, it completes the actual arbitration round and then stops.
Before starting a conversion, select the active mode for ANONS.
Requires the wakeup time (see below).

Wakeup Time from Analog Powerdown

When the converter is activated, it needs a certain wakeup time to settle before a conversion can be properly executed. This wakeup time can be established by waiting the required period before starting a conversion, or by adding it to the intended sample time.

The wakeup time is approximately 15 μ s.

Exact numbers can be found in the respective Data Sheets.

Note: The wakeup time is also required after initially enabling the converter.

Calibration

Calibration automatically compensates deviations caused by process, temperature, and voltage variations. This ensures precise results throughout the operation time.

An initial start-up calibration is required once after a reset for all calibrated converters and is triggered globally. All calibrated converters must be enabled (ANONS = 11_B) before initiating the start-up calibration. Conversions may be started after the initial calibration sequence. This is indicated by bit CAL = 0_B.

After that, postcalibration cycles will compensate the effects of drifting parameters.

20.5 Conversion Request Generation

The conversion request unit of a group autonomously handles the generation of conversion requests. Three request sources (2 group-specific sources and the background source) can generate requests for the conversion of an analog channel. The arbiter resolves concurrent requests and selects the channel to be converted next.

Upon a trigger event, the request source requests the conversion of a certain analog input channel or a sequence of channels.

- **Software triggers**
directly activate the respective request source.
- **External triggers**
synchronize the request source activation with external events, such as a trigger pulse from a timer generating a PWM signal or from a port pin.

Application software selects the trigger, the channel(s) to be converted, and the request source priority. A request source can also be activated directly by software without requiring an external trigger.

The arbiter regularly scans the request sources for pending conversion requests and selects the conversion request with the highest priority. This conversion request is then forwarded to the converter to start the conversion of the requested channel.

Each request source can operate in single-shot or in continuous mode:

- **In single-shot mode,**
the programmed conversion (sequence) is requested once after being triggered. A subsequent conversion (sequence) must be triggered again.
- **In continuous mode,**
the programmed conversion (sequence) is automatically requested repeatedly after being triggered once.

For each request source, external triggers are generated from one of 16 selectable trigger inputs (REQTRx[P:A]) and from one of 16 selectable gating inputs (REQGTx[P:A]). The available trigger signals for the XMC4[78]00 are listed in [Section 20.14.3](#).

Note: [Figure 20-3 “Conversion Request Unit” on Page 20-6](#) summarizes the request sources.

Versatile Analog-to-Digital Converter (VADC)

Two types of requests sources are available:

- **A queued source** can issue conversion requests for an arbitrary sequence of input channels. The channel numbers for this sequence can be freely programmed¹⁾. This supports application-specific conversion sequences that cannot be covered by a channel scan source. Also, multiple conversions of the same channel within a sequence are supported.

A queued source converts a series of input channels permanently or on a regular time base. For example, if programmed with medium priority, some input channels can be converted upon a specified event (e.g. synchronized to a PWM). Conversions of lower priority sources are suspended in the meantime.

Request source 0 is a group-specific 8-stage queued source.

- **A channel scan source** can issue conversion requests for a coherent sequence of input channels. This sequence begins with the highest enabled channel number and continues towards lower channel numbers. All available channels¹⁾ can be enabled for the scan sequence. Each channel is converted once per sequence.

A scan source converts a series of input channels permanently or on a regular time base. For example, if programmed with low priority, some input channels can be scanned in a background task to update information that is not time-critical.

- Request source 1 is a group-specific channel scan source.
- Request source 2 is a global channel scan source (background source).

The background source can request all channels of all groups.

1) The availability of input channels depends on the package of the used product type. A summary can be found in [Section 20.14.2](#).

The background source can only request non-priority channels, i.e. channels that are not selected in registers GxCHASS. Priority channels are reserved for the group-specific request sources 0 and 1.

20.5.1 Queued Request Source Handling

A queued request source supports short conversion sequences (up to 8) of arbitrary channels (contrary to a scan request source with a fixed conversion order for the enabled channels). The programmed sequence is stored in a queue buffer (based on a FIFO mechanism). The requested channel numbers are entered via the queue input, while queue stage 0 defines the channel to be converted next.

A conversion request is only issued to the request source arbiter if a valid entry is stored in queue stage 0.

If the arbiter aborts a conversion triggered by a queued request source due to higher priority requests, the corresponding conversion parameters are automatically saved in the backup stage. This ensures that an aborted conversion is not lost but takes part in the next arbitration round (before stage 0).

The trigger and gating unit generates trigger events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Trigger events start a queued sequence and can be generated either via software or via the selected hardware triggers. The occurrence of a trigger event is indicated by bit QSRx.EV. This flag is cleared when the corresponding conversion is started or by writing to bit QMRx.CEV.

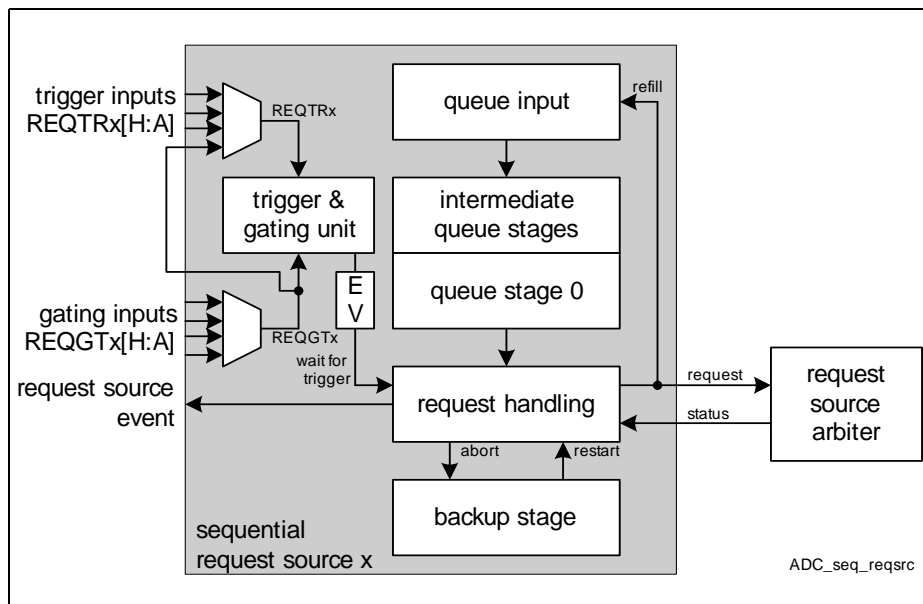

Figure 20-5 Queued Request Source

Versatile Analog-to-Digital Converter (VADC)

A sequence is defined by entering conversion requests into the queue input register (**GxQINR0 (x = 0 - 3)**). Each entry selects the channel to be converted and can enable an external trigger, generation of an interrupt, and an automatic refill (i.e. copy this entry to the top of the queue after conversion). The entries are stored in the queue buffer stages.

The content of stage 0 (**GxQ0R0 (x = 0 - 3)**) selects the channel to be converted next. When the requested conversion is started, the contents of this queue stage is invalidated and copied to the backup stage. Then the next queue entry can be handled (if available).

Note: The contents of the queue stages cannot be modified directly, but only by writing to the queue input or by flushing the queue.

*The current status of the queue is shown in register **GxQSR0 (x = 0 - 3)**.*

If all queue entries have automatic refill selected, the defined conversion sequence can be repeated without re-programming.

Properties of the Queued Request Source

Queued request source 0 provides 8 buffer stages and can handle sequences of up to 8 input channel entries. It supports short application-specific conversion sequences, especially for timing-critical sequences containing also multiple conversions of the same channel.

Queued Source Operation

Configure the queued request source by executing the following actions:

- Define the sequence by writing the entries to the queue input **GxQINR0 (x = 0 - 3)**. Initialize the complete sequence before enabling the request source, because with enabled refill feature, software writes to QINRx are not allowed.
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper transitions by programming **GxQCTRL0 (x = 0 - 3)**. Enable the trigger and select the gating mode by programming bitfield ENGT in register **GxQMR0 (x = 0 - 3)**.¹⁾
- Enable the corresponding arbitration slot (0) to accept conversion requests from the queued source (see register **GxARBPR (x = 0 - 3)**).

Start a queued sequence by generating a trigger event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software trigger event by setting **GxQMR0.TREV = 1**.

1) If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid un expected signal transitions.

Versatile Analog-to-Digital Converter (VADC)

- Write a new entry to the queue input of an empty queue. This leads to a (new) valid queue entry that is forwarded to queue stage 0 and starts a conversion request (if enabled by GxQMR0.ENGST and without waiting for an external trigger).

Note: If the refill mechanism is activated, a processed entry is automatically reloaded into the queue. This permanently repeats the respective sequence (autoscan).

In this case, do not write to the queue input while the queued source is running.

Write operations to a completely filled queue are ignored.

Stop or abort an ongoing queued sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the queue entries, but only prevents issuing conversion requests to the arbiter.
- Disable the corresponding arbitration slot (0) in the arbiter. This does not modify the queue entries, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the queued source by clearing bitfield ENGST = 00_B.
 - Invalidate the next pending queue entry by setting bit GxQMR0.CLRV = 1.
If the backup stage contains a valid entry, this one is invalidated, otherwise stage 0 is invalidated.
 - Remove all entries from the queue by setting bit GxQMR0.FLUSH = 1.

Queue Request Source Events and Service Requests

A request source event of a queued source occurs when a conversion is finished. A source event service request can be generated based on a request source event according to the structure shown in [Figure 20-6](#). If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect. The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.

The interrupt enable bit is taken from stage 0 for a normal sequential conversion, or from the backup stage for a repeated conversion after an abort.

The service request output line SRx that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by GxQ0R0.ENS1, or GxQBUR0.ENS1 respectively) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

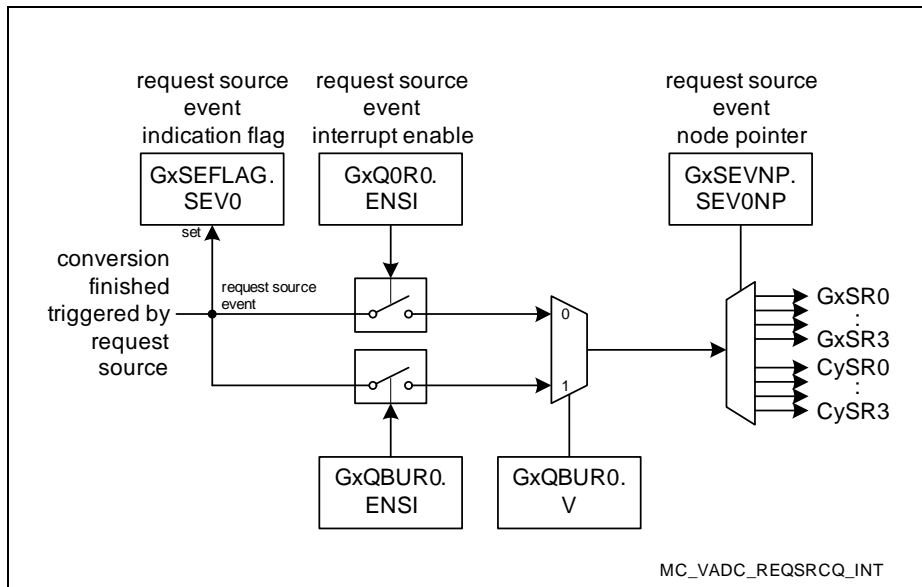

Figure 20-6 Interrupt Generation of a Queued Request Source

20.5.2 Channel Scan Request Source Handling

The VADC provides two types of channel scan sources:

- Source 1: Group scan source
This scan source can request all channels of the corresponding group.
- Source 2: Background scan source
This scan source can request all channels of all groups.
Priority channels selected in registers **GxCHASS** ($x = 0 - 3$) cannot take part in background conversion sequences.

Both sources operate in the same way and provide the same register interface. The background source provides more request/pending bits because it can request all channels of all groups.

Each analog input channel can be included in or excluded from the scan sequence by setting or clearing the corresponding channel select bit in register **GxASSEL** ($x = 0 - 3$) or **BRSELx** ($x = 0 - 3$). The programmed register value remains unchanged by an ongoing scan sequence. The scan sequence starts with the highest enabled channel number and continues towards lower channel numbers.

Upon a load event, the request pattern is transferred to the pending bits in register **GxASPND** ($x = 0 - 3$) or **BRSPNDx** ($x = 0 - 3$). The pending conversion requests indicate

Versatile Analog-to-Digital Converter (VADC)

which input channels are to be converted in an ongoing scan sequence. Each conversion start that was triggered by the scan request source, automatically clears the corresponding pending bit. If the last conversion triggered by the scan source is finished and all pending bits are cleared, the current scan sequence is considered finished and a request source event is generated.

A conversion request is only issued to the request source arbiter if at least one pending bit is set.

If the arbiter aborts a conversion triggered by the scan request source due to higher priority requests, the corresponding pending bit is automatically set. This ensures that an aborted conversion is not lost but takes part in the next arbitration round.

The trigger and gating unit generates load events from the selected external (outside the ADC) trigger and gating signals. For example, a timer unit can issue a request signal to synchronize conversions to PWM events.

Load events start a scan sequence and can be generated either via software or via the selected hardware triggers. The request source event can also generate an automatic load event, so the programmed sequence is automatically repeated.

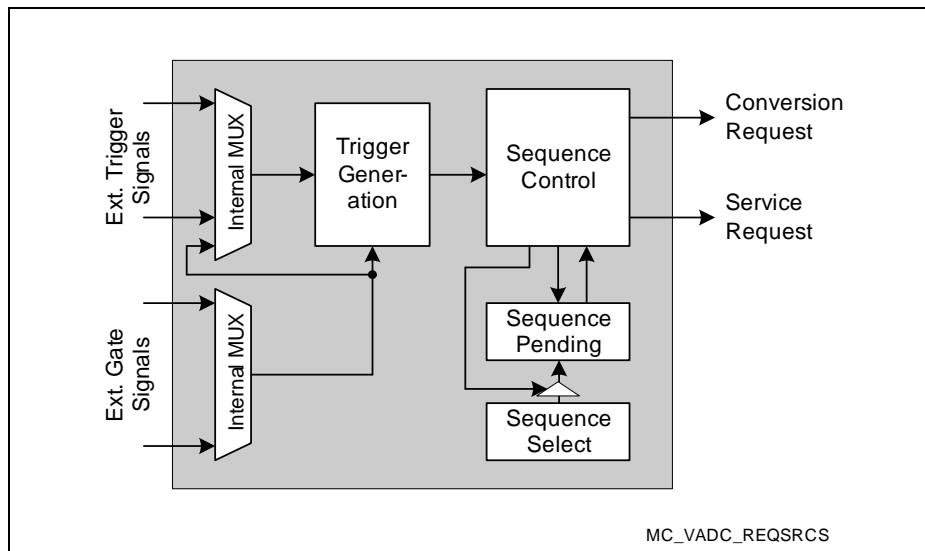

Figure 20-7 Scan Request Source

Scan Source Operation

Configure the scan request source by executing the following actions:

- Select the input channels for the sequence by programming **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)**
- If hardware trigger or gating is desired, select the appropriate trigger and gating inputs and the proper signal transitions by programming **GxASCTRL (x = 0 - 3)** or **BRCTRL**. Enable the trigger and select the gating mode by programming **GxASMR (x = 0 - 3)** or **BRSMR**.¹⁾
- Define the load event operation (handling of pending bits, autoscan mode) by programming **GxASMR (x = 0 - 3)** or **BRSMR**.
 A load event with bit LDM = 0 copies the content of **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (overwrite mode). This starts a new scan sequence and aborts any pending conversions from a previous scan sequence.
 A load event with bit LDM = 1 OR-combines the content of **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** to **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)** (combine mode). This starts a scan sequence that includes pending conversions from a previous scan sequence.
- Enable the corresponding arbitration slot (1) to accept conversion requests from the channel scan source (see register **GxARBPR (x = 0 - 3)**).

Start a channel scan sequence by generating a load event:

- If a hardware trigger is selected and enabled, generate the configured transition at the selected input signal, e.g. from a timer or an input pin.
- Generate a software load event by setting LDEV = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).
- Generate a load event by writing the scan pattern directly to the pending bits in **GxASPND (x = 0 - 3)** or **BRSPNDx (x = 0 - 3)**. The pattern is copied to **GxASSEL (x = 0 - 3)** or **BRSELx (x = 0 - 3)** and a load event is generated automatically.
 In this case, a scan sequence can be defined and started with a single data write action, e.g. under PEC control (provided that the pattern fits into one register).

Note: If autoscan is enabled, a load event is generated automatically each time a request source event occurs when the scan sequence has finished. This permanently repeats the defined scan sequence (autoscan).

Stop or abort an ongoing scan sequence by executing the following actions:

- If external gating is enabled, switch the gating signal to the defined inactive level. This does not modify the conversion pending bits, but only prevents issuing conversion requests to the arbiter.

¹⁾ If PDOUT signals from the ERU are used, initialize the ERU accordingly before enabling the gate inputs to avoid an unexpected signal transitions.

Versatile Analog-to-Digital Converter (VADC)

- Disable the corresponding arbitration slot (1 or 2) in the arbiter. This does not modify the contents of the conversion pending bits, but only prevents the arbiter from accepting requests from the request handling block.
- Disable the channel scan source by clearing bitfield ENGT = 00_B. Clear the pending request bits by setting bit CLRPND = 1 (**GxASMR (x = 0 - 3)** or **BRSMR**).

Scan Request Source Events and Service Requests

A request source event of a scan source occurs if the last conversion of a scan sequence is finished (all pending bits = 0). A request source event interrupt can be generated based on a request source event. If a request source event is detected, it sets the corresponding indication flag in register **GxSEFLAG (x = 0 - 3)**. These flags can also be set by writing a 1 to the corresponding bit position, whereas writing 0 has no effect.

The service request output SR_x that is selected by the request source event interrupt node pointer bitfields in register **GxSEVNP (x = 0 - 3)** becomes activated each time the related request source event is detected (and enabled by ENSI) or the related bit position in register **GxSEFLAG (x = 0 - 3)** is written with a 1 (this write action simulates a request source event).

The indication flags can be cleared by SW by writing a 1 to the corresponding bit position in register **GxSEFCLR (x = 0 - 3)**.¹⁾

1) Please refer to “**Service Request Generation**” on Page 20-56.

20.6 Request Source Arbitration

The request source arbiter regularly polls the request sources, one after the other, for pending conversion requests. Each request source is assigned to a certain time slot within an arbitration round, called arbitration slot. The duration of an arbitration slot is user-configurable via register **GLOBALCFG**.

The priority of each request source is user-configurable via register **GxARBPR (x = 0 - 3)**, so the arbiter can select the next channel to be converted, in the case of concurrent requests from multiple sources, according to the application requirements.

An unused arbitration slot is considered empty and does not take part in the arbitration. After reset, all slots are disabled and must be enabled (register **GxARBPR (x = 0 - 3)**) to take part in the arbitration process.

Figure 20-8 summarizes the arbitration sequence. An arbitration round consists of one arbitration slot for each available request source. The synchronization source is always evaluated in the last slot and has a higher priority than all other sources. At the end of each arbitration round, the arbiter has determined the highest priority conversion request.

If a conversion is started in an arbitration round, this arbitration round does not deliver an arbitration winner. In the XMC4[78]00, the following request sources are available:

- Arbitration slot 0: **Group Queued source**, 8-stage sequences in arbitrary order
- Arbitration slot 1: **Group Scan source**, sequences in defined order within group
- Arbitration slot 2: **Background Scan source**, sequences in defined order, all groups
- Last arbitration slot: **Synchronization source**, synchronized conversion requests from another ADC kernel (always handled with the highest priority in a synchronization slave kernel).

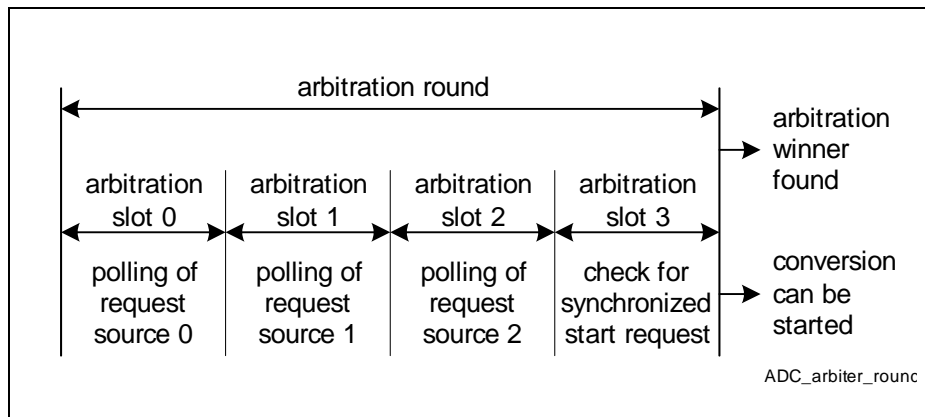

Figure 20-8 Arbitration Round with 4 Arbitration Slots

20.6.1 Arbiter Operation and Configuration

The timing of the arbiter (i.e. of an arbitration round) is determined by the number of arbitration slots within an arbitration round and by the duration of an arbitration slot.

An arbitration round consist of 4...20 arbitration slots (defined by bitfield **GxARBCFG (x = 0 - 3).ARBND**). 4 slots are sufficient for the XMC4[78]00, more can be programmed to obtain the same arbiter timing for different products.

The duration of an arbitration slot is configurable $t_{\text{Slot}} = (\text{DIVD}+1) / f_{\text{ADC}}$.

The duration of an arbitration round, therefore, is $t_{\text{ARB}} = 4 \times t_{\text{Slot}}$.

The period of the arbitration round introduces a timing granularity to detect an incoming conversion request signal and the earliest point to start the related conversion. This granularity can introduce a jitter of maximum one arbitration round. The jitter can be reduced by minimizing the period of an arbitration round.

To achieve a reproducible reaction time (constant delay without jitter) between the trigger event of a conversion request (e.g. by a timer unit or due to an external event) and the start of the related conversion, mainly the following two options exist. For both options, the converter has to be idle and other conversion requests must not be pending for at least one arbiter round before the trigger event occurs:

- If bit **GxARBCFG (x = 0 - 3).ARBM** = 0, the **arbiter runs permanently**. In this mode, synchronized conversions of more than one ADC kernel are possible.¹⁾
 The trigger for a conversion request has to be generated synchronously to the arbiter timing. Incoming triggers should have exactly n-times the granularity of the arbiter ($n = 1, 2, 3, \dots$). In order to allow some flexibility, the duration of an arbitration slot can be programmed in cycles of f_{ADC} .
- If bit **GxARBCFG (x = 0 - 3).ARBM** = 1, the **arbiter stops after an arbitration round** when no conversion request have been found pending any more. The arbiter is started again if at least one enabled request source indicates a pending conversion request. The trigger for a conversion request does not need to be synchronous to the arbiter timing.

In this mode, parallel conversions are not possible for synchronization slave kernels.

Each request source has a configurable priority, so the arbiter can resolve concurrent conversion requests from different sources. The request with the highest priority is selected for conversion. These priorities can be adapted to the requirements of a given application (see register **GxARBPR (x = 0 - 3)**).

The **Conversion Start Mode** determines the handling of the conversion request that has won the arbitration.

1) For more information, please refer to **"Synchronization of Conversions" on Page 20-47**.

20.6.2 Conversion Start Mode

When the arbiter has selected the request to be converted next, the handling of this channel depends on the current activity of the converter:

- Converter is currently idle: the conversion of the arbitration winner is started immediately.
- Current conversion has same or higher priority: the current conversion is completed, the conversion of the arbitration winner is started after that.
- Current conversion has lower priority: the action is user-configurable:
 - **Wait-for-start mode:** the current conversion is completed, the conversion of the arbitration winner is started after that. This mode provides maximum throughput, but can produce a jitter for the higher priority conversion.

Example in **Figure 20-9**:

Conversion A is requested (t1) and started (t2). Conversion B is then requested (t3), but started only after completion of conversion A (t4).

- **Cancel-inject-repeat mode:** the current conversion is aborted, the conversion of the arbitration winner is started after the abortion ($3 f_{ADC}$ cycles).

The aborted conversion request is restored in the corresponding request source and takes part again in the next arbitration round. This mode provides minimum jitter for the higher priority conversions, but reduces the overall throughput.

Example in **Figure 20-9**:

Conversion A is requested (t6) and started (t7). Conversion B is then requested (t8) and started (t9), while conversion A is aborted but requested again. When conversion B is complete (t10), conversion A is restarted.

Exception: If both requests target the same result register with wait-for-read mode active (see **Section 20.8.3**), the current conversion cannot be aborted.

Note: A cancelled conversion can be repeated automatically in each case, or it can be discarded if it was cancelled. This is selected for each source by bit RPTDIS in the corresponding source's mode register.

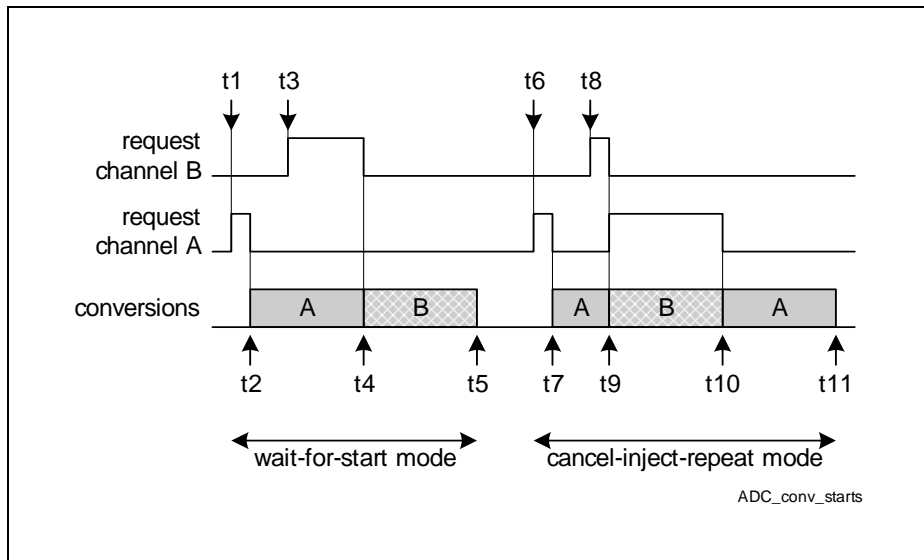

Figure 20-9 Conversion Start Modes

The conversion start mode can be individually programmed for each request source by bits in register **GxARBPR (x = 0 - 3)** and is applied to all channels requested by the source. In this example, channel A is issued by a request source with a lower priority than the request source requesting the conversion of channel B.

20.7 Analog Input Channel Configuration

For each analog input channel a number of parameters can be configured that control the conversion of this channel. The channel control registers define the following parameters:

- **Channel Parameters:** The sample time for this channel and the data width of the result are defined via input classes. Each channel can select one of two classes of its own group or one of two global classes.
- **Reference selection:** an alternate reference voltage can be selected for most channels (exceptions are marked in [Section 20.14.2](#))
- **Result target:** The conversion result values are stored either in a group-specific result register or in the global result register. The group-specific result registers are selected in several ways:
 - channel-specific, selected by bitfield RESREG in register **G0CHCTRY** ($y = 0 - 7$) etc., with bitfield SRCRESREG = 0000_B
 - source-specific, selected by bitfield SRCRESREG in register **GxQCTRL0** ($x = 0 - 3$), **GxASCTRL** ($x = 0 - 3$) or **BRCTRL** with bitfield SRCRESREG \neq 0000_B
- **Result position:** The result values can be stored left-aligned or right-aligned. The exact position depends also on the configured result width and on the data accumulation mode.
 See also [Figure 20-16 “Result Storage Options” on Page 20-36](#).
- **Compare with Standard Conversions (Limit Checking):** Channel events can be generated whenever a new result value becomes available. Channel event generation can be restricted to values that lie inside or outside a user-configurable band.
 In Fast Compare Mode, channel events can be generated depending on the transitions of the (1-bit) result.
- **Broken Wire Detection:** This safety feature can detect a missing connection to an analog signal source (sensor).
- **Synchronization of Conversions:** Synchronized conversions are executed at the same time on several converters.

The **Alias Feature** redirects conversion requests for channels CH0 and/or CH1 to other channels.

20.7.1 Channel Parameters

Each analog input channel is configured by its associated channel control register.

Note: For the safety feature “Broken Wire Detection”, refer to [Section 20.10.1](#).

The following features can be defined for each channel:

- The conversion class defines the result width and the sample time
- Generation of channel events and the result value band, if used
- Target of the result defining the target register and the position within the register

Versatile Analog-to-Digital Converter (VADC)

The group-specific input class registers define the sample time and data conversion mode for each channel of the respective group that selects them via bitfield ICLSEL in its channel control register GxCHCTR_x.

The global input class registers define the sample time and data conversion mode for each channel of any group that selects them via bitfield ICLSEL in its channel control register GxCHCTR_x.

20.7.2 Conversion Timing

The total time required for a conversion depends on several user-definable factors:

- The ADC conversion clock frequency, where $f_{\text{ADCI}} = f_{\text{ADC}} / (\text{DIVA} + 1)^{1)}$
- The selected sample time, where $t_{\text{S}} = (2 + \text{STC}) \times t_{\text{ADCI}}$
(STC = additional sample time, see also [Table 20-9](#))
- The selected operating mode (normal conversion / fast compare mode)
- The result width N (8/10/12 bits) for normal conversions
- The post-calibration time PC, if selected (PC = 2, otherwise 0)
- Synchronization steps done at module clock speed

The conversion time is the sum of sample time, conversion steps, and synchronization. It can be computed with the following formulas:

Standard conversions: $t_{\text{CN}} = (2 + \text{STC} + \text{N} + \text{PC}) \times t_{\text{ADCI}} + 2 \times t_{\text{ADC}}$

Fast compare mode: $t_{\text{CN}} = (2 + \text{STC} + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{ADC}}$

The frequency at which conversions are triggered also depends on several configurable factors:

- The selected conversion time, according to the input class definitions. For conversions using an external multiplexer, also the extended sample times count.
- Delays induced by cancelled conversions that must be repeated.
- Delays due to equidistant sampling of other channels.
- The configured arbitration cycle time.
- The frequency of external trigger signals, if enabled.

Timing Examples

System assumptions:

$f_{\text{ADC}} = 120 \text{ MHz}$ i.e. $t_{\text{ADC}} = 8.3 \text{ ns}$, $\text{DIVA} = 3$, $f_{\text{ADCI}} = 30 \text{ MHz}$ i.e. $t_{\text{ADCI}} = 33.3 \text{ ns}$

According to the given formulas the following minimum conversion times can be achieved:

12-bit calibrated conversion:

$$t_{\text{CN12C}} = (2 + 12 + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{ADC}} = 16 \times 33.3 \text{ ns} + 2 \times 8.3 \text{ ns} = 550 \text{ ns}$$

10-bit uncalibrated conversion:

$$t_{\text{CN10}} = (2 + 10) \times t_{\text{ADCI}} + 2 \times t_{\text{ADC}} = 12 \times 33.3 \text{ ns} + 2 \times 8.3 \text{ ns} = 417 \text{ ns}$$

Fast comparison:

$$t_{\text{FCM}} = (2 + 2) \times t_{\text{ADCI}} + 2 \times t_{\text{ADC}} = 4 \times 33.3 \text{ ns} + 2 \times 8.3 \text{ ns} = 150 \text{ ns}$$

1) The minimum prescaler factor for calibrated converters is 2.

20.7.3 Alias Feature

The Alias Feature redirects conversion requests for channels CH0 and/or CH1 to other channel numbers. This feature can be used to trigger conversions of the same input channel by independent events and to store the conversion results in different result registers.

- The same signal can be measured twice without the need to read out the conversion result to avoid data loss. This allows triggering both conversions quickly one after the other and being independent from CPU/DMA service request latency.
- The sensor signal is connected to only one analog input (instead of two analog inputs). This saves input pins in low-cost applications and only the leakage of one input has to be considered in the error calculation.
- Even if the analog input CH0 is used as alternative reference (see [Figure 20-10](#)), the internal trigger and data handling features for channel CH0 can be used.
- The channel settings for both conversions can be different (boundary values, service requests, etc.).

In typical low-cost AC-drive applications, only one common current sensor is used to determine the phase currents. Depending on the applied PWM pattern, the measured value has different meanings and the sample points have to be precisely located in the PWM period. [Figure 20-10](#) shows an example where the sensor signal is connected to one input channel (CHx) but two conversions are triggered for two different channels (CHx and CH0). With the alias feature, a conversion request for CH0 leads to a conversion of the analog input CHx instead of CH0, but taking into account the settings for CH0. Although the same analog input (CHx) has been measured, the conversion results can be stored and read out from the result registers RESx (conversion triggered for CHx) and RESy (conversion triggered for CH0). Additionally, different interrupts or limit boundaries can be selected, enabled or disabled.

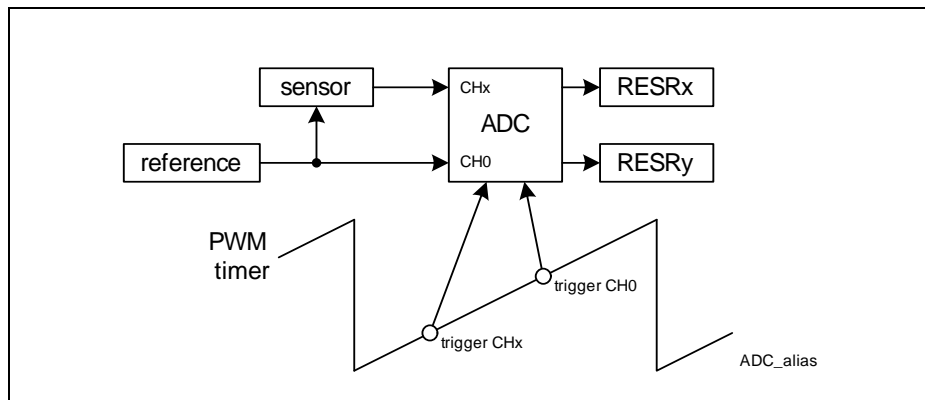

Figure 20-10 Alias Feature

20.7.4 Conversion Modes

A conversion can be executed in several ways. The conversion mode is selected according to the requested resolution of the digital result and according to the acceptable conversion time ([Section 20.7.2](#)).

Use bitfield CMS/CME in register **GxICLASS0 (x = 0 - 3)** etc. to select a mode.

Standard Conversions

A standard conversion returns a result value with a predefined resolution. 8-bit, 10-bit, and 12-bit resolution can be selected.

These result values can be accumulated, filtered, or used for digital limit checking and determination of extrema.

Note: The calibrated converters can operate with and without post-calibration.

Fast Compare Mode

In Fast Compare Mode, the selected input voltage is directly compared with a digital value that is stored in the corresponding result register. This compare operation returns a binary result indicating if the compared input voltage is above or below the given reference value. This result is generated quickly and thus supports monitoring of boundary values.

Fast Compare Mode uses a 10-bit compare value stored left-aligned at bit position 11. Separate positive and negative delta values define an arbitrary hysteresis band.

Selecting Compare Values

Values for digital or analog compare operations can be selected from several sources. The separate GxBOUND registers provide software-defined compare values. Compare values can also be taken from a result register where it can be provided by another channel building a reference.

In Fast Compare Mode, the result registers provide the compare value while the bitfields of local GxBOUND registers define positive and negative delta values.

20.7.5 Compare with Standard Conversions (Limit Checking)

The limit checking mechanism can automatically compare each digital conversion result to an upper and a lower boundary value. A channel event can then be generated when the result of a conversion/comparison is inside or outside a user-defined band (see bitfield CHEVMODE and [Figure 20-11](#)).

This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain predefined conditions.

Note: Channel events can also be generated for each result value (ignoring the band) or they can be suppressed completely.

The boundary values to which results are compared can be selected from several sources (see register GxCHCTRY).

While bitfield BNDSELX = 0000_B, bitfields BNDSELU and BNDSELL select the valid upper/lower boundary value either from the group-specific boundary register **GxBOUND** (x = 0 - 3) or from the global boundary register **GLOBBOUND**. The group boundary register can be selected for each channel of the respective group, the global boundary register can be selected by each available channel.

Otherwise, the compare values are taken from result registers, where bitfield BNDSELX selects the upper boundary value (GxRES1 ... GxRES15), the concatenated bitfields BNDSELU||BNDSELL select the lower boundary value (GxRES0 ... GxRES15).

Figure 20-11 Result Monitoring through Limit Checking

Versatile Analog-to-Digital Converter (VADC)

A result value is considered inside the defined band when both of the following conditions are true:

- the value is less than or equal to the selected upper boundary
- the value is greater than or equal to the selected lower boundary

The result range can also be divided into two areas:

To select the lower part as valid band, set the lower boundary to the minimum value (000_H) and set the upper boundary to the highest intended value.

To select the upper part as valid band, set the upper boundary to the maximum value (FFF_H) and set the lower boundary to the lowest intended value.

Finding Extrema (Peak Detection)

The limit checking mechanism uses standard conversions and, therefore, always can provide the actual conversion result that was used for comparison. Combining this with a special FIFO mode, that only updates the corresponding FIFO stage if the result was above (or below) the current value of the stage, provides the usual conversion results and at the same time stores the highest (or lowest) result of a conversion sequence. For this operation the FIFO stage below the standard result must be selected as the compare value. Mode selection is done via bitfield FEN in register GxRCRy.

Before starting a peak detection sequence, write a reasonable start value to the result bitfield in the peak result register (e.g. 0000_H to find the maximum and $FFFF_H$ to find the minimum).

20.7.6 Utilizing Fast Compare Mode

In Fast Compare Mode, the input signal is directly compared to a value in the associated result register. This comparison just provides a binary result (above/below). If the exact result value is not required, this saves conversion time. A channel event can then be generated when the input signal becomes higher (or lower) than the compare value (see bitfield CHEVMODE and [Figure 20-12](#)).

The compare value in Fast Compare Mode is taken from the result register. Bitfields BOUNDARY1 and BOUNDARY0 in register **GxBOUND (x = 0 - 3)** define delta limits in this case. These deltas are added to (or subtracted from) the original compare value and allow defining an arbitrary hysteresis band.

The actual used compare value depends on the Fast Compare Result FCR (see registers **G0RESy (y = 0 - 15)**, etc.):

GxRESy.FCR = 0: reference value + upper delta

(GxRESy.RESULT + GxBOUND.BOUNDARY0)

GxRESy.FCR = 1: reference value - lower delta

(GxRESy.RESULT - GxBOUND.BOUNDARY1)

Figure 20-12 Result Monitoring through Compare with Hysteresis

20.7.7 Boundary Flag Control

Both limit checking mechanisms can be configured to automatically control the boundary flags. These boundary flags are also available as control signals for other modules. The flags can be set or cleared when the defined level is exceeded and the polarity of the output signal can be selected. A gate signal can be selected to enable the boundary flag operation while the gate is active.

Each boundary flag is available at group-specific output lines. Node pointers additionally route them to one of four boundary signals or one of the associated common service request lines, see register **GxBFLNP (x = 0 - 3)**.

For standard conversions, a boundary flag will be set/cleared when the conversion result is above the defined band, and will be cleared/set when the conversion result is below the defined band.

The band between the two boundary values defines a hysteresis for setting/clearing the boundary flags.

Using this feature on three channels that monitor linear hall elements can produce signals to feed the three hall position inputs of a unit that generates the corresponding PWM control signals.

In Fast Compare Mode, a boundary flag reflects the result of the comparisons, i.e. it will be set/cleared when the compared signal level is above the compare value, and will be cleared/set when the signal level is below the compare value. The delta values define a hysteresis band around the compare value.

Note: Clear register GxBOUND (i.e. the deltas) if a hysteresis is not wanted.

Figure 20-13 Boundary Flag Switching

Versatile Analog-to-Digital Converter (VADC)

Boundary flags can be switched by each compare operation, or the influence of compare operations can be restricted to the active phases of the corresponding request source gate signal (see **GxBFLC (x = 0 - 3)**).

Note: If a boundary flag is used together with Fast Compare Mode, it is recommended not to direct results from other channels to the corresponding result register.

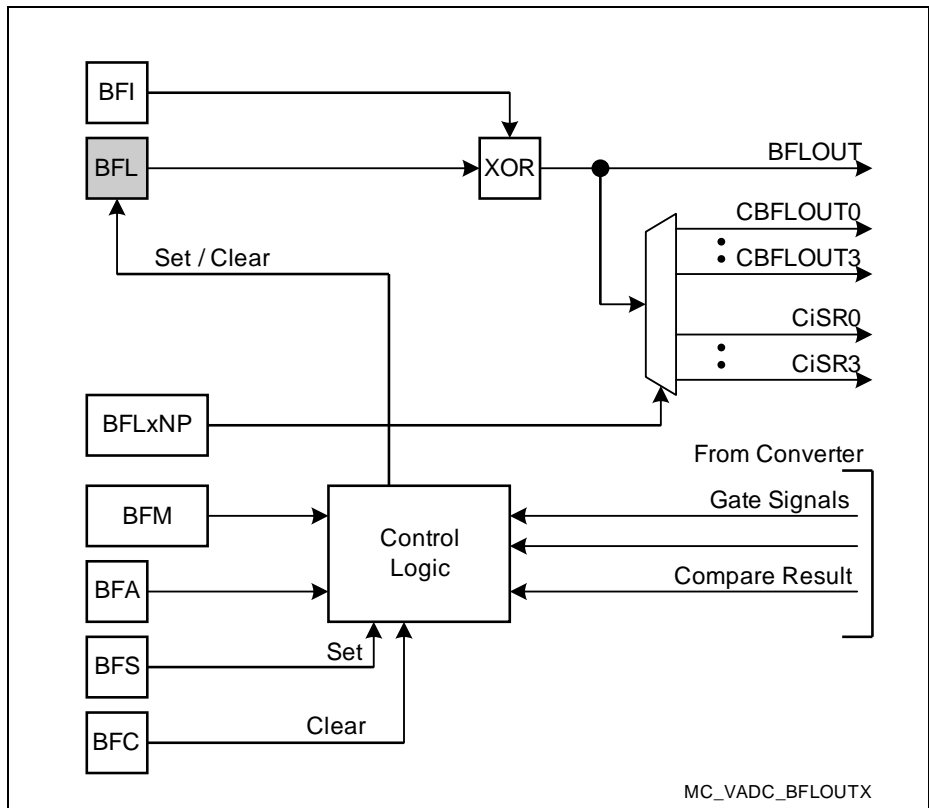

Figure 20-14 Boundary Flag Control

A boundary flag BFLy is assigned to result register GxRESy and thus to an arbitrary channel.

20.8 Conversion Result Handling

The A/D converters can preprocess the conversions result data to a certain extent before storing them for retrieval by the CPU or a DMA channel. This supports the subsequent handling of result data by the application software.

Conversion result handling comprises the following functions:

- **Storage of Conversion Results** to user-configurable registers
- **Data Alignment** according to result width and endianness
- **Wait-for-Read Mode** to avoid loss of data
- **Result Event Generation**
- Data reduction or anti-aliasing filtering (see [Section 20.8.6](#))

20.8.1 Storage of Conversion Results

The conversion result values of a certain group can be stored in one of the 16 associated group result registers or in the common global result register (can be used, for example, for the channels of the background source (see [Selecting a Result Register](#)).

This structure provides different locations for the conversion results of different sets of channels. Depending on the application needs (data reduction, auto-scan, alias feature, etc.), the user can distribute the conversion results to minimize CPU load and/or optimize the performance of DMA transfers.

Each result register has an individual data valid flag (VF) associated with it. This flag indicates when “new” valid data has been stored in the corresponding result register and can be read out.

For standard conversions, result values are available in bitfield RESULT. Conversions in Fast Compare Mode use bitfield RESULT for the reference value, so the result of the operation is stored in bit FCR.

Result registers can be read via two different views. These views use different addresses but access the same register data:

- When a result register is read via the **application view**, the corresponding valid flag is automatically cleared when the result is read. This provides an easy handshake between result generation and retrieval. This also supports wait-for-read mode.
- When a result register is read via the **debug view**, the corresponding valid flag remains unchanged when the result is read. This supports debugging by delivering the result value without disturbing the handshake with the application.

The application can retrieve conversion results through several result registers:

- Group result register:
Returns the result value and the channel number
- Global result register:
Returns the result value and the channel number and the group number

Versatile Analog-to-Digital Converter (VADC)

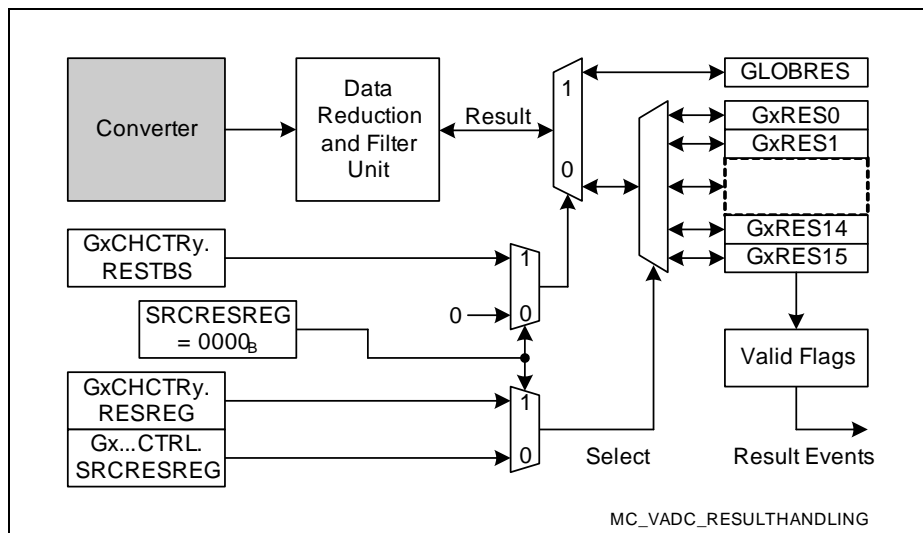

Figure 20-15 Conversion Result Storage

Selecting a Result Register

Conversion results are stored in result registers that can be assigned by the user according to the requirements of the application. The following bitfields direct the results to a register:

- **SRCRESREG** in register **GxQCTRL0 (x = 0 - 3)**, **GxASCTRL (x = 0 - 3)** or **BRSCCTRL**
 Selects the group-specific result register **GxRES1 ... GxRES15** when source-specific result registers are used
- **RESTBS** in register **G0CHCTry (y = 0 - 7)** etc.
 Selects the global result register for results requested by the background source
- **RESREG** in register **G0CHCTry (y = 0 - 7)** etc.
 Selects the group-specific result register **GxRES0 ... GxRES15** when channel-specific result registers are used

Using source-specific result registers allows separating results from the same channel that are requested by different request sources. Usually these request sources are used by different tasks and are triggered at different times.

Versatile Analog-to-Digital Converter (VADC)

20.8.2 Data Alignment

The position of a conversion result value within the selected result register depends on 3 configurations (summary in **Figure 20-16**):

- The selected result width (12/10/8 bits, selected by the conversion mode)
- The selected result position (Left/Right-aligned)
- The selected data accumulation mode (data reduction)

These options provide the conversion results in a way that minimizes data handling for the application software.

| Bit in Result Register | | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------------------|----------------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Standard Conversions | 12-Bit | 0 | 0 | 0 | 0 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 10-Bit Left-Aligned | 0 | 0 | 0 | 0 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 |
| | 10-Bit Right-Aligned | 0 | 0 | 0 | 0 | 0 | 0 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 8-Bit Left-Aligned | 0 | 0 | 0 | 0 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 | 0 | 0 |
| | 8-Bit Right-Aligned | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Accumulated Conversions | 12-Bit | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 10-Bit Left-Aligned | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 |
| | 10-Bit Right-Aligned | 0 | 0 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| | 8-Bit Left-Aligned | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 0 | 0 | 0 | 0 |
| | 8-Bit Right-Aligned | 0 | 0 | 0 | 0 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

MC_VADC_RESPOS

Figure 20-16 Result Storage Options

Bitfield RESULT can be written by software to provide the reference value for Fast Compare Mode. In this mode, bits 11-2 are evaluated, the other bits are ignored.

20.8.3 Wait-for-Read Mode

The wait-for-read mode prevents data loss due to overwriting a result register with a new conversion result before the CPU (or DMA) has read the previous data. For example, auto-scan conversion sequences or other sequences with “relaxed” timing requirements may use a common result register. However, the results come from different input channels, so an overwrite would destroy the result from the previous conversion¹⁾.

Wait-for-read mode automatically suspends the start of a conversion for this channel from this source until the current result has been read. So a conversion or a conversion sequence can be requested by a hardware or software trigger, while each conversion is only started after the result of the previous one has been read. This automatically aligns the conversion sequence with the CPU/DMA capability to read the formerly converted result (latency).

If wait-for-read mode is enabled for a result register (bit GxRCRy.WFR = 1), a request source does not generate a conversion request while the targeted result register contains valid data (indicated by the valid flag VF = 1) or if a currently running conversion targets the same result register.

If two request sources target the same result register with wait-for-read mode selected, a higher priority source cannot interrupt a lower priority conversion request started before the higher priority source has requested its conversion. Cancel-inject-repeat mode does not work in this case. In particular, this must be regarded if one of the involved sources is the background source (which usually has lowest priority). If the higher priority request targets a different result register, the lower priority conversion can be cancelled and repeated afterwards.

Note: Wait-for-read mode is ignored for synchronized conversions of synchronization slaves (see [Section 20.9](#)).

1) Repeated conversions of a single channel that use a separate result register will not destroy other results, but rather update their own previous result value. This way, always the actual signal data is available in the result register.

20.8.4 Result FIFO Buffer

Result registers can either be used as direct target for conversion results or they can be concatenated with other result registers of the same ADC group to form a result FIFO buffer (first-in-first-out buffer mechanism). A result FIFO stores several measurement results that can be read out later with a “relaxed” CPU response timing. It is possible to set up more than one FIFO buffer structure with the available result registers.

Result FIFO structures of two or more registers are built by concatenating result registers to their following “neighbor” result register (with next higher index, see [Figure 20-17](#)). This is enabled by setting bitfield GxRCRy.FEN = 01_B.

Conversion results are stored to the register with the highest index of a FIFO structure. Software reads the values from the FIFO register with the lowest index.

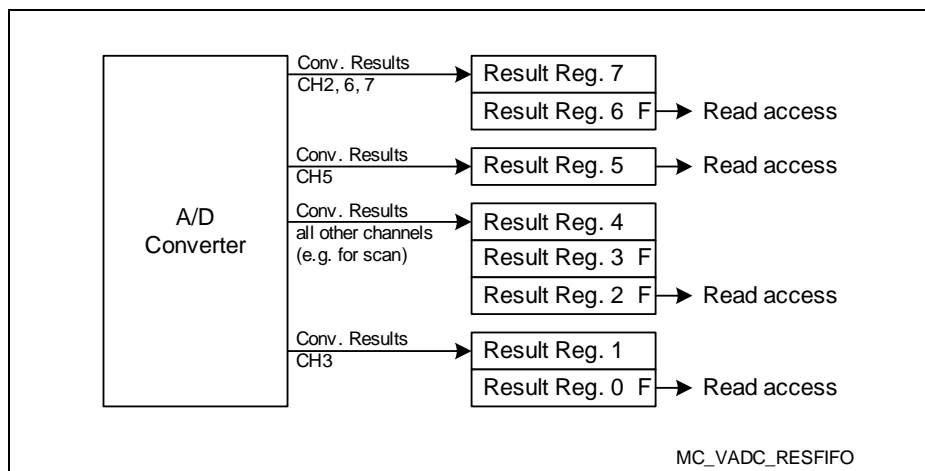

Figure 20-17 Result FIFO Buffers

In the example shown the result registers have been configured in the following way:

- 2-stage buffer consisting of result registers 7-6
- dedicated result register 5
- 3-stage buffer consisting of result registers 4-3-2
- 2-stage buffer consisting of result registers 1-0

Table 20-3 summarizes the required configuration of result registers if they are combined to build result FIFO buffers.

Table 20-3 Properties of Result FIFO Registers

| Function | Input Stage | Intermed. Stage | Output Stage |
|------------------------|-----------------|-----------------|-----------------|
| Result target | YES | no | no |
| Application read | no | no | YES |
| Data reduction mode | YES | no | no |
| Wait-for-read mode | YES | no | no |
| Result event interrupt | no | no | YES |
| FIFO enable (FEN) | 00 _B | 01 _B | 01 _B |
| Registers in example | 7, 4, 1 | 3 | 6, 2, 0 |

Note: If enabled, a result interrupt is generated for each data word in the FIFO.

20.8.5 Result Event Generation

A result event can be generated when a new value is stored to a result register. Result events can be restricted due to data accumulation and be generated only if the accumulation is complete.

Result events can also be suppressed completely.

20.8.6 Data Modification

The data resulting from conversions can be automatically modified before being used by an application. Several options can be selected (bitfield DMM in register **G0RCRy (y = 0 - 15)** etc.) which reduce the CPU/DMA load required to unload and/or process the conversion data.

- **Standard Data Reduction Mode (for GxRES0 ... GxRES15):**
 Accumulates 2, 3, or 4 result values within each result register before generating a result interrupt. This can remove some noise from the input signal.
- **Result Filtering Mode (FIR, for GxRES7, GxRES15):**
 Applies a 3rd order Finite Impulse Response Filter (FIR) with selectable coefficients to the conversion results for the selected result register.
- **Result Filtering Mode (IIR, for GxRES7, GxRES15):**
 Applies a 1st order Infinite Impulse Response Filter (IIR) with selectable coefficients to the conversion results for the selected result register.
- **Difference Mode (for GxRES1 ... GxRES15):**
 Subtracts the contents of result register GxRES0 from the conversion results for the selected result register. Bitfield DRCTR is not used in this mode.

Table 20-4 Function of Bitfield DRCTR

| DRCTR | Standard Data Reduction Mode (DMM = 00 _B) | DRCTR | Result Filtering Mode (DMM = 01 _B) ¹⁾ |

Versatile Analog-to-Digital Converter (VADC)

Standard Data Reduction Mode

The data reduction mode can be used as digital filter for anti-aliasing or decimation purposes. It accumulates a maximum of 4 conversion values to generate a final result.

Each result register can be individually enabled for data reduction, controlled by bitfield DRCTR in registers **G0CHCTry (y = 0 - 7)**. The data reduction counter DRC indicates the actual status of the accumulation.

Note: Conversions for other result registers can be inserted between conversions to be accumulated.

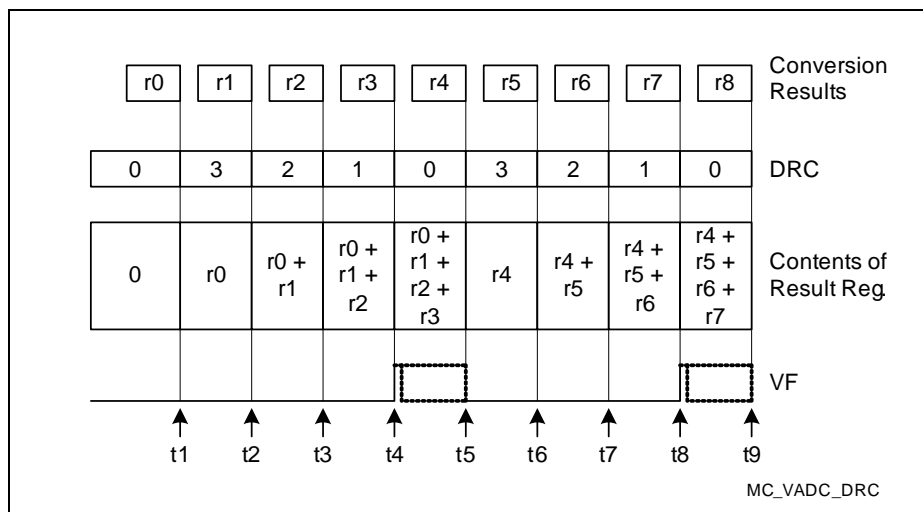

Figure 20-18 Standard Data Reduction Filter

This example shows a data reduction sequence of 4 accumulated conversion results. Eight conversion results (r0 ... r7) are accumulated and produce 2 final results.

When a conversion is complete and stores data to a result register that has data reduction mode enabled, the data handling is controlled by the data reduction counter DRC:

- If DRC = 0 (t1, t5, t9 in the example), the conversion result is stored to the register. DRC is loaded with the contents of bitfield DRCTR (i.e. the accumulation begins).
- If DRC > 0 (t2, t3, t4 and t6, t7, t8 in the example), the conversion result is added to the value in the result register. DRC is decremented by 1.
- If DRC becomes 0, either decremented from 1 (t4 and t8 in the example) or loaded from DRCTR, the valid bit for the respective result register is set and a result register event occurs.

Versatile Analog-to-Digital Converter (VADC)

The final result must be read before the next data reduction sequence starts (before t5 or t9 in the example). This automatically clears the valid flag.

*Note: Software can clear the data reduction counter DRC by clearing the corresponding valid Flag (via **GxVFR (x = 0 - 3)**).*

The response time to read the final data reduction results can be increased by associating the adjacent result register to build a result FIFO (see [Figure 20-19](#)). In this case, the final result of a data reduction sequence is loaded to the adjacent register. The value can be read from this register until the next data reduction sequence is finished (t8 in the 2nd example).

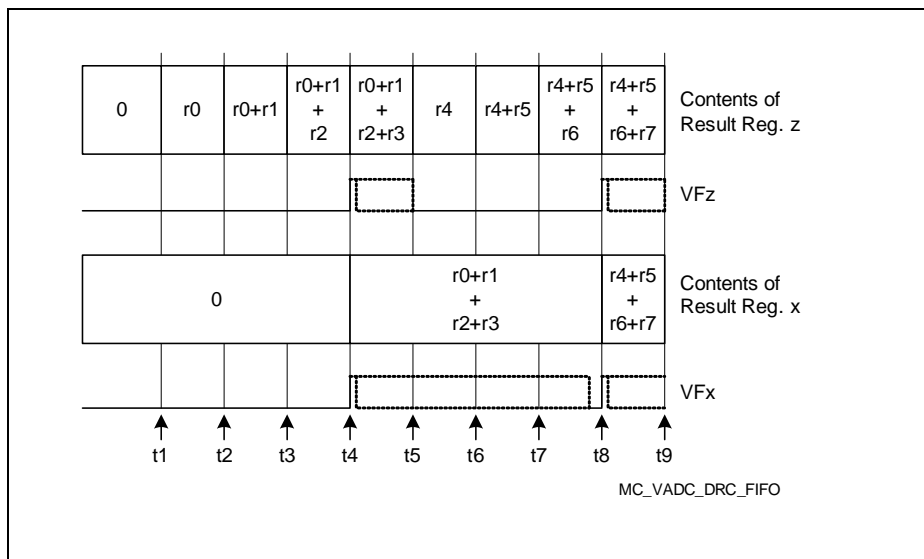

Figure 20-19 Standard Data Reduction Filter with FIFO Enabled

Versatile Analog-to-Digital Converter (VADC)

Finite Impulse Response Filter Mode (FIR)

The FIR filter (see [Figure 20-20](#)) provides 2 result buffers for intermediate results (RB1, RB2) and 3 configurable tap coefficients (a, b, c).

The conversion result and the intermediate result buffer values are added weighted with their respective coefficients to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in [Table 20-4](#)) in registers **G0RESy (y = 0 - 15)** and **GLOBRES**. These coefficients lead to a gain of 3 or 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

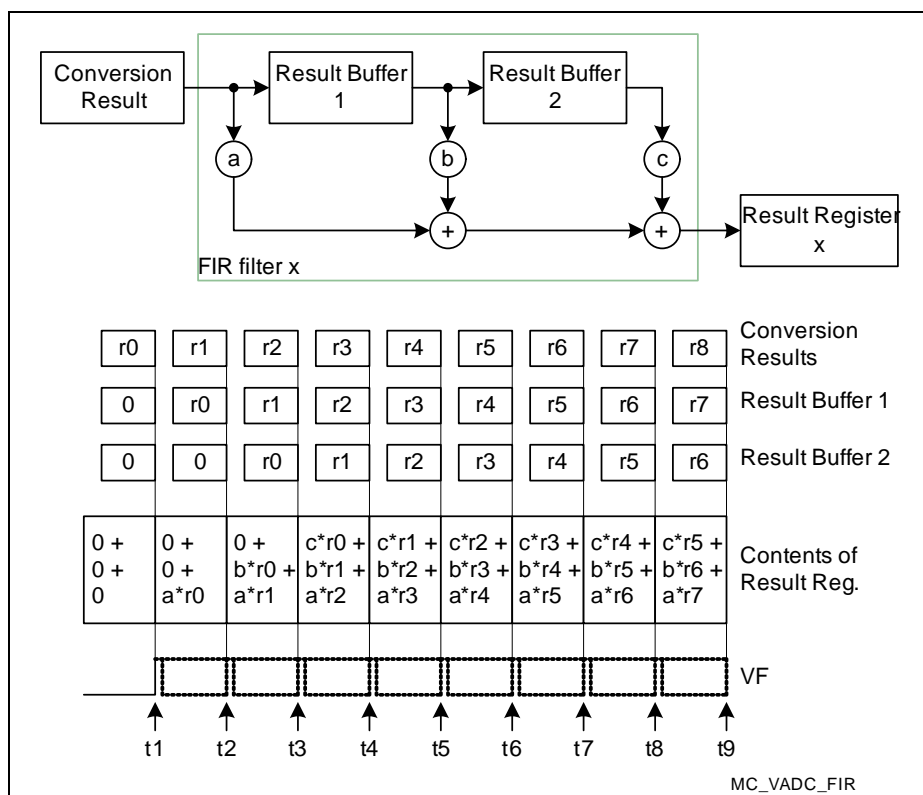

Figure 20-20 FIR Filter Structure

Note: The filter registers are cleared while bitfield DMM ≠ 01_B.

Versatile Analog-to-Digital Converter (VADC)

Infinite Impulse Response Filter Mode (IIR)

The IIR filter (see [Figure 20-21](#)) provides a result buffer (RB) and 2 configurable coefficients (a, b). It represents a first order low-pass filter.

The conversion result, weighted with the respective coefficient, and a fraction of the previous result are added to form the final value for the result register. Several predefined sets of coefficients can be selected via bitfield DRCTR (coding listed in [Table 20-4](#)) in registers **G0RESy (y = 0 - 15)** and **GLOBRES**. These coefficients lead to a gain of 4 to the ADC result producing a 14-bit value. The valid flag (VF) is activated for each sample after activation, i.e. for each sample generates a valid result.

Note: Conversions for other result registers can be inserted between conversions to be filtered.

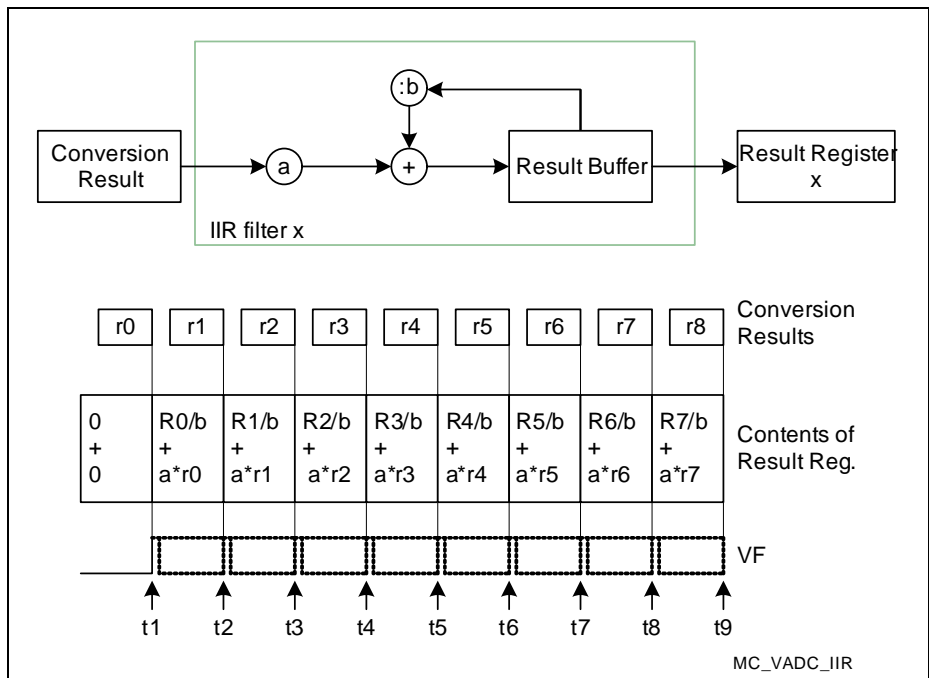

Figure 20-21 IIR Filter Structure

Note: The filter registers are cleared while bitfield DMM \neq 01_B.

Difference Mode

Subtracting the contents of result register 0 from the actual result puts the results of the respective channel in relation to another signal. No software action is required.

The reference channel must store its result(s) into result register 0. The reference value can be determined once and then be used for a series of conversions, or it can be converted before each related conversion.

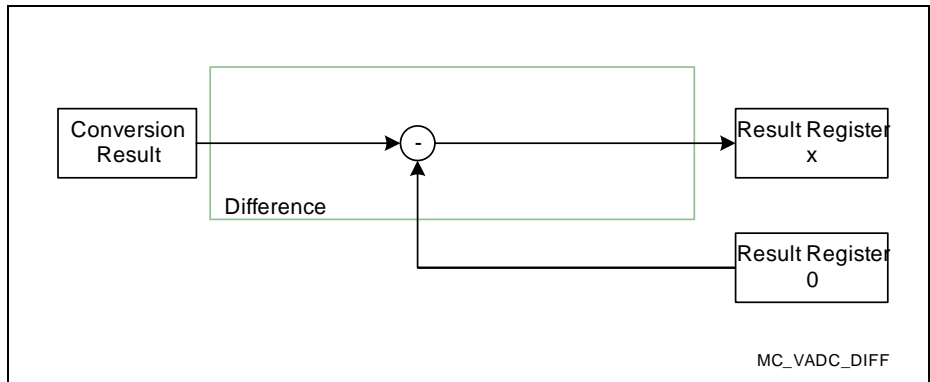

Figure 20-22 Result Difference

20.9 Synchronization of Conversions

The conversions of an ADC kernel can be scheduled either self-timed according to the kernel's configuration or triggered by external (outside the ADC) signals:

Synchronized Conversions for Parallel Sampling support parallel conversion of channels within a synchronization group¹⁾. This optimizes e.g. the control of electrical drives.

Equidistant Sampling supports conversions in a fixed raster with minimum jitter. This optimizes e.g. filter algorithms or audio applications.

20.9.1 Synchronized Conversions for Parallel Sampling

Several independent ADC kernels¹⁾ implemented in the XMC4[78]00 can be synchronized for simultaneous measurements of analog input channels. While no parallel conversion is requested, the kernels can work independently.

The synchronization mechanism for parallel conversions ensures that the sample phases of the related channels start simultaneously. Synchronized kernels convert the same channel that is requested by the master. Different values for the resolution and the sample phase length of each kernel for a parallel conversion are supported.

A parallel conversion can be requested individually for each input channel (one or more). In the example shown in **Figure 20-23**, input channels CH3 of the ADC kernels 0 and 1 are converted synchronously, whereas other input channels do not lead to parallel conversions.

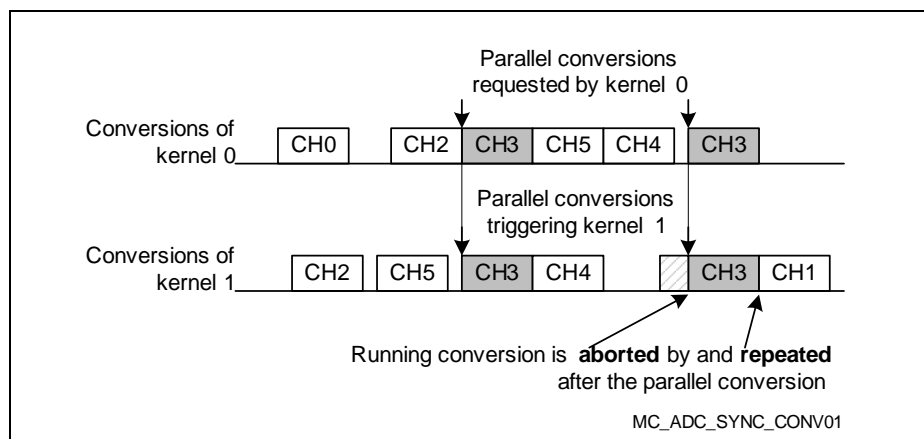

Figure 20-23 Parallel Conversions

1) For a summary, please refer to **"Synchronization Groups in the XMC4[78]00"** on Page 20-134.

Versatile Analog-to-Digital Converter (VADC)

One kernel operates as synchronization master, the other kernel(s) operate(s) as synchronization slave. Each kernel can play either role. The arbiters of all involved kernels must run synchronously. This is achieved by switching off all involved kernels before the initialization and switching on the master kernel at the end of the initialization sequence.

Master and slave kernels form a “conversion group” to control parallel sampling:

- The arbiters must run permanently (bits **GxARBCFG (x = 0 - 3).ARBM** = 0). Initialize the slave before the master to have the arbiters run synchronously. Set the master's **GxARBCFG.ANONC** at the end of the initialization.
- **The synchronization master** controls the slave(s) by providing the control information **GxARBCFG (x = 0 - 3).ANONS** (see [Figure 20-24](#)) and the requested channel number.
 - Bitfield **GxSYNCTR (x = 0 - 3).STSEL** = 00_B selects the master's ANON information as the source of the ANON information for all kernels of the synchronization group.¹⁾
 - The ready signals indicate when a slave kernel is ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 3).EVALRy** = 1 enables the control by the ready signal (in the example kernel 1 is the slave, so **EVALR1** = 1).
 - The master requests a synchronized conversion of a certain channel (**SYNC** = 1 in the corresponding channel control register **GxCHCTRy**), which is also requested in the connected slave ADC kernel(s).
 - Wait-for-read mode is supported for the master.
- **The synchronization slave** reacts to incoming synchronized conversion requests from the master. While no synchronized conversions are requested, the slave kernel can execute “local” conversions.
 - Bitfield **GxSYNCTR (x = 0 - 3).STSEL** = 01_B/10_B/11_B selects the master's ANON information as the source of the ANON information for all kernels of the synchronization group¹⁾ (in the example kernel 0 is the master, so **STSEL** = 01_B).
 - The ready signals indicate when the master kernel and the other slave kernels are ready to start the sample phase of a parallel conversion. Bit **GxSYNCTR (x = 0 - 3).EVALRy** = 1 enables the control by the ready signal (in the example kernel 0 is the master, so **EVALR1** = 1).
 - The slave timing must be configured according to the master timing (**ARBRND** in register **GxARBCFG (x = 0 - 3)**) to enable parallel conversions.
 - A parallel conversion request is always handled with highest priority and cancel-inject-repeat mode.
 - Wait-for-read mode is ignored in the slave. Previous results may be overwritten, in particular, if the same result register is used by other conversions.

1) **STSEL** = 00_B selects the own ANON information. The other control inputs (**STSEL** = 01_B/10_B/11_B) are connected to the other kernels of a synchronization group in ascending order (see also [Table 20-11 “Synchronization Groups in the XMC4\[78\]00” on Page 20-134](#)).

Versatile Analog-to-Digital Converter (VADC)

- Once started, a parallel conversion cannot be aborted.

Note: Synchronized conversions request the same channel number, defined by the master. Using the alias feature (see [Section 20.7.3](#)), analog signals from different input channels can be converted. This is advantageous if e.g. CH0 is used as alternate reference.

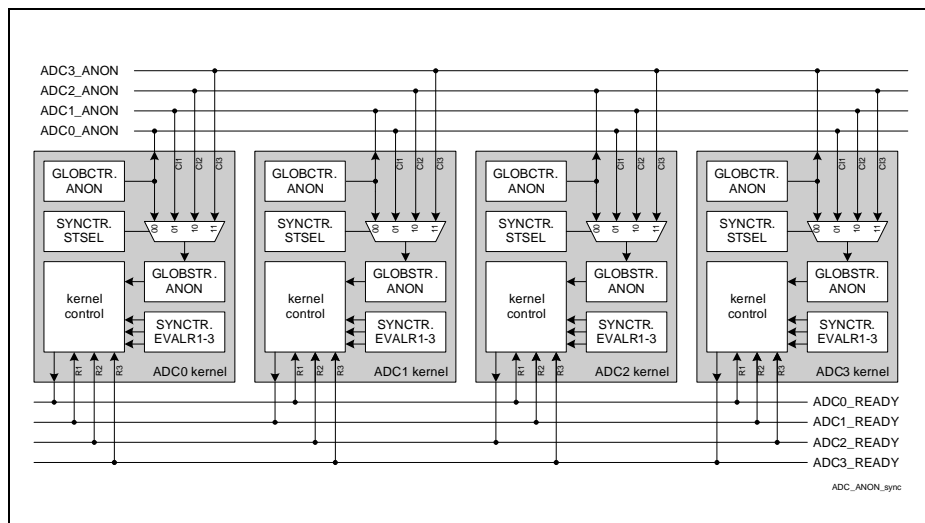

Figure 20-24 Synchronization via ANON and Ready Signals

20.9.2 Equidistant Sampling

To optimize the input data e.g. for filter or audio applications, conversions can be executed in a fixed timing raster. Conversions for equidistant sampling are triggered by an external signal (e.g. a timer). To generate the trigger signal synchronous to the arbiter, the ADC provides an output signal (ARBCNT) that is activated once per arbitration round and serves as timing base for the trigger timer. In this case, the arbiter must run permanently (**GxARBCFG (x = 0 - 3).ARBM = 0**). If the timer has an independent time base, the arbiter can be stopped while no requests are pending. The preface time (see **Figure 20-25**) must be longer than one arbitration round and the highest possible conversion time.

Select timer mode (TMEN = 1 in register **GxQCTRL0 (x = 0 - 3)** or **GxASCTRL (x = 0 - 3)**) for the intended source of equidistant conversions. In timer mode, a request of this source is triggered and arbitrated, but only started when the trigger signal is removed (see **Figure 20-25**) and the converter is idle.

To ensure that the converter is idle and the start of conversion can be controlled by the trigger signal, the equidistant conversion requests must receive highest priority. The preface time between request trigger and conversion start must be long enough for a currently active conversion to finish.

The frequency of signal REQTRx defines the sampling rate and its high time defines the preface time interval where the corresponding request source takes part in the arbitration.

Depending on the used request source, equidistant sampling is also supported for a sequence of channels. It is also possible to do equidistant sampling for more than one request source in parallel if the preface times and the equidistant conversions do not overlap.

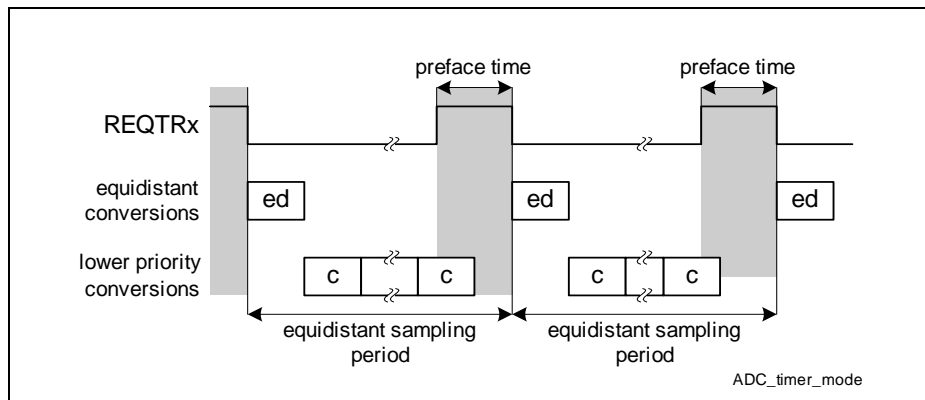

Figure 20-25 Timer Mode for Equidistant Sampling

20.10 Safety Features

Several test features can be enabled to verify the validity of the analog input signals of an application. These test features aim at different sections of the signal flow:

- **Broken Wire Detection** validates the connection from the sensor to the input pin,
- **Multiplexer Diagnostics** validates the operation of the internal analog input multiplexer,
- **Converter Diagnostics** validates the operation of the Analog/Digital converter itself.

20.10.1 Broken Wire Detection

To test the proper connection of an external analog sensor to its input pin, the converter's capacitor can be precharged to a selectable value before the regular sample phase. If the connection to the sensor is interrupted the subsequent conversion value will rather represent the precharged value than the expected sensor result. By using a precharge voltage outside the expected result range (broken wire detection preferably uses V_{AGND} and/or V_{AREF}) a valid measurement (sensor connected) can be distinguished from a failure (sensor detached).

While broken wire detection is disabled, the converter's capacitor is precharged to $V_{AREF}/2$.

Note: The duration of the complete conversion is increased by the preparation phase (same as the sample phase) if the broken wire detection is enabled. This influences the timing of conversion sequences.

Broken wire detection can be enabled for each channel separately by bitfield BW DEN in the corresponding channel control register (**G0CHCTry (y = 0 - 7)**). This bitfield also selects the level for the preparation phase.

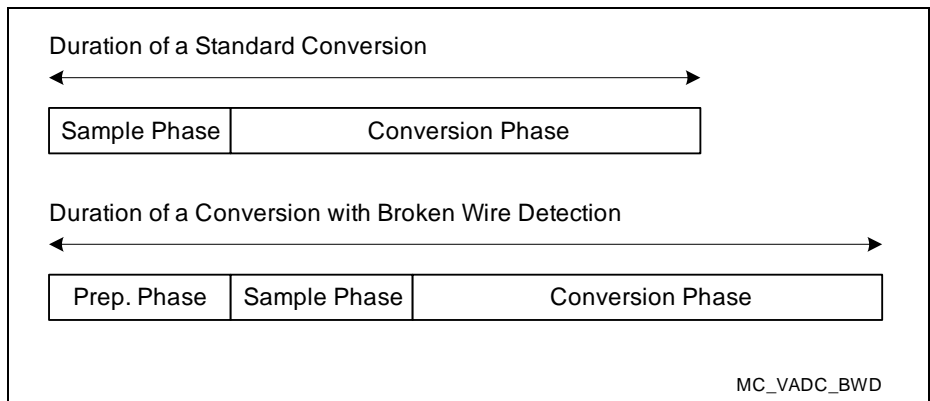

Figure 20-26 Broken Wire Detection

20.10.2 Signal Path Test Modes

Additional test structures can be activated to test the signal path from the sensor to the input pin and the internal signal path from the input pin through the multiplexer to the converter. These test structures apply additional loads to the signal path (see summary in [Figure 20-27](#)).

Multiplexer Diagnostics

To test the proper operation of the internal analog input multiplexer, additional pull-up and/or pull-down devices can be connected to a channel. In combination with a known external input signal this test function shows if the multiplexer connects any pin to the converter input and if this is the correct pin. These pull-up/pull-down devices are controlled via the port logic.

Pull-Down Diagnostics

One single input channel provides a further strong pull-down (R_{PDD}) that can be activated to verify the external connection to a sensor.

Converter Diagnostics

To test the proper operation of the converter itself, several signals can be connected to the converter input. The test signals can be connected to the converter input either instead of the standard input signal or in parallel to the standard input signal.

The test signal can be selected from four different signals as shown in [Figure 20-27](#).

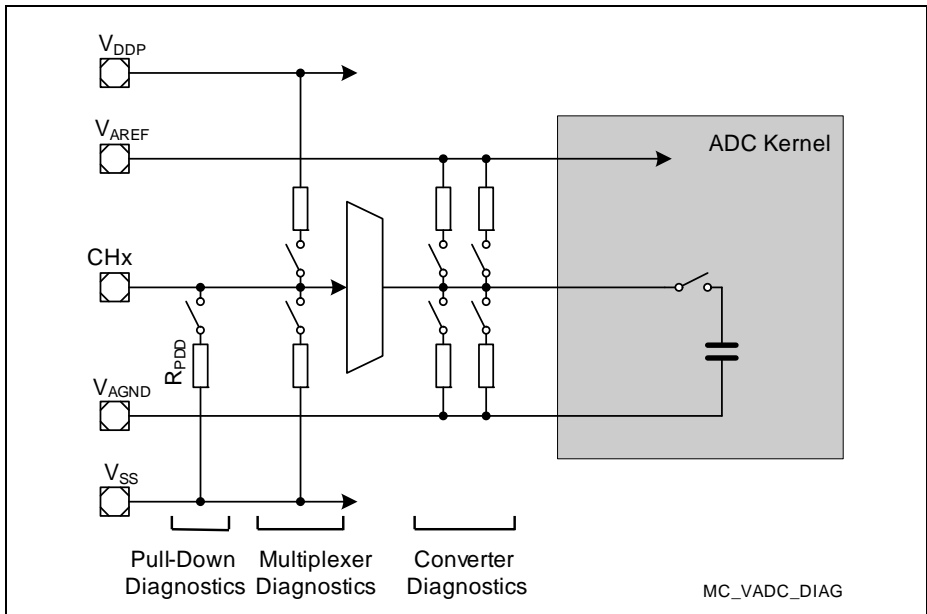

Figure 20-27 Signal Path Test

20.10.3 Configuration of Test Functions

The pull-up and pull-down devices for the test functions can be enabled individually under software control. Various test levels can be applied controlling the devices in an adequate way. Because these test functions interfere with the normal operation of the A/D Converters, they are controlled by a separate register set or by port registers.

Not all test options are available for each channel. Selecting an unavailable function has no effect.

20.11 External Multiplexer Control

The number of analog input channels can be increased by connecting external analog multiplexers to an input channel. The ADC can be configured to control these external multiplexers automatically.

For each available EMUX interface (see register **EMUXSEL**) one channel can be selected for this operating mode. The ADC supports 1-out-of-8 multiplexers with several control options:

- **Sequence mode** automatically converts all configured external channels when the selected channel is encountered. In the example in **Figure 20-28** the following conversions are done: --4-32-31-30-2-1-0--4-32-31-30-2-1-0--...
- **Single-step mode** converts one external channel of the configured sequence when the selected channel is encountered. In the example in **Figure 20-28** the following conversions are done: --4-32-2-1-0--4-31-2-1-0--4-30-2-1-0--4-32-... (Single-step mode works best with one channel)
- **Steady mode** converts the configured external channel when the selected channel is encountered. In the example in **Figure 20-28** the following conversions are done: --4-32-2-1-0--4-32-2-1-0--4-32-2-1-0--...

*Note: The example in **Figure 20-28** has an external multiplexer connected to channel CH3. The start selection value EMUXSET is assumed as 2.*

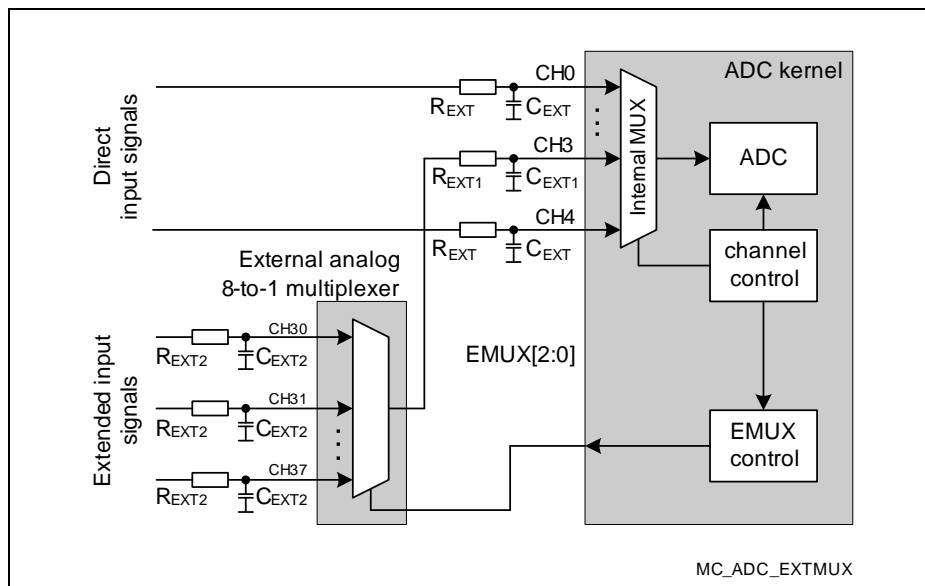

Figure 20-28 External Analog Multiplexer Example

Versatile Analog-to-Digital Converter (VADC)

Bitfield EMUXACT determines the control information sent to the external multiplexer. In single-step mode, EMUXACT is updated after each conversion of an enabled channel. If $EMUXACT = 000_B$ it is reloaded from bitfield EMUXSET, otherwise it is decremented by 1.

Additional external channels may have different properties due to the modified signal path. Local filters may be used at the additional inputs (R_{EXT2} - C_{EXT2} on CH3x in [Figure 20-28](#)). For applications where the external multiplexer is located far from the ADC analog input, it is recommended to add an RC filter directly at the analog input of the ADC (R_{EXT1} - C_{EXT1} on CH3 in [Figure 20-28](#)).

Note: Each RC filter limits the bandwidth of the analog input signal.

Conversions for external channels, therefore, use the alternate conversion mode setting CME. This automatically selects a different conversion mode if required.

Switching the external multiplexer usually requires an additional settling time for the input signal. Therefore, the alternate sample time setting STCE is applied each time the external channel is changed. This automatically fulfills the different sampling time requirements in this case.

In each group an arbitrary channel can be assigned to external multiplexer control (register **GxEMUXCTR** ($x = 0 - 3$)). Each available port interface selects the group whose control lines are output (register **EMUXSEL**).

Control Signals

The external channel number that controls the external multiplexer can be output in standard binary format or Gray-coded. Gray code avoids intermediate multiplexer switching when selecting a sequence of channels, because only one bit changes at a time. [Table 20-5](#) indicates the resulting codes.

Table 20-5 EMUX Control Signal Coding

| Channel | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
|---------|---------|---------|---------|---------|---------|---------|---------|---------|
| Binary | 000_B | 001_B | 010_B | 011_B | 100_B | 101_B | 110_B | 111_B |
| Gray | 000 | 001 | 011 | 010 | 110 | 111 | 101 | 100 |

Operation Without External Multiplexer

If no external multiplexers are used in an application, the reset values of the control registers provide the appropriate setup.

$EMUXMODE = 00_B$ disables the automatic EMUX control.

Since the control output signals are alternate port output signals, they are only visible at the respective pins if explicitly selected.

20.12 Service Request Generation

Each A/D Converter can activate up to 4 group-specific service request output signals and up to 4 shared service request output signals to issue an interrupt or to trigger a DMA channel. Two common service request groups are available, see [Table 20-10 “General Converter Configuration in the XMC4\[78\]00” on Page 20-133](#).

Several events can be assigned to each service request output. Service requests can be generated by three types of events:

- **Request source events:** indicate that a request source completed the requested conversion sequence and the application software can initiate further actions.
 For a scan source (group or background), the event is generated when the complete defined set of channels (pending bits) has been converted.
 For a group queue source, the event is generated according to the programming, i.e. when a channel with enabled source interrupt has been converted or when an invalid entry is encountered.
- **Channel events:** indicate that a conversion is finished. Optionally, channel events can be restricted to result values within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Optionally, result events can be generated only at a reduced rate if data reduction is active.
 For example, a single DMA channel can read the results for a complete auto-scan sequence, if all channels of the sequence target the same result register and the transfers are triggered by result events.

Each ADC event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of ADC events (the ADC event can generate a service request without the need to clear the indication flag).

Event flag registers indicate all types of events that occur during the ADC's operation. Software can set each flag by writing a 1 to the respective position in register GxCEFLAG/GxRFLAG to trigger an event. Software can clear each flag by writing a 1 to the respective position in register GxCEFCLR/GxREFCLR. If enabled, service requests are generated for each occurrence of an event, even if the associated flag remains set.

Node Pointer Registers

Requests from each event source can be directed to a set of service request nodes via associated node pointers. Requests from several sources can be directed to the same node; in this case, they are ORed to the service request output signal.

Software Service Request Activation

Each service request can be activated via software by setting the corresponding bit in register **GxSRACT (x = 0 - 3)**. This can be used for evaluation and testing purposes.

Note: For shared service request lines see common groups in [Table 20-10](#).

Versatile Analog-to-Digital Converter (VADC)

20.13 Registers

The Versatile ADC is built from a series of converter blocks that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see [Table 20-7](#)). The exact register location is obtained by adding the respective register offset to the base address (see [Table 20-6](#)) of the corresponding group.

Due to the regular group structure, several registers appear within each group. Other registers are provided for each channel. This is indicated in the register overview table by placeholders:

- $X###_H$ means: $x \times 0400_H + 0###_H$, for $x = 0 - 3$
- $###Y_H$ means: $###0_H + y \times 0004_H$, for $y = 0 - N$ (depends on register type)

Table 20-6 Registers Address Space

20.13.1 Module Identification

The module identification register indicates the version of the ADC module that is used in the XMC4[78]00.

ID

Module Identification Register (0008_H) **Reset Value: 00C5 C0XX_H**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---------|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| r | | | | | | | | | | | | | | | | r | | | | | | | | r | | | | | | | |

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Indicates the revision number of the implementation. This information depends on the design step. |
| MOD_TYPE | [15:8] | r | Module Type This internal marker is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Indicates the module identification number (00C5 _H = SARADC). |

20.13.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleep mode signal.

CLC

Clock Control Register

(0000_H)

Reset Value: 0000 0003_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----------|----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| r | r | r | r | r | r | r | r | r | r | r | r | rw | r | r | rw |

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| DISR | 0 | rw | Module Disable Request Bit Used for enable/disable control of the module. Also the analog section is disabled by clearing ANONS. 0 _B On request: enable the module clock 1 _B Off request: stop the module clock |
| DISS | 1 | r | Module Disable Status Bit 0 _B Module clock is enabled 1 _B Off: module is not clocked |
| 0 | 2 | r | Reserved, write 0, read as 0 |
| EDIS | 3 | rw | Sleep Mode Enable Control Used to control module's reaction to sleep mode. 0 _B Sleep mode request is enabled and functional 1 _B Module disregards the sleep mode control signal |
| 0 | [31:4] | r | Reserved, write 0, read as 0 |

Versatile Analog-to-Digital Converter (VADC)

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging) and includes the module-related control bits for the OCDS Trigger Bus (OTGB).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status Register (0028_H)

Reset Value: 0000 0000_H

| r | r | r | r | r | r | r | r | rw | r | rw | | r | r | rw | |

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| ANONC | [1:0] | rw | Analog Converter Control Defines the value of bitfield ANONS in a stand-alone converter or a converter in master mode. Coding see ANONS or Section 20.4 . |
| 0 | [3:2] | r | Reserved, write 0, read as 0 |
| ARBRND | [5:4] | rw | Arbitration Round Length Defines the number of arbitration slots per arb. round (arbitration round length = t_{ARB}). ¹⁾ 00 _B 4 arbitration slots per round ($t_{ARB} = 4 / f_{ADCD}$) 01 _B 8 arbitration slots per round ($t_{ARB} = 8 / f_{ADCD}$) 10 _B 16 arbitration slots per round ($t_{ARB} = 16 / f_{ADCD}$) 11 _B 20 arbitration slots per round ($t_{ARB} = 20 / f_{ADCD}$) |
| 0 | 6 | r | Reserved, write 0, read as 0 |

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| ARBM | 7 | rw | Arbitration Mode 0_B The arbiter runs permanently. This setting is required for a synchronization slave (see Section 20.9.1) and for equidistant sampling using the signal ARBCNT (see Section 20.9.2). 1_B The arbiter only runs if at least one conversion request of an enabled request source is pending. This setting ensures a reproducible latency from an incoming request to the conversion start, if the converter is idle. Synchronized conversions are not supported. |
| 0 | [15:8] | r | Reserved, write 0, read as 0 |
| ANONS | [17:16] | rh | Analog Converter Control Status Defined by bitfield ANONC in a stand-alone kernel or a kernel in master mode. In slave mode, this bitfield is defined by bitfield ANONC of the respective master kernel. See also Section 20.4 . 00_B Analog converter off 01_B Reserved 10_B Reserved 11_B Normal operation (permanently on) |
| 0 | [27:18] | r | Reserved, write 0, read as 0 |
| CAL | 28 | rh | Start-Up Calibration Active Indication Indicates the start-up calibration phase of the corresponding analog converter. 0_B Completed or not yet started 1_B Start-up calibration phase is active <i>Note: Start conversions only after the start-up calibration phase is complete.</i> |
| 0 | 29 | r | Reserved, write 0, read as 0 |
| BUSY | 30 | rh | Converter Busy Flag 0_B Not busy 1_B Converter is busy with a conversion |

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|---------------|------|------|---|
| SAMPLE | 31 | rh | Sample Phase Flag 0_B Converting or idle 1_B Input signal is currently sampled |

1) The default setting of 4 arbitration slots is sufficient for correct arbitration. The duration of an arbitration round can be increased if required to synchronize requests.

The Arbitration Priority Register defines the request source priority and the conversion start mode for each request source.

Note: Only change priority and conversion start mode settings of a request source while this request source is disabled, and a currently running conversion requested by this source is finished.

GxARBPR (x = 0 - 3)

Arbitration Priority Register, Group x

$$(x * 0400_H + 0484_H)$$

Versatile Analog-to-Digital Converter (VADC)

The Queue Status Register indicates the current status of the queued source. The filling level and the empty information refer to the queue intermediate stages (if available) and to the queue register 0. An aborted conversion stored in the backup stage is not indicated by these bits (therefore, see QBURx.V).

GxQSR0 (x = 0 - 3)

Queue 0 Status Register, Group x

(x * 0400_H + 0508_H)

Reset Value: 0000 0020_H

| RPTDIS | 16 | rw | Repeat Disable 0_B A cancelled conversion is repeated 1_B A cancelled conversion is discarded |
| 0 | [31:17] | r | Reserved, write 0, read as 0 |

Versatile Analog-to-Digital Converter (VADC)

The Channel Select Registers select the channels to be converted by the background request source (channel scan source). Its bits are used to update the pending registers, when a load event occurs.

The number of valid channel bits depends on the channels available in the respective product type (please refer to **“Product-Specific Configuration” on Page 20-133**).

*Note: Priority channels selected in registers **GxCHASS (x = 0 - 3)** will not be converted.*

BRSELx (x = 0 - 3)

Background Request Source Channel Select Register, Group x
(0180_H + x * 0004_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| 0 | [15:0] | r | Reserved, write 0, read as 0 |
| DRCTR | [19:16] | rw | Data Reduction Control Defines how result values are stored/accumulated in this register for the final result. The data reduction counter DRC can be loaded from this bitfield. The function of bitfield DRCTR is determined by bitfield DMM. |
| DMM | [21:20] | rw | Data Modification Mode 00 _B Standard data reduction (accumulation) 01 _B Result filtering mode ¹⁾ 10 _B Difference mode 11 _B Reserved See “Data Modification” on Page 20-40 |
| 0 | [23:22] | r | Reserved, write 0, read as 0 |

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| WFR | 24 | rw | Wait-for-Read Mode Enable 0 _B Overwrite mode 1 _B Wait-for-read mode enabled for this register |
| FEN | [26:25] | rw | FIFO Mode Enable 00 _B Separate result register 01 _B Part of a FIFO structure: copy each new valid result 10 _B Maximum mode: copy new result if bigger 11 _B Minimum mode: copy new result if smaller |
| 0 | [30:27] | r | Reserved, write 0, read as 0 |
| SRGEN | 31 | rw | Service Request Generation Enable 0 _B No service request 1 _B Service request after a result event |

1) The filter registers are cleared while bitfield DMM ≠ 01_B.

Versatile Analog-to-Digital Converter (VADC)

The group result registers provide a selectable storage location for all channels of a given group.

Note: The preset value used in fast compare mode is written to the respective result register. The debug result registers are not writable.

G0RESy (y = 0 - 15)

Group 0 Result Register y $(0700_H + y * 0004_H)$ **Reset Value: 0000 0000_H**

G1RESy (y = 0 - 15)

Group 1 Result Register y $(0B00_H + y * 0004_H)$ **Reset Value: 0000 0000_H**

G2RESy (y = 0 - 15)

Group 2 Result Register y $(0F00_H + y * 0004_H)$ **Reset Value: 0000 0000_H**

G3RESy (y = 0 - 15)

Group 3 Result Register y $(1300_H + y * 0004_H)$ **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------|---------|------|---|
| RESULT | [15:0] | rwh | Result of Most Recent Conversion The position of the result bits within this bitfield depends on the configured operating mode. Please, refer to Section 20.8.2 . |
| DRC | [19:16] | rh | Data Reduction Counter Indicates the number of values still to be accumulated for the final result. The final result is available and valid flag VF is set when bitfield DRC becomes zero (by decrementing or by reload). See “Data Modification” on Page 20-40 |
| CHNR | [24:20] | rh | Channel Number Indicates the channel number corresponding to the value in bitfield RESULT. |

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| EMUX | [27:25] | rh | External Multiplexer Setting Indicates the setting of the external multiplexer, corresponding to the value in bitfield RESULT. <i>Note: Available in GxRES0 only.</i> <i>Use GxRES0 if EMUX information is required.</i> |
| CRS | [29:28] | rh | Converted Request Source Indicates the request source that as requested the conversion to which the result value in bitfield RESULT belongs. 00 _B Request source 0 01 _B Request source 1 10 _B Request source 2 11 _B Reserved |
| FCR | 30 | rh | Fast Compare Result Indicates the result of an operation in Fast Compare Mode. 0 _B Signal level was below compare value 1 _B Signal level was above compare value |
| VF | 31 | rh | Valid Flag Indicates a new result in bitfield RESULT or bit FCR. 0 _B No new result available 1 _B Bitfield RESULT has been updated with new result value and has not yet been read, or bit FCR has been updated |

The debug view of the group result registers provides access to all result registers of a given group, however, without clearing the valid flag.

Versatile Analog-to-Digital Converter (VADC)

G0RESDy (y = 0 - 15)

Group 0 Result Reg. y, Debug ($0780_H + y * 0004_H$) **Reset Value:** 0000 0000_H

G1RESDy (y = 0 - 15)

Group 1 Result Reg. y, Debug ($0B80_H + y * 0004_H$) **Reset Value:** 0000 0000_H

G2RESDy (y = 0 - 15)

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| DRCTR | [19:16] | rw | Data Reduction Control Defines how result values are stored/accumulated in this register for the final result. The data reduction counter DRC can be loaded from this bitfield. 0000 _B Data reduction disabled others: see “Function of Bitfield DRCTR” on Page 20-40 ¹⁾ |
| 0 | [23:20] | r | Reserved, write 0, read as 0 |
| WFR | 24 | rw | Wait-for-Read Mode Enable 0 _B Overwrite mode 1 _B Wait-for-read mode enabled for this register |
| 0 | [30:25] | r | Reserved, write 0, read as 0 |
| SRGEN | 31 | rw | Service Request Generation Enable 0 _B No service request 1 _B Service request after a result event |

1) Only standard data reduction is available for the global result register, i.e. DMM is assumed as 00_B.

The global result register provides a common storage location for all channels of all groups.

GLOBRES

Global Result Register (0300_H) **Reset Value: 0000 0000_H**

GLOBRESD

Global Result Register, Debug (0380_H) **Reset Value: 0000 0000_H**

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| RESULT | [15:0] | rwh | Result of most recent conversion The position of the result bits within this bitfield depends on the configured operating mode. ¹⁾ Please, refer to Section 20.8.2 . |
| GNR | [19:16] | rh | Group Number Indicates the group to which the channel number in bitfield CHNR refers. |
| CHNR | [24:20] | rh | Channel Number Indicates the channel number corresponding to the value in bitfield RESULT. |
| EMUX | [27:25] | rh | External Multiplexer Setting Indicates the setting of the external multiplexer, corresponding to the value in bitfield RESULT. |
| CRS | [29:28] | rh | Converted Request Source Indicates the request source that as requested the conversion to which the result value in bitfield RESULT belongs. |
| FCR | 30 | rh | Fast Compare Result Indicates the result of an operation in Fast Compare Mode. 0 _B Signal level was below compare value 1 _B Signal level was above compare value |
| VF | 31 | rwh | Valid Flag Indicates a new result in bitfield RESULT or bit FCR. 0 _B Read access: No new valid data available Write access: No effect 1 _B Read access: Bitfield RESULT contains valid data and has not yet been read, or bit FCR has been updated Write access: Clear this valid flag and the data reduction counter (overrides a hardware set action) ¹⁾ |

1) Only writable in register GLOBRES, not in register GLOBRESD.

The valid flag register summarizes the valid flags of all result registers.

Versatile Analog-to-Digital Converter (VADC)

GxVFR (x = 0 - 3)

Valid Flag Register, Group x ($x * 0400_H + 05F8_H$) **Reset Value: 0000 0000_H**

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| ALIAS0 | [4:0] | rw | Alias Value for CH0 Conversion Requests Indicates the channel that is converted instead of channel CH0. The conversion is done with the settings defined for channel CH0. |
| 0 | [7:5] | r | Reserved, write 0, read as 0 |
| ALIAS1 | [12:8] | rw | Alias Value for CH1 Conversion Requests Indicates the channel that is converted instead of channel CH1. The conversion is done with the settings defined for channel CH1. |
| 0 | [31:13] | r | Reserved, write 0, read as 0 |

Versatile Analog-to-Digital Converter (VADC)

The local boundary register GxBOUND defines group-specific boundary values or delta limits for Fast Compare Mode.

The global boundary register GLOBBOUND defines general compare values for all channels.

Depending on the conversion width, the respective left 12/10/8 bits of a bitfield are used. For 10/8-bit results, the lower 2/4 bits must be zero!

GxBOUND (x = 0 - 3)

Boundary Select Register, Group x

$$(x * 0400_H + 04B8_H)$$

Reset Value: 0000 0000_H

GLOBBOUND

Global Boundary Select Register

$$(00B8_H)$$

Reset Value: 0000 0000_H

Versatile Analog-to-Digital Converter (VADC)

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| EMUXACT | [10:8] | rh | External Multiplexer Actual Selection Defines the current value for the external multiplexer selection. This bitfield is loaded from bitfield EMUXSET and modified according to the operating mode selected by bitfield EMUXMODE. |
| 0 | [15:11] | r | Reserved, write 0, read as 0 |
| EMUXCH | [25:16] | rw | External Multiplexer Channel Select Defines the channel(s) to which the external multiplexer control is applied. EMXCSS = 0: Channel number , the lower 5 bits select an arbitrary channel (valid numbers are limited by the number of available channels, unused bits shall be 0) EMXCSS = 1: Channel enable , each bit enables the associated channel (multiple channels can be selected/enabled) |
| EMUXMODE | [27:26] | rw | External Multiplexer Mode 00 _B Software control (no hardware action) 01 _B Steady mode (use EMUXSET value) 10 _B Single-step mode ¹⁾²⁾ 11 _B Sequence mode ¹⁾ |
| EMXCOD | 28 | rw | External Multiplexer Coding Scheme 0 _B Output the channel number in binary code 1 _B Output the channel number in Gray code |
| EMXST | 29 | rw | External Multiplexer Sample Time Control 0 _B Use STCE whenever the setting changes 1 _B Use STCE for each conversion of an external channel |
| EMXCSS | 30 | r | External Multiplexer Channel Selection Style 0 _B Channel number: Bitfield EMUXCH selects an arbitrary channel 1 _B Channel enable: Each bit of bitfield EMUXCH selects the associated channel for EMUX control |
| EMXWC | 31 | w | Write Control for EMUX Configuration 0 _B No write access to EMUX cfg. 1 _B Bitfields EMUXMODE, EMXCOD, EMXST, EMXCSS can be written |

Versatile Analog-to-Digital Converter (VADC)

- 1) For single-step mode and sequence mode: Select the start value before selecting the respective mode.
- 2) Single-step mode modifies the EMUX channel number each time an EMUX-enabled channel is converted. Therefore, single-step mode works best with a single channel, because otherwise some external channels may be skipped.

Versatile Analog-to-Digital Converter (VADC)

Register EMUXSEL is a global register which assigns an arbitrary group to each of the EMUX interfaces.

EMUXSEL

External Multiplexer Select Register

(03F0_H)

Reset Value: 0000 0000_H

20.14 Interconnects

This section describes the actual implementation of the ADC module into the XMC4[78]00, i.e. the incorporation into the microcontroller system.

20.14.1 Product-Specific Configuration

The functional description describes the features and operating modes of the A/D Converters in a general way. This section summarizes the configuration that is available in this product (XMC4[78]00).

Each converter group is equipped with a separate analog converter module and a dedicated analog input multiplexer.

Table 20-10 General Converter Configuration in the XMC4[78]00

| Converter Group | Input Channels | Channels with Alternate Reference | 12-bit Performance | Common Service Request Group |
|------------------------|-----------------------|--|---------------------------|-------------------------------------|
| G0 | 0 ... 7 | 7 | Calibrated | C0 |
| G1 | 0 ... 7 | 7 | Calibrated | C0 |
| G2 | 0 ... 7 | 7 | Calibrated | C0 |
| G3 | 0 ... 7 | 7 | Calibrated | C0 |

Synchronization Groups in the XMC4[78]00

The converter kernels in the XMC4[78]00 can be connected to synchronization groups to achieve parallel conversion of several input channels.

Table 20-11 summarizes which kernels can be synchronized for parallel conversions.

Table 20-11 Synchronization Groups in the XMC4[78]00

| ADC Kernel | Synchr. Group | Master selected by control input Clx ¹⁾ | | | |
|------------|---------------|--|-------|-------|-------|
| | | Cl0 ²⁾ | Cl1 | Cl2 | Cl3 |
| ADC00 | A | ADC00 | ADC01 | ADC02 | ADC03 |
| ADC01 | A | ADC01 | ADC00 | ADC02 | ADC03 |
| ADC02 | A | ADC02 | ADC00 | ADC01 | ADC03 |
| ADC03 | A | ADC03 | ADC00 | ADC01 | ADC02 |

1) The control input is selected by bitfield STSEL in register **GxSYNCTR (x = 0 - 3)**.

Select the corresponding ready inputs accordingly by bits EVALRx.

2) Control input Cl0 always selects the own control signals of the corresponding ADC kernel. This selection is meant for the synchronization master or for stand-alone operation.

Versatile Analog-to-Digital Converter (VADC)

20.14.2 Analog Module Connections in the XMC4[78]00

The VADC module accepts a number of analog input signals. The analog input multiplexers select the input channels to be converted from the signals available in this product.

The exact number of analog input channels and the available connection to port pins depend on the employed product type (see also [Table 20-10](#)). A summary of channels enclosing all versions of the XMC4[78]00 can be found in [Table 20-12](#).

Input channels marked “PDD” provide a pull-down device for pull-down diagnostics.

Input channels marked “noAltref” cannot select the alternate reference voltage from channel 0 of the corresponding converter.

Table 20-12 Analog Connections in the XMC4[78]00

| Signal | Dir. | Source/Destin. | Description |
|-------------|------|----------------|-----------------------------------|
| V_{AREF} | I | VAREF | positive analog reference |

21 Delta-Sigma Demodulator (DSD)

The Delta-Sigma Demodulator module (DSD) of the XMC4[78]00 provides a series of digital input channels accepting data streams from external modulators using the Delta/Sigma (DS) conversion principle.

The on-chip demodulator channels convert these inputs to discrete digital values.

The number of inputs and DSD channels depends on the chosen product type (please refer to **“Interconnects” on Page 21-45**).

Table 21-1 Abbreviations used in the DSD Chapter

| | |
|------------------|---|
| ADC | Analog to Digital Converter |
| CIC | Cascaded Integrator Comb (filter) |
| DMA | Direct Memory Access (controller) |
| DS | Delta-Sigma (conversion principle) |
| INL | Integral Non-Linearity (error) |
| LSB _n | Least Significant Bit: finest granularity of the analog value in digital format, represented by one least significant bit of the conversion result with n bits resolution (measurement range divided in 2 ⁿ equally distributed steps) |
| OSR | Oversampling Ratio |
| PWM | Pulse Width Modulation |

21.1 Overview

Each converter channel can operate independent of the others, controlled by a dedicated set of registers. The results of each channel can be stored in a dedicated channel-specific result register.

The on-chip filter stages generate digital results from the selected modulator signal.

The DSD accepts data from different types of external modulators. Their data streams can be fed to selectable input pins.

Features

The following features describe the functionality of a Delta-Sigma Converter:

- Options to connect external standard Delta-Sigma modulators
 - Selectable data stream inputs
 - Selectable DS clock input or output
- Main demodulator (concatenated hardware filter stages)

Delta-Sigma Demodulator (DSD)

- Configurable CIC filter with decimation rates of 4...256
- Integration stage with external gating
- Automatic offset compensation
- Time-stamp support
- Parallel auxiliary demodulator for limit checking
 - Configurable CIC filter with decimation rates of 4...32
 - Two-level boundary comparator
- Built-in support for resolver applications
 - Carrier signal generator
 - Delay compensation for position signals
 - Carrier cancelation by integrator unit
- DMA/Service-requests
 - Result events on new valid results with external gating
 - Alarm events from limit checking

Table 21-2 DSD Applications

| Use Case DSD | Application |
|---|---------------------------------------|
| Galvanically decoupled phase current measurement | Motor control, Power conversion |
| Resolver signal evaluation and generation of excitation signal | Motor control |
| Adjustable resolution for input signals with wide dynamic range | Motorcontrol, Metering, Medical |

Delta-Sigma Demodulator (DSD)

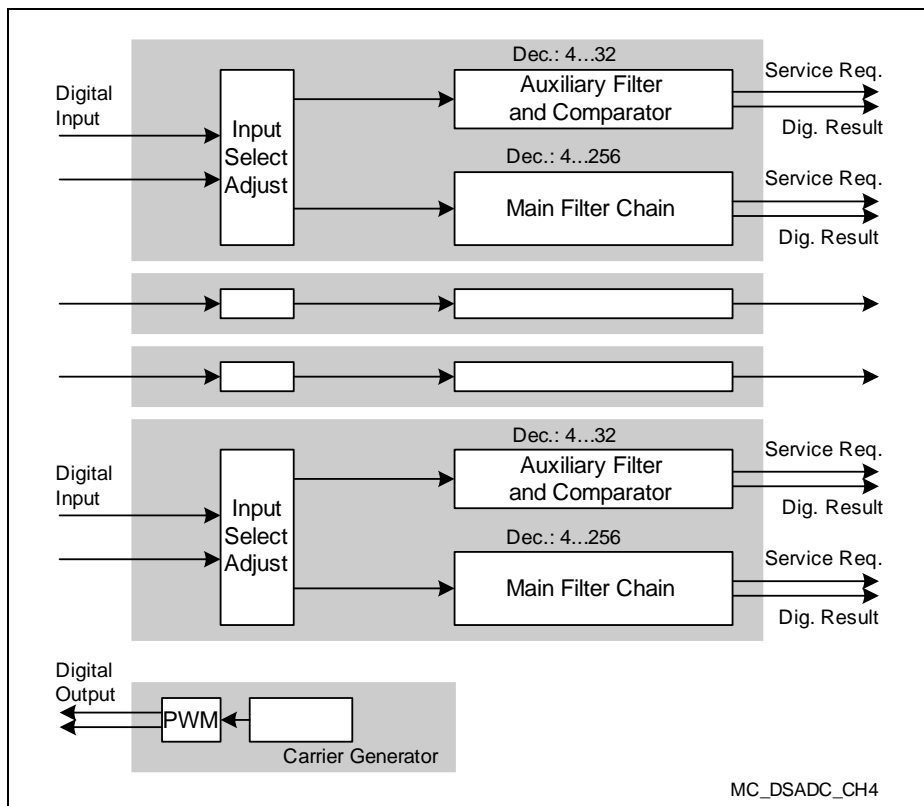

Figure 21-1 DSD Module Overview

21.2 Introduction and Basic Structure

The Delta-Sigma Analog to Digital Converter module of the XMC4[78]00 provides several channels with a main and an auxiliary demodulator including configurable filters for decimation (see [Figure 21-2](#)).

Several types of external modulators can be connected to the input path. The modulator clock signal can be generated internally or can be fed from an external clock source.

The main chain of digital filters builds the demodulator which produces result values at a configurable output rate. The elements of the filter chain can be selected according to the requirements of the application. The filter chain configuration determines the attenuation and delay properties of the filter. The decimation at a configurable rate reduces the input sampling rate to a lower result data rate.

The configurable CIC filter provides the basic filtering and decimation with a selectable decimation rate.

The integrator accumulates a configurable amount of result values. The number of samples is programmable or can be controlled by a hardware signal. This function supports resolver applications to get the baseband signal for the motor position calculation. Furthermore, the integrator can be also used in shunt current measurement applications.

A smaller but quicker parallel auxiliary filter with a comparator supports limit checking, e.g. for overcurrent detection. Two limit values can be defined to restrict the generation of service requests to result values within a configurable area. This saves CPU performance and/or DMA bandwidth.

A carrier signal can be generated to support resolver applications.

The on-chip carrier signal generator produces a selectable output signal (sine, triangle, rectangle) which can be used to drive a resolver. Synchronization of each input signal to the carrier signal ensures correct integration of the resolver input signals.

Service requests can be generated to trigger DMA transfers or to request CPU service.

The basic module clock f_{DSD} is connected to the system clock signal f_{PERIPH} .

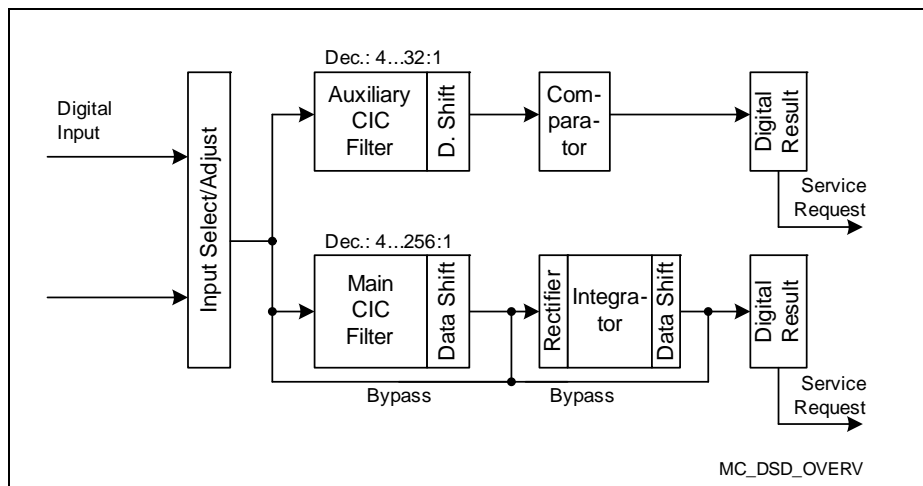

Figure 21-2 DSD Structure Overview

21.3 Configuration of General Functions

Several parameters can be configured to adapt the functionality of the DSD to the requirements of the actual application.

The DSD of the XMC4[78]00 can operate in several configurations:

- Using an external modulator, running on a clock generated on-chip
- Using an external modulator, running on its own clock

The global configuration register **GLOBCFG** selects the source for the internal clock signal which can be used to drive the modulators (alternatively, a clock signal can be input from an external modulator).

The global run control register **GLOBRC** controls the general operation of the available channels.

21.4 Input Channel Configuration

The input data for a channel can be obtained from different sources:

- **External Modulator Without Clock Source:** This type of modulator requires a modulator clock signal. This clock signal is provided by the XMC4[78]00, the data stream produced by the modulator is input as a digital signal.
- **External Modulator With Clock Source:** This type of modulator generates the modulator clock signal along with the data stream. In this case, both the modulator clock and the data stream produced by the modulator are input as digital signals.

Delta-Sigma Demodulator (DSD)

Note: An external modulator can be used, in particular, in systems where high voltages are to be sampled. This allows for galvanic decoupling.
Several input pins can be selected.

The modulator clock can be generated in different ways:

- The modulator clock can be derived on-chip from the module clock and is output via a modulator clock pin to be used by an external modulator.
- The external modulator can generate the clock signal which is then input via one of the modulator clock pins.

Note: Select the same frequency for modulator clock and the on-chip carrier generator.
This enables synchronous operation of carrier generator and integrator.

A trigger signal can be input from a selectable input. These inputs are connected to on-chip peripherals or to pins (see [Section 21.13.2](#)). This trigger signal can be used for different purposes:

- Integration trigger:
The external signal defines the integration window, i.e. the timespan during which result values are integrated.
- Timestamp trigger:
The external signal requests the actualization of the timestamp register.

Note: To avoid unintended triggers, select the trigger source first before enabling the corresponding function.

The figure below summarizes these three signal paths and indicates the source of the corresponding control information.

Delta-Sigma Demodulator (DSD)

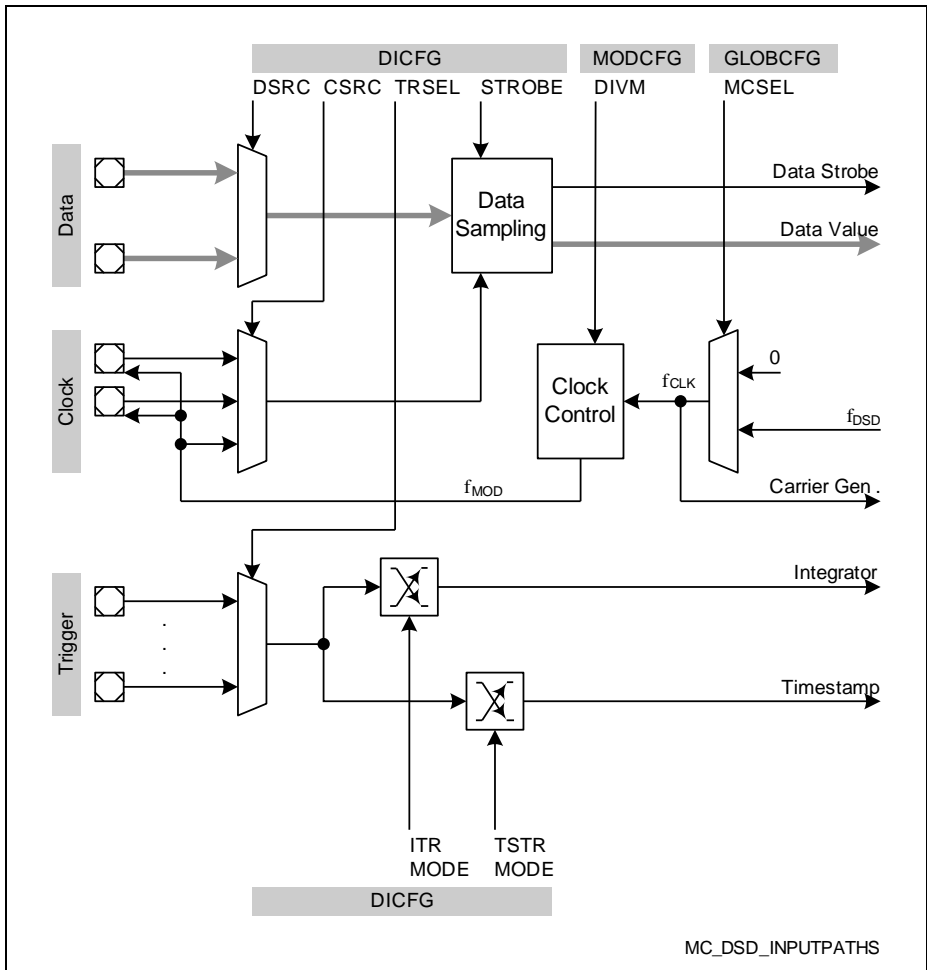

Figure 21-3 Input Path Summary

21.4.1 Modulator Clock Selection and Generation

The modulator clock signal can be generated on-chip by a programmable prescaler (clock output) or can be generated by an external modulator and be input through a pin (clock input). For internal clock generation, the on-chip clock signal is enabled by bitfield MCSEL.

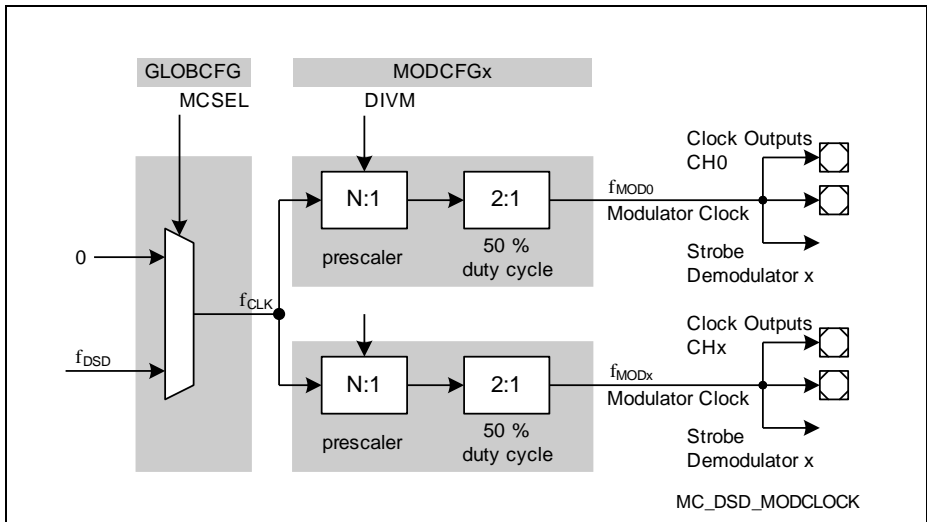

Figure 21-4 Modulator Clock Configuration

The selected clock source is synchronized to the module clock. A configurable edge detector selects the clock signal edges that generate the data strobes which read the next input data and trigger the demodulator (see [Figure 21-5](#)).

Note: To ensure proper synchronization, an external clock signal must have high/low phases of at least one period of f_{DSD} to be safely synchronized ($f_{IN} < f_{DSD}/2$).

When the clock signal is generated on-chip (see [Figure 21-4](#)) and is selected as an output signal at a connected pin (see connection list in [Section 21.13](#)), this clock signal can drive an external modulator.

Bitfield CSRC in register **DICFGx (x = 0 - 3)** selects the clock source for each channel. Bitfield STROBE selects the clocking mode, i.e. the clock edges that put a new input data sample into the filter chain.

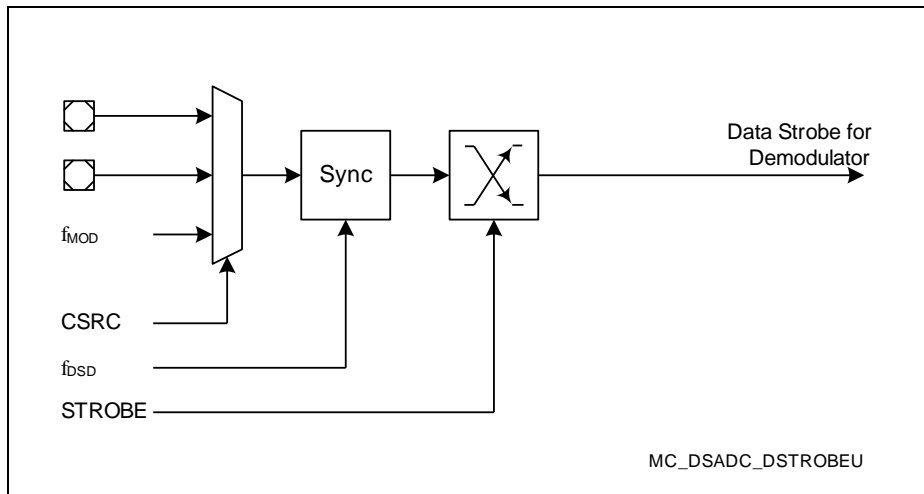

Figure 21-5 Demodulator Data Strobe Selection

21.4.2 Input Data Selection

The data stream of an external modulator can be input from a selectable pin. This signal can optionally be inverted.

The selected input datastream is converted to the CIC filter's input format.

Delta-Sigma Demodulator (DSD)

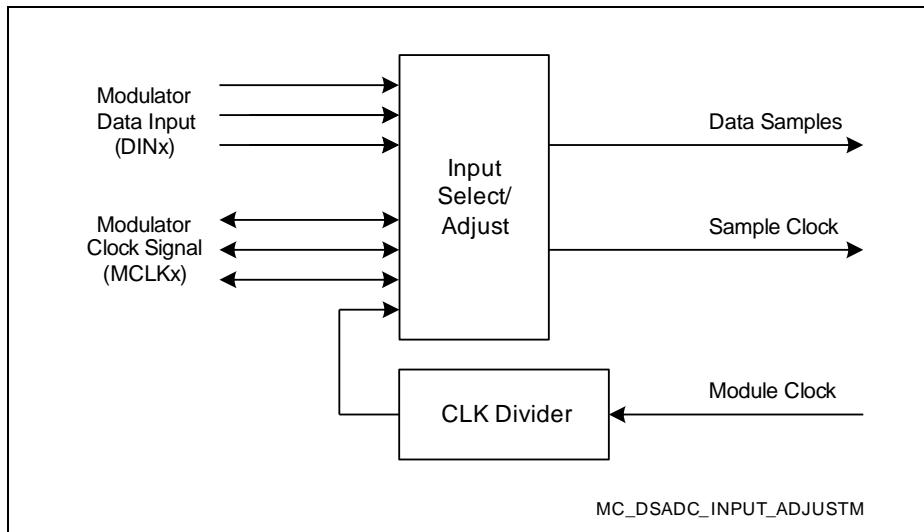

Figure 21-6 Input Control Unit

All options are configured by the demodulator input configuration register **DICFGx (x = 0 - 3)**.

21.4.3 External Modulator

The input data stream can be obtained from an external modulator via a selectable pin. This modulator may, for example, be connected to a high driving voltage and be galvanically decoupled.

In this case, the modulator's data output is connected to the selected pin. The Input Select/Adjust block will then format the selected input data stream to the format required by the subsequent filter.

The source of the 1-bit input data can be selected as well as the source of the sample clock signal. The data strobe that enters a new value into the filter chain can be generated upon configurable clock edges of the modulator clock to support different types of modulators.

21.4.4 Input Path Control

The input for the DSD is fed through several stages before being evaluated and filtered. Registers MODCFGx and DICFGx select the available options for these signal stages.

The following features can be configured:

- Signal input pin selection

Delta-Sigma Demodulator (DSD)

- Generation method of input data
- Modulator clock source and/or frequency
- Trigger input pin selection

With this flexibility the DSD can be adjusted to many available types of modulators.

21.5 Main Filter Chain

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio.

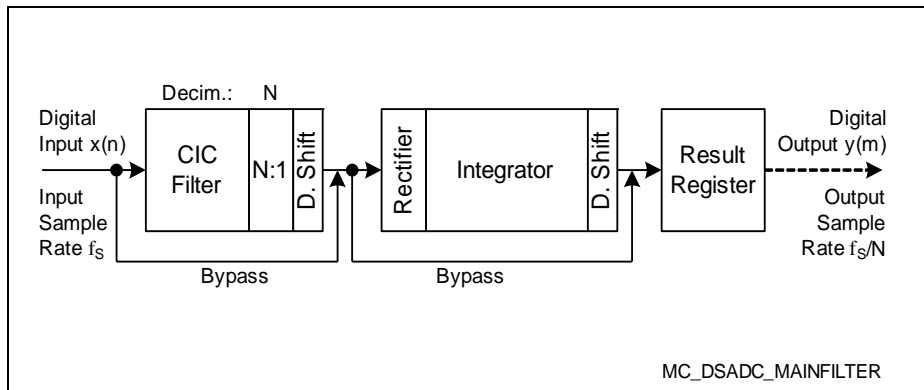

Figure 21-7 Structure of the Main Filter Chain

The elements of the filter can be bypassed, i.e. the filter chain is configurable and its behavior can be adapted to the requirements of the actual application. This comprises the frequency attenuation as well as the total decimation rate.

Note: Only configure or reconfigure filter parameters while the channel is inactive. After the configuration, start the channel by setting the corresponding bit CHxRUN.

21.5.1 CIC Filter

The Cascaded Integrator Comb filter (CIC filter, a.k.a. SINC filter) is a simple but very efficient low-pass filter. Up to three comb filter stages can be cascaded to improve the frequency characteristics. The number of active filter stages can be selected (CIC1, CIC2, CIC3) to find the optimum tradeoff between delay and frequency characteristics.

In addition, a combined mode can be selected (CICF) which represents a compromise between a 2-stage and a 3-stage filter.

To synchronize filters of different channels with fine granularity, the decimation counter starts from an arbitrary start value. This start value can be different from the decimation factor and is loaded only once when the counter is started.

Delta-Sigma Demodulator (DSD)

The decimation counter is also restarted (i.e. loaded with the start value) when an integration starts (see [Section 21.5.2](#)).

The decimation factor can be selected in a wide range from 4 to 256.

A CIC filter with length N can be described in the following ways:

Time domain, frequency domain, z replaced with $e^{j\omega}$ (with $\omega = 2\pi f/f_s$):

$$y(n) = \sum_{i=0}^{N-1} x(n-i) \quad H(z) = \sum_{n=0}^{N-1} z^{-n} = \frac{1-z^{-N}}{1-z^{-1}} \quad |H(j\omega)| = \frac{\sin(\omega N / 2)}{\sin(\omega / 2)}$$

The CIC filter is very efficient for the implementation of a decimation low pass filter when combined with a decimator with decimation factor N.

Cascading k stages of CIC filters improves the frequency performance and leads to the CICK decimation filter shown in [Figure 21-8](#).

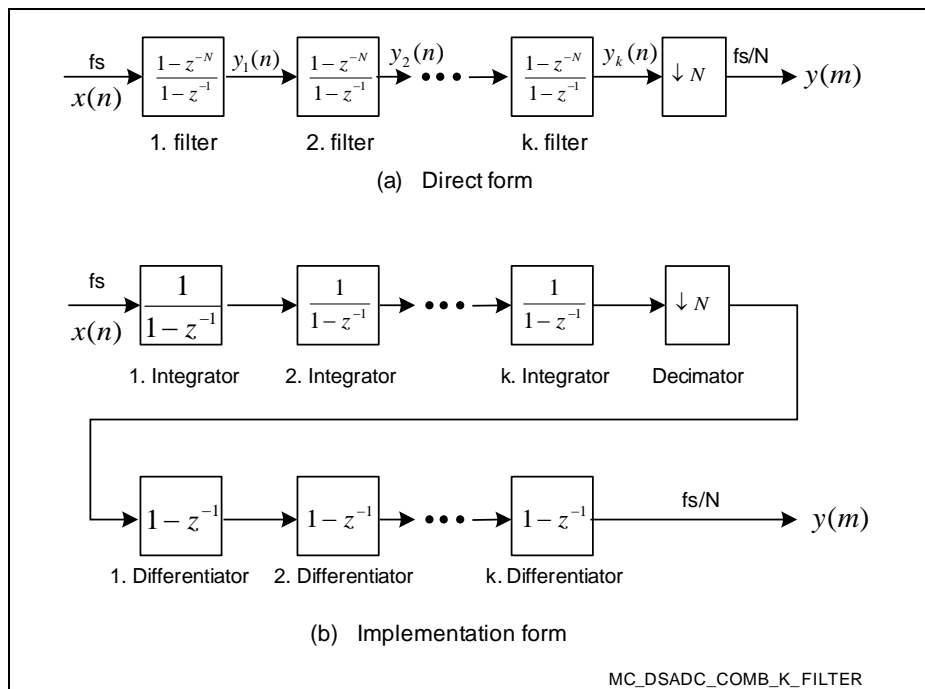

Figure 21-8 Equivalent Structure of a CICK Decimation Filter

In the frequency-domain, the CICK filter can be described in the following ways:

Frequency domain, frequency response function:

Delta-Sigma Demodulator (DSD)

$$H(z) = \left(\frac{1 - z^{-N}}{1 - z^{-1}} \right)^k$$

$$|H(j\omega)| = \left(\frac{\sin(\omega N / 2)}{\sin(\omega / 2)} \right)^k$$

In the time-domain, the following equations are according to **Figure 21-8(a)**:

$$\begin{aligned} y_1(n) &= x(n) + x(n-1) + \dots + x(n-(N-1)) \\ y_2(n) &= y_1(n) + y_1(n-1) + \dots + y_1(n-N+1) \\ &\dots \\ y_k(n) &= y_{k-1}(n) + y_{k-1}(n-1) + \dots + y_{k-1}(n-N+1) \\ y(m) &= y_k(mN) \end{aligned}$$

At the CIC filter output 16 data bits are selected for the subsequent blocks. The position of these 16 CIC output bits depends on the selected number of CIC filter stages and on the selected decimation factor.

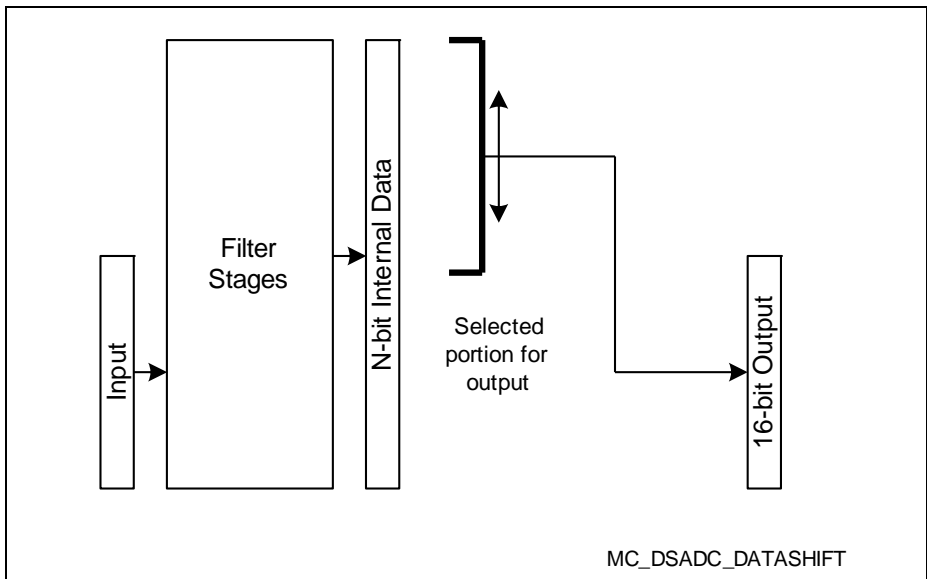

Figure 21-9 Data Shift Unit

The selected portion of the filter output is determined by the selected decimation factor and the CIC filter operating mode. These two parameters define the maximum possible data value and, hence, the proper position for the extracted output value.

Table 21-3 Data Shifter Position¹⁾ Dep. on Filter Mode and Decimation

| Decimation | CIC1 | CIC2 | CIC3 | CICF |
|-------------------|-------------|-------------|-------------|-------------|
| 4 - 32 | 15:0 | 15:0 | 15:0 | 15:0 |
| 33 - 40 | 15:0 | 15:0 | 16:1 * | 15:0 |
| 41 - 50 | 15:0 | 15:0 | 17:2 * | 15:0 |
| 51 - 64 | 15:0 | 15:0 | 18:3 * | 15:0 |
| 65 - 80 | 15:0 | 15:0 | 19:4 * | 15:0 |
| 81 - 101 | 15:0 | 15:0 | 20:5 * | 15:0 |
| 102 - 128 | 15:0 | 15:0 | 21:6 * | 15:0 |
| 129 - 181 | 15:0 | 15:0 | 22:7 * | 16:1 * |
| 182 - 203 | 15:0 | 16:1 * | 23:8 * | 17:2 * |
| 204 - 256 | 15:0 | 16:1 | 24:9 * | 17:2 |

1) * indicates a change.

21.5.2 Integrator Stage

The integrator integrates the result values generated during the defined integration window by adding a configurable number of values to build the final result value. The integration window can be started triggered by an internal or external signal.

A configurable number of values can automatically be discarded after the trigger before the integration window is started. This positions the integration window exactly into a timeframe where the filter is stable or where the signal to be measured is free of system-generated noise.

Integration can be used to measure currents through shunt resistors at defined positions in the signal waveform. It also can remove the carrier signal component in resolver applications. In this case, the values to be integrated can be rectified to yield the maximum amplitude of the receiver signal. The delay between the carrier signal (generated by the on-chip carrier generator) and the received position signals can be compensated automatically. Also refer to [Section 21.10](#).

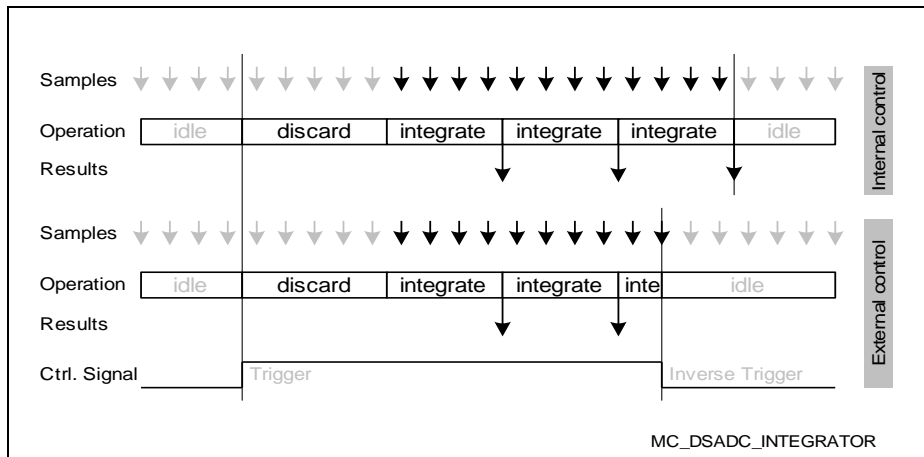

Figure 21-10 Integrator Operation

Note: The integrator can add up to 64 values, while enabled. Its output, therefore, is shifted by 6 bits (1d 64). This leads to reduced result magnitudes when less than 64 values are accumulated.

Starting the Integration Window

The integration window starts when bit INTEN becomes 1:

- Select software-controlled integration mode by setting bitfield ITRMODE = 11_B
- Select trigger-controlled integration mode (ITRMODE = 01_B or 10_B) and generate the selected trigger edge at the configured trigger input

The external integration trigger signal is selected by bitfield TRSEL in register **DICFGx (x = 0 - 3)**. Bitfield ITRMODE selects the transition of the selected signal to generate the trigger event. Select the trigger source first before enabling it.

Also, the decimation counter of the CIC filter is restarted, i.e. loaded with its start value (see [Section 21.5.1](#)).

When the integration window is started (INTEN becomes 1) the integration counter starts counting. After <NVALDIS> values the counter is reset and the integrator is started (if NVALDIS is zero the integration starts immediately).

Executing Integration Cycles

During an integration cycle <NVALINT+1> input values are integrated. After that, the integration result is stored in the result register and the integrator and the counter are cleared. If bit INTEN = 1 the next integration cycle is started.

Stopping the Integration Window

The integration window stops when bit INTEN becomes 0:

- Disable software-controlled integration mode by setting bitfield ITRMODE = 00_B
- Internally controlled end-of-integration (IWS = 0, see upper part of [Figure 21-10](#)):
 - After <REPVAL+1> integration cycles INTEN is cleared and the integration window closes, after (<NVALINT+1> × <REPVAL+1>) input values
- Externally controlled end-of-integration (IWS = 1, see lower part of [Figure 21-10](#)):
 - Generate the selected inverse trigger edge at the configured trigger input (ITRMODE = 01_B or 10_B)

Note: When the integration window is closed by an external signal (INTEN cleared by inverse trigger), the integrator and the counter are cleared also.

21.6 Auxiliary Filter

The parallel auxiliary filter uses a CIC filter for decimation, similar to the one used in the main filter chain. The decimation rate is restricted to 32. This also reduces the filter delay, so the auxiliary filter can be used to supervise the input signal and detect abnormal input values earlier than the main filter chain.

The subsequent comparator provides automatic limit checking by comparing each result to two configurable reference values. The comparator can generate a separate service request.

The two values are defined in the boundary select register and determine the valid result value band if limit checking is enabled.

Figure 21-11 Result Monitoring through Limit Checking

A result value is considered inside the defined band when both of the following conditions are true:

Delta-Sigma Demodulator (DSD)

- the value is less than or equal to the selected upper boundary (BOUNDARYU)
- the value is greater than or equal to the selected lower boundary (BOUNDARYL)

The result range can also be divided into two areas:

To select the lower part as valid band, set the lower boundary to the minimum value (8000_H) and set the upper boundary to the highest intended value.

To select the upper part as valid band, set the upper boundary to the maximum value ($7FFF_H$) and set the lower boundary to the lowest intended value.

The auxiliary filter can generate the following output:

Service requests, optionally restricted by the comparators. Select the condition via bitfields SRGA and ESEL in register **FCFGAx** ($x = 0 - 3$).

An alarm event can be generated when a new conversion result becomes available. Alarm events can be restricted to result values that are inside or outside a user-defined band (see [Figure 21-11](#)). This feature supports automatic range monitoring and minimizes the CPU load by issuing service requests only under certain conditions. For example, an input value can be monitored and an alarm indicates a certain threshold.

Note: Limit checking uses the parallel auxiliary filter at a low decimation rate and, therefore, the alarm is generated earlier than the threshold values are seen at the output of the regular filter chain.

Alarm events can also be suppressed completely (see **FCFGAx** ($x = 0 - 3$)).

The range signals are generated independent of service requests.

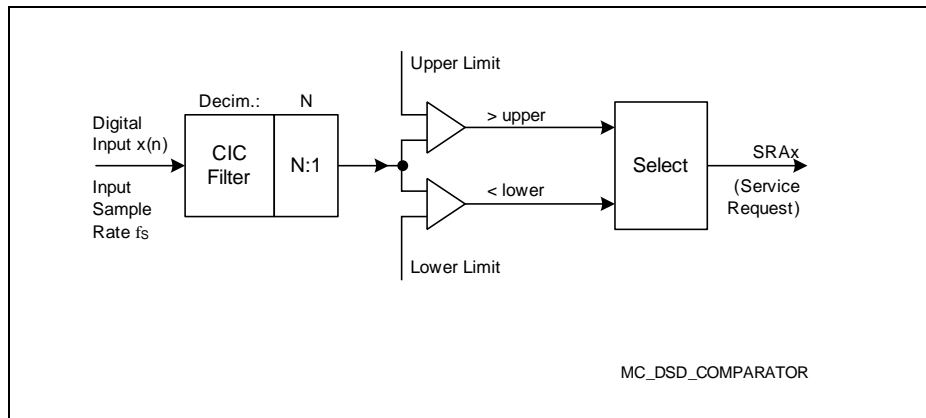

Figure 21-12 Comparator Structure

21.7 Group Delay

Data that enter a digital filter need a certain number of filter clocks before they appear at the filter's output and can be used by the system. The effective group delay depends on

Delta-Sigma Demodulator (DSD)

the configuration of the filter chain. **Table 21-4** summarizes the delays incurred by the elements of the filter chain (steady state). "N" indicates the selected oversampling rate (decimation factor) of the CIC filter. Delays are listed in modulator clock cycles.

Table 21-4 Group Delay Summary

| Filter Chain Element | Delay [t_{MOD}] | Notes |
|--------------------------|----------------------|---|
| Input select/adjust unit | 1 | Synchronization |
| CIC1 | $1 \times (N-1) / 2$ | |
| CIC2 | $2 \times (N-1) / 2$ | |
| CIC3 | $3 \times (N-1) / 2$ | |
| CICF | $(2 \times N) - 1$ | |
| Integrator | X | Depending on the selected number of discarded and integrated values |
| Offset correction | 0 | |

Example

$f_{MOD} = 10 \text{ MHz}$, $t_{MOD} = 100 \text{ ns}$, $OSR(CIC3) = 32$, no integration.

Group delay:

$$[1 + (3 \times 31 / 2) + 0] \times t_{MOD} =$$

$$(1 + 46.5 + 0) \times t_{MOD} = 47.5 \times t_{MOD} = 4.75 \mu\text{s}$$

At the given oversampling rate of 32 this equals a delay of $1.48 \times t_D$ (data output rate cycles).

21.8 Conversion Result Handling

The DSD preprocesses the conversion result data before storing them for retrieval by the CPU or a DMA channel.

Conversion result handling comprises the following functions:

- Filtering and Post-Processing
- Storage of Conversion Results
- Result Event Generation

The result data words are generated by feeding the input data stream through a chain of filter elements and decimating it by a selectable ratio. The selectable integrator can further reduce the output data rate.

A programmable offset is subtracted automatically from each result value before being stored in the result register. This offset value is stored in the corresponding register **OFFMx (x = 0 - 3)**. It may be an arbitrary value defined by the application. Usually, the offset value is measured for each channel separately.

Delta-Sigma Demodulator (DSD)

The result values of the auxiliary filter are also available for the application, although in many cases the comparator output signal will be sufficient.

The conversion result values are stored in result register **RESM_x (x = 0 - 3)** and **RESA_x (x = 0 - 3)**, respectively.

Result Representation

The results are signed values stored in a 16-bit two's complement format. The CIC filter's output value depends on the selected filter parameters and decimation factor. An automatic data shifter extracts the most significant bits from this filter result.

21.9 Service Request Generation

The DSD can activate service request output signals to issue an interrupt, to trigger a DMA channel, or to trigger other on-chip modules.

Service request connections can be found in [Table 21-8 “Digital Connections in the XMC4\[78\]00” on Page 21-46](#).

Several events are assigned to each service request output. Service requests can be generated by two types of events:

- **Result events:** indicate a new valid result in a result register. Usually, this triggers a read action by the CPU (or DMA). Result events are generated at the output rate of the configured filter chain.
Can be issued via SR_{Ax} and SR_{Mx}.
- **Alarm events:** indicate that a conversion result value is within a programmable value range. This offloads the CPU/DMA from background tasks, i.e. a service request is only activated if the specified conversion result range is met or exceeded.
Can be issued via SR_{Ax}.
- **Special events:** indicate specific circumstances of previously configured functions.
 - Capture event for sign delay measurement can generate a service request.
Can be issued via SR_{Ax}.

Each event is indicated by a dedicated flag that can be cleared by software. If a service request is enabled for a certain event, the service request is generated for each event, independent of the status of the corresponding event indication flag. This ensures efficient DMA handling of DSD events (the event can generate a service request without the need to clear the indication flag).

Note: For service request signals to occur, they must be activated via bitfields SRGM and/or SRGA.

Gating Requests of Auxiliary Channel

Result/Alarm events on service request SR_{Ax} can be suppressed while the integrator is enabled and is controlled by an external signal. When bit EGT in register is set, result

Delta-Sigma Demodulator (DSD)

events ($ESEL = 00_B$) or alarm events ($ESEL = 01_B$ or $ESEL = 10_B$) only generate service requests while the integrator is active after the programmed discard phase.

This prevents alarm requests from being generated while the signal is not evaluated via the main filter chain.

Note: While the integrator is disabled ($ITRMODE = 00_B$), bit EGT has no effect on the generation of auxiliary service requests.

The **Service Request Registers** provide a set of bits for each available channel. The number of available channels depends on the chosen device type.

21.10 Resolver Support

Resolver applications determine the rotation angle by evaluating the signals from two orthogonally placed coils. These coils are excited by the magnetic field of a third coil. The DSD can read the two return signals using two input channels and can also generate the excitation sine signal (carrier). It also provides synchronization logic to compensate the delay between the generated carrier signal and the received position signals. The integrator stage converts the carrier-based return signals to position-based values (carrier cancellation).

21.10.1 Carrier Signal Generation

The carrier signal generator (CG) is supplied with the selected internal clock signal (f_{CLK}) and outputs a PWM signal that induces a sine signal in the excitation coil of the resolver. Alternatively, it can generate PWM patterns that resemble triangle or square signals (see [Figure 21-14](#)). The polarity of the carrier signal can be selected.

A carrier signal period consists of 32 steps. Each step equals a PWM period of 32 cycles.

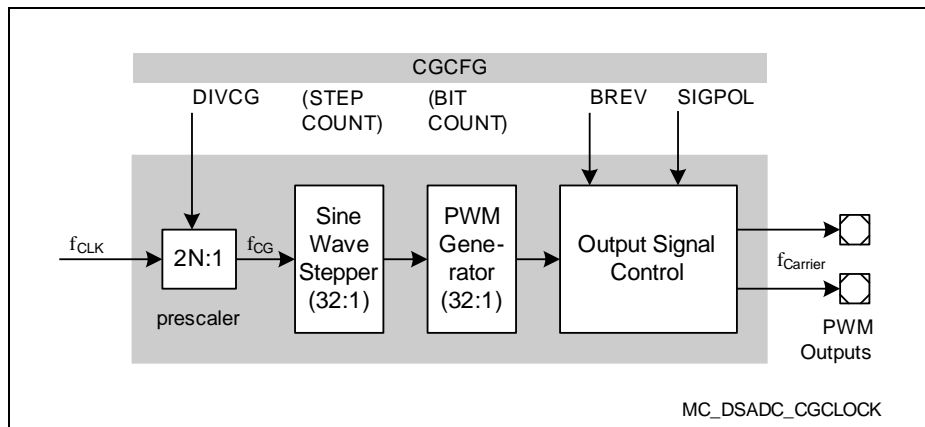

Figure 21-13 Carrier Generator Block Diagram

Delta-Sigma Demodulator (DSD)

Bit-reverse generation mode increases the frequency spectrum to yield a smoother induced sine signal. This is done by distributing the 0 and 1 bits over the 32 cycles of a PWM period.

The generated pattern is actually a cosine signal, i.e. it starts at the maximum output value. This is advantageous if the output pin is pulled high before the carrier signal is generated. In case of a pull-down the inverted output signal should be selected.

Figure 21-14 Example Pattern/Waveform Outputs

21.10.2 Return Signal Synchronization

In a resolver, the received return signals are induced by the carrier signal and their amplitudes are modulated with the sine and cosine magnitudes corresponding to the current resolver position. These amplitudes are determined by integrating the return signals over a carrier signal period.

To properly integrate their magnitude, the return signals must be rectified. For this purpose the carrier generator provides the sign information of the generated carrier signal (SGNCG in register **CGCFG**).

Alternatively, an external carrier signal generator can be used. If this generator delivers a sign signal, this can be input to a pin and is then used as external carrier sign signal. If no sign signal is available, the carrier signal itself can be converted by the next adjacent input channel and its sign signal is then used as alternate carrier sign signal.

Delta-Sigma Demodulator (DSD)

*Note: The resulting sign signal is called SGNCS in **Figure 21-15**.*

The rectification of the received signals must be delayed to compensate the round trip delay through the system (driver, resolver coils, cables, etc.). For the rectification, the received values are multiplied with the delayed carrier sign signal (SGND in register **RECTCFGx (x = 0 - 3)**). This synchronization is done for each channel separately, to achieve the maximum possible amplitudes for each signal.

Note: The rectification unit is part of the integrator stage. Therefore, it is only active while the integrator is active.

The delay is realized with the sign delay counter SDCOUNT. SDCOUNT is cleared and started upon a falling edge of the selected sign signal (SGNCS in **Figure 21-15**), i.e. at the begin of the positive halfwave of the carrier signal. After counting SDPOS results from the filter chain, also the rectification signal (SGND) is cleared, indicating positive values from now on. After counting SDNEG values, the rectification signal is set, indicating negative values (see also **Figure 21-15**).

The compare values SDPOS and SDNEG are stored by the application software. SDPOS is the delay value that accounts for the resolver signal's round trip delay. This delay is constantly measured by capturing the current counter value into bitfield SDCAP when the first positive result (after negative results) is received in the respective channel. Software can read these value and compute a delay value e.g. by averaging a series of measured values to compensate noise. The delay for the negative halfwave (SGND = 0) is determined by adding the duration of a carrier signal halfwave. This value is written to bitfield SDNEG.

A new captured value is indicated by setting the flag SDVAL. This flag is cleared when reading register CGSYNCx.

Capturing a new value can trigger a service request. The service request line of the auxiliary channel is used for this purpose. This alternate request source is selected by bitfield SRGA in register **FCFGAx (x = 0 - 3)**.

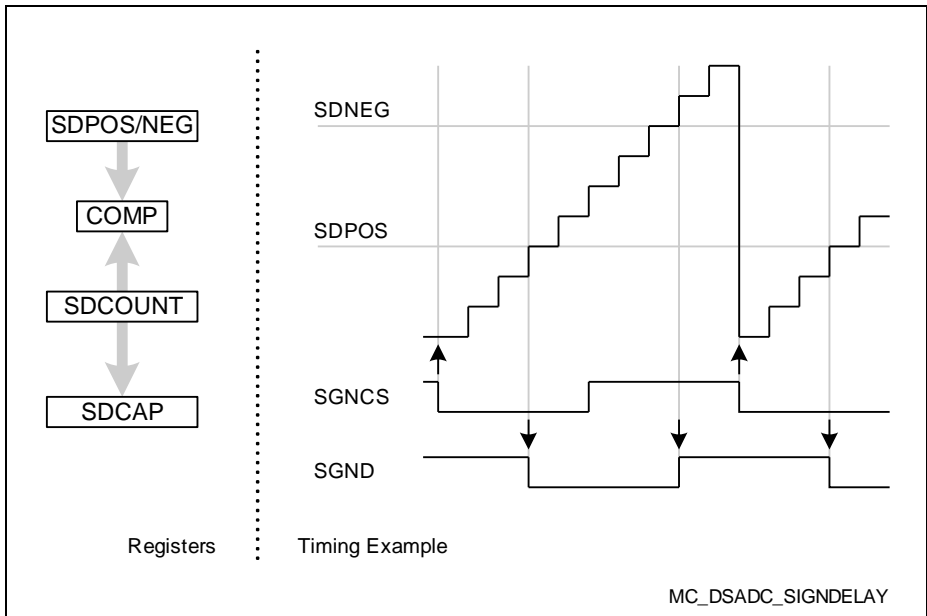

Figure 21-15 Sign Delay Example

21.11 Time-Stamp Support

Some applications need to determine the result value at certain points of time inbetween two regular output values. The interpolation algorithm needs to determine the position of the required point of time in relation to the regular results.

This interpolation is supported by providing a timestamp that marks the delay since the last regular output value. This timestamp is composed of:

- the last regular result value
- the current decimation counter value
- the current integrator counter value

All timestamp information is combined into one register, so the complete timestamp can easily be stored away by a single DMA transfer. The timestamp information is captured into register TSTMPx upon a hardware trigger. For this purpose, the trigger signal is used, which is selected by bitfield TRSEL in register **DICFGx (x = 0 - 3)**. Bitfield TSTRMODE selects the edge(s) that capture timestamp information.

21.12 Registers

The DSD is built from a series of channels that are controlled in an identical way. This makes programming versatile and scalable. The corresponding registers, therefore, have an individual offset assigned (see [Table 21-6](#)). The exact register location is obtained by adding the respective register offset to the base address (see [Table 21-5](#)) of the corresponding channel.

Due to the regular structure, several registers appear within each channel. This is indicated in the register overview table by placeholders:

- $0X\#\#_H$ means: $x \times 0100_H + 01\#\#_H$, for $x = 0 - 3$

Table 21-5 Registers Address Space

| MOD_NUMBER | [31:16] | r | Module Number Indicates the module identification number (00A4 _H = DSD) |

21.12.2 System Registers

A set of standardized registers provides general access to the module and controls basic system functions.

The Clock Control Register **CLC** allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application. Register **CLC** controls the module clock signal and the reactivity to the sleepde signal.

CLC

Clock Control Register

(0000_H)
Reset Value: 0000 0003_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----------|----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| r | r | r | r | r | r | r | r | r | r | r | r | r | r | r | r |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | E DIS | 0 | DIS S | DIS R |

| Field | Bits | Type | Description |
|-------------|------|------|--|
| DISR | 0 | rw | Module Disable Request Bit Used for enable/disable control of the module. 0 _B On request: enable the module clock 1 _B Off request: stop the module clock |
| DISS | 1 | r | Module Disable Status Bit 0 _B Module clock is enabled 1 _B Off: module is not clocked |
| 0 | 2 | r | Reserved, write 0, read as 0 |

Delta-Sigma Demodulator (DSD)

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| EDIS | 3 | rw | Sleep Mode Enable Control Used to control module's reaction to sleep mode. 0 _B Sleep mode request is enabled and functional 1 _B Module disregards the sleep mode control signal |
| 0 | [31:4] | r | Reserved, write 0, read as 0 |

The OCDS control and status register OCS controls the module's behavior in suspend mode (used for debugging).

The OCDS Control and Status (OCS) register is cleared by Debug Reset.

The OCS register can only be written when the OCDS is enabled.

If OCDS is being disabled, the OCS register value will not change.

When OCDS is disabled the OCS suspend control is ineffective.

Write access is 32 bit wide only and requires Supervisor Mode.

OCS

OCDS Control and Status Register (0028_H)

Reset Value: 0000 0000_H

- 1) The integration trigger mode controls bit INTEN in register **IWCTR_x** (**x = 0 - 3**) and hence the operation of the integrator:
 Bit INTEN is set when ITRMODE = 11_B or when the selected trigger signal transition occurs.
 Bit INTEN is cleared when ITRMODE = 00_B or when the inverse trigger signal transition occurs.
- 2) The timestamp trigger mode controls capturing the timestamp information to register **TSTMP_x** (**x = 0 - 3**).

21.12.5 Filter Configuration

FCFGC_x (x = 0 - 3)

Filter Configuration Register x, Main CIC Filter

$$(x * 0100_H + 0114_H)$$

Reset Value: 0000 0000_H

CGSYNCx (x = 0 - 3)

Carrier Generator Synchronization Register x

$$(x * 0100_H + 01A0_H)$$

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| SDCOUNT | [7:0] | rh | Sign Delay Counter Counts the result values from the filter chain to delay the carrier sign signal |
| SDCAP | [15:8] | rh | Sign Delay Capture Value Indicates the result values counted between the begin of the positive halfwave of the carrier signal and the first received positive value. |
| SDPOS | [23:16] | rw | Sign Delay Value for Positive Halfwave Defines the content of SDCOUNT to generate a negative delayed sign signal (positive values). |
| SDNEG | [31:24] | rw | Sign Delay Value for Negative Halfwave Defines the content of SDCOUNT to generate a positive delayed sign signal (negative values). |

Delta-Sigma Demodulator (DSD)

TSTMPx (x = 0 - 3)

Time-Stamp Register x (x * 0100_H + 0150_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------|---------|------|---|
| RESULT | [15:0] | rh | Result of most recent conversion This value is copied from register RESMx (x = 0 - 3) . |
| CFMDCNT | [23:16] | rh | CIC Filter (Main Chain) Decimation Counter This value is copied from register FCFGCx (x = 0 - 3) . |
| NVALCNT | [29:24] | rh | Number of Values Counted This value is copied from register IWCTRx (x = 0 - 3) . |
| 0 | [31:30] | r | Reserved, write 0, read as 0 |

21.13 Interconnects

This section describes the actual implementation of the DSD module into the XMC4[78]00, i.e. the incorporation into the microcontroller system.

21.13.1 Product-Specific Configuration

The functional description describes the features and operating modes of the DSD in a general way. This section summarizes the configuration that is available in this product (XMC4[78]00).

Table 21-7 General Converter Configuration in the XMC4[78]00

| Channel | Digital Inputs | Notes |
|---------|----------------|-------|
| 0 | 4 | |
| 1 | 4 | |

Delta-Sigma Demodulator (DSD)

| 3 | 4 | |

21.13.2 Digital Module Connections in the XMC4[78]00

The DSD module accepts a number of digital input signals and generates a number of output signals. This section summarizes the connection of these signals to other on-chip modules or to external resources via port pins.

Note: The exact port connections (pins) are listed in the ports chapter.

Table 21-8 Digital Connections in the XMC4[78]00

22 Digital to Analog Converter (DAC)

This chapter describes the two Digital to Analog Converter (DAC) channels available in the module.

22.1 Overview

The module consists of two separate 12-bit digital to analog converters (DACs). It converts two digital input signals into two analog voltage signal outputs at a maximum conversion rate of 5 MHz. The available design structure is based on a current steering architecture with internal reference generation and provides buffered voltage outputs. In order to reduce power consumption during inactive periods, a power down mode is available.

A built-in wave generator mode allows the CPU free generation of a selectable choice of wave forms. Alternatively values can be feed via CPU or DMA directly to one or both DAC channels. Additionally an offset can be added and the amplitude can be scaled. Several time trigger sources are possible.

22.1.1 Features

Analog features

- DAC resolution 12 bit;
- Conversion rate up to 5 MHz with reduced accuracy;
- Conversion rate up to 2 MHz at full accuracy;
- Maximum settling time of 2 μ s for a full scale 12-bit input code transition;
- Buffered voltage output;
- Direct drive of 5 k Ω / 50 pF terminated load;
- Segmented current steering architecture;
- Low glitch energy;
- Power down mode;
- DAC output and ADC input share the same analog input pin. ADC measurement is possible in parallel to DAC usage.
- V_{DDA} analog supply;

Digital features

- One Advanced Microcontroller Bus Architecture (AMBA) 32-bit AHB-Lite bus interface for data transfer and control of both DACs;
- Self triggered Direct Memory Access (DMA) handling capability with independent or simultaneous data handling for the two DAC channels (see [Section 22.2.4](#));
- First In First Out (FIFO) data buffers to allow a longer service request latency and to guarantee a continuous data transfer to the DACs (see [Section 22.2.4](#));

Digital to Analog Converter (DAC)

- Pattern generators available with freely programmable waveforms for both DACs (see [Section 22.2.5](#));
- Independent noise generators available for both DACs (see [Section 22.2.6](#));
- Data scaling by shift operation (multiplication and division by 2, 4, 8,..., 128) of the DACs' input data;
- Data offset value addition to the DACs input data;
- 8 selectable external trigger inputs;
- Internal integer clock divider for DAC trigger generation;
- Software trigger option;
- V_{DDC} digital supply;

22.1.2 Block Diagram

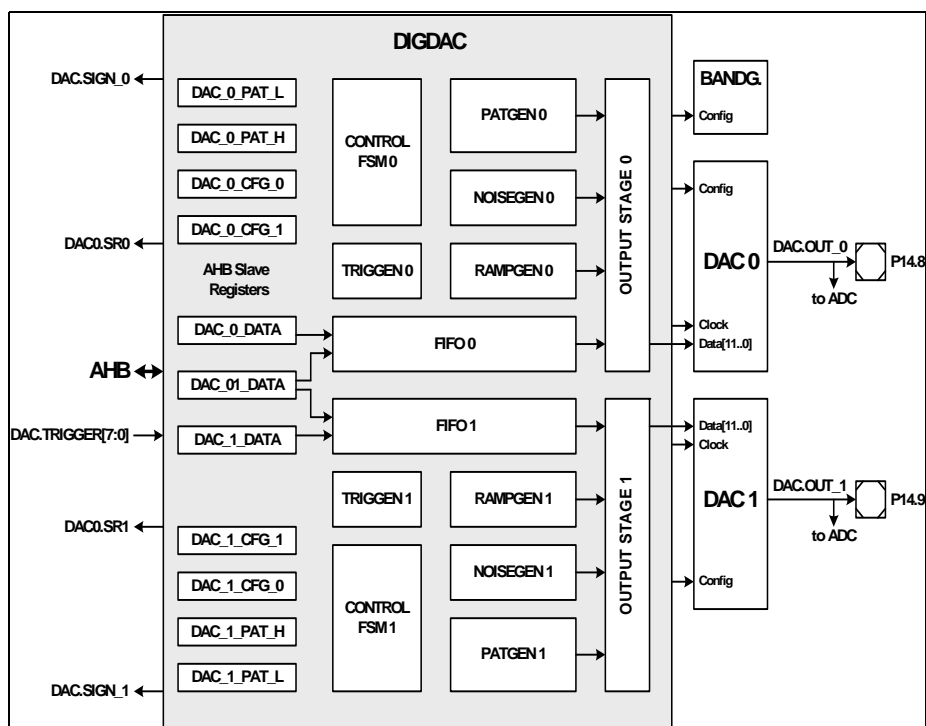

Figure 22-1 Block Diagram of DAC Module including Digdac Submodule

22.2 Operating Modes

The following chapters describe all the DAC's functional operating modes and how to use them. All used configuration parameters in this chapter are part of the registers described in [Section 22.6](#).

22.2.1 Hardware features

To facilitate the understanding of the different operating modes, a brief description of the supporting hardware features is given here:

Control and Data Registers

All control and data registers shown on the left hand side of [Figure 22-1](#) are described in [Section 22.6](#) in detail. They are connected to the AHB-Lite bus via an AHB-Lite slave interface. The interface also handles the necessary error response generation without introducing any latency.

Control Logic - Finite State Machines (FSM)

The two control finite state machines control all data processing modes of the DAC (see [Figure 22-1](#)). This means that they are responsible for the start and stop operating sequence, the service request generation for DMA handling for the so called data-mode and the control of the data FIFOs, the pattern generators, the noise generators and the ramp generators. Both FSMs are equivalent in structure and both are able to operate fully independent for the two DAC channels. For the simultaneous data-mode both FSMs are active, but only the service request signal of channel 0 (DAC0.Service Request(SR)0) should be evaluated by the DMA controller. Of course in that simultaneous data-mode the trigger source has to be the same for both channels.

22.2.1.1 Trigger Generators (TG)

The block diagram in [Figure 22-2](#) shows one of the two DAC's trigger generators.

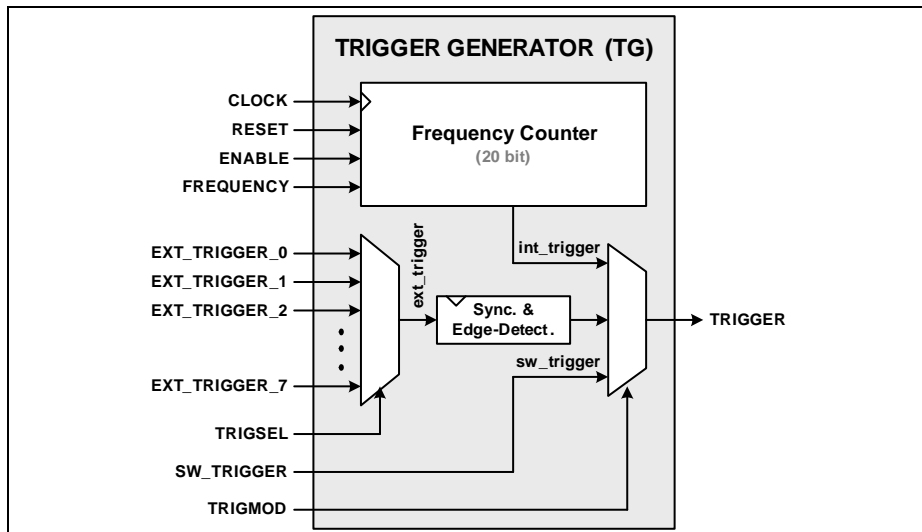

Figure 22-2 Trigger Generator Block Diagram

The TG consists of two multiplexers and one frequency counter. The first multiplexer selects between one of the eight external trigger sources whereas the second one enables switching between this selected external trigger source, an internally generated trigger and an additional software trigger input. The internal trigger is generated by the frequency counter which operates as a simple integer clock divider. So the internal trigger period can only be a multiple of the DACs system clock period. In order to guarantee correct operation of the analog part of the DAC the smallest frequency divider value is limited to 16 by hardware.

The external trigger inputs are synchronized to the system clock and only the rising edge is evaluated by the TG.

The software trigger input is connected to a register bit which is automatically cleared after it has been set to one. For this reason the output trigger of the TG is always a pulse with a pulse width of one system clock cycle for all three trigger possible modes.

22.2.1.2 Data FIFO buffer (FIFO)

The block diagram in [Figure 22-3](#) shows one of the two data FIFO buffers, one for each DAC.

Figure 22-3 Data FIFO Block Diagram

This data FIFO buffer with four FIFO registers is introduced to allow a longer service request latency and to guarantee a continuous data processing for the DAC channels. It is used for DAC's so called data processing mode described in [Section 22.2.4](#). All FIFO's read and write operations are controlled by the corresponding Control FSM. A read operation is triggered by the chosen trigger and a write operation is initiated by an Advanced High-performance Bus (AHB) write operation to the currently used data register. The FIFO's status outputs named full, empty and index can be read by the software. A FIFO bypass used for all other DACs operating modes is also available.

22.2.1.3 Data output stage

The block diagram in [Figure 22-4](#) shows one of the two DACs' data output stages.

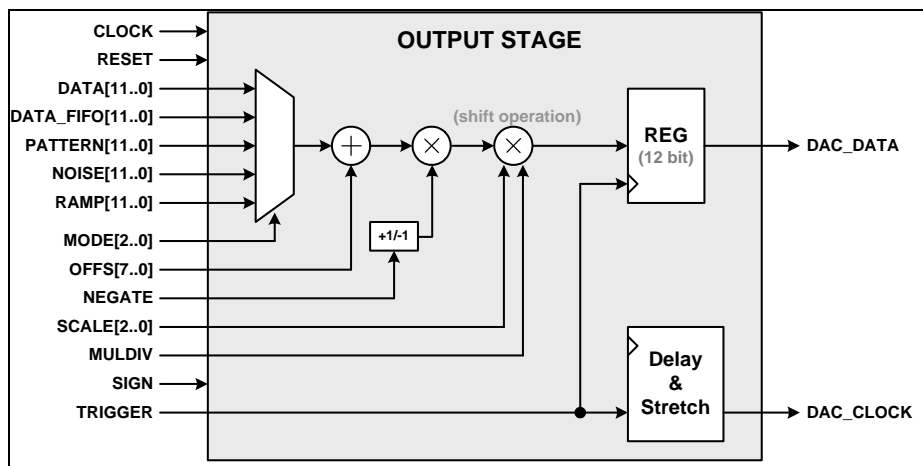

Figure 22-4 Data Output Stage Block Diagram

Digital to Analog Converter (DAC)

This output stage is the last element in the DAC's data path before the data is converted to the analog. It consists of a multiplexer, an adder, a multiplier, an output register and the generation of the DAC clock output.

The multiplexer selects between the five possible data sources and is programmed with the mode parameter. The adder stage gives the possibility to add an 8-bit offset value which is mainly needed for the PG mode in order to also process unsigned signal patterns to the DACs. In that case a certain offset value can be added to the signed output pattern values. The multiplier enables scaling by simple binary shifting of the data values. Therefore it allows multiplication and division by a programmed 2^n scale value. Additionally the output value can be negated, i.e. converted to its two's complement value. These operations are possible in all functional operating modes. The output register contains the final sample delivered together with the corresponding trigger to the analog converter.

The clock output for operating the analog part of the DAC is generated using the DAC's trigger generator (TG). For that purpose the TG's trigger output is delayed by four system clock periods and stretched to a high-length of eight system clock periods.

22.2.1.4 Pattern Generators (PG) - Waveform Generator

The block diagram in [Figure 22-5](#) shows one of the two DAC's pattern generators.

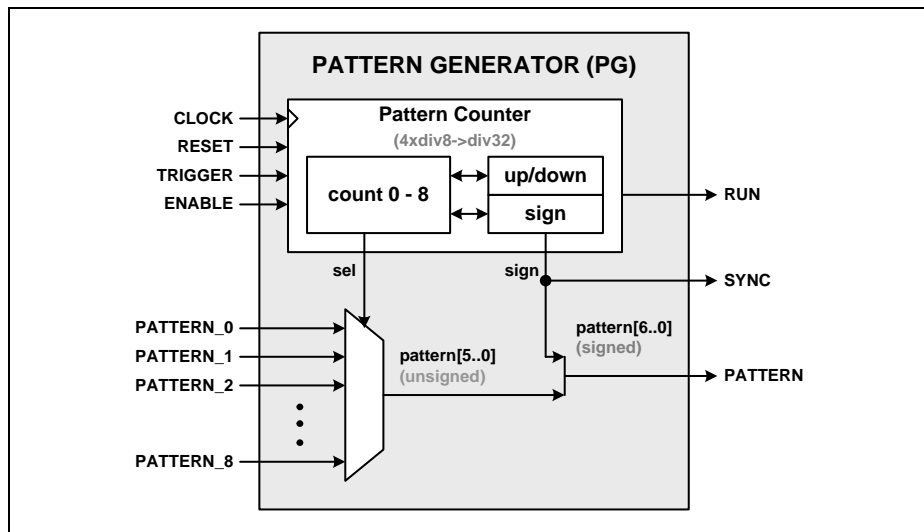

Figure 22-5 Pattern Generator Block Diagram

The nine pattern inputs on the left side of the PG block diagram are directly connected to the pattern registers described in [Section 22.6.3.4](#). The pattern registers contain only

Digital to Analog Converter (DAC)

one quarter of the actual programmed periodic pattern. The output of the pattern counter in the PG is used to select one of the nine input patterns. This pattern counter is an up-down counter with an additional sign output which is inverted every time the counter reaches zero. Since the sign information is concatenated with the currently selected pattern, it is possible to generate a complete pattern sequence for a full period of any $2^* \pi$ periodic waveform. For a detailed description how to operate the pattern generator please also refer to [Section 22.2.5](#).

22.2.1.5 Noise Generators (NG) - Pseudo Random Number Generator

The block diagram in [Figure 22-6](#) shows one of the two DAC's noise generators.

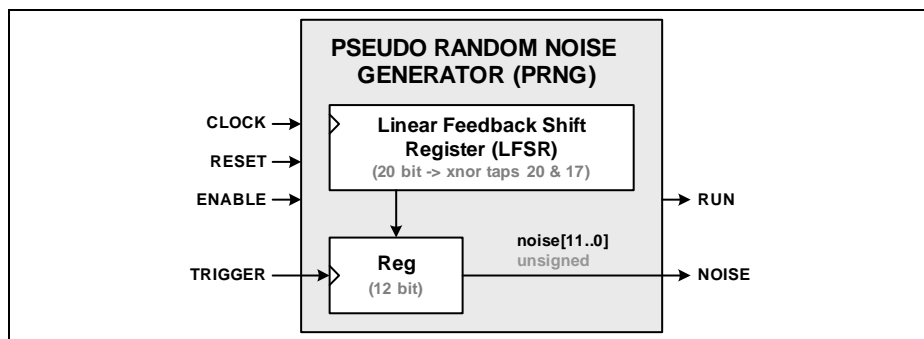

Figure 22-6 Noise Generator Block Diagram

The NG outputs a 12-bit pseudo random number. A 20-bit LFSR (linear feedback shift register) operating at the system clock frequency and a sample output register which is triggered by the NG's trigger inputs are used for this purpose. After enabling the NG, the LFSR is set back to its reset value and therefore it always starts outputting the same pseudo random number sequence.

22.2.1.6 Ramp Generators (RG)

The block diagram in [Figure 22-7](#) shows one of the two DAC's ramp generators.

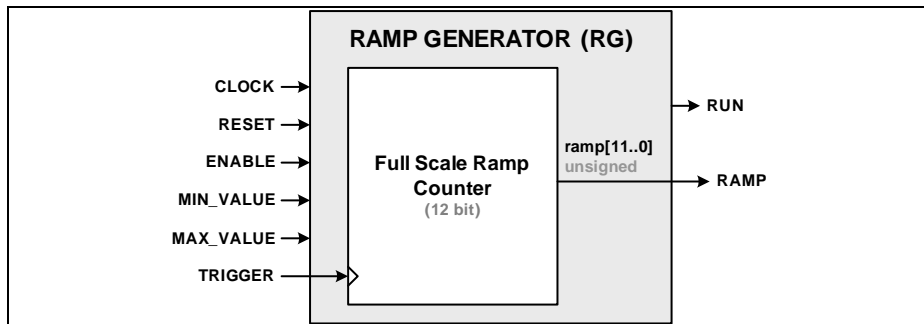

Figure 22-7 Ramp Generator Block Diagram

The ramp generator is basically an 12-bit up counter representing the full DAC range. If the RG is enabled it always starts at the programmed minimum value. The up-counting by ones is triggered by the selected trigger of the DAC channel. If the ramp counter reaches the programmed maximum value it restarts from the minimum value. This allows the generation of ramps within any desired value range and by variation of the trigger frequency also the ramp's slope can be modified.

22.2.2 Entering any Operating Mode

Before entering the desired operating mode with the **MODE** parameter, the corresponding analog DAC channel should be enabled with **ANAEN** and the startup time of the analog DAC channel should be considered.

Setting the **DATMOD** parameter to one enables simultaneous data processing. This means that both DAC channels use the same trigger source and both channels are always started and stopped synchronously. Hence the parameter setting of **MODE**, **TRIGMOD**, **TRIGSEL** and **FREQ** for DAC channel 0 is used for DAC channel 1 also.

22.2.3 Single Value Mode

By setting **MODE** to "single value mode", it is possible to convert only one single data value by the DACs. To start a conversion, a data value can be written to either **DATA0** or **DATA1** in **DAC0DATA** or **DAC1DATA** registers. This write operation itself then initiates a single trigger pulse and the value gets processed by DAC0 or DAC1. Only for this mode, no further external, internal or software trigger pulse is necessary. The DAC holds the processed value until a new value is written to **DATA0** or **DATA1**. This operating mode is intended for outputting static DAC output values. For processing sequential data streams in this "self triggered", single value mode, it is important not to exceed the maximum DAC data rate. If the **DATMOD** parameter is set to zero, data from the independent data registers **DAC0DATA** or **DAC1DATA** is processed. Whereas if

Digital to Analog Converter (DAC)

DATMOD is set to one, data from the simultaneous data register **DAC01DATA** is processed for both DACs.

22.2.4 Data Processing Mode

This operating mode is intended for continuous data processing from the system memory to DAC0 and/or DAC1. To enable it, the **MODE** parameter has to be set to data mode. Also, the desired trigger source has to be selected by setting **TRIGMOD**, **TRIGSEL** and **FREQ** in the configuration registers. The DAC can operate either with an internal generated trigger, one of the eight external trigger sources (see [Figure 22-2](#)) or the software trigger bit **SWTRIG**.

Simultaneous and independent Data Modes

With the **DATMOD** parameter, either the simultaneous or the independent “data mode” can be selected. In the simultaneous mode, both DACs receive their data from the same register **DAC01DATA**. In the independent “data mode” DAC0 gets its data from **DAC0DATA** and DAC1 from **DAC1DATA**. The two data paths are shown in [Figure 22-8](#) and also in [Figure 22-3](#). Both DAC channels can activate a service request output signal to trigger a DMA channel, if they are configured in this mode and if the corresponding **SREN** bit is set to one. The service requests are DAC0.SR0 for the DAC0 channel and DAC0.SR1 for the DAC1 channel. For the simultaneous mode either DAC0.SR0 or DAC0.SR1 can be used by the DMA controller.

Start-Stop Operation

Before the DAC is started in “data mode”, all configuration registers **DACx_CFG_x** should be set according to the desired processing mode (see [Section 22.6.3.2](#)). Once this has been done, the DAC can be started by setting the **MODE** parameter to “data mode”. The control FSM will then start its operation until it reaches the run status indicated by the read parameter **RUN**. The run state can be left either by an operation error or by setting the **MODE** parameter to “disable DAC” again. An operation error can be a FIFO overflow or a FIFO underflow (see [Figure 22-3](#) and [Figure 22-8](#)).

22.2.4.1 FIFO Data Handling

[Figure 22-8](#) shows the data handling for the FIFO of the DAC0 channel. Certainly the same structure also exists for the DAC1 channel (see [Figure 22-1](#) and [Figure 22-3](#) also). The data word **DATA0** from either data register **DAC0DATA** or **DAC01DATA** on the left hand side in [Figure 22-8](#) is loaded into one of the FIFO buffers registers. The load position in the FIFO depends on its actual filling level represented by the read parameters **FIFOIND**, **FIFOEMP** and **FIFOFUL**. If the FIFO is empty, **FIFOIND** = 0. If it is full, **FIFOIND** = 3. If a trigger occurs and the FIFO is not empty, the data is shifted to the next register (from left to right). At the same time, a service request (DAC0.SR0 or DAC0.SR1) is initiated in order to fill up the FIFO again. The service request should end

Digital to Analog Converter (DAC)

with a write operation to **DAC0DATA** or **DAC01DATA**. This write operation itself then triggers a write from the data registers to the FIFO buffer registers. If the FIFO stores only one last element (**FIFOIND** = 0 and **FIFOEMP** = 0) and a trigger has occurred, a service request is initiated and additionally **FIFOEMP** is set to 1. On the other hand, if there is only one last free register in the FIFO (**FIFOIND** = 2) and a write operation has been initiated, the **FIFOFUL** bit is set to 1. All the control signals for the FIFO handling are generated by the DAC's control FSM. This includes filling up the FIFO when "data mode" is entered and emptying the FIFO when leaving "data mode".

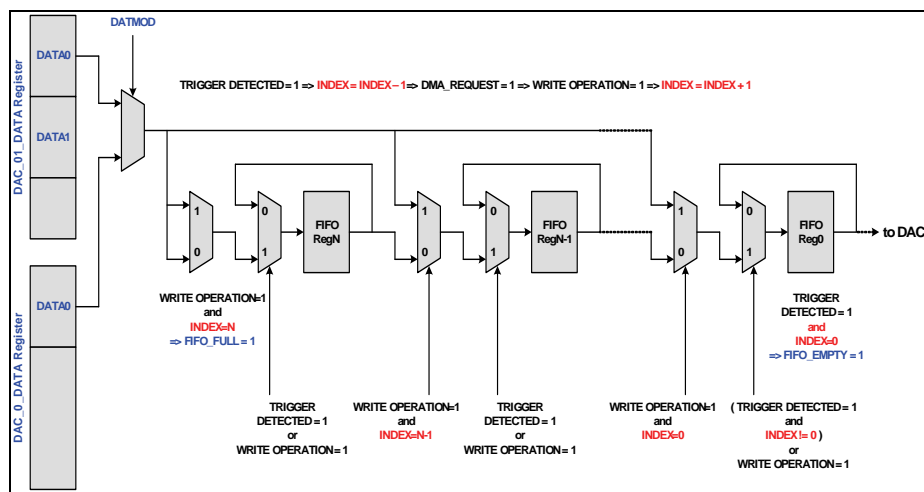

Figure 22-8 Data Handling for the FIFO Buffer

22.2.5 Pattern Generation Mode

This chapter describes the operation of the pattern generator. This mode is used to output a pattern or waveform to the DACs and it is activated by setting the **MODE** configuration parameter to "patgen mode".

Like in the "data mode" (see [Section 22.2.4](#)), the DAC in "patgen mode" can operate either with an internally generated trigger, one of the eight external trigger sources or a software trigger bit.

The desired pattern or waveform is freely programmable with the 5-bit parameters **PAT0** to **PAT8**. The pattern registers contain only one quadrant of the full waveform. The other quadrants of the 2π periodic odd function are generated out of the first one with the help of a counter. The counter generates also the sign bit of the output pattern, therefore the 6-bit output signed values are in the range of -31 to +31.

In order to use the full range of the DAC in signed mode, a scaling by 32 by setting **SCALE** to "101" in the output stage is necessary. If the DAC should output a full range

Digital to Analog Converter (DAC)

pattern in unsigned mode, it is also possible to add an offset value programmed with **OFFS** to the output stage before doing the scaling. All the control signals for the pattern generators are generated by the DAC's control FSM.

Figure 22-9 Example 5-bit Patterns and their corresponding Waveform Output

Figure 22-9 gives examples of lookup table entries for triangular, sine and rectangular pattern. These values can be programmed to **PAT0** to **PAT8** in order to get the corresponding waveforms at the DAC's output like shown in the chart on the right hand side. If the pattern generation is restarted / enabled again, it always starts with the first value of the first quarter of the actual programmed pattern (positive value and up-counting). The current sign information of the generated pattern is one of the DAC's system on chip outputs (see [Section 22.7.2.3](#)) and can be enabled using the parameter **SIGNEN**.

22.2.6 Noise Generation Mode

A 20-bit linear feedback shift register (LFSR) is used to produce a pseudo random number. In order to enable the noise generator, the **MODE** parameter has to be set to "noise mode". The LFSR itself runs with the system clock. The 12-bit random numbers is sampled with the preselected trigger source using **TRIGMOD**, **TRIGSEL** and optionally also **FREQ** or **SWTRIG** into an output register. The 12-bit values can be interpreted as signed or unsigned values. By setting the **MODE** parameter to "disable DAC" again, the noise generation stops and the DAC holds its last processed value. **Figure 22-10** shows an example pseudo random noise output. After restarting the noise generation mode, the LFSR is set back to its reset value and therefore it always starts outputting the same pseudo random number sequence.

Figure 22-10 Signed 12-bit pseudo random Noise Example Output

22.2.7 Ramp Generation Mode

A 12-bit ramp counter is also part of the DAC. It is activated by setting the **MODE** parameter to "ramp mode". The trigger source can be selected using **TRIGMOD**, **TRIGSEL** and optionally also **FREQ** or **SWTRIG**. The ramp counter starts at a programmed start value and each trigger pulse increments the counter by one. The start values are programmable via **DATA0** for DAC channel 0 and **DATA1** for DAC channel 1 of the independent data registers. The stop values are programmable via **DATA0** or **DATA1** of the simultaneous data register. If the ramp counter reaches its stop value, it restarts from the start value with the next trigger pulse. This allows the generation of ramps within any desired value range. The ramp's slope can be modified by varying the trigger frequency. **Figure 22-11** shows two examples of ramp generation output waveforms.

Figure 22-11 Unsigned 12-bit Ramp Generator Example Output

22.3 Service Request Generation

Service Requests are available in **Data Processing Mode** only.

22.4 Power, Reset and Clock

As long as **ANAEN** is set to default value “standby”, the corresponding DAC channel stays in power down mode, and its output is floating.

By setting **ANAEN** to “enable DAC”, the analog output is starting up; the max. possible startup time (t_{STARTUP}) is specified in the Data Sheet. Note, that in case the output is triggered before the startup time expired, the programmed value is not passed to the output driver. The DAC output will then continue to drive the default value, till the first trigger event after elapsing the startup time. ¹⁾

The DAC module reset is shared with the peripheral bus reset line, as well as the module clock is shared with the peripheral bus clock line.

With **FREQ** the clock divider ratio of the internal trigger generator is set.

22.5 Initialization

A feasible initialization sequence of the DAC reads as follows:

1st Step: De-assert the reset of DAC module by setting DACRS bit in PRCLR1 register and disable gating by setting DAC bit in CGATCLR1 register.

2nd Step: Write the DACxCFG0 register values. Here you select the operating mode of the corresponding DAC channel by writing the **MODE** field, e.g. Patgen mode. By setting or clearing the **SIGN** bit, the choice between signed and unsigned input data format is made.

In the same step service request generation can be enabled with the **SREN** bit, as well as sign output with **SIGNEN** bit. Also the frequency divider of the internal trigger generator can be set up by writing the **FREQ** field.

3rd Step: Write the DACxCFG1 register values. Here you select the trigger source by writing the **TRIGMOD** field, e.g. software trigger. The DAC channel output is enabled by setting the **ANAEN** bit. You also need to choose now your values for **SCALE**, **MULDIV**, **OFFS**, and **DATMOD** fields.

4th Step: Configure the chosen data source. E.g. in case you selected Patgen mode, the pattern must be defined by programming DACxPATL and DACxPATH registers.

5th Step: E.g. in case software trigger is selected, the runtime code is responsible for generating the trigger signals by setting **SWTRIG** bit inside DACxCFG1 register. In this case, please mind the startup time (t_{STARTUP}) after setting **ANAEN** bit (see also [Section 22.4](#)).

C code example

The C code of this example is given below:

1) Please note, that the RUN status bit is set by hardware, before the startup time has expired.

Digital to Analog Converter (DAC)

```

void DAC_init()
{
//RESET MODULE
    SCU_RESET->PRCLR1 |= 0x00000020; //De-asserts reset for
VADC module
    SCU_CLK->CGATCLR1 |= SCU_CLK_CGATCLR1_DAC_Msk; //Disable
Gating
//DAC0 CONFIGURATION AS PATTERN GENERATOR
    DAC->DAC0CFG0=0x20300FFF;           //Pattern gen enable,
Signal enabled and Frequency
    DAC->DAC0CFG1=0x010405FD;           //Enable AN, Software
trigger
                                           // Offset and
Scale divider set up.

    DAC->DAC0PATL=0x3568B0C0;           //Sinus waveform
configuration
    DAC->DAC0PATH=0x00007FDD;           //Sinus waveform
configuration
    //For triangle waveform use:
    //DAC->DAC0PATL=0x27062080;         //Triangle waveform
configuration
    //DAC->DAC0PATH=0x00007F77;         //Triangle waveform
configuration

//DAC1 CONFIGURATION AS RAMP GENERATOR
    DAC->DAC1CFG0=0x20500000;           //Ramp Mode, Signal enabled
and Frequency
    DAC->DAC1CFG1=0x01000000;           //Enable AN. No offset or
scaling. Internal Trigger

    DAC->DAC1DATA=0x00000003F;         //Start value
    DAC->DAC01DATA=0x0AFF0000;         //Stop value
}

-----
//For SW trigger in runtime code (after waiting startup time):

    DAC->DAC0CFG1|=0x00010000;         //Software Trigger of DAC0

```

22.6 Registers

22.6.1 Address Map

The DAC is available at the following base address:

Table 22-1 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|-------|
| DAC | 4801 8000 _H | 4801 BFFF _H | 16 kB |

22.6.2 Register Overview

Table 22-2 shows all registers required for the operation of the DAC module:

Table 22-2 Register Overview of DAC

| Short Name | Description | Offset Addr. ¹⁾ | Access Mode | | Description See |

22.6.3 Register Description

22.6.3.1 DAC_ID Register

The DAC module identification register contains the XMC4000 ID code.

DAC_ID

Module Identification Register (000_H) **Reset Value: 00A5 C0XX_H**

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| MODR | [7:0] | r | Module Revision MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first rev.). |
| MODT | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |

Digital to Analog Converter (DAC)

| Field | Bits | Type | Description |
|----------------|------|------|--|
| FIFOEMP | 26 | rh | Indicate if the FIFO is empty 0 _B FIFO not empty 1 _B FIFO empty |
| FIFOFUL | 27 | rh | Indicate if the FIFO is full 0 _B FIFO not full 1 _B FIFO full |
| NEGATE | 28 | rw | Negates the DAC0 output 0 _B DAC output not negated 1 _B DAC output negated Negation means the DAC value is converted to its two's complement value. |
| SIGNEN | 29 | rw | Enable Sign Output of DAC0 Pattern Generator 0 _B Disable 1 _B Enable |
| SREN | 30 | rw | Enable DAC0 service request interrupt generation 0 _B disable 1 _B enable |
| RUN | 31 | rh | RUN indicates the current DAC0 operation status 0 _B DAC0 channel disabled 1 _B DAC0 channel in operation RUN is set/cleared by hardware. |

| SCALE | [2:0] | rw | Scale value for up- or downscale of the DAC1 input data in steps by the power of 2 (=shift operation) 000 _B no shift = multiplication/division by 1 001 _B shift by 1 = multiplication/division by 2 010 _B shift by 2 = multiplication/division by 4 011 _B shift left by 3 = multiplication/division by 8 100 _B shift left by 4 = multiplication/division by 16 101 _B shift left by 5 = multiplication/division by 32 110 _B shift left by 6 = multiplication/division by 64 111 _B shift left by 7 = multiplication/division by 128 |

Digital to Analog Converter (DAC)

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| MULDIV | 3 | rw | Switch between up- and downscale of the DAC1 input data values 0 _B downscale = division (shift SCALE positions to the right) 1 _B upscale = multiplication (shift SCALE positions to the left) |
| OFFS | [11:4] | rw | 8-bit offset value addition e.g.: PATGEN output is a sine wave -31 to +31 and OFFS = 31 => the DAC1 input data will be a sine wave with an amplitude between 0 and 62. Depending on the SIGN bit this value is interpreted as signed or unsigned. |
| TRIGSEL | [14:12] | rw | Selects one of the eight external trigger sources for DAC1 TRIGSEL for DAC1 is not applicable if DATMOD is set to 1 = simultaneous data mode. |
| 0 | 15 | r | Reserved Read as 0; Should be written with 0. |
| SWTRIG | 16 | rwh | Software Trigger Triggers DAC channel 1 if TRIGMOD is set to 10. Setting the bit to 1 generates one trigger pulse. The bit is cleared (set to 0) automatically. If DATMOD is set to simultaneous data mode (see DATMOD parameter) this bit is not applicable and the SWTRIG bit from channel 0 is used for channel 1 also. |
| TRIGMOD | [18:17] | rw | Select the trigger source for channel 1 00 _B internal Trigger (integer divided clock - see FREQ parameter) 01 _B external Trigger (preselected trigger by TRIGSEL parameter) 10 _B software Trigger (see SWTRIG parameter) 11 _B reserved |
| ANACFG | [23:19] | rw | DAC1 analog configuration/calibration parameters reserved for future use |
| ANAEN | 24 | rw | Enable analog DAC for channel 1 0 _B DAC1 is set to standby (analog output only) 1 _B enable DAC1 (analog output only) |

Digital to Analog Converter (DAC)

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| 0 | [27:25] | r | Reserved Read as 0; Should be written with 0. |
| REFCFGH | [31:28] | rw | Higher 4 band-gap configuration/calibration parameters reserved for future use |

22.6.3.3 DAC Data Registers

The DAC data registers contain the data provided to DAC0 and DAC1 either in simultaneous data mode (DAC01DATA) or in independent data mode (DAC0DATA and DAC1DATA).

DAC0DATA

DAC0 Data Register

(014_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| DATA0 | [11:0] | rw | DAC0 Data Bits Used as DAC0 data value and as counter start value in ramp generation mode |
| 0 | [31:12] | r | Reserved Read as 0; Should be written with 0. |

22.7 Interconnects

22.7.1 Analog Connections

The analog interface lines of the DAC are listed below:

Table 22-3 Analog Connections

| Input/Output | I/O | Connected To | Descriptions |
|--------------|-----|--------------|----------------------------|
| DAC.OUT_0 | O | P14.8 | Analog output of channel 0 |
| DAC.OUT_1 | O | P14.9 | Analog output of channel 1 |

22.7.2 Digital Connections

The DAC has the following system level connections to other modules:

22.7.2.1 Service Request Connections

Two service requests DAC.SR0 and DAC.SR1 are used for simultaneous and independent data mode. DAC.SR1 can be enabled on DMA channel 2 and DAC.SR0 can be enabled on DMA channel 3.

Table 22-4 Service Request Connections

| Input/Output | I/O | Connected To | Descriptions |
|--------------|-----|---------------|-----------------|
| DAC.SR0 | O | NVIC GPDMA | Service request |
| DAC.SR1 | O | NVIC GPDMA | Service request |

22.7.2.2 Trigger Connections

The eight trigger inputs are connected to the following sources:

Table 22-5 Trigger Connections

| Input/Output | I/O | Connected To | Descriptions |
|----------------|-----|--------------|--------------|
| DAC.TRIGGER[0] | I | CCU80.SR1 | Trigger |
| DAC.TRIGGER[1] | I | reserved | Trigger |
| DAC.TRIGGER[2] | I | CCU40.SR1 | Trigger |
| DAC.TRIGGER[3] | I | CCU41.SR1 | Trigger |

| DAC.SIGN_1 | O | VADC.G1REQGTI VADC.G3REQGTI ERU1.2A3 | |

Industrial Control Peripherals

23 Capture/Compare Unit 4 (CCU4)

The CCU4 peripheral is a major component for systems that need general purpose timers for signal monitoring/conditioning and Pulse Width Modulation (PWM) signal generation. Power electronic control systems like switched mode power supplies or uninterruptible power supplies, can easily be implemented with the functions inside the CCU4 peripheral.

The internal modularity of CCU4, translates into a software friendly system for fast code development and portability between applications.

Table 23-1 Abbreviations table

| | |
|------------|---|
| PWM | Pulse Width Modulation |
| CCU4x | Capture/Compare Unit 4 module instance x |
| CC4y | Capture/Compare Unit 4 Timer Slice instance y |
| ADC | Analog to Digital Converter |
| POSIF | Position Interface peripheral |
| SCU | System Control Unit |
| f_{ccu4} | CCU4 module clock frequency |
| f_{tclk} | CC4y timer clock frequency |

Note: A small “y” or “x” letter in a register indicates an index

23.1 Overview

Each CCU4 module is comprised of four identical 16 bit Capture/Compare Timer slices, CC4y. Each timer slice can work in compare mode or in capture mode. In compare mode one compare channel is available while in capture mode, up to four capture registers can be used in parallel.

Each CCU4 module has four service request lines and each timer slice contains a dedicated output signal, enabling the generation of up to four independent PWM signals. Straightforward timer slice concatenation is also possible, enabling up to 64 bit timing operations. This offers a flexible frequency measurement, frequency multiplication and pulse width modulation scheme.

A programmable function input selector for each timer slice, that offers up to nine functions, discards the need of complete resource mapping due to input ports availability.

A built-in link between the CCU4 and several other modules enable flexible digital motor control loops implementation, e.g. with Hall Sensor monitoring or direct coupling with Encoders.

23.1.1 Features

CCU4 module features

Each CCU4 represents a combination of four timer slices, that can work independently in compare or capture mode. Each timer slice has a dedicated output for PWM signal generation.

All four CCU4 timer slices, CC4y, are identical in terms of available functions and operating modes. Avoiding this way the need of implementing different software routines, depending on which resource of CCU4 is used.

A built-in link between the four timer slices is also available, enabling this way a simplified timer concatenation and sequential operations.

General Features

- 16 bit timer cells
- capture and compare mode for each timer slice
 - four capture registers in capture mode
 - one compare channel in compare mode
- programmable low pass filter for the inputs
- built-in timer concatenation
 - 32, 48 or 64 bit width
- shadow transfer for the period and compare values
- programmable clock prescaler
- normal timer mode
- gated timer mode
- three counting schemes
 - center aligned
 - edge aligned
 - single shot
- PWM generation
- TRAP function
- start/stop can be controlled by external events
- counting external events
- four dedicated service request lines per CCU4

Additional features

- external modulation function
- load controlled by external events
- dithering PWM
- floating point pre scaler
- output state override by an external event
- suitable and flexible connectivity to several modules:
 - motor and power conversion applications
 - high number of signal conditioning possibilities

CCU4 features vs. applications

On [Table 23-2](#) a summary of the major features of the CCU4 unit mapped with the most common applications.

Table 23-2 Applications summary

| Feature | Applications |
|---|---|
| Four independent timer cells | Independent PWM generation: <ul style="list-style-type: none"> • Multiple buck/boost converter control (with independent frequencies) • Different modes of operation for each timer, increasing the resource optimization • Up to 2 Half-Bridges control • multiple Zero Voltage Switch (ZVS) converter control with easy link to the ADC channels. |
| Concatenated timer cells | Easy to configure timer extension up to 64 bit: <ul style="list-style-type: none"> • High dynamic trigger capturing • High dynamic signal measurement |
| Dithering PWM | Generating a fractional PWM frequency or duty cycle: <ul style="list-style-type: none"> • To avoid big steps on frequency or duty cycle adjustment in slow control loop applications • Increase the PWM signal resolution over time |
| Floating prescaler | Automated control signal measurement: <ul style="list-style-type: none"> • decrease SW activity for monitoring signals with high or unknown dynamics • emulating more than a 16 bit timer for system control |
| Up to 9 functions via external signals for each timer | Flexible resource optimization: <ul style="list-style-type: none"> • The complete set of external functions is always available • Several arrangements can be done inside a CCU4, e.g., one timer working in capture mode and one working in compare |

Table 23-2 Applications summary (cont'd)

| Feature | Applications |
|-----------------------------------|---|
| 4 dedicated service request lines | Specially developed for: <ul style="list-style-type: none"> • generating interrupts for the microprocessor • flexible connectivity between peripherals, e.g. ADC triggering. |
| Linking with other modules | Flexible profiles for: <ul style="list-style-type: none"> • Hall Sensor feedback/monitoring • Motor Encoders feedback/monitoring • PWM parallel modulation • Flexible signal conditioning |

23.1.2 Block Diagram

Each CCU4 timer slice can operate independently from the other slices for all the available modes. Each timer slice contains a dedicated input selector for functions linked with external events and has a dedicated compare output signal, for PWM signal generation.

The built-in timer concatenation is only possible with adjacent slices, e.g. CC40/CC41. Combinations for slice concatenations like, CC40/CC42 or CC40/CC43 are not possible.

The individual service requests for each timer slice (four per slice) are multiplexed into four module service requests lines, [Figure 23-1](#).

Capture/Compare Unit 4 (CCU4)

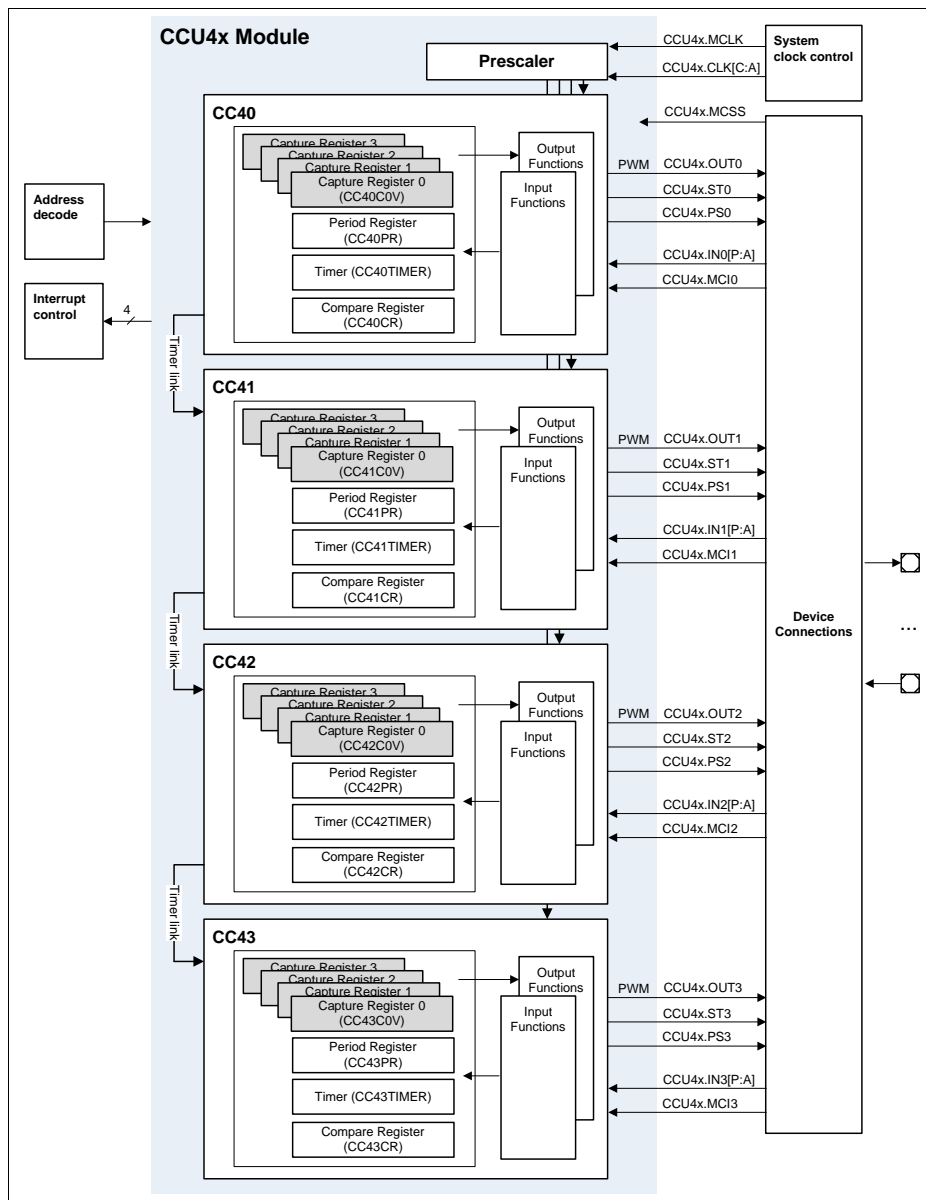

Figure 23-1 CCU4 block diagram

23.2 Functional Description

23.2.1 CC4y Overview

The input path of a CCU4 slice is comprised of a selector ([Section 23.2.2](#)) and a connection matrix unit ([Section 23.2.3](#)). The output path contains a service request control unit, a timer concatenation unit and two units that control directly the state of the output signal for each specific slice (for TRAP and modulation handling), see [Figure 23-2](#).

The timer core is built of a 16 bit counter one period and one compare register in capture mode, or up to four capture registers in capture mode.

In compare mode the period register sets the maximum counting value while the compare channel is controlling the ACTIVE/PASSIVE state of the dedicated comparison slice output.

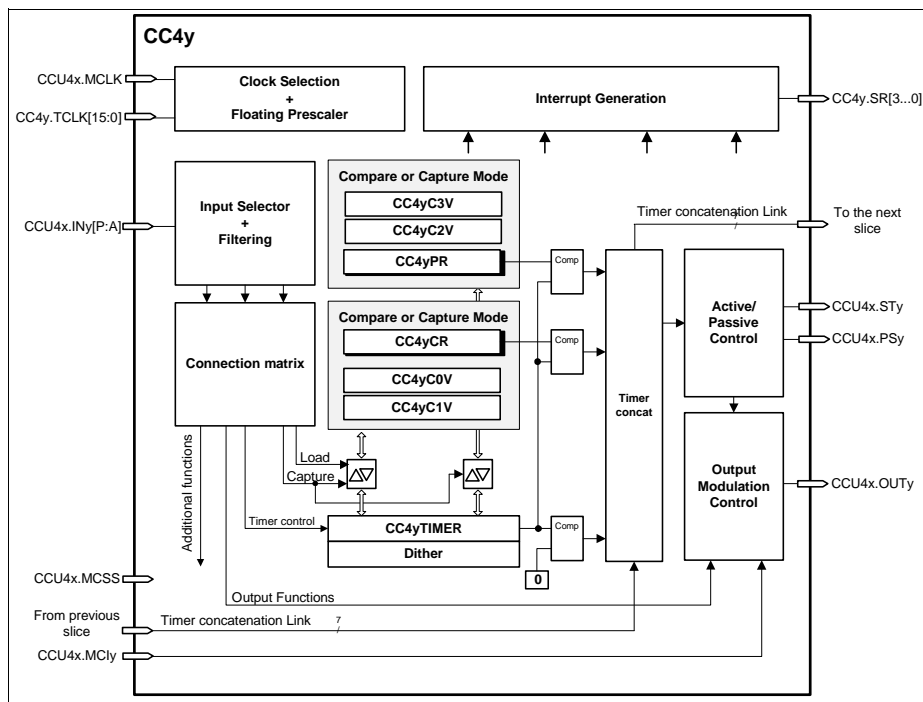

Figure 23-2 CCU4 slice block diagram

Capture/Compare Unit 4 (CCU4)

Each CCU4 slice, with the exception of the first, contains six dedicated inputs outputs that are used for the built-in timer concatenation functionality.

Inputs and outputs that are not seen at the CCU4 boundaries have a nomenclature of CC4y.<name>, whilst CCU4 module inputs and outputs are described as CCU4x.<signal_name>y (indicating the variable y the object slice).

Table 23-3 CCU4 slice pin description

| Pin | I/O | Description |
|-----------------|-----|--|
| CCU4x.MCLK | I | Module clock |
| CC4y.TCLK[15:0] | I | Clocks from the pre scaler |
| CCU4x.INy[P:A] | I | Slice functional inputs (used to control the functionality throughout slice external events) |
| CCU4x.MCIy | I | Multi Channel mode input |
| CCU4x.MCSS | I | Multi Channel shadow transfer trigger |
| CC4y.SR[3...0] | O | Slice service request lines |
| CC4x.STy | O | Slice comparison status value |
| CCU4x.PSy | O | Multi channel pattern update trigger |
| CCU4x.OUTy | O | Slice dedicated output pin |

Note:

- The status bit outputs of the Kernel, CCU4x.STy, are extended for one more kernel clock cycle.*
- The Service Request signals at the output of the kernel are extended for one more kernel clock cycle.*
- The maximum output signal frequency of the CCU4x.STy outputs is module clock divided by 4.*

The slice timer, can count up or down depending on the selected operating mode. A direction flag holds the actual counting direction.

The timer is connected to two stand alone comparators, one for the period match and one for a compare match. The registers used for period match and comparison match can be programmed to serve as capture registers enabling sequential capture capabilities on external events.

In normal edge aligned counting scheme, the counter is cleared to 0000_H each time that matches the period value defined in the period register. In center aligned mode, the counter direction changes from 'up counting' to 'down counting' after reaching the period

Capture/Compare Unit 4 (CCU4)

value. Both period and compare registers have an aggregated shadow register, which enables the update of the PWM period and duty cycle on the fly.

A single shot mode is also available, where the counter stops after it reaches the value set in the period register.

The start and stop of the counter can be controlled via software access or by a programmable input pin.

Functions like, load, counting direction (up/down), TRAP and output modulation can also be controlled with external events, see [Section 23.2.3](#).

23.2.2 Input Selector

The first unit of the slice input path, is used to select which inputs are used to control the available external functions.

Inside this block the user also has the possibility to perform a low pass filtering of the signals and selecting the active edge(s) or level of the external event, see [Figure 23-3](#).

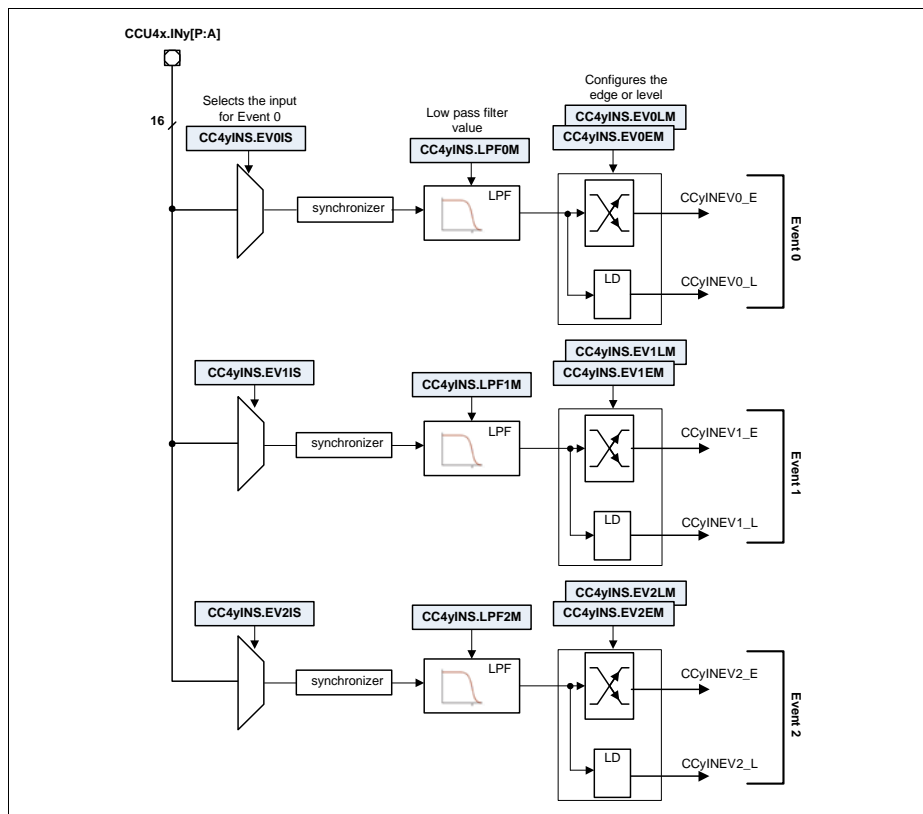

Figure 23-3 Slice input selector diagram

The user has the possibility of selecting any of the CCU4x.INy[P:A] inputs as the source of an event.

At the output of this unit we have a user selection of three events, that were configured to be active at rising, falling or both edges, or level active. These selected events can then be mapped to several functions.

Notice that each decoded event contains two outputs, one edge active and one level active, due to the fact that some functions like counting, capture or load are edge sensitive events while, timer gating or up down counting selection are level active.

23.2.3 Connection Matrix

The connection matrix maps the events coming from the input selector to several user configured functions, [Figure 23-4](#). The following functions can be enabled on the connection matrix:

Table 23-4 Connection matrix available functions

| Function | Brief description | Map to figure Figure 23-4 |
|---------------------|---|--|
| Start | Edge signal to start the timer | CCystrt |
| Stop | Edge signal to stop the timer | CCcystp |
| Count | Edge signal used for counting events | CCycnt |
| Up/down | Level signal used to select up or down counting direction | CCyupd |
| Capture 0 | Edge signal that triggers a capture into the capture registers 0 and 1 | CCycapt0 |
| Capture 1 | Edge signal that triggers a capture into the capture register 2 and 3 | CCycapt1 |
| Gate | Level signal used to gate the timer clock | CCygate |
| Load | Edge signal that loads the timer with the value present at the compare register | CCyload |
| TRAP | Level signal used for fail-safe operation | CCytrap |
| Modulation | Level signal used to modulate/clear the output | CCymod |
| Status bit override | Status bit is going to be overridden with an input value | CCyoval for the value CCyoset for the trigger |

Inside the connection matrix we also have a unit that performs the built-in timer concatenation. This concatenation enables a completely synchronized operation between the concatenated slices for timing operations and also for capture and load actions. The timer slice concatenation is done via the [CC4yCMC.TCE](#) bitfield. For a complete description of the concatenation function, please address [Section 23.2.9](#).

Capture/Compare Unit 4 (CCU4)

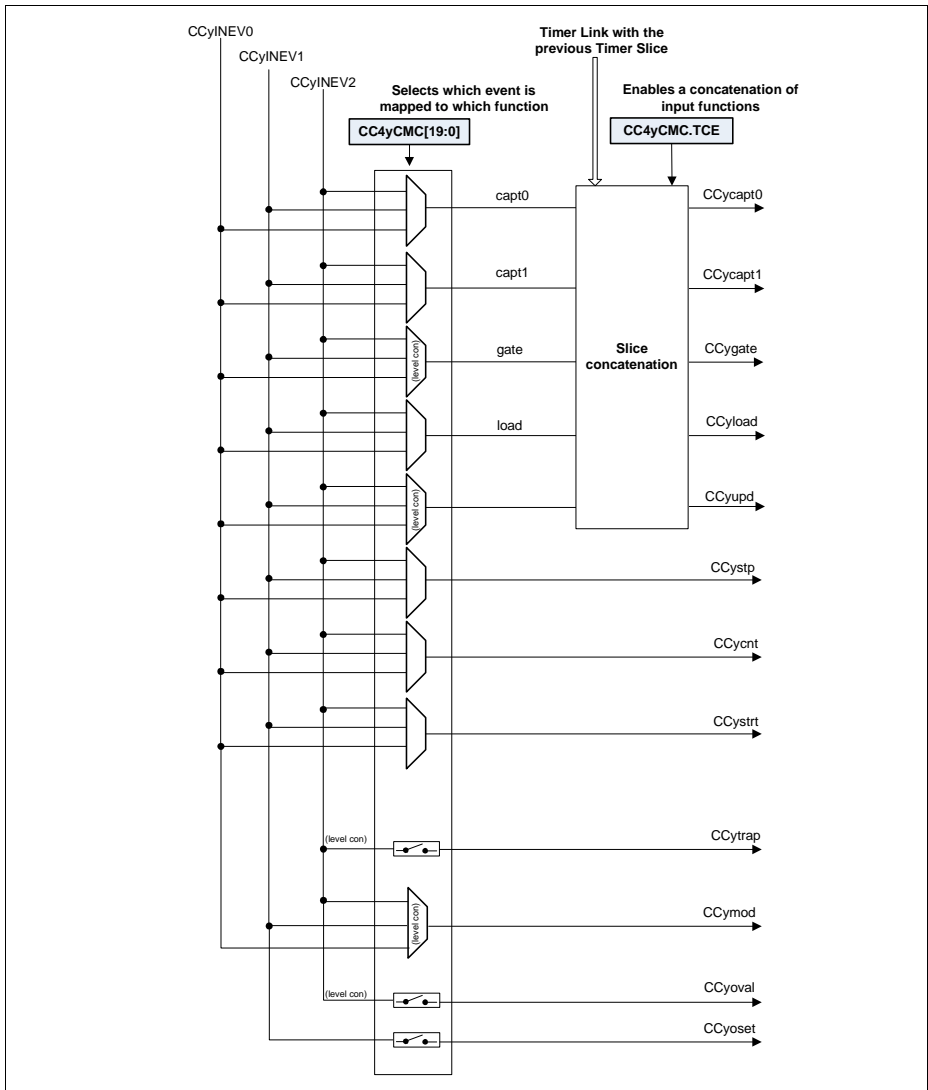

Figure 23-4 Slice connection matrix diagram

23.2.4 Starting/Stopping the Timer

Each timer slice contains a run bit register that indicates the actual status of the timer, **CC4yTCST.TRB**. The start and stop of the timer can be done via software access or can be controlled directly by external events, see [Figure 23-5](#).

Selecting an external signal that acts as a start trigger does not force the user to use an external stop trigger and vice versa.

Selecting the single shot mode, imposes that after the counter reaches the period value the run bit, **CC4yTCST.TRB**, is going to be cleared and therefore the timer is stopped.

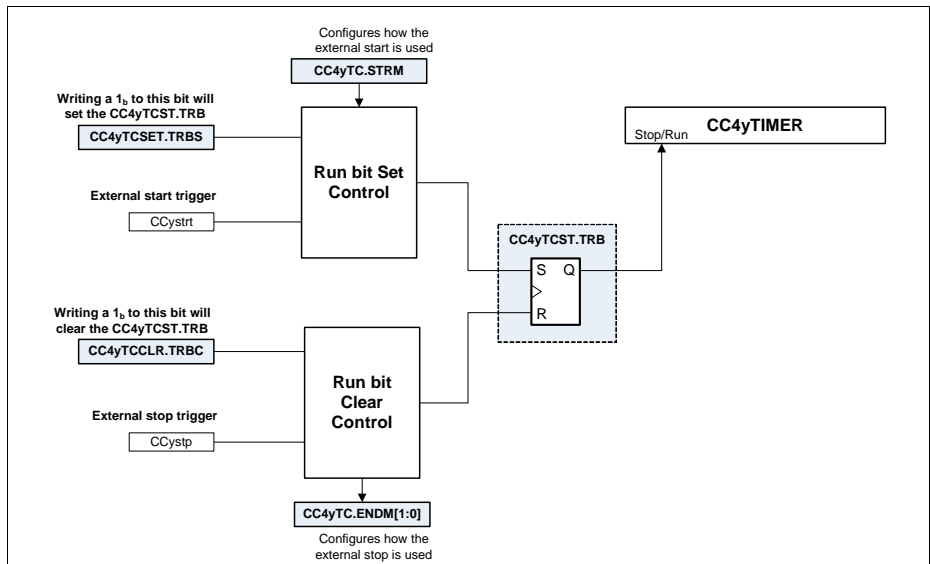

Figure 23-5 Timer start/stop control diagram

One can use the external stop signal to perform the following functions (configuration via **CC4yTC.ENDM**):

- Clear the run bit (stops the timer) - default
- Clear the timer (to 0000_H) but it does not clear the run bit (timer still running)
- Clear the timer and the run bit

One can use the external start to perform the following functions (configuration via **CC4yTC.STRM**):

- Start the timer (resume operation)
- Clear and start the timer

The set (start the timer) of the timer run bit, always has priority over a clear (stop the timer).

Capture/Compare Unit 4 (CCU4)

To start multiple CCU4 timers at the same time/synchronously one should use a dedicated input as external start (see [Section 23.2.7.1](#) for a description how to configure an input as start function). This input should be connected to all the Timers that need to be started synchronously (see [Section 23.8](#) for a complete list of module connections), [Figure 23-6](#).

For starting the timers synchronously via software there is a dedicated input signal, controlled by the SCU (System Control Unit), that is connected to all the CCU4 timers. This signal should then be configured as an external start signal (see [Section 23.2.7.1](#)) and then the software must write a 1_B/0_B (depending on the configuration of the external start signal) to the specific bitfield of the CCUCON register (this register is described on the SCU chapter).

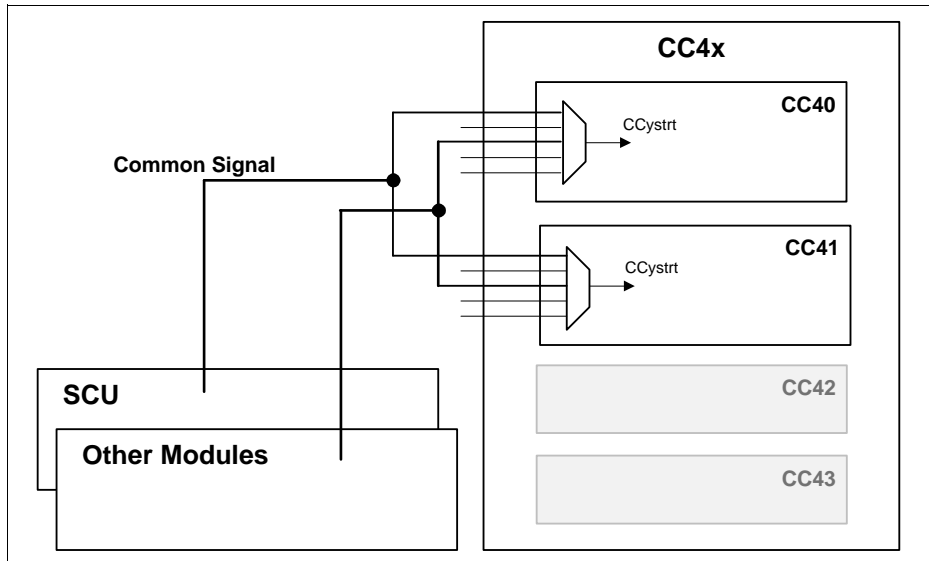

Figure 23-6 Starting multiple timers synchronously

23.2.5 Counting Modes

Each CC4y timer slice can be programmed into three different counting schemes:

- Edge aligned (default)
- Center aligned
- Single shot (can be edge or center aligned)

These three counting schemes can be used as stand alone without the need of selecting any inputs as external event sources. Nevertheless it is also possible to control the

Capture/Compare Unit 4 (CCU4)

counting operation via external events like, timer gating, counting trigger, external stop, external start, etc.

For all the counting modes, it is possible to update on the fly the values for the timer period and compare channel. This enables a cycle by cycle update of the PWM frequency and duty cycle.

The compare channel of each CC4y Timer Slice, has an associated Status Bit (**GCST.CC4yST**), that indicates the active or passive state of the channel, **Figure 23-7**. The set and clear of the status bit and the respective PWM signal generation is dictated by the timer period, compare value and the current counting mode. See the different counting mode descriptions, **Section 23.2.5.3** to **Section 23.2.5.5** to understand how this bit is set and cleared.

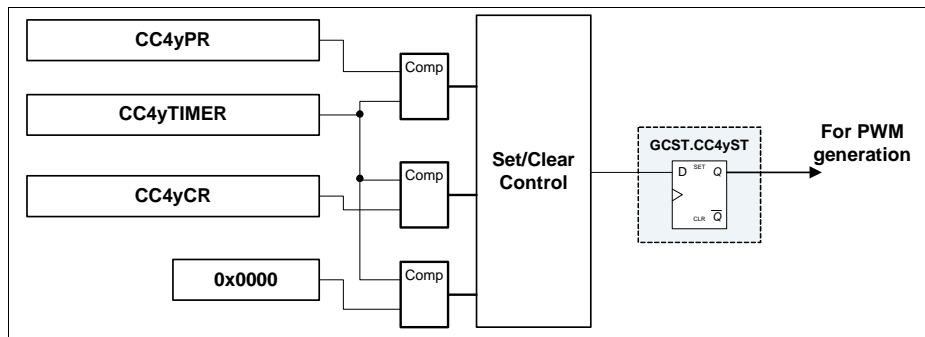

Figure 23-7 CC4y Status Bit

23.2.5.1 Calculating the PWM Period and Duty Cycle

The period of the timer is determined by the value in the period register, **CC4yPR** and by the timer mode.

The base for the PWM signal frequency and duty cycle, is always related to the clock frequency of the timer itself and not to the frequency of the module clock (due to the fact that the timer clock can be a scaled version of the module clock).

In Edge Aligned Mode, the timer period is:

$$T_{\text{per}} = \text{<Period-Value>} + 1; \text{ in } f_{\text{tclk}} \quad (23.1)$$

In Center Aligned Mode, the timer period is:

$$T_{\text{per}} = (\text{<Period-Value>} + 1) \times 2; \text{ in } f_{\text{tclk}} \quad (23.2)$$

For each of these counting schemes, the duty cycle of generated PWM signal is dictated by the value programmed into the **CC4yCR** register.

Capture/Compare Unit 4 (CCU4)

In Edge Aligned and Center Aligned Mode, the PWM duty cycle is:

$$DC = 1 - \frac{\text{Compare-Value}}{(\text{Period-Value} + 1)} \quad (23.3)$$

Both **CC4yPR** and **CC4yCR** can be updated on the fly via software, enabling a glitch free transition between different period and duty cycle values for the generated PWM signal, **Section 23.2.5.2**

23.2.5.2 Updating the Period and Duty Cycle

Each CCU4 timer slice provides an associated shadow register for the period and compare values. This facilitates a concurrent update by software for these two parameters, with the objective of modifying during run time the PWM signal period and duty cycle.

In addition to the shadow registers for the period and compare values, one also has available shadow registers for the floating prescaler and dither functions, **CC4yFPCS** and **CC4yDITS** respectively (please address **Section 23.2.11** and **Section 23.2.10** for a complete description of these functions).

The structure of the shadow registers can be seen in **Figure 23-8**.

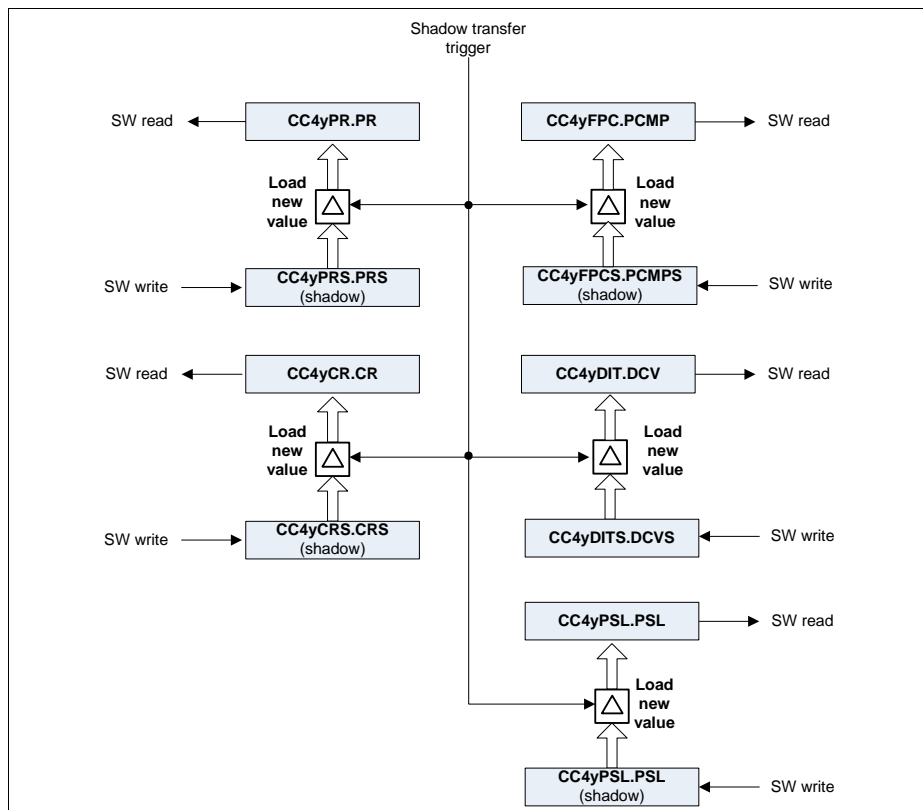

Figure 23-8 Shadow registers overview

The update of these registers can only be done by writing a new value into the associated shadow register and wait for a shadow transfer to occur.

Each group of shadow registers have an individual shadow transfer enable bit, [Figure 23-9](#). The software must set this enable bit to 1_B, whenever an update of the values is needed. These bits are automatically cleared by the hardware, whenever an update of the values is finished. Therefore every time that an update of the registers is needed the software must set again the specific bit(s).

Nevertheless it is also possible to clear the enable bit via software. This can be used in the case that an update of the values needs to be cancelled (after the enable bit has already been set).

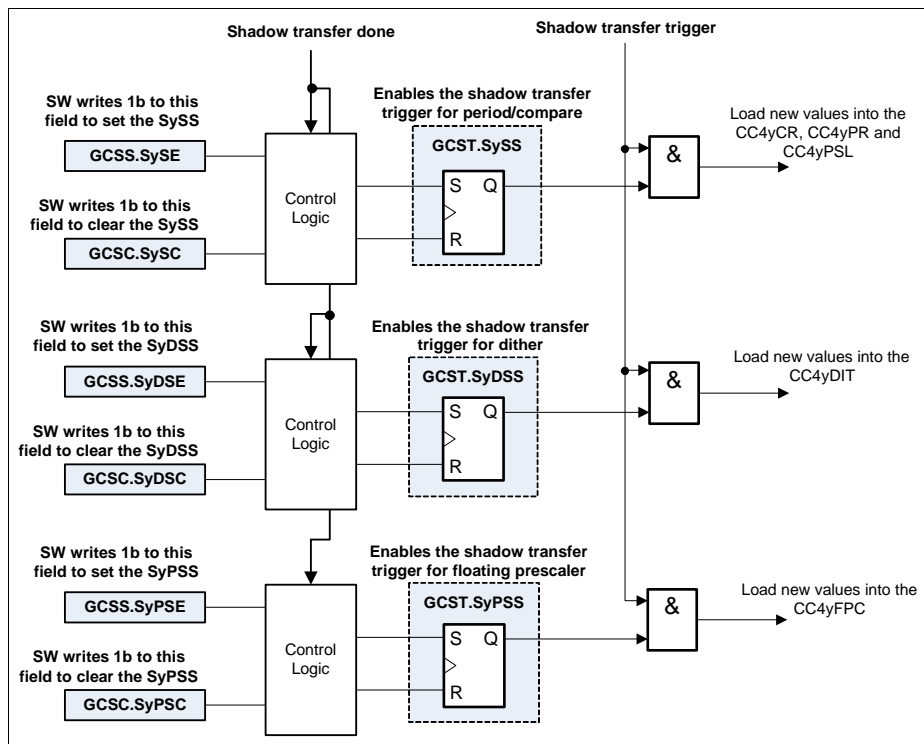

Figure 23-9 Shadow transfer enable logic

The shadow transfer operation is going to be done in the immediately next occurrence of a shadow transfer trigger, after the shadow transfer enable is set (**GCST.SySS**, **GCST.SyDSS**, **GCST.SyPSS** set to 1_B).

The occurrence of the shadow transfer trigger is imposed by the timer counting scheme (edge aligned or center aligned). Therefore the slots when the values are updated can be:

- in the next clock cycle after a Period Match while counting up
- in the next clock cycle after an One Match while counting down
- immediately, if the timer is stopped and the shadow transfer enable bit(s) is set

Figure 23-10 shows an example of the shadow transfer control when the timer slice has been configured into center aligned mode. For a complete description of all the timer slice counting modes, please address [Section 23.2.5.3](#), [Section 23.2.5.4](#) and [Section 23.2.5.5](#).

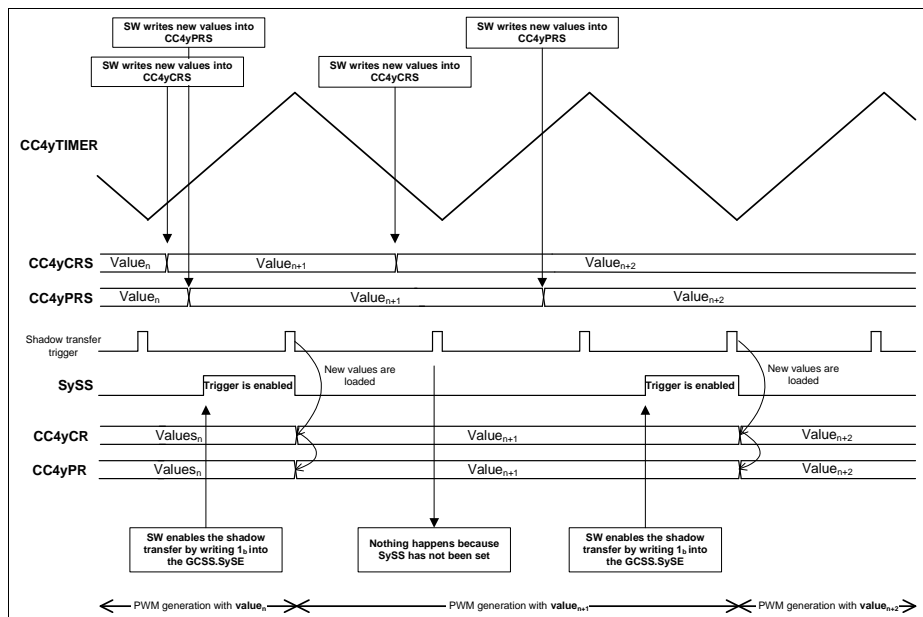

Figure 23-10 Shadow transfer timing example - center aligned mode

In some application cases it may be necessary to request shadow transfers not by software but by hardware. To perform this action each CCU4 contains a dedicated input that can be used to request a shadow transfer by hardware, the CCU4x.MCSS.

This input, when enabled, is used to set the shadow transfer enable bitfields (**GCST.SySS**, **GCST.SyDSS** and **GCST.SyPSS**) of the specific slice. It is possible to select which slice is using this input to perform the synchronization via the **GCTRL.MSEy** bit field. It is also possible to enable the usage of this signal for the three different shadow transfer signals: compare and period values, dither compare value and prescaler compare value. This can be configured on the **GCTRL.MSDE** field.

The structure for using the CCU4x.MCSS input signal can be seen in [Figure 23-9](#). The usage of this signal is just an add on to the shadow transfer control and therefore all the previous described functions are still available.

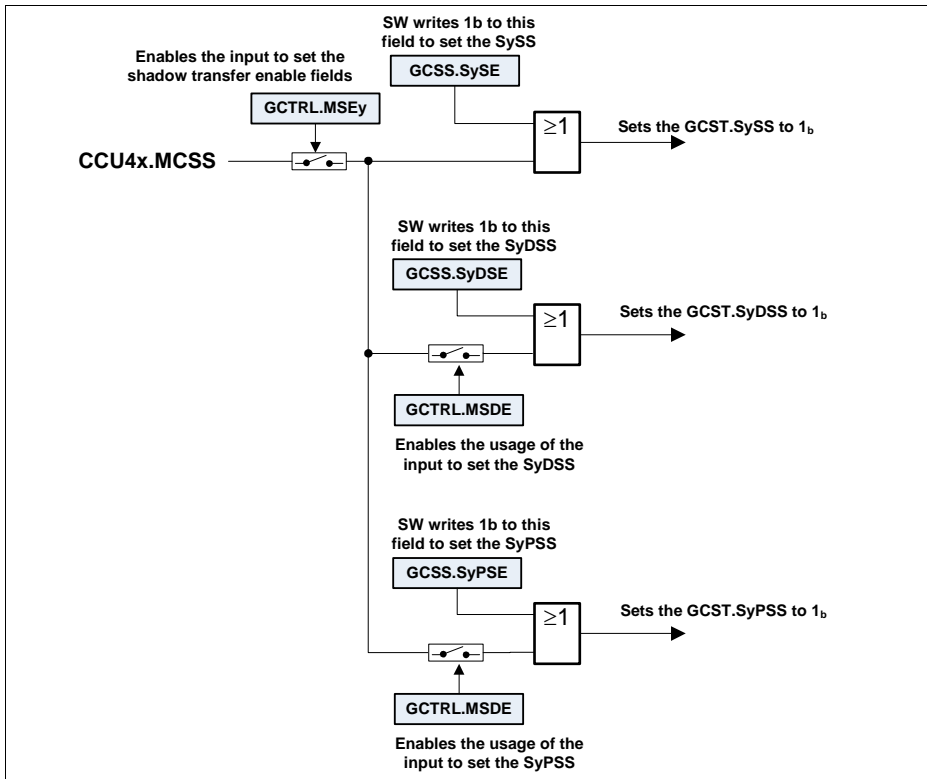

Figure 23-11 Usage of the CCU4x.MCSS input

23.2.5.3 Edge Aligned Mode

Edge aligned mode is the default counting scheme. In this mode, the timer is incremented until it matches the value programmed in the period register, **CC4yPR**. When period match is detected the timer is cleared to 0000_H and continues to be incremented.

In this mode, the value of the period register and compare register are updated with the value written by software into the correspondent shadow register, every time that an overflow occurs (period match), see **Figure 23-12**.

In edge aligned mode, the status bit of the comparison (CC4yST) is set one clock cycle after the timer hits the value programmed into the compare register. The clear of the status bit is done one clock cycle after the timer reaches 0000_H.

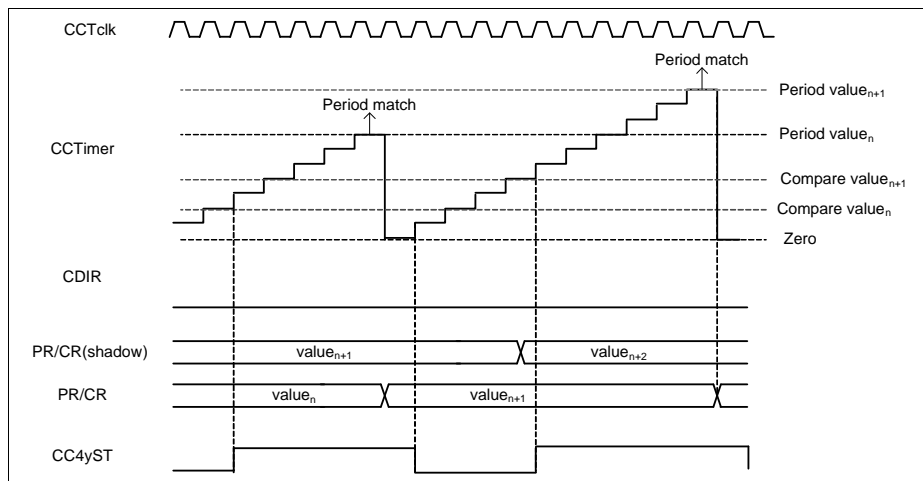

Figure 23-12 Edge aligned mode, $\text{CC4yTCM} = 0_B$

23.2.5.4 Center Aligned Mode

In center aligned mode, the timer is counting up or down with respect to the following rules:

- The counter counts up while $\text{CC4yTCST.CDIR} = 0_B$ and it counts down while $\text{CC4yTCST.CDIR} = 1_B$.
- Within the next clock cycle, the count direction is set to counting up ($\text{CC4yTCST.CDIR} = 0_B$) when the counter reaches 0001_H while counting down.
- Within the next clock cycle, the count direction is set to counting down ($\text{CC4yTCST.CDIR} = 1_B$), when the period match is detected while counting up.

The status bit (CC4yST) is always 1_B when the counter value is equal or greater than the compare value and 0_B otherwise.

While in edge aligned mode, the shadow transfer for compare and period registers is executed once per period. It is executed twice in center aligned mode as follows

- Within the next clock cycle after the counter reaches the period value, while counting up ($\text{CC4yTCST.CDIR} = 0_B$).
- Within the next clock cycle after the counter reaches 0001_H , while counting down ($\text{CC4yTCST.CDIR} = 1_B$).

Note: Bit CC4yTCST.CDIR changes within the next timer clock after the one-match or the period-match, which means that the timer continues counting in the previous direction for one more cycle before changing the direction.

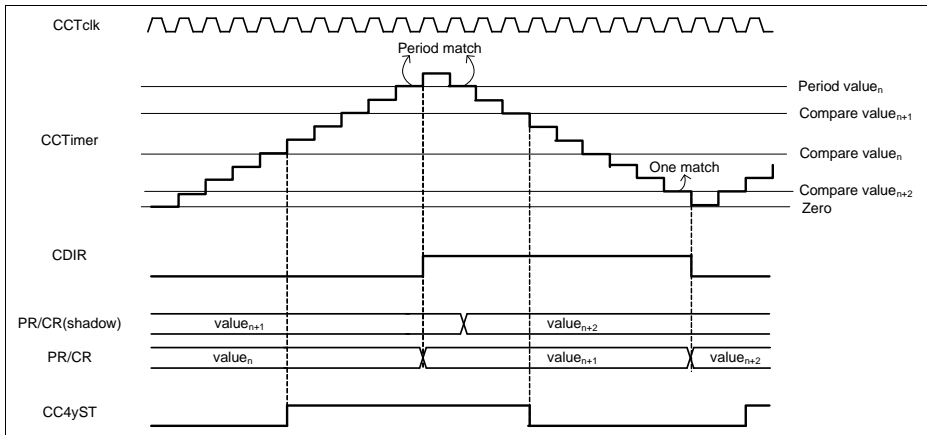

Figure 23-13 Center aligned mode, $CC4yTC.TCM = 1_B$

23.2.5.5 Single Shot Mode

In single shot mode, the timer is stopped after the current timer period is finished. This mode can be used with center or edge aligned scheme.

In edge aligned mode, **Figure 23-14**, the timer is stopped when it is cleared to 0000_H after having reached the period value. In center aligned mode, **Figure 23-15**, the period is finished when the timer has counted down to 0000_H.

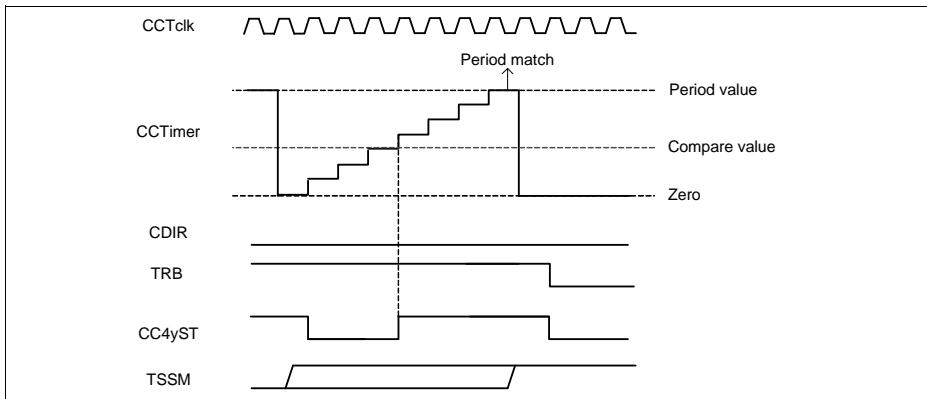

Figure 23-14 Single shot edge aligned - $CC4yTC.TSSM = 1_B$, $CC4yTC.TCM = 0_B$

Figure 23-15 Single shot center aligned - $\text{CC4yTC.TSSM} = 1_B$, $\text{CC4yTC.TCM} = 1_B$

23.2.6 Active/Passive Rules

The general rules that set or clear the associated timer slice status bit (CC4yST), can be generalized independently of the timer counting mode.

The following events set the Status bit (CC4yST) to Active:

- in the next f_{tclk} cycle after a compare match while counting up
- in the next f_{tclk} cycle after a zero match while counting down

The following events set the Status bit (CC4yST) to Inactive:

- in the next f_{tclk} cycle after a zero match (and not compare match) while counting up
- in the next f_{tclk} cycle after a compare match while counting down

If external events are being used to control the timer operation, these rules are still applicable.

The status bit state can only be 'override' via software or by the external status bit override function, [Section 23.2.7.10](#).

The software can at any time write a 1_B into the [GCSS.SySTS](#) bitfield, which will set the status bit [GCST.CC4yST](#) of the specific timer slice. Writing a 1_B into the [GCSC.SySTC](#) bitfield will clear the specific status bit.

23.2.7 External Events Control

Each CCU4 timer slice has the possibility of using up to three different input events, see [Section 23.2.2](#). These three events can then be mapped to Timer Slice functions (the full set of available functions is described at [Section 23.2.3](#))

These events can be mapped to any of the CCU4x.INy[P...A] inputs and there isn't any imposition that an event cannot be used to perform several functions, or that an input

cannot be mapped to several events (e.g. input X triggers event 0 with rising edge and triggers event 1 with the falling edge).

23.2.7.1 External Start/Stop

To select an external start function, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** field and indicating the active edge of the signal on the **CC4yINS.EVxEM** field.

This event should be then mapped to the start or stop functionality by setting the **CC4yCMC.STRTS** (for the start) or the **CC4yTC.ENDM** (for the stop) with the proper value.

Notice that both start and stop functions are edge and not level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

The external stop by default just clears the run bit (**CC4yTCST.TRB**), while the start functions does the opposite. Nevertheless one can select an extended subset of functions for the external start and stop. This subset is controlled by the registers **CC4yTC.ENDM** (for the stop) and **CC4yTC.STRM** (for the start).

For the start subset (**CC4yTC.STRM**):

- sets the run bit/starts the timer (resume operation)
- clears the timer, sets the run bit/starts the timer (flush and start)

For the stop subset (**CC4yTC.ENDM**):

- clears the run/stops the timer (stop)
- clears the timer (flush)
- clears the timer, clears the run bit/stops the timer (flush and stop)

If in conjunction with an external start/stop (configured also/only as flush) and external up/down signal is used, during the flush operation the timer is going to be set to 0000_H if the actual counting direction is up or set with the value of the period register if the counting direction is down.

Figure 23-16 to **Figure 23-19** shows the usage of two signals to perform the start/stop functions in all the previously mentioned subsets. External Signal(1) acts as an active HIGH start signal, while External Signal(2) is used as an active HIGH stop function.

Figure 23-16 Start (as start)/ stop (as stop) - $CC4yTC.STRM = 0_B$, $CC4yTC.ENDM = 00_B$

Figure 23-17 Start (as start)/ stop (as flush) - $CC4yTC.STRM = 0_B$, $CC4yTC.ENDM = 01_B$

**Figure 23-18 Start (as flush and start)/ stop (as stop) - $CC4yTC.STRM = 1_B$,
 $CC4yTC.ENDM = 00_B$**

**Figure 23-19 Start (as start)/ stop (as flush and stop) - $CC4yTC.STRM = 0_B$,
 $CC4yTC.ENDM = 10_B$**

23.2.7.2 External Counting Direction

There is the possibility of selecting an input signal to act as increment/decrement control. To select an external up/down control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** field and indicating the active level of the signal on the **CC4yINS.EVxLM**. This event should be then mapped to the up/down functionality by setting **CC4yCMC.UDS** with the proper value.

Capture/Compare Unit 4 (CCU4)

Notice that the up/down function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The status bit of the slice (**CC4yST**) is always set when the timer value is equal or greater than the value stored in the compare register, see [Section 23.2.6](#).

The update of the period and compare register values is done when:

- with the next clock after a period match, while counting up (**CC4yTCST.CDIR** = 0_B)
- with the next clock after a one match, while counting down (**CC4yTCST.CDIR** = 1_B)

The value of the **CC4yTCST.CDIR** register is updated accordingly with the changes on the decoded event. The Up/Down direction is always understood as **CC4yTCST.CDIR** = 1_B when counting down and **CC4yTCST.CDIR** = 0_B when counting up. Using an external signal to perform the up/down counting function and configuring the event as active HIGH means that the timer is counting up when the signal is HIGH and counting down when LOW.

Figure 23-20 shows an external signal being used to control the counting direction of the time. This signal was selected as active HIGH, which means that the timer is counting down while the signal is HIGH and counting up when the signal is LOW.

*Note: For a signal that should impose an increment when LOW and a decrement when HIGH, the user needs to set the **CC4yINS.EVxLM** = 0_B. When the operation is switched, then the user should set **CC4yINS.EVxLM** = 1_B.*

Note: Using an external counting direction control, sets the slice in edge aligned mode.

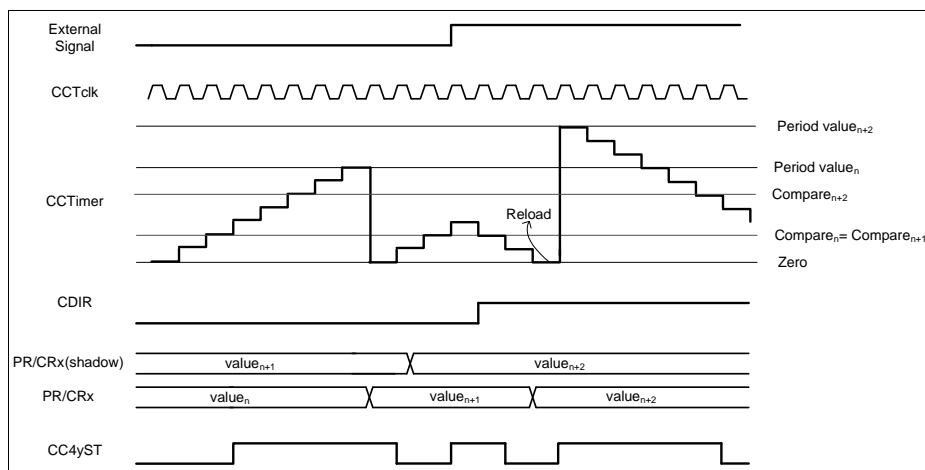

Figure 23-20 External counting direction

23.2.7.3 External Gating Signal

For pulse measurement, the user has the possibility of selecting an input signal that operates as counting gating.

To select an external gating control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active level of the signal on the **CC4yINS.EVxLM** register. This event should be then mapped to the gating functionality by setting the **CC4yCMC.GATES** with the proper value.

Notice that the gating function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The status bit during an external gating signal continues to be asserted when the compare value is reached and deasserted when the counter reaches 0000_H. One should note that the counter continues to use the period register to identify the wrap around condition. **Figure 23-21** shows the usage of an external signal for gating the slice counter. The signal was set as active LOW, which means the counter gating functionality is active when the external value is zero.

Figure 23-21 External gating

For any type of usage of the external gating function, the specific run bit of the Timer Slice, **CC4yTCST.TRB**, needs to be set. This can be done via an additional external signal or directly via software.

23.2.7.4 External Count Signal

There is also the possibility of selecting an external signal to act as the counting event.

To select an external counting, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the **CC4yINS.EVxEM** register.

Capture/Compare Unit 4 (CCU4)

This event should be then mapped to the counting functionality by setting the **CC4yCMC.CNTS** with the proper value.

Notice that the counting function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

One can select just a the rising, falling or both edges to perform a count. On **Figure 23-22**, the external signal was selected as a counter event for both falling and rising edges. Wrap around condition is still applied with a comparison with the period register.

Figure 23-22 External count

For any type of usage of the external gating function, the specific run bit of the Timer Slice, **CC4yTCST.TRB**, needs to be set. This can be done via an additional external signal or directly via software.

23.2.7.5 External Load

Each slice of the CCU4 also has a functionality that enables the user to select an external signal as trigger for reloading the value of the timer with the current value of the compare register (if **CC4yTCST.CDIR** = 0_B) or with the value of the period register (if **CC4yTCST.CDIR** = 1_B).

To select an external load signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the **CC4yINS.EVxEM** register. This event should be then mapped to the load functionality by setting the **CC4yCMC.LDS** with the proper value.

Notice that the load function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

On figure **Figure 23-23**, the external signal (1) was used to act as a load trigger, active on the rising edge. Every time that a rising edge on external signal (1) is detected, the

Capture/Compare Unit 4 (CCU4)

timer value is loaded with the value present on the compare register. If an external signal is being used to control the counting direction, up or down, the timer value can be loaded also with the value set in the period register. The External signal (2) represents the counting direction control (active HIGH). If at the moment that a load trigger is detected, the signal controlling the counting direction is imposing a decrement, then the value set in the timer is the period value.

Figure 23-23 External load

23.2.7.6 External Capture

When selecting an external signal to be used as a capture trigger (if **CC4yCMC.CAP0S** or **CC4yCMC.CAP1S** are different from 0_H), the user is automatically setting the specific slice into capture mode.

In capture mode the user can have up to four capture registers, see **Figure 23-26**: capture register 0 (**CC4yC0V**), capture register 1 (**CC4yC1V**), capture register 2 (**CC4yC2V**) and capture register 3 (**CC4yC3V**).

These registers are shared between compare and capture modes which imposes:

- if **CC4yC0V** and **CC4yC1V** are used for capturing, the compare registers **CC4yCR** and **CC4yCRS** are not available (no compare channel)
- if **CC4yC2V** and **CC4yC3V** are used for capturing, the period registers **CC4yPR** and **CC4yPRS** are not available (no period control)

To select an external capture signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active edge of the signal on the

Capture/Compare Unit 4 (CCU4)

CC4yINS.EVxEM register. This event should be then mapped to the capture functionality by setting the **CC4yCMC.CAP0S/CC4yCMC.CAP1S** with the proper value.

Notice that the capture function is edge active and therefore the active/passive configuration is set only by the **CC4yINS.EVxEM**.

The user has the possibility of selecting the following capture schemes:

- Different capture events for **CC4yC0V/CC4yC1V** and **CC4yC2V/CC4yC3V**
- The same capture event for **CC4yC0V/CC4yC1V** and **CC4yC2V/CC4yC3V** with the same capture edge. For this capture scheme, only the CCcap1 functionality needs to be programmed. To enable this scheme, the field **CC4yTC.SCE** needs to be set to 1.

Different Capture Events (SCE = 0_B)

Every time that a capture trigger 1 occurs, CCcap1, the actual value of the timer is captured into the capture register 3 and the previous value stored in this register is transferred into capture register 2.

Every time that a capture trigger 0 occurs, CCcap0, the actual value of the timer is captured into the capture register 1 and the previous value stored in this register is transferred into capture register 0.

Every time that a capture procedure into one of the registers occurs, the respective full flag is set. This flag is cleared automatically by HW when the SW reads back the value of the capture register (by reading the specific capture register or by reading the extended capture read value, see [Section 23.2.7.7](#)).

The capture of a new value into a specific capture registers is dictated by the status of the full flag as follows:

$$CC4yC1V_{\text{capt}} = \text{NOT}(CC4yC1V_{\text{full_flag}} \text{ AND } CC4yC0V_{\text{full_flag}}) \quad (23.4)$$

$$CC4yC0V_{\text{capt}} = CC4yC1V_{\text{full_flag}} \text{ AND NOT}(CC4yC0V_{\text{full_flag}}) \quad (23.5)$$

It is also possible to disable the effect of the full flags reset by setting the **CC4yTC.CCS** = 1_B. This enables a continuous capturing independent if the values captured have been read or not.

*Note: When using the period registers for capturing, **CC4yCMC.CAP1S** different from 00_B, the counter always uses its full 16 bit width as period value.*

On [Figure 23-24](#), an external signal was selected as an event for capturing the timer value into the **CC4yC0V/CC4yC1V** registers. The status bit, CC4yST, during capture mode is asserted whenever a capture trigger is detected and deasserted when the counter matches 0000_H.

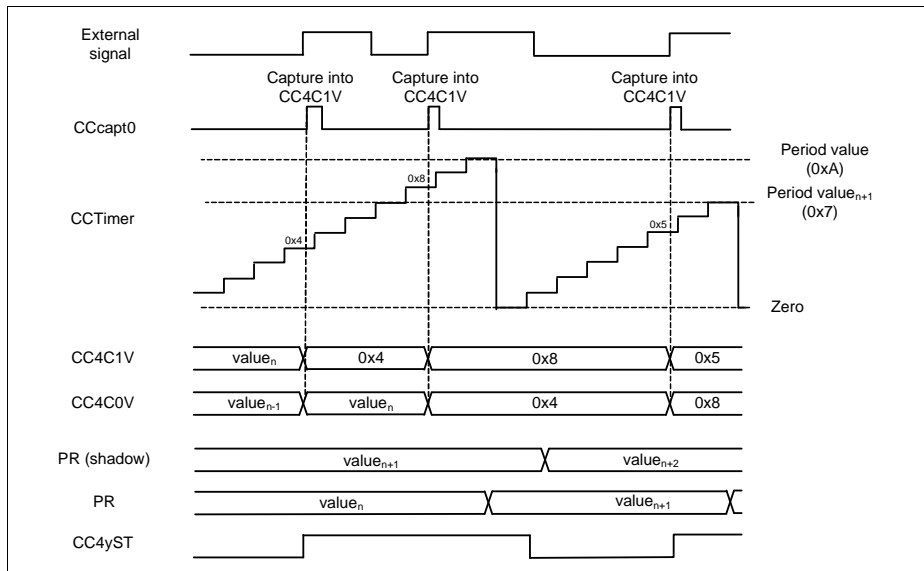

Figure 23-24 External capture - $CC4yCMC.CAP0S \neq 00_B$, $CC4yCMC.CAP1S = 00_B$

On [Figure 23-25](#), two different signals were used as source for capturing the timer value into the [CC4yC0V/CC4yC1V](#) and [CC4yC2V/CC4yC3V](#) registers.

External signal(1) was selected as rising edge active capture source for [CC4yC0V/CC4yC1V](#). External signal(2) was selected as the capture source for [CC4yC2V/CC4yC3V](#), but as opposite to the external signal(1), the active edge was selected as falling.

See [Section 23.2.12.4](#), for the complete capture mode usage description.

Capture/Compare Unit 4 (CCU4)

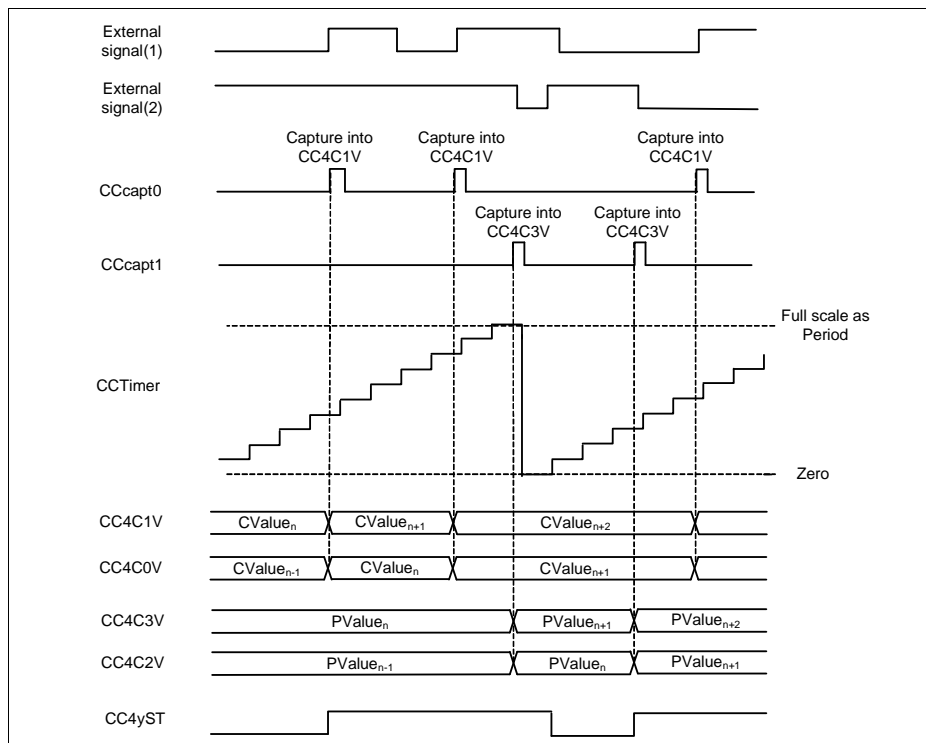

Figure 23-25 External capture - $CC4yCMC.CAP0S \neq 00_B$, $CC4yCMC.CAP1S \neq 00_B$

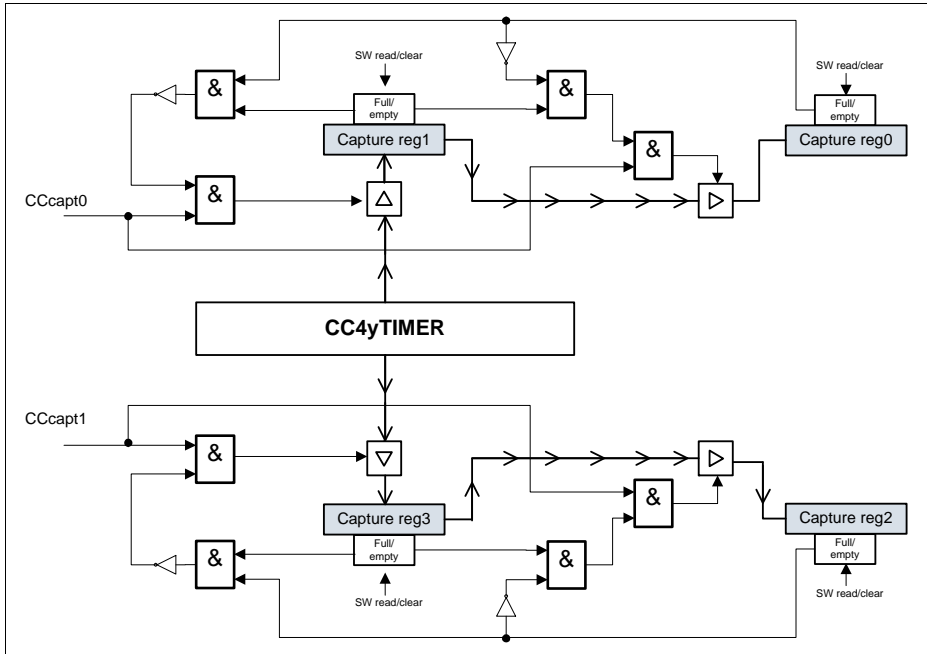

Figure 23-26 Slice capture logic

Same Capture Event (SCE = 1_B)

Setting the field **CC4yTC.SCE** = 1_B, enables the possibility of having 4 capture registers linked with the same capture event, **Figure 23-28**. The function that controls the capture is the **CCCapt1**.

The capture logic follows the same structure shown in **Figure 23-26** but extended to a four register chain, see **Figure 23-27**. The same full flag lock rules are applied to the four register chain (it also can be disabled by setting the **CC4yTC.CCS** = 1_B):

$$CC4yC3V_{\text{capt}} = \text{NOT}(CC4yC3V_{\text{full_flag}} \text{ AND } CC4yC2V_{\text{full_flag}} \text{ AND } CC4yC2V_{\text{full_flag}} \text{ AND } CC4yC1V_{\text{full_flag}}) \quad (23.6)$$

$$CC4yC2V_{\text{capt}} = CC4yC3V_{\text{full_flag}} \text{ AND NOT}(CC4yC2V_{\text{full_flag}} \text{ AND } CC4yC1V_{\text{full_flag}} \text{ AND } CC4yC0V_{\text{full_flag}}) \quad (23.7)$$

$$CC4yC1V_{\text{capt}} = CC4yC2V_{\text{full_flag}} \text{ AND NOT}(CC4yC1V_{\text{full_flag}} \text{ AND } CC4yC0V_{\text{full_flag}}) \quad (23.8)$$

$$CC4yC0V_{\text{capt}} = CC4yC1V_{\text{full_flag}} \text{ AND NOT}(CC4yC0V_{\text{full_flag}}) \quad (23.9)$$

Capture/Compare Unit 4 (CCU4)

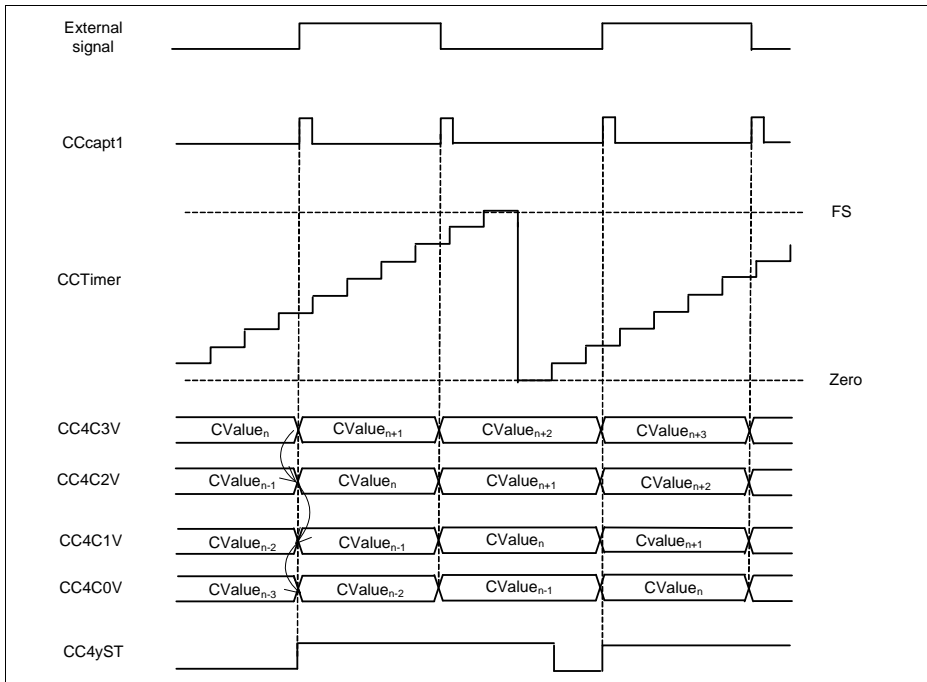

Figure 23-27 External Capture - CC4yTC.SCE = 1_B

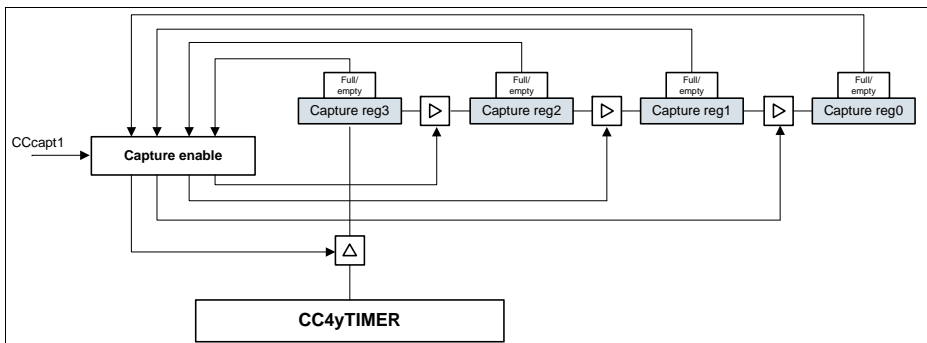

Figure 23-28 Slice Capture Logic - CC4yTC.SCE = 1_B

23.2.7.7 Capture Extended Read Back Mode

Each Timer Slice capture logic can operate in a FIFO read back mode. This mode can be enabled by setting the **CC4yTC.ECM** = 1_B. This Extended Read back mode allows the software to read back the capture data always from the same address (**CC4yECRD0** for the structure linked with the capture trigger 0 or **CC4yECRD1** for the one linked with capture trigger 1). This read back will always return the oldest captured value, enabling an easy software routine implementation for reconstructing the capture data.

This function allows the usage of a FIFO structure for each capturing trigger. This relaxes the software read back routine when multiple capture triggers are present, and the software is not fast enough to perform a read operation in each capture event.

This FIFO read back function is present for a depth-4 and depth-2 FIFO structure.

The read back data contains also a lost value bitfield, that indicates if a capture trigger was lost due to the fact that the FIFO structure was full. This bitfield is set whenever a capture event was sensed and the FIFO was full (regardless if the continuous capture mode was enabled or not). This bitfield is cleared automatically by HW whenever the next read of the **CC4yECRD0/CC4yECRD1** register occurs. This bitfield does not indicate how many capture events were lost, it just indicates that between two ECRD reads at least a capture event was lost (this can help the SW evaluate which part of the data read, can be used for calculation).

*Note: When the ECM bitfield is set, reading the individual capture registers is still possible. Nevertheless the full flags can only be cleared by the HW when a read back is done via the **CC4yECRD0/CC4yECRD1** address.*

Depth 4 Structure

The FIFO depth-4 structure is present in the hardware when the capture trigger 1 is enabled and the **CC4yTC.SCE** = 1_B (same capture event), **Figure 23-29**.

Capture/Compare Unit 4 (CCU4)

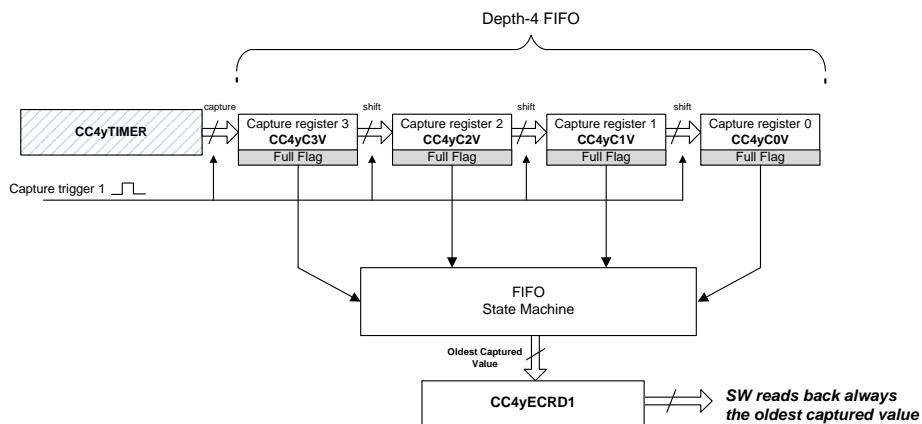

Figure 23-29 Capture Extended Read Back - Depth 4

Capture/Compare Unit 4 (CCU4)

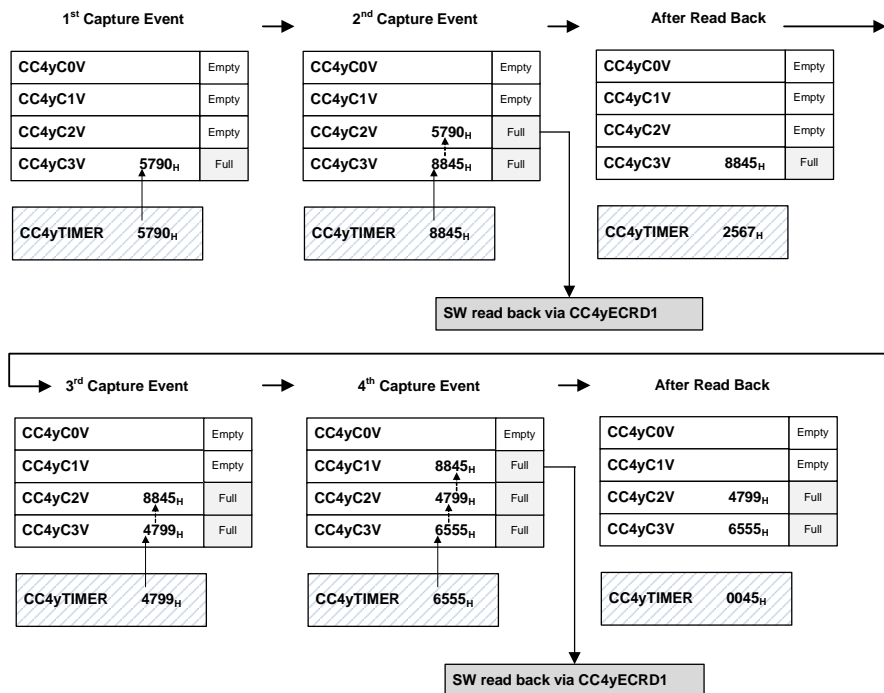

Figure 23-30 Depth 4 software access example

Depth 2 Structure

Each Timer Slice can have two capture structures of depth-2: one used with capture trigger 0 and another with capture trigger 1.

The one linked with capture trigger 0, is accessed via the **CC4yECRD0** while the one linked with the capture trigger 1 is accessed via the **CC4yECRD1**, [Figure 23-31](#).

Figure 23-31 Capture Extended Read Back - Depth 2

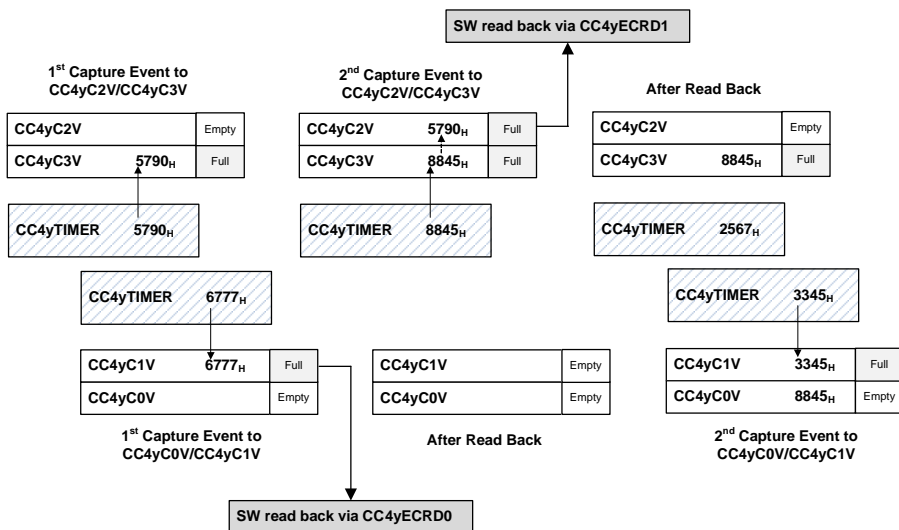

Figure 23-32 Depth 2 software access example

23.2.7.8 External Modulation

An external signal can be used to perform a modulation at the output of each timer slice.

To select an external modulation signal, one should map one of the input signals to one of the events, by setting the required value in the **CC4yINS.EVxIS** register and indicating the active level of the signal on the **CC4yINS.EVxLM** register. This event should be then

Capture/Compare Unit 4 (CCU4)

mapped to the modulation functionality by setting the **CC4yCMC.MOS** = 01_B if event 0 is being used, **CC4yCMC.MOS** = 10_B if event 1 or **CC4yCMC.MOS** = 11_B if event 2.

Notice that the modulation function is level active and therefore the active/passive configuration is set only by the **CC4yINS.EVxLM**.

The modulation has two modes of operation:

- modulation event is used to clear the CC4yST bit - **CC4yTC.EMT** = 0_B
- modulation event is used to gate the outputs - **CC4yTC.EMT** = 1_B

On **Figure 23-33**, we have an external signal configured to act as modulation source that clears the CC4yST bit, **CC4yTC.EMT** = 0_B. It was programmed to be an active LOW event and therefore, when this signal is LOW the output value follows the normal ACTIVE/PASSIVE rules.

When the signal is HIGH (inactive state), then the CC4yST bit is cleared and the output is forced into the PASSIVE state. Notice that the values of the status bit, CC4yST and the specific output CCU4x.OUTy are not linked together. One can choose for the output to be active LOW or HIGH through the PSL bit.

The exit of the external modulation inactive state is synchronized with the PWM signal due to the fact that the CC4yST bit is cleared and cannot be set while the modulation signal is inactive.

The entering into inactive state also can be synchronized with the PWM signal, by setting **CC4yTC.EMS** = 1_B. With this all possible glitches at the output are avoided, see **Figure 23-34**.

Figure 23-33 External modulation clearing the ST bit - **CC4yTC.EMT = 0_B**

Figure 23-34 External modulation clearing the ST bit - $\text{CC4yTC.EMT} = 0_B$, $\text{CC4yTC.EMS} = 1_B$

On **Figure 23-35**, the external modulation event was used as gating signal of the outputs, $\text{CC4yTC.EMT} = 1_B$. The external signal was configured to be active HIGH, $\text{CC4yINS.EVxLM} = 0_B$, which means that when the external signal is HIGH the outputs are set to the PASSIVE state. In this mode, the gating event can also be synchronized with the PWM signal by setting the $\text{CC4yTC.EMS} = 1_B$.

Figure 23-35 External modulation gating the output - $\text{CC4yTC.EMT} = 1_B$

23.2.7.9 TRAP Function

The TRAP functionality allows the PWM outputs to react on the state of an input pin. This functionality can be used to switch off the power devices if the TRAP input becomes active.

To select the TRAP functionality, one should map one of the input signals to event number 2, by setting the required value in the **CC4yINS.EV2IS** register and indicating the active level of the signal on the **CC4yINS.EV2LM** register. This event should be then mapped to the trap functionality by setting the **CC4yCMC.TS = 1_B**.

Notice that the trap function is level active and therefore the active/passive configuration is set only by the **CC4yINTS.EV2LM**.

There are two bitfields that can be monitored via software to crosscheck the TRAP function, **Figure 23-36**:

- The TRAP state bit, **CC4yINTS.E2AS**. This bitfield if the TRAP is currently active or not. This bitfield is therefore setting the specific Timer Slice output, into ACTIVE or PASSIVE state.
- The TRAP Flag, **CC4yINTS.TRPF**. This bitfield is used as a remainder in the case that the TRAP condition is cleared automatically via hardware. This field needs to be cleared by the software.

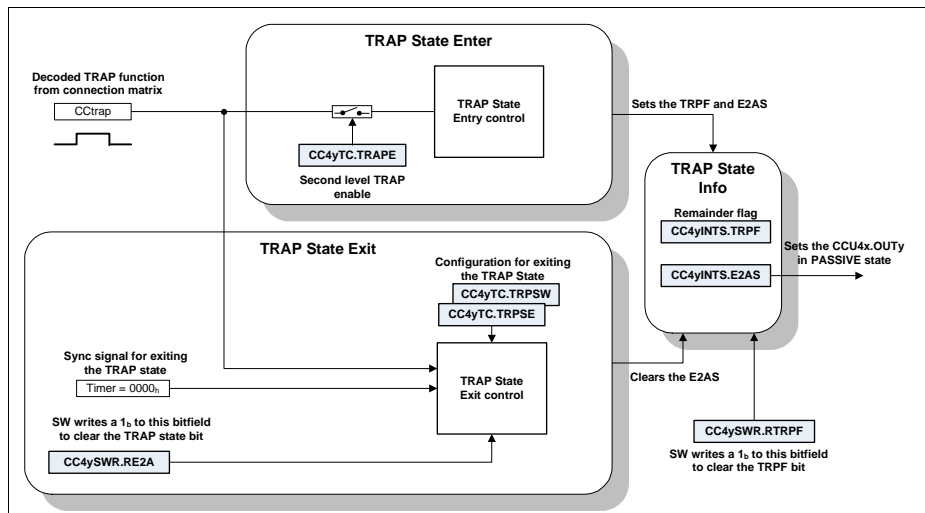

Figure 23-36 Trap control diagram

When a TRAP condition is detected at the selected input pin, both the Trap Flag and the Trap State bit are set to 1_B. The Trap State is entered immediately, by setting the CCU4xOUTy into the programmed PASSIVE state, **Figure 23-37**.

Capture/Compare Unit 4 (CCU4)

Exiting the Trap State can be done in two ways (**CC4yTC**.TRPSW register):

- automatically via HW, when the TRAP signal becomes inactive - **CC4yTC**.TRPSW = 0_B
- by SW only, by clearing the **CC4yINTS**.E2AS. The clearing is only possible if the input TRAP signal is in inactive state - **CC4yTC**.TRPSW = 1_B

Figure 23-37 Trap timing diagram, **CC4yPSL**.PSL = 0_B (output passive level is 0_B)

It is also possible to synchronize the exiting of the TRAP state with the PWM signal, **Figure 23-38**. This function is enabled when the bitfield **CC4yTC**.TRPSE = 1_B .

Figure 23-38 Trap synchronization with the PWM signal, **CC4yTC.TRPSE = 1_B**

23.2.7.10 Status Bit Override

For complex timed output control, each Timer Slice has a functionality that enables the override of the status bit (CC4yST) with a value passed through an external signal.

The override of the status bit, can then lead to a change on the output pin, CCU4xOUTy (from inactive to active or vice versa).

To enable this functionality, two signals are needed:

- One signal that acts as a trigger to override the status bit (edge active)
- One signal that contains the value to be set in the status bit (level active)

To use the status bit override functionality, one should map the signal that acts as trigger to the event number 1, by setting the required value in the **CC4yINS.EV1IS** register and indicating the active edge of the signal on the **CC4yINS.EV1EM** register.

The signal that carries the value to be set on the status bit, needs to be mapped to the event number 2, by setting the required value in the **CC4yINS.EV2IS** register. The **CC4yINS.EV2LM** register should be set to 0_B if no inversion on the signal is needed and to 1_B otherwise.

The events should be then mapped to the status bit functionality by setting the **CC4yCMC.OFS = 1_B**.

Figure 23-39 shows the functionality of the status bit override, when the external signal(1) was selected as trigger source (rising edge active) and the external signal(2) was selected as override value.

Figure 23-39 Status bit override

23.2.8 Multi-Channel Control

The multi channel control mode is selected individually in each slice by setting the **CC4yTC.MCME** = 1_B.

Within this mode, the output state of the Timer Slices (the ones set in multi channel mode) can be controlled in parallel by a single pattern.

The pattern is controlled via the CCU4 inputs, CCU4x.MCI0, CCU4x.MCI1, CCU4x.MCI2 and CCU4x.MCI3. Each of these inputs is connected directly to the associated slice input, e.g. CCU4x.MCI0 to CC40MCI, CCU4x.MCI1 to CC41MCI.

This pattern can be controlled directly by other module. The connectivity of each device may allow different control possibilities therefore one should address [Section 23.8](#) to check what modules are connected to these inputs.

When using the Multi Channel support of the CCU4, one can achieve a complete synchronicity between the output state update, CCU4x.OUTy, and the update of a new pattern, [Figure 23-40](#). This synchronicity feature can be enabled by using some specific modules and therefore one should address [Section 23.8](#) to check which module is controlling the CCU4x.MCIy inputs.

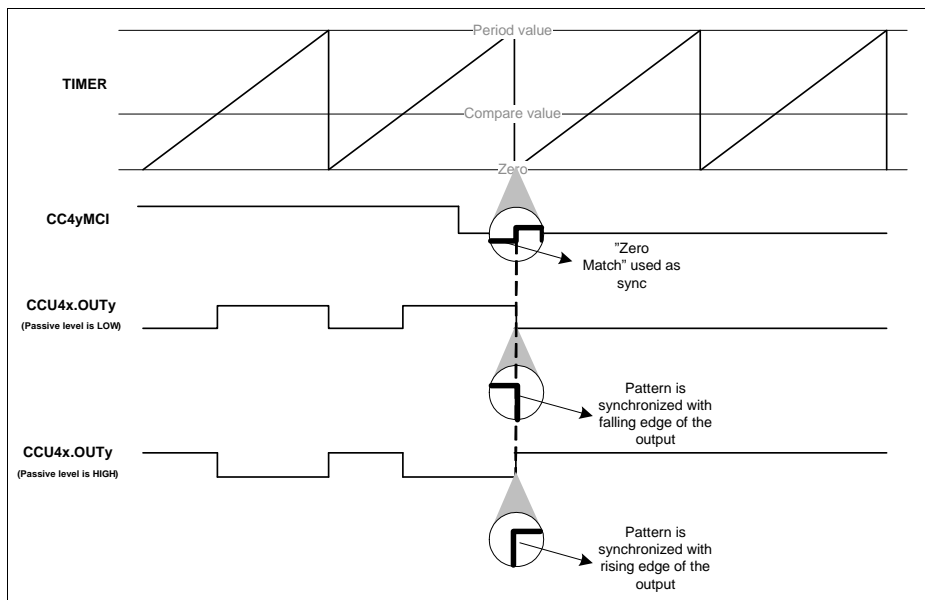

Figure 23-40 Multi channel pattern synchronization

Figure 23-41 shows the usage of the multi channel mode in conjunction with all four Timer Slices inside the CCU4.

Figure 23-41 Multi Channel mode for multiple Timer Slices

The synchronization between the CCU4 and the module controlling the multi-channel pattern is achieved, by adding a 3 cycle delay on the output path of each Timer Slice

Capture/Compare Unit 4 (CCU4)

(between the status bit, CC4yST and the direct control of the output pin). This path is only selected when **CC4yTC.MCME** = 1_B, see **Figure 23-42**.

The multi pattern input synchronization can be seen on **Figure 23-43**. To achieve a synchronization between the update of the status bit, the sampling of a new multi channel pattern input is controlled by the period match or one match signal.

In a straightforward utilization of this synchronization feature, the module controlling the multi channel pattern signals, receives a sync signal from the CCU4, the CCU4x.PSy. This signal is then used by this module to update the multi-channel pattern. Due to the structure of the synchronization scheme inside the CCU4, the module controlling the multi-channel pattern needs to update this pattern, within 4 clock cycles after the CCU4x.PSy signal is asserted, **Figure 23-43**.

In a normal operation, where no external signal is used to control the counting direction, the signal used to enable the sampling of the pattern is always the period match when in edge aligned and the one match when in center aligned mode. When an external signal is used to control the counting direction, depending if the counter is counting up or counting down, the period match or the one match signal is used, respectively.

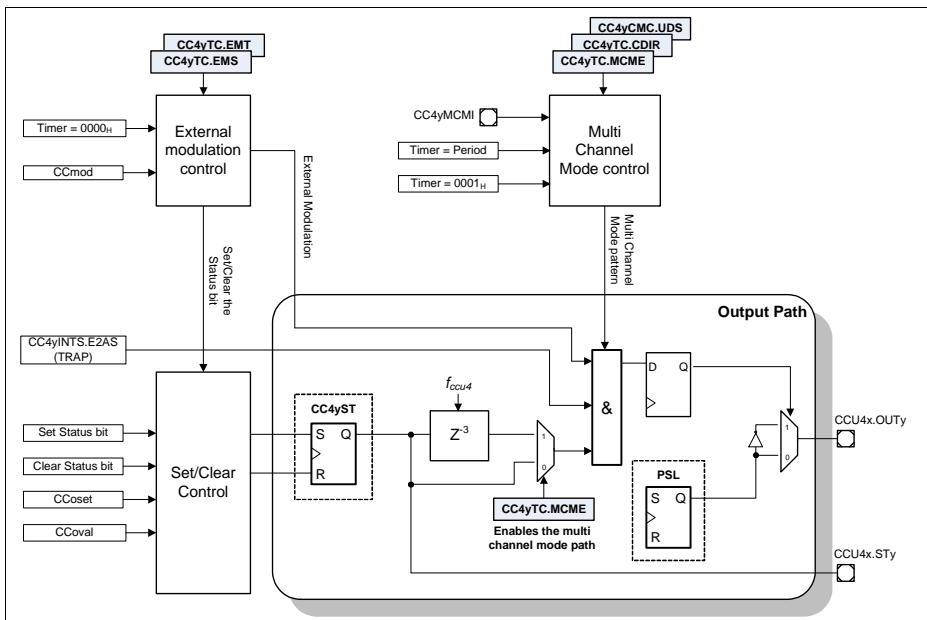

Figure 23-42 CC4y Status bit and Output Path

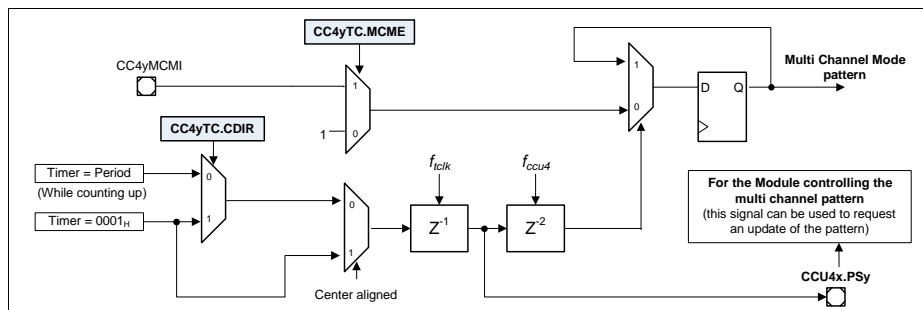

Figure 23-43 Multi Channel Mode Control Logic

23.2.9 Timer Concatenation

The CCU4 offers a very easy mechanism to perform a synchronous timer concatenation. This functionality can be used by setting the **CC4yCMC.TCE** = 1_B . By doing this the user is doing a concatenation of the actual CCU4 slice with the previous one, see [Figure 23-44](#).

Notice that it is not possible to perform concatenation with non adjacent slices and that timer concatenation automatically sets the slice mode into Edge Aligned. It is not possible to perform timer concatenation in Center Aligned mode.

To enable a 64 bit timer, one should set the **CC4yCMC.TCE** = 1_B in all the slices (with the exception of the CC40 due to the fact that it doesn't contain this control register).

To enable a 48 bit timer, one should set the **CC4yCMC.TCE** = 1_B in two adjacent slices and to enable a 32 bit timer, the **CC4yCMC.TCE** is set to 1_B in the slice containing the MSBs. Notice that the timer slice containing the LSBs should always have the TCE bitfield set to 0_B .

Several combinations for timer concatenation can be made inside a CCU4 module:

- one 64 bit timer
- one 48 bit timer plus a 16 timer
- two 32 bit timers
- one 32 bit timer plus two 16 bit timers

Each Timer Slice is connected to the adjacent Timer Slices via a dedicated concatenation interface. This interface allows the concatenation of not only the Timer counting operation, but also a synchronous input trigger handling for capturing and loading operations, **Figure 23-45**.

Reference Manual
CCU4, V1.15

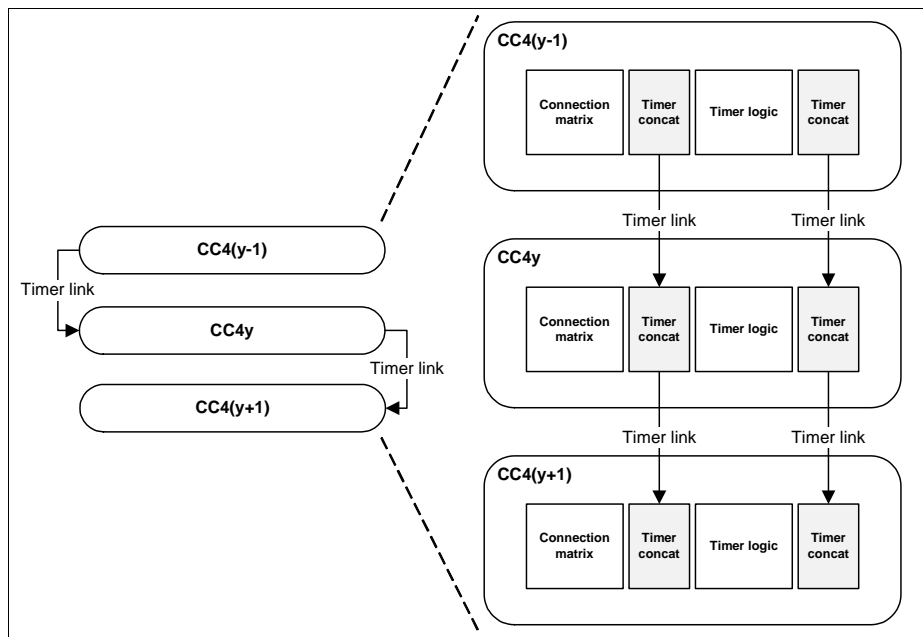

Figure 23-45 Timer Concatenation Link

Seven signals are present in the timer concatenation interface:

- Timer Period match (CC4yPM)
- Timer Zero match (CC4yZM)
- Timer Compare match (CC4yCM)
- Timer counting direction function (CCupd)
- Timer load function (CCload)
- Timer capture function for CC4yC0V and CC4yC1V registers (CCcap0)
- Timer capture function for CC4yC2V and CC4yC3V registers (CCcap1)

The first four signals are used to perform the synchronous timing concatenation at the output of the Timer Logic, like it is seen in [Figure 23-45](#). With this link, the timer length can be easily adjusted to 32, 48 or 64 bits (counting up or counting down).

The last three signals are used to perform a synchronous link between the capture and load functions, for the concatenated timer system. This means that the user can have a capture or load function programmed in the first Timer Slice, and propagate this capture or load trigger synchronously from the LSBs until the MSBs, [Figure 23-46](#).

The capture or load function only needs to be configured in the first Timer Slice (the one holding the LSBs). From the moment that **CC4yCMC.TCE** is set to 1_B, in the following Timer Slices, the link between these functions is done automatically by the hardware.

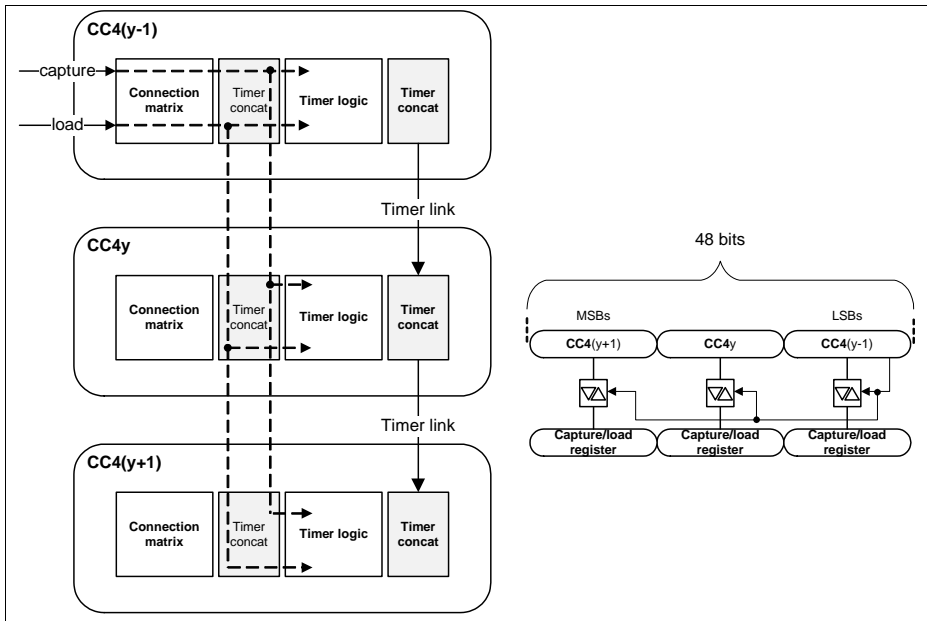

Figure 23-46 Capture/Load Timer Concatenation

The period match (CC4yPM) or zero match (CC4yZM) from the previous Timer Slice (with the immediately next lower index) are used in concatenated mode, as gating signal for the counter. This means that the counting operation of the MSBs only happens when a wrap around condition is detected, avoiding additional DSP operations to extract the counting value.

With the same methodology, the compare match (CC4yCM), zero match and period match are gated with the specific signals from the previous slice. This means that the timing information is propagated throughout all the slices, enabling a completely synchronous match between the LSB and MSB count, see [Figure 23-47](#).

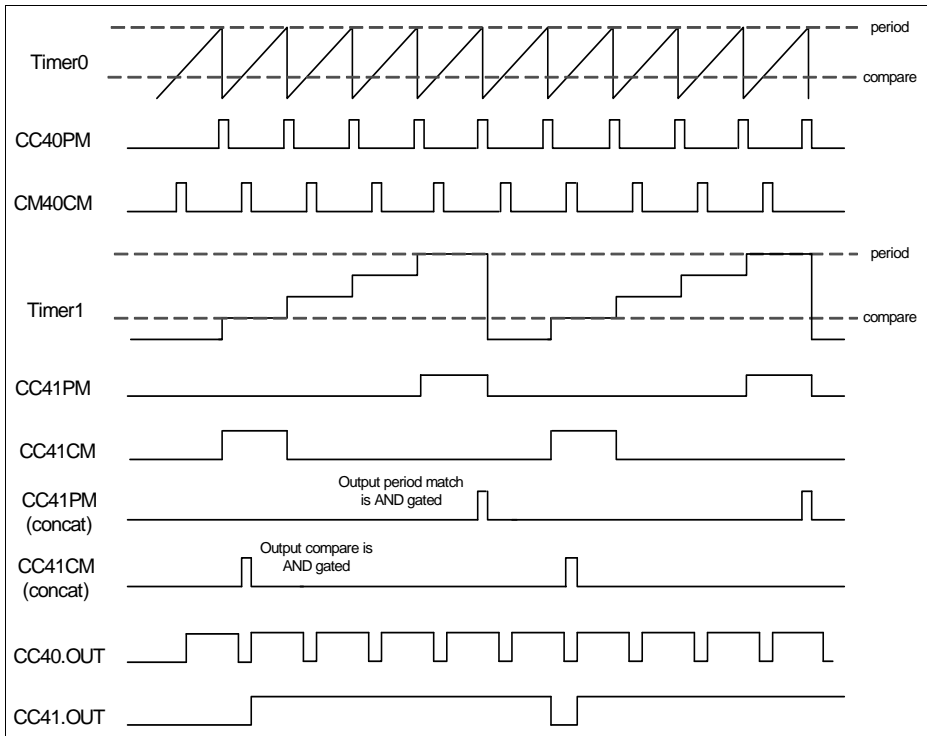

Figure 23-47 32 bit concatenation timing diagram

Note: The counting direction of the concatenated timer needs to be fixed. The timer can count up or count down, but the direction cannot be updated on the fly.

Figure 23-48 gives an overview of the timer concatenation logic. Notice that all the mechanism is controlled solely by the **CC4yCMC.TCE** bitfield.

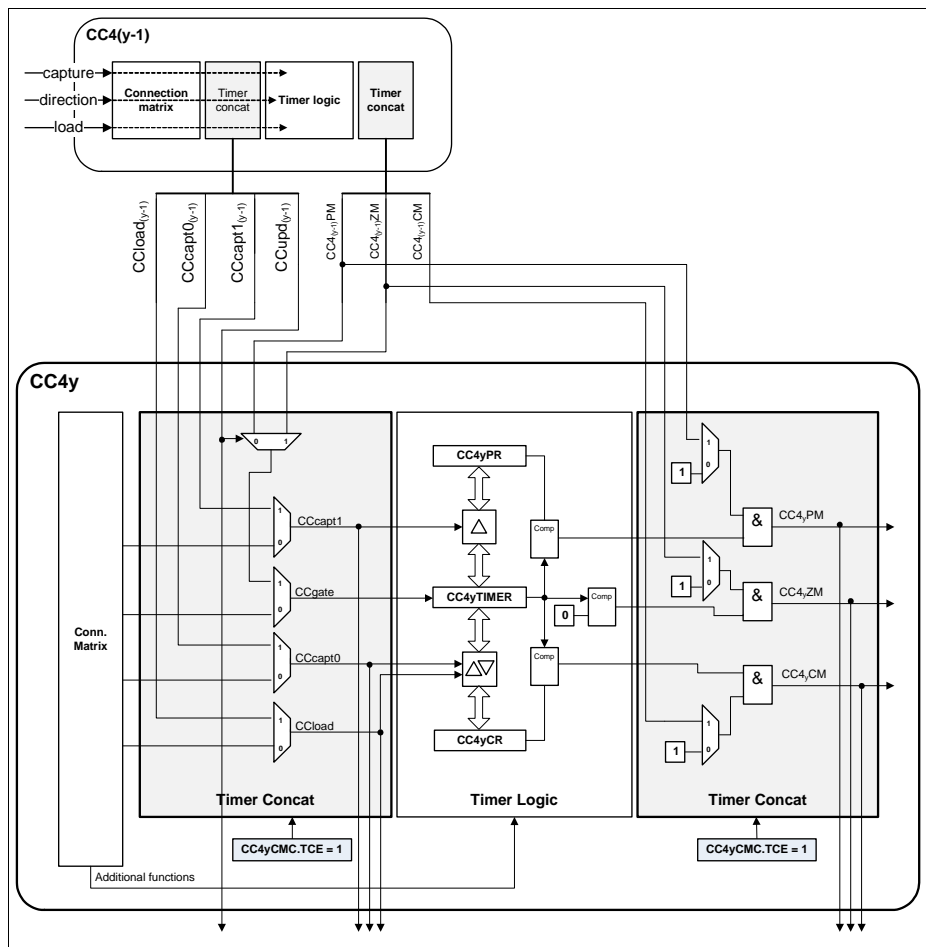

Figure 23-48 Timer concatenation control logic

23.2.10 PWM Dithering

The CCU4 has an automatic PWM dithering insertion function. This functionality can be used with very slow control loops that cannot update the period/compare values in a fast manner, and by that fact the loop can lose precision on long runs. By introducing dither on the PWM signal, the average frequency/duty cycle is then compensated against that error.

Each slice contains a dither control unit, see [Figure 23-49](#).

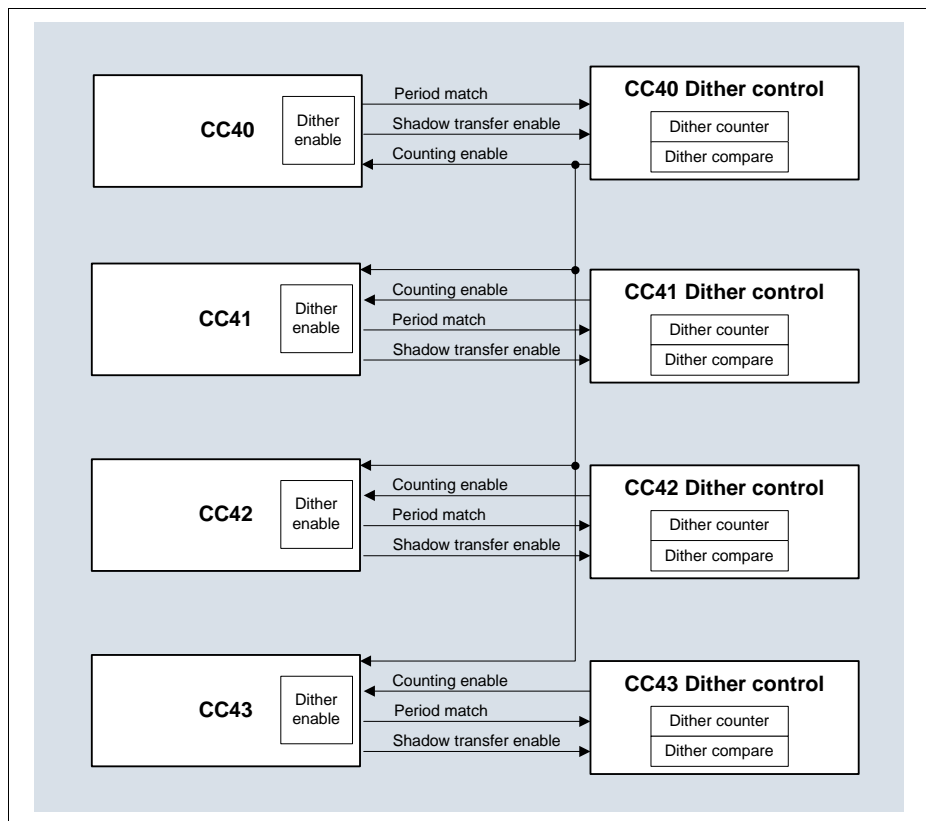

Figure 23-49 Dither structure overview

The dither control unit contains a 4 bit counter and a compare value. The four bit counter is incremented every time that a period match occurs. The counter works in a bit reverse mode so the distribution of increments stays uniform over 16 counter periods, see [Table 23-5](#).

Table 23-5 Dither bit reverse counter

| counter[3] | counter[2] | counter[1] | counter[0] |
|------------|------------|------------|------------|
| 0 | 0 | 0 | 0 |
| 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 |
| 1 | 1 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 |
| 0 | 1 | 1 | 0 |
| 1 | 1 | 1 | 0 |
| 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 1 |
| 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 1 |
| 0 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 |

The counter is then compared against a programmed value, **CC4yDIT.DCV**. If the counter value is smaller than the programmed value, a gating signal is generated that can be used to extend the period, to delay the compare or both (controlled by the **CC4yTC.DITHE** field, see [Table 23-6](#)) for one clock cycle.

Table 23-6 Dither modes

| DITHE[1] | DITH[0] | Mode |
|----------|---------|--|
| 0 | 0 | Dither is disabled |
| 0 | 1 | Period is increased by 1 cycle |
| 1 | 0 | Compare match is delayed by 1 cycle |
| 1 | 1 | Period is increased by 1 cycle and compare is delayed by 1 cycle |

The dither compare value also has an associated shadow register that enables concurrent update with the period/compare register of CC4y. The control logic for the dithering unit is represented on [Figure 23-50](#).

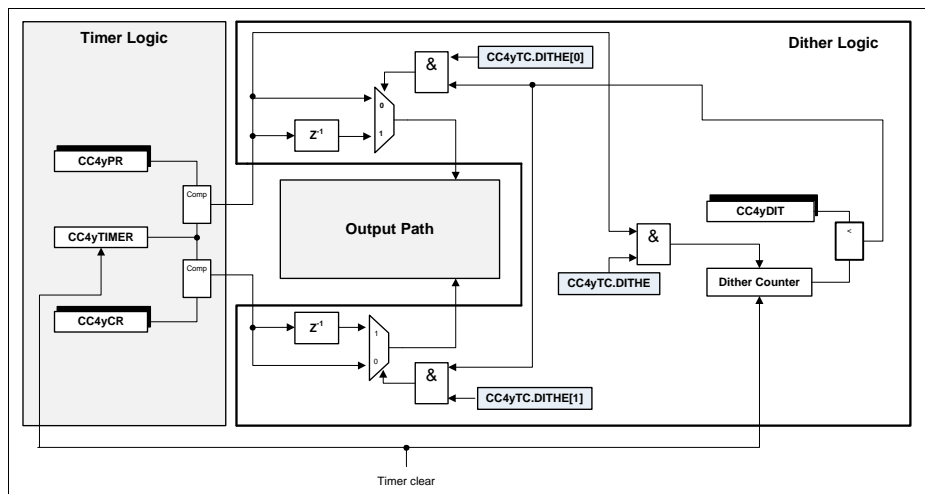

Figure 23-50 Dither control logic

Figure 23-51 to **Figure 23-56** show the effect of the different configurations for the dithering function, **CC4yTC.DITHE**, for both counting schemes, Edge and Center Aligned mode. In each figure, the bit reverse scheme is represented for the dither counter and the compare value was programmed with the value 8_H . In each figure, the variable T , represents the period of the counter, while the variable d indicates the duty cycle (status bit is set HIGH).

Figure 23-51 Dither timing diagram in edge aligned - **CC4yTC.DITHE = 01_B**

Figure 23-52 Dither timing diagram in edge aligned - $\text{CC4yTC.DITHE} = 10_{\text{B}}$

Figure 23-53 Dither timing diagram in edge aligned - $\text{CC4yTC.DITHE} = 11_{\text{B}}$

Figure 23-54 Dither timing diagram in center aligned - $\text{CC4yTC.DITHE} = 01_{\text{B}}$

Figure 23-55 Dither timing diagram in center aligned - **CC4yTC.DITHE = 10_B**

Figure 23-56 Dither timing diagram in center aligned - **CC4yTC.DITHE = 11_B**

Note: When using the dither, is not possible to select a period value of FS when in edge aligned mode. In center aligned mode, the period value must be at least FS - 2.

23.2.11 Prescaler

The CCU4 contains a 4 bit prescaler that can be used in two operating modes for each individual slice:

- normal prescaler mode
- floating prescaler mode

The run bit of the prescaler can be set/cleared by SW by writing into the registers, **GIDLC.SPRB** and **GIDLS.CPRB** respectively, and it can also be cleared by the run bit of a specific slice. With the last mechanism, the run bit of the prescaler is cleared one clock cycle after the clear of the run bit of the selected slice. To select which slice can perform this action, one should program the **GCTRL.PRBC** register.

23.2.11.1 Normal Prescaler Mode

In Normal prescaler mode the clock fed to the CC4y counter is a normal fixed division by N, accordingly to the value set in the **CC4yPSC**.PSIV register. The values for the possible division values are listed in **Table 23-7**. The **CC4yPSC**.PSIV value is only modified by a SW access. Notice that each slice has a dedicated prescaler value selector (**CC4yPSC**.PSIV), which means that the user can select different counter clocks for each Timer Slice (CC4y).

Table 23-7 Timer clock division options

| CC4yPSC.PSIV | Resulting clock |
|---------------------|------------------------|
| 0000 _B | f_{CCU4} |
| 0001 _B | $f_{CCU4}/2$ |
| 0010 _B | $f_{CCU4}/4$ |
| 0011 _B | $f_{CCU4}/8$ |
| 0100 _B | $f_{CCU4}/16$ |
| 0101 _B | $f_{CCU4}/32$ |
| 0110 _B | $f_{CCU4}/64$ |
| 0111 _B | $f_{CCU4}/128$ |
| 1000 _B | $f_{CCU4}/256$ |
| 1001 _B | $f_{CCU4}/512$ |
| 1010 _B | $f_{CCU4}/1024$ |
| 1011 _B | $f_{CCU4}/2048$ |
| 1100 _B | $f_{CCU4}/4096$ |
| 1101 _B | $f_{CCU4}/8192$ |
| 1110 _B | $f_{CCU4}/16384$ |
| 1111 _B | $f_{CCU4}/32768$ |

23.2.11.2 Floating Prescaler Mode

The floating prescaler mode can be used individually in each slice by setting the register **CC4yTC**.FPE = 1_B. With this mode, the user can not only achieve a better precision on the counter clock for compare operations but also reduce the SW read access for the capture mode.

The floating prescaler mode contains additionally to the initial configuration value register, **CC4yPSC**.PSIV, a compare register, **CC4yFPC**.PCMP with an associated shadow register mechanism.

Capture/Compare Unit 4 (CCU4)

Figure 23-57 shows the structure of the prescaler in floating mode when the specific slice is in compare mode (no external signal is used for capture). In this mode, the value of the clock division is incremented by 1_D every time that a timer overflow/underflow (overflow if in Edge Aligned Mode, underflow if in Center Aligned Mode) occurs.

In this mode, the Compare Match from the timer is AND gated with the Compare Match of the prescaler and every time that this event occurs, the value of the clock division is updated with the **CC4yPSC.PSIV** value in the immediately next timer overflow/underflow event.

The shadow transfer of the floating prescaler compare value, **CC4yFPC.PCMP**, is done following the same rules described on **Section 23.2.5.2**.

Figure 23-57 Floating prescaler in compare mode overview

When the specific CC4y is operating in capture mode (when at least one external signal is decoded as capture functionality), the actual value of the clock division also needs to be stored every time that a capture event occurs. The floating prescaler can have up to 4 capture registers (the maximum number of capture registers is dictated by the number of capture registers used in the specific slice).

The clock division value continues to be incremented by 1_D every time that a timer overflow (in capture mode, the slice is always operating in Edge Aligned Mode) occurs and it is loaded with the PSIV value every time that a capture triggers is detected.

See the **Section 23.2.12.2** for a full description of the usage of the floating prescaler mode in conjunction with compare and capture modes.

Figure 23-58 Floating Prescaler in capture mode overview

23.2.12 CCU4 Usage

23.2.12.1 PWM Signal Generation

The CCU4 offers a very flexible range in duty cycle configurations. This range is comprised between 0 to 100%.

To generate a PWM signal with a 100% duty cycle in Edge Aligned Mode, one should program the compare value, **CC4yCR.CR**, to 0000_H, see [Figure 23-59](#).

In the same manner a 100% duty cycle signal can be generated in Center Aligned Mode, see [Figure 23-60](#).

Figure 23-59 PWM with 100% duty cycle - Edge Aligned Mode

Figure 23-60 PWM with 100% duty cycle - Center Aligned Mode

To generate a PWM signal with 0% duty cycle in Edge Aligned Mode, the compare register should be set with the value programmed into the period value plus 1. In the case that the timer is being used with the full 16 bit capability (counting from 0 to 65535), setting a value bigger than the period value into the compare register is not possible and therefore the smallest duty cycle that can be achieved is 1/FS, see [Figure 23-61](#).

In Center Aligned Mode, the counter is never running from 0 to 65535_D, due to the fact that it has to overshoot for one clock cycle the value set in the period register. Therefore the user never has a FS counter, which means that generating a 0% duty cycle signal is

Capture/Compare Unit 4 (CCU4)

always possible by setting a value in the compare register bigger than the one programmed into the period register, see [Figure 23-62](#).

Figure 23-61 PWM with 0% duty cycle - Edge Aligned Mode

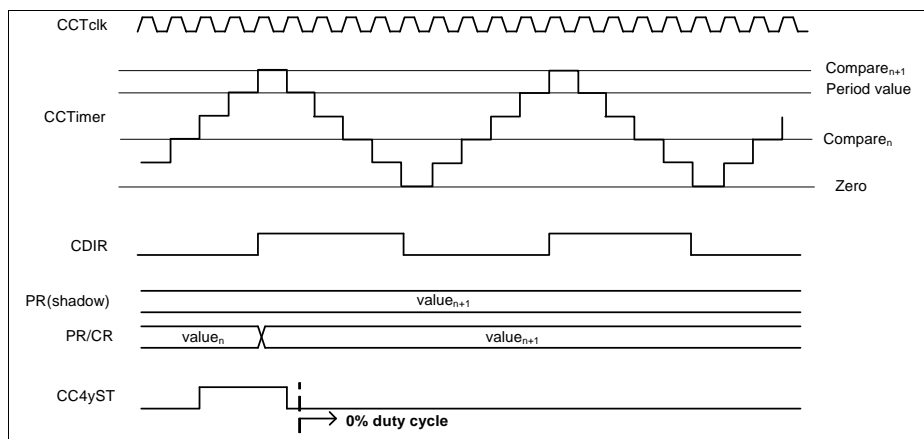

Figure 23-62 PWM with 0% duty cycle - Center Aligned Mode

23.2.12.2 Prescaler Usage

In Normal Prescaler Mode, the frequency of the f_{clk} fed to the specific CC4y is chosen from the [Table 23-7](#), by setting the **CC4yPSC.PSIV** with the required value.

In Floating Prescaler Mode, the frequency of the f_{clk} can be modified over a selected timeframe, within the values specified in [Table 23-7](#). This mechanism is specially useful if, when in capture mode, the dynamic of the capture triggers is very slow or unknown.

Capture/Compare Unit 4 (CCU4)

In Capture Mode, the Floating Prescaler value is incremented by 1 every time that a timer overflow happens and it is set with the initial programmed value when a capture event happens, see [Figure 23-63](#).

When using the Floating Prescaler Mode in Capture Mode, the timer should be cleared each time that a capture event happens, **CC4yTC.CAPC** = 11_B. By operating the Capture mode in conjunction with the Floating Prescaler, even for capture signals that have a periodicity bigger that 16 bits, it is possible to use just a single CCU4 Timer Slice without monitoring the interrupt event of the timer overflow, cycle by cycle. For this the user just needs to know what is the timer captured value and the actual prescaler configuration at the time that the capture event occurred. These values are contained in each CC4yCxV register.

Figure 23-63 Floating Prescaler capture mode usage

When in Compare Mode, the Floating Prescaler function may be used to achieve a fractional PWM frequency or to perform some frequency modulation.

The same incrementing by 1_D mechanism is done every time that a overflow/underflow of the Timer occurs and the actual Prescaler value, doesn't match the one programmed into the **CC4yFPC.PCMP** register.

When a Compare Match from the Timer occurs and the actual Prescaler value is equal to the one programmed on the **CC4yFPC.PCMP** register, then the Prescaler value is set with the initial value, **CC4yPSC.PSIV**, when the next occurrence of a timer overflow/underflow.

In [Figure 23-64](#), the Compare value of the Floating Prescaler was set to PSIV + 2. Every time that a timer overflow occurs, the value of the Prescaler is incremented by 1, which means that if we give f_{tclk} as the reference frequency for the **CC4yPSC.PSIV** value, we have $f_{tclk}/2$ for **CC4yPSC.PSIV + 1** and $f_{tclk}/4$ for **CC4yPSC.PSIV + 2**.

The period over time of the counter becomes:

$$Period = (1/f_{tclk} + 2/f_{tclk} + 4/f_{tclk}) / 3 \quad (23.10)$$

Capture/Compare Unit 4 (CCU4)

The same mechanism is used in Center Aligned Mode, but to keep the rising arcade and falling arcade always symmetrical, instead of the overflow of the timer, the underflow is used, see [Figure 23-65](#).

Figure 23-64 Floating Prescaler compare mode usage - Edge Aligned

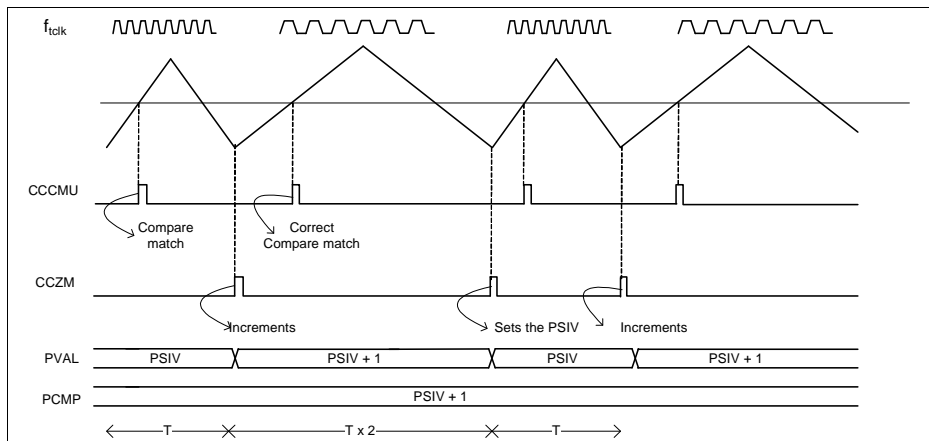

Figure 23-65 Floating Prescaler compare mode usage - Center Aligned

23.2.12.3 PWM Dither

The Dither functionality can be used to achieve a very fine precision on the periodicity of the output state in compare mode. The value set in the dither compare register, **CC4yDIT.DCV** is crosschecked against the actual value of the dither counter and every

Capture/Compare Unit 4 (CCU4)

time that the dither counter is smaller than the comparison value one of the follows actions is taken:

- The period is extended for 1 clock cycle - **CC4yTC.DITHE** = 01_B; in edge aligned mode
- The period is extended for 2 clock cycles - **CC4yTC.DITHE** = 01_B; in center aligned mode
- The comparison match while counting up (**CC4yTCST.CDIR** = 0_B) is delayed (this means that the status bit is going to stay in the SET state 1 cycle less) for 1 clock cycle - **CC4yTC.DITHE** = 10_B;
- The period is extended for 1 clock cycle and the comparison match while counting up is delayed for 1 clock cycle - **CC4yTC.DITHE** = 11_B; in edge aligned mode
- The period is extended for 2 clock cycles and the comparison match while counting up is delayed for 1 clock cycle; center aligned mode

The bit reverse counter distributes the number programmed in the **CC4yDIT.DCV** throughout a window of 16 timer periods.

Table 23-8 describes the bit reverse distribution versus the programmed value on the **CC4yDIT.DCV** field. The fields marked as '0' indicate that in that counter period, one of the above described actions, is going to be performed.

Table 23-8 Bit reverse distribution

| | DCV | | | | | | | | | | | | | | | |
|----------------|-----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| Dither counter | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| C | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 |
| 2 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| A | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 |
| 6 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| E | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 |
| 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 9 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| 5 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 3 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| B | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |

Table 23-8 Bit reverse distribution (cont'd)

| | DCV | | | | | | | | | | | | | | | |
|----------------|-----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| Dither counter | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 7 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| F | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

The bit reverse distribution versus the programmed **CC4yDIT.DCV** value results in the following values for the Period and duty cycle:

DITHE = 01_B

Period = [(16 - DCV) x T + DCV x (T + 1)]/16; in Edge Aligned Mode (23.11)

Duty cycle = [(16 - DCV) x d/T + DCV x (d+1)/(T + 1)]/16; in Edge Aligned Mode(23.12)

Period = [(16 - DCV) x T + DCV x (T + 2)]/16; in Center Aligned Mode (23.13)

Duty cycle = [(16 - DCV) x d/T + DCV x (d+2)/(T + 2)]/16; in Center Aligned Mode(23.14)

DITHE = 10_B

Period = T ; in Edge Aligned Mode (23.15)

Duty cycle = [(16 - DCV) x d/T + DCV x (d-1)/T]/16; in Edge Aligned Mode (23.16)

Period = T ; in Center Aligned Mode (23.17)

Duty cycle = [(16 - DCV) x d/T + DCV x (d-1)/T]/16; in Center Aligned Mode (23.18)

DITHE = 11_B

Period = [(16 - DCV) x T + DCV x (T + 1)]/16; in Edge Aligned Mode (23.19)

Duty cycle = [(16 - DCV) x d/T + DCV x d/(T + 1)]/16; in Edge Aligned Mode (23.20)

Period = [(16 - DCV) x T + DCV x (T + 2)]/16; in Center Aligned Mode (23.21)

Duty cycle = [(16 - DCV) x d/T + DCV x (d+1)/(T + 2)]/16; in Center Aligned Mode(23.22)

where:

T - Original period of the signal, see [Section 23.2.5.1](#)

d - Original duty cycle of the signal, see [Section 23.2.5.1](#)

23.2.12.4 Capture Mode Usage

Each Timer Slice can make use of 2 or 4 capture registers. Using only 2 capture registers means that only 1 Event was linked to a captured trigger. To use the four capture registers, both capture triggers need to be mapped into an Event (it can be the same signal with different edges selected or two different signals) or the **CC4yTC.SCE** field needs to be set to 1, which enables the linking of the 4 capture registers.

The internal slice mechanism for capturing is the same for the capture trigger 1 or capture trigger 0.

Different Capture Events - SCE = 0_B

Capture trigger 1 (CCcapt1) is appointed to the capture register 2, **CC4yC2V** and capture register 3, **CC4yC3V**, while trigger 0 (CCcapt0) is appointed to capture register 1, **CC4yC1V** and 0, **CC4yC0V**.

In each CCcapt0 event, the timer value is stored into **CC4yC1V** and the value of the **CC4yC1V** is transferred into the **CC4yC0V**.

In each CCcapt1 event, the timer value is stored into capture register **CC4yC3V** and the value of the capture register **CC4yC3V** is transferred into **CC4yC2V**.

The capture/transfer mechanism only happens if the specific register is not full. A capture register becomes full when receives a new value and becomes empty after the SW has read back the value.

The full flag is cleared every time that the SW reads back the **CC4yC0V**, **CC4yC1V**, **CC4yC2V** or **CC4yC3V** register. The SW can be informed of a new capture trigger by enabling the interrupt source linked to the specific Event. This means that every time that a capture is made an interrupt pulse is generated.

In the case that the Floating Prescaler Mode is being used, the actual value of the clock division is also stored in the capture register (CC4yCxV).

Figure 23-66 shows an example of how the capture/transfer may be used in a Timer Slice that is using an external signal as count function (to measure the velocity of a rotating device), and an equidistant capture trigger that is used to dictate the timestamp for the velocity calculation (two Timer waveforms are plotted, one that exemplifies the clearing of the timer in each capture event and another without the clearing function active).

Figure 23-66 Capture mode usage - single channel

Same Capture Event - SCE = 1_B

If the **CC4yTC.SCE** is set to 1_B, all the four capture registers are chained together, emulating a fifo with a depth of 4. In this case, only the capture trigger 1, CCcapt1, is used to perform a capture event.

As an example for this mode, one can consider the case where one Timer Slice is being used in capture mode with SCE = 1_B, with another external signal that controls the counting. This timer slice can be incremented at different speeds, depending on the frequency of the counting signal.

An additional Timer Slice is used to control the capture trigger, dictating the time stamp for the capturing.

A simple scheme for this can be seen in **Figure 23-67**. The CC40ST output of slice 0 was used as capture trigger in the CC41 slice (active on rising and falling edge). The CC40ST output is used as known timebase marker, while the slice timer used for capture is being controlled by external events, e.g. external count.

Due to the fact that we have available 4 capture registers, every time that the SW reads back the complete set of values, 3 speed profiles can be measured.

Figure 23-67 Three Capture profiles - CC4yTC.SCE = 1_B

To calculate the three different profiles in [Figure 23-67](#), the 4 capture registers need to be read during the pointed read window. After that, the profile calculation is done:

$$\text{Profile 1} = \text{CC41C1V}_{\text{info}} - \text{CC41C0V}_{\text{info}}$$

$$\text{Profile 2} = \text{CC41C2V}_{\text{info}} - \text{CC41C1V}_{\text{info}}$$

Profile 3= CC41C3V_{info} - CC41C2V_{info}

Note: This is an example and therefore several Timer Slice configurations and software loops can be implemented.

High Dynamics Capturing

In some cases the dynamics of the capture trigger(s) may vary greatly over time. This will impose that the software needs to be prepared for the worst case scenario, where the frequency of the capture triggers may be very high. In applications where cycle-by-cycle calculation is needed (calculation in each capture trigger), then this constraints needs to be met by the software. Nevertheless for applications where a cycle-by-cycle calculation is not needed, the software can read back the FIFO data register in a periodic base and fetch all the data that has been captured so far, **Figure 23-68**.

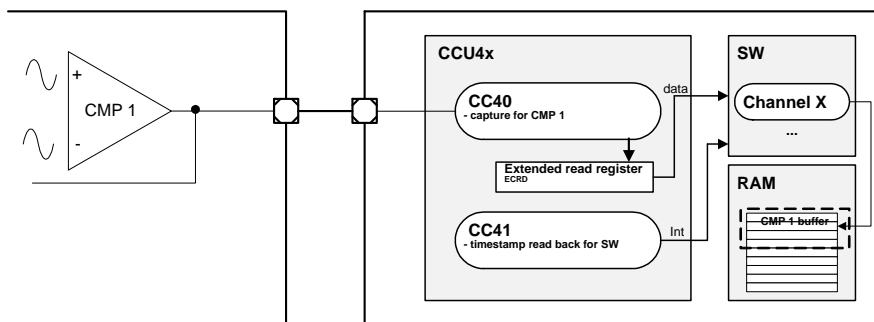

Figure 23-68 High dynamics capturing with software controlled timestamp

In this scenario, the software/CPU will read back the complete set of capture registers (2 or 4 depending on the chosen configuration), every time that an interrupt is triggered from the timestamp timer (the periodicity of this timer can also be adjusted on-the-fly).

Due to the fact that every capture register offers a full flag status bit, the software/CPU can always read back the complete set of registers. At the time of the data processing, this full flag is then checked, indicating if this value needs to be processed or not.

This FIFO read back functionality can also be used for applications that impose a heavy load on the system, which may not guarantee fixed access times to read back the captured data.

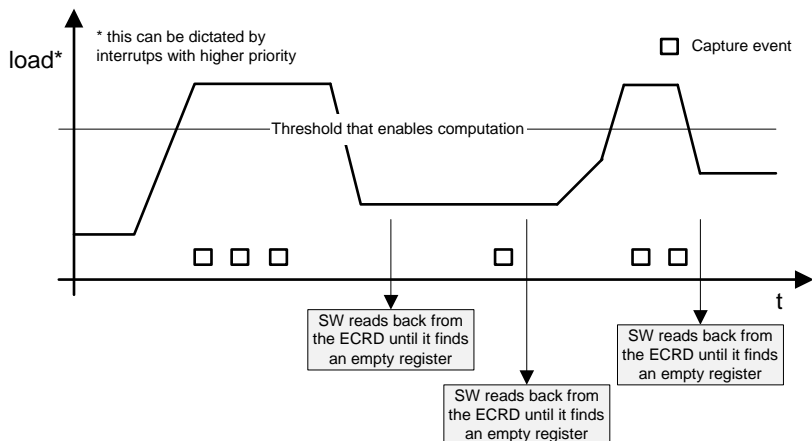

Figure 23-69 Extended read back during high load

Capture Grouping

In applications where multiple capture Timers are needed and the priority of the capture routines, does not imply that a cycle-by-cycle calculation needs to be done for every event, it may be suitable to group all the timers in the same CCU4x unit, [Figure 23-70](#).

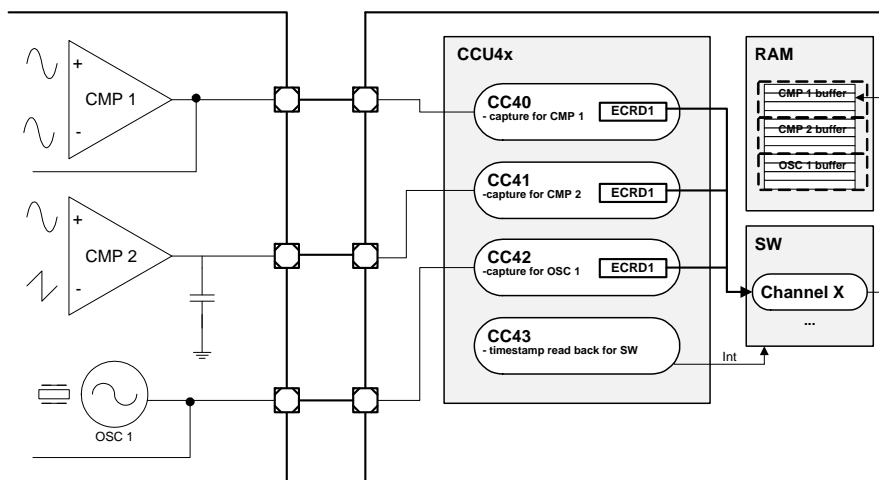

Figure 23-70 Capture grouping with extended read back

Capture/Compare Unit 4 (CCU4)

By setting the ECM bitfield for the Timer Slices used for capturing, the extended read back mode enables the reading back of data always in the proper capture order (from oldest to newest data). A timestamp timer is then used to trigger the Software/CPU to read back all the capture data present in the Timer Slices.

Every time that the interrupt is sensed, the Software/CPU (in this example) reads back the complete set of capture registers (via the ECRD address) for all Timer Slices. Due to the fact that each data read has a full flag indicator, the Software/CPU can read back the complete set of capture registers from all timers. This allows a fixed memory allocation that is as big as the number of captured registers, **Figure 23-71** (in this example 4 capture registers for each Timer Slice are being used).

The additional lost value bitfield (LCV) on the header of each ECRD data, will indicate if any capture trigger was lost between read operations (this can happen if the capture triggers are faster than the routine that is reading back the values).

Figure 23-71 Memory structure for extended read back

23.3 Service Request Generation

Each CCU4 slice has an interrupt structure as the one in [Figure 23-72](#). The register **CC4yINTS** is the status register for the interrupt sources. Each dedicated interrupt

Capture/Compare Unit 4 (CCU4)

source can be set or cleared by SW, by writing into the specific bit in the **CC4ySWS** and **CC4ySWR** registers respectively.

Each interrupt source can be enabled/disabled via the **CC4yINTE** register. An enabled interrupt source will always generate a pulse on the service request line even if the specific status bit was not cleared. **Table 23-9** describes the interrupt sources of each CCU4 slice.

The interrupt sources, Period Match while counting up and one Match while counting down are ORed together. The same mechanism is applied to the Compare Match while counting up and Compare Match while counting down.

The interrupt sources for the external events are directly linked with the configuration set on the **CC4yINS.EVxEM**. If an event is programmed to be active on both edges, that means that service request pulse is going to be generated when any transition on the external signal is detected. If the event is linked with a level function, the **CC4yINS.EVxEM** still can be programmed to enable a service request pulse. The TRAP event doesn't need any of extra configuration for generating the service request pulse when the slice enters the TRAP state.

Table 23-9 Interrupt sources

| Signal | Description |
|----------------|--|
| CCINEV0_E | Event 0 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCINEV1_E | Event 1 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCINEV2_E | Event 2 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCPM_U | Period Match while counting up |
| CCCM_U | Compare Match while counting up |
| CCCM_D | Compare Match while counting down |
| CCOM_D | One Match while counting down |
| Trap state set | Entering Trap State. Will set the E2AS |

Capture/Compare Unit 4 (CCU4)

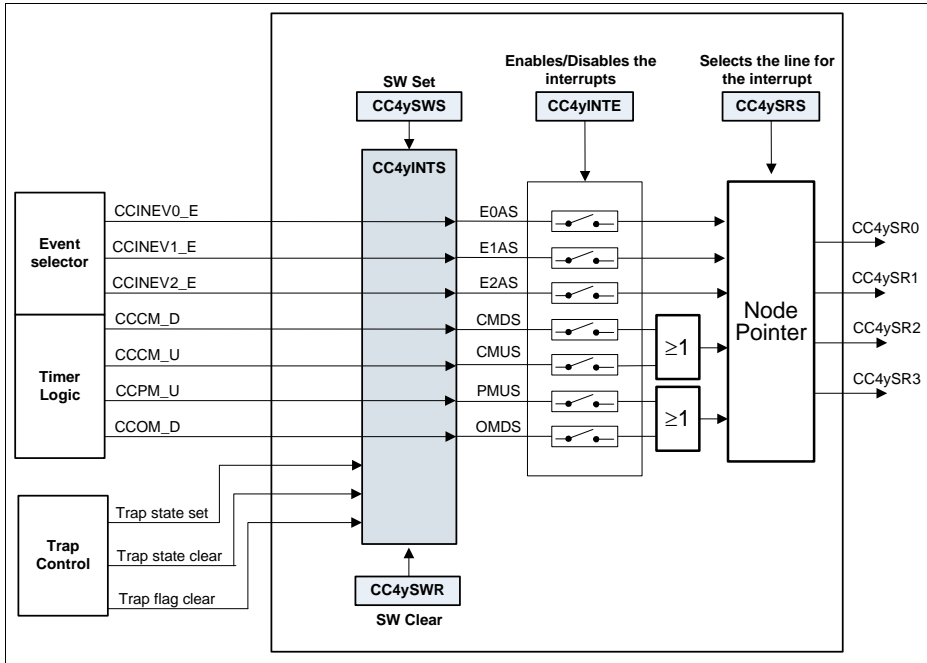

Figure 23-72 Slice interrupt structure overview

Each of the interrupt events can then be forwarded to one of the slice's four service request lines, [Figure 23-73](#). The value set on the **CC4ySRS** controls which interrupt event is mapped into which service request line.

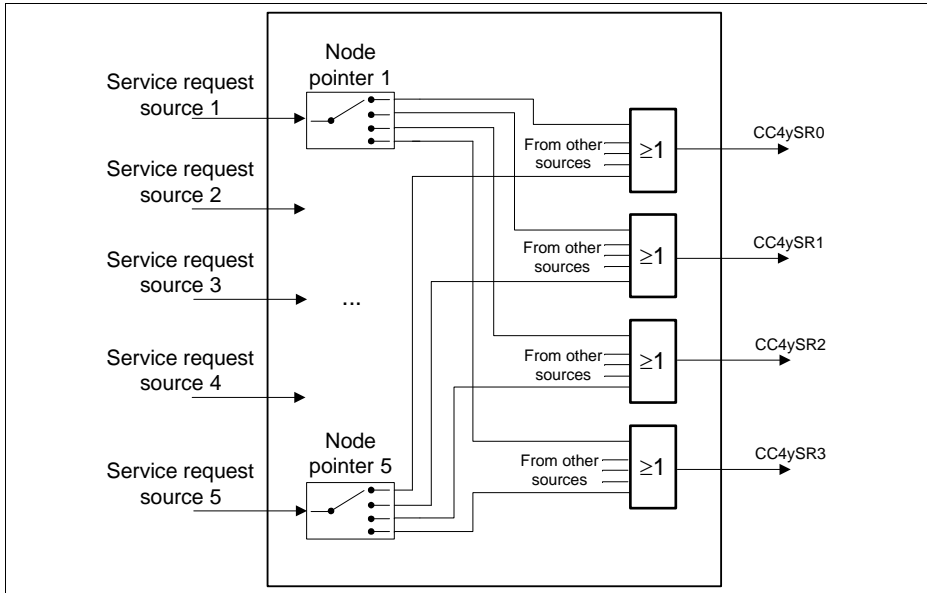

Figure 23-73 Slice Interrupt Node Pointer overview

The four service request lines of each slice are OR together inside the kernel of the CCU4, see [Figure 23-74](#). This means that there are only four service request lines per CCU4, that can have in each line interrupt requests coming from different slices.

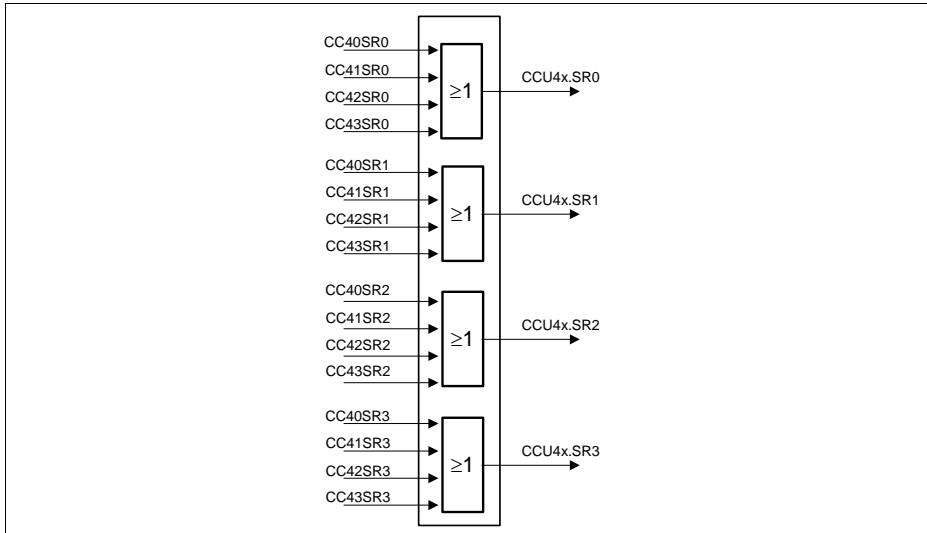

Figure 23-74 CCU4 service request overview

23.4 Debug Behavior

In suspend mode, the functional clocks for all slices as well the prescaler are stopped. The registers can still be accessed by the CPU (read only). This mode is useful for debugging purposes, e.g. where the current device status should be frozen in order to get a snapshot of the internal values. In suspend mode, all the slice timers are stopped. The suspend mode is non-intrusive concerning the register bits. This means register bits are not modified by hardware when entering or leaving the suspend mode.

Entry into suspend mode can be configured at the kernel level by means of the field **GCTRL.SUSCFG**.

The module is only functional after the suspend signal becomes inactive.

23.5 Power, Reset and Clock

The following sections describe the operating conditions, characteristics and timing requirements for the CCU4. All the timing information is related to the module clock, f_{CCU4} .

23.5.1 Clocks

Module Clock

The module clock of the CCU4 module is described in the SCU chapter as f_{CCU} .

The bus interface clock of the CCU4 module is described in the SCU chapter as f_{PERIPH} .

Capture/Compare Unit 4 (CCU4)

The module clock for the CCU4 is controlled via a specific control bit inside the SCU (System Control Unit), register CLKSET.

It is possible to disable the module clock for the CCU4 via the **GSTAT** register, nevertheless, there may be a dependency of the f_{ccu4} through the different CCU4 instances. One should address the SCU Chapter for a complete description of the product clock scheme.

If module clock dependencies exist through different IP instances, then one can disable the module clock internally inside the specific CCU4, by disabling the prescaler (**GSTAT.PR** = 0_B).

External Clock

It is possible to use an external clock as source for the prescaler, and consequently for all the timer Slices, CC4y. This external source can be connected to one of the CCU4x.CLK[C...A] inputs.

This external source is nevertheless synchronized against f_{ccu4} .

Table 23-10 External clock operating conditions

| Parameter | Symbol | Values | | | Unit | Note / Test Condition |
|-----------|---------------|--------------------|------|--------------|------|------------------------------|
| | | Min. | Typ. | Max. | | |
| Frequency | f_{eclk} | — | — | $f_{ccu4}/4$ | MHz | |
| ON time | ton_{eclk} | $2T_{ccu4}^{1)2)}$ | — | — | ns | |
| OFF time | $toff_{eclk}$ | $2T_{ccu4}^{1)2)}$ | — | — | ns | Only the rising edge is used |

1) Only valid if the signal was not previously synchronized/generated with the fccu4 clock (or a synchronous clock)

2) 50% duty cycle is not obligatory

23.5.2 Module Reset

Each CCU4 has one reset source. This reset source is handled at system level and it can be generated independently via a system control register, PRSET0/PRSET1 (address SCU chapter for a full description).

After reset release, the complete IP is set to default configuration. The default configuration for each register field is addressed on [Section 23.7](#).

23.5.3 Power

The CCU4 is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) chapter.

An internal power down mode for the CCU4, can be achieved by disabling the clock inside the CCU4 itself. For this one should set the **GSTAT** register with the default reset value (via the idle mode set register, **GIDLS**).

23.6 Initialization and System Dependencies

23.6.1 Initialization Sequence

The initialization sequence for an application that is using the CCU4, should be the following:

1st Step: Apply reset to the CCU4, via the specific SCU bitfield on the PRSET0/PRSET1 register.

2nd Step: Release reset of the CCU4, via the specific SCU bitfield on the PRCLR0/PRCLR1 register

3rd Step: Enable the CCU4 clock via the specific SCU register, CLKSET.

4th Step: Enable the prescaler block, by writing 1_B to the **GIDLC**.SPRB field.

5th Step: Configure the global CCU4 register **GCTRL**

6th Step: Configure all the registers related to the required Timer Slice(s) functions, including the interrupt/service request configuration.

7th Step: If needed, configure the startup value for a specific Compare Channel Status, of a Timer Slice, by writing 1_B to the specific **GCSS**.SyTS.

8th Step: Enable the specific timer slice(s), CC4y, by writing 1_B to the specific **GIDLC**.CSyl.

9th Step: For all the Timer Slices that should be started synchronously via SW, the specific system register localized in the SCU, CCUCON, that enables a synchronous timer start should be addressed. The SCU.GSC4x input signal needs to be configured previously as a start function, see **Section 23.2.7.1**.

23.6.2 System Dependencies

Each CCU4 may have different dependencies regarding module and bus clock frequencies. This dependencies should be addressed in the SCU and System Architecture Chapters.

Capture/Compare Unit 4 (CCU4)

Dependencies between several peripherals, regarding different clock operating frequencies may also exist. This should be addressed before configuring the connectivity between the CCU4 and some other peripheral.

The following topics must be taken into consideration for good CCU4 and system operation:

- CCU4 module clock must be at maximum two times faster than the module bus interface clock
- Module input triggers for the CCU4 must not exceed the module clock frequency (if the triggers are generated internally in the device)
- Module input triggers for the CCU4 must not exceed the frequency dictated in [Section 23.5.1](#)
- Frequency of the CCU4 outputs used as triggers/functions on other modules, must be crosschecked on the end point
- Applying and removing CCU4 from reset, can cause unwanted operations in other modules. This can occur if the modules are using CCU4 outputs as triggers/functions.

23.7 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 23-11 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|-----------------------|-----------------------|------|

1) The absolute register address is calculated as follows:

Module Base Address + Offset Address (shown in this column)

23.7.1 Global Registers

GCTRL

The register contains the global configuration fields that affect all the timer slices inside CCU4.

Capture/Compare Unit 4 (CCU4)

GCTRL

Global Control Register

(0000_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|------|-------|-------|-------|-------|--------|----|----|----|----|------|----|----|------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MSDE | MSE 3 | MSE 2 | MSE 1 | MSE 0 | SUSCFG | 0 | | | | PCIS | 0 | | PRBC | | |
| rw | rw | rw | rw | rw | rw | r | | | | rw | r | | rw | | |

| Field | Bits | Type | Description |
|-------|-------|------|--|
| PRBC | [2:0] | rw | Prescaler Clear Configuration This register controls how the prescaler Run Bit and internal registers are cleared. 000 _B SW only 001 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC40 is cleared. 010 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC41 is cleared. 011 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC42 is cleared. 100 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC43 is cleared. |
| PCIS | [5:4] | rw | Prescaler Input Clock Selection 00 _B Module clock 01 _B CCU4x.ECLKA 10 _B CCU4x.ECLKB 11 _B CCU4x.ECLKC |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------|-------|------|--|
| SUSCFG | [9:8] | rw | Suspend Mode Configuration This field controls the entering in suspend mode for all the CAPCOM4 slices. 00 _B Suspend request ignored. The module never enters in suspend 01 _B Stops all the running slices immediately. Safe stop is not applied. 10 _B Stops the block immediately and clamps all the outputs to PASSIVE state. Safe stop is applied. 11 _B Waits for the roll over of each slice to stop and clamp the slices outputs. Safe stop is applied. |
| MSE0 | 10 | rw | Slice 0 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 0 can be requested not only by SW but also via the CCU4x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU4x.MCSS input. |
| MSE1 | 11 | rw | Slice 1 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 1 can be requested not only by SW but also via the CCU4x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU4x.MCSS input. |
| MSE2 | 12 | rw | Slice 2 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 2 can be requested not only by SW but also via the CCU4x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU4x.MCSS input. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| MSE3 | 13 | rw | <p>Slice 3 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 3 can be requested not only by SW but also via the CCU4x.MCSS input.</p> <p>0_B Shadow transfer can only be requested by SW 1_B Shadow transfer can be requested via SW and via the CCU4x.MCSS input.</p> |
| MSDE | [15:14] | rw | <p>Multi Channel shadow transfer request configuration This field configures the type of shadow transfer requested via the CCU4x.MCSS input. The field CC4yTC.MSEy needs to be set in order for this configuration to have any effect.</p> <p>00_B Only the shadow transfer for period and compare values is requested 01_B Shadow transfer for the compare, period and prescaler compare values is requested 10_B Reserved 11_B Shadow transfer for the compare, period, prescaler and dither compare values is requested</p> |
| 0 | 3, [7:6], [31:16] | r | <p>Reserved A read always returns 0.</p> |

GSTAT

The register contains the status of the prescaler and each timer slice (idle mode or running).

GSTAT

Global Status Register

(0004_H)

Reset Value: 0000000F_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|-----|----|----|----|----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0 | | | | | | PSIC | CPR B | 0 | | | | SS3I | SS2I | SS1I | SS0I |
| r | | | | | | w | w | r | | | | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|--|
| SS0I | 0 | w | CC40 IDLE mode set Writing a 1_B to this bit sets the CC40 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS1I | 1 | w | CC41 IDLE mode set Writing a 1_B to this bit sets the CC41 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|-------------------|------|---|
| SS2I | 2 | w | CC42 IDLE mode set Writing a 1 _B to this bit sets the CC42 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS3I | 3 | w | CC43 IDLE mode set Writing a 1 _B to this bit sets the CC43 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| CPRB | 8 | w | Prescaler Run Bit Clear Writing a 1 _B into this register clears the Run Bit of the prescaler. Prescaler internal registers are not cleared. A read always returns 0. |
| PSIC | 9 | w | Prescaler clear Writing a 1 _B to this register clears the prescaler counter. It also loads the PSIV into the PVAL field for all Timer Slices. This performs a re alignment of the timer clock for all Slices. The Run Bit of the prescaler is not cleared. A read always returns 0. |
| 0 | [7:4], [31:10] | r | Reserved Read always returns 0. |

GIDLC

Through this register one can remove the prescaler and the specific timer slices from idle mode.

Capture/Compare Unit 4 (CCU4)

GIDLC

Global Idle Clear

(000C_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|------------------|------|---|
| CS0I | 0 | w | CC40 IDLE mode clear Writing a 1 _B to this bit removes the CC40 from IDLE mode. A read access always returns 0. |
| CS1I | 1 | w | CC41 IDLE mode clear Writing a 1 _B to this bit removes the CC41 from IDLE mode. A read access always returns 0. |
| CS2I | 2 | w | CC42 IDLE mode clear Writing a 1 _B to this bit removes the CC42 from IDLE mode. A read access always returns 0. |
| CS3I | 3 | w | CC43 IDLE mode clear Writing a 1 _B to this bit removes the CC43 from IDLE mode. A read access always returns 0. |
| SPRB | 8 | w | Prescaler Run Bit Set Writing a 1 _B into this register sets the Run Bit of the prescaler. A read always returns 0. |
| 0 | [7:4], [31:9] | r | Reserved Read always returns 0. |

GCSS

Through this register one can request a shadow transfer for the specific timer slice(s) and set the status bit for each of the compare channels.

GCSS

Global Channel Set

| Field | Bits | Type | Description |
|--------------|------|------|--|
| S0SE | 0 | w | Slice 0 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S0DSE | 1 | w | Slice 0 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S0PSE | 2 | w | Slice 0 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S0PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S1SE | 4 | w | Slice 1 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S1DSE | 5 | w | Slice 1 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|--|
| S1PSE | 6 | w | Slice 1 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S1PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S2SE | 8 | w | Slice 2 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S2DSE | 9 | w | Slice 2 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S2PSE | 10 | w | Slice 2 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S2PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S3SE | 12 | w | Slice 3 shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3SS field, enabling then a shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S3DSE | 13 | w | Slice 3 Dither shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3DSS field, enabling then a shadow transfer for the Dither compare value. A read always returns 0. |
| S3PSE | 14 | w | Slice 3 Prescaler shadow transfer set enable Writing a 1 _B to this bit will set the GCST.S3PSS field, enabling then a shadow transfer for the prescaler compare value. A read always returns 0. |
| S0STS | 16 | w | Slice 0 status bit set Writing a 1 _B into this field sets the status bit of slice 0 (GCST.CC40ST) to 1 _B . A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-----------------------------|------|---|
| S1STS | 17 | w | Slice 1 status bit set Writing a 1 _B into this field sets the status bit of slice 1 (GCST.CC41ST) to 1 _B . A read always returns 0. |
| S2STS | 18 | w | Slice 2 status bit set Writing a 1 _B into this field sets the status bit of slice 2 (GCST.CC42ST) to 1 _B . A read always returns 0. |
| S3STS | 19 | w | Slice 3 status bit set Writing a 1 _B into this field sets the status bit of slice 3 (GCST.CC43ST) to 1 _B . A read always returns 0. |
| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

GCSC

Through this register one can reset a shadow transfer request for the specific timer slice and clear the status bit for each the compare channels.

GCSC

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S0SC | 0 | w | Slice 0 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S0DSC | 1 | w | Slice 0 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S0PSC | 2 | w | Slice 0 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S0PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S1SC | 4 | w | Slice 1 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S1DSC | 5 | w | Slice 1 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S1PSC | 6 | w | Slice 1 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S1PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S2SC | 8 | w | Slice 2 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S2DSC | 9 | w | Slice 2 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S2PSC | 10 | w | Slice 2 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S2PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S3SC | 12 | w | Slice 3 shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3SS field, canceling any pending shadow transfer for the Period, Compare and Passive level values. A read always returns 0. |
| S3DSC | 13 | w | Slice 3 Dither shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3DSS field, canceling any pending shadow transfer for the Dither compare value. A read always returns 0. |
| S3PSC | 14 | w | Slice 3 Prescaler shadow transfer clear Writing a 1 _B to this bit will clear the GCST.S3PSS field, canceling any pending shadow transfer for the prescaler compare value. A read always returns 0. |
| S0STC | 16 | w | Slice 0 status bit clear Writing a 1 _B into this field clears the status bit of slice 0 (GCST.CC40ST) to 0 _B . A read always returns 0. |
| S1STC | 17 | w | Slice 1 status bit clear Writing a 1 _B into this field clears the status bit of slice 1 (GCST.CC41ST) to 0 _B . A read always returns 0. |
| S2STC | 18 | w | Slice 2 status bit clear Writing a 1 _B into this field clears the status bit of slice 2 (GCST.CC42ST) to 0 _B . A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-----------------------------|------|---|
| S3STC | 19 | w | Slice 3 status bit clear Writing a 1 _B into this field clears the status bit of slice 3 (GCST.CC43ST) to 0 _B . A read always returns 0. |
| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

GCST

This register holds the information of the shadow transfer requests and of each timer slice status bit.

|-------|------|------|--|
| S0SS | 0 | rh | Slice 0 shadow transfer status 0 _B Shadow transfer has not been requested 1 _B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S0DSS | 1 | rh | Slice 0 Dither shadow transfer status 0 _B Dither shadow transfer has not been requested 1 _B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S0PSS | 2 | rh | Slice 0 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S1SS | 4 | rh | Slice 1 shadow transfer status 0_B Shadow transfer has not been requested 1_B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S1DSS | 5 | rh | Slice 1 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S1PSS | 6 | rh | Slice 1 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S2SS | 8 | rh | Slice 2 shadow transfer status 0_B Shadow transfer has not been requested 1_B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S2DSS | 9 | rh | Slice 2 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|-----------------------------|------|---|
| S2PSS | 10 | rh | Slice 2 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S3SS | 12 | rh | Slice 3 shadow transfer status 0_B Shadow transfer has not been requested 1_B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S3DSS | 13 | rh | Slice 3 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S3PSS | 14 | rh | Slice 3 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| CC40ST | 16 | rh | Slice 0 status bit |
| CC41ST | 17 | rh | Slice 1 status bit |
| CC42ST | 18 | rh | Slice 2 status bit |
| CC43ST | 19 | rh | Slice 3 status bit |
| 0 | 3, 7, 11, 15, [31:20] | r | Reserved Read always returns 0. |

MIDR

This register contains the module identification number.

MIDR

Module Identification

(0080_H)

Reset Value: 00A6C0XX_H

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| MODR | [7:0] | r | Module Revision This bit field indicates the revision number of the module implementation (depending on the design step). The given value of 00 _H is a placeholder for the actual number. |
| MODT | [15:8] | r | Module Type |
| MODN | [31:16] | r | Module Number |

23.7.2 Slice (CC4y) Registers

CC4yINS

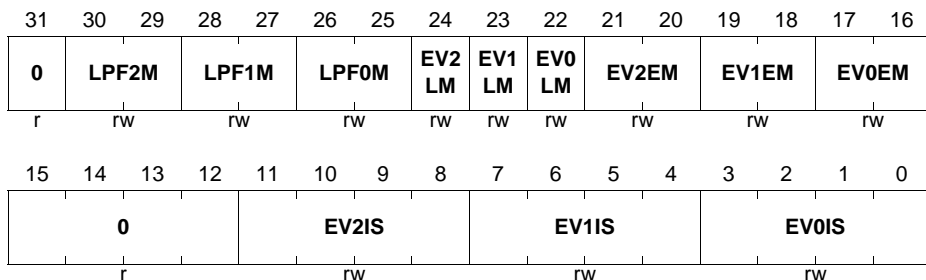

The register contains the configuration for the input selector.

CC4yINS (y = 0 - 3)

Input Selector Configuration

(0100_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| EV0IS | [3:0] | rw | Event 0 signal selection This field selects which pins is used for the event 0. 0000 _B CCU4x.INyA 0001 _B CCU4x.INyB 0010 _B CCU4x.INyC 0011 _B CCU4x.INyD 0100 _B CCU4x.INyE 0101 _B CCU4x.INyF 0110 _B CCU4x.INyG 0111 _B CCU4x.INyH 1000 _B CCU4x.INyI 1001 _B CCU4x.INyJ 1010 _B CCU4x.INyK 1011 _B CCU4x.INyL 1100 _B CCU4x.INyM 1101 _B CCU4x.INyN 1110 _B CCU4x.INyO 1111 _B CCU4x.INyP |
| EV1IS | [7:4] | rw | Event 1 signal selection Same as EV0IS description |
| EV2IS | [11:8] | rw | Event 2 signal selection Same as EV0IS description |
| EV0EM | [17:16] | rw | Event 0 Edge Selection 00 _B No action 01 _B Signal active on rising edge 10 _B Signal active on falling edge 11 _B Signal active on both edges |
| EV1EM | [19:18] | rw | Event 1 Edge Selection Same as EV0EM description |
| EV2EM | [21:20] | rw | Event 2 Edge Selection Same as EV0EM description |
| EV0LM | 22 | rw | Event 0 Level Selection 0 _B Active on HIGH level 1 _B Active on LOW level |
| EV1LM | 23 | rw | Event 1 Level Selection Same as EV0LM description |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-----------------|------|---|
| EV2LM | 24 | rw | Event 2 Level Selection Same as EV0LM description |
| LPF0M | [26:25] | rw | Event 0 Low Pass Filter Configuration This field sets the number of consecutive counts for the Low Pass Filter of Event 0. The input signal value needs to remain stable for this number of counts (f_{CCU4}), so that a level/transition is accepted. 00 _B LPF is disabled 01 _B 3 clock cycles of f_{CCU4} 10 _B 5 clock cycles of f_{CCU4} 11 _B 7 clock cycles of f_{CCU4} |
| LPF1M | [28:27] | rw | Event 1 Low Pass Filter Configuration Same description as LPF0M |
| LPF2M | [30:29] | rw | Event 2 Low Pass Filter Configuration Same description as LPF0M |
| 0 | [15:12] , 31 | r | Reserved Read always returns 0. |

CC4yCMC

The register contains the configuration for the connection matrix.

CC4yCMC (y = 0 - 3)

Connection Matrix Control (0104_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|------|----|-----|----|-----|----|-------|----|-------|----|-------|-----|------|----|-------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | TCE | MOS | TS | OFS | |
| r | | | | | | | | | | | rw | rw | rw | rw | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CNTS | | LDS | | UDS | | GATES | | CAP1S | | CAP0S | | ENDS | | STRTS | |
| rw | | rw | | rw | | rw | | rw | | rw | | rw | | rw | |

| Field | Bits | Type | Description |
|-------|-------|------|---|
| STRTS | [1:0] | rw | External Start Functionality Selector Selects the Event that is going to be linked with the external start functionality. 00 _B External Start Function deactivated 01 _B External Start Function triggered by Event 0 10 _B External Start Function triggered by Event 1 11 _B External Start Function triggered by Event 2 |
| ENDS | [3:2] | rw | External Stop Functionality Selector Selects the Event that is going to be linked with the external stop functionality. 00 _B External Stop Function deactivated 01 _B External Stop Function triggered by Event 0 10 _B External Stop Function triggered by Event 1 11 _B External Stop Function triggered by Event 2 |
| CAP0S | [5:4] | rw | External Capture 0 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 1 and 0. 00 _B External Capture 0 Function deactivated 01 _B External Capture 0 Function triggered by Event 0 10 _B External Capture 0 Function triggered by Event 1 11 _B External Capture 0 Function triggered by Event 2 |
| CAP1S | [7:6] | rw | External Capture 1 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 3 and 2. 00 _B External Capture 1 Function deactivated 01 _B External Capture 1 Function triggered by Event 0 10 _B External Capture 1 Function triggered by Event 1 11 _B External Capture 1 Function triggered by Event 2 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| GATES | [9:8] | rw | External Gate Functionality Selector Selects the Event that is going to be linked with the counter gating function. This function is used to gate the timer increment/decrement procedure. 00 _B External Gating Function deactivated 01 _B External Gating Function triggered by Event 0 10 _B External Gating Function triggered by Event 1 11 _B External Gating Function triggered by Event 2 |
| UDS | [11:10] | rw | External Up/Down Functionality Selector Selects the Event that is going to be linked with the Up/Down counting direction control. 00 _B External Up/Down Function deactivated 01 _B External Up/Down Function triggered by Event 0 10 _B External Up/Down Function triggered by Event 1 11 _B External Up/Down Function triggered by Event 2 |
| LDS | [13:12] | rw | External Timer Load Functionality Selector Selects the Event that is going to be linked with the timer load function. 00 _B - External Load Function deactivated 01 _B - External Load Function triggered by Event 0 10 _B - External Load Function triggered by Event 1 11 _B - External Load Function triggered by Event 2 |
| CNTS | [15:14] | rw | External Count Selector Selects the Event that is going to be linked with the count function. The counter is going to be increment/decremented each time that a specific transition on the event is detected. 00 _B External Count Function deactivated 01 _B External Count Function triggered by Event 0 10 _B External Count Function triggered by Event 1 11 _B External Count Function triggered by Event 2 |
| OFS | 16 | rw | Override Function Selector This field enables the ST bit override functionality. 0 _B Override functionality disabled 1 _B Status bit trigger override connected to Event 1; Status bit value override connected to Event 2 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| TS | 17 | rw | Trap Function Selector This field enables the trap functionality. 0_B Trap function disabled 1_B TRAP function connected to Event 2 |
| MOS | [19:18] | rw | External Modulation Functionality Selector Selects the Event that is going to be linked with the external modulation function. 00_B - Modulation Function deactivated 01_B - Modulation Function triggered by Event 0 10_B - Modulation Function triggered by Event 1 11_B - Modulation Function triggered by Event 2 |
| TCE | 20 | rw | Timer Concatenation Enable This bit enables the timer concatenation with the previous slice. 0_B Timer concatenation is disabled 1_B Timer concatenation is enabled <i>Note: In CC40 this field doesn't exist. This is a read only reserved field. Read access always returns 0.</i> |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yTCST

The register holds the status of the timer (running/stopped) and the information about the counting direction (up/down).

CC4yTCST (y = 0 - 3)

Slice Timer Status (0108_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | | | | CDIR | TRB |
| r | | | | | | | | | | | | | | rh | rh |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TRB | 0 | rh | Timer Run Bit This field indicates if the timer is running. 0_B Timer is stopped 1_B Timer is running |
| CDIR | 1 | rh | Timer Counting Direction This field indicates if the timer is being increment or decremented 0_B Timer is counting up 1_B Timer is counting down |
| 0 | [31:2] | r | Reserved Read always returns 0 |

CC4yTCSET

Through this register it is possible to start the timer.

CC4yTCSET (y = 0 - 3)

Slice Timer Run Set (010C_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TRBS | 0 | w | Timer Run Bit set Writing a 1_B into this field sets the run bit of the timer. Read always returns 0. |
| 0 | [31:1] | r | Reserved Read always returns 0 |

CC4yTCCLR

Through this register it is possible to stop and clear the timer, and clearing also the dither counter

CC4yTCCLR (y = 0 - 3)

Slice Timer Clear

(0110_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TRBC | 0 | w | Timer Run Bit Clear Writing a 1 _B into this field clears the run bit of the timer. The timer is not cleared. Read always returns 0. |
| TCC | 1 | w | Timer Clear Writing a 1 _B into this field clears the timer to 0000 _H . Read always returns 0. |
| DITC | 2 | w | Dither Counter Clear Writing a 1 _B into this field clears the dither counter to 0 _H . Read always returns 0. |
| 0 | [31:3] | r | Reserved Read always returns 0 |

CC4yTC

This register holds the several possible configurations for the timer operation.

Capture/Compare Unit 4 (CCU4)

CC4yTC (y = 0 - 3)

Slice Timer Control

(0114_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|-----|-------|----|-----|-----|----------|----------|-----|-----|-----------|-----------|-----|----------|----------|-----------|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | MCM E | EMT | EMS | TRP SW | TRP SE | 0 | | | TRA PE | FPE |
| r | | | | | | rw | rw | rw | rw | rw | | r | | rw | rw |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| DIM | DITHE | | CCS | SCE | STR M | ENDM | | 0 | CAPC | | ECM | CMO D | CLS T | TSS M | TCM |
| rw | rw | | rw | rw | rw | rw | | r | rw | | rw | rh | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|---|
| TCM | 0 | rw | Timer Counting Mode This field controls the actual counting scheme of the timer. 0 _B Edge aligned mode 1 _B Center aligned mode <i>Note: When using an external signal to control the counting direction, the counting scheme is always edge aligned.</i> |
| TSSM | 1 | rw | Timer Single Shot Mode This field controls the single shot mode. This is applicable in edge and center aligned modes. 0 _B Single shot mode is disabled 1 _B Single shot mode is enabled |
| CLST | 2 | rw | Shadow Transfer on Clear Setting this bit to 1 _B enables a shadow transfer when a timer clearing action is performed. Notice that the shadow transfer enable bitfields on the GCST register still need to be set to 1 _B via software. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------|------|---|
| CMOD | 3 | rh | Capture Compare Mode This field indicates in which mode the slice is operating. The default value is compare mode. The capture mode is automatically set by the HW when an external signal is mapped to a capture trigger. 0 _B Compare Mode 1 _B Capture Mode |
| ECM | 4 | rw | Extended Capture Mode This field control the Capture mode of the specific slice. It only has effect if the CMOD bit is 1 _B . 0 _B Normal Capture Mode. Clear of the Full Flag of each capture register is done by accessing the registers individually only. 1 _B Extended Capture Mode. Clear of the Full Flag of each capture register is done not only by accessing the individual registers but also by accessing the ECRD register. When reading the ECRD register, only the capture register register full flag pointed by the ECRD.VPTR is cleared. |
| CAPC | [6:5] | rw | Clear on Capture Control 00 _B Timer is never cleared on a capture event 01 _B Timer is cleared on a capture event into capture registers 2 and 3. (When SCE = 1 _B , Timer is always cleared in a capture event) 10 _B Timer is cleared on a capture event into capture registers 0 and 1. (When SCE = 1 _B , Timer is always cleared in a capture event) 11 _B Timer is always cleared in a capture event. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------|------|--|
| ENDM | [9:8] | rw | Extended Stop Function Control This field controls the extended functions of the external Stop signal. 00 _B Clears the timer run bit only (default stop) 01 _B Clears the timer only (flush) 10 _B Clears the timer and run bit (flush/stop) 11 _B Reserved <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is counting up and with the Period value if the counter is being decremented.</i> |
| STRM | 10 | rw | Extended Start Function Control This field controls the extended functions of the external Start signal. 0 _B Sets run bit only (default start) 1 _B Clears the timer and sets run bit (flush/start) <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is being incremented and with the Period value if the counter is being decremented.</i> |
| SCE | 11 | rw | Equal Capture Event enable 0 _B Capture into CC4yC0V/CC4yC1V registers control by CCycapt0 and capture into CC4yC3V/CC4yC2V control by CCycapt1 1 _B Capture into CC4yC0V/CC4yC1V and CC4yC3V/CC4yC2V control by CCycapt1 |
| CCS | 12 | rw | Continuous Capture Enable 0 _B The capture into a specific capture register is done with the rules linked with the full flags, described at Section 23.2.7.6 . 1 _B The capture into the capture registers is always done regardless of the full flag status (even if the register has not been read back). |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| DITHE | [14:13] | rw | Dither Enable This field controls the dither mode for the slice. See Section 23.2.10 . 00 _B Dither is disabled 01 _B Dither is applied to the Period 10 _B Dither is applied to the Compare 11 _B Dither is applied to the Period and Compare |
| DIM | 15 | rw | Dither input selector This fields selects if the dither control signal is connected to the dither logic of the specific slice of is connected to the dither logic of slice 0. Notice that even if this field is set to 1 _B , the field DITHE still needs to be programmed. 0 _B Slice is using its own dither unit 1 _B Slice is connected to the dither unit of slice 0. |
| FPE | 16 | rw | Floating Prescaler enable Setting this bit to 1 _B enables the floating prescaler mode. 0 _B Floating prescaler mode is disabled 1 _B Floating prescaler mode is enabled |
| TRAPE | 17 | rw | TRAP enable Setting this bit to 1 _B enables the TRAP action at the output pin. After mapping an external signal to the TRAP functionality, the user must set this field to 1 _B to activate the effect of the TRAP on the output pin. Writing a 0 _B into this field disables the effect of the TRAP function regardless of the state of the input signal. 0 _B TRAP functionality has no effect on the output 1 _B TRAP functionality affects the output |
| TRPSE | 21 | rw | TRAP Synchronization Enable Writing a 1 _B into this bit enables a synchronous exiting with the PWM signal of the trap state. 0 _B Exiting from TRAP state isn't synchronized with the PWM signal 1 _B Exiting from TRAP state is synchronized with the PWM signal |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------------|------|---|
| TRPSW | 22 | rw | TRAP State Clear Control 0_B The slice exits the TRAP state automatically when the TRAP condition is not present 1_B The TRAP state can only be exited by a SW request. |
| EMS | 23 | rw | External Modulation Synchronization Setting this bit to 1_B enables the synchronization of the external modulation functionality with the PWM period. 0_B External Modulation functionality is not synchronized with the PWM signal 1_B External Modulation functionality is synchronized with the PWM signal |
| EMT | 24 | rw | External Modulation Type This field selects if the external modulation event is clearing the CC4yST bit or if is gating the outputs. 0_B External Modulation functionality is clearing the CC4yST bit. 1_B External Modulation functionality is gating the outputs. |
| MCME | 25 | rw | Multi Channel Mode Enable 0_B Multi Channel Mode is disabled 1_B Multi Channel Mode is enabled |
| 0 | 7, [20:18] , [31:26] | r | Reserved Read always returns 0 |

CC4yPSL

This register holds the configuration for the output passive level control.

Capture/Compare Unit 4 (CCU4)

CC4yPSL (y = 0 - 3)

Passive Level Config

(0118_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------|--------|------|---|
| PSL | 0 | rw | Output Passive Level This field controls the passive level of the output pin. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| 0 | [31:1] | r | Reserved A read access always returns 0 |

CC4yDIT

This register holds the current dither compare and dither counter values.

CC4yDIT (y = 0 - 3)

Dither Config

(011C_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| DCV | [3:0] | rh | Dither compare Value This field contains the value used for the dither comparison. This value is updated when a shadow transfer occurs with the CC4yDITS.DCVS . |
| DCNT | [11:8] | rh | Dither counter actual value |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0. |

CC4yDITS

This register contains the value that is going to be loaded into the **CC4yDIT.DCV** when the next shadow transfer occurs.

CC4yDITS (y = 0 - 3)

Dither Shadow Register **(0120_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| DCVS | [3:0] | rw | Dither Shadow Compare Value This field contains the value that is going to be set on the dither compare value, CC4yDIT.DCV , within the next shadow transfer. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yPSC

This register contains the value that is loaded into the prescaler during restart.

Capture/Compare Unit 4 (CCU4)

CC4yPSC (y = 0 - 3)

Prescaler Control (0124_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PSIV | [3:0] | rw | Prescaler Initial Value This field contains the value that is applied to the Prescaler at startup. When floating prescaler mode is used, this value is applied when a timer compare match AND prescaler compare match occurs or when a capture event is triggered. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yFPC

This register contains the value used for the floating prescaler compare and the actual prescaler division value.

Capture/Compare Unit 4 (CCU4)

CC4yFPC (y = 0 - 3)

Floating Prescaler Control **(0128_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|-------------------------------|------|--|
| PCMP | [3:0] | rh | Floating Prescaler Compare Value This field contains comparison value used in floating prescaler mode. The comparison is triggered by the Timer Compare match event. See Section 23.2.11.2 . |
| PVAL | [11:8] | rwh | Actual Prescaler Value See Table 23-7 . Writing into this register is only possible when the prescaler is stopped. When the floating prescaler mode is not used, this value is equal to the CC4yPSC.PSIV . |
| 0 | [7:4], [15:12], [31:16] | r | Reserved Read always returns 0. |

CC4yFPCS

This register contains the value that is going to be transferred to the [CC4yFPC.PCMP](#) field within the next shadow transfer update.

Capture/Compare Unit 4 (CCU4)

CC4yFPCS (y = 0 - 3)

Floating Prescaler Shadow **(012C_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PCMP | [3:0] | rw | Floating Prescaler Shadow Compare Value This field contains the value that is going to be set on the CC4yFPC .PCMP within the next shadow transfer. See Table 23-7 . |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC4yPR

This register contains the actual value for the timer period.

CC4yPR (y = 0 - 3)

Timer Period Value **(0130_H + 0100_H * y)** **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| PR | [15:0] | rh | Period Register Contains the value of the timer period. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, PR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yPRS

This register contains the value for the timer period that is going to be transferred into the **CC4yPR.PR** field when the next shadow transfer occurs.

CC4yPRS (y = 0 - 3)

Timer Shadow Period Value **(0134_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| PRS | [15:0] | rw | Period Register Contains the value of the timer period, that is going to be passed into the CC4yPR.PR field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, the PRS is not accessible for writing. A read always returns 0.</i> |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yCR

This register contains the value for the timer comparison.

CC4yCR (y = 0 - 3)

Timer Compare Value (0138_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| CR | [15:0] | rh | Compare Register Contains the value for the timer comparison. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, a read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yCRS

This register contains the value that is going to be loaded into the **CC4yCR.CR** field when the next shadow transfer occurs.

CC4yCRS (y = 0 - 3)

Timer Shadow Compare Value ($013C_H + 0100_H * y$)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| CRS | [15:0] | rw | Compare Register Contains the value for the timer comparison, that is going to be passed into the CC4yCR.CR field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, a read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC4yTIMER

This register contains the current value of the timer.

CC4yTIMER (y = 0 - 3)

Timer Value $(0170_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|---------|------|--|
| TVAL | [15:0] | rwh | Timer Value This field contains the actual value of the timer. A write access is only possible when the timer is stopped. |
| 0 | [31:16] | r | Reserved A read access always returns 0 |

CC4yC0V

This register contains the values associated with the Capture 0 field.

CC4yC0V (y = 0 - 3)

Capture Register 0 $(0174_H + 0100_H * y)$ **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 0 value. See Figure 23-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 0. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 0 after the last read access. See Figure 23-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC1V

This register contains the values associated with the Capture 1 field.

CC4yC1V (y = 0 - 3)

Capture Register 1 (0178_H + 0100_H * y) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 1 value. See Figure 23-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 1. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 1 after the last read access. See Figure 23-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC2V

This register contains the values associated with the Capture 2 field.

CC4yC2V (y = 0 - 3)

Capture Register 2 ($017C_H + 0100_H * y$) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPT | [15:0] | rh | Capture Value This field contains the capture register 2 value. See Figure 23-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 2. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 2 after the last read access. See Figure 23-26 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yC3V

This register contains the values associated with the Capture 3 field.

CC4yC3V (y = 0 - 3)

Capture Register 3 (0180_H + 0100_H * y) **Reset Value: 00000000_H**

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 3 value. See Figure 23-26 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value at the time of the capture event into the capture register 3. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 3 after the last read access. See Figure 23-26 . In compare mode a read access always returns 0. 0 _B No new value was captured into the specific capture register 1 _B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC4yINTS

This register contains the status of all interrupt sources.

CC4yINTS (y = 0 - 3)

Interrupt Status (01A0_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|------------|------------|------------|------------|----|----|----|----|------------|------------|------------|------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | TRP | E2A | E1A | E0A | 0 | | | | CMD | CMU | OMD | PMU |
| r | | | | rh | rh | rh | rh | r | | | | rh | rh | rh | rh |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|------|------|---|
| PMUS | 0 | rh | Period Match while Counting Up 0_B Period match while counting up not detected 1_B Period match while counting up detected |
| OMDS | 1 | rh | One Match while Counting Down 0_B One match while counting down not detected 1_B One match while counting down detected |
| CMUS | 2 | rh | Compare Match while Counting Up 0_B Compare match while counting up not detected 1_B Compare match while counting up detected |
| CMDS | 3 | rh | Compare Match while Counting Down 0_B Compare match while counting down not detected 1_B Compare match while counting down detected |
| E0AS | 8 | rh | Event 0 Detection Status Depending on the user selection on the CC4yINS.EV0EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 0 not detected 1_B Event 0 detected |
| E1AS | 9 | rh | Event 1 Detection Status Depending on the user selection on the CC4yINS.EV1EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 1 not detected 1_B Event 1 detected |
| E2AS | 10 | rh | Event 2 Detection Status Depending on the user selection on the CC4yINS.EV1EM , this bit can be set when a rising, falling or both transitions are detected. 0_B Event 2 not detected 1_B Event 2 detected <i>Note: If this event is linked with the TRAP function, this field is automatically cleared when the slice exits the Trap State.</i> |
| TRPF | 11 | rh | Trap Flag Status This field contains the status of the Trap Flag. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| 0 | [7:4], [31:12] | r | Reserved A read always returns 0. |

CC4yINTE

Through this register it is possible to enable or disable the specific interrupt source(s).

CC4yINTE (y = 0 - 3)

Interrupt Enable Control (01A4_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | E2A E | E1A E | E0A E | 0 | | | | CMD E | CMU E | OME | PME |
| r | | | | | rw | rw | rw | r | | | | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|--|
| PME | 0 | rw | Period match while counting up enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a period match while counting up occurs. 0 _B Period Match interrupt is disabled 1 _B Period Match interrupt is enabled |
| OME | 1 | rw | One match while counting down enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time an one match while counting down occurs. 0 _B One Match interrupt is disabled 1 _B One Match interrupt is enabled |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|-------------------|------|--|
| CMUE | 2 | rw | Compare match while counting up enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a compare match while counting up occurs. 0 _B Compare Match while counting up interrupt is disabled 1 _B Compare Match while counting up interrupt is enabled |
| CMDE | 3 | rw | Compare match while counting down enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time a compare match while counting down occurs. 0 _B Compare Match while counting down interrupt is disabled 1 _B Compare Match while counting down interrupt is enabled |
| E0AE | 8 | rw | Event 0 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 0 is detected. 0 _B Event 0 detection interrupt is disabled 1 _B Event 0 detection interrupt is enabled |
| E1AE | 9 | rw | Event 1 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 1 is detected. 0 _B Event 1 detection interrupt is disabled 1 _B Event 1 detection interrupt is enabled |
| E2AE | 10 | rw | Event 2 interrupt enable Setting this bit to 1 _B enables the generation of an interrupt pulse every time that Event 2 is detected. 0 _B Event 2 detection interrupt is disabled 1 _B Event 2 detection interrupt is enabled |
| 0 | [7:4], [31:11] | r | Reserved A read always returns 0 |

CC4ySRS

Through this register it is possible to select to which service request line each interrupt source is forwarded.

CC4ySRS (y = 0 - 3)

Service Request Selector (01A8_H + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|-------|------|---|
| POSR | [1:0] | rw | Period/One match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Period match while counting up and One match while counting down are going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| CMSR | [3:2] | rw | Compare match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Compare match while counting up and Compare match while counting down are going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| E0SR | [9:8] | rw | Event 0 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 0 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| E1SR | [11:10] | rw | Event 1 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 1 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| E2SR | [13:12] | rw | Event 2 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 2 detection is going to be forward. 00 _B Forward to CC4ySR0 01 _B Forward to CC4ySR1 10 _B Forward to CC4ySR2 11 _B Forward to CC4ySR3 |
| 0 | [7:4], [31:14] | r | Reserved Read always returns 0. |

CC4ySWS

Through this register it is possible for the SW to set a specific interrupt status flag.

CC4ySWS (y = 0 - 3)

Interrupt Status Set (01AC_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | STR PF | SE2 A | SE1 A | SE0 A | 0 | | | | SCM D | SCM U | SOM | SPM |
| r | | | | w | w | w | w | r | | | | w | w | w | w |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| SPM | 0 | w | Period match while counting up set Writing a 1 _B into this field sets the CC4yINTS.PMUS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SOM | 1 | w | One match while counting down set Writing a 1 _B into this bit sets the CC4yINTS.OMDS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCMU | 2 | w | Compare match while counting up set Writing a 1 _B into this field sets the CC4yINTS.CMUS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCMD | 3 | w | Compare match while counting down set Writing a 1 _B into this bit sets the CC4yINTS.CMDS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE0A | 8 | w | Event 0 detection set Writing a 1 _B into this bit sets the CC4yINTS.E0AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE1A | 9 | w | Event 1 detection set Writing a 1 _B into this bit sets the CC4yINTS.E1AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE2A | 10 | w | Event 2 detection set Writing a 1 _B into this bit sets the CC4yINTS.E2AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| STRPF | 11 | w | Trap Flag status set Writing a 1 _B into this bit sets the CC4yINTS.TRPF bit. A read always returns 0. |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0 |

CC4ySWR

Through this register it is possible for the SW to clear a specific interrupt status flag.

Capture/Compare Unit 4 (CCU4)

CC4ySWR (y = 0 - 3)

Interrupt Status Clear

(01B0_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|----|----|----------|----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | RTR PF | RE2 A | RE1 A | RE0 A | 0 | | | | RCM D | RCM U | ROM | RPM |
| r | | | | w | w | w | w | r | | | | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|---|
| RPM | 0 | w | Period match while counting up clear Writing a 1 _B into this field clears the CC4yINTS .PMUS bit. A read always returns 0. |
| ROM | 1 | w | One match while counting down clear Writing a 1 _B into this bit clears the CC4yINTS .OMDS bit. A read always returns 0. |
| RCMU | 2 | w | Compare match while counting up clear Writing a 1 _B into this field clears the CC4yINTS .CMUS bit. A read always returns 0. |
| RCMD | 3 | w | Compare match while counting down clear Writing a 1 _B into this bit clears the CC4yINTS .CMDS bit. A read always returns 0. |
| RE0A | 8 | w | Event 0 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E0AS bit. A read always returns 0. |
| RE1A | 9 | w | Event 1 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E1AS bit. A read always returns 0. |
| RE2A | 10 | w | Event 2 detection clear Writing a 1 _B into this bit clears the CC4yINTS .E2AS bit. A read always returns 0. |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| RTRPF | 11 | w | Trap Flag status clear Writing a 1 _B into this bit clears the CC4yINTS .TRPF bit. Not valid if CC4yTC .TRPEN = 1 _B and the Trap State is still active. A read always returns 0. |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0 |

CC4yECRD0

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 0. The read back is only valid if the **CC4yTC**.ECM = 1_B.

CC4yECRD0 (y = 0 - 3)

Extended Read Back 0 (01B8_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|------|----|----|----|----|----|-----|-----|------|------|------|----|----|----|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| r | | | | | | rh | rh | rh | rh | rh | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CAPV | | | | | | | | | | | | | | | |
| rh | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------|---------|------|---|
| CAPV | [15:0] | rh | Timer Capture Value This field contains the timer captured value |
| FPCV | [19:16] | rh | Prescaler Capture value This field contains the value of the prescaler clock division associated with the specific CAPV field |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC40 01 _B CC41 10 _B CC42 11 _B CC43 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0 _B No new value was captured into this register 1 _B A new value has been captured into this register |
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0 _B No capture was lost 1 _B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

CC4yECRD1

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 1. The read back is only valid if the **CC4yTC.ECM** = 1_B.

Capture/Compare Unit 4 (CCU4)

CC4yECRD1 (y = 0 - 3)

Extended Read Back 1

(01BC_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPV | [15:0] | rh | Timer Capture Value This field contains the timer captured value |
| FPCV | [19:16] | rh | Prescaler Capture value This field contains the value of the prescaler clock division associated with the specific CAPV field |
| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC40 01 _B CC41 10 _B CC42 11 _B CC43 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0 _B No new value was captured into this register 1 _B A new value has been captured into this register |

Capture/Compare Unit 4 (CCU4)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0 _B No capture was lost 1 _B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

23.8 Interconnects

The tables that refer to the “global pins” are the ones that contain the inputs/outputs of each module that are common to all slices.

The GPIO connections are available at the Ports chapter.

23.8.1 CCU40 Pins

Table 23-13 CCU40 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|-----------------------|-----|--------------|---|
| CCU40.MCLK | I | SCU.CCUCLK | Kernel clock |
| CCU40.CLKA | I | ERU1.IOUT0 | another count source for the prescaler |
| CCU40.CLKB | I | ERU1.IOUT1 | another count source for the prescaler |
| CCU40.CLKC | I | 0 | another count source for the prescaler |
| CCU40.MCSS | I | 0 | Multi pattern sync with shadow transfer trigger |

Table 23-13 CCU40 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|-----------------------|-----|---|----------------------|
| CCU40.SR0 | O | NVIC; DMA; POSIF0.MSETA; VADC.G0REQGTC; VADC.G1REQGTC; VADC.G2REQGTC; VADC.G3REQGTC; VADC.BGREQGTC; | Service request line |
| CCU40.SR1 | O | NVIC; DMA; DAC.TRIGGER[2]; U0C0.DX2E; | Service request line |
| CCU40.SR2 | O | NVIC; VADC.G0REQTRA; VADC.G1REQTRA; VADC.G2REQTRA; VADC.G3REQTRA; VADC.BGREQTRA; | Service request line |
| CCU40.SR3 | O | NVIC; CCU80.IGBTB; VADC.G0REQTRB; VADC.G1REQTRB; VADC.G2REQTRB; VADC.G3REQTRB; VADC.BGREQTRB; CCU80.IN0K; CCU81.IN0K; | Service request line |

Table 23-14 CCU40 - CC40 Pin Connections

| Input/Output | I/O | Connected To | Description |
|--------------|-----|--------------|--------------------------|
| CCU40.IN0A | I | PORTS | General purpose function |
| CCU40.IN0B | I | PORTS | General purpose function |
| CCU40.IN0C | I | PORTS | General purpose function |
| CCU40.IN0D | I | ERU1.PDOUT1 | General purpose function |
| CCU40.IN0E | I | POSIF0.OUT0 | General purpose function |

Capture/Compare Unit 4 (CCU4)
Table 23-14 CCU40 - CC40 Pin Connections

| Input/Output | I/O | Connected To | Description |
|--------------|-----|---|--|

24 Capture/Compare Unit 8 (CCU8)

The CCU8 peripheral functions play a major role in applications that need complex Pulse Width Modulation (PWM) signal generation, with complementary high side and low side switches, multi phase control or output parity checking. These functions in conjunction with a very flexible and programmable signal conditioning scheme, make the CCU8 the must have peripheral for state of the art motor control, multi phase and multi level power electronics systems.

The internal modularity of CCU8, translates into a software friendly system for fast code development and portability between applications.

Table 24-1 Abbreviations table

| | |
|------------|---|
| PWM | Pulse Width Modulation |
| CCU8x | Capture/Compare Unit 8 module instance x |
| CC8y | Capture/Compare Unit 8 Timer Slice instance y |
| ADC | Analog to Digital Converter |
| POSIF | Position Interface peripheral |
| SCU | System Control Unit |
| f_{ccu8} | CCU8 module clock frequency |
| f_{tclk} | CC8y timer clock frequency |

Note: A small “y” or “x” letter in a register indicates an index

24.1 Overview

The CCU8 unit is comprised of four identical 16 bit Capture/Compare Timer slices, CC8y. Each Timer Slice can work in Compare or in Capture Mode. In Compare Mode, one has two dedicated compare channels that enable the generation of up to 4 PWM signals per Timer Slice (up to 16 PWM outputs per CCU8 unit), with dead time insertion to prevent short circuits in the switches. In Capture Mode a set of up to four capture registers is available.

Each CCU8 module has four service request lines that can be easily programmed to act as synchronized triggers between the PWM signal generation and an ADC conversion.

Straightforward timer slice concatenation is also possible, enabling up to 64 bit timing operations. This offers a flexible frequency measurement, frequency multiplication and pulse width modulation scheme.

A programmable function input selector for each timer slice, that offers up to nine functions, discards the need of complete resource mapping due to input ports availability.

Capture/Compare Unit 8 (CCU8)

A built-in link between the CCU8 and POSIF modules also enable a flexible digital motor control loop implementation, with direct coupling with Hall Sensors for Brushless DC Motor Control.

24.1.1 Features**CCU8 Module Features**

Each CCU8 represents a combination of four Timer Slices, that can work independently in compare or capture mode. Each timer slice has 4 dedicated outputs for PWM signal generation.

All four CCU8 timer slices, CC8y, are identical in terms of available functions and operating modes. Avoiding this way the need of implementing different software routines, depending on which resource of CCU8 is used.

A built-in link between the four timer slices is also available, enabling this way a simplified timer concatenation and sequential operations.

General Features

- 16 bit timer cells
- programmable low pass filter for the inputs
- built-in timer concatenation
 - 32, 48 or 64 bit width
- shadow transfer for the period and compare channels
- four capture registers in capture mode
- programmable clock prescaler
- normal timer mode
- gated timer mode
- three counting schemes
 - center aligned
 - edge aligned
 - single shot
- PWM generation
- asymmetric PWM generation
- TRAP function
- dead time generation
- start/stop can be controlled by external events
- counting external events
- four dedicated service request lines per CCU8

Additional features

- external modulation function
- load controlled by external events

Capture/Compare Unit 8 (CCU8)

- dithering PWM
- floating point pre scaler
- output state override by an external event
- programmable output parity checker
- easy connection with POSIF unit for
 - hall sensor mode
 - rotary encoder mode
 - multi channel/multi phase control

CCU8 features vs. applications

On [Table 24-2](#) a summary of the major features of the CCU8 unit mapped with the most common applications.

Table 24-2 Applications summary

| Feature | Applications |
|--------------------------------------|--|
| Four independent timer cells | Independent PWM generation: <ul style="list-style-type: none"> • Multiple buck/boost converter control (with independent frequencies) • Different mode of operation for each timer, increasing the resources optimization • Up to 2 H-Bridge control • multiple Zero Voltage Switch (ZVS) converter control with easy link to the ADC channels. • Multi Level Inverters |
| Two compare channels per Timer Slice | Linking between the two compare channels or linking between two Timer Slices: <ul style="list-style-type: none"> • Asymmetric PWM signal generation possibility decreases the number of current sensors • Linking between timer slices enable Phase Shift Full Bridge topologies control • Linking between slices enable N-Phase DC/DC converter control |

Table 24-2 Applications summary (cont'd)

| Feature | Applications |
|---|---|
| Two Dead Time Generators | <p>Independent dead time values for rising and falling transitions and independent channel dead time counter:</p> <ul style="list-style-type: none"> • Each channel can work stand alone with different dead time values. This enables the control of up to 2 Half-Bridges with different dead time values and the same frequency • Different dead time values for rising and falling transitions can be used to optimize the switching activity of the MOSFETs |
| Concatenated timer cells | <p>Easy to configure timer extension up to 64 bit:</p> <ul style="list-style-type: none"> • High dynamic trigger capturing • High dynamic signal measurement |
| Dithering PWM | <p>Generating a fractional PWM frequency or duty cycle:</p> <ul style="list-style-type: none"> • To avoid big steps on frequency or duty cycle adjustment in slow control loop applications • Increase the PWM signal resolution over time |
| Floating prescaler | <p>Automated control signal measurement:</p> <ul style="list-style-type: none"> • decrease SW activity for monitoring signals with high or unknown dynamics • generating a more than 16 bit timer for system control |
| Up to 9 functions via external signals for each timer | <p>Flexible resource optimization:</p> <ul style="list-style-type: none"> • The complete set of external functions is always available • Several arrangements can be done inside a CCU8, e.g., one timer working in capture mode and one working in compare |
| Output Parity Checker | <p>Automated Mosfet signal monitoring:</p> <ul style="list-style-type: none"> • parity checker can be used to monitor the output of the IGBTs and comparing them against the complete set of PWM outputs of CCU8. • Avoiding short circuits in a multi Mosfet system. |

Table 24-2 Applications summary (cont'd)

| Feature | Applications |
|-----------------------------------|---|
| 4 dedicated service request lines | Specially developed for: <ul style="list-style-type: none"> • generating interrupts for the microprocessor • flexible connectivity between peripherals, e.g., ADC triggering. |
| Linking with POSIF | Flexible profiles for: <ul style="list-style-type: none"> • Rotary Encoder connection • Hall Sensor • Modulating the 4 timer outputs via SW |

24.1.2 Block Diagram

Each CCU8 timer slice can operate independently from the other slices for all the available modes. Each timer slice contains a dedicated input selector for functions linked with external events and has 4 dedicated compare output signals, for PWM signal generation.

The built-in timer concatenation is only possible with adjacent slices, e.g. CC80/CC81. Combinations for slice concatenations like, CC80/CC82 or CC80/CC83 are not possible.

The individual service requests for each timer slice (four per slice) are multiplexed into four module service requests lines, [Figure 24-1](#).

24.2 Functional Description

24.2.1 Overview

The input path of a CCU8 slice is comprised of a selector ([Section 24.2.2](#)) and a connection matrix unit ([Section 24.2.3](#)). The output path contains a service request control unit, a timer concatenation unit and two units that control directly the state of the output signal for each specific slice (for TRAP, dead time generation and modulation handling), see [Figure 24-2](#).

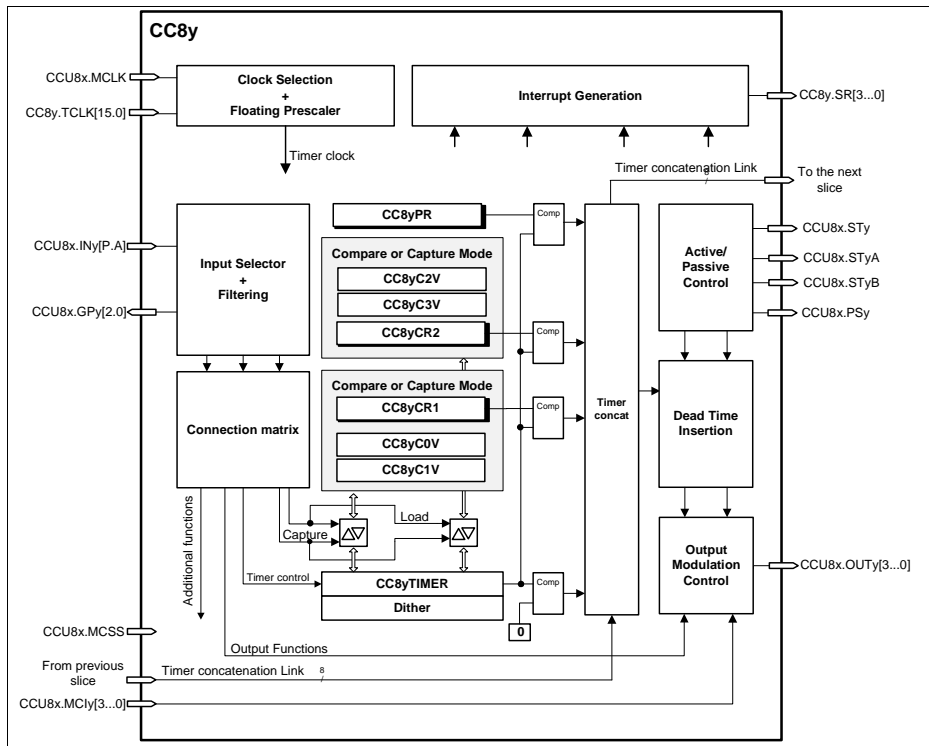

Figure 24-2 CCU8 slice block diagram

The timer core is built of 16 bit counter and one period register and two compare channels in compare mode, or four capture channels plus the period register in capture mode.

Capture/Compare Unit 8 (CCU8)

Individual timer clocks can be selected for each and every Timer Slice, enabling a very flexible resource organization inside each CCU8 module.

In compare mode the period sets the maximum counting value while the two compare registers are used to control the ACTIVE/PASSIVE state of the four dedicated comparison slice outputs.

Each CCU8 slice contains a dedicated timer link interface that is used to perform timer concatenation, up to 64 bits. This timer concatenation is controlled via a single bit field configuration.

Table 24-3 describes the inputs and outputs for each CCU8 Timer Slice.

Inputs and outputs that are not seen at the CCU8 module boundaries have a nomenclature of CC8y.<name>, whilst CCU8 module inputs and outputs are described as CCU8x.<signal_name>y (indicating the variable y the object slice).

Table 24-3 CCU8 slice pin description

| Pin | I/O | Description |
|-------------------|-----|--|
| CCU8x.MCLK | I | Module clock |
| CC8y.TCLK | | Clock from the pre scaler |
| CCU8x.INy[P:A] | I | Slice functional inputs (used to control the functionality throughout slice external events) |
| CCU8x.MCly[3...0] | I | Multi Channel mode inputs |
| CCU8x.MCSS | I | Multi Channel shadow transfer trigger |
| CC8y.SR[3...0] | O | Slice service request lines |
| CCU8x.GPy[2...0] | O | Signals decoded from the input selector (used for the parity checker function) |
| CCU8x.STy | O | This signal can be the slice comparison status value of channel 1, channel 2 or a AND between both |
| CCU8x.STyA | O | Slice comparison status value of channel 1 |
| CCU8x.STyB | O | Slice comparison status value of channel 2 |
| CCU8x.PSy | O | Period match |
| CCU8x.OUTy[3...0] | O | Slice dedicated output pins |

Note:

- The status bit outputs of the Kernel, CCU8x.STy, CCU8x.STyA and CCU8x.STyB are extended for one more kernel clock cycle.*
- The Service Request signals at the output of the kernel are extended for one more kernel clock cycle.*

Capture/Compare Unit 8 (CCU8)

8. *The maximum output signal frequency of the CCU8x.STy, CCU8x.STyA and CCU8x.STyA is module clock divided by 4.*

The slice timer, can count up or down depending on the selected operating mode. A direction flag contains the actual counting direction.

The timer is connected to three stand alone comparators, one for the period match and two for the compare match of each compare channel. The registers used for comparison match of both compare channels, can be programmed to serve as capture registers, enabling sequential capture capabilities on external events.

In normal edge aligned counting scheme, the counter is cleared to 0000_H each time it matches the period value defined in the period register. In center aligned mode, the counter direction changes from 'up counting' to 'down counting' after reaching the period value. Both period and compare registers have an aggregated shadow register, which enables the update of the PWM period and duty cycle on the fly.

A single shot mode is also available, where the counter stops after it reaches the value set in the period register.

The start and stop of the counter can be set/clear by software access or by a programmable input pin.

The dead time generator can be programmed with different values for the rising and falling edge of the output.

Functions like, load, counting direction (up/down), TRAP, output modulation can also be controlled with external events, see [Section 24.2.3](#).

24.2.2 Input Selector

The first unit of the slice input path, is used to select from which are used to control the available external functions.

Inside this block the user also has the possibility to perform a low pass filtering of the signals and selecting the active edge(s) or level of the external event, see [Figure 24-3](#).

The user has the possibility of selecting any of the CCU8x.INy[P:A] inputs has the source of an event.

At the output of this unit we have a user selection of three events, that were configured to be active at rising, falling or both edges, or level active. These selected events can then be mapped to several functions.

Notice that each decoded event contains two outputs, one edge active and one level active, due to the fact that some functions like counting, capture or load are edge sensitive events while, timer gating or up down counting selection are level active.

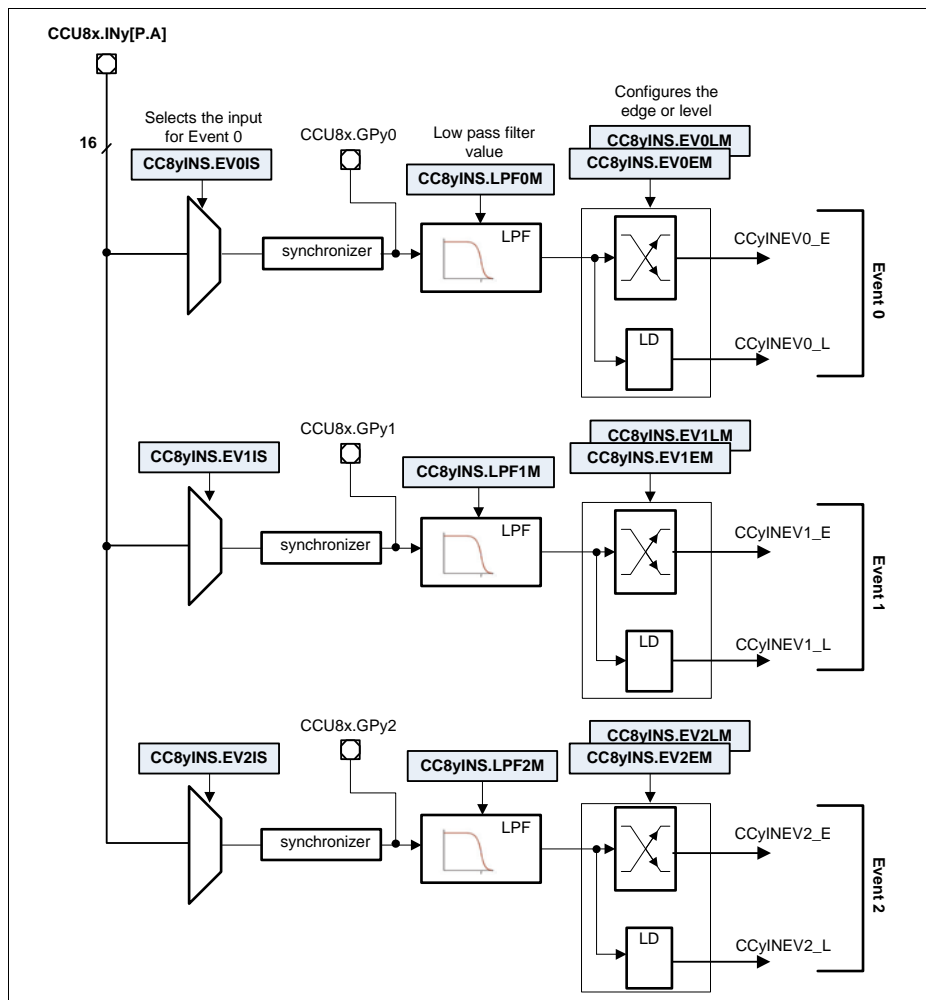

Figure 24-3 Slice input selector diagram

24.2.3 Connection Matrix

The connection matrix maps the events coming from the input selector to several user configured functions, [Figure 24-4](#). The following functions can be enabled on the connection matrix:

Table 24-4 Connection matrix available functions

| Function | Brief description | Map to figure Figure 24-4 |
|---------------------|---|--|
| Start | Edge signal to start the timer | CCystrt |
| Stop | Edge signal to stop the timer | CCcystp |
| Count | Edge signal used for counting events | CCycnt |
| Up/down | Level signal used to select up or down counting direction | CCyupd |
| Capture 0 | Edge signal that triggers a capture into the capture registers 0 and 1 | CCycapt0 |
| Capture 1 | Edge signal that triggers a capture into the capture registers 2 and 3 | CCycapt1 |
| Gate | Level signal used to gate the timer clock | CCygate |
| Load | Edge signal that loads the timer with the value present at the compare register | CCyload |
| TRAP | Level signal used for fail-safe operation | CCytrap |
| Modulation | Level signal used to modulate/clear the output | CCymod |
| Status bit override | Status bit is going to be overridden with an input value | CCyoval for the value CCyoset for the trigger |

Inside the connection matrix we also have a unit that performs the built-in timer concatenation. This concatenation enables a completely synchronized operation between the concatenated slices for timing operations and also for capture and load actions. The timer slice concatenation is done via the [CC8yCMC.TCE](#) bitfield. For a complete description of the concatenation function, please address [Section 24.2.10](#).

Capture/Compare Unit 8 (CCU8)

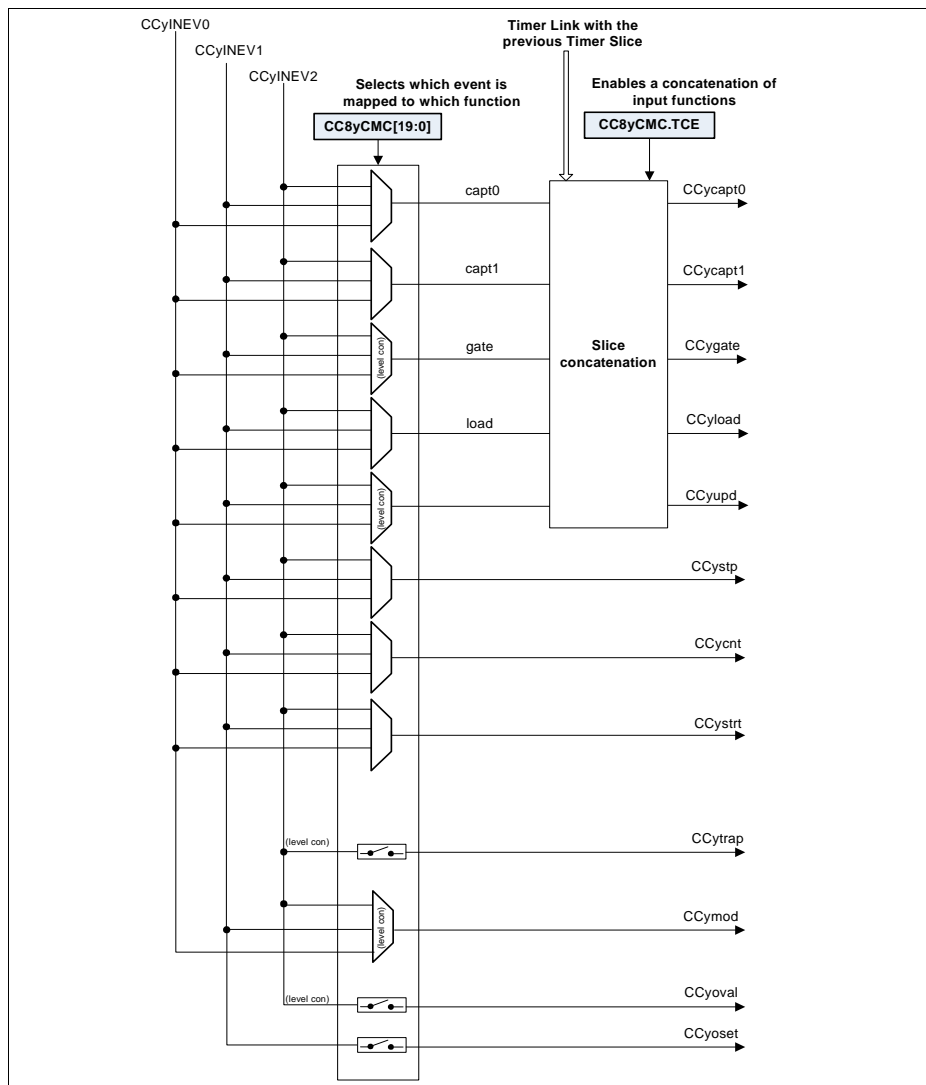

Figure 24-4 Slice connection matrix diagram

24.2.4 Start/Stop Control

Each slice contains a run bit register, that indicates the actual status of the timer, **CC8yTCST.TRB**. The start and stop of the timer can be done by software access or can be controlled directly by external events, see [Figure 24-5](#).

Selecting an external signal that acts as a start trigger does not force the user to use an external stop trigger and vice versa.

Selecting the single shot mode, imposes that after the counter reaches the period value the run bit, **CC8yTCST.TRB**, is going to be cleared and therefore the timer is stopped.

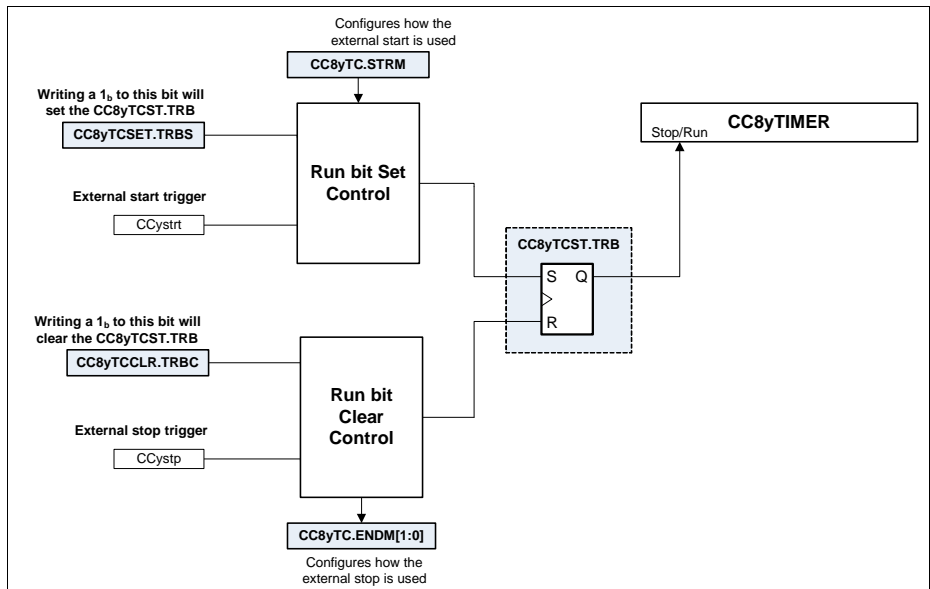

Figure 24-5 Timer start/stop control diagram

One can use the external stop signal to perform the following functions (configuration via **CC8yTC.ENDM**):

- Clear the run bit (stops the timer) - default
- Clear the timer (to 0000_H) but it does not clear the run bit (timer still running)
- Clear the timer and the run bit

One can use the external start to perform the following functions (configuration via **CC8yTC.STRM**):

- Start the timer (resume operation)
- Clear and starts the timer

Capture/Compare Unit 8 (CCU8)

The set (start the timer) of the timer run bit, always has priority over a clear (stop the timer).

To start multiple CCU8 timers at the same time/synchronously one should use a dedicated input as external start (see [Section 24.2.8.1](#) for a description how to configure an input as start function). This input should be connected to all the Timers that need to started synchronously (see [Section 24.8](#) for a complete list of module connections), [Figure 24-6](#).

For starting the timers synchronously via software there is a dedicated input signal, controlled by the SCU (System Control Unit), that is connected to all the CCU8 timers. This signal should then be configured as an external start signal (see [Section 24.2.8.1](#)) and then the software must write $1_B/0_B$ (depending on the external start function configuration) to the specific bitfield of the CCUCON register (this register is described on the SCU chapter).

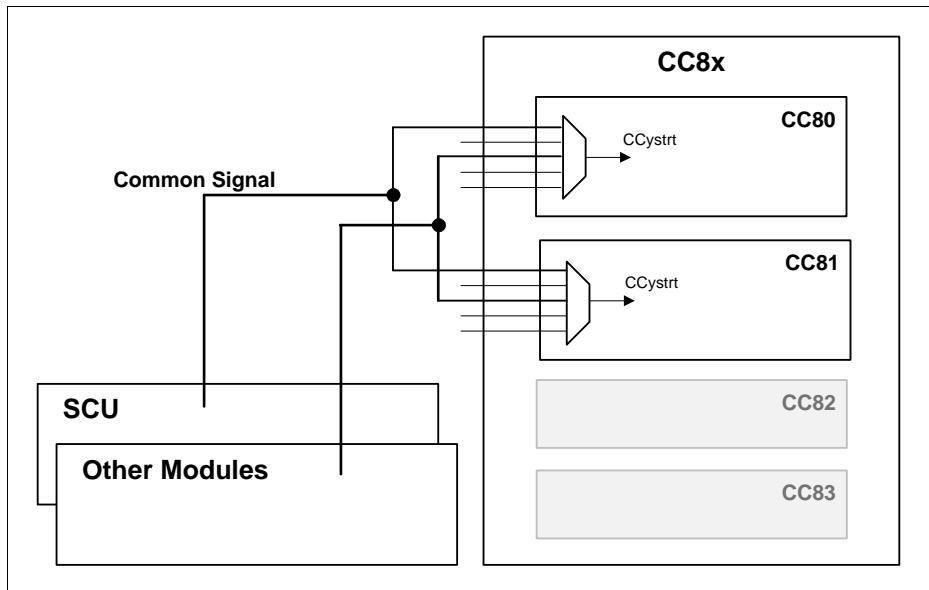

Figure 24-6 Start multiple timers synchronously

24.2.5 Counting Modes

Each CC8y timer can be programmed into three different counting schemes:

- Edge aligned (default)
- Center aligned
- Single shot (edge or center aligned)

Capture/Compare Unit 8 (CCU8)

These three counting schemes can be used as stand alone without the need of selecting any inputs as external event sources. Nevertheless it is also possible to control the counting operation via external events like, timer gating, counting trigger, external stop, external start, etc.

For all the counting modes, it is possible to update on the fly the values for the timer period and compare channel. This enables a cycle by cycle update of the PWM frequency and duty cycle.

Each compare channel of the CC8y Timer Slice has an associated Status Bit (**GCST.CC8yST1** for compare channel 1 and **GCST.CC8yST2** for compare channel 2), that indicates the active or passive state of the channel, **Figure 24-7**. The set and clear of the status bits and the respective PWM signal generation is dictated by the timer period, compare value and the current counting mode. See the different counting mode descriptions, **Section 24.2.5.3** to **Section 24.2.5.5** to understand how these bits are set and cleared.

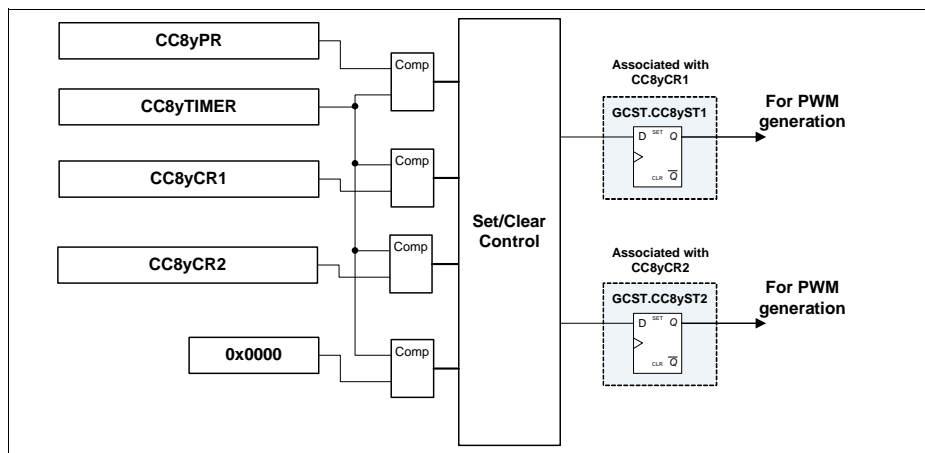

Figure 24-7 CC8y Status Bits

24.2.5.1 Calculating the PWM Period and Duty Cycle

The period of the timer is determined by the value in the period register, **CC8yPR** and by the timer mode.

The base for the PWM signal frequency and duty cycle, is always related to the clock frequency of the timer itself and not to the frequency of the module clock (due to the fact that the timer clock can be a scaled version of the module clock).

In Edge Aligned Mode, the timer period is:

$$T_{\text{per}} = \text{<Period-Value>} + 1; \text{ in } f_{\text{tclk}} \quad (24.1)$$

In Center Aligned Mode, the timer period is:

$$T_{\text{per}} = (<\text{Period-Value}> + 1) \times 2; \text{ in } f_{\text{clk}} \quad (24.2)$$

For each of these counting schemes, the duty cycle of generated PWM signal is dictated by the value programmed into the compare channel registers, **CC8yCR1** and **CC8yCR2**. Notice that one can have different duty cycle values for each of the compare channels.

In Edge Aligned and Center Aligned Mode, the PWM duty cycle is:

$$DC = 1 - <\text{Compare-Value}>/(<\text{Period-Value}> + 1) \quad (24.3)$$

Both the period and compare registers, **CC8yPR**, **CC8yCR1** and **CC8yCR2** respectively, can be updated on the fly via software enabling a glitch free transition between different period and duty cycle values for the generated PWM signal, [Section 24.2.5.2](#)

24.2.5.2 Updating the Period and Duty Cycle

Standard Shadow Transfer Control

Each CCU8 timer slice provides an associated shadow register for the period and the two compare values. This facilitates a concurrent update by software for these three parameters, with the objective of modifying during run time the PWM signal period and duty cycle.

In addition to the shadow registers for the period and compare values, one also has available shadow registers for the floating prescaler, dither and passive level, **CC8yFPCS**, **CC8yDITS** and **CC8yPSL** respectively (please address [Section 24.2.13](#) and [Section 24.2.12](#) for a complete description of these functions).

The structure of the shadow registers can be seen in [Figure 24-8](#).

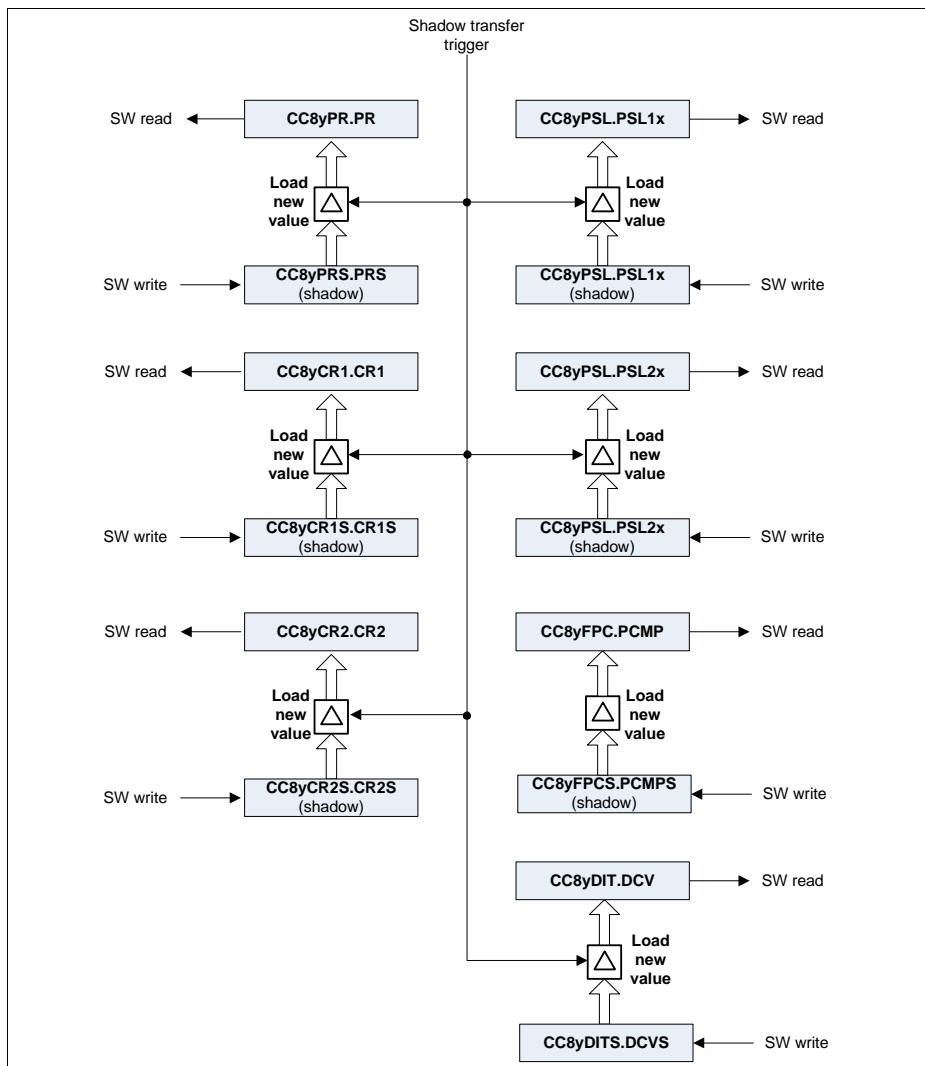

Figure 24-8 Shadow registers overview

The update of these registers can only be done by writing a new value into the associated shadow register and wait for a shadow transfer to occur.

Each group of shadow registers have an individual shadow transfer enable bit, [Figure 24-9](#). The software must set this enable bit to 1_B, whenever an update of the

Capture/Compare Unit 8 (CCU8)

values is needed. These bits are automatically cleared by the hardware, whenever an update of the values is finished. Therefore every time that an update of the registers is needed the software must set again the specific bit(s).

Nevertheless it is also possible to clear the enable bit via software. This can be used in the case that an update of the values needs to be cancelled (after the enable bit has already been set).

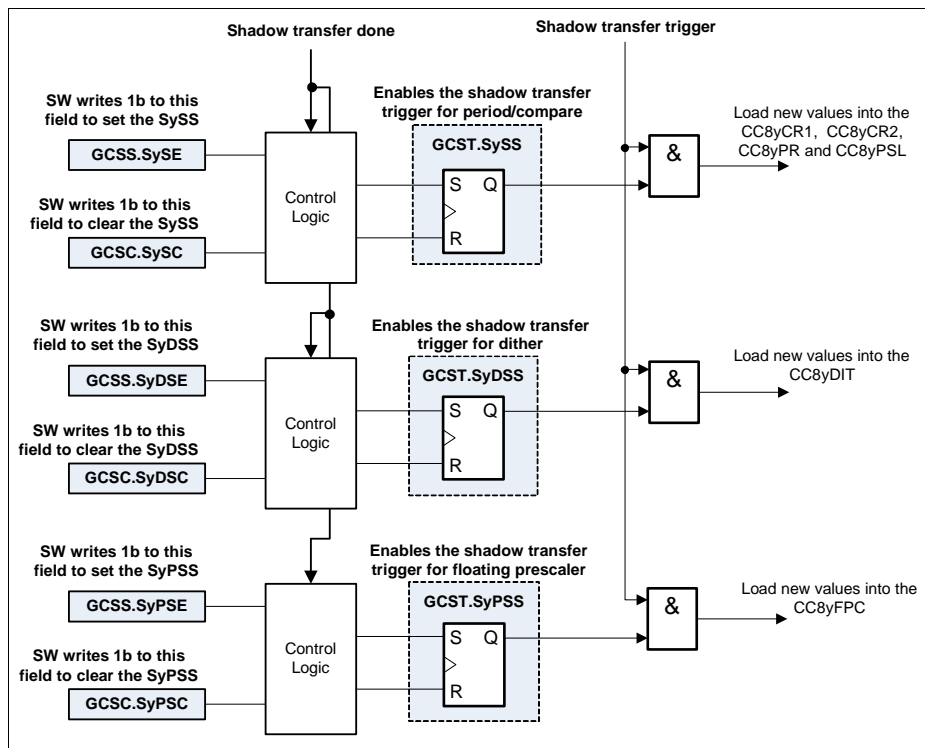

Figure 24-9 Shadow transfer enable logic

The shadow transfer operation is going to be done in the immediately next occurrence of a shadow transfer trigger, after the shadow transfer enable is set (**GCST.SySS**, **GCST.SyDSS**, **GCST.SyPSS** set to 1_B).

The occurrence of the shadow transfer trigger is imposed by the timer counting scheme (edge aligned or center aligned). Therefore the slots when the values are updated can be:

- in the next clock cycle after a Period Match while counting up
- in the next clock cycle after an One Match while counting down

Capture/Compare Unit 8 (CCU8)

- immediately, if the timer is stopped and the shadow transfer enable bit(s) is set

Figure 24-10 shows an example of the shadow transfer control when the timer slice has been configured into center aligned mode. For a complete description of all the timer slice counting modes, please address [Section 24.2.5.3](#), [Section 24.2.5.4](#) and [Section 24.2.5.5](#).

It is also possible to control in which slot the shadow transfer is done, via the STM field. This is only valid in Center Aligned Mode:

- CC8ySTC.STM** = 00_B (default) - Shadow transfer is done at the Period Match and One match slot
- CC8ySTC.STM** = 01_B - Shadow transfer is done only at the Period Match slot
- CC8ySTC.STM** = 10_B - Shadow transfer is done only at the One Match slot

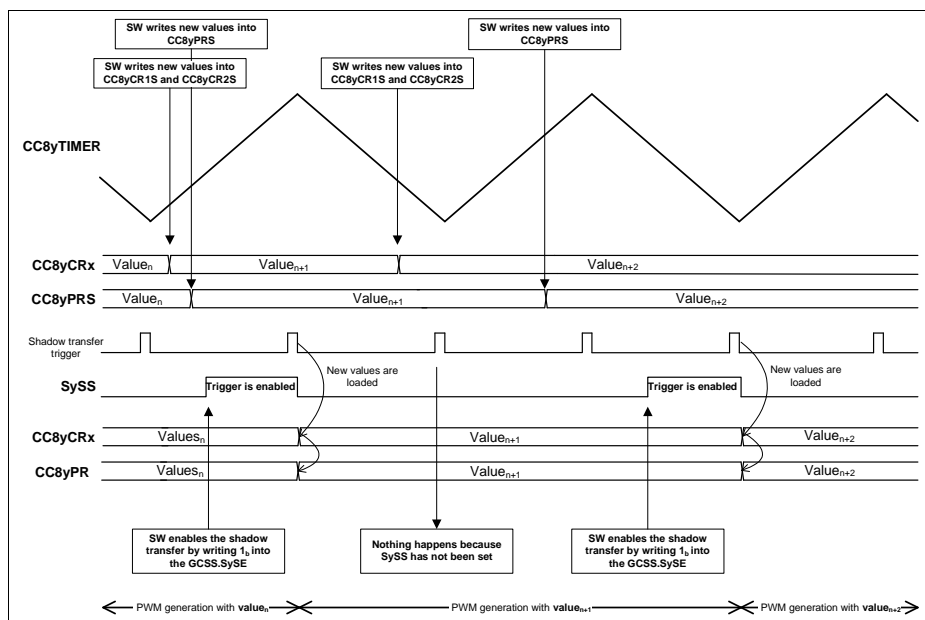

Figure 24-10 Shadow transfer timing example - center aligned mode

When using the CCU8 in conjunction with the POSIF to control the multi channel mode, it can be necessary in some cases, to perform the shadow transfers synchronously with the update of the multi channel pattern. To perform this action, each CCU8 contains a dedicated input that can be used to synchronize the two events, the CCU8x.MCSS.

This input, when enabled, is used to set the shadow transfer enable bitfields (**GCST.SySS**, **GCST.SyDSS** and **GCST.SyPSS**) of the specific slice. It is possible to select which slice is using this input to perform the synchronization via the **GCTRL.MSEy**

Capture/Compare Unit 8 (CCU8)

bit field. It is also possible to enable the usage of this signal for the three different shadow transfer signals: compare and period values, either compare value and prescaler compare value. This can be configured on the **GCTRL.MSDE** field.

The structure for using the CCU8x.MCSS input signal can be seen in **Figure 24-11**. The usage of this signal is just an add on to the shadow transfer control and therefore all the previous described functions are still available.

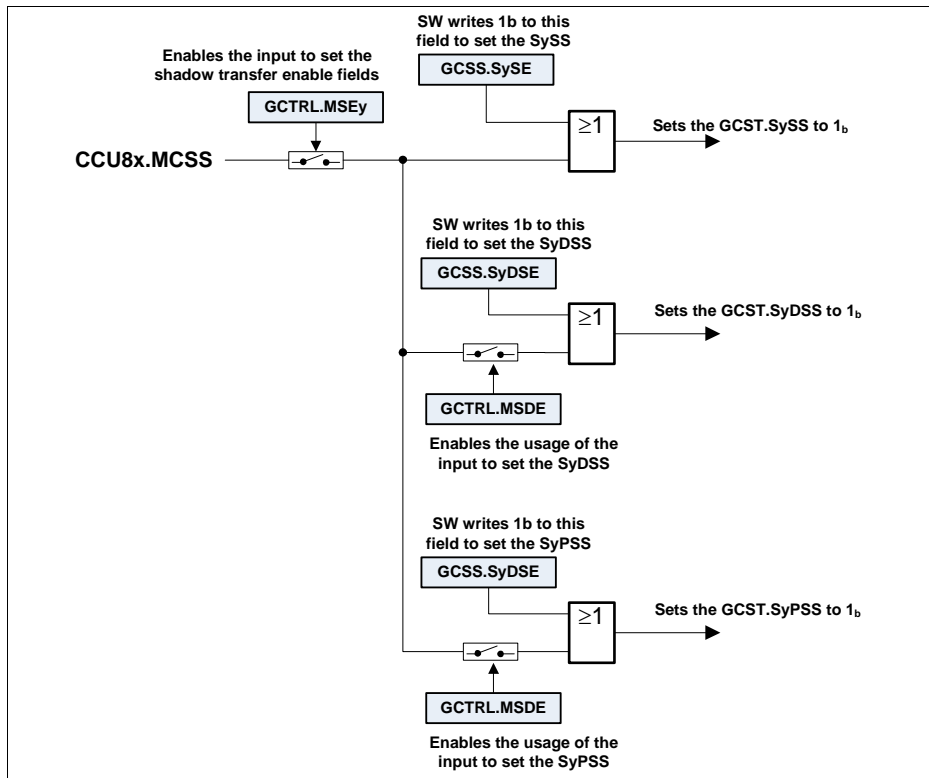

Figure 24-11 Usage of the CCU8x.MCSS input

Cascaded Shadow Transfer

It is possible to cascade the shadow transfer operation throughout the CCU8 timer slices. The specific shadow transfer of a timer slice is cascaded with the adjacent timer slices, **Figure 24-12**.

To enable the cascaded shadow transfer function, the bitfield **CC8ySTC.CSE** of the specific timer slice needs to be set to 1_B.

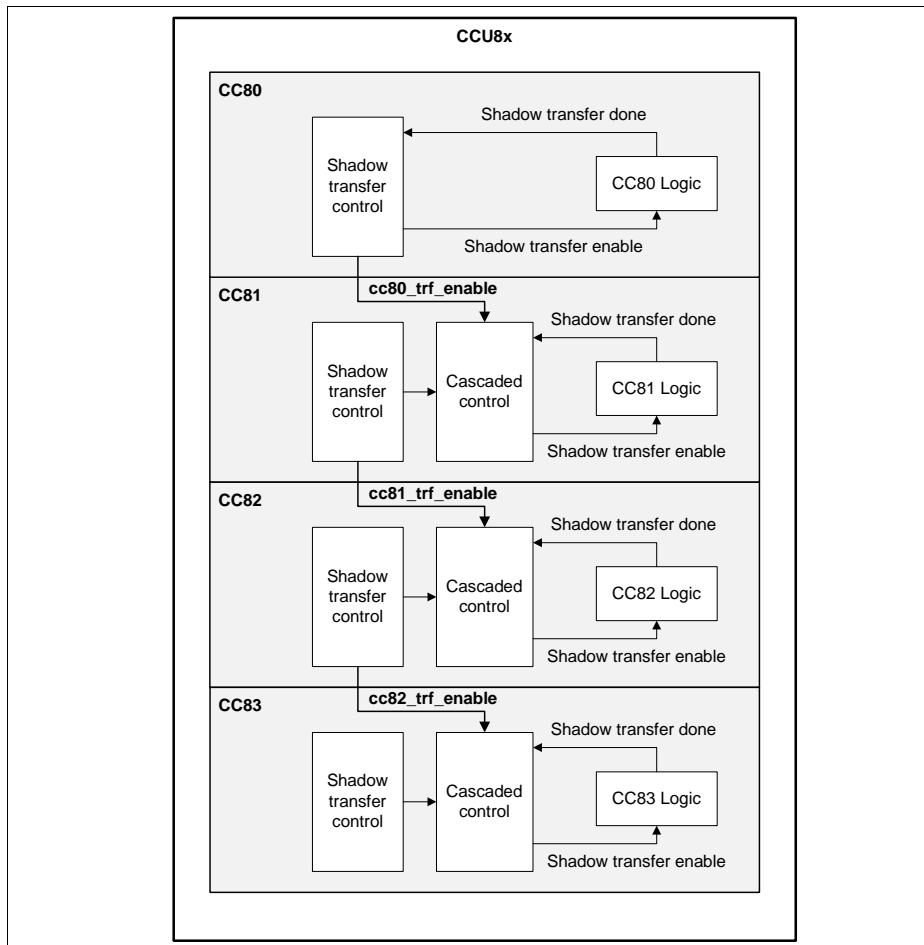

Figure 24-12 Cascaded shadow transfer linking

The shadow transfer enable bits, still need to be set via SW for each of the individual slices, [Figure 24-13](#).

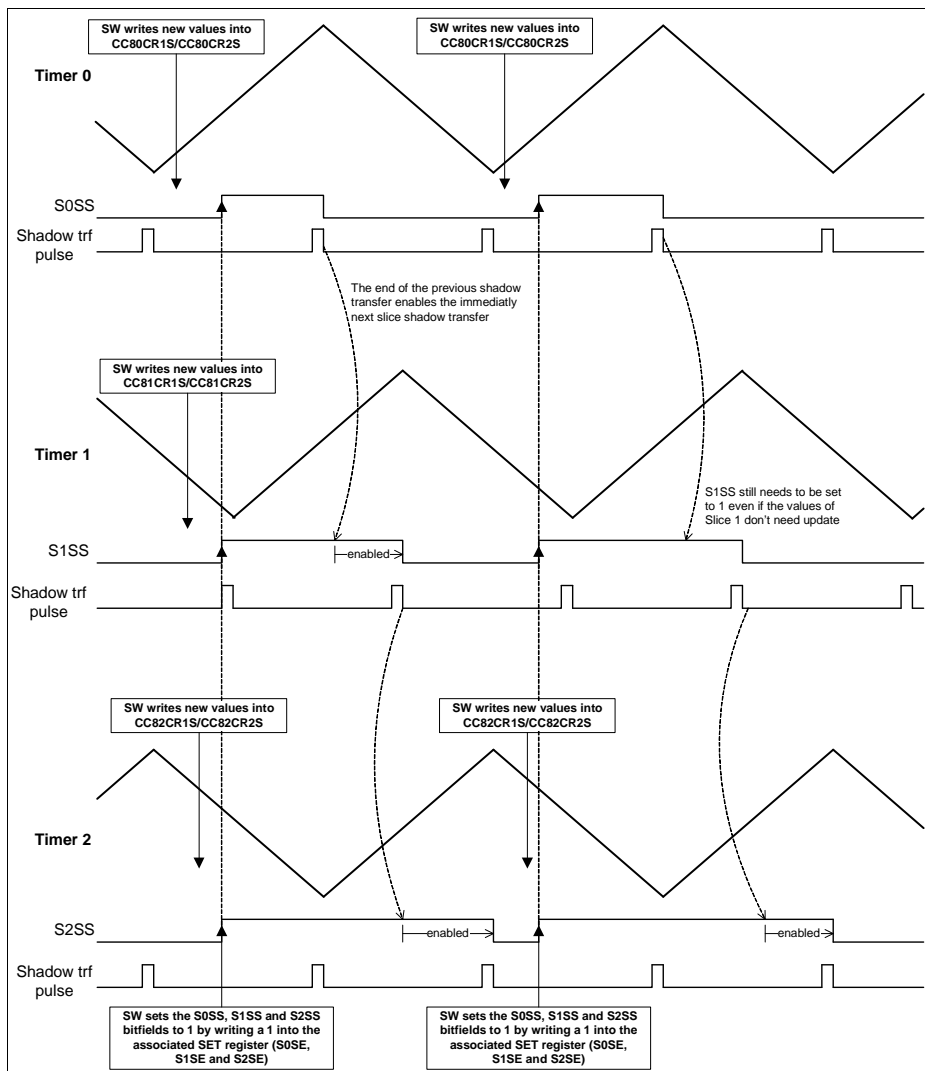

Figure 24-13 Cascade shadow transfer timing

Note: The shadow transfer enable bits, need to be set in all timer slices that are being used in the cascaded architecture, at the same time. The shadow transfer enable bits, also need to be set for all slices even if the shadow values of some slices were not updated.

24.2.5.3 Edge Aligned Mode

Edge aligned mode is the default counting scheme. In this mode, the timer is incremented until it matches the value programmed in the period register, **CC8yPR**. When period match is detected the timer is cleared to 0000_H and continues to be incremented.

In this mode, the value of the period register and compare registers are updated with the values written by software into the correspondent shadow register, every time that an overflow occurs (period match), see **Figure 24-14**.

In edge aligned mode, the status bit of the comparison (CC8ySTx) is set one clock cycle after the timer hits the value programmed into the compare register. The clear of the status bit is done one clock cycle after the timer reaches 0000_H.

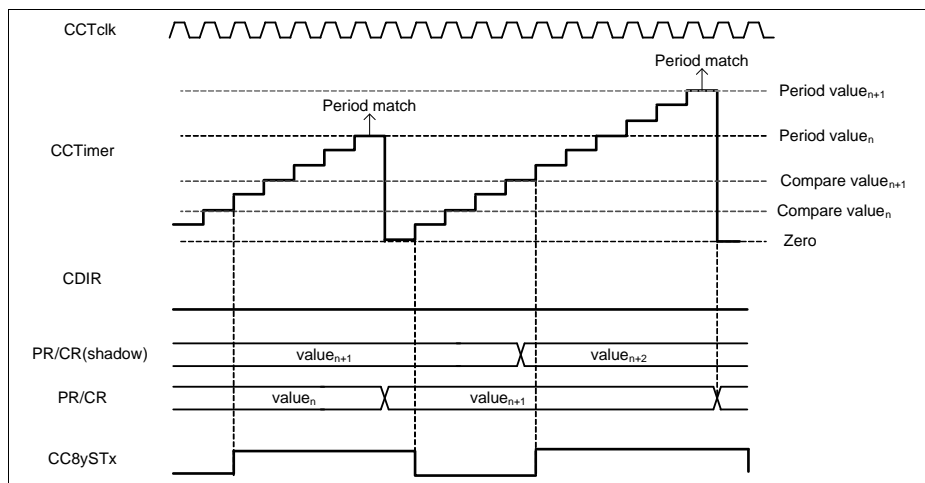

Figure 24-14 Edge aligned mode, **CC8yTC.TCM = 0_B**

24.2.5.4 Center Aligned Mode

In center aligned mode, the timer is counting up or down with respect to the following rules:

- The counter counts up while **CC8yTCST.CDIR = 0_B** and it counts down while **CC8yTCST.CDIR = 1_B**.
- Within the next clock cycle, the count direction is set to counting up (**CC8yTCST.CDIR = 0_B**) when the counter reaches 0001_H while counting down.
- Within the next clock cycle, the count direction is set to counting down (**CC8yTCST.CDIR = 1_B**), when the period match is detected while counting up.

Capture/Compare Unit 8 (CCU8)

The status bit (CC8ySTx) is always 1_B when the counter value is equal or greater than the compare value and 0_B otherwise.

While in edge aligned mode, the shadow transfer for compare and period registers is executed once per period. It is executed twice in center aligned mode as follows

- Within the next clock cycle after the counter reaches the period value, while counting up (CC8yTCST.CDIR = 0_B).
- Within the next clock cycle after the counter reaches 0001_H, while counting down (CC8yTCST.CDIR = 1_B).

Note: Bit CC8yTCST.CDIR changes within the next timer clock after the one-match or the period-match, which means that the timer continues counting in the previous direction for one more cycle before changing the direction.

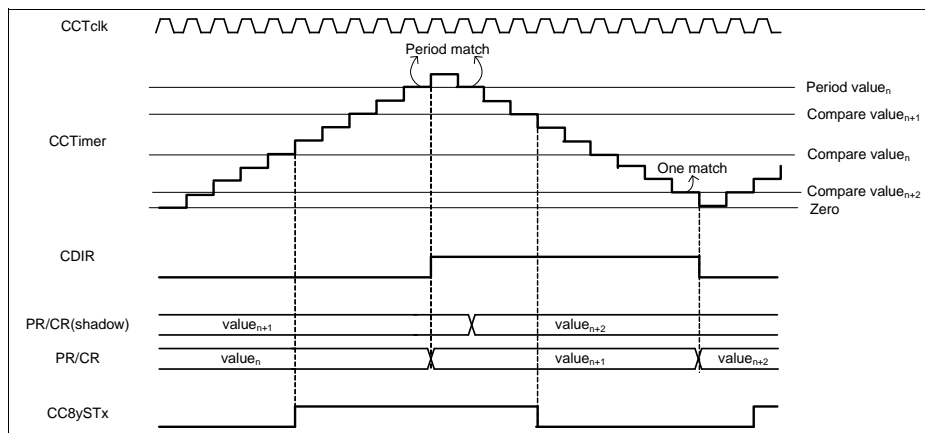

Figure 24-15 Center aligned mode, CC8yTC.TCM = 1_B

24.2.5.5 Single Shot Mode

In single shot mode, the timer is stopped after the current timer period is finished. This mode can be used with a center or edge aligned scheme.

In edge aligned mode, **Figure 24-16**, the timer is stopped when it is cleared to 0000_H after having reached the period value. In center aligned mode, **Figure 24-17**, the period is finished when the timer has counted down to 0000_H.

Figure 24-16 Single shot edge aligned - $\text{CC8yTC.TSSM} = 1_B$, $\text{CC8yTC.TCM} = 0_B$

Figure 24-17 Single shot center aligned - $\text{CC8yTC.TSSM} = 1_B$, $\text{CC8yTC.TCM} = 1_B$

24.2.6 Active/Passive Rules

The general rules that set or clear the associated timer slice status bit, can be generalized independently of the timer counting mode.

The following events set the Status bit to Active:

- in the next f_{tclk} cycle after a compare match while counting up
- in the next f_{tclk} cycle after a zero match while counting down

The following events set the Status bit to Inactive:

- in the next f_{tclk} cycle after a zero match (and not compare match) while counting up
- in the next f_{tclk} cycle after a compare match while counting down

Capture/Compare Unit 8 (CCU8)

If external events are being used to control the timer operation, these rules are still applicable.

The status bit state can only be 'override' via software or by the external status bit override function, [Section 24.2.8.10](#).

The software at any time can write a 1_B into the **GCSS.SySTS** bitfield, which will set the status bit **GCST.CC8yST** of the specific timer slice. By writing a 1_B into the **GCSC.SySTC** bitfield, the software imposes a clear of the specific status bit.

24.2.7 Compare Modes

Compare Channel Scheme

Each CCU8 slice has two compare channels and two dead time generators, one for each channel, see [Figure 24-18](#). Each compare uses the information of the status bit, CC8ySTx, to generate two complementary outputs. All the outputs, CCU8x.OUTy0, CCU8x.OUTy1, CCU8x.OUTy2 and CCU8x.OUTy3, have a dedicated passive level control bit.

Each compare channel can work in an individual manner for both edge and center aligned modes. This means that two different complementary PWM signals can be generated by using the available compare channels. The PWM frequency is the same for both channels, but the duty cycle can be programmed independently for each channel.

It is also possible to select an asymmetric output scheme, by setting the field **CC8yCHC.ASE** = 1_B. In the asymmetric mode, the compare channels are grouped together to generate a single complementary PWM signal at the CCU8x.OUTy0 and CCU8x.OUTy1 pins.

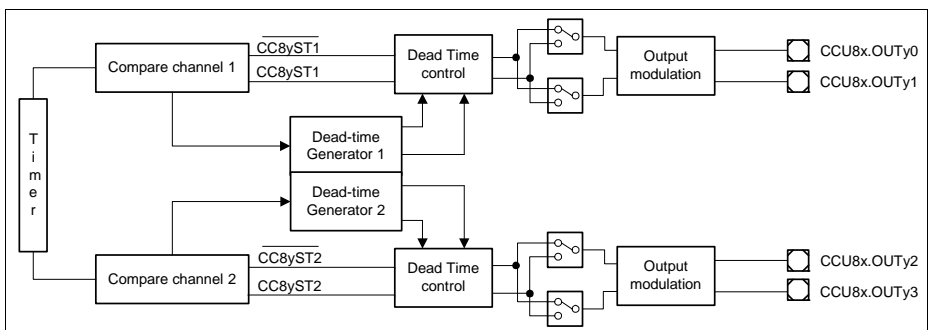

Figure 24-18 Compare channels diagram

Dead Time Generator

In most cases the switching behavior regarding the switch-on and switch-off times is not symmetrical, which can lead to a short circuit if the switch-on time is smaller than the switch-off time. To overcome this problem, each Timer Slice channel contains a dead time generator, which is able to delay the switching edges of the output signals, **Figure 24-19**.

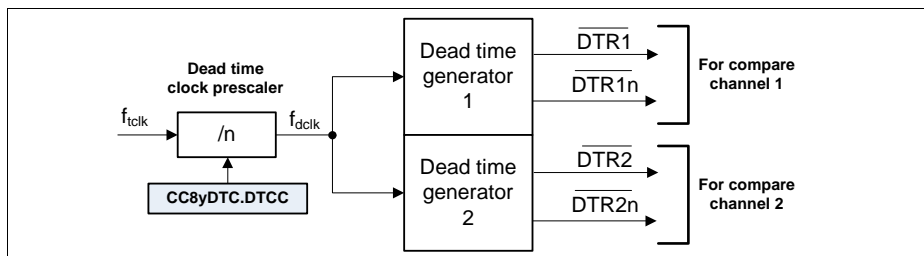

Figure 24-19 Dead Time scheme

Each dead time generator contains an eight bit counter with a different programmable reload value for rise and fall times. The dead time generators contain a programmable prescaler for the dead time counter clock, to enable large dead time insertion values, **Table 24-5**.

Table 24-5 Dead time prescaler values

| CC8yDTC.DTCC[1:0] | Frequency |
|--------------------------|------------------|
| 00 _B | f_{tclk} |
| 01 _B | $f_{tclk}/2$ |
| 10 _B | $f_{tclk}/4$ |
| 11 _B | $f_{tclk}/8$ |

Any transition on the associated status bits, CC8ySTx, will trigger the start of the specific dead time generator, **Figure 24-20**.

When a SET (CC8ySTx passes from 0_B to 1_B) action for the CC8ySTx bit is detected, the dead time counter is reloaded with the value present on the **CC8yDC1R.DT1R** or **CC8yDC2R.DT2R** (depending on which channel we are addressing).

When a CLEAR action for the CC8ySTx bit is detected (CC8ySTx passes from 0_B to 1_B), the dead time counter is reloaded with the value present on the **CC8yDC1R.DT1F** or **CC8yDC2R.DT2F** (depending on which channel we are addressing).

Capture/Compare Unit 8 (CCU8)

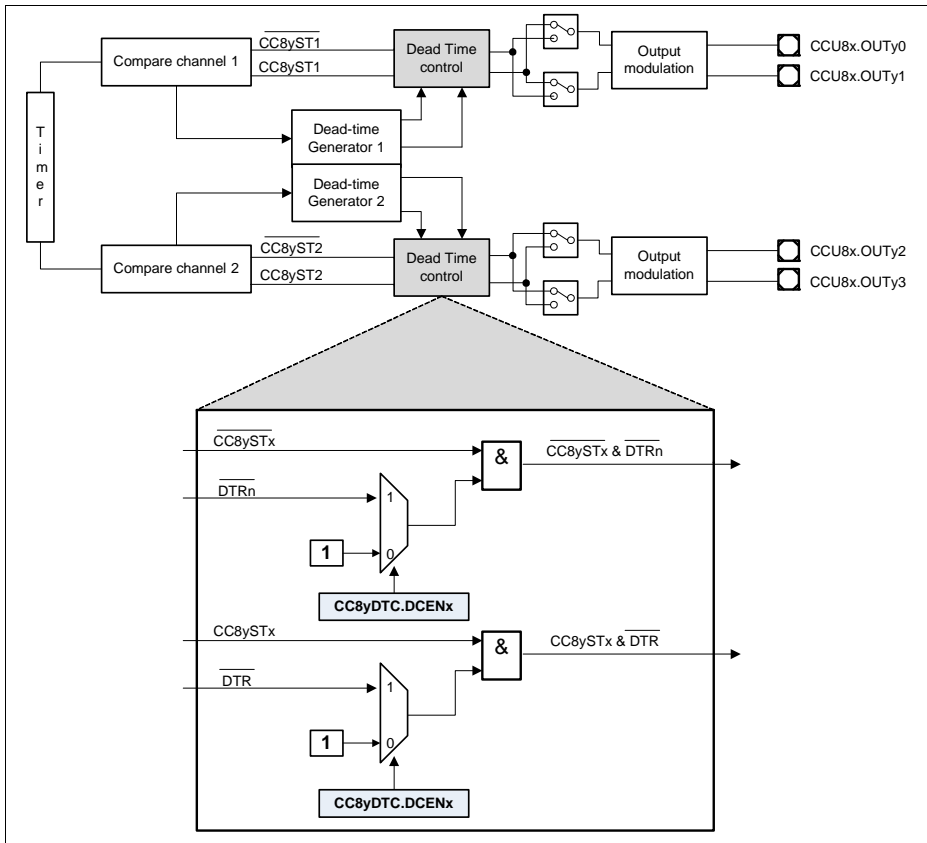

Figure 24-21 Dead Time control cell

When using the Multi Channel mode, $CC8yTC.MCMEy = 1_B$, there can be the scenario where the generated PWM signal has 100% duty cycle. This means that the respective status bit is always set and it is the Multi Channel pattern that is controlling the output modulation. In this case, we can have a transition from Inactive to Active state at the output, without having a transition on the specific status bit, creating a short on the switches due to the non existence of dead time insertion.

To overcome this possible short on the switches, a trigger from the multi channel control, CCMP_TRIG on [Figure 24-20](#), is fed to the dead time generators. [Figure 24-22](#) shows the scheme for the generation of the CCMP_TRIG, where the signals, CCMCMx0 and CCMCMx1 represent the sampled multi channel pattern for a specific channel.

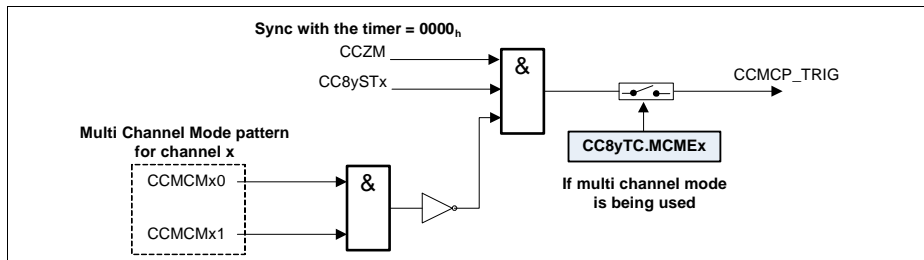

Figure 24-22 Dead Time trigger with the Multi Channel pattern

24.2.7.1 Edge Aligned Compare Modes

Standard Edge Aligned Mode

When the Timer Slice is programmed in edge aligned mode, the two channels can work independently, which means that the compare values can be programmed with different values (originating different duty cycles). In this scenario, each channel can output a pair of PWM signals used to control a high and low side switches, see [Figure 24-23](#).

In this mode, for each channel the dead time for rise and fall transitions are controlled by the values programmed in the [CC8yDC1R.DT1R](#) and [CC8yDC2R.DT2R](#), and [CC8yDC1R.DT1F](#) and [CC8yDC2R.DT2F](#) fields, respectively.

[Figure 24-24](#) shows the timing diagrams for a specific slice when the compare values of each channel are different.

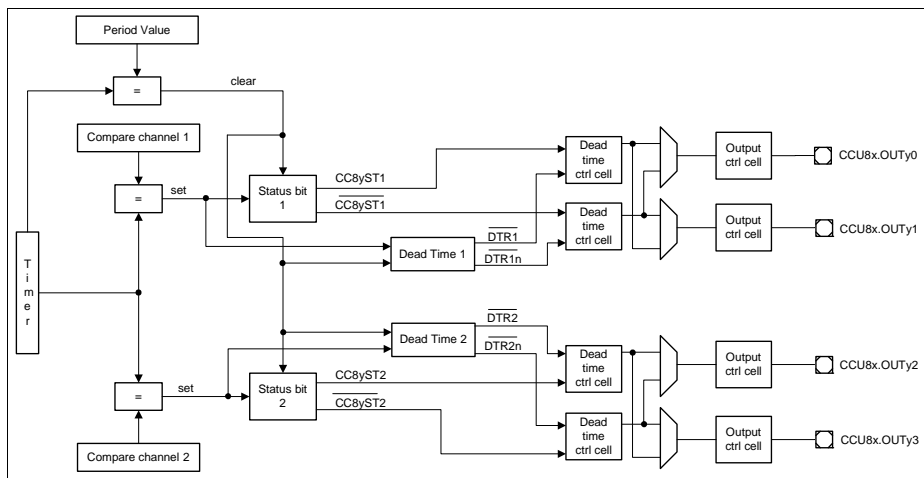

Figure 24-23 Edge Aligned with two independent channels scheme

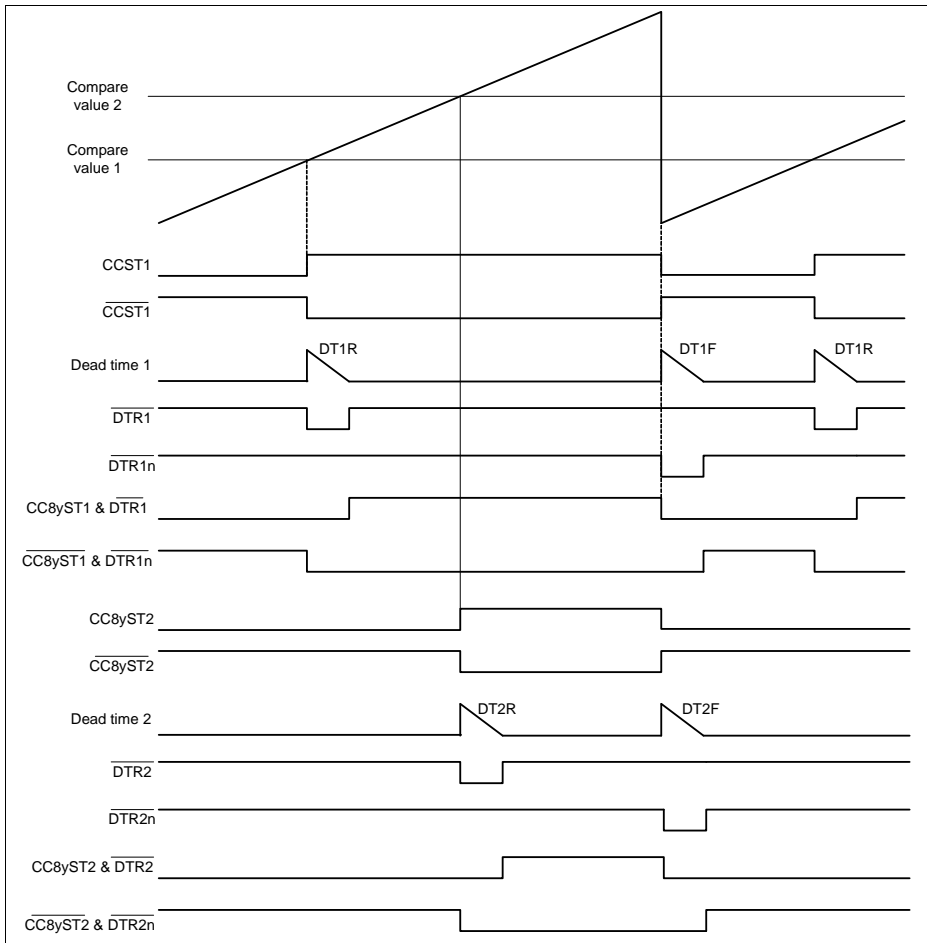

Figure 24-24 Edge Aligned - four outputs with dead time

Asymmetrical Edge Aligned Mode

There is also the possibility of using the two channels combined to generate an asymmetric PWM output. This mode is selected by setting the field **CC8yCHC.ASE** = 1_B.

In this mode, the compare channel 2 is disabled and therefore the outputs linked with this path are always in the passive state.

The status bit of the compare channel 1 is set when a compare match with the compare value 1 (field **CC8yCR1.CR1**) occurs and is cleared when a compare match with the compare value 2 (field **CC8yCR2.CR2**) occurs, see [Figure 24-25](#).

Capture/Compare Unit 8 (CCU8)

When the **CC8yCR2.CR2** is programmed with a value smaller than the one present in **CC8yCR1.CR1**, the **CCST1** bit is always 0_B.

The dead time values for the rising and falling transitions are controlled by the fields **CC8yDC1R.DT1R** and **CC8yDC1R.DT1F**, respectively.

Figure 24-26 and **Figure 24-27** show the timing diagram for the Edge Aligned mode when the asymmetric scheme is active.

Note: When an external signal is used to control the counting direction, the asymmetric mode cannot be enabled.

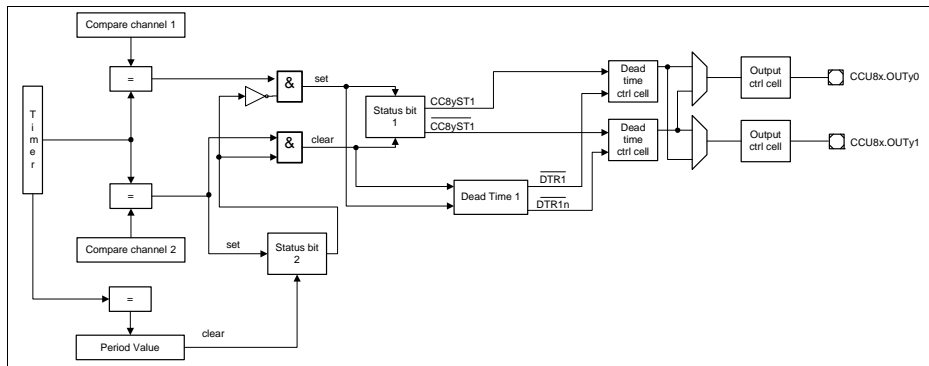

Figure 24-25 Edge Aligned with combined channels scheme

Figure 24-26 Edge Aligned - Asymmetric PWM timing, $CC8yCR1.CR1 < CC8yCR2.CR2$

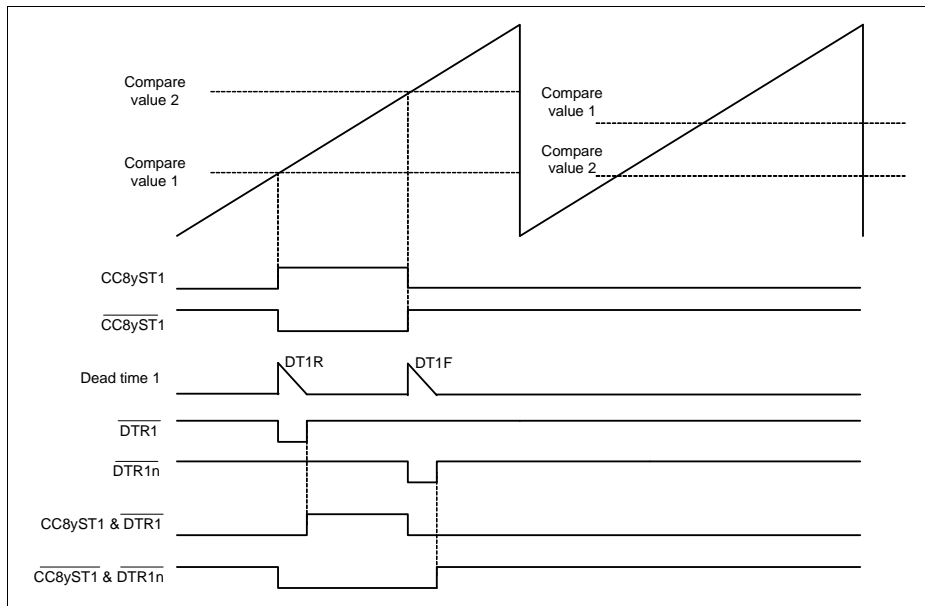

Figure 24-27 Edge Aligned - Asymmetric PWM timing, $CC8yCR1.CR1 > CC8yCR2.CR2$

24.2.7.2 Center Aligned Compare Modes

Standard Center Aligned Mode

In center aligned mode, like in edge aligned, it is possible to use the two compare channels independently. In this mode, each channel can generate a pair of PWM complementary signals with different duty cycle values, controlled via the **CC8yCR1** for channel 1 and **CC8yCR2** for channel 2.

For the dead time insertion, each channel as a pair of programmable values for the rise and fall transitions: **CC8yDC1R.DT1R** and **CC8yDC1R.DT1F** for channel 1; **CC8yDC2R.DT2R** and **CC8yDC2R.DT2F** for channel 2.

The major difference between the center and the edge aligned mode is directly linked to the set/clear logic of the status bit, see [Section 24.2.5](#).

Figure 24-28 shows the scheme for both channels for this operating mode and **Figure 24-29** shows the timing diagrams for a specific channel.

Note: When an external signal is used to control the counting direction, the counting scheme is always edge aligned.

Capture/Compare Unit 8 (CCU8)

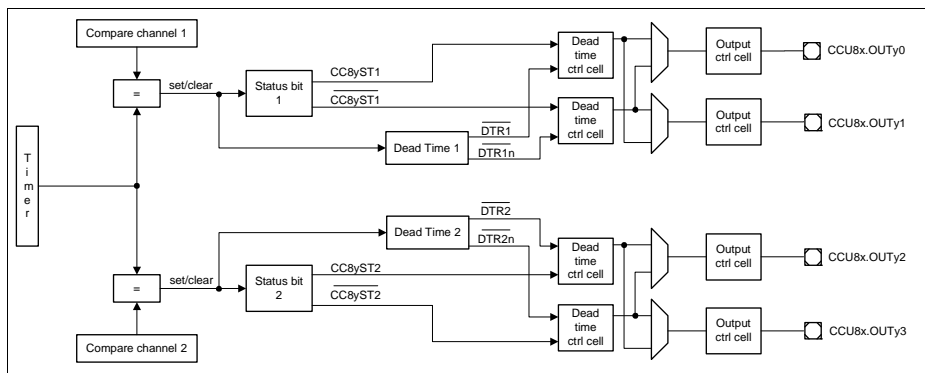

Figure 24-28 Center Aligned with two independent channels scheme

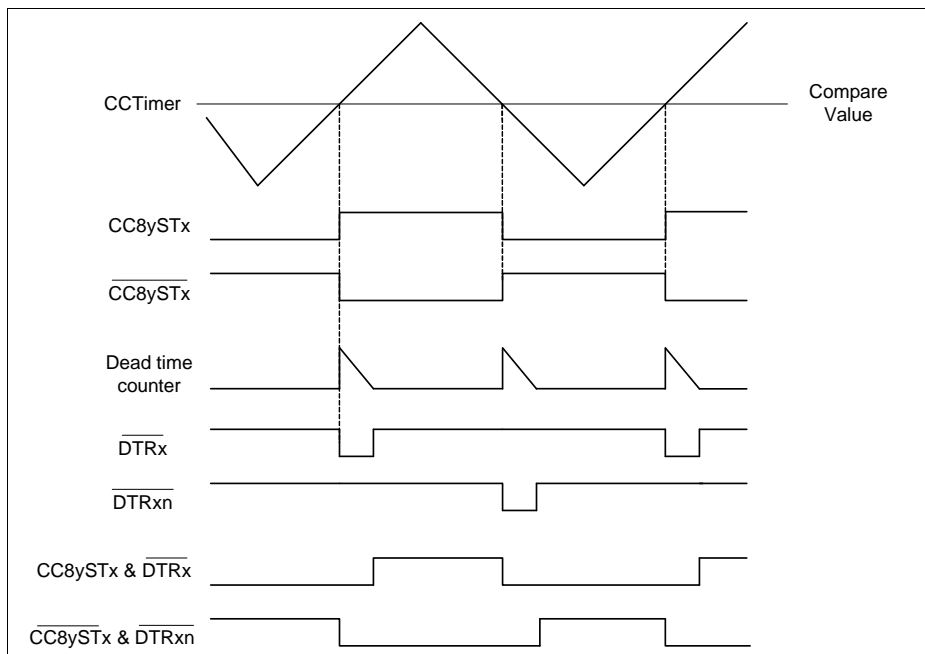

Figure 24-29 Center aligned - Independent channel with dead time

Asymmetrical Center Aligned Mode

The asymmetric mode is enabled in center aligned by setting the field **CC8yCHC.ASE** to 1_B.

Capture/Compare Unit 8 (CCU8)

In this mode, like in Edge Aligned, the outputs linked with the compare channel 2 are set to their passive levels.

The status bit, CC8yST1, is set when a compare match of channel 1 occurs while counting up, and is cleared when a compare match of channel 2 occurs while counting down, see [Figure 24-30](#).

The dead time rise and fall times are controlled by the values programmed into the fields, [CC8yDC1R.DT1R](#) and [CC8yDC1R.DT1F](#), respectively.

[Figure 24-31](#) shows the timing diagram for the asymmetric mode. Notice that even in asymmetric mode the dead time can be disabled in each of the outputs independently.

Note: When an external signal is used to control the counting direction, the asymmetric mode cannot be enabled.

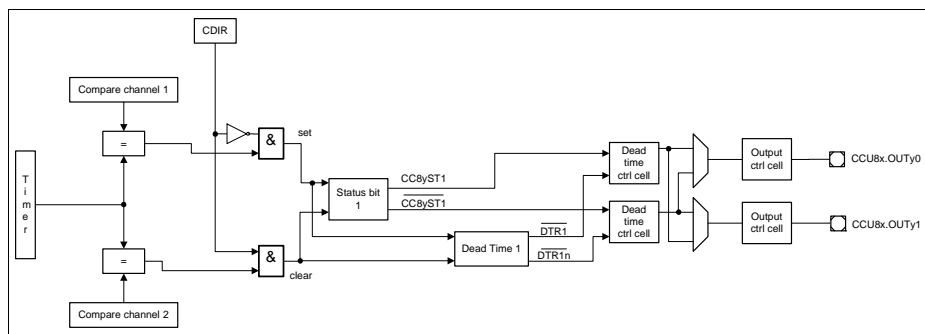

Figure 24-30 Center Aligned Asymmetric mode scheme

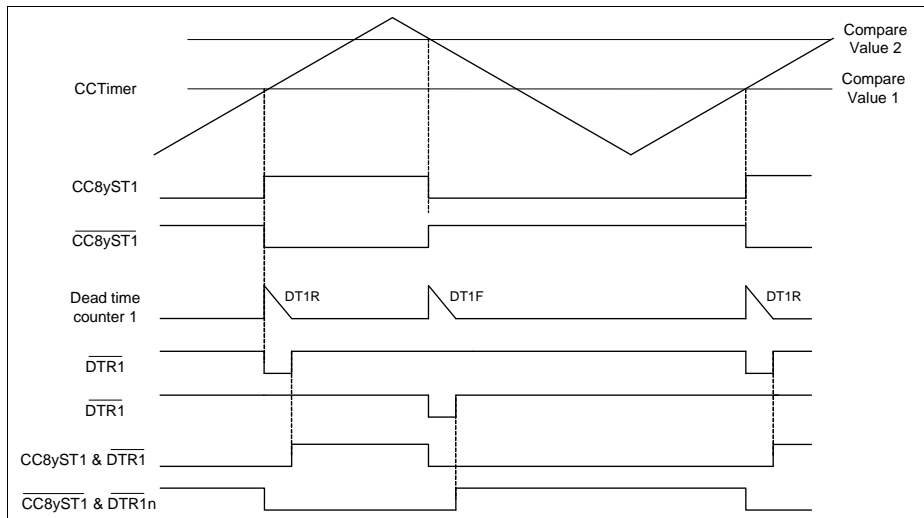

Figure 24-31 Asymmetric Center aligned mode with dead time

24.2.8 External Events Control

Each CCU8 slice has the possibility of using up to three different input events, see [Section 24.2.2](#). These three events can then be mapped to Timer Slice functions (the full set of available functions is described at [Section 24.2.3](#)).

These events can be mapped to any of the CCU8x.INy[P...A] inputs and there isn't any imposition that an event cannot be used to perform several functions or, that an input cannot be mapped to several events (e.g. input X triggers event 0 with rising edge and triggers event 1 with the falling edge).

24.2.8.1 External Start/Stop

To select an external start function, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the [CC8yINS.EVxIS](#) register and indicating the active edge of the signal on the [CC8yINS.EVxEM](#) register.

This event should be then mapped to the start or stop functionality by setting the [CC8yCMC.STRTS](#) (for the start) or the [CC8yTC.ENDM](#) (for the stop) with the proper value.

The same procedure is applicable to the stop functionality.

Notice that both start and stop functions are edge and not level active and therefore the active/passive configuration is set only by the [CC8yINS.EVxEM](#).

Capture/Compare Unit 8 (CCU8)

The external stop by default just clears the run bit (**CC8yTCST.TRB**), while the start functions does the opposite. Nevertheless one can select an extended subset of functions for the external start and stop. This subset is controlled by the registers **CC8yTC.ENDM** (for the stop) and **CC8yTC.STRM** (for the start).

For the start subset (**CC8yTC.STRM**):

- sets the run bit/starts the timer (resume operation)
- clears the timer, sets the run bit/starts the timer (flush and start)

For the stop subset (**CC8yTC.ENDM**):

- clears the run/stops the timer (stop)
- clears the timer (flush)
- clears the timer, clears the run bit/stops the timer (flush and stop)

If in conjunction with an external start/stop (configured also/only as flush) and external up/down signal is used, during the flush operation the timer is going to be set to 0000_H if the actual counting direction is up or set with the value of the period register if the counting direction is down.

Figure 24-32 to **Figure 24-35** shows the usage of two signals to perform the start/stop functions in all the previously mentioned subsets. External Signal(1) acts as an active HIGH start signal, while External Signal(2) is used as an active HIGH stop function.

Figure 24-32 Start (as start)/ stop (as stop) - **CC8yTC.STRM = 0_B , **CC8yTC.ENDM** = 00_B**

Figure 24-33 Start (as start)/ stop (as flush) - $CC8yTC.STRM = 0_B$, $CC8yTC.ENDM = 01_B$

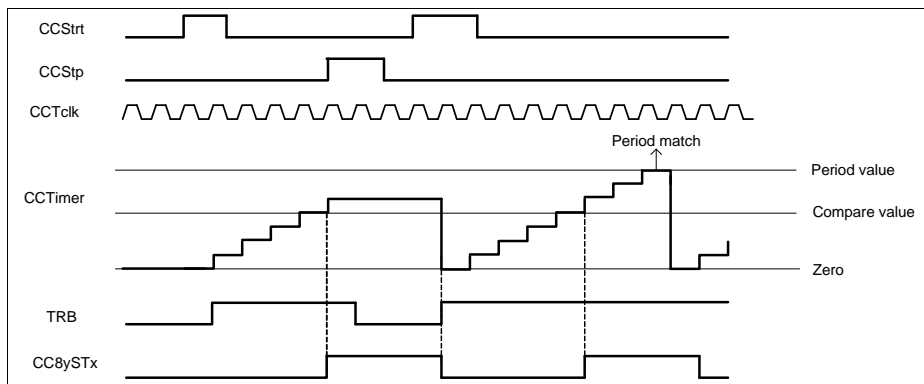

Figure 24-34 Start (as flush and start)/ stop (as stop) - $CC8yTC.STRM = 1_B$, $CC8yTC.ENDM = 00_B$

**Figure 24-35 Start (as start)/ stop (as flush and stop) - $CC8yTC.STRM = 0_B$,
 $CC8yTC.ENDM = 10_B$**

24.2.8.2 External Counting Direction

There is the possibility of selecting an input signal to act as counting up/counting down control.

To select an external up/down control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active level of the signal on the **CC8yINS.EVxLM** register. This event should be then mapped to the up/down functionality by setting the **CC8yCMC.UDS** with the proper value.

Notice that the up/down function is level active and therefore the active/passive configuration is set only by the **CC8yINS.EVxLM**.

The status bit of the slice (CCSTx) is always set when the timer value is equal or greater than the value stored in the compare register, see **Section 24.2.6**.

The update of the period and compare register values is done when:

- with the next clock after a period match, while counting up (**CC8yTCST.CDIR** = 0_B)
- with the next clock after a one match, while counting down (**CC8yTCST.CDIR** = 1_B)

The value of the **CC8yTCST.CDIR** register is updated accordingly with the changes on the decoded event. The Up/Down direction is always understood as **CC8yTCST.CDIR** = 1 when counting down and **CC8yTCST.CDIR** = 0_B when counting up. Using an external signal to perform the up/down counting function and configuring the event as active HIGH means that the timer is counting up when the signal is HIGH and counting down when LOW.

Figure 24-36 shows an external signal being used to control the counting direction of the time. This signal was selected as active HIGH, which means that the timer is counting down while the signal is HIGH and counting up when the signal is LOW.

*Note: For a signal that should impose an increment when LOW and a decrement when HIGH, the user needs to set the **CC8yINS.EVxLM** = 0_B. When the operation is switched, then the user should set **CC8yINS.EVxLM** = 1_B.*

Note: Using an external counting direction control, sets the slice in edge aligned mode.

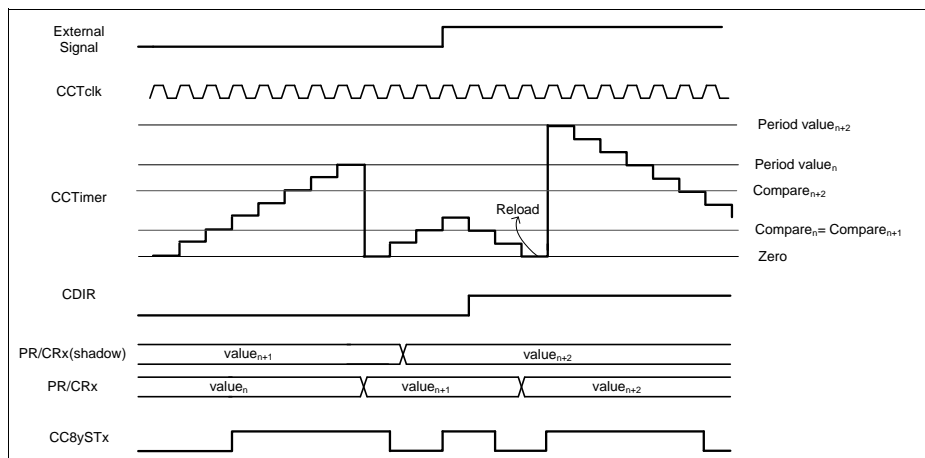

Figure 24-36 External counting direction

24.2.8.3 External Gating Signal

For pulse measurement, the user has the possibility of selecting an input signal that operates as counting gating.

To select an external gating control, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active level of the signal on the **CC8yINS.EVxLM** register. This event should be then mapped to the gating functionality by setting the **CC8yCMC.GATES** with the proper value.

Notice that the gating function is level active and therefore the active/passive configuration is set only by the **CC8yINS.EVxLM**.

The status bit during an external gating signal continues to be asserted when the compare value is reached and deasserted when the counter reaches 0000_H. One should note that the counter continues to use the period register to identify a wrap around condition. **Figure 24-37** shows the usage of an external signal for gating the slice

counter. The signal was set as active LOW, which means the counter gating functionality is active when the external value is zero.

Figure 24-37 External gating

24.2.8.4 External Count Signal

There is also the possibility of selecting an external signal to act as the counting event.

To select an external counting, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active edge of the signal on the **CC8yINS.EVxEM** register. This event should be then mapped to the counting functionality by setting the **CC8yCMC.CNTS** with the proper value.

Notice that the counting function is edge active and therefore the active/passive configuration is set only by the **CC8yINS.EVxEM**.

One can select just a the rising, falling or both edges to perform a count. On **Figure 24-38**, the external signal was selected as a counter event for both falling and rising edges. Wrap around condition is still applied with a comparison with the period register.

Figure 24-38 External count

24.2.8.5 External Load

Each slice of the CCU8 also has a functionality that enables the user to select an external signal as trigger for reloading the value of the timer with the current value of one compare register (if **CC8yTCST.CDIR** = 0_B) or with the value of the period register (if **CC8yTCST.CDIR** = 1_B).

The timer can be reloaded with the value from the compare channel 1 or compare channel 2 depending on the value set in the **CC8yTC.TLS** field, see [Figure 24-39](#).

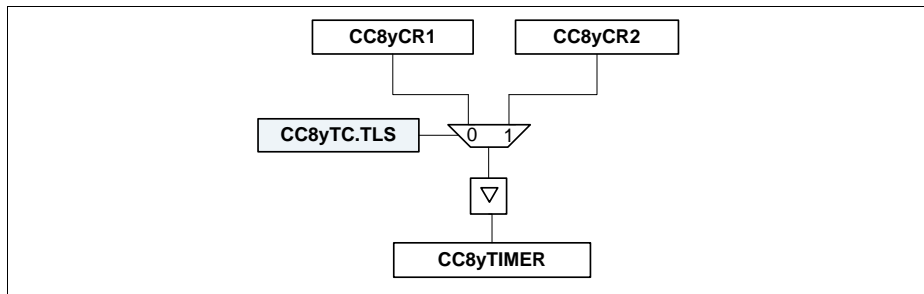

Figure 24-39 Timer load selection

To select an external load signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active edge of the signal on the **CC8yINS.EVxEM** register. This event should be then mapped to the load functionality by setting the **CC8yCMC.LDS** with the proper value.

Notice that the load function is edge active and therefore the active/passive configuration is set only by the **CC8yINS.EVxEM**.

Capture/Compare Unit 8 (CCU8)

On figure **Figure 24-40**, the external signal (1) was used to act as a load trigger, active on the rising edge. Every time that a rising edge on external signal (1) is detected, the timer value is loaded with the value present on the compare register. If an external signal is being used to control the counting direction, up or down, the timer value can be loaded also with the value set in the period register. The External signal (2) represents the counting direction control (active HIGH). If at the moment that a load trigger is detected, the signal controlling the counting direction is imposing a decrement, then the value set in the timer is the period value.

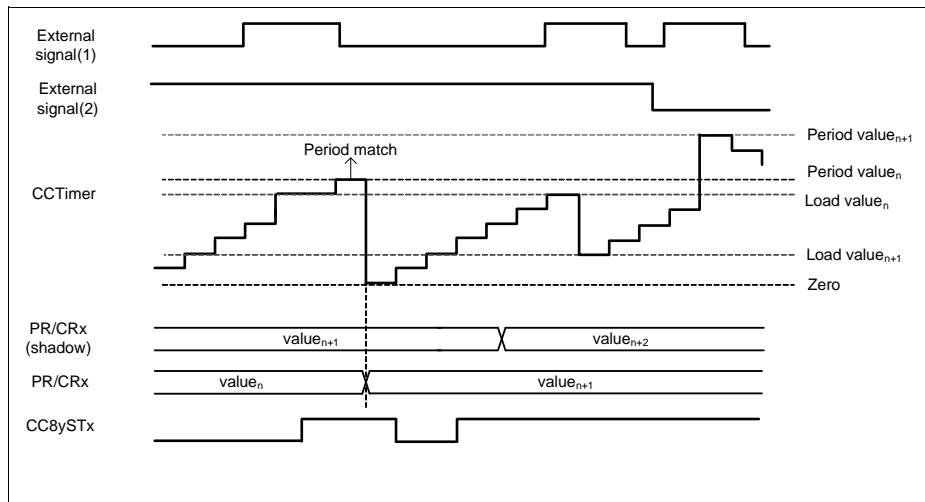

Figure 24-40 External load

24.2.8.6 External Capture

When selecting an external signal to be used as a capture trigger (if **CC8yCMC.CAP0S** or **CC8yCMC.CAP1S** are different from 0_H), the user is automatically setting the specific slice into capture mode.

In capture mode the user can have up to four capture registers, see **Figure 24-43**: capture register 0 (**CC8yC0V**), capture register 1 (**CC8yC1V**), capture register 2 (**CC8yC2V**) and capture register 3 (**CC8yC3V**).

These registers are shared between compare and capture modes, which imposes:

- if **CC8yC0V** and **CC8yC1V** are used for capturing, the compare registers **CC8yCR1** and **CC8yCR1S** are not available (compare channel 1 is not available)
- if **CC8yC2V** and **CC8yC3V** are used for capturing, the compare registers **CC8yCR2** and **CC8yCR2S** are not available (compare channel 2 is not available)

Capture/Compare Unit 8 (CCU8)

To select an external capture signal, one should map one of the events (output of the input selector) to a specific input signal, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active edge of the signal on the **CC8yINS.EVxEM** register.

This event should be then mapped to the capture functionality by setting the **CC8yCMC.CAP0S/CC8yCMC.CAP1S** with the proper value.

Notice that the capture function is edge active and therefore the active/passive configuration is set only by the **CC8yINS.EVxEM**.

The user has the possibility of selecting the following capture schemes:

- Different capture events for **CC8yC0V/CC8yC1V** and **CC8yC2V/CC8yC3V**
- The same capture event for **CC8yC0V/CC8yC1V** and **CC8yC2V/CC8yC3V** with the same capture edge. For this capture scheme, only the CCapt1 functionality needs to be programmed. To enable this scheme, the field **CC8yTC.SCE** needs to be set to 1_B.

Different Capture Events (SCE = 0_B)

Every time that a capture trigger 1 occurs, CCapt1, the actual value of the timer is captured into the capture register 3 and the previous value stored in this register is transferred into capture register 2.

Every time that a capture trigger 0 occurs, CCapt0, the actual value of the timer is captured into the capture register 1 and the previous value stored in this register is transferred into capture register 0.

Every time that a capture procedure into one of the registers occurs, the respective full flag is set. This flag is cleared automatically by HW when the SW reads back the value of the capture register (by reading the specific capture register or by reading the extended capture read value, see [Section 24.2.8.7](#)).

The capture of a new value into a specific capture registers is dictated by the status of the full flag as follows:

$$CC8yC1V_{\text{capt}} = \text{NOT}(CC8yC1V_{\text{full_flag}} \text{ AND } CC8yC0V_{\text{full_flag}}) \quad (24.4)$$

$$CC8yC0V_{\text{capt}} = CC8yC1V_{\text{full_flag}} \text{ AND NOT}(CC8yC0V_{\text{full_flag}}) \quad (24.5)$$

It is also possible to disable the effect of the full flags by setting the **CC8yTC.CCS** = 1_B. This enables a continuous capturing independent if the values captured have been read or not.

On [Figure 24-41](#), an external signal was selected as an event for capturing the timer value into the **CC8yC0V/CC8yC1V** registers. The status bit, CC8ySTx, during capture mode is asserted whenever a capture trigger is detected and de asserted when the counter matches 0000_H.

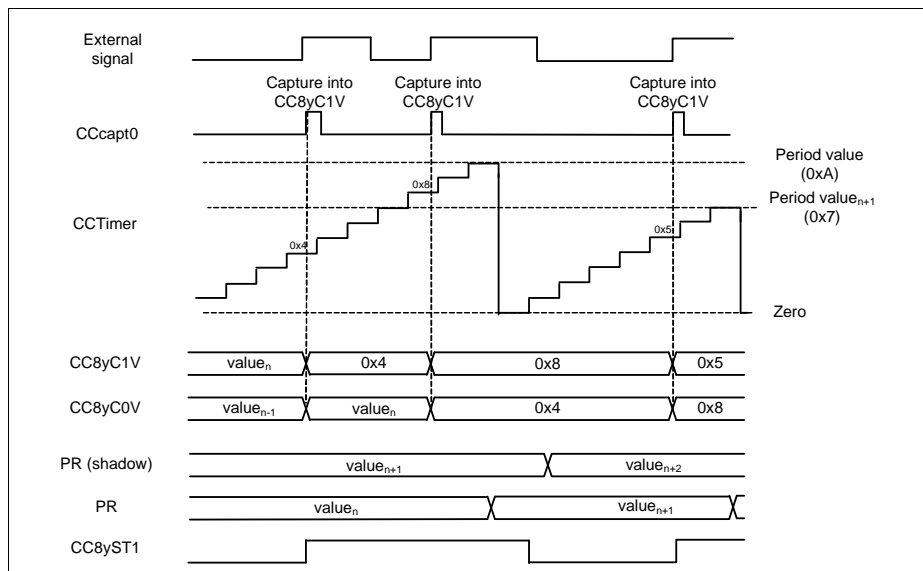

Figure 24-41 External capture - $CC8yCMC.CAP0S \neq 00_B$, $CC8yCMC.CAP1S = 00_B$

On [Figure 24-42](#), two different signals were used as trigger sources for capturing the timer value into the [CC8yC0V/CC8yC1V](#) and [CC8yC2V/CC8yC3V](#) registers. External signal(1) was selected as an rising edge active source for the channel 1 capture trigger. External signal(2) was selected has the source for the channel 2 capture trigger, but as opposite to the external signal(1), the active edge was set as falling.

See [Section 24.2.14.4](#) for the complete capture mode usage description.

Capture/Compare Unit 8 (CCU8)

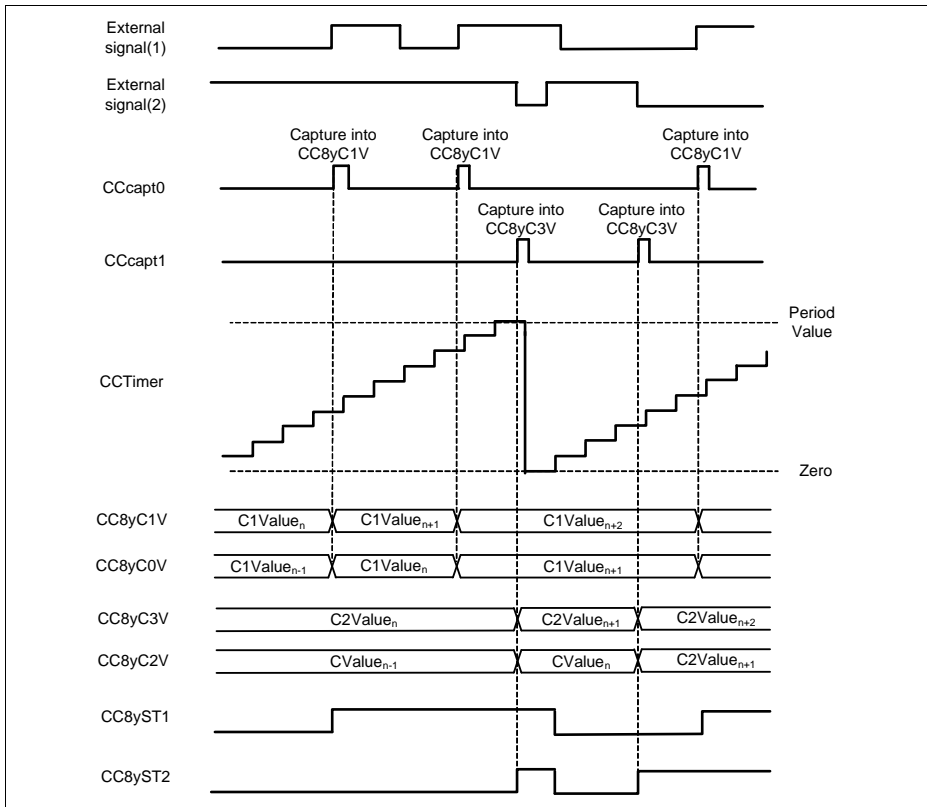

Figure 24-42 External capture - $\text{CC8yCMC.CAP0S} \neq 00_B$, $\text{CC8yCMC.CAP1S} \neq 00_B$

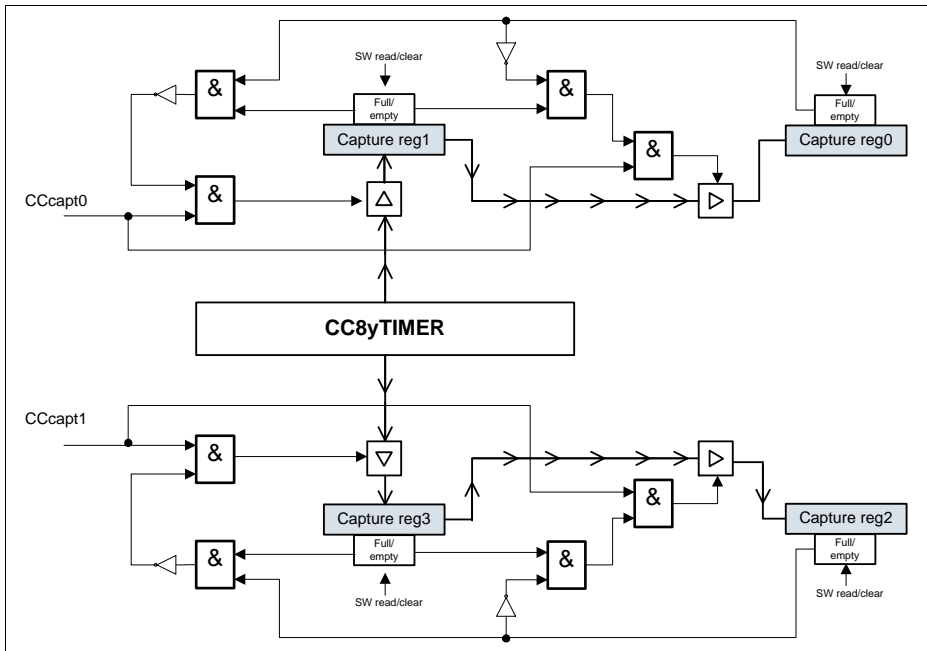

Figure 24-43 Slice capture logic

Same Capture Event (SCE = 1_B)

Setting the field **CC8yTC.SCE = 1_B**, enables the possibility of having 4 capture registers linked with the same capture event, **Figure 24-45**. The functionality that controls the capture is the CCcapt1.

The capture logic follows the same structure shown in **Figure 24-43** but extended to a four register chain, see **Figure 24-44**. The same full flag lock rules are applied to the four register chain (it also can be disabled by setting the **CC8yTC.CCS = 1_B**):

$$CC8yC3V_{capt} = \text{NOT}(CC8yC3V_{full_flag} \text{ AND } CC8yC2V_{full_flag} \text{ AND } CC8yC2V_{full_flag} \text{ AND } CC8yC1V_{full_flag}) \quad (24.6)$$

$$CC8yC2V_{capt} = CC8yC3V_{full_flag} \text{ AND NOT}(CC8yC2V_{full_flag} \text{ AND } CC8yC1V_{full_flag} \text{ AND } CC8yC0V_{full_flag}) \quad (24.7)$$

$$CC8yC1V_{capt} = CC8yC2V_{full_flag} \text{ AND NOT}(CC8yC1V_{full_flag} \text{ AND } CC8yC0V_{full_flag}) \quad (24.8)$$

$$CC8yC0V_{capt} = CC8yC1V_{full_flag} \text{ AND NOT}(CC8yC0V_{full_flag}) \quad (24.9)$$

Capture/Compare Unit 8 (CCU8)

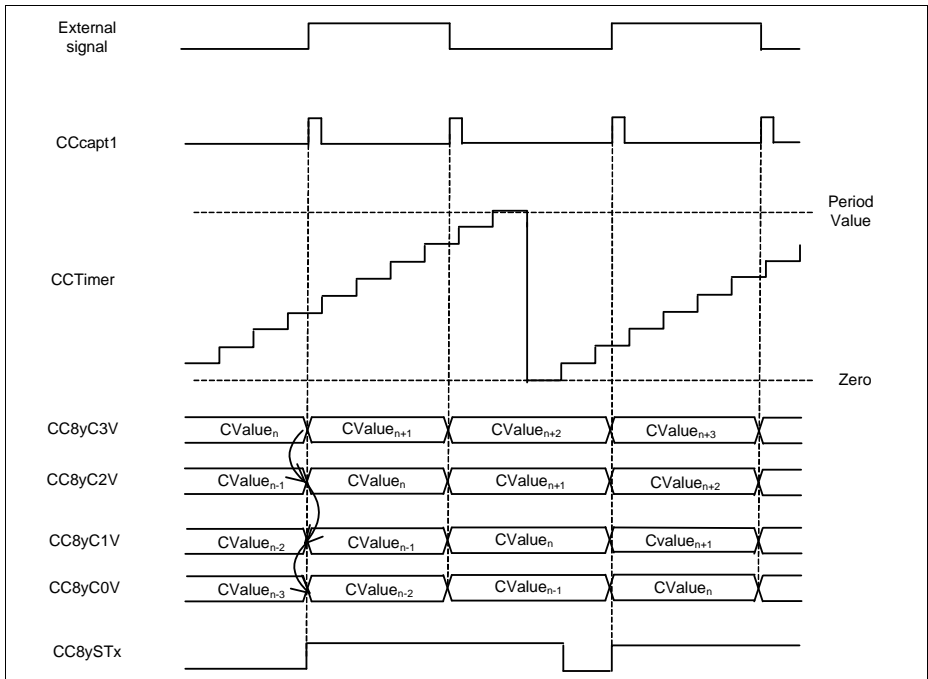

Figure 24-44 External Capture - CC8yTC.SCE = 1_B

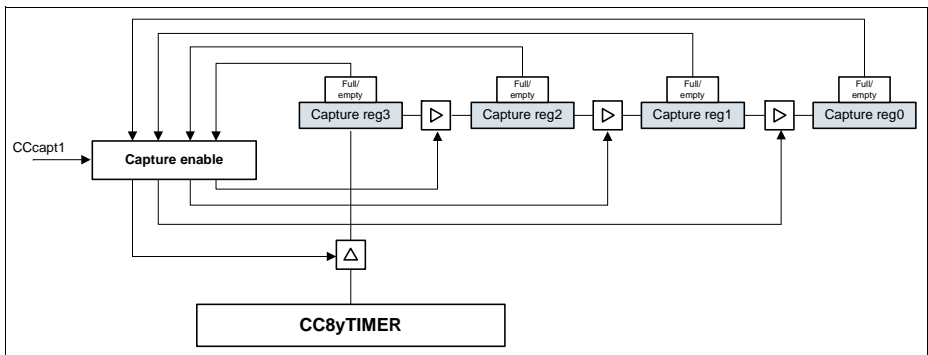

Figure 24-45 Slice Capture Logic - CC8yTC.SCE = 1_B

24.2.8.7 Capture Extended Read Back Mode

Each Timer Slice capture logic can operate in a FIFO read back mode. This mode can be enabled by setting the **CC8yTC.ECM** = 1_B. This Extended Read back mode allows the software to read back the capture data always from the same address (**CC8yECRD0** for the structure linked with the capture trigger 0 or **CC8yECRD1** for the one linked with capture trigger 1). This read back will always return the oldest captured value, enabling an easy software routine implementation for reconstructing the capture data.

This function allows the usage of a FIFO structure for each capturing trigger. This relaxes the software read back routine when multiple capture triggers are present, and the software is not fast enough to perform a read operation in each capture event.

This FIFO read back function is present for a depth-4 and depth-2 FIFO structure.

The read back data contains also a lost value bitfield, that indicates if a capture trigger was lost due to the fact that the FIFO structure was full. This bitfield is set whenever a capture event was sensed and the FIFO was full (regardless if the continuous capture mode was enabled or not). This bitfield is cleared automatically by HW whenever the next read of the **CC8yECRD0/CC8yECRD1** register occurs. This bitfield does not indicate how many capture events were lost, it just indicates that between two ECRD reads at least a capture event was lost (this can help the SW evaluate which part of the data read, can be used for calculation).

*Note: When the ECM bitfield is set, reading the individual capture registers is still possible. Nevertheless the full flags can only be cleared by the HW when a read back is done via the **CC8yECRD0/CC8yECRD1** address.*

Depth 4 Structure

The FIFO depth-4 structure is present in the hardware when the capture trigger 1 is enabled and the **CC8yTC.SCE** = 1_B (same capture event), **Figure 24-46**.

Capture/Compare Unit 8 (CCU8)

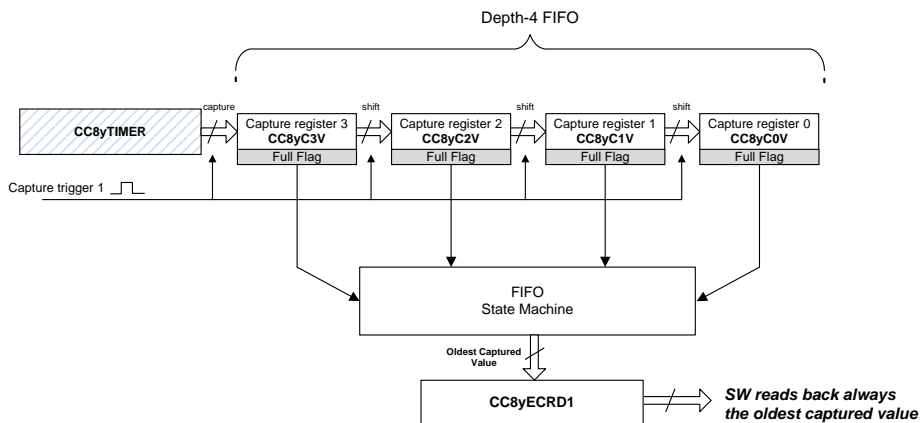

Figure 24-46 Capture Extended Read Back - Depth 4

Capture/Compare Unit 8 (CCU8)

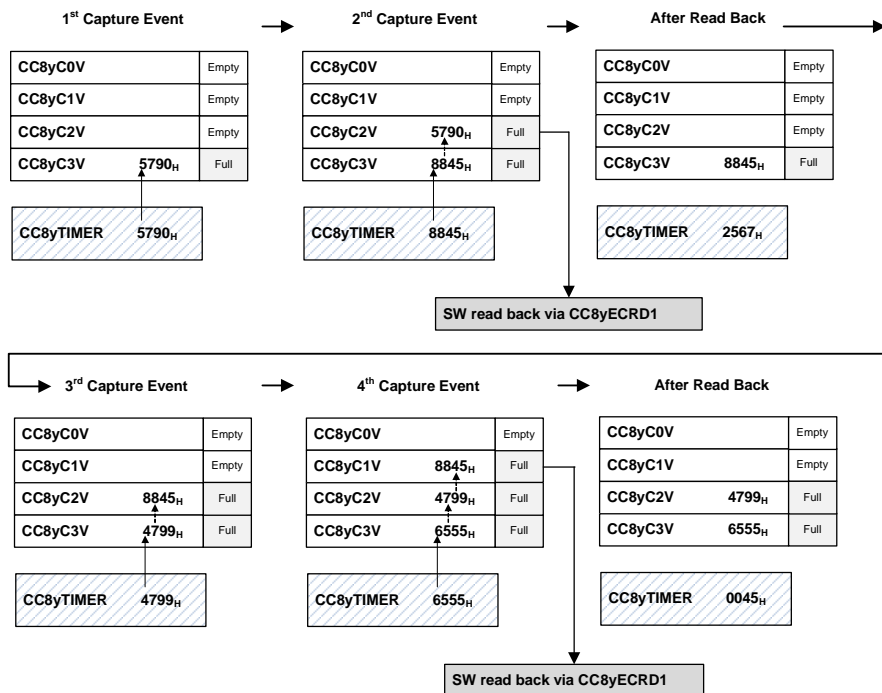

Figure 24-47 Depth 4 software access example

Depth 2 Structure

Each Timer Slice can have two capture structures of depth-2: one used with capture trigger 0 and another with capture trigger 1.

The one linked with capture trigger 0, is accessed via the **CC8yECDR0** while the one linked with the capture trigger 1 is accessed via the **CC8yECDR1**, [Figure 24-48](#).

Figure 24-48 Capture Extended Read Back - Depth 2

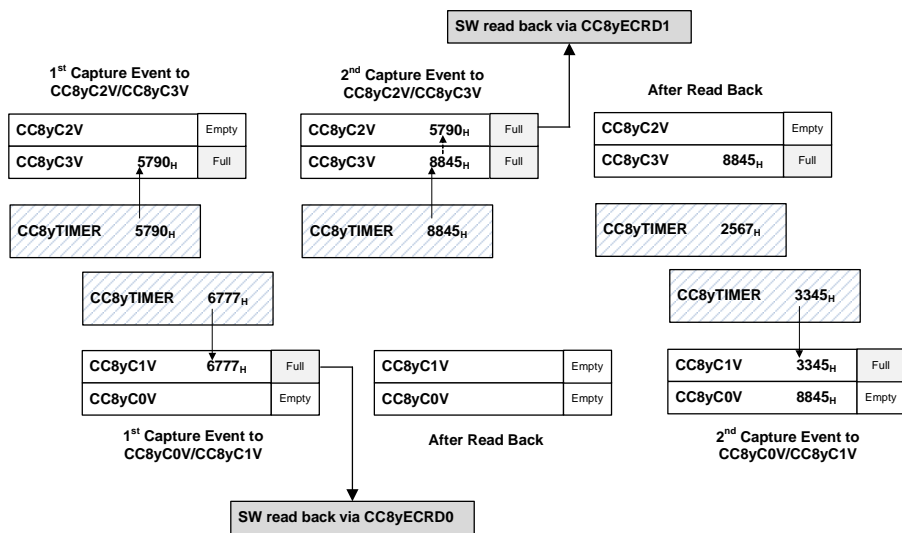

Figure 24-49 Depth 2 software access example

24.2.8.8 External Modulation

An external signal can be used also to perform a modulation at the output of each slice. To select an external modulation signal, one should map one of the input signals to one of the events, by setting the required value in the **CC8yINS.EVxIS** register and indicating the active level of the signal on the **CC8yINS.EVxLM** register. This event should be then

Capture/Compare Unit 8 (CCU8)

mapped to the modulation functionality by setting the **CC8yCMC.MOS** = 01_B if event 0 is being used, **CC8yCMC.MOS** = 10_B if event 1 or **CC8yCMC.MOS** = 11_B if event 2.

Notice that the modulation function is level active and therefore the active/passive configuration is set only by the **CC8yINS.EVxLM**.

The external modulation signal can be applied to each compare channel independently, or it can be applied to both channels, by setting **CC8yTC.EME** = 11_B .

The modulation has two modes of operation:

- modulation event is used to reset the CC8ySTx bit - **CC8yTC.EMT** = 0_B
- modulation event is used to gate the outputs - **CC8yTC.EMT** = 1_B

On **Figure 24-50**, we have a external signal configured to act as modulation source that clears the ST bit, **CC8yTC.EMT** = 0_B . It was programmed to be an active LOW event and therefore, when this signal is LOW the output value is following the normal ACTIVE/PASSIVE rules.

When the signal is HIGH (inactive state), then the CC8ySTx bit is cleared and the output is forced into the PASSIVE state. Notice that the values of the status bit, CC8ySTx and the specific output CCU8x.OUTy are not linked together. One can choose for the output to be active LOW through the **CC8yPSL.PSLx** bit.

The exit of the external modulation inactive state is synchronized with the PWM period due to the fact that the CC8ySTx bit is cleared and cannot be set while the modulation signal is inactive.

The entering into inactive state also can be synchronized with the PWM period, by setting **CC8yTC.EMS** = 1_B . With this all possible glitches at the output are avoided, see **Figure 24-51**.

Figure 24-50 External modulation resets the ST bit - **CC8yTC.EMS = 0_B**

Figure 24-51 External modulation clearing the ST bit - $\text{CC8yTC.EMS} = 1_B$

On **Figure 24-52**, the external modulation event was used as gating signal of the outputs, $\text{CC8yTC.EMT} = 1_B$. The external signal was configured to be active HIGH, $\text{CC8yINS.EVxLM} = 0_B$, which means that when the external signal is HIGH the outputs are set to the PASSIVE state. In this mode, the gating event can also be synchronized with the PWM signal by setting the $\text{CC8yTC.EMS} = 1_B$.

Figure 24-52 External modulation gating the output - $\text{CC8yTC.EMT} = 1_B$

24.2.8.9 Trap Function

The TRAP functionality allows the PWM outputs to react on the state of an input pin. This functionality can be used to switch off the power devices if the TRAP input becomes active.

Capture/Compare Unit 8 (CCU8)

To select the trap functionality, one should map one of the input signals to event number 2, by setting the required value in the **CC8yINS.EV2IS** register and indicating the active level of the signal on the **CC8yINS.EV2LM** register. This event should be then mapped to the trap functionality by setting the **CC8yCMC.TS = 1_B**.

Notice that the trap function is level active and therefore the active/passive configuration is set only by the **CC8yINS.EV2LM**.

There are two bitfields that can be monitored via software to crosscheck the TRAP function, **Figure 24-53**:

- The TRAP state bit, **CC8yINTS.E2AS**. This bitfield if the TRAP is currently active or not. This bitfield is therefore setting the specific Timer Slice output, into ACTIVE or PASSIVE state.
- The TRAP Flag, **CC8yINTS.TRPF**. This bitfield is used as a remainder in the case that the TRAP condition is cleared automatically via hardware. This field needs to be cleared by the software.

The E2AS can be configured to affect all of the CCU8 slice outputs, or a specific sub set of outputs via the **CC8yTC.TRAPEy** bit fields.

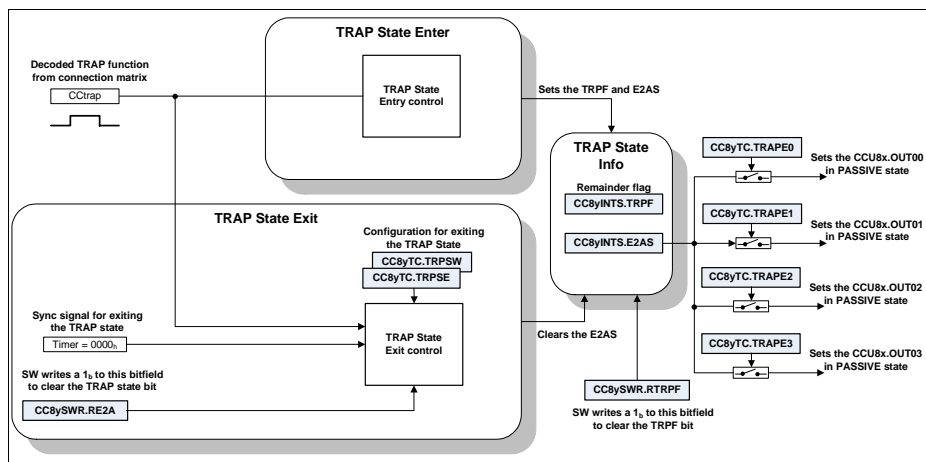

Figure 24-53 Trap control diagram

When a TRAP condition is detected at the selected input pin, both the Trap Flag and the Trap State bit are set to 1_B. The Trap State is entered immediately, by setting the CCU8xOUTy into the programmed PASSIVE state, **Figure 24-54**.

Exiting the Trap State can be done in two ways (**CC8yTC.TRPSW** register):

- automatically via HW, when the TRAP signal becomes inactive - **CC8yTC.TRPSW = 0_B**

Capture/Compare Unit 8 (CCU8)

- by SW only, by clearing the **CC8yINTS.E2AS**. The clearing is only possible if the input TRAP signal is in inactive state - **CC8yTC.TRPSW = 1_B**

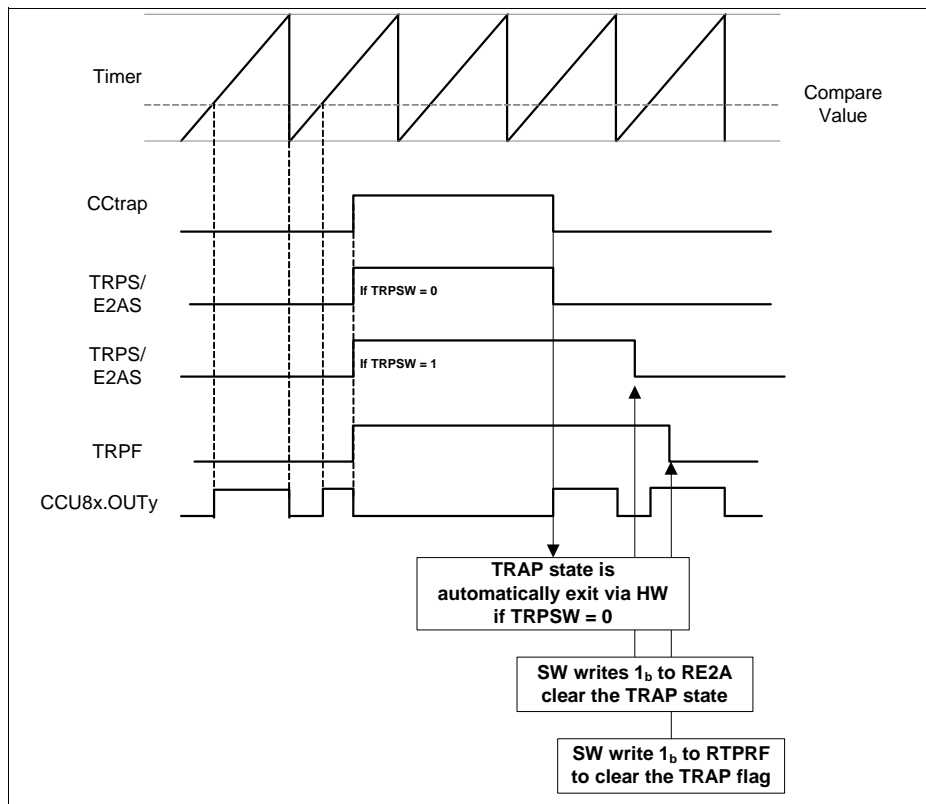

Figure 24-54 Trap timing diagram, **CC8yTCST.CDIR = 0** **CC8yPSL.PSL = 0**

It is also possible to synchronize the exiting of the TRAP state with the PWM signal, **Figure 24-55**. This function is enabled when the bitfield **CC8yTC.TRPSE = 1_B**.

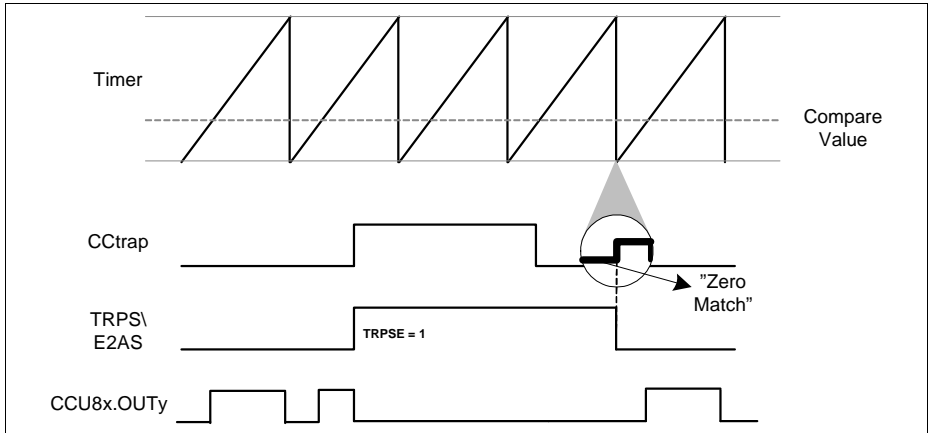

Figure 24-55 Trap synchronization with the PWM signal

24.2.8.10 Status Bit Override

For complex timed output control, each slice has a functionality that enables the override of the status bit of compare channel 1 (CC8yST1) with a value passed through an external signal.

The override of the status bit, can then lead to a change on the output pins CCU8x.OUTy0 and CCU8x.OUTy1 (from inactive to active or vice versa).

To enable this functionality, two signals are needed:

- One signal that acts as a trigger to override the status bit (edge active)
- One signal that contains the value to be set in the status bit (level active)

To select the status bit override functionality, one should map the signal that acts as trigger to the event number 1, by setting the required value in the **CC8yINS.EV1IS** register and indicating the active edge of the signal on the **CC8yINS.EV1EM** register.

The signal that carries the value to be set on the status bit, needs to be mapped to the event number 2, by setting the required value in the **CC8yINS.EV2IS** register. The **CC8yINS.EV2LM** register should be set to 0_B if no inversion on the signal is needed and to 1_B otherwise.

The events should be then mapped to the status bit functionality by setting the **CC8yCMC.OFS = 1_B**.

Figure 24-56 shows the functionality of the status bit override, when the external signal(1) was selected as trigger source (rising edge active) and the external signal(2) was selected as override value.

Figure 24-56 Status bit override

24.2.9 Multi-Channel Support

The multi channel control mode is selected individually in each slice by setting the **CC8yTC.MCME_x = 1_B**.

With this mode, the output state of the Timer Slices PWM signal(s) (the ones set in multichannel mode) can be controlled in parallel by a single pattern.

The pattern is controlled via the CCU8 inputs, CCU8x.MCIy[3:0]. Each group of these inputs is connected accordingly to the specific Timer Slice: for slice 0, CCU8xMCI1[3:0] for slice 1, CCU8xMCI2[3:0] for slice 2 and CCU8xMCI3[3:0] for slice 3.

This pattern can be controlled directly by one of the POSIF modules and be updated in parallel for all the Timer Slices.

Using the POSIF module in conjunction with the Multi Channel support of the CCU8, one can achieve a complete synchronicity between the output state update, CCU8x.OUTy and the update of a new pattern, **Figure 24-57**.

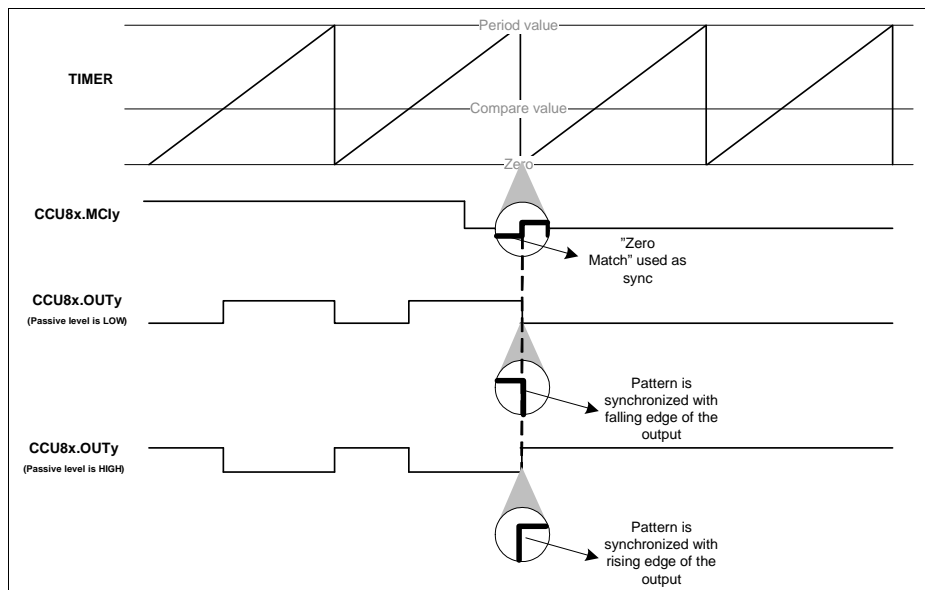

Figure 24-57 Multi channel pattern synchronization

These pattern inputs are going to be used in the output modulation control unit to put the specific PWM output into active or passive state: CCU8x.MCly[0] has effect on the CC8yST1 path and therefore controls the CC8xOUT00 pin, CCU8x.MCly[1] is used in the same manner for the inverted CC8yST1 path, CCU8x.MCly[2] and CCU8x.MCly[3] are linked to the CC8yST2 and inverted CC8yST2 path respectively. [Figure 24-58](#) shows the simplified scheme for the multi channel control.

[Figure 24-59](#), shows the usage of the multi channel mode in conjunction with two Timer Slices of the CCU8. The multi channel pattern is driven via the POSIF module, which enables a glitch free update of all the outputs of the CCU8.

Capture/Compare Unit 8 (CCU8)

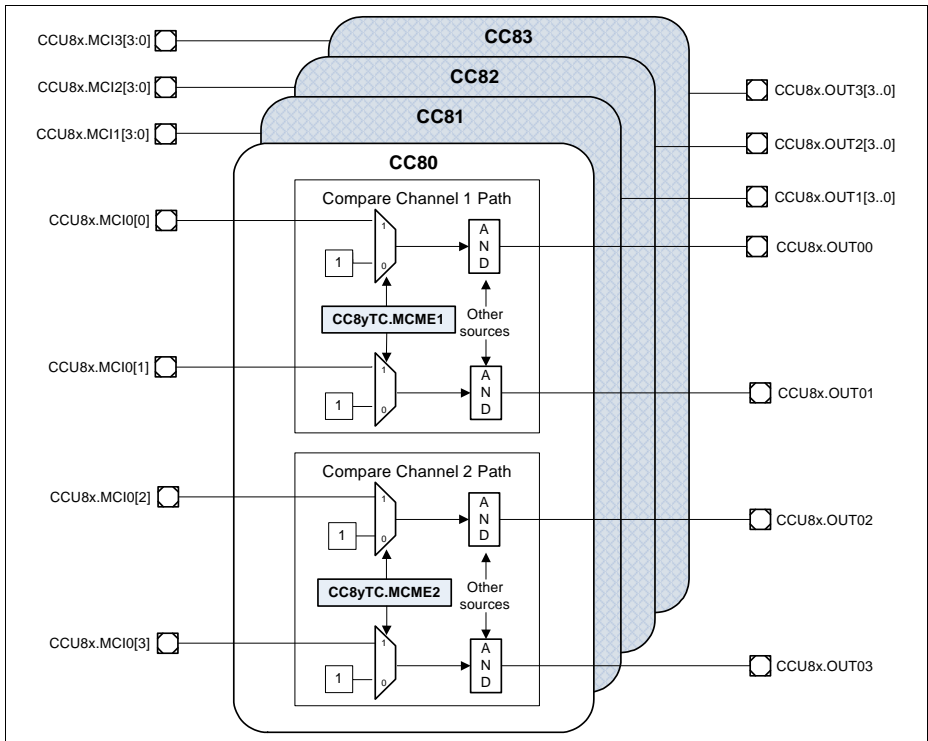

Figure 24-58 CCU8 Multi Channel overview

Figure 24-59 Multi Channel mode for multiple Timer Slices

The synchronization between the CCU8 and the POSIF is achieved, by adding a 3 cycle delay on the output path of each Timer Slice (between the status bit, CC8ySTx and the direct control of the output pin). This path is only selected when **CC8yTC.MCME_x = 1_B**.

On [Figure 24-60](#) the control of the CC8yST1 path is represented. The control of remaining paths follows the same mechanism (the multi channel is only enabled for the CC8yST2 path if **CC8yTC.MCME₂ = 1_B**).

The multi pattern input synchronization can be seen on [Figure 24-61](#). To achieve a synchronization between the update of the status bit, the sampling of a new multi channel pattern input is controlled by the period match or one match signal.

In a normal operation, where no external signal is used to control the counting direction, the signal used to enable the sampling of the pattern is always the period match when in edge aligned and the one match when in center aligned mode. When an external signal is used to control the counting direction, depending if the counter is counting up or counting down, the period match or the one match signal is used, respectively.

Capture/Compare Unit 8 (CCU8)

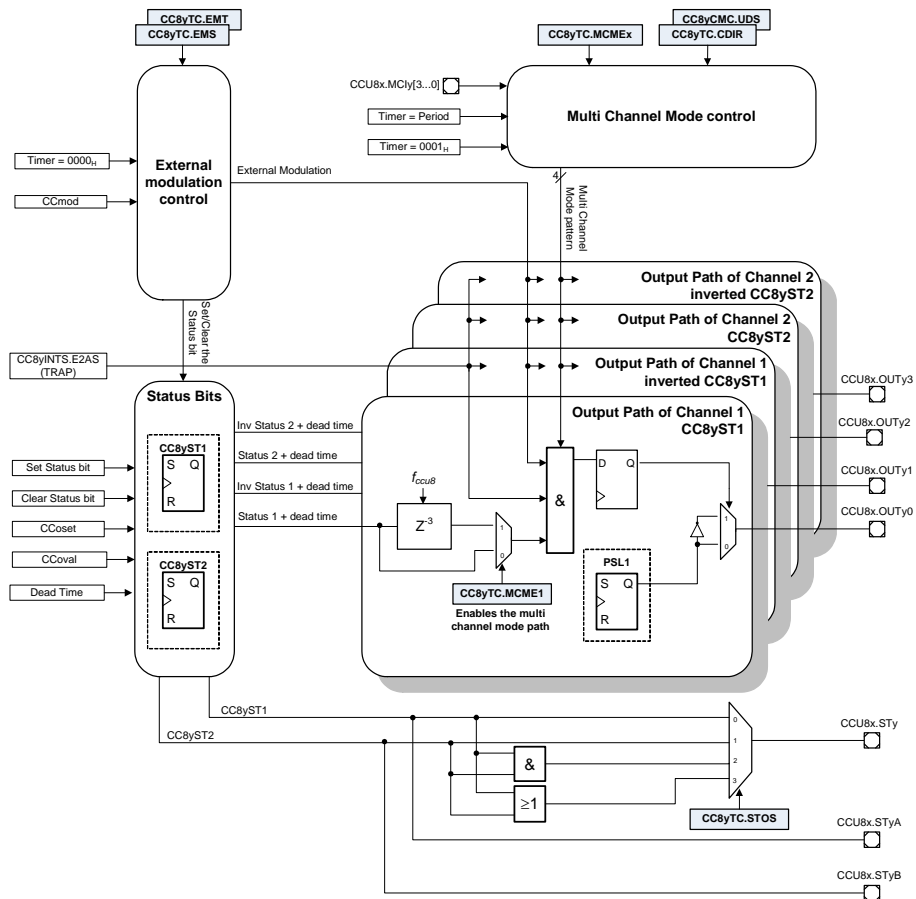

Figure 24-60 Output Control Diagram

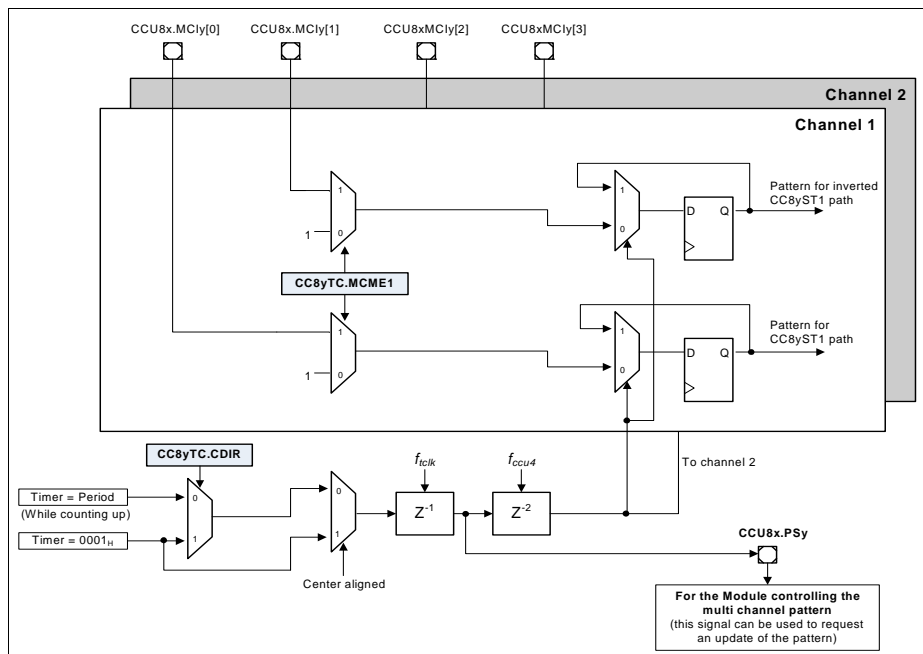

Figure 24-61 Multi Channel Pattern Synchronization Control

24.2.10 Timer Concatenation

The CCU8 offers a very easy mechanism to perform a synchronous timer concatenation. This functionality can be used by setting the **CC8yCMC.TCE** = 1_B. By doing this the user is doing a concatenation of the actual CCU8 slice with the previous one, see [Figure 24-62](#).

Notice that it is not possible to perform concatenation with non adjacent slices and that timer concatenation automatically sets the slice mode into Edge Aligned. It is not possible to perform timer concatenation in Center Aligned mode.

To enable a 64 bit timer, one should set the **CC8yCMC.TCE** = 1_B in all the slices (with the exception of the CC80 due to the fact that it doesn't contain this control field).

To enable a 48 bit timer, one should set the **CC8yCMC.TCE** = 1_B in two adjacent slices and to enable a 32 bit timer, the **CC8yCMC.TCE** is set to 1_B in the slice containing the MSBs. Notice that the timer slice containing the LSBs should always have the TCE bitfield set to 0_B.

Several combinations for timer concatenation can be made inside a CCU8 module:

- one 64 bit timer

Capture/Compare Unit 8 (CCU8)

- one 48 bit timer plus a 16 bit timer
- two 32 bit timers
- one 32 bit timer plus two 16 bit timers

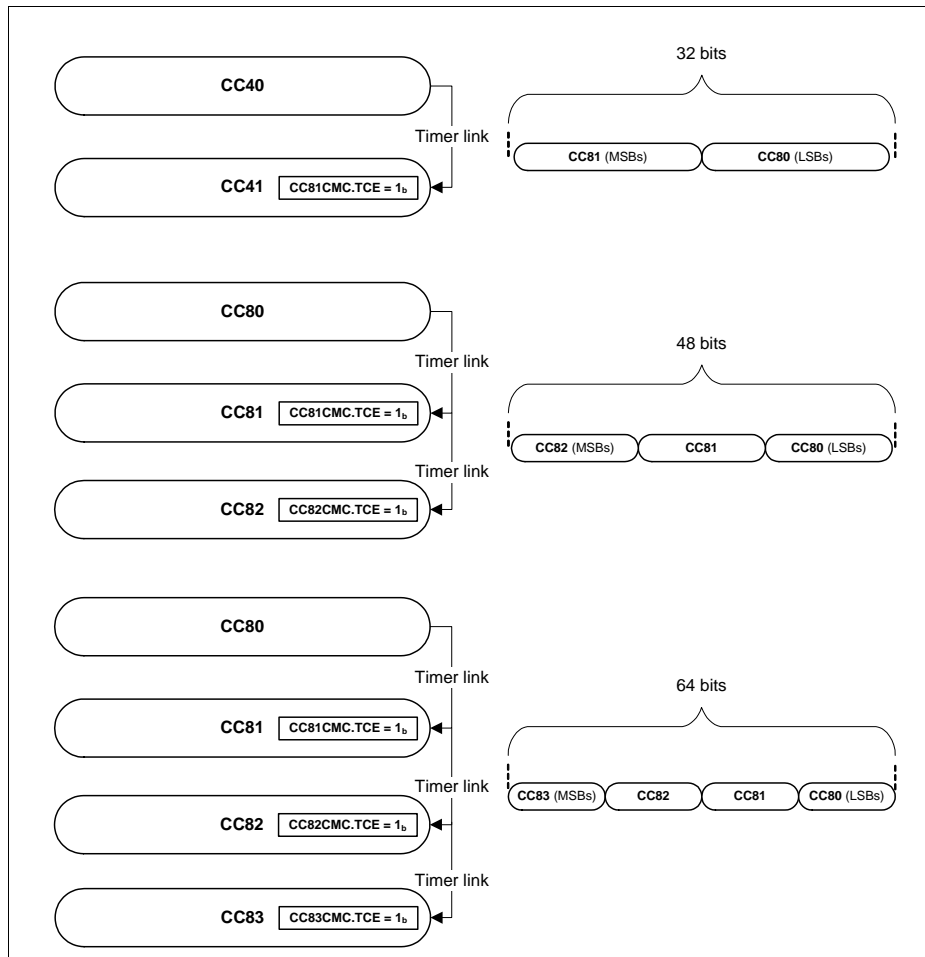

Figure 24-62 Timer concatenation example

Each Timer Slice is connected to the adjacent Timer Slices via a dedicated concatenation interface. This interface allows the concatenation of not only the Timer counting operation, but also a synchronous input trigger handling for capturing and loading operations, [Figure 24-63](#).

Capture/Compare Unit 8 (CCU8)

Note: For all the cases, CC80 and CC83 are not considered adjacent slices

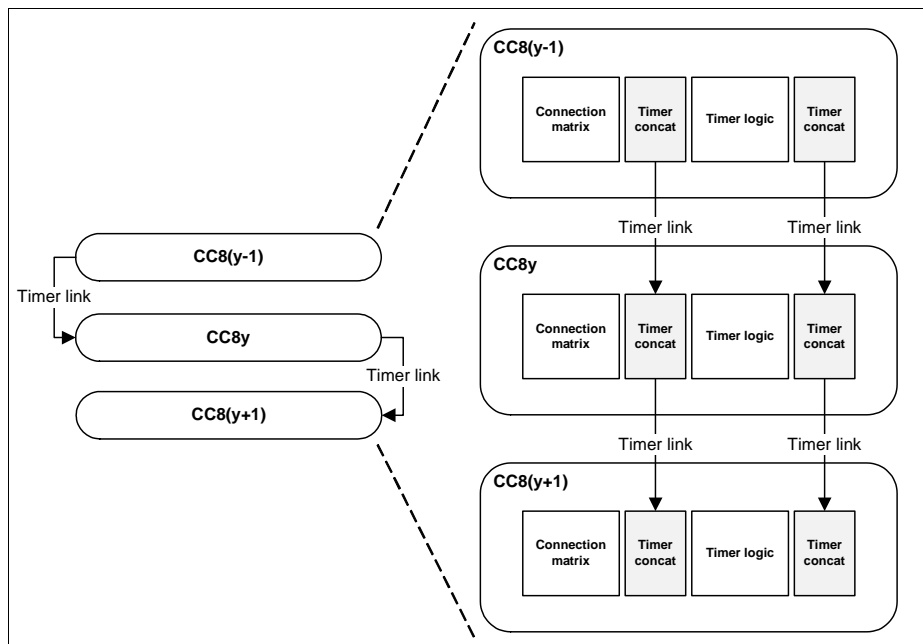

Figure 24-63 Timer concatenation link

Eight signals are present in the timer concatenation interface:

- Timer Period Match (CC8yPM)
- Timer Zero Match (CC8yZM)
- Timer Compare Match from channel 1 (CC8yCM1)
- Timer Compare Match from channel 2 (CC8yCM2)
- Timer counting direction function (CCupd)
- Timer load function (CCload)
- Timer capture function for CC8yC0V and CC8yC1V registers (CCcap0)
- Timer capture function for CC8yC2V and CC8yC3V registers (CCcap1)

The first five signals are used to perform the synchronous timing concatenation at the output of the Timer Logic, like it is seen in [Figure 24-63](#). With this link, the timer length can be easily adjusted to 32, 48 or 64 bits (counting up or counting down)

The last three signals are used to perform a synchronous link between the capture and load functions, for the concatenated timer system. This means that the user can have a capture or load function programmed in the first Timer Slice, and propagate this capture or load trigger synchronously from the LSBs until the MSBs, [Figure 24-64](#).

Capture/Compare Unit 8 (CCU8)

The capture or load function only needs to be configured in the first Timer Slice (the one holding the LSBs). From the moment that **CC8yCMC.TCE** is set to 1_B, in the following Timer Slices, the link between these functions is done automatically by the hardware.

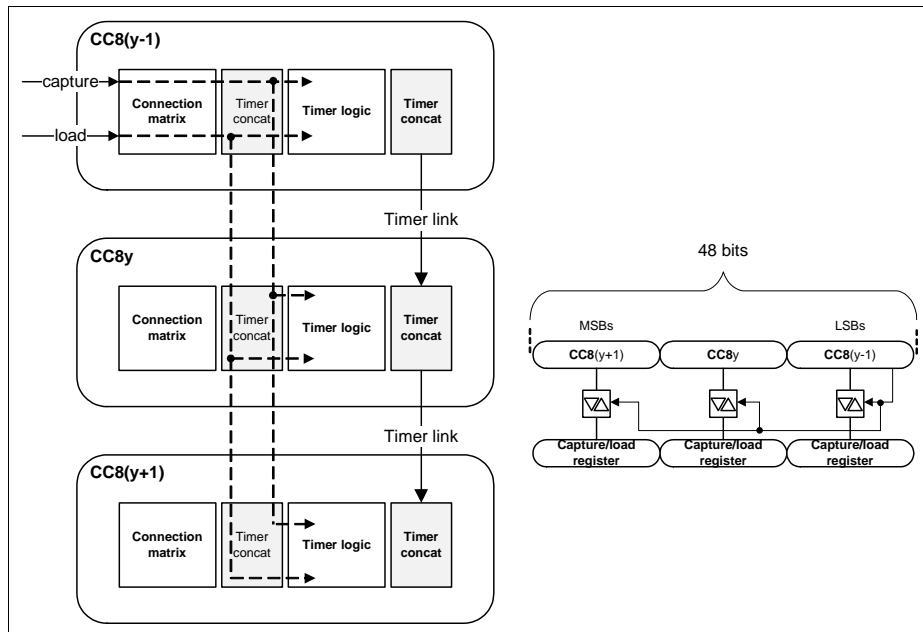

Figure 24-64 Capture/Load Timer Concatenation

the period match (CC8yPM) or zero match (CC8yZM) from the previous Timer Slice (with the immediately next lower index) are used in concatenated mode, as gating signal for the counter. This means that the counting operation of the MSBs only happens when a wrap around condition is detected (in the previous Timer Slice), avoiding additional DSP operations to extract the counting value.

With the same methodology, the compare match (CC8yCM1 and CC8yCM2), zero match and period match are gated with the specific signals from the previous Timer Slice. This means that the timing information is propagated throughout all the slices, enabling a completely synchronous match between LSB and MSB count, see [Figure 24-65](#).

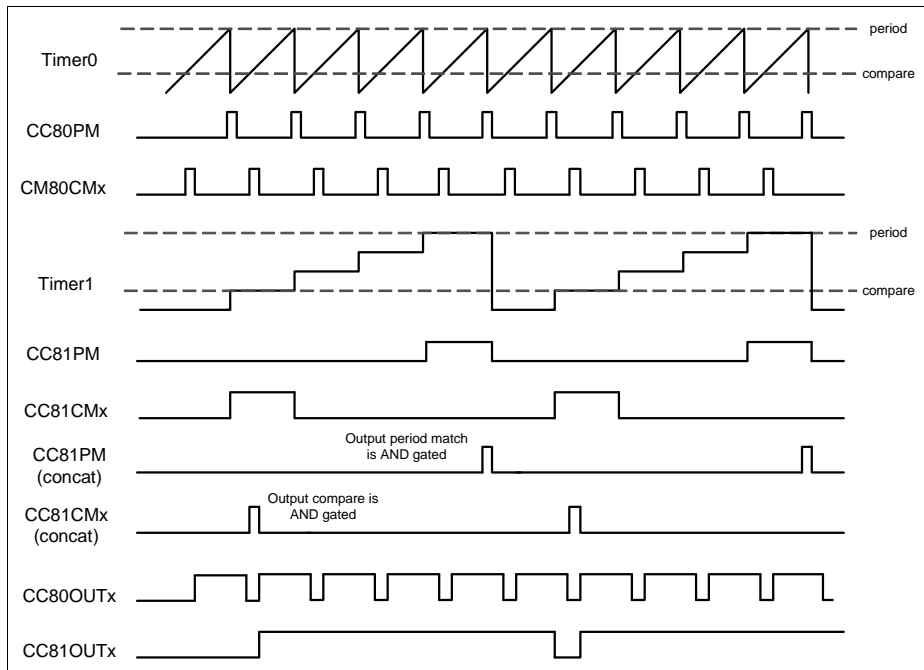

Figure 24-65 32 bit concatenation timing diagram

Note: the counting direction of the concatenated timer needs to be fixed. The timer can count up or count down, but the direction cannot be updated on the fly.

Figure 24-66 gives an overview of the timer concatenation logic. Notice that all the mechanism is controlled solely by the **CC8yCMC.TCE** bitfield.

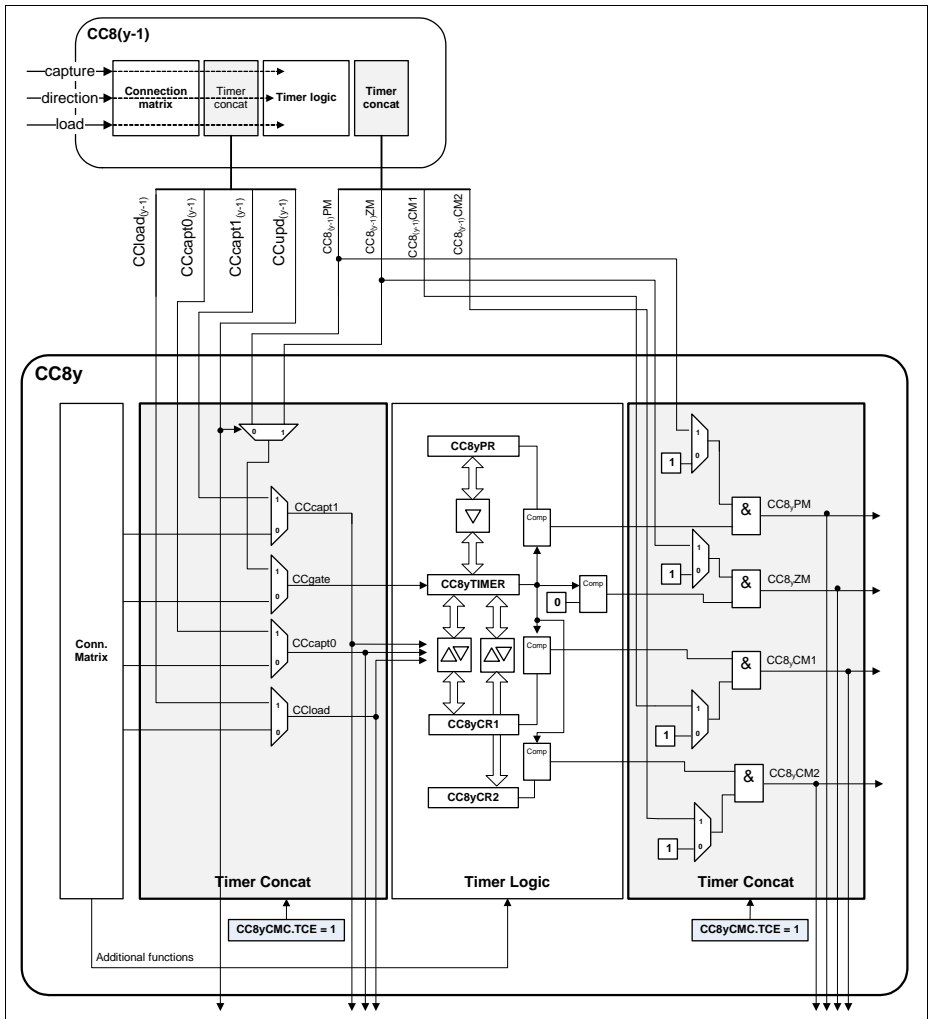

Figure 24-66 Timer concatenation control logic

24.2.11 Output Parity Checker

The parity checker function can be enabled by setting the **GIDLC.PCH** bit field to 1_B (parity checker is disabled while **GSTAT.PCRB** is 0_B).

Capture/Compare Unit 8 (CCU8)

This parity checker function, crosschecks the value at the output of the CCU8 module versus an input signal that should be connected to a driver XOR structure.

It is also possible to add a delay between the switching of the outputs and the evaluation of the input signal coming from the driver structure, and select which type of parity, even or odd (via the **GPCHK.PCTS** bit field). **Figure 24-67** shows the structure of the parity checker unit.

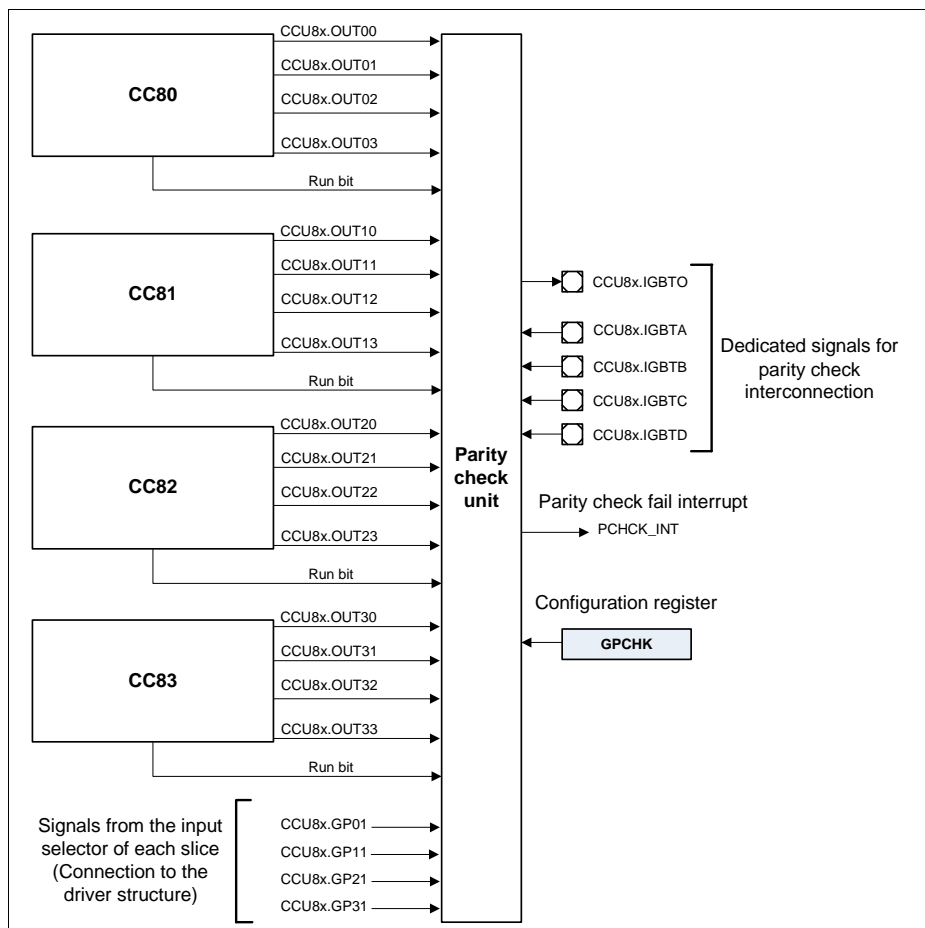

Figure 24-67 Parity checker structure

To use the parity check function, the user must select which signal is connected to the driver parity structure:

Capture/Compare Unit 8 (CCU8)

- The signal can be connected to any of the slices inputs
- The signal must be selected throughout the input selector mux of each slice. The signal must be mapped to the Event 1 of a slice.

Each of the CCU8 outputs can be individually selected to be part of the parity string and an interrupt is generated every time the input signal, coming from the driver structure, does not match the internally generated XOR result.

The interrupt is connected to the E1AS status bit of the slice where the driver parity output is connected:

- If **GPCHK**.PISEL = 00_B then the error status is in CC80INTS.E1AS
- If **GPCHK**.PISEL = 01_B then the error status is in CC81INTS.E1AS
- If **GPCHK**.PISEL = 10_B then the error status is in CC82INTS.E1AS
- If **GPCHK**.PISEL = 11_B then the error status is in CC83INTS.E1AS

The logic structure of the parity check is described on [Figure 24-68](#). For a more detailed description of resource usage for the parity checker function, please address [Section 24.2.14.5](#).

Configuration Example:

Driver parity output is connected to the input CCU8x.IN1B (where x = CCU8 unit). The input used to control the switching delay is the CCU8x.IGBTCCCU8. The driver is using 12 outputs coming from the first three slices with an even parity (PCTS field is in default).

The following registers should then be programmed:

CC8yINS.EV1IS = 0001_B; selects the input CCU8x.IN1B

GPCHK.PISEL = 01_B; selects the Event 1 coming from slice 1

GPCHK.PCDS = 10_B; selects the CCU8x.IGTBC input for delay control

GPCHK.PCSEL = 0FFF_H; selects only the output signals of the first three slices for parity check

GIDLC.SPCH = 1_B; starts the parity function

When a mismatch between the driver output and the parity checker is detected, an interrupt is generated on Timer Slice 1. The interrupt status bit that stores the information is **CC8yINTS**.E1AS.

Capture/Compare Unit 8 (CCU8)

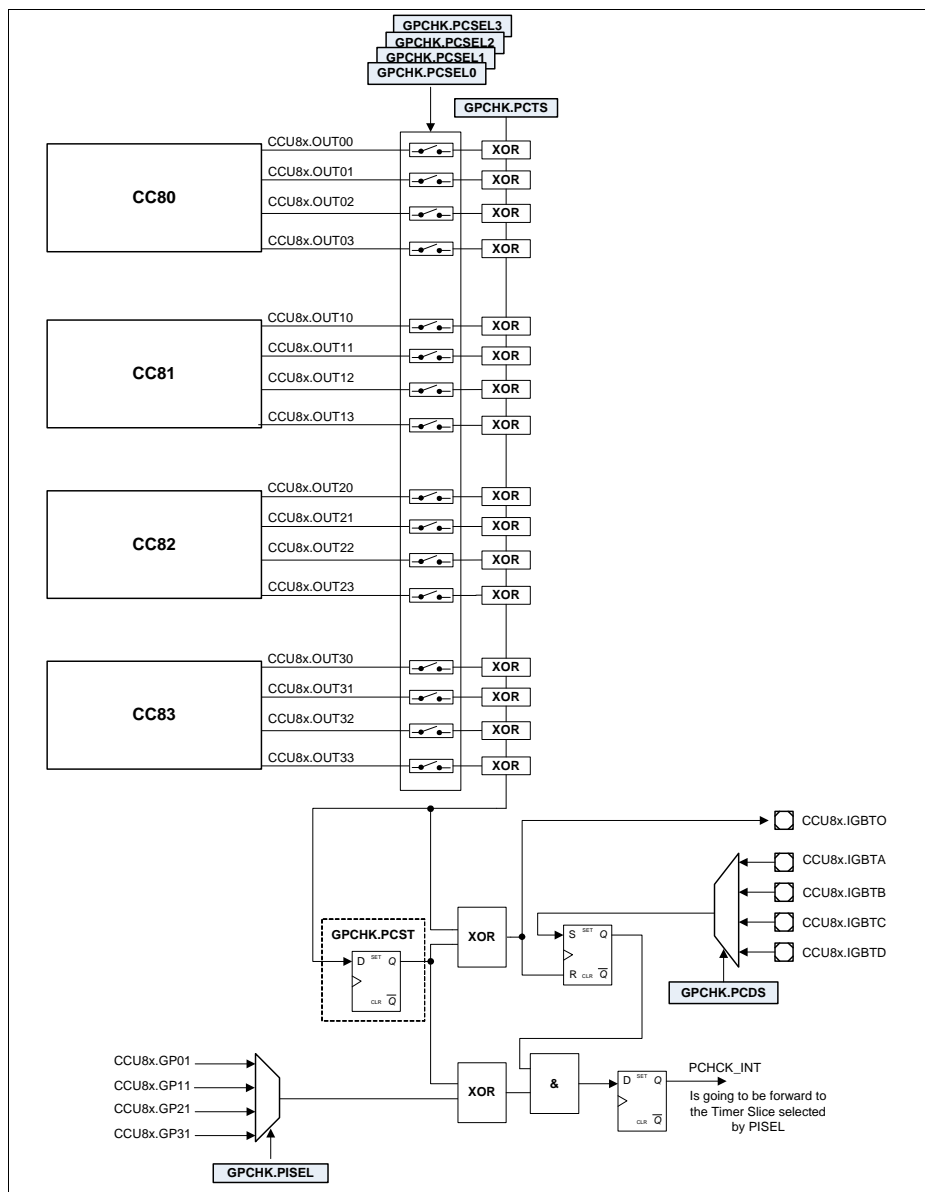

Figure 24-68 Parity checker logic

24.2.12 PWM Dithering

The CCU8 has an automatic PWM dithering insertion function. This functionality can be used with very slow control loops that cannot update the period/compare values in a fast manner, and by that fact the loop can lose precision on long runs. By introducing dither on the PWM signal, the average frequency/duty cycle is then compensated against that error.

Each slice contains a dither control unit, see [Figure 24-69](#).

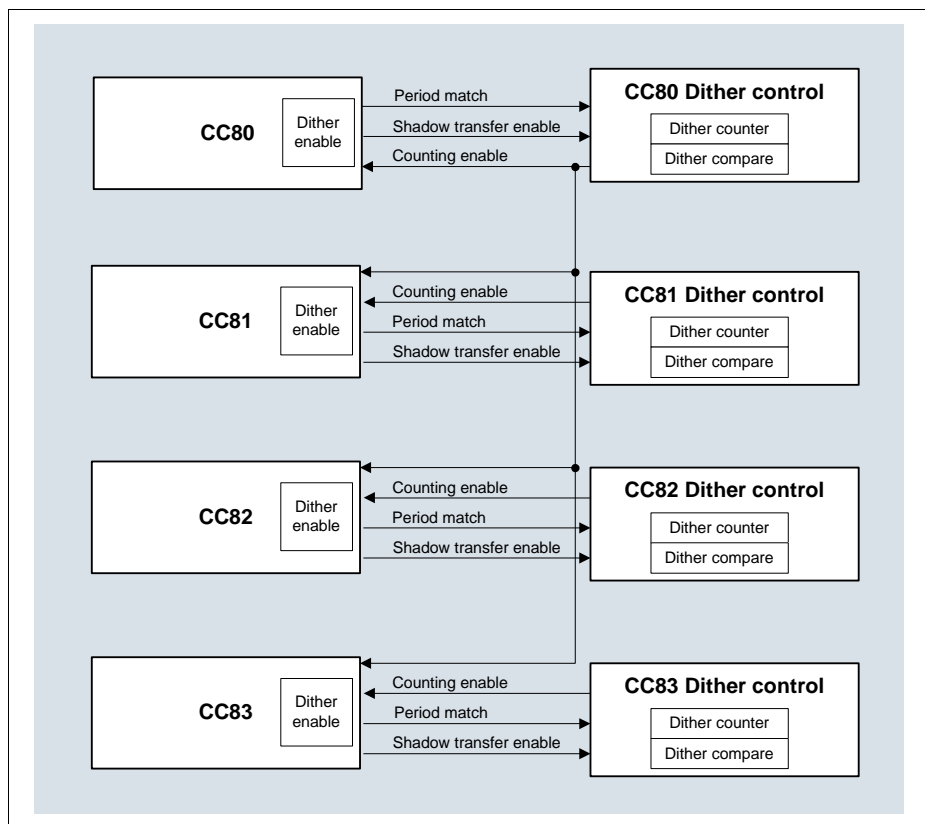

Figure 24-69 Dither structure overview

The dither control unit contains a 4 bit counter and a compare value. The four bit counter is incremented every time that a period match occurs. The counter works in a bit reverse mode so the distribution of increments stays uniform over 16 counter periods, see [Table 24-6](#).

Table 24-6 Dither bit reverse counter

| counter[3] | counter[2] | counter[1] | counter[0] |
|------------|------------|------------|------------|
| 0 | 0 | 0 | 0 |
| 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 |
| 1 | 1 | 0 | 0 |
| 0 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 |
| 0 | 1 | 1 | 0 |
| 1 | 1 | 1 | 0 |
| 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 1 |
| 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 1 |
| 0 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 |

The counter is then compared against a programmed value, **CC8yDIT.DCV**. If the counter value is smaller than the programmed value, a gating signal is generated that can be used to extend the period, to delay the compare or both (controlled by the **CC8yTC.DITHE** field, see [Table 24-7](#)) for one clock cycle.

Table 24-7 Dither modes

| DITHE[1] | DITH[0] | Mode |
|----------|---------|--|
| 0 | 0 | Dither is disabled |
| 0 | 1 | Period is increased by 1 cycle |
| 1 | 0 | Compare match is delayed by 1 cycle |
| 1 | 1 | Period is increased by 1 cycle and compare is delayed by 1 cycle |

The dither compare value also has an associated shadow register that enables concurrent update with the period/compare registers of each CC8y. The control logic for the dithering unit is represented on [Figure 24-70](#).

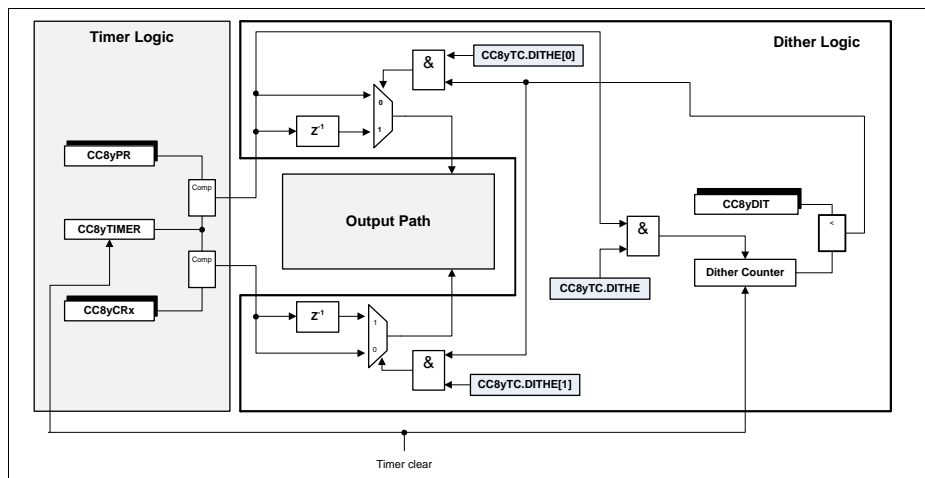

Figure 24-70 Dither control logic

Figure 24-71 to **Figure 24-76** show the effect of the different configurations of the dither, **CC8yTC.DITHE**, for both counting schemes, Edge and Center Aligned mode. In each figure, the bit reverse scheme is represented for the dither counter and the compare value was programmed with the value 8_H . In each figure, the variable T , represents the period of the counter, while the variable d indicates the duty cycle (status bit is set HIGH).

Figure 24-71 Dither timing diagram in edge aligned - **CC8yTC.DITHE = 01_B**

Figure 24-72 Dither timing diagram in edge aligned - $\text{CC8yTC.DITHE} = 10_B$

Figure 24-73 Dither timing diagram in edge aligned - $\text{CC8yTC.DITHE} = 11_B$

Figure 24-74 Dither timing diagram in center aligned - $\text{CC8yTC.DITHE} = 01_B$

Figure 24-75 Dither timing diagram in center aligned - CC8yTC.DITHE = 10_B

Figure 24-76 Dither timing diagram in edge aligned - CC8yTC.DITHE = 11_B

Note: When using the dither, is not possible to select a period value of FS when in edge aligned mode. In center aligned mode, the period value must be at least FS - 2.

24.2.13 Prescaler

The CCU8 contains a 4 bit prescaler that can be used in two operating modes for each individual slice:

- normal prescaler mode
- floating prescaler mode

The run bit of the prescaler can be set/cleared by SW by writing into the registers, **GIDLC.SPRB** and **GIDLS.CPRB** respectively or can also be cleared by the run bit of a specific slice. With the last mechanism, the run bit of the prescaler is cleared one clock cycle after the clear of the run bit of the selected slice. To select which slice can perform this action, one should program the **GCTRL.PRBC** register.

24.2.13.1 Normal Prescaler Mode

In Normal prescaler mode the clock fed to the CC8y counter is a normal fixed division by N, accordingly to the value set in the **CC8yPSC**.PSIV register. The values for the possible division values are listed in **Table 24-8**. The **CC8yPSC**.PSIV value is only modified by a SW access. Notice that each slice has a dedicated prescaler value selector (**CC8yPSC**.PSIV), which means that the user can select different counter clocks for every and each Timer Slice (CC8y).

Table 24-8 Timer clock division options

| CC8yPSC.PSIV | Resulting clock |
|---------------------|------------------------|
| 0000 _B | f_{CCU8} |
| 0001 _B | $f_{CCU8}/2$ |
| 0010 _B | $f_{CCU8}/4$ |
| 0011 _B | $f_{CCU8}/8$ |
| 0100 _B | $f_{CCU8}/16$ |
| 0101 _B | $f_{CCU8}/32$ |
| 0110 _B | $f_{CCU8}/64$ |
| 0111 _B | $f_{CCU8}/128$ |

24.2.13.2 Floating Prescaler Mode

The floating prescaler mode can be used individually in each slice by setting the register **CC8yTC**.FPE = 1_B. With this mode, the user can not only achieve a better precision on the counter clock for compare operations but also reduce the SW read access for the capture mode.

The floating prescaler mode contains additionally to the initial value register, **CC8yPSC**.PSIV, a compare register, **CC8yFPC**.PCMP with an associated shadow register.

Capture/Compare Unit 8 (CCU8)

Figure 24-77 shows the structure of the prescaler in floating mode when the specific slice is in compare mode (no external signal is used for capture). In this mode, the value of the clock division is incremented by 1_D every time that a timer overflow/underflow (overflow if in Edge Aligned Mode, underflow if in Center Aligned Mode) occurs.

In this mode, the Compare Match (both channels) from the timer is AND gated with the Compare Match of the prescaler and every time that this event occurs, the value of the clock division is updated with the **CC8yPSC.PSIV** value in the immediately next timer overflow/underflow event.

To use just one compare channel to control the floating prescaler, the other compare channel must be disabled. To do this, the compare value, **CC8yCR1** or **CC8yCR2** (depending on which channel is used) needs to be set with a value bigger than the period, **CC8yPR**. This means that in edge aligned mode, the maximum value for the timer period is 65534_D , because the compare value of one channel needs to be set to 65535_D .

The shadow transfer of the floating prescaler compare value, **CC8yFPC.PCMP**, is done following the same rules described on **Section 24.2.5.2**.

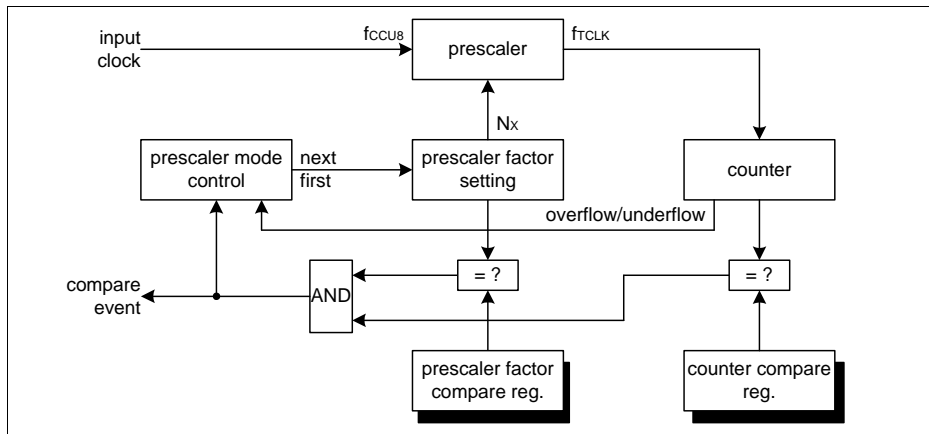

Figure 24-77 Floating prescaler in compare mode overview

When the specific CCU8 is operating in capture mode (when at least one external signal is decoded as capture functionality), the actual value of the clock division also needs to be stored every time that a capture event occurs. The floating prescaler can have up to 4 capture registers (the maximum number of capture registers is dictated by the number of capture registers used in the specific slice).

The clock division value continues to be incremented by 1 every time that a timer overflow (in capture mode, the slice is always operating in Edge Aligned Mode) occurs and it is loaded with the PSIV value every time that a capture triggers is detected.

Capture/Compare Unit 8 (CCU8)

See the [Section 24.2.14](#) for a full description of the usage of the floating prescaler mode in conjunction with compare and capture modes.

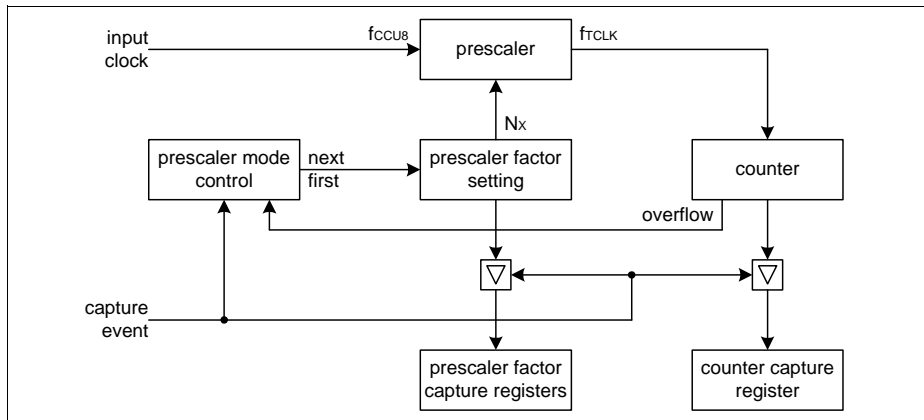

Figure 24-78 Floating Prescaler in capture mode overview

24.2.14 CCU8 Usage

24.2.14.1 PWM Signal Generation

The CCU8 offers a very flexible range in duty cycle configurations. This range is comprised between 0 to 100%.

To generate a PWM signal with a 100% duty cycle in Edge Aligned Mode, one should program the compare value, **CC8yCR1.CR1/CC8yCR2.CR2**, to 0000_H, [Figure 24-79](#).

In the same manner a 100% duty cycle signal can be generated in Center Aligned Mode, [Figure 24-80](#).

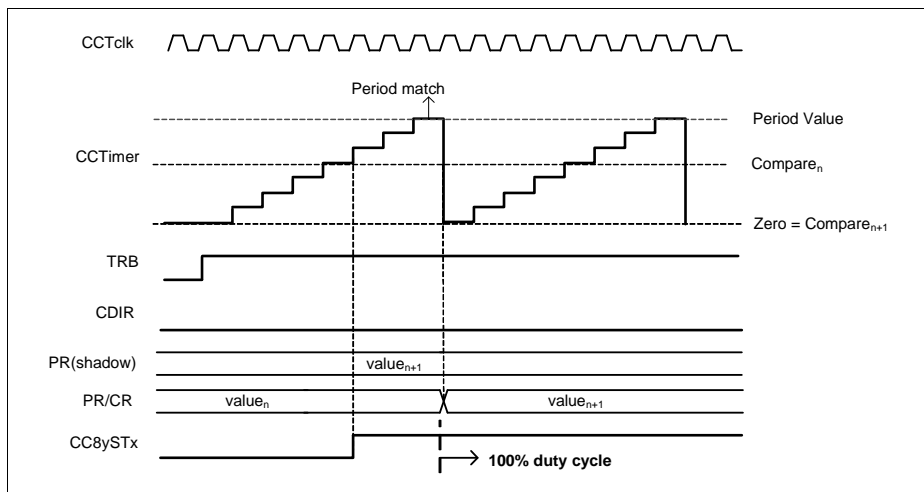

Figure 24-79 PWM with 100% duty cycle - Edge Aligned Mode

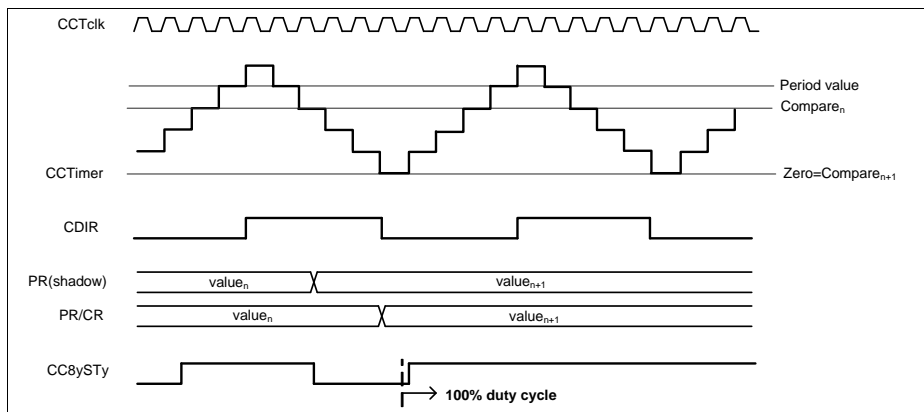

Figure 24-80 PWM with 100% duty cycle - Center Aligned Mode

To generate a PWM signal with 0% duty cycle in Edge Aligned Mode, the compare register should be set with the value programmed into the period value plus 1. In the case that the timer is being used with the full 16 bit capability (counting from 0 to 65535), setting a value bigger than the period value into the compare register is not possible and therefore the smallest duty cycle that can be achieved is 1/FS, see [Figure 24-81](#).

In Center Aligned Mode, the counter is never running from 0_D to 65535_D, due to the fact that it has to overshoot for one clock cycle the value set in the period register. Therefore

Capture/Compare Unit 8 (CCU8)

the user never has a FS counter, which means that generating a 0% duty cycle signal is always possible by setting a value in the compare register bigger than the one programmed into the period register, see [Figure 24-82](#).

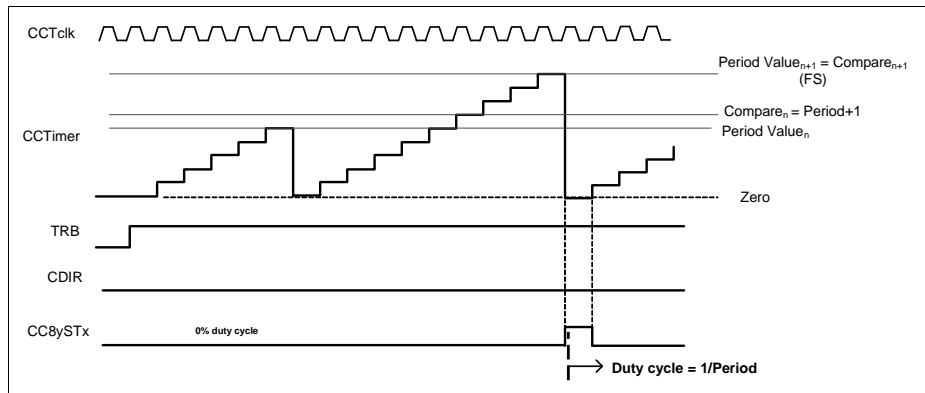

Figure 24-81 PWM with 0% duty cycle - Edge Aligned Mode

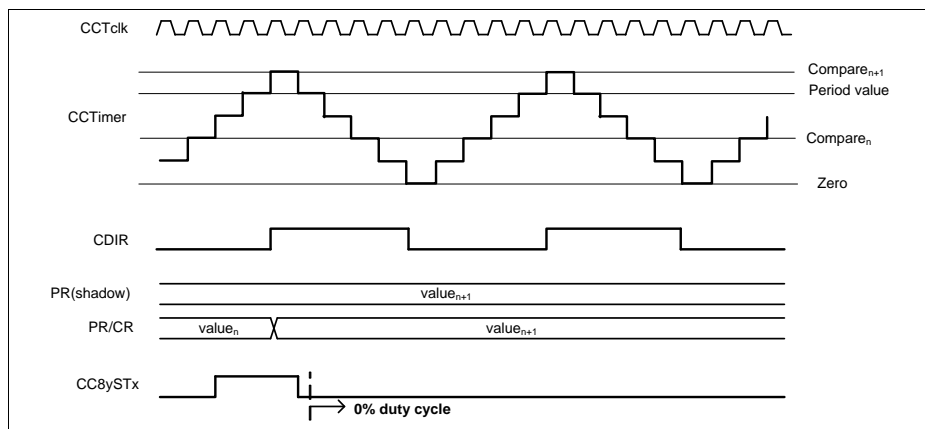

Figure 24-82 PWM with 0% duty cycle - Center Aligned Mode

24.2.14.2 Prescaler Usage

In Normal Prescaler Mode, the frequency of the f_{clk} fed to the specific CC8y is chosen from the [Table 24-8](#), by setting the **CC8yPSC.PSIV** with the required value.

In Floating Prescaler Mode, the frequency of the f_{clk} can be modified over a selected timeframe, within the values specified in [Table 24-8](#). This mechanism is specially useful if, in capture mode, the dynamic of the capture triggers is very slow or unknown.

Capture/Compare Unit 8 (CCU8)

In Capture Mode, the Floating Prescaler value is incremented by 1_D every time that a timer overflow happens and it is set with the initial programmed value when a capture event happens, see [Figure 24-83](#).

When using the Floating Prescaler Mode in Capture Mode, the timer should be cleared each time that a capture event happens, **CC8yTC.CAPC** = 11_B . By operating the Capture mode in conjunction with the Floating Prescaler, even for capture signals that have a periodicity bigger than 16 bits, it is possible to use just a single CCU8 slice without monitoring the interrupt events triggered by the timer overflow. For this the user just needs to know what is the timer capture value and the actual prescaler configuration at the time that the capture event occurred. These values are contained in each CC8yCxV register.

Figure 24-83 Floating Prescaler capture mode usage

When used in Compare Mode, the Floating Prescaler function may be used to achieve a fractional PWM frequency or to perform some frequency modulation.

The same incrementing by 1_D mechanism is done every time that an overflow/underflow of the Timer occurs (from any of the compare channels) and the actual Prescaler value doesn't match the one programmed into the **CC8yFPC.PCMP** register.

When a Compare Match from the Timer (from any of the compare channels) occurs and the actual Prescaler value is equal to the one programmed on the **CC8yFPC.PCMP** register, then the Prescaler value is set with the initial value, **CC8yPSC.PSIV**, in the immediately next occurrence of a timer overflow/underflow.

To use just one compare channel to control the floating prescaler, the other compare channel must be disabled. To do this, the compare value, **CC8yCR1** or **CC8yCR2** (depending on which channel is used) needs to be set with a value bigger than the period, **CC8yPR**. This means that in edge aligned mode, the maximum value for the timer period is 65534_D , because the compare value of one channel needs to be set to 65535_D (so the compare match of the associated channel is disabled).

In [Figure 24-84](#), the Compare value of the Floating Prescaler was set to **PSIV + 2**. Every time that a timer overflow occurs, the value of the Prescaler is incremented by 1, which

Capture/Compare Unit 8 (CCU8)

means that if we give f_{tclk} as the reference frequency for the **CC8yPSC**.PSIV value, we have $f_{\text{tclk}}/2$ for **CC8yPSC**.PSIV + 1 and $f_{\text{tclk}}/4$ for **CC8yPSC**.PSIV + 2. With the period overtime of the counter becomes:

$$\text{Period} = (1/f_{\text{tclk}} + 2/f_{\text{tclk}} + 4/f_{\text{tclk}})/3$$

The same mechanism is used in Center Aligned Mode, but to keep the rising arcade and falling arcade always symmetrical, instead of the overflow of the timer, the underflow is used, see [Figure 24-85](#).

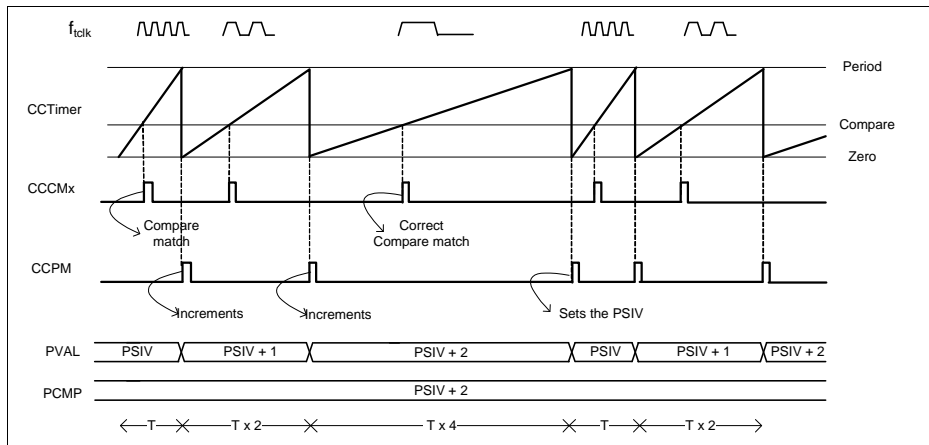

Figure 24-84 Floating Prescaler compare mode usage - Edge Aligned

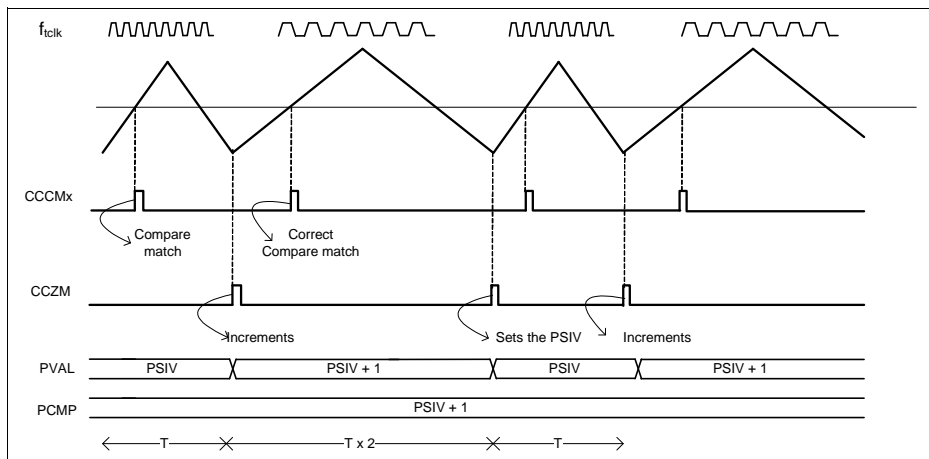

Figure 24-85 Floating Prescaler compare mode usage - Center Aligned

24.2.14.3 PWM Dither

The Dither function can be used to achieve a very fine precision on the periodicity of the output state in compare mode. The value set in the dither compare register, **CC8yDIT.DCV** is crosschecked against the actual value of the dither counter and every time that the dither counter is smaller than the comparison value one of the follows actions is taken:

- The period is extended for 1 clock cycle - **CC8yTC.DITHE** = 01_B; in edge aligned mode
- The period is extended for 2 clock cycles - **CC8yTC.DITHE** = 01_B; in center aligned mode
- The comparison match while counting up (**CC8yTCST.CDIR** = 0_B) is delayed (this means that the status bit is going to stay in the SET state 1 cycle less) for 1 clock cycle - **CC8yTC.DITHE** = 10_B;
- The period is extended for 1 clock cycle and the comparison match while counting up is delayed for 1 clock cycle - **CC8yTC.DITHE** = 11_B; in edge aligned mode
- The period is extended for 2 clock cycles and the comparison match while counting up is delayed for 1 clock cycle; center aligned mode

The bit reverse counter distributes the number programmed in the **CC8yDIT.DCV** throughout 16 timer periods.

Table 24-9, describes the bit reverse distribution versus the programmed value on the **CC8yDIT.DCV** field. The fields marked as '0' indicate that in that counter period, one of the above described actions, is going to be performed.

Table 24-9 Bit reverse distribution

| Dither counter | DCV | | | | | | | | | | | | | | | |
|----------------|-----|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 4 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

| 9 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |

Table 24-9 Bit reverse distribution (cont'd)

| | DCV | | | | | | | | | | | | | | | |
|-----------------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|-----------|-----------|-----------|-----------|-----------|-----------|
| Dither counter | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| 5 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| D | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 |
| 3 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| B | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |
| 7 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| F | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

The bit reverse distribution versus the programmed **CC8yDIT.DCV** value results in the following values for the Period and duty cycle:

DITHE = 01_B

$$Period = [(16 - DCV) \times T + DCV \times (T + 1)]/16; \text{ in Edge Aligned Mode} \quad (24.10)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times (d+1)/(T + 1)]/16; \text{ in Edge Aligned Mode} \quad (24.11)$$

$$Period = [(16 - DCV) \times T + DCV \times (T + 2)]/16; \text{ in Center Aligned Mode} \quad (24.12)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times (d+2)/(T + 2)]/16; \text{ in Center Aligned Mode} \quad (24.13)$$

DITHE = 10_B

$$Period = T ; \text{ in Edge Aligned Mode} \quad (24.14)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times (d-1)/T]/16; \text{ in Edge Aligned Mode} \quad (24.15)$$

$$Period = T ; \text{ in Center Aligned Mode} \quad (24.16)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times (d-1)/T]/16; \text{ in Center Aligned Mode} \quad (24.17)$$

DITHE = 11_B

$$Period = [(16 - DCV) \times T + DCV \times (T + 1)]/16; \text{ in Edge Aligned Mode} \quad (24.18)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times d/(T + 1)]/16; \text{ in Edge Aligned Mode} \quad (24.19)$$

$$Period = [(16 - DCV) \times T + DCV \times (T + 2)]/16; \text{ in Center Aligned Mode} \quad (24.20)$$

$$Duty\ cycle = [(16 - DCV) \times d/T + DCV \times (d+1)/(T + 2)]/16; \text{ in Center Aligned Mode} \quad (24.21)$$

where:

T - Original period of the signal, see [Section 24.2.5.1](#)

d - Original duty cycle of the signal, see [Section 24.2.5.1](#)

24.2.14.4 Capture Mode Usage

Each slice has the possibility of using 2 or 4 capture registers. Using only 2 capture registers means that only 1 Event was linked to a captured trigger. To use the four capture registers, both capture triggers need to be mapped into an Event (it can be the same signal with different edges selected or two different signals) or the **CC8yTC.SCE** field needs to be set to 1_B, which enables the linking of the 4 capture registers.

The internal slice mechanism for capturing is the same for the capture trigger 1 or capture trigger 0.

Different Capture Events - SCE = 0_B

Capture trigger 1 (CCcapt1) is appointed to the capture register 2, **CC8yC2V** and capture register 3, **CC8yC3V**, while trigger 0 is appointed to capture register 1, **CC8yC1V** and 0, **CC8yC0V**.

In each CCcapt0 event, the timer value is stored into **CC8yC1V** and the value of the **CC8yC1V** is transferred into the **CC8yC0V**.

In each CCcapt1 event, the timer value is stored into capture register **CC8yC3V** and the value of the capture register **CC8yC3V** is transferred into **CC8yC2V**.

The previous capture/transfer mechanism only happens if the specific register is not full. A capture register becomes full when receives a new value and becomes empty after the SW has read back the value.

The full flag is cleared every time that the SW reads back the **CC8yC0V**, **CC8yC1V**, **CC8yC2V** or **CC8yC3V** register. The SW can be informed of a new capture trigger by enabling the interrupt source linked to the specific Event. This means that every time that a capture is made an interrupt pulse is generated.

In the case that the Floating Prescaler Mode is being used, the actual value of the clock division is also stored in the capture register (CC8yCxV).

Figure 24-86 shows an example of how the capture/transfer may be used in a Timer Slice that is using an external signal as count function (to measure the velocity of a rotating device), and an equidistant capture trigger that is used to dictate the timestamp

Capture/Compare Unit 8 (CCU8)

for the velocity calculation (two Timer waveforms are plotted, one that exemplifies the clearing of the timer in each capture event and another without the clearing function active).

Figure 24-86 Capture mode usage - single channel

Same Capture Event - SCE = 1_B

If **CC8yTC**.SCE is set to 1_B, all the four capture registers are chained together, emulating a fifo with a depth of 4. In this case, only the capture trigger 1, CCcapt1, is used to perform a capture event.

As an example for this mode, one can consider the case where one Timer Slice is being used in capture mode with SCE = 1_B, with another external signal that controls the counting. This timer slice can be incremented at different speeds, depending on the frequency of the counting signal.

An additional Timer Slice is used to control the capture trigger, dictating the time stamp for the capturing.

A simple scheme for this can be seen in **Figure 24-87**. The CC80ST output of slice 0 was used as capture trigger in the CC81 slice (active on rising and falling edge). The CC80ST output is used as known timebase marker, while the slice timer used for capture is being controlled by external events, e.g. external count.

Capture/Compare Unit 8 (CCU8)

Due to the fact that we have 4 capture registers available, every time that the SW reads back the complete set of values, 3 speed profiles can be measured.

Figure 24-87 Three Capture profiles - CC8yTC.SCE = 1_B

To calculate the three different profiles in [Figure 24-87](#), the 4 capture registers need to be read during the pointed read window. After that, the profile calculation is done:

Profile 1 = $CC81C1V_{info} - CC81C0V_{info}$

Profile 2 = $CC81C2V_{info} - CC81C1V_{info}$

Profile 3 = $CC81C3V_{info} - CC81C2V_{info}$

Note: This is an example and therefore several Timer Slice configurations and software loops can be implemented.

High Dynamics Capturing

In some cases the dynamics of the capture trigger(s) may vary greatly over time. This will impose that the software needs to be prepared for the worst case scenario, where the frequency of the capture triggers may be very high. In applications where cycle-by-cycle calculation is needed (calculation in each capture trigger), then this constraints needs to be met by the software. Nevertheless for applications where a cycle-by-cycle calculation is not needed, the software can read back the FIFO data register in a periodic base and fetch all the data that has been captured so far, [Figure 24-88](#).

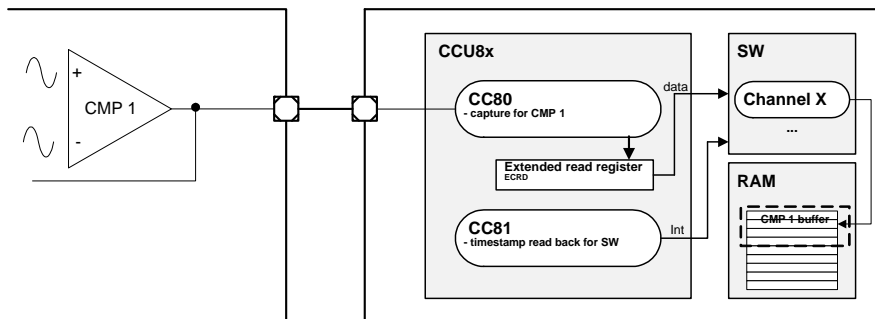

Figure 24-88 High dynamics capturing with software controlled timestamp

In this scenario, the software will read back the complete set of capture registers (2 or 4 depending on the chosen configuration), every time that an interrupt is triggered from the timestamp timer (the periodicity of this timer can also be adjusted on-the-fly).

Due to the fact that every capture register offers a full flag status bit, the software can always read back the complete set of registers. At the time of the data processing, this full flag is then checked, indicating if this value needs to be processed or not.

This FIFO read back functionality can also be used for applications that impose a heavy load on the system, which may not guarantee fixed access times to read back the captured data.

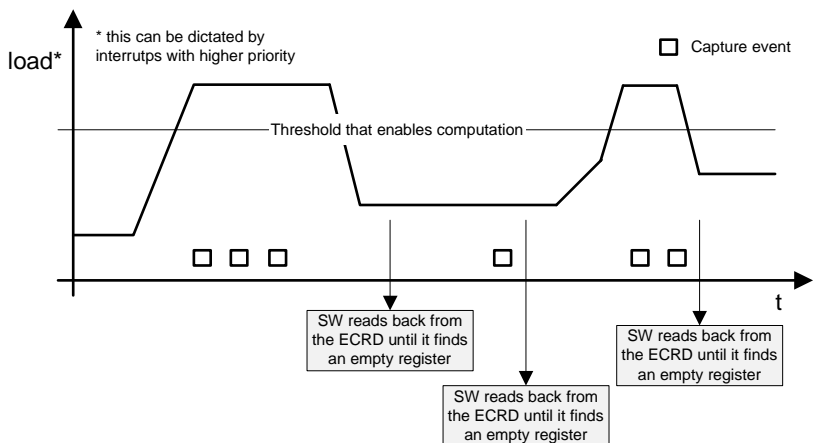

Figure 24-89 Extended read back during high load

Capture Grouping

In applications where multiple capture Timers are needed and the priority of the capture routines, does not imply that a cycle-by-cycle calculation needs to be done for every event, it may be suitable to group all the timers in the same CCU4x unit, [Figure 24-90](#).

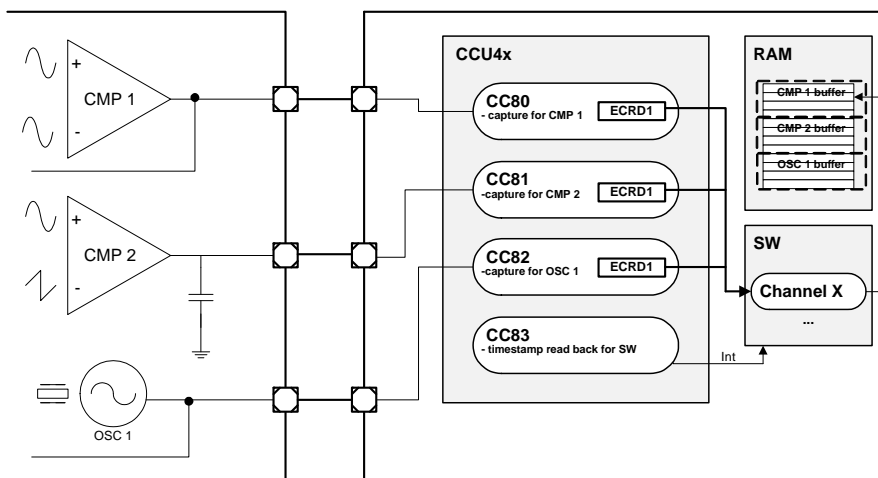

Figure 24-90 Capture grouping with extended read back

Capture/Compare Unit 8 (CCU8)

By setting the ECM bitfield for the Timer Slices used for capturing, the extended read back mode enables the reading back of data always in the proper capture order (from oldest to newest data). A timestamp timer is then used to trigger the CPU/Software to read back all the capture data present in the Timer Slices.

Every time that the interrupt is sensed, the CPU/Software (in this example) reads back the complete set of capture registers (via the ECRD address) for all Timer Slices. Due to the fact that each data read has a full flag indicator, the CPU/Software can read back the complete set of capture registers from all timers. This allows a fixed memory allocation that is as big as the number of captured registers, **Figure 24-91** (in this example 4 capture registers for each Timer Slice are being used).

The additional lost value bitfield (LCV) on the header of each ECRD data, will indicate if any capture trigger was lost between read operations (this can happen if the capture triggers are faster than the routine that is reading back the values).

24.2.14.5 Parity Checker Usage

The parity checker function available on the CCU8 uses of one CCU4 timer slice, to control the delay between the update of the outputs and the consequent update on the external switch/driver.

Capture/Compare Unit 8 (CCU8)

This CCU4 timer slice is configured to work in edge aligned mode, with single shot mode active and with a configured external flush & start function. This function is connected to the parity checker update output signal, CCU8x.IGBT0. The timer slice compare and period values need to be programmed accordingly to the delay that is foreseen between the outputs of the CCU8 and the consequent update on the driver/switch parity output. The connections between the CCU8, CCU4 and the external HW can be seen on [Figure 24-92](#).

[Figure 24-93](#) shows the timing waveforms for an usage example of the parity checker (case of even parity, **GPCHK**.PCTS field takes the default value). In this example only two outputs of CCU8 were considered to avoid extreme complexity on the diagram.

Every time an update of the selected outputs leads to a modification of the value **GPCHK**.PCST (parity checker status), or in other words, every time the result of the XOR chain changes, a trigger is generated on the CCU8x.IGBT0. This signal, as described previously, is used as a flush & start for a CCU4 slice.

When the CCU4 slice timer reaches the compare value, the specific status output, CCU4x.STy is asserted. After this elapsed delay, the value on the CCU8x.GPy1 (the parity value coming from the external HW) is crosschecked against the result of the internal XOR chain (**GPCHK**.PCST). If the values are different, a Service Request pulse can be generated, if it was previously enabled.

Notice that when an update of the CCU8 outputs leads to an equal result on the XOR chain, the CCU4 slice is not retriggered (the output parity from the external hardware remains with the same value).

Capture/Compare Unit 8 (CCU8)

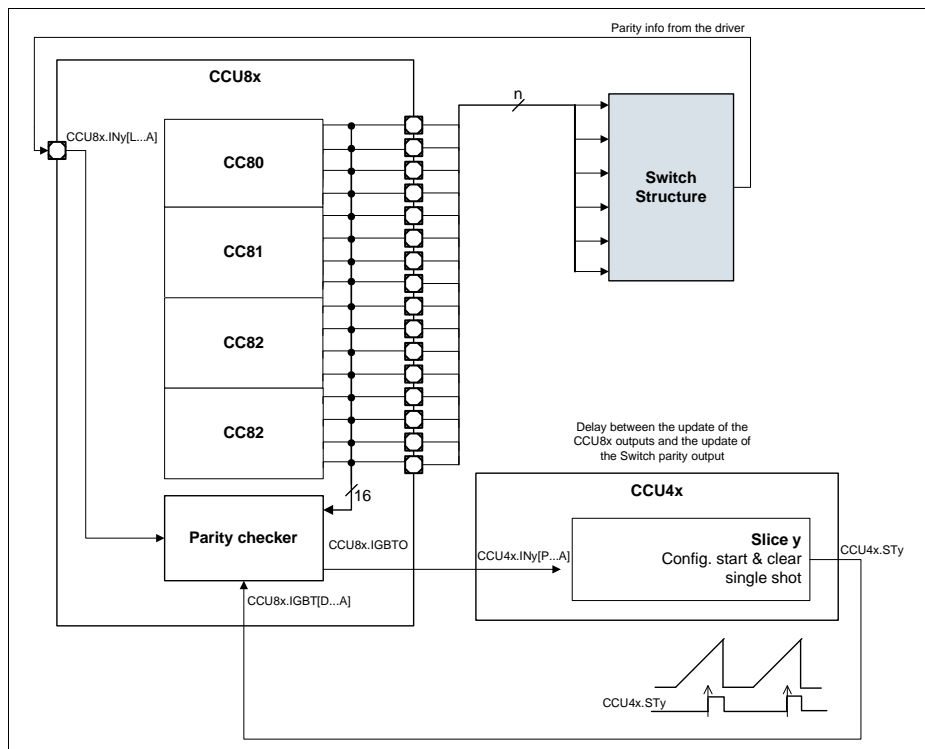

Figure 24-92 Parity Checker connections

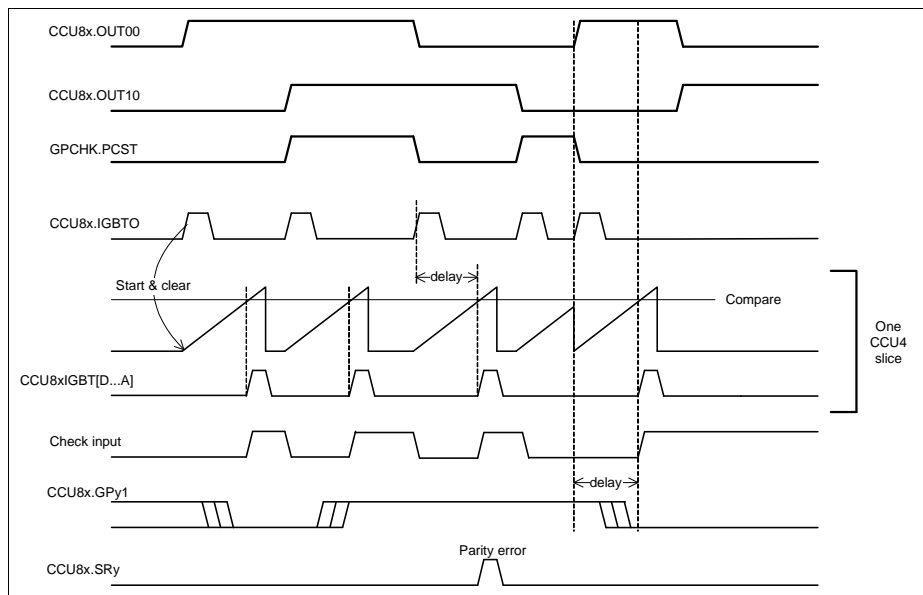

Figure 24-93 Parity Checker timing example

24.3 Service Request Generation

Each CCU8 slice has an interrupt structure as the one seen in [Figure 24-94](#). The register **CC8yINTS** is the status register for the interrupt sources. Each dedicated interrupt source can be set or cleared by SW, by writing into the specific bit in the **CC8ySWS** and **CC8ySWR** registers respectively.

Each interrupt source can be enabled/disabled via the **CC8yINTE** register. An enabled interrupt source will always generate a pulse on the service request line even if the specific status bit was not cleared. [Table 24-10](#) describes the interrupt sources of each CCU8 slice.

The interrupt sources, Period Match while counting up and one Match while counting down are ORed together. The same mechanism is applied to the Compare Match while counting up and Compare Match while counting down of both compare channels.

The interrupt sources for the external events are directly linked with the configuration set on the **CC8yINS.EVxEM**. If an event is programmed to be active on both edges, that means that service request pulse is going to be generated when any transition on the external signal is detected. If the event is linked with a level function, the **CC8yINS.EVxEM** still can be programmed to enable a service request pulse. The TRAP

Capture/Compare Unit 8 (CCU8)

event doesn't need any extra configuration for generating the service request pulse when the slice enters the TRAP state.

Table 24-10 Interrupt sources

| Signal | Description |
|----------------|--|
| CCINEV0_E | Event 0 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCINEV1_E | Event 1 edge(s) information from event selector. Used when an external signal should trigger an interrupt (It also can be the parity checker pattern fail information, if the parity checker was enabled). |
| CCINEV2_E | Event 2 edge(s) information from event selector. Used when an external signal should trigger an interrupt. |
| CCPM_U | Period Match while counting up. |
| CCCM1_U | Compare Match while counting up from compare channel 1. |
| CCCM1_D | Compare Match while counting down from compare channel 1. |
| CCCM2_U | Compare Match while counting up from compare channel 2. |
| CCCM2_D | Compare Match while counting down from compare channel 2. |
| CCOM_D | One Match while counting down. |
| Trap state set | Entering Trap State. Will set the E2AS. |

Each of the interrupt events can then be forwarded to one, of the slice's four service request lines, [Figure 24-95](#). The value set on the **CC8ySRS** controls which interrupt event is mapped into which service request line.

Capture/Compare Unit 8 (CCU8)

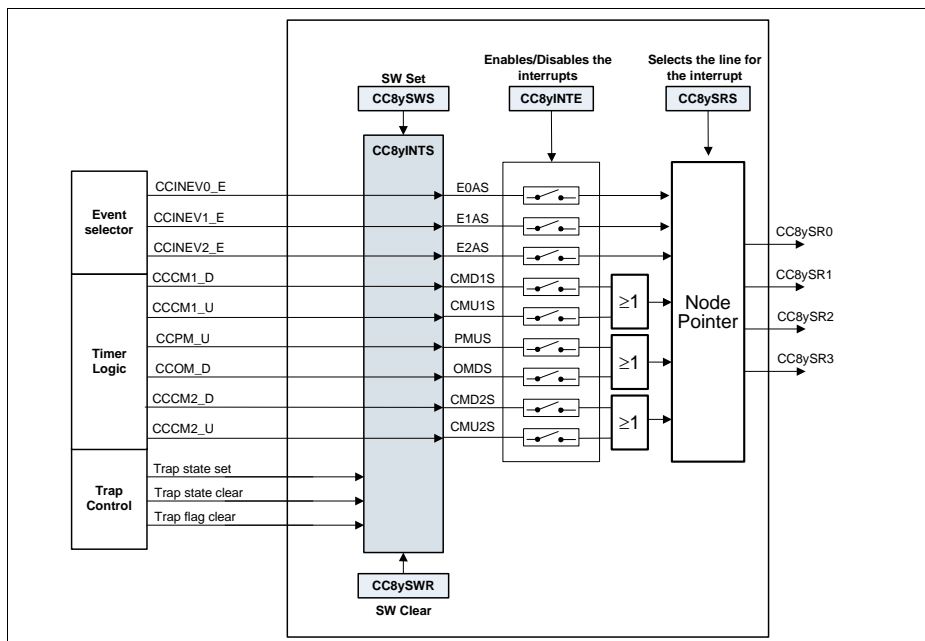

Figure 24-94 Slice interrupt node pointer overview

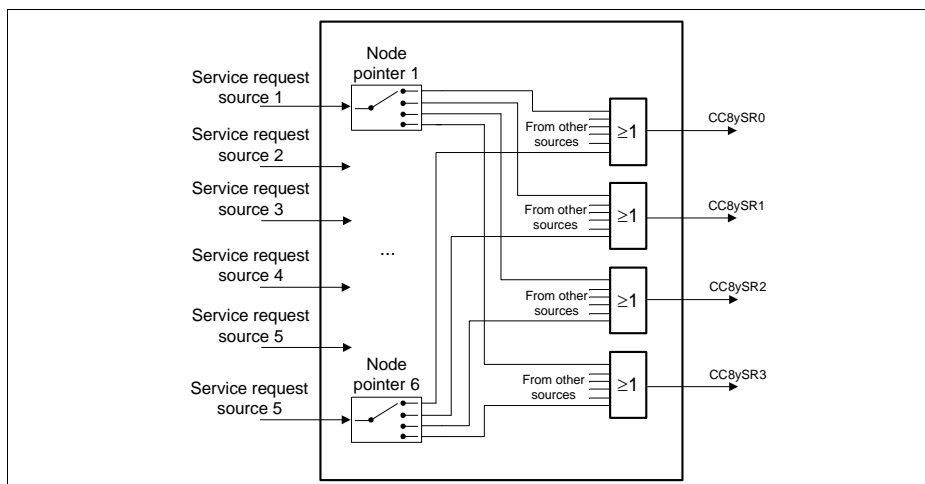

Figure 24-95 Slice interrupt selector overview

Capture/Compare Unit 8 (CCU8)

The four service request lines of each slice are OR together inside the kernel of the CCU8, see [Figure 24-96](#). This means that there are only four service request lines per CCU8, that can have in each line interrupt requests coming from different slices.

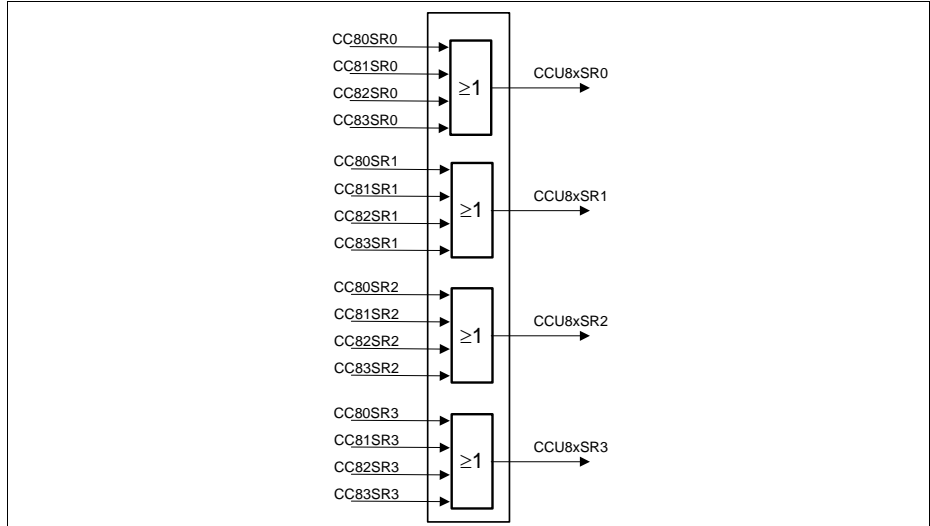

Figure 24-96 CCU8 service request overview

24.4 Debug Behavior

In suspend mode, the functional clocks for all slices as well the prescaler are stopped. The registers can still be accessed by the CPU (read only). This mode is useful for debugging purposes, e.g., where the current device status should be frozen in order to get a snapshot of the internal values. In suspend mode, all the slice counters are stopped. The suspend mode is non-intrusive concerning the register bits. This means register bits are not modified by hardware when entering or leaving the suspend mode.

Entry into suspend mode can be configured at the kernel level by means of the field [GCTRL.SUSCFG](#).

The module is only functional after the suspend signal becomes inactive.

24.5 Power, Reset and Clock

The following sections describe the operating conditions, characteristics and timing requirements for the CCU8. All the timing information is related to the module clock, f_{CCU8} .

24.5.1 Clocks

Module Clock

The module clock of the CCU8 module is described in the SCU chapter as f_{CCU} .

The bus interface clock of the CCU8 module is described in the SCU chapter as f_{PERIPH} .

The module clock for the CCU8 is controlled via a specific control bit inside the SCU (System Control Unit), register CLKSET.

It is possible to disable the module clock for the CCU8 via the **GSTAT**, nevertheless, there may be a dependency of the f_{CCU8} through the different CCU8 instances. One should address the SCU Chapter for a complete description of the product clock scheme.

If module clock dependencies exist through different IP instances, then one can disable the module clock internally inside the specific CCU8, by disabling the prescaler (**GSTAT.PRB** = 0_B).

External Clock

It is possible to use an external clock as source for the prescaler, and consequently for all the timer Slices, CC8y. This external source can be connected to one of the CCU8x.CLK[C...A] inputs.

This external source is nevertheless synchronized against f_{CCU8} .

Table 24-11 External clock operating conditions

| Parameter | Symbol | Values | | | Unit | Note / Test Condition |
|-----------|---------------|--------------------|------|--------------|------|------------------------------|
| | | Min. | Typ. | Max. | | |
| Frequency | f_{eclk} | — | — | $f_{CCU8}/4$ | MHz | |
| ON time | ton_{eclk} | $2T_{CCU8}^{1)2)}$ | — | — | ns | |
| OFF time | $toff_{eclk}$ | $2T_{CCU8}^{1)2)}$ | — | — | ns | Only the rising edge is used |

1) Only valid if the signal was not previously synchronized/generated with the fccu4 clock (or a synchronous clock)

2) 50% duty cycle is not obligatory

24.5.2 Module Reset

Each CCU8 has one reset source. This reset source is handled at system level and it can be generated independently via a system control register, PRSET0/PRSET1 (address SCU chapter for a full description).

Capture/Compare Unit 8 (CCU8)

After reset release, the complete IP is set to default configuration. The default configuration for each register field is addressed on [Section 24.7](#).

24.5.3 Power

The CCU8 is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For a explanation about the different power domains, please address the SCU (System Control Unit) chapter.

An internal power down mode for the CCU8, can be achieved by disabling the clock inside the CCU8 itself. For this one should set the [GSTAT](#) register with the default reset value (via the idle mode set register, [GIDLS](#)).

24.6 Initialization and System Dependencies**24.6.1 Initialization Sequence**

The initialization sequence for an application that is using the CCU8, should be the following:

1st Step: Apply reset to the CCU8, via the specific SCU bitfield on the PRSET0/PRSET1 register.

2nd Step: Release reset of the CCU8, via the specific SCU bitfield on the PRCLR0/PRCLR1 register.

3rd Step: Enable the CCU8 clock via the specific SCU register, CLKSET.

4th Step: Enable the prescaler block, by writing 1_B to the [GIDLC](#).SPRB field.

5th Step: Configure the global CCU8 register [GCTRL](#).

6th Step: Configure all the registers related to the required Timer Slice(s) functions, including the interrupt/service request configuration.

7th Step: If needed, configure the startup value for a specific Compare Channel Status, of a Timer Slice, by writing 1_B to the specific [GCSS](#).SyTS.

8th Step: Configure the parity checker function if used, by programming the [GPCHK](#) register

9th Step: Enable the specific timer slice(s), CC8y, by writing 1_B to the specific [GIDLC](#).CSyl.

10th Step: For all the Timer Slices that should be started synchronously via SW, the specific system register localized in the SCU, CCUCON, that enables a synchronous timer start should be addressed. The SCU.GSC8x input signal needs to be configured previously as a start function, see [Section 24.2.8.1](#).

24.6.2 System Dependencies

Each CCU8 may have different dependencies regarding module and bus clock frequencies. These dependencies should be addressed in the SCU and System Architecture Chapters.

Dependencies between several peripherals, regarding different clock operating frequencies may also exist. This should be addressed before configuring the connectivity between the CCU8 and some other peripheral.

The following topics must be taken into consideration for good CCU8 and system operation:

- CCU8 module clock must be at maximum two times faster than the module bus interface clock
- Module input triggers for the CCU8 must not exceed the module clock frequency (if the triggers are generated internally in the device)
- Module input triggers for the CCU8 must not exceed the frequency dictated in [Section 24.5.1](#)
- Frequency of the CCU8 outputs used as triggers/functions on other modules, must be crosschecked on the end point
- Applying and removing CCU8 from reset, can cause unwanted operations in other modules. This can occur if the modules are using CCU8 outputs as triggers/functions.

24.7 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 24-12 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|-----------------------|-----------------------|------|
| CCU80 | 40020000 _H | 40023FFF _H | |
| CCU81 | 40024000 _H | 40027FFF _H | |

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

24.7.1 Global Registers

GCTRL

The register contains the global configuration fields that affect all the timer slices inside CCU8.

Capture/Compare Unit 8 (CCU8)

GCTRL

Global Control Register

(0000_H)

Reset Value: 00000000_H

| rw | rw | rw | rw | rw | rw | r | | | | rw | r | | rw | | |

| Field | Bits | Type | Description |
|-------|-------|------|--|
| PRBC | [2:0] | rw | Prescaler Clear Configuration This register controls how the prescaler Run Bit and internal registers are cleared. 000 _B SW only 001 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC80 is cleared. 010 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC81 is cleared. 011 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC82 is cleared. 100 _B GSTAT .PRB and prescaler registers are cleared when the Run Bit of CC83 is cleared. |
| PCIS | [5:4] | rw | Prescaler Input Clock Selection 00 _B Module clock 01 _B CCU8x.ECLKA 10 _B CCU8x.ECLKB 11 _B CCU8x.ECLKC |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------|-------|------|---|
| SUSCFG | [9:8] | rw | Suspend Mode Configuration This field controls the entering in suspend mode for all the CCU8 slices. 00 _B Suspend request ignored. The module never enters in suspend 01 _B Stops all the running slices immediately. Safe stop is not applied. 10 _B Stops the block immediately and clamps all the outputs to PASSIVE state. Safe stop is applied. 11 _B Waits for the roll over of each slice to stop and clamp the slices outputs. Safe stop is applied. |
| MSE0 | 10 | rw | Slice 0 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 0 can be requested not only by SW but also via the CCU8x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU8x.MCSS input. |
| MSE1 | 11 | rw | Slice 1 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 1 can be requested not only by SW but also via the CCU8x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU8x.MCSS input. |
| MSE2 | 12 | rw | Slice 2 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 2 can be requested not only by SW but also via the CCU8x.MCSS input. 0 _B Shadow transfer can only be requested by SW 1 _B Shadow transfer can be requested via SW and via the CCU8xMCSS input. |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| MSE3 | 13 | rw | <p>Slice 3 Multi Channel shadow transfer enable When this field is set, a shadow transfer of slice 3 can be requested not only by SW but also via the CCU8x.MCSS input.</p> <p>0_B Shadow transfer can only be requested by SW 1_B Shadow transfer can be requested via SW and via the CCU8x.MCSS input.</p> |
| MSDE | [15:14] | rw | <p>Multi Channel shadow transfer request configuration This field configures the type of shadow transfer requested via the CCU8x.MCSS input. The field CC8yTC.MSEx needs to be set in order for this configuration to have any effect.</p> <p>00_B Only the shadow transfer for period and compare values is requested 01_B Shadow transfer for the compare, period and prescaler compare values is requested 10_B Reserved 11_B Shadow transfer for the compare, period, prescaler and dither compare values is requested</p> |
| 0 | 3, [7:6], [31:16] | r | <p>Reserved A read always returns 0.</p> |

GSTAT

The register contains the status of the prescaler and each timer slice (idle mode or running).

GSTAT

Global Status Register

(0004_H)

Reset Value: 0000000F_H

| r | | | | | w | w | w | r | | | | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|--|
| SS0I | 0 | w | CC80 IDLE mode set Writing a 1 _B to this bit sets the CC80 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| SS1I | 1 | w | CC81 IDLE mode set Writing a 1 _B to this bit sets the CC81 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS2I | 2 | w | CC82 IDLE mode set Writing a 1 _B to this bit sets the CC82 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| SS3I | 3 | w | CC83 IDLE mode set Writing a 1 _B to this bit sets the CC83 slice in IDLE mode. The clocks for the slice are stopped when in IDLE mode. When entering IDLE, the internal slice registers are not cleared. A read access always returns 0. |
| CPRB | 8 | w | Prescaler_B Run Bit Clear Writing a 1 into this register clears the Run Bit of the prescaler. Prescaler internal registers are not cleared. A read always returns 0. |
| PSIC | 9 | w | Prescaler clear Writing a 1 _B to this register clears the prescaler counter. It also loads the PSIV into the PVAL field for all Timer Slices. This performs a re alignment of the timer clock for all Slices. The Run Bit of the prescaler is not cleared. A read always returns 0. |
| CPCH | 10 | w | Parity Checker Run bit clear Writing a 1 _B to this register clears the run bit of the parity checker. All the internal registers are cleared. The status bit value is kept, GPCHK.PCST . A read always returns 0. |
| 0 | [7:4], [31:11] | r | Reserved Read always returns 0. |

GIDLC

Through this register one can remove the prescaler and the specific timer slices from idle mode.

GIDLC

Global Idle Clear

(000C_H)

Reset Value: 00000000_H

| S0DSS | 1 | rh | Slice 0 Dither shadow transfer status 0 _B Dither shadow transfer has not been requested 1 _B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S0PSS | 2 | rh | Slice 0 Prescaler shadow transfer status 0 _B Prescaler shadow transfer has not been requested 1 _B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S1SS | 4 | rh | Slice 1 shadow transfer status 0 _B Shadow transfer has not been requested 1 _B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |

| Field | Bits | Type | Description |
|--------------|------|------|---|
| S1DSS | 5 | rh | Slice 1 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S1PSS | 6 | rh | Slice 1 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S2SS | 8 | rh | Slice 2 shadow transfer status 0_B Shadow transfer has not been requested 1_B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S2DSS | 9 | rh | Slice 2 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S2PSS | 10 | rh | Slice 2 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S3SS | 12 | rh | Slice 3 shadow transfer status 0_B Shadow transfer has not been requested 1_B Shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------------|-----------------------------|------|---|
| S3DSS | 13 | rh | Slice 3 Dither shadow transfer status 0_B Dither shadow transfer has not been requested 1_B Dither shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| S3PSS | 14 | rh | Slice 3 Prescaler shadow transfer status 0_B Prescaler shadow transfer has not been requested 1_B Prescaler shadow transfer has been requested This field is cleared by HW after the requested shadow transfer has been executed. |
| CC80ST1 | 16 | rh | Slice 0 compare channel 1 status bit |
| CC81ST1 | 17 | rh | Slice 1 compare channel 1 status bit |
| CC82ST1 | 18 | rh | Slice 2 compare channel 1 status bit |
| CC83ST1 | 19 | rh | Slice 3 compare channel 1 status bit |
| CC80ST2 | 20 | rh | Slice 0 compare channel 2 status bit |
| CC81ST2 | 21 | rh | Slice 1 compare channel 2 status bit |
| CC82ST2 | 22 | rh | Slice 2 compare channel 2 status bit |
| CC83ST2 | 23 | rh | Slice 3 compare channel 2 status bit |
| 0 | 3, 7, 11, 15, [31:24] | r | Reserved Read always returns 0. |

GPCHK

This register contains the configuration for the Parity Check function of CCU8.

GPCHK

Parity Checker Configuration

(001C_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|------------------|----------|----|----|---------------|----|----|----|------------------|-------------|--------------|-------------|------------------|----|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| rh | r | | | | | | | rw | rw | rw | rw | rw | | | |

| Field | Bits | Type | Description |
|--------------|-------|------|--|
| PASE | 0 | rw | Parity Checker Automatic start/stop If this field is set, the parity checker run bit is automatically set, when the run bit of the selected slice is set and it is cleared when the run bit of the slice is cleared. The field PACS needs to be programmed accordingly. |
| PACS | [2:1] | rw | Parity Checker Automatic start/stop selector This fields selects to which slice the automatic start/stop of the parity checker is associated: 00 _B CC80 01 _B CC81 10 _B CC82 11 _B CC83 |
| PISEL | [4:3] | rw | Driver Input signal selector This fields selects which signal contains the driver parity information: 00 _B CC8x.GP01 - driver output is connected to event 1 of slice 0 01 _B CC8x.GP11 - drive output is connected to event 1 of slice 1 10 _B CC8x.GP21 - driver output is connected to event 1 of slice 2 11 _B CC8x.GP31 - driver output is connected to event 1 of slice 3 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| PCDS | [6:5] | rw | Parity Checker Delay Input Selector This fields selects which signal is controlling the delay between the change at the CCU8 outputs and effective change at the driver parity output: 00 _B CCU8x.IGBTA 01 _B CCU8x.IGBTB 10 _B CCU8x.IGBTC 11 _B CCU8x.IGBTD |
| PCTS | 7 | rw | Parity Checker type selector This fields selects if we have an odd or even parity: 0 _B Even parity enabled 1 _B Odd parity enabled |
| PCST | 15 | rh | Parity Checker XOR status This field contains the current value of the XOR chain. |
| PCSEL0 | [19:16] | rw | Parity Checker Slice 0 output selection This fields selects which slice 0 outputs are going to be used to perform the parity check. The respective bit field needs to be set to 1 _B to enable the output in the parity function. PCSEL0[0] - CCU8x.OUT00 PCSEL0[1] - CCU8x.OUT01 PCSEL0[2] - CCU8x.OUT02 PCSEL0[3] - CCU8x.OUT03 |
| PCSEL1 | [23:20] | rw | Parity Checker Slice 1 output selection Same description as PCSEL0. |
| PCSEL2 | [27:24] | rw | Parity Checker Slice 2 output selection Same description as PCSEL0. |
| PCSEL3 | [31:28] | rw | Parity Checker Slice 3 output selection Same description as PCSEL0. |
| 0 | [14:8] | r | Reserved Read always returns 0. |

MIDR

This register contains the module identification number.

MIDR

Module Identification

(0080_H)

Reset Value: 00A7C0XX_H

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| MODR | [7:0] | r | Module Revision This bit field indicates the revision number of the module implementation (depending on the design step). The given value of 00 _H is a placeholder for the actual number. |
| MODT | [15:8] | r | Module Type |
| MODN | [31:16] | r | Module Number |

24.7.2 Slice (CC8y) Registers

CC8yINS

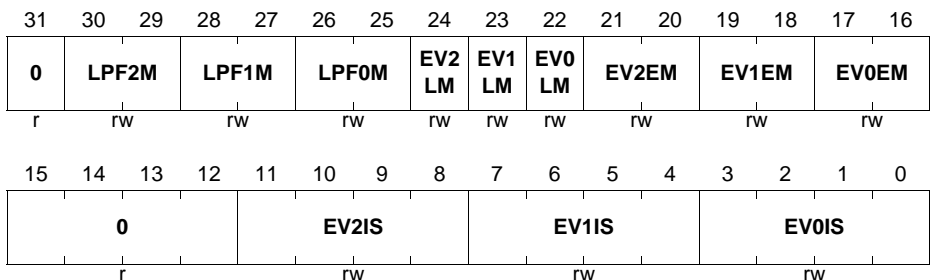

The register contains the configuration for the input selector.

CC8yINS (y = 0 - 3)

Input Selector Configuration

(0100_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| EV0IS | [3:0] | rw | Event 0 signal selection This field selects which pins is used for the event 0. 0000 _B CCU8x.INyA 0001 _B CCU8x.INyB 0010 _B CCU8x.INyC 0011 _B CCU8x.INyD 0100 _B CCU8x.INyE 0101 _B CCU8x.INyF 0110 _B CCU8x.INyG 0111 _B CCU8x.INyH 1000 _B CCU8x.INyI 1001 _B CCU8x.INyJ 1010 _B CCU8x.INyK 1011 _B CCU8x.INyL 1100 _B CCU8x.INyM 1101 _B CCU8x.INyN 1110 _B CCU8x.INyO 1111 _B CCU8x.INyP |
| EV1IS | [7:4] | rw | Event 1 signal selection Same as EV0IS description |

| CNTS | | LDS | | UDS | | GATES | | CAP1S | | CAP0S | | ENDS | | STRTS | |
| rw | | rw | | rw | | rw | | rw | | rw | | rw | | rw | |

| Field | Bits | Type | Description |
|-------|-------|------|---|
| STRTS | [1:0] | rw | External Start Functionality Selector Selects the Event that is going to be linked with the external start functionality. 00 _B External Start Function deactivated 01 _B External Start Function triggered by Event 0 10 _B External Start Function triggered by Event 1 11 _B External Start Function triggered by Event 2 |
| ENDS | [3:2] | rw | External Stop Functionality Selector Selects the Event that is going to be linked with the external stop functionality. 00 _B External Stop Function deactivated 01 _B External Stop Function triggered by Event 0 10 _B External Stop Function triggered by Event 1 11 _B External Stop Function triggered by Event 2 |
| CAP0S | [5:4] | rw | External Capture 0 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 1 and 0. This function is used to capture the value of the timer into the capture registers 1 and 0. 00 _B External Capture 0 Function deactivated 01 _B External Capture 0 Function triggered by Event 0 10 _B External Capture 0 Function triggered by Event 1 11 _B External Capture 0 Function triggered by Event 2 <i>Note: If the field SCE is set, this functionality is deactivated.</i> |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| CAP1S | [7:6] | rw | External Capture 1 Functionality Selector Selects the Event that is going to be linked with the external capture for capture registers number 3 and 2. This function is used to capture the value of the timer into the capture registers 3 and 2. 00 _B External Capture 1 Function deactivated 01 _B External Capture 1 Function triggered by Event 0 10 _B External Capture 1 Function triggered by Event 1 11 _B External Capture 1 Function triggered by Event 2 |
| GATES | [9:8] | rw | External Gate Functionality Selector Selects the Event that is going to be linked with the counter gating function. This function is used to gate the timer increment/decrement procedure. 00 _B External Gating Function deactivated 01 _B External Gating Function triggered by Event 0 10 _B External Gating Function triggered by Event 1 11 _B External Gating Function triggered by Event 2 |
| UDS | [11:10] | rw | External Up/Down Functionality Selector Selects the Event that is going to be linked with the Up/Down counting direction control. This function is used to control externally the timer increment/decrement operation. 00 _B External Up/Down Function deactivated 01 _B External Up/Down Function triggered by Event 0 10 _B External Up/Down Function triggered by Event 1 11 _B External Up/Down Function triggered by Event 2 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|---------|------|--|
| LDS | [13:12] | rw | External Timer Load Functionality Selector Selects the Event that is going to be linked with the timer load function. The value present in the CC8yCR1/CC8yCR2 (depending on the value of CC8yTC.TLS) is loaded into the specific slice timer. 00 _B - External Load Function deactivated 01 _B - External Load Function triggered by Event 0 10 _B - External Load Function triggered by Event 1 11 _B - External Load Function triggered by Event 2 |
| CNTS | [15:14] | rw | External Count Selector Selects the Event that is going to be linked with the count function. The counter is going to be increment/decremented each time that a specific transition on the event is detected. 00 _B External Count Function deactivated 01 _B External Count Function triggered by Event 0 10 _B External Count Function triggered by Event 1 11 _B External Count Function triggered by Event 2 <i>Note: In CC40 this field doesn't exist. This is a read only reserved field. Read access always returns 0.</i> |
| OFS | 16 | rw | Override Function Selector This field enables the ST bit override functionality. 0 _B Override functionality disabled 1 _B Status bit trigger override connected to Event 1; Status bit value override connected to Event 2 |
| TS | 17 | rw | Trap Function Selector This field enables the trap functionality. 0 _B Trap function disabled 1 _B TRAP function connected to Event 2 |
| MOS | [19:18] | rw | External Modulation Functionality Selector Selects the Event that is going to be linked with the external modulation function. 00 _B - Modulation Function deactivated 01 _B - Modulation Function triggered by Event 0 10 _B - Modulation Function triggered by Event 1 11 _B - Modulation Function triggered by Event 2 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| TCE | 20 | rw | Timer Concatenation Enable This bit enables the timer concatenation with the previous slice. 0_B Timer concatenation is disabled 1_B Timer concatenation is enabled <i>Note: In CC80 this field doesn't exist. This is a read only reserved field. Read access always returns 0.</i> |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC8yTCST

The register holds the status of the timer (running/stopped) and the information about the counting direction (up/down).

CC8yTCST (y = 0 - 3)

Slice Timer Status (0108_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----------|----------|----|------|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0 | | | | | | | | | | | | | | | TRB S |
| r | | | | | | | | | | | | | | | |
| | | | | | | | | | | | | | | | w |

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| TRBS | 0 | w | Timer Run Bit set Writing a 1_B into this field sets the run bit of the timer. The timer is not cleared. Read always returns 0. |
| 0 | [31:1] | r | Reserved Read always returns 0 |

CC8yTCCLR

Through this register it is possible to stop and clear the timer, and clearing also the dither counter

CC8yTCCLR (y = 0 - 3)

Slice Timer Clear

(0110_H + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| TRBC | 0 | w | Timer Run Bit Clear Writing a 1 _B into this field clears the run bit of the timer. The timer is not cleared. Read always returns 0. |
| TCC | 1 | w | Timer Clear Writing a 1 _B into this field clears the timer value. Read always returns 0. |
| DITC | 2 | w | Dither Counter Clear Writing a 1 _B into this field clears the dither counter. Read always returns 0. |
| DTC1C | 3 | w | Dead Time Counter 1 Clear Writing a 1 _B into this field clears the channel 1 dead time counter. The counter is stopped until a new start trigger is detected. Read always returns 0. |
| DTC2C | 4 | w | Dead Time Counter 2 Clear Writing a 1 _B into this field clears the channel 2 dead time counter. The counter is stopped until a new start trigger is detected. Read always returns 0. |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| 0 | [31:5] | r | Reserved Read always returns 0 |

CC8yTC

This register holds the several possible configurations for the timer operation.

CC8yTC (y = 0 - 3)

Slice Timer Control

$$(0114_H + 0100_H * y)$$

Reset Value: 18000000_H

| | | | | | | | | | | | | | | | |

| rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|---|
| TCM | 0 | rw | Timer Counting Mode This field controls the actual counting scheme of the timer. 0 _B Edge aligned mode 1 _B Center aligned mode <i>Note: When using an external signal to control the counting direction, the counting scheme is always edge aligned.</i> |
| TSSM | 1 | rw | Timer Single Shot Mode This field controls the single shot mode. This is applicable in edge and center aligned modes. 0 _B Single shot mode is disabled 1 _B Single shot mode is enabled |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|-------|------|---|
| CLST | 2 | rw | Shadow Transfer on Clear Setting this bit to 1 _B enables a shadow transfer when a timer clearing action is done (by SW or by an external event). Notice that the shadow transfer enable bitfields on the GCST register still need to be set to 1 _B via software. |
| CMOD | 3 | rh | Capture Compare Mode This field indicates in which mode the slice is operating. The default value is compare mode. The capture mode is automatically set by the HW when an external signal is mapped to a capture trigger. 0 _B Compare Mode 1 _B Capture Mode |
| ECM | 4 | rw | Extended Capture Mode This field control the Capture mode of the specific slice. It only has effect if the CMOD bit is 1 _B . 0 _B Normal Capture Mode. Clear of the Full Flag of each capture register is done by accessing the registers individually only. 1 _B Extended Capture Mode. Clear of the Full Flag of each capture register is done not only by accessing the individual registers but also by accessing the ECRD register. When reading the ECRD register, only the capture register register full flag pointed by the VPTR is cleared |
| CAPC | [6:5] | rw | Clear on Capture Control 00 _B Timer is never cleared on a capture event 01 _B Timer is cleared on a capture event into capture registers 2 and 3. (When SCE = 1 _B , Timer is always cleared in a capture event) 10 _B Timer is cleared on a capture event into capture registers 0 and 1. (When SCE = 1 _B , Timer is always cleared in a capture event) 11 _B Timer is always cleared in a capture event. |
| TLS | 7 | rw | Timer Load selector 0 _B Timer is loaded with the value of CR1 1 _B Timer is loaded with the value of CR2 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|-------|------|--|
| ENDM | [9:8] | rw | Extended Stop Function Control This field controls the extended functions of the external Stop signal. 00 _B Clears the timer run bit only (default stop) 01 _B Clears the timer only (flush) 10 _B Clears the timer and run bit (flush/stop) 11 _B Reserved <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is counting up and with the Period value if the counter is being decremented.</i> |
| STRM | 10 | rw | Extended Start Function Control This field controls the extended functions of the external Start signal. 0 _B Sets run bit only (default start) 1 _B Clears the timer and sets run bit, if not set (flush/start) <i>Note: When using an external up/down signal the flush operation sets the timer with zero if the counter is being incremented and with the Period value if the counter is being decremented.</i> |
| SCE | 11 | rw | Equal Capture Event enable 0 _B Capture into CC8yC0V/CC8yC1V registers control by CCycapt0 and capture into CC8yC3V/CC8yC2V control by CCycapt1 1 _B Capture into CC8yC0V/CC8yC1V and CC8yC3V/CC8yC2V control by CCycapt1 |
| CCS | 12 | rw | Continuous Capture Enable 0 _B The capture into a specific capture register is done with the rules linked with the full flags, described at Section 24.2.8.6 . 1 _B The capture into the capture registers is always done regardless of the full flag status (even if the register has not been read back). |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| DITHE | [14:13] | rw | Dither Enable This field controls the dither mode for the slice. See Section 24.2.12 . 00 _B Dither is disabled 01 _B Dither is applied to the Period 10 _B Dither is applied to the Compare 11 _B Dither is applied to the Period and Compare |
| DIM | 15 | rw | Dither input selector This fields selects if the dither control signal is connected to the dither logic of the specific slice of is connected to the dither logic of slice 0. Notice that even if this field is set to 1 _B , the field DITHE still needs to be programmed. 0 _B Slice is using it own dither unit 1 _B Slice is connected to the dither unit of slice 0. |
| FPE | 16 | rw | Floating Prescaler enable Setting this bit to 1 _B enables the floating prescaler mode. 0 _B Floating prescaler mode is disabled 1 _B Floating prescaler mode is enabled |
| TRAPE0 | 17 | rw | TRAP enable for CCU8x.OUTy0 Setting this bit to 1 enables the TRAP action at the CCU8x.OUTy0 output pin. After mapping an external signal to the TRAP functionality, the user must set this field to 1 to activate the effect of the TRAP on the specific output pin. Writing a 0 into this field disables the effect of the TRAP function regardless of the state of the input signal. 0 _B TRAP functionality has no effect on the CCU8x.OUTy0 output 1 _B TRAP functionality affects the CCU8x.OUTy0 output |
| TRAPE1 | 18 | rw | TRAP enable for CCU8x.OUTy1 TRAP enable for the CCU8x.OUTy1. Same description as for the TRAPE0 field. |
| TRAPE2 | 19 | rw | TRAP enable for CCU8x.OUTy2 TRAP enable for the CCU8x.OUTy2. Same description as for the TRAPE0 field. |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------|------|------|---|
| TRAPE3 | 20 | rw | TRAP enable for CCU8x.OUTy3 TRAP enable for the CCU8x.OUTy3. Same description as for the TRAPE0 field. |
| TRPSE | 21 | rw | TRAP Synchronization Enable Writing a 1 into this bit enables a synchronous exiting with the PWM period of the trap state. 0 _B Exiting from TRAP state isn't synchronized with the PWM signal 1 _B Exiting from TRAP state is synchronized with the PWM signal |
| TRPSW | 22 | rw | TRAP State Clear Control 0 _B The slice exits the TRAP state automatically when the TRAP condition is not present (Trap state cleared by HW and SW) 1 _B The TRAP state can only be exited by a SW request. |
| EMS | 23 | rw | External Modulation Synchronization Setting this bit to 1 enables the synchronization of the external modulation functionality with the PWM period. 0 _B External Modulation functionality is not synchronized with the PWM signal 1 _B External Modulation functionality is synchronized with the PWM signal |
| EMT | 24 | rw | External Modulation Type This field selects if the external modulation event is clearing the CC8ySTx bits or if is gating the outputs. 0 _B External Modulation functionality is clearing the CC8ySTx bits. 1 _B External Modulation functionality is gating the outputs. |
| MCME1 | 25 | rw | Multi Channel Mode Enable for Channel 1 0 _B Multi Channel Mode in Channel 1 is disabled 1 _B Multi Channel Mode in Channel 1 is enabled |
| MCME2 | 26 | rw | Multi Channel Mode Enable for Channel 2 0 _B Multi Channel Mode in Channel 2 is disabled 1 _B Multi Channel Mode in Channel 2 is enabled |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| EME | [28:27] | rw | External Modulation Channel enable This field controls in which channel, the modulation functionality has effect. The modulations functionality needs to be previously enabled by setting the CC8yCMC.MOS accordingly. 00 _B External Modulation functionality doesn't affect any channel 01 _B External Modulation only applied on channel 1 10 _B External Modulation only applied on channel 2 11 _B External Modulation applied on both channels |
| STOS | [30:29] | rw | Status bit output selector This field selects to which channel the output CC8ySTy is mapped. 00 _B CC8yST1 forward to CCU8x.STy 01 _B CC8yST2 forward to CCU8x.STy 10 _B CC8yST1 AND CC8yST2 forward to CCU8x.STy 11 _B CC8yST1 OR CC8yST2 forward to CCU8x.STy |
| 0 | 31 | r | Reserved Read always returns 0. |

CC8yPSL

This register holds the configuration for the output passive level control.

CC8yPSL (y = 0 - 3)

Passive Level Config

(0118_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| r | | | | | | | | | | | | 22 | 21 | 12 | 11 |
| | | | | | | | | | | | | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| PSL11 | 0 | rw | Output Passive Level for CCU8x.OUTy0 This field controls the passive level of the CCU8x.OUTy0. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| PSL12 | 1 | rw | Output Passive Level for CCU8x.OUTy1 This field controls the passive level of the CCU8x.OUTy1. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| PSL21 | 2 | rw | Output Passive Level for CCU8x.OUTy2 This field controls the passive level of the CCU8x.OUTy2. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| PSL22 | 3 | rw | Output Passive Level for CCU8x.OUTy3 This field controls the passive level of the CCU8x.OUTy3. 0 _B Passive Level is LOW 1 _B Passive Level is HIGH A write always addresses the shadow register, while a read always returns the current used value. |
| 0 | [31:4] | r | Reserved A read access always returns 0 |

CC8yDIT

This register holds the current dither compare and dither counter values.

CC8yDIT (y = 0 - 3)

Dither Config $(011C_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| DCV | [3:0] | rh | Dither compare Value This field contains the value used for the dither comparison. This value is updated when a shadow transfer occurs with the CC8yDITS.DCVS . |
| DCNT | [11:8] | rh | Dither counter actual value |
| 0 | [7:4], [31:12] | r | Reserved Read always returns 0. |

CC8yDITS

This register contains the value that is going to be loaded into the **CC8yDIT.DCV** when the next shadow transfer occurs.

CC8yDITS (y = 0 - 3)

Dither Shadow Register $(0120_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| DCVS | [3:0] | rw | Dither Shadow Compare Value This field contains the value that is going to be set on the dither compare value, CC8yDIT.DCV , within the next shadow transfer. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC8yPSC

This register contains the value that is loaded into the prescaler during restart.

CC8yPSC (y = 0 - 3)

| Prescaler Control | | | | | | | | | | | | | | | | (0124 _H + 0100 _H * y) | | | | Reset Value: 00000000 _H | | | | | | | |
|-------------------|----|----|----|----|----|----|----|----|----|----|----|------|----|----|----|---|--|--|--|------------------------------------|--|--|--|--|--|--|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | | | | | | | | | | | | |
| 0 | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | | | | | | | | | |
| 0 | | | | | | | | | | | | PSIV | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | rw | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| PSIV | [3:0] | rw | Prescaler Initial Value This field contains the value that is applied to the Prescaler at startup. When floating prescaler mode is used, this value is applied when a timer compare match AND prescaler compare match occurs or when a capture event is triggered. |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC8yFPC

This register contains the value used for the floating prescaler compare and the actual prescaler division value.

CC8yFPC (y = 0 - 3)

Floating Prescaler Control **(0128_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|-------------------------------|------|--|
| PCMP | [3:0] | rh | Floating Prescaler Compare Value This field contains the value used to compare the actual prescaler value. The comparison is triggered by the Timer Compare match event. See Section 24.2.13.2 . |
| PVAL | [11:8] | rwh | Actual Prescaler Value See Table 24-8 . Writing into this register is only possible when the prescaler is stopped. When the floating prescaler mode is not used, this value is equal to the CC8yPSC.PSIV . |
| 0 | [7:4], [15:12], [31:16] | r | Reserved Read always returns 0. |

CC8yFPCS

This register contains the value that is going to be transferred to the [CC8yFPC.PCMP](#) field within the next shadow transfer update.

Capture/Compare Unit 8 (CCU8)

CC8yFPCS (y = 0 - 3)

Floating Prescaler Shadow **(012C_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| PCMP | [3:0] | rw | Floating Prescaler Shadow Compare Value This field contains the value that is going to be set on the CC8yFPC .PCMP within the next shadow transfer. See Table 24-8 . |
| 0 | [31:4] | r | Reserved Read always returns 0. |

CC8yPR

This register contains the actual value for the timer period.

CC8yPR (y = 0 - 3)

Timer Period Value **(0130_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-----------|---------|------|---|
| PR | [15:0] | rh | Period Register Contains the value of the timer period. |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yPRS

This register contains the value for the timer period that is going to be transferred into the **CC8yPR.PR** field when the next shadow transfer occurs.

CC8yPRS (y = 0 - 3)

Timer Shadow Period Value $(0134_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|------------|---------|------|--|
| PRS | [15:0] | rw | Period Register Contains the value of the timer period, that is going to be passed into the CC8yPR.PR field when the next shadow transfer occurs. |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yCR1

This register contains the value for the timer comparison of channel 1.

CC8yCR1 (y = 0 - 3)

Channel 1 Compare Value **(0138_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|---------|------|---|
| CR1 | [15:0] | rh | Compare Register for Channel 1 Contains the value for the timer comparison. A write always addresses the shadow register, while a read returns the actual value. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, the CR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yCR1S

This register contains the value that is going to be loaded into the **CC8yCR1.CR** field when the next shadow transfer occurs.

CC8yCR1S (y = 0 - 3)

Channel 1 Compare Shadow Value(013C_H + 0100_H * y) **Reset Value:** 00000000_H

| Field | Bits | Type | Description |
|-------|---------|------|---|
| CR1S | [15:0] | rw | Shadow Compare Register for Channel 1 Contains the value for the timer comparison, that is going to be passed into the CC8yCR1.CR1 field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 0 and 1, the CR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yCR2

This register contains the value for the timer comparison of channel 2.

CC8yCR2 (y = 0 - 3)

Channel 2 Compare Value **(0140_H + 0100_H * y)** **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|------------|---------|------|---|
| CR2 | [15:0] | rh | Compare Register for Channel 2 Contains the value for the timer comparison. A write always addresses the shadow register, while a read returns the actual value. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, the CR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yCR2S

This register contains the value that is going to be loaded into the **CC8yCR2.CR** field when the next shadow transfer occurs.

CC8yCR2S (y = 0 - 3)

Channel 2 Compare Shadow Value(0144_H + 0100_H * y) Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CR2S | [15:0] | rw | Shadow Compare Register for Channel 2 Contains the value for the timer comparison, that is going to be passed into the CC8yCR2.CR2 field when the next shadow transfer occurs. <i>Note: In Capture Mode when a external signal is selected for capturing the timer value into the capture registers 2 and 3, the CR is not accessible for writing. A read always returns 0.</i> |
| 0 | [31:16] | r | Reserved A read always returns 0. |

CC8yCHC

This register contains the configuration for the output connections from the two compare channels and the enable for the asymmetric mode.

CC8yCHC (y = 0 - 3)

Channel Control

(0148_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| ASE | 0 | rw | Asymmetric PWM mode Enable 0 _B Asymmetric PWM is disabled 1 _B Asymmetric PWM is enabled |
| OCS1 | 1 | rw | Output selector for CCU8x.OUTy0 0 _B CC8yST1 signal path is connected to the CCU8x.OUTy0 1 _B Inverted CC8yST1 signal path is connected to the CCU8x.OUTy0 |
| OCS2 | 2 | rw | Output selector for CCU8x.OUTy1 0 _B Inverted CC8yST1 signal path is connected to the CCU8x.OUTy1 1 _B CC8yST1 signal path is connected to the CCU8x.OUTy1 |
| OCS3 | 3 | rw | Output selector for CCU8x.OUTy2 0 _B CC8yST2 signal path is connected to the CCU8x.OUTy2 1 _B Inverted CCST2 signal path is connected to the CCU8x.OUTy2 |
| OCS4 | 4 | rw | Output selector for CCU8x.OUTy3 0 _B Inverted CC8yST2 signal path is connected to the CCU8x.OUTy3 1 _B CC8yST2 signal path is connected to the CCU8x.OUTy3 |
| 0 | [31:5] | r | Reserved A read access always returns 0 |

CC8yDTC

This register contains the configuration for the dead time generator.

CC8yDTC (y = 0 - 3)

Dead Time Control (014C_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|------|----|--------|--------|--------|--------|-------|-------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| DTE1 | 0 | rw | Dead Time Enable for Channel 1 This field enables the dead time counter for the compare channel 1. 0 _B Dead Time for channel 1 is disabled 1 _B Dead Time for channel 1 is enabled |
| DTE2 | 1 | rw | Dead Time Enable for Channel 2 This field enables the dead time counter for the compare channel 2. 0 _B Dead Time for channel 2 is disabled 1 _B Dead Time for channel 2 is enabled |
| DCEN1 | 2 | rw | Dead Time Enable for CC8yST1 0 _B Dead Time for CC8yST1 path is disabled 1 _B Dead Time for CC8yST1 path is enabled |
| DCEN2 | 3 | rw | Dead Time Enable for inverted CC8yST1 0 _B Dead Time for inverted CC8yST1 path is disabled 1 _B Dead Time for inverted CC8yST1 path is enabled |
| DCEN3 | 4 | rw | Dead Time Enable for CC8yST2 0 _B Dead Time for CC8yST2 path is disabled 1 _B Dead Time for CC8yST2 path is enabled |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------------|--------------------|------|---|
| DCEN4 | 5 | rw | Dead Time Enable for inverted CC8yST2 0_B Dead Time for inverted CC8yST2 path is disabled 1_B Dead Time for inverted CC8yST2 path is enabled |
| DTCC | [7:6] | rw | Dead Time clock control This field controls the prescaler clock configuration for the dead time counters. 00_B f_{clk} 01_B $f_{clk}/2$ 10_B $f_{clk}/4$ 11_B $f_{clk}/8$ |
| 0 | [15:8], [31:16] | r | Reserved A read always returns 0. |

CC8yDC1R

This register contains the dead time value for the rising transition.

CC8yDC1R (y = 0 - 3)

Channel 1 Dead Time Values ($0150_H + 0100_H * y$) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------------|-------|------|--|
| DT1R | [7:0] | rw | Rise Value for Dead Time of Channel 1 This field contains the delay value that is applied every time that a 0 to 1 transition occurs in the CC8yST1. |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| DT1F | [15:8] | rw | Fall Value for Dead Time of Channel 1 This field contains the delay value that is applied every time that a 1 to 0 transition occurs in the CC8yST1. |
| 0 | [31:16] | r | Reserved A read access always returns 0 |

CC8yDC2R

This register contains the dead time value for the falling transition.

CC8yDC2R (y = 0 - 3)

Channel 2 Dead Time Values $(0154_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------------|---------|------|--|
| DT2R | [7:0] | rw | Rise Value for Dead Time of Channel 2 This field contains the delay value that is applied every time that a 0 to 1 transition occurs in the CC8yST2. |
| DT2F | [15:8] | rw | Fall Value for Dead Time of Channel 2 This field contains the delay value that is applied every time that a 1 to 0 transition occurs in the CC8yST2. |
| 0 | [31:16] | r | Reserved A read access always returns 0 |

CC8yTIMER

This register contains the current value of the timer.

CC8yTIMER (y = 0 - 3)

Timer Value $(0170_H + 0100_H * y)$ **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------|---------|------|--|
| TVAL | [15:0] | rwh | Timer Value This field contains the actual value of the timer. A write access is only possible when the timer is stopped. |
| 0 | [31:16] | r | Reserved A read access always returns 0 |

CC8yC0V

This register contains the values associated with the Capture 0 field.

CC8yC0V (y = 0 - 3)

Capture Register 0 $(0174_H + 0100_H * y)$ **Reset Value: 00000000_H**

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 0 value. See Figure 24-43 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value when the time of the capture event into the capture register 0. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 0 after the last read access. See Figure 24-43 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC8yC1V

This register contains the values associated with the Capture 1 field.

CC8yC1V (y = 0 - 3)

Capture Register 1 (0178_H + 0100_H * y) **Reset Value: 00000000_H**

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPT | [15:0] | rh | Capture Value This field contains the capture register 1 value. See Figure 24-43 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value when the time of the capture event into the capture register 1. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 1 after the last read access. See Figure 24-43 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC8yC2V

This register contains the values associated with the Capture 2 field.

CC8yC2V (y = 0 - 3)

Capture Register 2 ($017C_H + 0100_H * y$) **Reset Value: 00000000_H**

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| CAPTV | [15:0] | rh | Capture Value This field contains the capture register 2 value. See Figure 24-43 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value when the time of the capture event into the capture register 2. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 2 after the last read access. See Figure 24-43 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC8yC3V

This register contains the values associated with the Capture 3 field.

CC8yC3V (y = 0 - 3)

Capture Register 3 $(0180_H + 0100_H * y)$ **Reset Value: 00000000_H**

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPT | [15:0] | rh | Capture Value This field contains the capture register 3 value. See Figure 24-43 . In compare mode a read access always returns 0. |
| FPCV | [19:16] | rh | Prescaler Value This field contains the prescaler value when the time of the capture event into the capture register 3. In compare mode a read access always returns 0. |
| FFL | 20 | rh | Full Flag This bit indicates if a new value was capture into the capture register 3 after the last read access. See Figure 24-43 . In compare mode a read access always returns 0. 0_B No new value was captured into the specific capture register 1_B A new value was captured into the specific register |
| 0 | [31:21] | r | Reserved A read always returns 0 |

CC8yINTS

This register contains the status of all interrupt sources.

CC8yINTS (y = 0 - 3)

Interrupt Status (01A0_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|--------------|-------|------|--|
| POSR | [1:0] | rw | Period/One match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Period match while counting up and One match while counting down are going to be forward. 00 _B Forward to CC8ySR0 01 _B Forward to CC8ySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |
| CM1SR | [3:2] | rw | Channel 1 Compare match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Compare match, of channel 1, while counting up and Compare match while counting down are going to be forward. 00 _B Forward to CC8ySR0 01 _B Forward to CC8ySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|--------------|-------------------|------|--|
| CM2SR | [5:4] | rw | Channel 2 Compare match Service request selector This field selects to which slice Service request line, the interrupt(s) generated by the Compare match, of channel 2, while counting up and Compare match while counting down are going to be forward. 00 _B Forward to CC8ySR0 01 _B Forward to CC8ySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |
| E0SR | [9:8] | rw | Event 0 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 0 detection are going to be forward. 00 _B Forward to CCvySR0 01 _B Forward to CC8ySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |
| E1SR | [11:10] | rw | Event 1 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 1 detection are going to be forward. 00 _B Forward to CC8ySR0 01 _B Forward to CC8ySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |
| E2SR | [13:12] | rw | Event 2 Service request selector This field selects to which slice Service request line, the interrupt generated by the Event 2 detection are going to be forward. 00 _B Forward to CC8ySR0 01 _B Forward to CCvySR1 10 _B Forward to CC8ySR2 11 _B Forward to CC8ySR3 |
| 0 | [7:6], [31:14] | r | Reserved Read always returns 0. |

CC8ySWS

Through this register it is possible for the SW to set a specific interrupt status flag.

CC8ySWS (y = 0 - 3)

Interrupt Status Set

(01AC_H + 0100_H * y)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|-----------|-----------|-----------|-----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |

| r | | | | w | w | w | w | r | | w | w | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|---|
| SPM | 0 | w | Period match while counting up set Writing a 1 _B into this field sets the CC8yINTS.PMUS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SOM | 1 | w | One match while counting down set Writing a 1 _B into this bit sets the CC8yINTS.OMDS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCM1U | 2 | w | Channel 1 Compare match while counting up set Writing a 1 _B into this field sets the CC8yINTS.CMU1S bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCM1D | 3 | w | Channel 1 Compare match while counting down set Writing a 1 _B into this bit sets the CC8yINTS.CMD1S bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SCM2U | 4 | w | Compare match while counting up set Writing a 1 _B into this field sets the CC8yINTS.CMU2S bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |

| Field | Bits | Type | Description |
|-------|-------------------|------|---|
| SCM2D | 5 | w | Compare match while counting down set Writing a 1 _B into this bit sets the CC8yINTS.CMD2S bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE0A | 8 | w | Event 0 detection set Writing a 1 _B into this bit sets the CC8yINTS.E0AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE1A | 9 | w | Event 1 detection set Writing a 1 _B into this bit sets the CC8yINTS.E1AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| SE2A | 10 | w | Event 2 detection set Writing a 1 _B into this bit sets the CC8yINTS.E2AS bit. An interrupt pulse is generated if the source is enabled. A read always returns 0. |
| STRPF | 11 | w | Trap Flag status set Writing a 1 _B into this bit sets the CC8yINTS.TRPF bit. A read always returns 0. |
| 0 | [7:6], [31:12] | r | Reserved Read always returns 0 |

CC8ySWR

Through this register it is possible for the SW to clear a specific interrupt status flag.

CC8ySWR (y = 0 - 3)

Interrupt Status Clear (01B0_H + 0100_H * y) **Reset Value: 00000000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|-----------|----------|----------|----------|----|----|-----------|-----------|-----------|-----------|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | RTR PF | RE2 A | RE1 A | RE0 A | 0 | | RCM 2D | RCM 2U | RCM 1D | RCM 1U | ROM | RPM |
| r | | | | w | w | w | w | r | | w | w | w | w | w | w |

| Field | Bits | Type | Description |
|-------|------|------|--|
| RPM | 0 | w | Period match while counting up clear Writing a 1 _B into this field clears the CC8yINTS .PMUS bit. A read always returns 0. |
| ROM | 1 | w | One match while counting down clear Writing a 1 into this bit clears the CC8yINTS .OMDS bit. A read always returns 0. |
| RCM1U | 2 | w | Channel 1 Compare match while counting up clear Writing a 1 _B into this field clears the CC8yINTS .CMU1S bit. A read always returns 0. |
| RCM1D | 3 | w | Channel 1 Compare match while counting down clear Writing a 1 _B into this bit clears the CC8yINTS .CMD1S bit. A read always returns 0. |
| RCM2U | 4 | w | Channel 2 Compare match while counting up clear Writing a 1 _B into this field clears the CC8yINTS .CMU2S bit. A read always returns 0. |
| RCM2D | 5 | w | Channel 2 Compare match while counting down clear Writing a 1 _B into this bit clears the CC8yINTS .CMD2S bit. A read always returns 0. |
| RE0A | 8 | w | Event 0 detection clear Writing a 1 _B into this bit clears the CC8yINTS .E0AS bit. A read always returns 0. |
| RE1A | 9 | w | Event 1 detection clear Writing a 1 _B into this bit clears the CC8yINTS .E1AS bit. A read always returns 0. |
| RE2A | 10 | w | Event 2 detection clear Writing a 1 _B into this bit clears the CC8yINTS .E2AS bit. A read always returns 0. |
| RTRPF | 11 | w | Trap Flag status clear Writing a 1 _B into this bit clears the CC8yINTS .TRPF bit. Not valid if CC8yTC .TRPEN = 1 _B and the Trap State is still active. A read always returns 0. |

| Field | Bits | Type | Description |
|-------|-------------------|------|--|
| 0 | [7:6], [31:12] | r | Reserved Read always returns 0 |

CC8ySTC

Through this register it is possible to configure the extended options for the shadow transfer mechanism.

CC8ySTC (y = 0 - 3)

Shadow transfer control (01B_{4H} + 0100_H * y) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| CSE | 0 | rw | Cascaded shadow transfer enable 0 _B Cascaded shadow transfer disabled 1 _B Cascaded shadow transfer enabled |
| STM | [2:1] | rw | Shadow transfer mode 00 _B Shadow transfer is done in Period Match and One match. 01 _B Shadow transfer is done only in Period Match. 10 _B Shadow transfer is done only in One Match. 11 _B Reserved <i>Note: This field only has effect if the timer is in Center Aligned Mode.</i> |
| 0 | [31:3] | r | Reserved Read always returns 0 |

CC8yECRD0

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 0. The read back is only valid if the **CC8yTC.ECM** = 1_B.

CC8yECRD0 (y = 0 - 3)

Extended Read Back 0

(01B_{8H} + 0100_H * y)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPV | [15:0] | rh | Timer Capture Value This field contains the timer captured value |
| FPCV | [19:16] | rh | Prescaler Capture value This field contains the value of the prescaler clock division associated with the specific CAPV field |
| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC80 01 _B CC81 10 _B CC82 11 _B CC83 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------|---------|------|---|
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0_B No new value was captured into this register 1_B A new value has been captured into this register |
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0_B No capture was lost 1_B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

CC8yECRD1

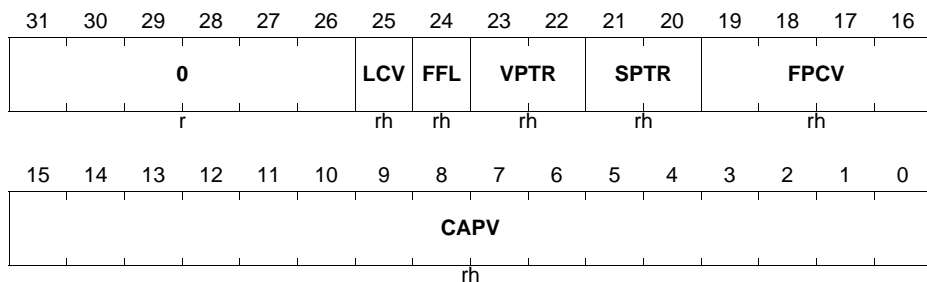

Through this register it is possible to read back the FIFO structure of the capture function that is linked with the capture trigger 1. The read back is only valid if the **CC8yTC.ECM** = 1_B .

CC8yECRD1 (y = 0 - 3)

Extended Read Back 1

($01BC_H + 0100_H * y$)

Reset Value: **00000000_H**

Capture/Compare Unit 8 (CCU8)

| Field | Bits | Type | Description |
|-------------|---------|------|---|
| CAPV | [15:0] | rh | Timer Capture Value This field contains the timer captured value |
| FPCV | [19:16] | rh | Prescaler Capture value This field contains the value of the prescaler clock division associated with the specific CAPV field |
| SPTR | [21:20] | rh | Slice pointer This field indicates the slice index in which the value was captured. 00 _B CC80 01 _B CC81 10 _B CC82 11 _B CC83 |
| VPTR | [23:22] | rh | Capture register pointer This field indicates the capture register index in which the value was captured. 00 _B Capture register 0 01 _B Capture register 1 10 _B Capture register 2 11 _B Capture register 3 |
| FFL | 24 | rh | Full Flag This bit indicates if the associated capture register contains a new value. 0 _B No new value was captured into this register 1 _B A new value has been captured into this register |
| LCV | 25 | rh | Lost Capture Value This field indicates if between two reads of the ECRD0 a capture trigger occurred while the FIFO structure was full. If a capture trigger occurred between two reads than a capture value was lost. This field is automatically cleared by the HW whenever a read to the ECRD occurs. 0 _B No capture was lost 1 _B A capture was lost |
| 0 | [31:26] | r | Reserved Read always returns 0 |

24.8 Interconnects

The tables that refer to the “global pins” are the ones that contain the inputs/outputs of each module that are common to all slices.

The GPIO mapping is available at the Ports unit.

24.8.1 CCU80 Pins

Table 24-14 CCU80 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|-----------------------|-----|---|---|
| CCU80.MCLK | I | SCU.CCUCLK | Kernel clock |
| CCU80.CLKA | I | ERU1.IOUT0 | another count source for the prescaler |
| CCU80.CLKB | I | ERU1.IOUT1 | another count source for the prescaler |
| CCU80.CLKC | I | 0 | another count source for the prescaler |
| CCU80.MCSS | I | POSIF0.OUT6 | Multi pattern sync with shadow transfer trigger |
| CCU80.IGBTA | I | CCU40.ST3; | Parity Checker delay finish trigger |
| CCU80.IGBTB | I | CCU40.SR3; | Parity Checker delay finish trigger |
| CCU80.IGBTC | I | CCU42.ST0; | Parity Checker delay finish trigger |
| CCU80.IGBTD | I | CCU42.SR0; | Parity Checker delay finish trigger |
| CCU80.IGBTO | O | CCU40.IN3H; CCU42.IN0H; | Parity Checker delay start trigger |
| CCU80.SR0 | O | NVIC; DMA; VADC.G0REQGTM; VADC.G1REQGTM; VADC.G2REQGTM; VADC.G3REQGTM; VADC.BGREQGTM; | Service request line |

Table 24-14 CCU80 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|-----------------------|-----|--|----------------------|
| CCU80.SR1 | O | NVIC; DMA; DAC.TRIGGER[0]; POSIF0.MSET0; VADC.G0REQGTN; VADC.G1REQGTN; VADC.G2REQGTN; VADC.G3REQGTN; U0C0.DX2F; U0C1.DX2F; VADC.BGREQGTN | Service request line |
| CCU80.SR2 | O | NVIC; VADC.G0REQTRI; VADC.G1REQTRI; VADC.G2REQTRI; VADC.G3REQTRI; VADC.BGREQTRI; | Service request line |
| CCU80.SR3 | O | NVIC; VADC.G0REQTRJ; VADC.G1REQTRJ; VADC.G2REQTRJ; VADC.G3REQTRJ; VADC.BGREQTRJ; CCU42.IN0G | Service request line |

Table 24-15 CCU80 - CC80 Pin Connections

| Input/Output | I/O | Connected To | Description |
|--------------|-----|--------------|--------------------------|
| CCU80.IN0A | I | PORTS | General purpose function |
| CCU80.IN0B | I | PORTS | General purpose function |
| CCU80.IN0C | I | PORTS | General purpose function |
| CCU80.IN0D | I | POSIF0.OUT2 | General purpose function |
| CCU80.IN0E | I | POSIF0.OUT5 | General purpose function |

25 Position Interface Unit (POSIF)

The POSIF unit is a flexible and powerful component for motor control systems that use Rotary Encoders or Hall Sensors as feedback loop. The several configuration schemes of the module, target a very large universe of motor control application requirements. This enables the build of simple and complex control feedback loops, for industrial and automotive motor applications, targeting high performance motion and position monitoring.

Table 25-1 Abbreviations table

| | |
|--------------------|---|
| PWM | Pulse Width Modulation |
| POSIFx | Position Interface module instance x |
| CCU8x | Capture/Compare Unit 8 module instance x |
| CCU4x | Capture/Compare Unit 4 module instance x |
| CC8y | Capture/Compare Unit 8 Timer Slice instance y |
| CC4y | Capture/Compare Unit 4 Timer Slice instance y |
| SCU | System Control Unit |
| f_{posif} | POSIF module clock frequency |

Note: A small “y” or “x” letter in a register indicates an index

25.1 Overview

The POSIF module is comprised of three major sub units, the Quadrature Decoder unit, the Hall Sensor Control unit and the Multi-Channel Mode unit.

The Quadrature Decoder Unit is used for position control linked with a rotary incremental encoder.

The Hall Sensor Control Unit is used for direct control of brushless DC motors.

The Multi-Channel Mode unit is used in conjunction with the Hall Sensor mode to output the wanted motor control pattern but also can be used in a stand-alone manner to perform a simple multi-channel control of several control units.

The POSIF module is used in conjunction with a CCU4 or CCU8 which enables a very flexible resource arrangement and optimization for any type of application.

25.1.1 Features

POSIF module features

The POSIF is built of three dedicated control units that can operate in a stand-alone manner.

The Quadrature Decoder Unit contains an output interface that enables position and velocity measurements when linked with a CCU4 module. The Hall Sensor Unit enables the control of a multi-channel pattern, that can be linked with up to 8 output control sources. The Multi-Channel unit offers a complete built-in interaction with the Hall Sensor Mode and an easy stand-alone control loop.

General Features

- Quadrature Decoder
 - interface for position measurement
 - interface for motor revolution measurement
 - interface for velocity measurement
 - interrupt sources for phase error, motor revolution, direction change and error on phase decoding
- Hall Sensor Mode
 - Simple build-in mode for brushless DC motor control
 - Shadow register for the multi-channel pattern
 - Complete synchronization with the PWM signals and the multi-channel pattern update
 - interrupt sources for Correct Hall Event detection, Wrong Hall Event Detection
- Multi-Channel Mode
 - Simple usage with Hall Sensor Mode
 - stand-alone Multi-Channel mode
 - Shadow register for the multi-channel pattern

Additional features

- Quadrature Decoder mode can be used in parallel with the stand-alone Multi-Channel mode
- Several profiles (via CCU4) to perform position and velocity measurement for the Quadrature Decoder mode
- Programmable delay times (via CCU4) for input pattern evaluation and new pattern value for the Hall Sensor Mode

POSIF features vs. applications

On [Table 25-2](#) a summary of the major features of the POSIF unit mapped with the most common applications.

Table 25-2 Applications summary

| Feature | Applications |
|-------------------------|---|
| Quadrature Decoder Mode | <p>Easy plug-in for rotary encoders:</p> <ul style="list-style-type: none"> • with or without index/top marker signal • gear-slip or shaft winding compensation • separate outputs for position, velocity and revolution control - matching different system requirements • extended profile for position tracking - with revolution measurement and multiple position triggers for each revolution • support for high dynamic speed changes due to tick-to-tick and tick-to-sync capturing method |
| Hall Sensor Mode | <p>Easy plug-in for Motor control using Hall Sensors:</p> <ul style="list-style-type: none"> • 2 or 3 Hall sensor topologies • extended input filtering to avoid unwanted pattern switch due to noisy input signals • synchronization with the PWM signals of the Capture/Compare Unit • Active freewheeling/synchronous rectification with dead time support (link with Capture/Compare Unit 8) • easy velocity measurement function by using a Capture/Compare unit Timer Slice |
| Multi-Channel Mode | <p>Modulating multiple PWM signals:</p> <ul style="list-style-type: none"> • parallel modulation controlled via SW for N PWM signals - for systems with multiple power converters • generating proprietary PWM modulations • parallel and synchronous shut down of N PWM signals due to system feedback |

25.1.2 Block Diagram

Each POSIF module can operate in three different modes, Quadrature Decoder, Hall Sensor and stand-alone Multi-channel Mode. To complete the control/measurement loop of all these three modes, the POSIF needs to be linked with a CCU4/CCU8 module.

Position Interface Unit (POSIF)

In the case of the Quadrature Decoder mode, one CCU4 unit is needed, for the Hall Sensor Mode, one needs one slice of one CCU4 and a CCU8 unit. The connectivity between the stand-alone Multi-Channel mode and CCU4/CCU8 module(s) does not follow any usage constraints.

Each POSIF module contains 30 inputs and 25 outputs (including service requests), **Figure 25-1**, that are going to be mapped to available functions of the module, depending in which configuration it was selected by the user: Quadrature Decoder, Hall Sensor or stand-alone Multi-Channel.

The module also has two dedicated Service request Lines, see **Section 25.3**.

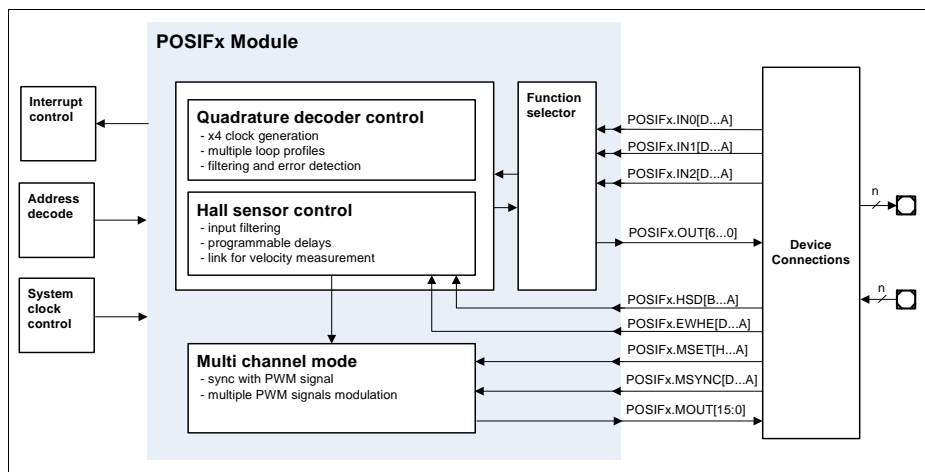

Figure 25-1 POSIF block diagram

25.2 Functional Description

25.2.1 Overview

The POSIF module contains a function selector unit, that is used in parallel by both Quadrature Decoder and Hall Sensor Control units. This block selects which input signals should be decoded for each control unit. The function selector is also decoding the outputs coming from these two modes (Quadrature and Hall Sensor Mode).

The POSIF module also contains a subset of inputs that are only used in Hall Sensor/Multi-Channel Mode. These inputs are connected to a timer structure (CCU4/CCU8) and are used to control the delays between pattern sampling, multi-channel pattern update and synchronization, etc.

Position Interface Unit (POSIF)

The Multi-Channel unit contains 16 dedicated outputs, that contain the current multi-channel pattern and that can be connected to a CCU8/CCU4.

The POSIF control unit contain a dedicated Run bit, that can be set/clear by SW. It can also generate a Sync start signal that can be connected to the timer units (CCU4/CCU8). For the Quadrature Decoder Mode, there is the possibility to define which of the signals is the leading phase and also the active level for each one.

The Quadrature Decoder Mode can also receive the clock and direction signals directly from an external source.

The Multi-Channel offers a shadow register, for the Multi-Channel pattern, enabling this way an update on the fly of these parameter. A write access always addresses the shadow register while a read, always returns the actual value of the Multi-Channel pattern.

Table 25-3 POSIF slice pin description

| Pin | I/O | Hall Sensor Mode | Quadrature Decoder Mode | Multi-Channel Mode (stand-alone) |
|---------------------|-----|--|------------------------------|--|
| POSIFx.IN0[D...A] | I | Hall Input 1 | Encoder Phase A or Clock | Not used |
| POSIFx.IN1[D...A] | I | Hall Input 2 | Encoder Phase B or Direction | Not used |
| POSIFx.IN2[D...A] | I | Hall Input 3 | Index/Zero marker | Not used |
| POSIFx.HSD[B...A] | I | Hall pattern sample delay | Not used | Not used |
| POSIFx.EWHE[D...A] | I | Wrong hall event emulation | Not used | Wrong hall event emulation |
| POSIFx.MSET[H...A] | I | Multi-Channel next pattern update set | Not used | Multi-Channel next pattern update set |
| POSIFx.MSYNC[D...A] | I | Multi-Channel pattern update synchronization | Not used | Multi-Channel pattern update synchronization |
| POSIFx.OUT0 | O | Hall inputs edge detection trigger | Quadrature clock | Not used |

Position Interface Unit (POSIF)
Table 25-3 POSIF slice pin description (cont'd)

| Pin | I/O | Hall Sensor Mode | Quadrature Decoder Mode | Multi-Channel Mode (stand-alone) |
|-------------------|-----|------------------------------|-------------------------|----------------------------------|
| POSIFx.OUT1 | O | Hall Correct event | Direction | Not used |
| POSIFx.OUT2 | O | Idle/ wrong hall event | Period clock | Not used |
| POSIFx.OUT3 | O | Stop | Clear/capt | Not used |
| POSIFx.OUT4 | O | Multi-Channel pattern update | Index | Not used |
| POSIFx.OUT5 | O | Sync start | Sync start | Not used |
| POSIFx.OUT6 | O | Multi Pattern sync trigger | Not used | Multi Pattern sync trigger |
| POSIFx.MOUT[15:0] | O | Multi-Channel pattern | Not used | Multi-Channel pattern |
| POSIFx.SR0 | O | Service request line 0 | Service request line 0 | Service request line 0 |
| POSIFx.SR1 | O | Service request line 1 | Service request line 1 | Service request line 1 |

Note: The Service Request signals at the output of the kernel are extended for one more kernel clock cycle.

25.2.2 Function Selector

The Function selector maps the input function signals to the selected operating mode, whether Quadrature or Hall Sensor Mode, [Figure 25-2](#). The outputs are also decoded throughout this unit.

For each function input, POSI0, POSI1 and POSI2, the user can select one of the 4 input pins via the fields **PCONF**.INSEL0, **PCONF**.INSEL1 and **PCONF**.INSEL2. It is also possible to perform a low pass filtering on the three inputs, the field **PCONF**.LPC controls the low pass filters cut frequency.

The Hall Sensor Mode is the default function, **PCONF**.FSEL = 00_B. In this mode, the Function selector maps the POSI0 to the Hall Input 1, the POSI1 to the Hall input 2 and the POSI2 to the Hall input 3.

When the Quadrature Decoder mode is selected, **PCONF**.FSEL = 01_B, POSI0 is mapped to Phase A or Clock, POSI1 to the Phase B or Direction and POSI2 to the Index signals coming from the rotary motor encoder. Notice that it is also possible to select the

Position Interface Unit (POSIF)

Quadrature Decoder and stand-alone Multi-Channel mode, by setting **PCONF.FSEL** = 11_B.

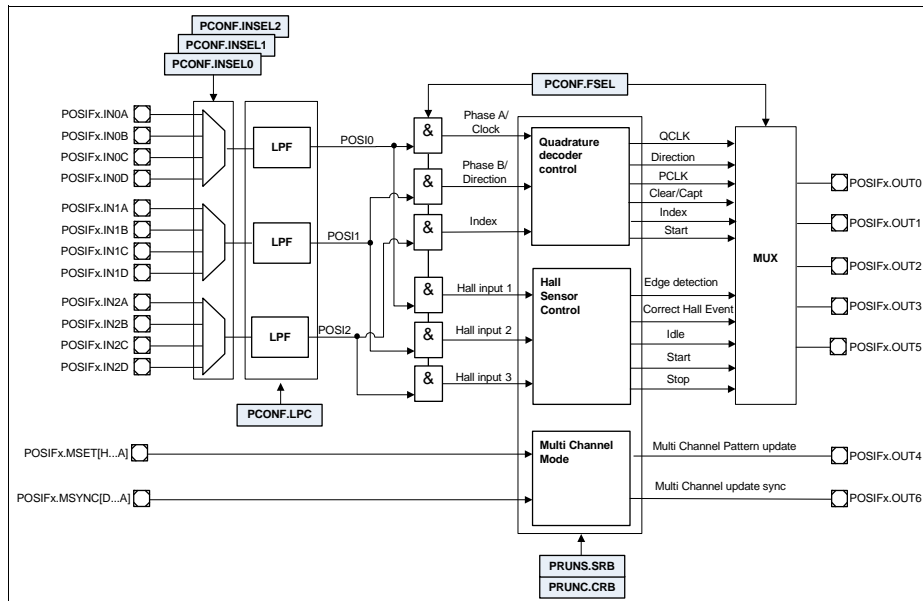

Figure 25-2 Function selector diagram

25.2.3 Hall Sensor Control

The Hall Sensor mode is divided in three major loops: detection of any update in the Hall inputs, delay between the detection and the sampling of the Hall inputs for comparison against the expected Hall Pattern and the update of the Multi-Channel pattern.

The Hall inputs are directly connected to an edge detection circuitry and with any modification in any of these three inputs, a signal is generated on the POSIFx.OUT0 pin, see [Figure 25-3](#). This pin can be connected to one CCU4 slice that is controlling the delay between the edge detection and the next step on the Hall sensor mode, the sampling of the Hall Inputs.

The signal used to trigger the sample of the Hall inputs is selected via the **PCONF.DSEL** field, and this trigger can be active at the rising or falling edge (**PCONF.SPES**).

When the sampling trigger is sensed, the Hall inputs are sampled and compared against the Current Pattern, **HALP.HCP** and the Expected Hall Pattern, **HALP.HEP** (to evaluate if the input pattern match the HEP or HCP values).

Position Interface Unit (POSIF)

The edge detection circuit generates an enable signal for sampling the hall inputs, PIFHSP and the sample logic generates a pulse every time that new values are captured, PIFHRDY, that is used inside the pattern compare logic.

When the sampled value matches the Expected Hall Pattern, a pulse is generated in the POSIFx.OUT1 pin to indicate a correct hall event. At the same time the next values programmed into the shadow registers are loaded. The **HALP.HCP**[LSB] is linked to the Hall input 1, and the **HALP.HCP**[MSB] is linked to the Hall input 3 (the same is applicable for the **HALP.HEP** register).

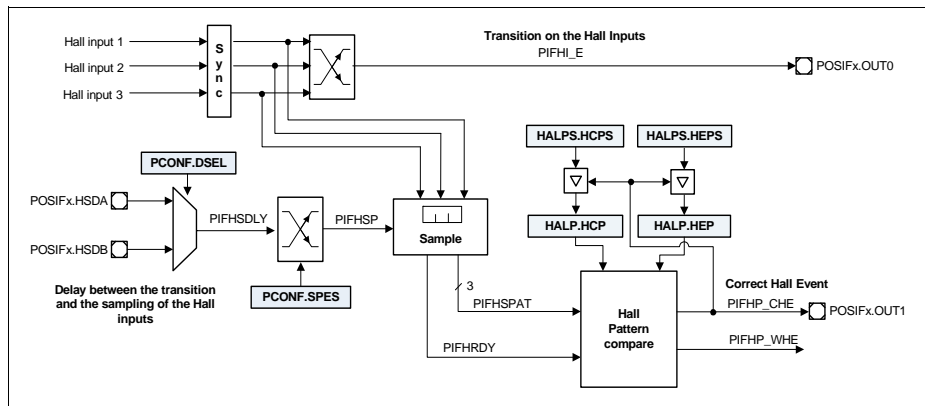

Figure 25-3 Hall Sensor Control Diagram

When the sampled value matches the Current Hall Pattern, a line glitch deemed to have occurred and no action is taken. When the sampled value does not match any of the values (the current and the expected pattern), a major error is deemed to have occurred and the Wrong Hall Event signal is generated. Every time that a sampled pattern leads to a wrong hall event or when it matches the current pattern a stop signal is generated throughout the POSIFx.OUT3 pin, **Figure 25-4**.

Position Interface Unit (POSIF)

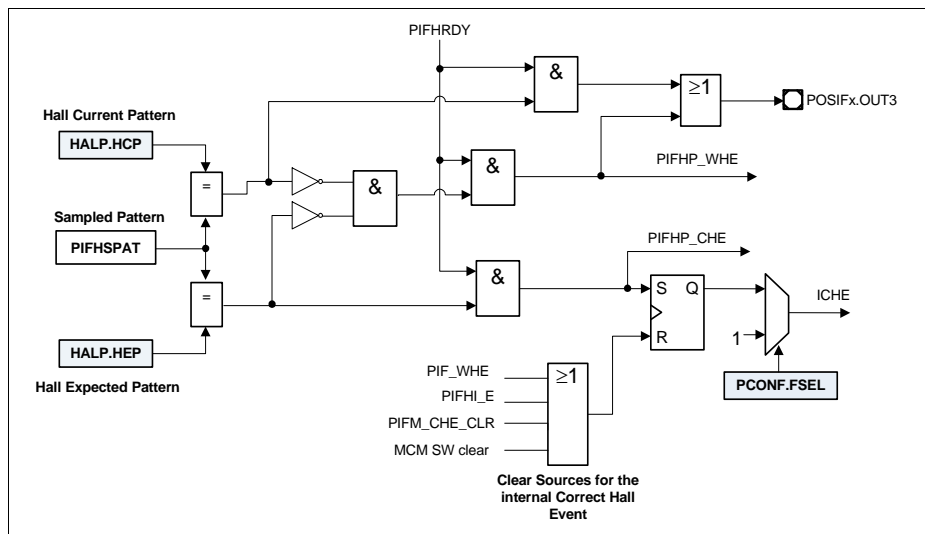

Figure 25-4 Hall Sensor Compare logic

A wrong hall event can generate an IDLE signal that is connected to the POSIFx.OUT2 and can be used to clear the run bit of the Hall Sensor Control unit.

The IDLE signal can also be connected to the PWM unit to perform a forced stop operation, [Figure 25-5](#). The wrong hall event/idle function can also be controlled via a pin.

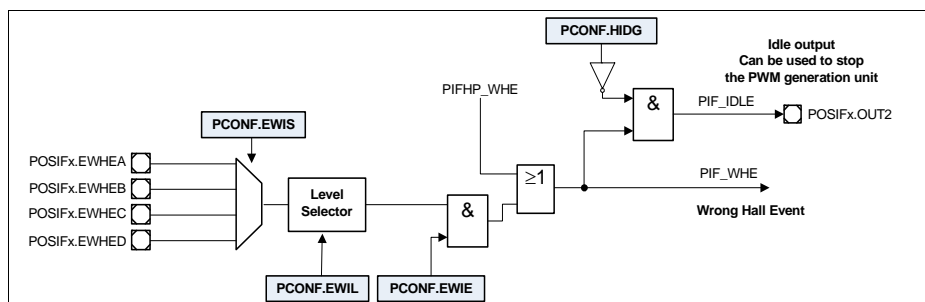

Figure 25-5 Wrong Hall Event/Idle logic

After the Correct Hall Event is detected, a delay can be generated between this detection and the update of the Multi-Channel pattern. On [Figure 25-6](#) it is demonstrated the control logic of the Multi-Channel mode.

Position Interface Unit (POSIF)

The delay for the update of the Multi-Channel pattern can be controlled directly by a CCU4 slice. The trigger that indicates that the delay is finished, can be mapped to one of the input signals POSIFx.MSET[H...A] (**PCONF**.MSETS selects the input signal used for this purpose). One can also select the active edge for the trigger via **PCONF**.MSES.

The **PCONF**.MCUE field selects the source that enables an update of the Multi-Channel pattern. When set to 1_B, the Multi-Channel pattern can only be updated after the SW has written a 1_B into the **MCMS**.MNPS field.

After the update delay, the Multi-Channel pattern still needs to be synchronized with the PWM signal. For this, the user selects a signal from the POSIFx.MSYNC[D...A] inputs via **PCONF**.MSYNS field. When a falling edge is detected in this signal, then the new multi pattern is applied at the POSIFx.MOUT[15:0] outputs, with the **MCM**.MCMP[15] linked to the POSIFx.MOUT[15] and **MCM**.MCMP[0] to POSIFx.MOUT[0].

The POSIFx.OUT6 pin is connected to the **MCMF**.MSS register field. This register field is enabling the Multi-Channel pattern update (that is done upon receiving the sync signal, PIFMSYNC) and can be used in conjunction with a CAPCOM module to perform a synchronous update of the Multi-Channel pattern and the compare values used inside of the CAPCOM.

When a wrong hall event is configured to set the Hall Sensor Control into IDLE, the Multi-Channel pattern is also cleared.

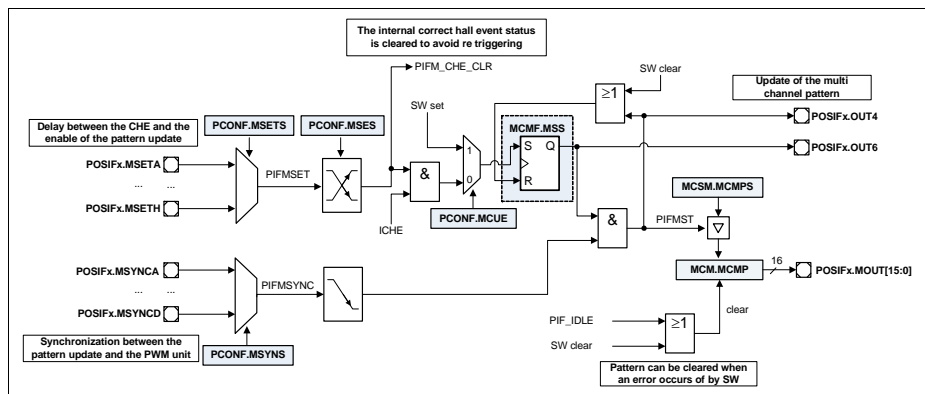

Figure 25-6 Multi-Channel Mode Diagram

Figure 25-7 shows all the previous described steps in the Hall Sensor Mode. Every time that a transition on a Hall input is detected, the pin POSIFx.OUT0 is asserted. This signal is used to start the timing delay between the transition detection and the sampling of the hall inputs.

In this scenario the status output (ST in **Figure 25-7**) of a timer cell was used to control the timing 1 (delay between the transition and the sampling of the hall inputs). With the

Position Interface Unit (POSIF)

rising edge of the ST signal, the hall inputs are sampled and if they match the expected pattern, signal POSIFx.OUT1 is asserted.

A service request line (SR signal) mapped to the same timer cell is used to control the delay between a correct Hall Event and the update of the Multi-Channel pattern. This service request is asserted when a period match is detected.

Another timer cell is used to measure the time between each correct hall event. This timer cell is represented by the Timing 2 on [Figure 25-7](#) (the CR symbolizes the capture register of the timer cell).

After the delay controlled by the Timing 1 (SR signal) is over, the update of the Multi-Channel pattern needs to be synchronized with the PWM signal. This is done by using one of the pattern synchronization outputs of the Capture/Compare Unit that is used to generate the PWM signals (as an example a CCU8 was used).

Position Interface Unit (POSIF)

Figure 25-7 Hall Sensor timing diagram

25.2.4 Quadrature Decoder Control

The Quadrature Decoder Mode is selected by setting **PCONF.FSEL** = 01_B or **PCONF.FSEL** = 11_B (in this case the Multi-Channel mode is also enabled).

Inside the Quadrature Decoder Mode, two different subsets are available:

- standard Quadrature Mode
- Direction Count Mode

The standard mode is used when the external rotary encoder provides two phase signals and additionally an index/marker signal that is generated once per shaft revolution. The Direction Count Mode is used when the external encoder only provides a clock and a direction signal, **Figure 25-8**.

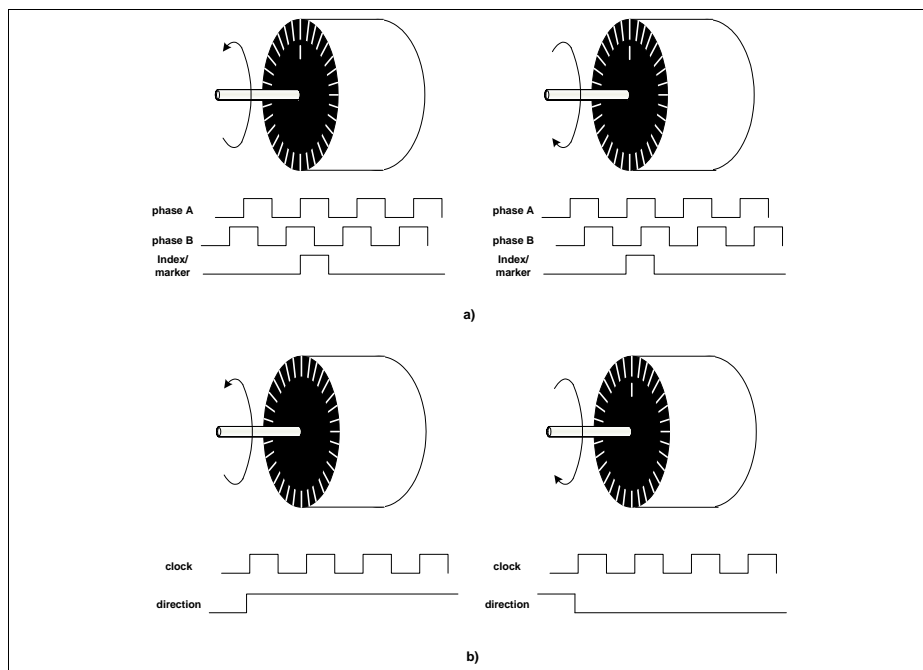

Figure 25-8 Rotary encoder types - a) standard two phase plus index signal; b) clock plus direction

Standard Quadrature Mode

The Quadrature Decoder unit offers a very flexible PhaseA/PhaseB configuration stage. Normally for a clockwise motor shaft rotation, Phase A should precede Phase B but nevertheless, the user can configure the leading phase as well the specific active state for each signal, **Figure 25-9**.

Position Interface Unit (POSIF)

There are two major blocks that build the Quadrature Decoder Control unit: the block that decodes the quadrature clock and motor shaft direction and the block that handles the index (motor revolution) control.

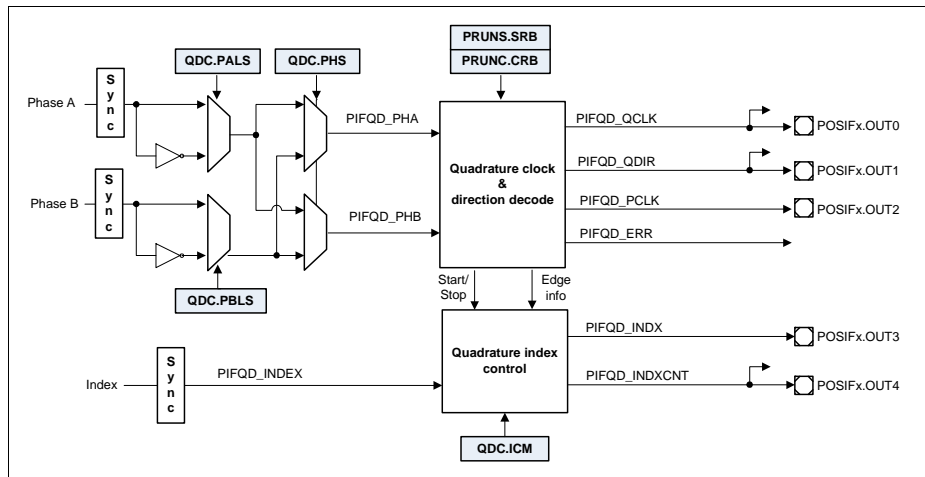

Figure 25-9 Quadrature Decoder Control Overview

The quadrature clock is connected to pin POSIFx.OUT0 and is used for position measurement. This clock is decoded from every edge of the phase signals and therefore there are 4 clock pulses per phase period.

Figure 25-10 Quadrature clock generation

A period clock is also generated for velocity measurement operations.

The direction of the motor rotation is connected to the POSIFx.OUT1 pin and is asserted HIGH when the motor is rotating clockwise and LOW when it is turning in the counterclockwise direction.

The index control logic, memorizes which was the first edge after the assertion of the index signal, so the same quadrature transition is used for index event operations. It also

Position Interface Unit (POSIF)

memorizes the direction of the first index, so that it can control when the revolution increment signal should be asserted.

An error signal, connected to a flag (and if enable an interrupt can be generated) also can be generated when a wrong phase pair is detected.

The Quadrature Decoder Control, uses the information of the current and previous phase pair to decode the direction and clocks. Both phase signals pass through a edge detection logic, from which the outputs are going to be used against the valid/invalid transitions stages, see [Figure 25-11](#). There is the possibility to reset the decoder state machine (but not the flags and static configuration) by writing a 1_B into the **PRUNC.CSM** field.

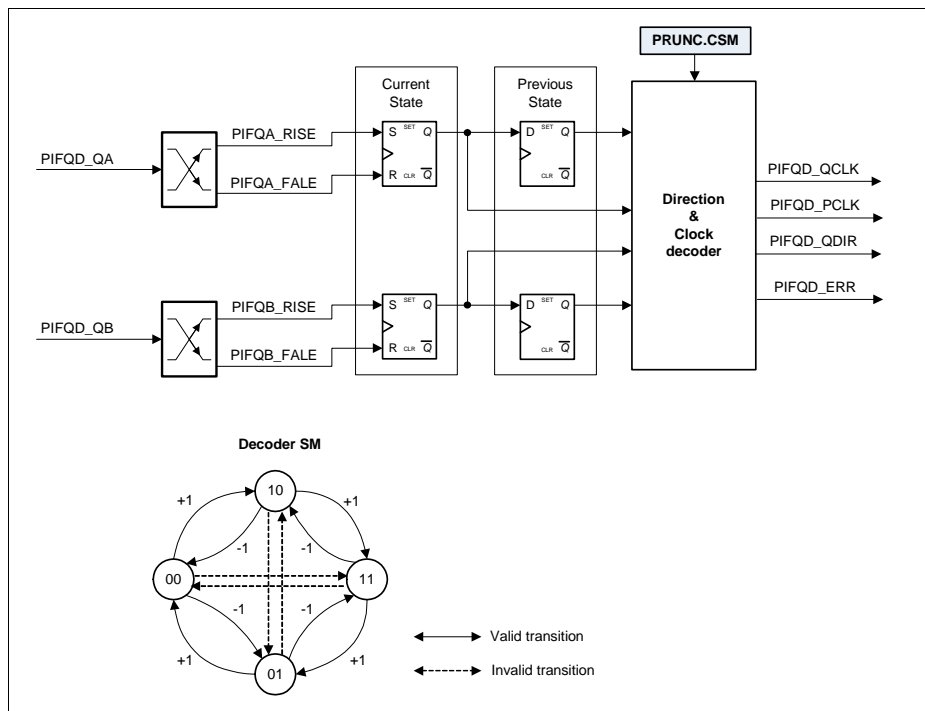

Figure 25-11 Quadrature Decoder States

Direction Count Mode

Some position encoders do not have the phase signals as outputs, instead, they provide two signals that contain the clock and direction information. This is known as the Direct Count Mode.

Position Interface Unit (POSIF)

When using a position encoder of this type, the user should set the **PCONF.QDCM** bit field to 1_B (enabling the direction count mode). In this case, the signal selected from the POSIFx.IN0[D...A] is used as clock and the selected signal from the POSIFx.IN1[D...A] contains the direction information.

The input signals are synchronized with the POSIF module clock and sent to the respective outputs. In this case the inputs and outputs linked with the index/zero marker are not used. The POSIFx.OUT2 output is also inactive.

25.2.4.1 Quadrature Clock and Direction decoding

The Quadrature Decoder unit outputs two clocks. One clock is used for position control and therefore is generated in each edge transition of the phase signals. The second clock is used for velocity measurements and is immune to possible glitches on the phase signals that can be present at very slow rotation speeds. These glitches are not normal line noise, but are due to the slow movement of the engine.

The decoding of the direction signal is done following the rules on **Figure 25-11**. **Figure 25-12** shows all the valid transitions of Phase A and Phase B signals.

Figure 25-13 shows the difference between the two clock signals in the case that some glitches are present in the phase signals.

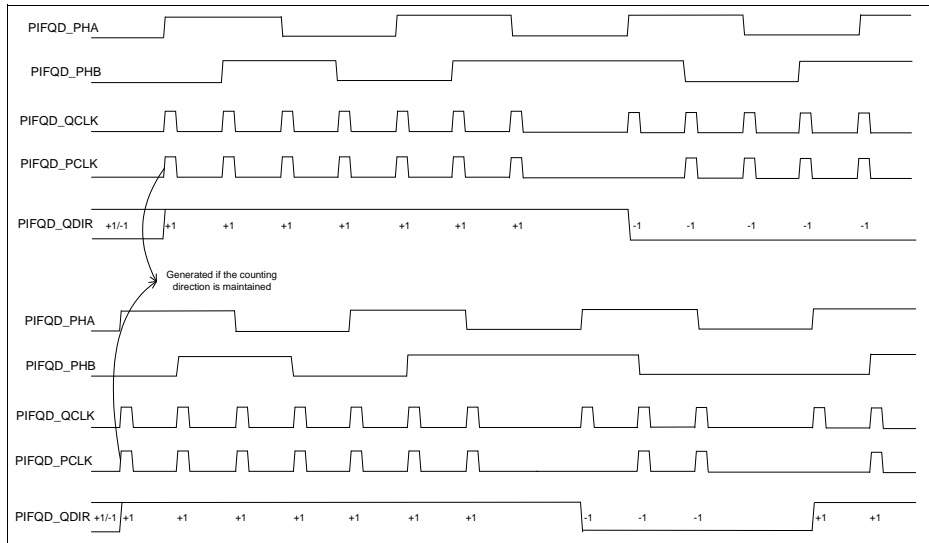

Figure 25-12 Quadrature clock and direction timings

Figure 25-13 Quadrature clock with jitter

25.2.4.2 Index Control

The Index Control logic has two different outputs. One is asserted every time that an index signal is detected (and the motor shaft rotation is the same), POSIFx.OUT4, and therefore it can be used in a revolution counter. With this, the SW can monitor not only the position of the shaft but also the total number of revolutions that have occurred.

The activity of the other output, POSIFx.OUT3, can be programmed via the **QDC.ICM** field. Depending on the value set in the **QDC.ICM**, this signal can be generated:

- in every index signal occurrence
- only on the first index signal occurrence
- disabled - this outputs is never asserted

This is useful for applications that need to reset the counters on every index event or only at the first one.

The Index Control logic memorizes the immediately next phase edge that follows a index so the generated signals have always the same reference. If the first phase edge after the index is the rising edge of Phase B signal, then the index signals are going to be generated in the next index event with the rising edge of the Phase B signal if the direction is kept or with the falling edge of Phase B signal if the direction has changed.

Figure 25-14 shows the timing diagram for the generation of the index signals. In this case the **QDC.ICM = 10_B**, which means that the POSIFx.OUT3 index signal is going to be generated in every occurrence of the input index.

Figure 25-14 Index signals timing

25.2.5 Stand-Alone Multi-Channel Mode

The Multi-Channel mode (Multi-Channel Mode logic can be seen on [Figure 25-6](#)) can be used without the Hall Sensor Control, by setting the **PCONF.FSEL** = 10_B or if the Quadrature Decoder Mode is also needed, by setting **PCONF.FSEL** = 11_B.

In stand-alone Multi-Channel Mode, the mechanism to update the multi-channel pattern is the same as the one described in [Section 25.2.3](#).

The trigger for a pattern update can come from the SW, by writing 1_B to **MCMS.MNPS**, or it can come from an external signal like in Hall sensor Mode. This external signal should then be mapped to the PIFMSET function by selecting the appropriate value in the **PCONF.MSETS** field.

The synchronization between the update of the new Multi-Channel pattern and control signal still needs to be done. The user needs to map one input signal of the POSIFx.MSYNC[D...A] range to this function.

The SW has the possibility of clearing the actual Multi-Channel pattern, by writing 1 into the **MCMC.MPC** field.

25.2.6 Synchronous Start

The POSIF module has a synchronous start output, POSIFx.OUTPUT5, that can be used together with the CAPCOM for a complete synchronous start of both modules. The synchronous start is linked with the run bit of the POSIF module, which means that every time that the run bit is set, a pulse is generated throughout the POSIFx.OUTPUT5 pin.

By using the synchronous start output, the SW does not perform two independent accesses to start the POSIF and the CCU4/CCU8 and therefore is guaranteed that both modules start their operation at the exact same time.

25.2.7 Using the POSIF

The POSIF module needs to be linked with a CCU4/CCU8 module to perform the full set of functions in each of the possible modes (due to the fact that doesn't contain built-in counters/timers).

To operate the POSIF in the Quadrature Decoder Mode, one CCU4 module is needed. The Hall Sensor Mode, needs a CCU8 (at least 3 slices are need to control a brushless DC motor) and also (at least) two CCU4 or CCU8 slices. The stand-alone Multi-Channel Mode linking configuration depends heavily on the use cases and therefore the number of slices of CCU4 or CCU8 used is freely chosen by the user.

25.2.7.1 Hall Sensor Mode Usage

When using the Hall Sensor Mode of the POSIF, the Multi-Channel Mode is also working. Due to that fact, the CCU8 module used to perform the Multi-Channel Modulation, needs to be configured in Multi-Channel Mode.

Standard Hall Sensor Mode Usage

On [Figure 25-15](#), the Hall Sensor Mode is used in conjunction with two CCU4 slices and one CCU8 module. The first slice of CCU4, slice 0 is being used to control the delays between the edge detection of the Hall Inputs and the actual sampling, and also to control the delay between a Correct Hall Event and the Multi-Channel Pattern update enable.

The rising edge of the CCU4x.ST0 is used as finish trigger for the first delay, while the Service request line is used for triggering the update of a new pattern after a Correct Hall Event. The service request is configured to be active on each period match hit of the specific slice.

Slice 0 is configured in single shot mode, so that the time delay can be re triggered every time that a request from the POSIF occurs.

The second slice of the CCU4 unit, Slice 1, is being used in Capture Mode, to capture the time between Correct Hall Events (storing this way the motor speed between two correct hall events). The POSIFx.OUT1 of the POSIF is used as capture trigger for the slice while the POSIFx.OUT3 is used as stop. The capture and stop triggers are configured in the specific timer slices as active on the rising edge.

The CCU8 is the module that is generating the PWM signals to control the motor and therefore, the Multi-Channel Pattern outputs POSIFx.MOUT[7:0] are linked to this unit.

To close the Multi-Channel loop, an output of the CCU8 needs to be connected to the POSIF module (one of the CCU8x.PSy signals), so that the Multi-Channel Pattern is updated synchronously with the PWM period.

Position Interface Unit (POSIF)

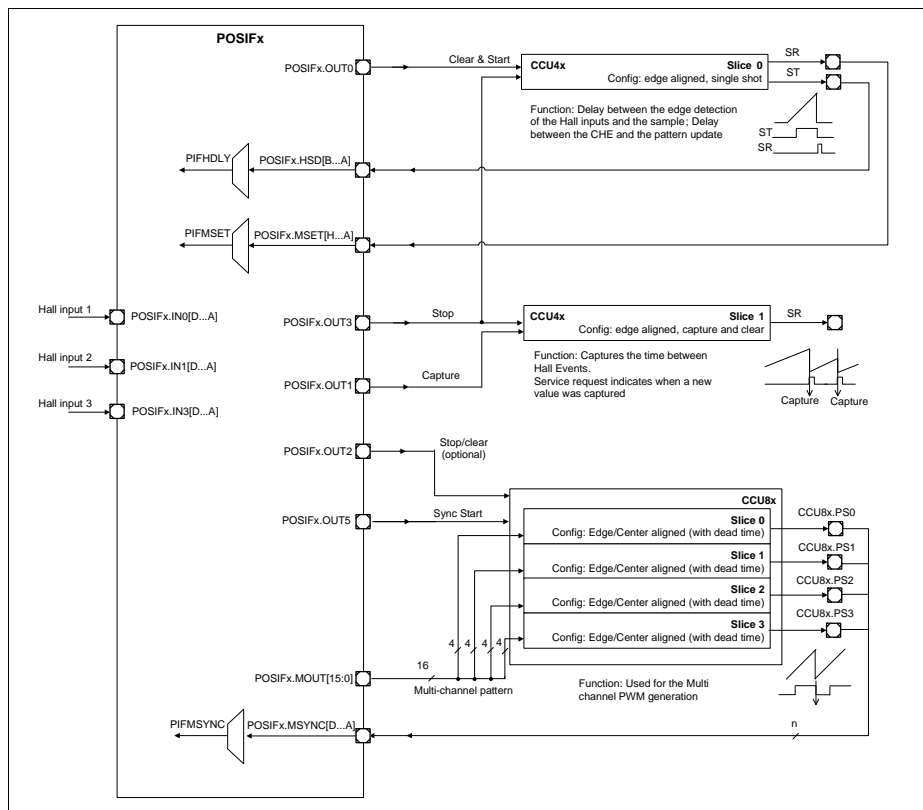

Figure 25-15 Hall Sensor Mode usage - profile 1

Hall Sensor Mode Usage - Flexible Time Control

On [Figure 25-16](#), another profile is demonstrated. In this case instead of 2 CCU4 slices, the Hall Sensor Mode is using 3 CCU4 slices. This profile gives more flexibility in terms of delay configuration. It uses two timer slices to control independently the delay between the transition of the hall inputs and sampling, and the delay between a Correct Hall Event and the update of the Multi-Channel pattern. At the same time it also removes the need of using a service request to control the pattern update delay.

Slice 0 is used to control the delay between a transition at the hall inputs and the actual sampling. Slice 2 is used to control the delay between a Correct Hall Event and the update of the Multi-Channel pattern.

Position Interface Unit (POSIF)

Slice 1 is used as keeper of the time stamp between Correct Hall events (the same function as Slice 1 in profile 1).

The synchronism between the PWM signal and the update of the Multi-Channel pattern is again done with one of the CCU8x.PSy outputs.

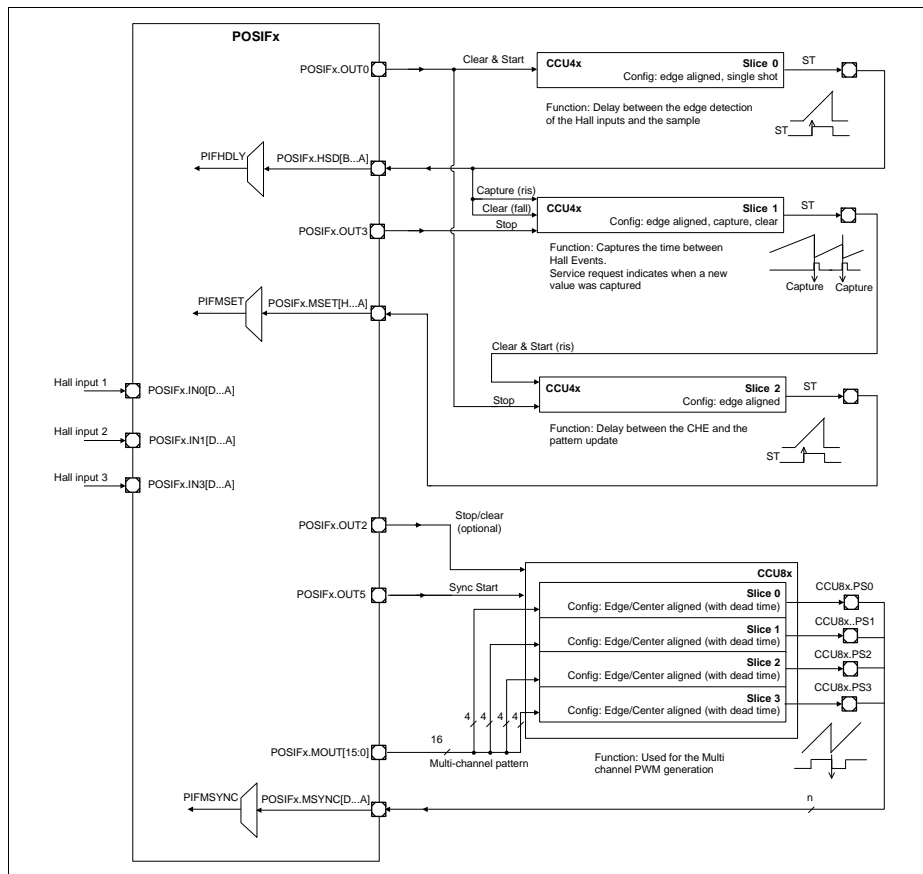

Figure 25-16 Hall Sensor Mode usage - profile 2

25.2.7.2 Quadrature Decoder Mode usage

The Quadrature Decoder Mode can be used in a very flexible way when connected with a CCU4 unit. The connection profile depends on the amount of functions that the user wants to perform in parallel: position control, revolution control and velocity measurement.

Quadrature Decoder Usage - Tick and Revolution Compare plus Velocity Between N Ticks

On [Figure 25-17](#), the POSIF is linked with a CCU4, using all the module timer slices. In this profile, the user in Quadrature Decoder Mode has a slice being used for position control (comparison), one for revolutions counter and two aggregated slices used for velocity measurement.

Slice 0 is connected to the POSIFx.OUT0 and POSIFx.OUT1 outputs, which means that one has to configure POSIFx.OUT0 as counting functionality and POSIFx.OUT1 as Up/Down counting function. This slice is then used to track the actual position of the system and the compare channel can be configured to trigger the required actions, when the position reaches a certain value.

Slice 1 is connected to POSIFx.OUT4 pin, which means that it is used as a motor revolution counter. The compare channel can be programmed to trigger an interrupt every time that the motor performs N revolutions.

Slice 2 and Slice 3 are used to perform velocity measurements. Slice 2 receives the Quadrature Decoder period clock via POSIFx.OUT2, that is mapped to a counting functionality. The compare channel of this slice is then used to trigger a capture event in Slice3. The last one is using the module clock and therefore in every capture event, the actual system ticks are captured. This way the user knows how much time has elapsed between N phase periods and can calculate the corresponding velocity profiles.

Position Interface Unit (POSIF)

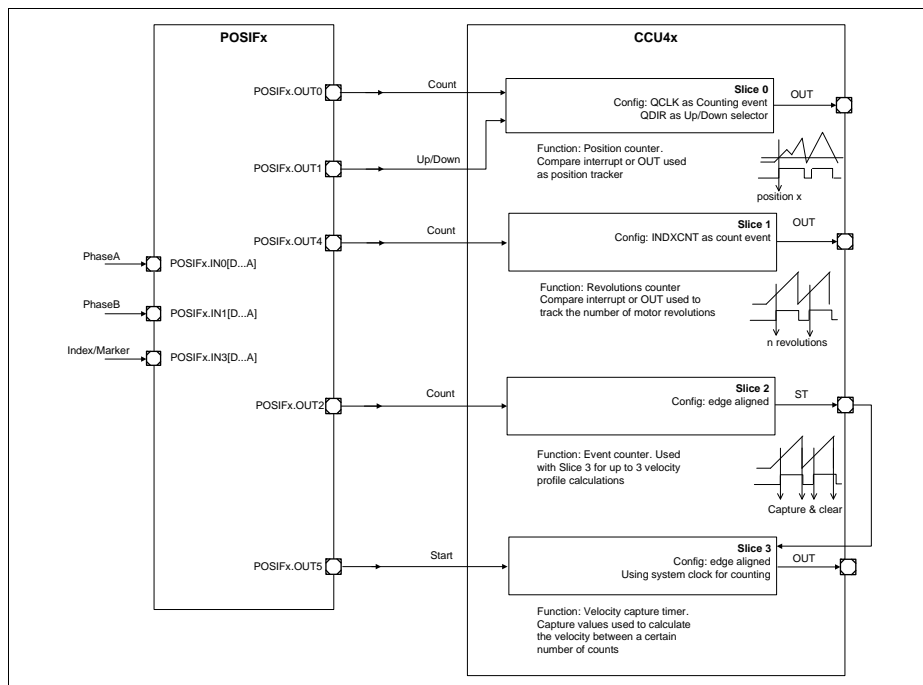

Figure 25-17 Quadrature Decoder Mode usage - profile 1

Quadrature Decoder Usage - Extended Tick Comparison plus Velocity Between N Ticks

The profile demonstrated in [Figure 25-18](#) enables the usage of 2 compare channels for the position control. This profile is especially useful for multi operations during just one motor revolution.

Slice 0 and Slice 1 are using the POSIFx.OUT0 as counting function and the POSIFxOUT1 as up/down control. The compare channels in each slice are then programmed with different compare values.

Slice 2 and Slice 3 are used in the same manner as profile 1, [Figure 25-18](#).

Position Interface Unit (POSIF)

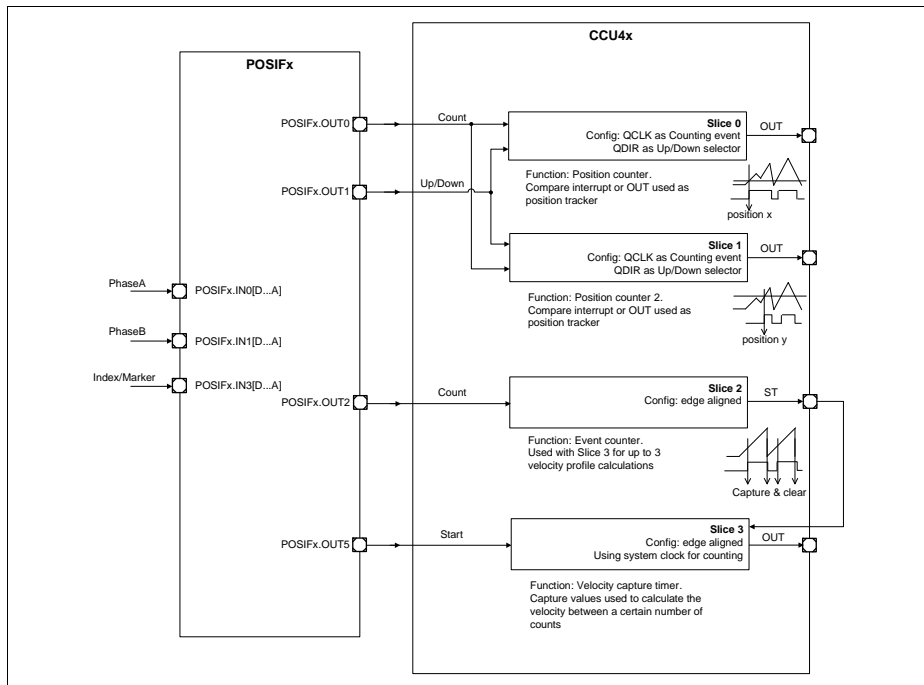

Figure 25-18 Quadrature Decoder Mode usage - profile 2

Quadrature Decoder Usage - Tick and Revolution Comparison with Index Clear plus Velocity Between N Ticks

In some applications it is useful to use the index marker as a clear signal for the position and velocity control. This clear action is linked with the POSIFx.OUT3 pin, that can be programmed to be asserted only at the first index marker or at all marker hits. This pin is then connected to the specific CCU4 slices and used as clear functionality. **Figure 25-19** shows the adaptation of profile 1 with the index marker signal used as clear signal.

The same procedure can be used in profile 2, so that we can have the 2 compare channels plus the velocity measurement and the index used as clear signal.

Position Interface Unit (POSIF)

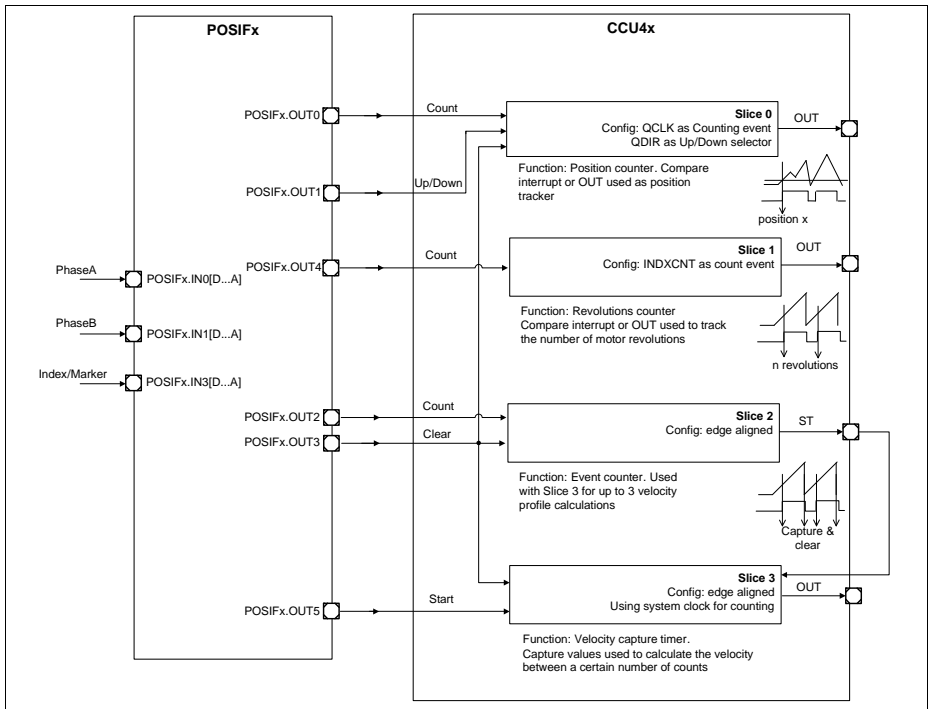

Figure 25-19 Quadrature Decoder Mode usage - profile 3

Quadrature Decoder Usage - Tick Comparison plus Micro Tick Velocity for Slow Rotating Speeds

When the motor rotating speed is slow, it may not be suitable to discard the time between each occurrence of a rotary encoder tick.

In a fast rotating system, the time between ticks is normally discarded and the velocity calculation can be done, by taking into account the number of ticks that have been elapsed since the last ISR. But in a slow rotating system, taking into account the number of ticks may not be enough (because of the associated error), and the software needs also to take into consideration, the time between the last tick and the actual ISR trigger.

Figure 25-20 shows a slow rotating system, where the ISR for the velocity calculation is triggered in a periodic way. In this case, because of the small amount of ticks between each ISR trigger, the software needs to know not only the amount of elapsed ticks but also the elapsed time between the last tick and the ISR occurrence.

Figure 25-20 Slow rotating system example

It is possible to build a profile with the POSIF and one CCU4 module to perform a control loop that is immune to this slow velocity calculation pitfalls. The resource usage is exemplified on [Figure 25-21](#).

One timer slice of a CCU4 module, Slice 0, is used to monitor the current position of the motor shaft.

Three additional timer slices are needed to build the slow velocity calculation loop: Slice 1, Slice 2 and Slice 3.

Timer Slice 1, is counting the number of ticks (PCLK) that are elapsed between each velocity ISR occurrence.

Timer Slice 2, is counting the time between each tick (PCLK) occurrence. This timer slice is cleared and started within every tick and therefore it always keeps the timing info between the last and the current tick.

Timer Slice 3, is controlling the periodicity of the velocity ISR. Every time that a velocity ISR is triggered, Slice 3 also triggers a capture in Slice 2 and a capture & clear in Slice 1.

With this mechanism, every time that the software reads back the captured values from Slice 1 and Slice 2, it can calculate the speed based on:

- the amount of ticks elapsed since the last ISR
- plus the amount of time elapsed between the last tick and the ISR

This control loop offers therefore a very accurate way to calculate the motor speed within systems with low velocity.

Position Interface Unit (POSIF)

Figure 25-21 Quadrature Decoder Mode usage - profile 4

25.2.7.3 Stand-alone Multi-Channel Mode

The Multi-Channel Mode can be used in the POSIF module without being linked with the Hall Sensor Mode. This is especially useful for performing generic control loops that need to be perfectly synchronized.

The stand-alone Multi-Channel Mode is very generic and depends very much on the control loop specified by the user. A generic profile for the Multi-Channel mode is to use a CCU4/CCU8 module to perform the signal generation and a slice from a CCU4 module linked with an external pin that is used as trigger for updating the Multi-Channel pattern.

On [Figure 25-22](#), a slice from a CCU4 unit is used to control the delay between the update of an external signal (e.g. external sensor) and the update of the Multi-Channel Pattern. Notice that this external signal can also be connected to the POSIF module if no timing delay is needed or it can be just controlled by SW, by writing an one into the **MCMS.MNPS** field.

Position Interface Unit (POSIF)

One output can then be chosen from the CCU4/CCU8 unit that is generating the PWM signals, to act as synchronization trigger between the generated signal and the update of the Multi-Channel pattern (CCU4x.PSy in case of CCU4 and CCU8x.PSy in case of CCU8).

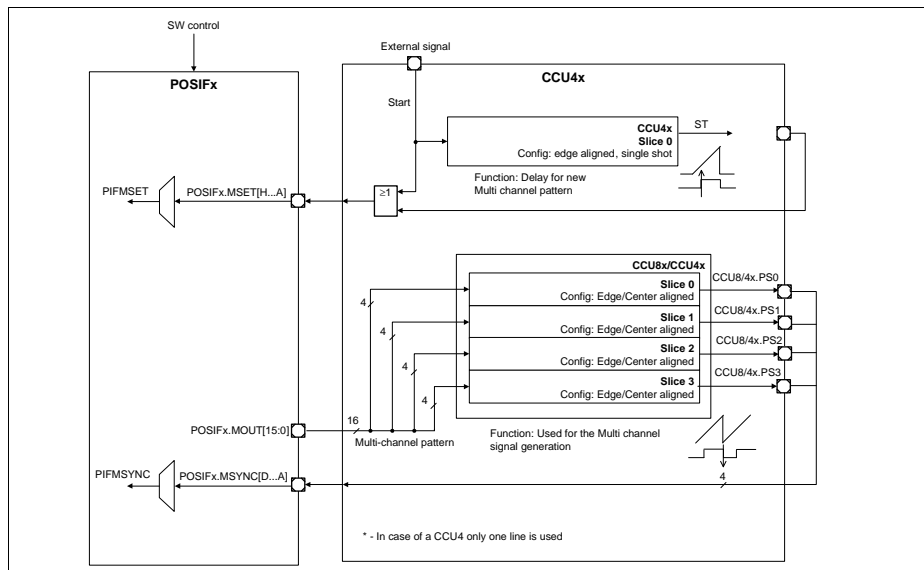

Figure 25-22 Stand-alone Multi-Channel Mode usage

25.3 Service Request Generation

The POSIF has several interrupt sources that are linked to the different operation modes: Hall Sensor Mode, Quadrature Decoder Mode and stand-alone Multi-Channel Mode.

The interrupt flags for the Hall Sensor Mode are described in [Section 25.3.1](#) while the interrupt flags of the Quadrature Decoder Mode are described in [Section 25.3.2](#).

The flags associated with the Multi-Channel function are available in all the modes. This is due to the fact that the Multi-Channel Mode can operate in parallel with the Quadrature Decoder Mode and is needed whenever the Hall Sensor Mode is activated.

Each of the interrupt sources, can be routed to the POSIFx.SR0 or POSIFx.SR1 output, depending on the value programmed in the **PFLGE** register.

25.3.1 Hall Sensor Mode flags

The Hall Sensor Control contains four flags that can be configured to generate an interrupt request pulse, see [Figure 25-23](#).

Position Interface Unit (POSIF)

The four interrupt sources are:

- Transition at the Hall Inputs (**PFLG.HIES**)
- occurrence of a correct hall event (**PFLG.CHES**)
- occurrence of a wrong hall event (**PFLG.WHES**)
- shadow transfer of the Multi-Channel pattern (**PFLG.MSTS**)

The last one is triggered every time the Multi-Channel pattern is updated (PIFMST), which means that the POSIFx.MOUT[15:0] output was updated with a new value (see also **Figure 25-6**).

Each of this interrupt sources can be enabled/disabled individually. The SW also has the possibility to set and clear the specific flags by writing a 1_B into the specific fields of **SPFLG** and **RPFLG** registers. By enabling an interrupt source, an interrupt pulse is generated every time that a flag set operation occurs, independently if the flag is already set or not.

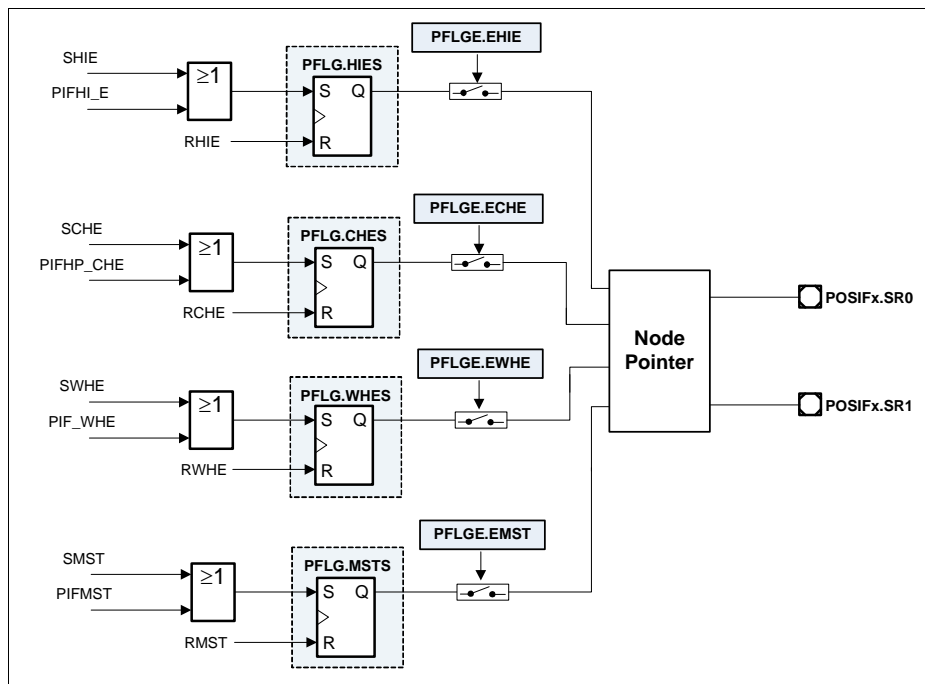

Figure 25-23 Hall Sensor Mode flags

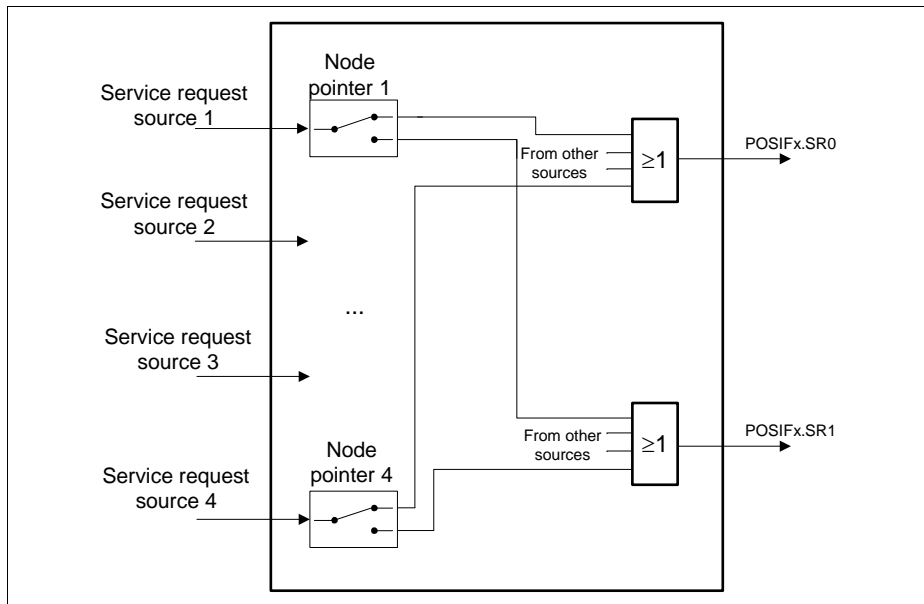

Figure 25-24 Interrupt node pointer overview - hall sensor mode

25.3.2 Quadrature Decoder Flags

The Quadrature Decoder Mode has five flags that can be enabled individually as interrupt sources (besides these five flags, the ones that are linked to the usage of Multi-Channel mode are also available: Multi-Channel Pattern update (**PFLG.MSTS**) and Wrong Hall event (**PFLG.WHES**). This can be useful if one selects the Quadrature Mode and the Multi-Channel stand-alone functionality.

These five flags are:

- Index event detection (**PFLG.INDXS**)
- phase detection error (**PFLG.ERRS**)
- quadrature clock generation (**PFLG.CNTS**)
- period clock generation (**PFLG.PCLKS**)
- direction change (**PFLG.DIRS**)

By enabling an interrupt source, an interrupt pulse is generated every time that a flag set operation occurs, independently if the flag is already set or not.

The index event detection flag is set every time that a index is detected.

The phase error flag is set when one invalid transition on the phase signals is detected, see [Figure 25-11](#).

Position Interface Unit (POSIF)

The quadrature clock and period clock flags are generated accordingly with the timings shown in **Figure 25-12**.

The direction change flag is set, every time that an inversion of the motor rotation happens.

Each flag can be set/cleared individually by SW, by writing into the specific field on the registers **SPFLG** and **RPFLG**, see **Figure 25-25**.

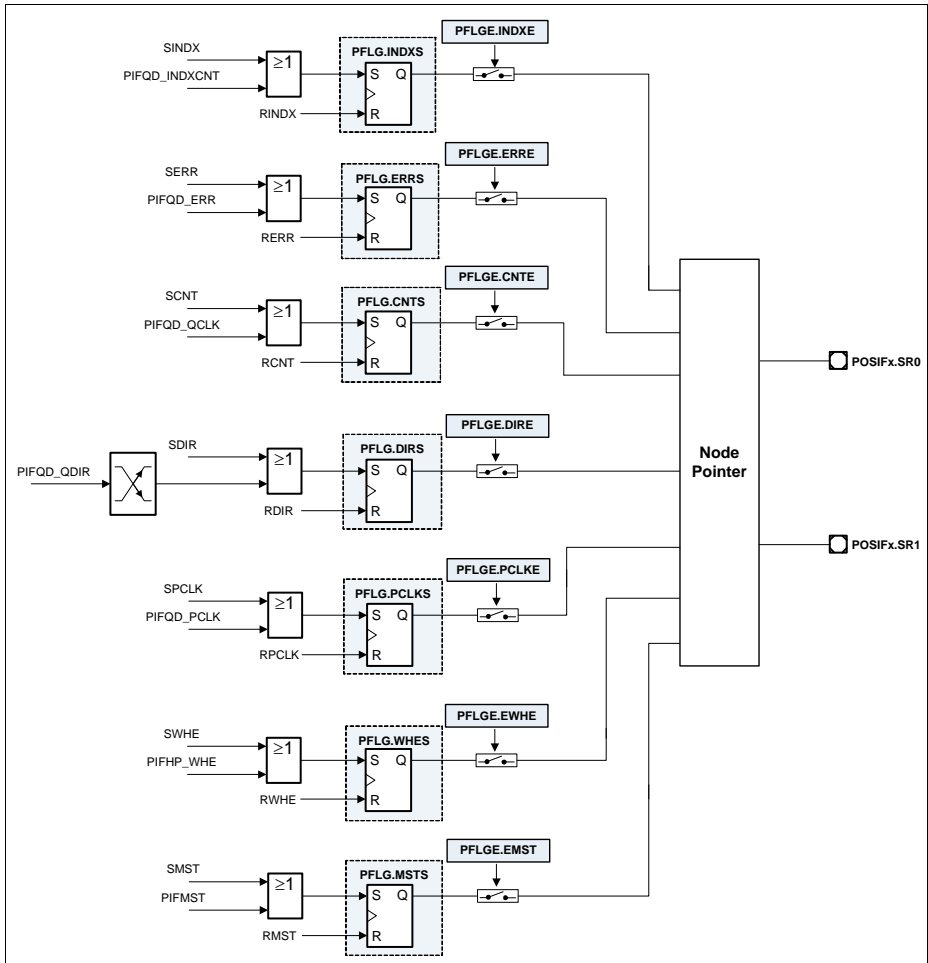

Figure 25-25 Quadrature Decoder flags

Figure 25-26 Interrupt node pointer overview - quadrature decoder mode

25.4 Debug Behavior

In suspend mode, the entire block is halted. The registers can still be accessed by the CPU (read only). This mode is useful for debugging purposes, e.g., where the current device status should be frozen in order to get a snapshot of the internal values. In suspend mode, all counters are stopped. The suspend mode is non-intrusive concerning the register bits. This means register bits are not modified by hardware when entering or leaving the suspend mode.

Entry into suspend mode can be configured at the kernel level by means of the register **PSUS**.

The module is only functional after the suspend signal becomes inactive.

25.5 Power, Reset and Clock

The following sections describe the operating conditions, characteristics and timing requirements for the POSIF. All the timing information is related to the module clock, f_{posif} .

25.5.1 Clocks

Module Clock

The module clock of the POSIF module is described in the SCU chapter as f_{CCU} .

The bus interface clock of the POSIF module is described in the SCU chapter as f_{PERIPH} .

The module clock for the POSIF is controlled via a specific control bit inside the SCU (System Control Unit), register CLKSET.

It is possible to disable the module clock for the POSIF, via a specific system control bit, nevertheless, there may be a dependency on the f_{posif} through the different POSIF instances or Capture/Compare Units. One should address the SCU Chapter for a complete description of the product clock scheme.

External Signals

The maximum frequency for the external signals, linked with the Hall Sensor and Rotary Encoder inputs can be seen in [Table 25-4](#).

Table 25-4 External Hall/Rotary signals operating conditions

| Parameter | Symbol | Values | | | Unit | Note / Test Condition |
|-----------|----------------------|---------------------|------|----------------------|------|-----------------------|
| | | Min. | Typ. | Max. | | |
| Frequency | f_{esig} | – | – | $f_{\text{posif}}/4$ | MHz | |
| ON time | ton_{esig} | $2T_{\text{posif}}$ | – | – | ns | |
| OFF time | $toff_{\text{esig}}$ | $2T_{\text{posif}}$ | – | – | ns | |

25.5.2 Module Reset

Each POSIF has one reset source. This reset source is handled at system level and it can be generated independently via a system control register, PRSET0 (address SCU chapter for a full description).

After reset release, the complete IP is set to default configuration. The default configuration for each register field is addressed on [Section 25.7](#).

25.5.3 Power

The POSIF is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For a explanation about the different power domains, please address the SCU (System Control Unit) chapter.

25.6 Initialization and System Dependencies

25.6.1 Initialization

The initialization sequence for an application that is using the POSIF, should be the following:

1st Step: Apply reset to the POSIF, via the specific SCU register, PRSET0.

2nd Step: Release reset of the POSIF, via the specific SCU register, PRCLR0.

3rd Step: Enable the POSIF clock via the specific SCU register, CLKSET.

4th Step: Configure the POSIF operation mode, **PCONF** register.

5th Step: Configure the POSIF registers linked to the wanted operation mode:

- For Hall Sensor Mode: **HALPS/HALP**, **MCSM/MCM**
- For Quadrature Decoder Mode: **QDC**
- For stand-alone Multichannel Mode: **MCSM/MCM**

5th Step: Apply the pre programmed patterns into the **HALP** and **MCM** registers, by writing 1_B into the **MCMS.STHR** and **MCMS.STMR** fields.

6th Step: Configure the POSIF interrupts/service requests via the **PFLGE** register.

7th Step: Configure the Capture/Compare Units associated with the POSIF operation mode.

8th Step: If the synchronous start function of the POSIF is being used inside the associated Capture/Compare units, then one just needs to set the run bit of the module, by writing a 1_B into **PRUNS.SRB**.

9th Step: If the synchronous start function of the POSIF is not being used inside the associated Capture/Compare units, then start first the POSIF by writing a 1_B into **PRUNS.SRB**. After that, start the associated Capture/Compare Unit timer slices, by addressing the specific bit field inside each timer slice or by using the synchronous start function available on the SCU, CCUCON register.

Note: Due to different startup conditions of the motor system itself (as well SW control loop implementation) it is possible to receive some erroneous interrupt triggers before the SW and HW loop are completely locked. To overcome this, the SW can ignore the interrupts during start up or the interrupt sources can be enabled only after a proper lock between HW and SW has been sensed.

25.6.2 System Dependencies

Each POSIF may have different dependencies regarding module and bus clock frequencies. These dependencies should be addressed in the SCU and System Architecture Chapters.

Dependencies between several peripherals, regarding different clock operating frequencies may also exist. This should be addressed before configuring the connectivity between the POSIF and some other peripheral.

The following topics must be taken into consideration for good POSIF and system operation:

- POSIF module clock must be at maximum two times faster than the module bus interface clock
- Module input triggers for the POSIF must not exceed the module clock frequency (if the triggers are generated internally in the device)
- Module input triggers for the POSIF must not exceed the frequency dictated in [Section 25.5.1](#)
- Frequency of the POSIF outputs used as triggers/functions on other modules, must be crosschecked on the end point
- Applying and removing POSIF from reset, can cause unwanted operations in other modules. This can occur if the modules are using POSIF outputs as triggers/functions.

25.7 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 25-5 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|-----------------------|-----------------------|------|
| POSIF0 | 40028000 _H | 4002BFFF _H | |
| POSIF1 | 4002C000 _H | 4002FFFF _H | |

| 0 | 3, [7:6], [15:14], 31 | r | Reserved Read always returns 0 |

PSUS

The register contains the suspend configuration for the POSIF.

Position Interface Unit (POSIF)

PSUS

POSIF Suspend Config

(0004_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| QSUS | [1:0] | rw | Quadrature Mode Suspend Config This field controls the entering in suspend for the quadrature decoder mode. 00 _B Suspend request ignored 01 _B Stop immediately 10 _B Suspend in the next index occurrence 11 _B Suspend in the next phase (PhaseA or PhaseB) occurrence |
| MSUS | [3:2] | rw | Multi-Channel Mode Suspend Config This field controls the entering in suspend for the Multi-Channel mode. The Hall sensor mode is also covered by this configuration. 00 _B Suspend request ignored 01 _B Stop immediately. Multi-Channel pattern is not set to the reset value. 10 _B Stop immediately. Multi-Channel pattern is set to the reset value. 11 _B Suspend with the synchronization of the PWM signal. Multi-Channel pattern is set to the reset value at the same time of the synchronization. |
| 0 | [31:4] | r | Reserved Read always returns 0 |

PRUNS

Via this register it is possible to set the run bit of the module.

Position Interface Unit (POSIF)

PRUNS

POSIF Run Bit Set

(0008_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| SRB | 0 | w | Set Run bit Writing an 1 _B into this bit sets the run bit of the module. Read always returns 0. |
| 0 | [31:1] | r | Reserved Read always returns 0 |

PRUNC

Via this register it is possible to clear the run bit and the internal state machines of the module.

PRUNC

POSIF Run Bit Clear

(000C_H)

Reset Value: 00000000_H

Position Interface Unit (POSIF)

| Field | Bits | Type | Description |
|------------|--------|------|---|
| CRB | 0 | w | Clear Run bit Writing an 1 _B into this bit clears the run bit of the module. The module is stopped. Read always returns 0. |
| CSM | 1 | w | Clear Current internal status Writing an 1 _B into this bit resets the state machine of the quadrature decoder and the current status of the Hall sensor and Multi-Channel mode registers. The flags and static configuration bit fields are not cleared. Read always returns 0. |
| 0 | [31:2] | r | Reserved Read always returns 0 |

PRUN

The register contains the run bit status of the POSIF.

PRUN

POSIF Run Bit Status (0010_H) Reset Value: 00000000_H

| 0 | [31:28] , [15:14] | r | Reserved A read always returns 0. |

MIDR

This register contains the module identification number.

MIDR

Module Identification register (0020_H) **Reset Value: 00A8C0XX_H**

| Field | Bits | Type | Description |
|-------|---------|------|---|
| MODR | [7:0] | r | Module Revision This bit field indicates the revision number of the module implementation (depending on the design step). |
| MODT | [15:8] | r | Module Type |
| MODN | [31:16] | r | Module Number |

25.7.2 Hall Sensor Mode Registers

HALP

The register contains the values for the Hall Expected Pattern and Hall Current Pattern.

Position Interface Unit (POSIF)

HALP

Hall Sensor Patterns (0030_H) Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| HCP | [2:0] | rh | Hall Current Pattern This field contains the Hall Current pattern. This field is updated with the HALPS.HCPS value every time that a correct hall event occurs. HCP[0] - Hall Input 1 HCP[1] - Hall Input 2 HCP[2] - Hall Input 3 |
| HEP | [5:3] | rh | Hall Expected Pattern This field contains the Hall Expected pattern. This field is updated with the HALPS.HEPS values every time that a correct hall event occurs. HEP[0] - Hall Input 1 HEP[1] - Hall Input 2 HEP[2] - Hall Input 3 |
| 0 | [31:6] | r | Reserved Read always returns 0 |

HALPS

The register contains the values that are going to be loaded into the **HALP** register when the next correct hall event occurs.

Position Interface Unit (POSIF)

HALPS

Hall Sensor Shadow Patterns

(0034_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| HCPS | [2:0] | rw | Shadow Hall Current Pattern This field contains the next Hall Current pattern value. This field is set on the HALP.HCP field every time that a correct hall event occurs. HCPS[0] - Hall Input 1 HCPS[1] - Hall Input 2 HCPS[2] - Hall Input 3 |
| HEPS | [5:3] | rw | Shadow Hall expected Pattern This field contains the next Hall Expected pattern. This field is set on the HALP.HEP field every time that a correct hall event occurs. HEPS[0] - Hall Input 1 HEPS[1] - Hall Input 2 HEPS[2] - Hall Input 3 |
| 0 | [31:6] | r | Reserved Read always returns 0 |

25.7.3 Multi-Channel Mode Registers

MCM

The register contains the value of the Multi-Channel pattern that is applied to the outputs POSIFx.OUT[15:0].

Position Interface Unit (POSIF)

MCM

Multi-Channel Pattern

(0040_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|---------|------|---|
| MCMP | [15:0] | rh | Multi-Channel Pattern This field contains the Multi-Channel Pattern that is going to be applied to the Multi-Channel outputs, POSIFx.MOUT[15:0]. This field is updated with the value of the MCSM.MCMP every time that a Multi-Channel pattern update is triggered. |
| 0 | [31:16] | r | Reserved Read always returns 0 |

MCSM

The register contains the value that is going to be loaded into the **MCM** register when the next Multi-Channel update trigger occurs.

Position Interface Unit (POSIF)

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| MNPS | 0 | w | Multi-Channel Pattern Update Enable Set Writing a 1 _B into this field enables the Multi-Channel pattern update (sets the MCMF.MSS bit). The update is not done immediately due to the fact that the trigger that synchronizes the update with the PWM is still needed. A read always returns 0. |
| STHR | 1 | w | Hall Pattern Shadow Transfer Request Writing a 1 _B into this field leads to an immediate update of the fields HALP.HCP and HALP.HEP . A read always returns 0. |
| STMR | 2 | w | Multi-Channel Shadow Transfer Request Writing a 1 _B into this field leads to an immediate update of the field MCM.MCMP . A read always returns 0. |
| 0 | [31:3] | r | Reserved Read always returns 0 |

MCMC

Through this register is possible to cancel a Multi-Channel pattern update and to clear the Multi-Channel pattern to the default value.

MCMC

Multi-Channel Pattern Control clear (004C_H)

Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | | | | MPC | MNP |
| r | | | | | | | | | | | | | | w | w |

Position Interface Unit (POSIF)

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| MNPC | 0 | w | Multi-Channel Pattern Update Enable Clear Writing a 1 _B into this field clears the MCMF.MSS bit. A read always returns 0. |
| MPC | 1 | w | Multi-Channel Pattern clear Writing a 1 _B into this field clears the Multi-Channel Pattern value to 0000 _H . A read always returns 0. |
| 0 | [31:2] | r | Reserved Read always returns 0 |

MCMF

The register contains the status of the Multi-Channel update request.

MCMF

Multi-Channel Pattern Control flag (0050_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------|--------|------|--|
| MSS | 0 | rh | Multi-Channel Pattern update status This field indicates if the Multi-Channel pattern is ready to be updated or not. When this field is set, the Multi-Channel pattern is updated when the triggering signal, selected from the POSIFx.MSYNC[D...A], becomes active. 0 _B Update of the Multi-Channel pattern is set 1 _B Update of the Multi-Channel pattern is not set |
| 0 | [31:1] | r | Reserved Read always returns 0 |

25.7.4 Quadrature Decoder Registers

QDC

The register contains the configuration for the operation of the Quadrature Decoder Mode.

QDC

Quadrature Decoder Control (0060_H) Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|------|------|---|
| PALS | 0 | rw | Phase A Level selector 0 _B Phase A is active HIGH 1 _B Phase A is active LOW |
| PBLS | 1 | rw | Phase B Level selector 0 _B Phase B is active HIGH 1 _B Phase B is active LOW |
| PHS | 2 | rw | Phase signals swap 0 _B Phase A is the leading signal for clockwise rotation 1 _B Phase B is the leading signal for clockwise rotation |

Position Interface Unit (POSIF)

| Field | Bits | Type | Description |
|-------|------------------|------|--|
| ICM | [5:4] | rw | Index Marker generations control This field controls the generation of the index marker that is linked to the output pin POSIFx.OUT3. 00 _B No index marker generation on POSIFx.OUT3 01 _B Only first index occurrence generated on POSIFx.OUT3 10 _B All index occurrences generated on POSIFx.OUT3 11 _B Reserved |
| DVAL | 8 | rh | Current rotation direction 0 _B Counterclockwise rotation 1 _B Clockwise rotation |
| 0 | 3, [7:6], [31:9] | r | Reserved Read always returns 0 |

25.7.5 Interrupt Registers

PFLG

The register contains the status of all the interrupt flags of the module.

PFLG

POSIF Interrupt Flags (0070_H) Reset Value: 00000000_H

| | | | | | | | | | | | | | | | |
|----|----|-----------|------|----------|----------|-----------|----|----|----------|----|------|----------|----------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |

25.8 Interconnects

The following tables, describe the connectivity present on the device for each POSIF module.

Position Interface Unit (POSIF)

The GPIO connections are available at the Ports chapter.

25.8.1 POSIF0 Pins
Table 25-7 POSIF0 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|------------------------------|------------|---------------------|--|
| POSIF0.CLK | I | SCU.CCUCLK | Module clock is the same one used by the capcoms |
| POSIF0.IN0A | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN0B | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN0C | I | VADC.G1BFL0 | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN0D | I | ERU1.PDOUT0 | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN1A | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN1B | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN1C | I | VADC.G1BFL1 | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN1D | I | ERU1.PDOUT1 | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN2A | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN2B | I | PORTS | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN2C | I | VADC.C0SR0 | Shared connection for rotary encoder and hall sensor |
| POSIF0.IN2D | I | ERU1.PDOUT2 | Shared connection for rotary encoder and hall sensor |
| POSIF0.HSDA | I | CCU40.ST0 | Used for the Hall pattern sample delay. |
| POSIF0.HSDB | I | 0 | Used for the Hall pattern sample delay. |

Position Interface Unit (POSIF)
Table 25-7 POSIF0 Pin Connections

| Global Inputs/Outputs | I/O | Connected To | Description |
|------------------------------|------------|---------------------|--|

General Purpose I/O Ports

26 General Purpose I/O Ports (PORTS)

The XMC4[78]00 has many digital port pins which can be used as General Purpose I/Os (GPIO) and are connected to the on-chip peripheral units.

26.1 Overview

The PORTS provide a generic and flexible software and hardware interface for all standard digital I/Os. Each port slice has the same software interfaces for the operation as General Purpose I/O and it further provides the connectivity to the on-chip periphery and the control for the pad characteristics. [Table 26-1](#) gives an overview of the available PORTS and other pins in the different packages of the XMC4[78]00:

Table 26-1 Port/Pin Overview

| Function | LFBGA-196 | LQFP-144 | LQFP-100 | Note |

26.1.1 Features

This is a list of the main features of the PORTS:

- same generic register interface for each port pin, [Section 26.8](#)
- simple and robust software access for General Purpose I/O functionality, [Section 26.2](#)
- separate set and clear output control to avoid read-modify-write operations, [Section 26.8.5](#)
- direct input connections to on-chip peripherals, [Section 26.2.1](#)
- parallel input of the same pin to different peripherals possible, for example triggering a capture event in a CAPCOM unit and a Service Request via the ERU
- up to four alternate output connections from peripherals selectable, [Section 26.2.2](#)
- separate input and output path, which allows to evaluate the input while the output is active (feedback, plausability check)
- dedicated hardware-controlled interface for EtherCAT, EBU, SDMMC, LEDTS and QSPI with select option, [Section 26.3](#)
- programmable open-drain or push-pull output driver stage, [Section 26.8.1](#)
- programmable driver strength and slew rate, [Page 26-6](#)
- programmable weak pull-up and pull-down devices, [Section 26.8.1](#)
- programmable input inverter, [Section 26.2.1](#)
- programmable power-save behavior in Deep Sleep mode, [Section 26.4](#)
- defined power-up/power-fail behavior, [Section 26.6](#)
- Privilege Mode restricted access to configuration registers to avoid accidental modification
- disabling of digital input stage on shared analog input ports, [Section 26.5](#)

26.1.2 Block Diagram

Below is a figure with the generic structure of a digital port pin, split into the port slice with the control logic and the pad with the pull devices and the input and output stages, [Figure 26-1](#).

General Purpose I/O Ports (PORTS)

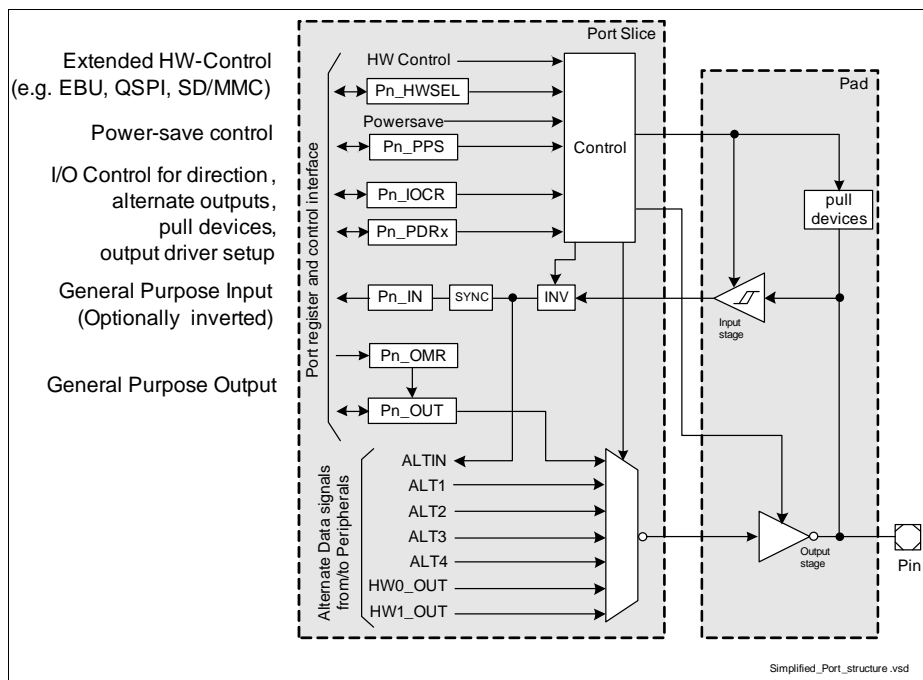

Figure 26-1 General Structure of a digital Port Pin

26.1.3 Definition of Terms

Some specific terms are used throughout this chapter:

- **Pin/Ball:** External connection of the device to the PCB.
- **Dedicated Pin:** A Pin with a dedicated function that is not under the control of the port logic (i.e. supply pins, $\overline{\text{PORST}}$).
- **Port Pin:** A pin under the control of the port logic (P0.1).
- **Port:** A group of up to 16 Port Pins sharing the same generic register set (P0).
- **Port Slice:** The “sum” of register bits and control logic used to control a port pin.
- **Pad:** Analog component containing the output driver, pull devices and input Schmitt-Trigger. Also interfaces the internal logic operating on V_{DDC} to the pad supply domain V_{DDP} .
- **GPIO:** General Purpose Input/Output. A port pin with the input and/or output function controlled by the application software.
- **Alternate Function:** Direct connection of a port pin with an on-chip peripheral.

26.2 GPIO and Alternate Function

The Ports can be operated as General Purpose Input/Outputs (GPIO) and with Alternate Functions of the on-chip peripheral, configured by the Port Input/Output Control Register (Pn_IOCR, [Section 26.8.1](#)). It selects between

- Direct or Inverted Input
 - with or without pull device
- Push-pull or Open-Drain Output driven by
 - Pn_OUT (GPIO)
 - selected peripheral output connections.

As GPIO the port pin is controlled by the application software, reading the input value by the Port Input register Pn_IN ([Section 26.8.6](#)) and/or defining the output value by the Output Modification Register Pn_OMR ([Section 26.8.5](#)). Output modification by Pn_OMR is preferred over the direct change of the output value with the Output register Pn_OUT ([Section 26.8.4](#)), as Pn_OMR allows the manipulation of individual port pins in a single access without “disturbing” other pins controlled by the same Pn_OUT register. If an application uses a GPIO as a bi-directional I/O line, register Pn_IOCR has to be written to switch between input and output functionality.

For the operation with Alternate Functions, the port pins are directly connected to input or output functions of the on-chip peripheral. This allows the peripheral to directly evaluate the input value or drive the output value of the port pin without further application software interaction after the initial configuration. The connection of alternate functions is used for control and communication interfaces, like a PWM from a CAPCOM unit or a SPI communication of a USIC channel. A detailed connectivity list of the peripherals to the port pins is given in the [Port I/O Functions](#) chapter. For specific functions, certain peripherals may also take direct control of “their” port pins, see [Hardware Controlled I/Os](#).

26.2.1 Input Operation

As an input, the actual voltage level at the port pin is translated into a logical 0_B or 1_B via a Schmitt-Trigger device within the pad. The resulting input value can be optionally inverted. As general purpose input the signal is synchronized and can be read with the Input register (Pn_IN, [Section 26.8.6](#)). Alternatively, the input can be connected to multiple on-chip peripherals via the ALTIN signal. Where necessary, these peripherals have internal controls to select the appropriate port pin with an input multiplexer stage, and will take care of synchronization and the further processing of the input signals (for more details on the input selection and handling see the respective peripheral chapters). With the Pn_IOCR register ([Section 26.8.1](#)) it is also possible to activate an internal weak pull-up or pull-down device in the pad.

The input register Pn_IN and the ALTIN signal always represent the state of the input, independent whether the port pin is configured as input or output. So, even if the port is

General Purpose I/O Ports (PORTS)

in output mode, the level of the pin can be read by software via Pn_IN and/or a peripheral can use the pin level as an input.

The ALTIN input signal of a port pin can be evaluated by multiple on-chip peripherals at the same time. For example, a pin used as slave select input of a USIC channel configured as SPI slave can also be used as trigger input of the ERU to trigger a service request or a wake-up event when the connected SPI master starts a communication.

26.2.2 Output Operation

In output mode, the output driver is activated and drives the value supplied through the output multiplexer to the port pin. Switching between input and output mode is accomplished through the Pn_IOCR register ([Section 26.8.1](#)), which

- enables or disables the output driver,
- selects between open-drain and push-pull mode,
- selects the general purpose or alternate function outputs.

The output multiplexer selects the signal source of the output with

- Pn_IOCR
 - general purpose output (Pn_OUT, [Section 26.8.4](#))
 - alternate peripheral functions, ALT1..ALT4
- hardware control, Pn_HWSEL
 - HWO0
 - HWO1

Note: It is recommended to complete the Port and peripheral configuration with respect to driver strength, operating mode and initial values before the port pin is switched to output mode.

The output function is exclusive, meaning that always only exactly one peripheral has control of the output path.

Used as general purpose output, software can directly modify the content of Pn_OUT to define the output value on the pin. A write operation to Pn_OUT updates all port pins of that port (e.g. P0) that are configured as general purpose output. Updating just one or a selected few general purpose output pins via Pn_OUT requires a masked read-modify-write operation to avoid disturbing pins that shall not be changed. Direct writes to Pn_OUT will also affect Pn_OUT bits configured for use with the Pin Power-save function, [Section 26.4](#).

Because of that, it is preferred to modify Pn_OUT bits by the Output Modification Register Pn_OMR ([Section 26.8.5](#)). The bits in Pn_OMR allow to individually set, clear or toggle the bits in the Pn_OUT register and only update the “addressed” Pn_OUT bits.

The data written by software into the output register Pn_OUT can also be used as input data to an on-chip peripheral. This enables, for example, peripheral tests and simulation via software without external circuitry.

General Purpose I/O Ports (PORTS)

Output lines of on-chip peripherals can directly control the output value of the output driver if selected via ALT1 to ALT4 as well as HW0_OUT and HW1_OUT. After initialization, this allows the connected peripherals to directly drive complex control and communication patterns without further software interaction with the ports.

The actual logic level at the pin can be examined through reading Pn_IN and compared against the applied output level (either applied by the output register Pn_OUT, or via an alternate output function of a peripheral unit). This can be used to detect some electrical failures at the pin caused through external circuitry. In addition, software-supported arbitration schemes between different “masters” can be implemented in this way, using the open-drain configuration and an external wired-AND circuitry. Collisions on the external communication lines can be detected when a high level (1_B) is output, but a low level (0_B) is seen when reading the pin value via the input register Pn_IN or directly by a peripheral (via ALTIN, for example a USIC channel in IIC mode).

Driver Mode

Before activating the push-pull driver, it is recommended to configure its driver strength and slew rate according to its pad class and the application need by the Pad Driver Mode register Pn_PDR ([Section 26.8.2](#)). Selecting the appropriate driver strength allows to optimize the outputs for the needed interface performance, can help to reduce power consumption, and limits noise, crosstalk and electromagnetic emissions.

There are three classes of GPIO output drivers:

- Class A1 pads (low speed 3.3V LVTTTL outputs)
- Class A1+ pads (medium speed 3.3V LVTTTL outputs)
- Class A2 pads (high speed 3.3V LVTTTL outputs, e.g. for EBU or fast serial interfaces)

Class A1 pins provide the choice between medium and weak output drivers.

Class A1+ pins provide the choice between strong/medium/weak output drivers. For the strong driver, the signal transition edge can be additionally selected as soft or slow.

Class A2 pins provide the choice between strong/medium/weak output drivers. For the strong driver, the signal transition edge can be additionally selected as sharp/medium/soft.

The assignment of each port pin to one of these pad classes is listed in the [Package Pin Summary](#) table. Further details about pad properties in the XMC4[78]00 are summarized in the Data Sheet.

26.3 Hardware Controlled I/Os

Some ports pins are overlaid with peripheral functions for which the connected peripheral needs direct hardware control, e.g. for the direction of a bi-directional data bus. There is a dedicated hardware control interface for these functions. As multiple peripherals need access to this interface, the Pn_HWSEL register ([Section 26.8.8](#))

General Purpose I/O Ports (PORTS)

allows to select between the hardware “masters”. The assigned functions are listed in the columns HWO0/HWO1/HWI0/HWI1 in the **Port I/O Functions** table.

Depending on the operating mode, the peripheral can take control of various functions:

- Pin direction, input or output, e.g. for bi-directional signals
- Driver type, open-drain or push-pull
- Pull devices under peripheral control or under standard control via Pn_IOCR

Some configurations remain under control by the standard configuration interface, the output driver strength by Pn_PDR and the direct or inverted input path by Pn_IOCR.

Pn_HWSEL.HWx just pre-assigns the hardware-control of the pin to a certain peripheral, but the peripheral itself decides to actually take control over it. As long as the peripheral does not take control of a given pin via HWx_EN, the configuration of this pin is still defined by the configuration registers and it is available as GPIO or for other alternate functions. This might be because the selected peripheral has controls to just activate a subset of its pins, or because the peripheral is not active at all. E.g. unused address lines of the EBU are free for use as GPIO.

This mechanism can also be used to prohibit the hardware control of certain pins to a peripheral, in case the application does not need the respective functionality and the peripheral has no controls to disable the hardware control selectively.

If not specified differently, hardware outputs activate the push-pull output driver and the strength is defined by Pn_PDR. Similarly, the default hardware input configuration and the pull devices are controlled by Pn_IOCR.

If the JTAG interface is selected by Pn_HWSEL of the respective port pins, pull device and output driver configuration is overridden by hardware.

If configured accordingly, the LEDTS module can also control the internal pull devices and change between push-pull and open-drain output drivers.

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control (Pn_HWSEL.HWx != 00_B). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

26.4 Power Saving Mode Operation

In Deep Sleep mode, the behavior of a pin depends on the setting of the Pin Power Save register Pn_PPS (**Section 26.8.7**). Basically, each pin can be configured to react to the Power Save Mode Request or to ignore it. In case a pin is configured to react to a Power Save Mode Request, the output driver is switched to tri-state, the input Schmitt-Trigger and the pull devices are switched off (see **Figure 26-2**). The input signal to the on-chip peripherals is optionally driven statically high or low, software-defined by a value stored in Pn_OUT or by the last input value sampled to the Pn_OUT register during normal operation. The actual reaction is configured with the Pn_IOCR register under power save conditions, see **Table 26-8**.

General Purpose I/O Ports (PORTS)

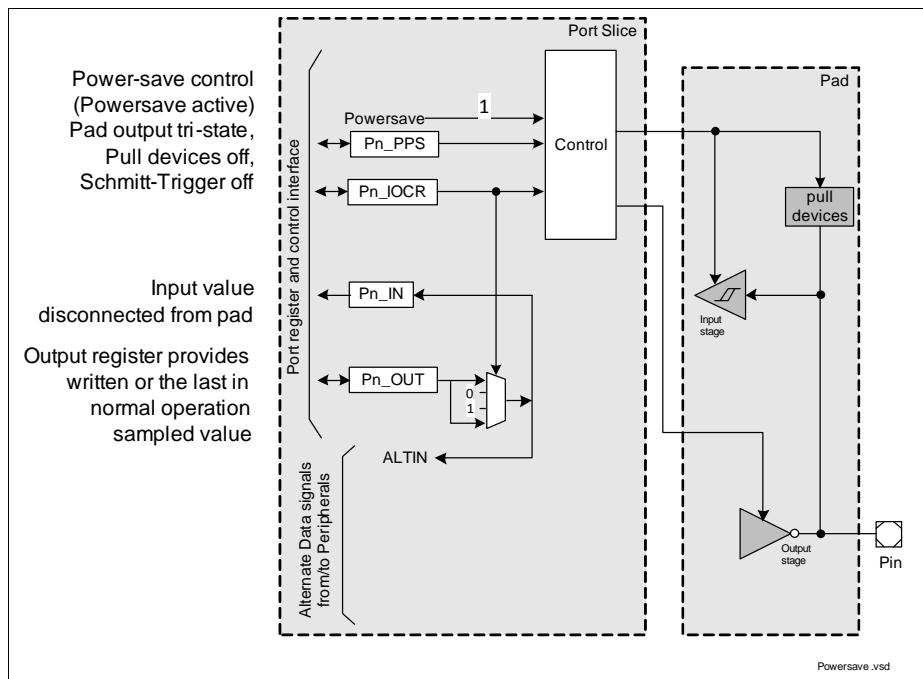

Figure 26-2 Port Pin in Power Save State

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control ($Pn_HWSEL.HWx \neq 00_B$). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

26.5 Analog Ports

P14 and P15 are analog and digital input ports with a simplified port and pad structure, see [Figure 26-3](#). The analog pads have no output drivers and the digital input Schmitt-Trigger can be controlled by the Pn_PDISC ([Section 26.8.3](#)) register. Accordingly, the port control interface is reduced in its functionality. The Pn_IOCRR register controls the pull devices, the optional input inversion and the input source in power-save mode. The Pn_OUT has only its power-save functionality, as described in [Section 26.4](#).

General Purpose I/O Ports (PORTS)

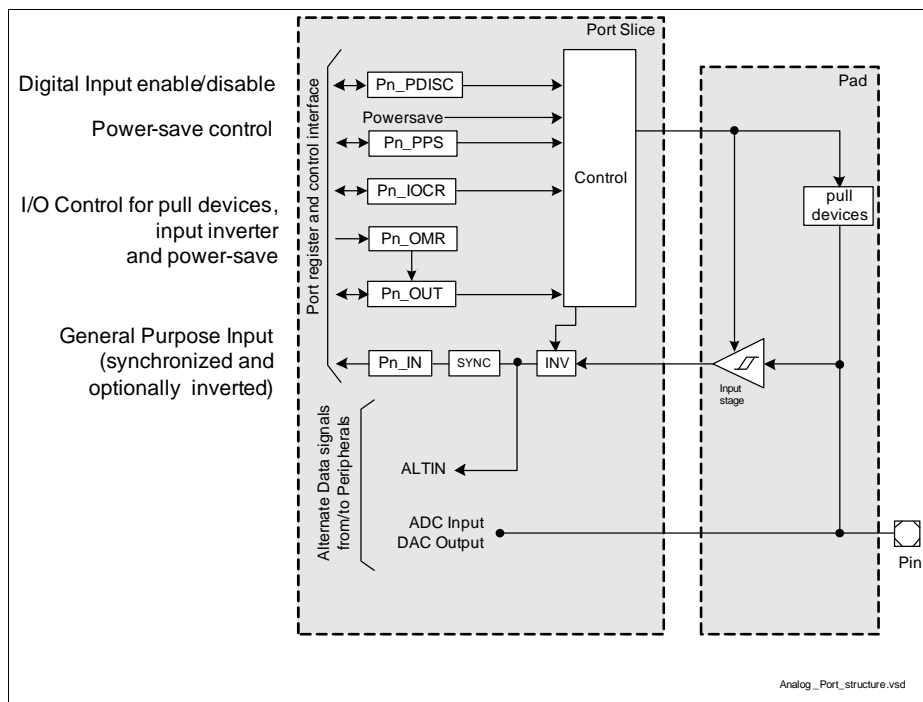

Figure 26-3 Analog Port Structure

26.6 Power, Reset and Clock

During power-up, until V_{DDC} and V_{DDP} voltage levels are stable and within defined limits, or during power-fail, while one/some voltage levels are outside the defined limits, the digital I/O pads are held in a defined state, which is tri-state input, output driver disabled and no pull devices active. The JTAG interface activates pull devices as default configuration.

The pins of the battery-buffered Hibernate Domain are independent to the supply monitoring of V_{DDC} and V_{DDP} , but are reset with the Standby Reset (see Reset Control chapter in the System Control Unit).

See the SCU Power Management chapter and the Data Sheet for details on the power-up, supply monitoring and voltage limits.

All Port registers are reset with the System Reset (see Reset Control chapter in the System Control Unit). The standard reset values are defined such that the port pins are configured as tri-state inputs, output driver disabled and no pull devices active.

General Purpose I/O Ports (PORTS)

Exceptions from these standard values are related to special interfaces (for example JTAG) or the analog input channels.

The Ports register interface is connected to Peripheral Bridge 1 (PBA1) and all registers of the Ports are clocked with f_{PERIPH} .

26.7 Initialization and System Dependencies

It is recommended to follow pre-defined routines for the initialization of the port pins.

Input

When a peripheral shall use a port pin as input, the actual pin levels may immediately trigger an unexpected peripheral event (e.g. clock edge at SPI). This can be avoided by forcing the "passive" level via pull-up/down programming.

The following steps are required to configure a port pin as an input:

- Pn_IOCR
input configuration with pull device and/or power-save mode configuration
- Hardware Control (if applicable)
 - Pn_HWSEL
switch hardware control to peripheral
- Pin Power Save (if applicable)
 - Pn_OMR/Pn_OUT
default value in power save mode (if applicable)
 - Pn_PPS
enable power save control

Output

When a port pin is configured as output for an on-chip peripheral, it is important that the peripheral is configured before the port switches the control to the peripheral in order to avoid spikes on the output.

The following steps are required to configure a port pin as an output:

- Pn_OMR/Pn_OUT
Initial output value (as general purpose output)
- Pn_PDR
Pad Driver Strength configuration
- GPIO or Alternate Output
 - Pn_IOCR
Output multiplexer select
Push-pull or open-drain output driver mode
Activates the output driver!
- Hardware Control

General Purpose I/O Ports (PORTS)

- Pn_IOCRR
depending on the hardware function Pn_IOCRR can enable the internal pull devices
- Pn_HWSEL
Switch hardware control to peripheral

Transitions

If a port pin is used for different functions that require a reconfiguration of the port registers, it is recommended to do this transition via an intermediate “neutral” tri-state input configuration.

- Pn_HWSEL
disable hardware selection; can be omitted if no hardware control is used on the port pin
- Pn_PPS
disable power save mode control of the pin; can be omitted if no power save configuration is used on the port pin
- Pn_IOCRR
tri-state input and no pull device active

26.8 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 26-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| P0 | 4802 8000 _H | 4802 80FF _H | |
| P1 | 4802 8100 _H | 4802 81FF _H | |

26.8.1 Port Input/Output Control Registers

The port input/output control registers select the digital output and input driver functionality and characteristics of a GPIO port pin. Port direction (input or output), pull-up or pull-down devices for inputs, and push-pull or open-drain functionality for outputs can be selected by the corresponding bit fields PCx (x = 0-15). Each 32-bit wide port input/output control register controls four GPIO port lines:

Register Pn_IOCR0 controls the Pn.[3:0] port lines

Register Pn_IOCR4 controls the Pn.[7:4] port lines

Register Pn_IOCR8 controls the Pn.[11:8] port lines

Register Pn_IOCR12 controls the Pn.[15:12] port lines

The diagrams below show the register layouts of the port input/output control registers with the PCx bit fields. One PCx bit field controls exactly one port line Pn.x.

Pn_IOCR0 (n=0-9)

Port n Input/Output Control Register 0

(4802 8010_H + n*100_H)

Reset Value: 0000 0000_H

Pn_IOCR0 (n=14-15)

Port n Input/Output Control Register 0

(4802 8010_H + n*100_H)

Reset Value: 0000 0000_H

Depending on the GPIO port functionality (number of GPIO lines of a port), not all of the port input/output control registers are implemented.

The structure with one control bit field for each port pin located in different register bytes offers the possibility to configure the port pin functionality of a single pin with byte-oriented accesses without accessing the other PCx bit fields.

General Purpose I/O Ports (PORTS)

Port Control Coding

Table 26-5 describes the coding of the PCx bit fields that determine the port line functionality.

The Pn_IOCry PCx bit field is also used to control the pin behavior in Deep Sleep mode if the Pin Power Save option is enabled, see [Section 26.8.7](#).

Table 26-5 Standard PCx Coding¹⁾

| PCx[4:0] | I/O | Output Characteristics | Selected Pull-up / Pull-down / Selected Output Function |
|--------------------|----------------|------------------------|---|
| 0X000 _B | Direct Input | — | No internal pull device active |
| 0X001 _B | | | Internal pull-down device active |
| 0X010 _B | | | Internal pull-up device active |
| 0X011 _B | | | No internal pull device active; Pn_OUTx continuously samples the input value |
| 0X100 _B | Inverted Input | — | No internal pull device active |
| 0X101 _B | | | Internal pull-down device active |
| 0X110 _B | | | Internal pull-up device active |
| 0X111 _B | | | No internal pull device active; Pn_OUTx continuously samples the input value |

General Purpose I/O Ports (PORTS)
Table 26-5 Standard PCx Coding¹⁾ (cont'd)

| PCx[4:0] | I/O | Output Characteristics | Selected Pull-up / Pull-down / Selected Output Function |

| 11110 _B | | | Reserved. |
| 11111 _B | | | Reserved. |

1) For the analog and digital input ports P14 and P15 the combinations with PCx[4]=1_B are reserved.

26.8.2 Pad Driver Mode Register

The pad structure of the XMC4[78]00 GPIO lines offers the possibility to select the output driver strength and the slew rate. These two parameters are controlled by the bit fields in the pad driver mode registers Pn_PDR0/1, independently from input/output and pull-up/pull-down control functionality as programmed in the Pn_IOCR register. Pn_PDR0 and Pn_PDR1 registers are assigned to each port.

Depending on the assigned pad class, the 3-bit wide pad driver mode selection bit fields PDx in the pad driver mode registers Pn_PDR make it possible to select the port line functionality as shown in [Table 26-6](#). Note that the pad driver mode registers are specific for each port.

Table 26-6 Pad Driver Mode Selection

| Pad Class | PDx.2 | PDx.1 | PDx.0 | Functionality |
|-----------|-------|-------|-------|----------------------------|
| A1 | X | X | 0 | Medium driver |
| | | | 1 | Weak driver |
| A1+ | 0 | X | 0 | Strong driver soft edge |
| | 0 | X | 1 | Strong driver slow edge |
| | 1 | X | 0 | Medium driver |
| | 1 | X | 1 | Weak driver |
| A2 | 0 | 0 | 0 | Strong driver, sharp edge |
| | 0 | 0 | 1 | Strong driver, medium edge |
| | 0 | 1 | 0 | Strong driver, soft edge |
| | 0 | 1 | 1 | Reserved |
| | 1 | 0 | 0 | Medium driver |
| | 1 | 0 | 1 | |
| | 1 | 1 | 0 | Reserved |
| | 1 | 1 | 1 | Weak driver |

Note: The XMC4[78]00 Data Sheet describes the DC characteristics of all pad classes.

Pad Driver Mode Registers

This is the general description of the PDR registers. Each port contains its own specific PDR registers, described additionally at each port, that can contain between one and eight PDx fields for PDR0 and PDR1 registers, respectively. Each field controls 1 pin. For coding of PDx, see [Table 26-6](#).

The analog and digital input ports P14 and P15 don't have Pn_PDR registers.

| Field | Bits | Type | Description |
|-----------------------------------|---------|------|--|
| PDISx (x = 0-15) | x | rw | Pad Disable for Port n Pin x This bit disables or enables the digital pad function. 0 _B Digital Pad input is enabled. Analog and digital input path active. 1 _B Digital Pad input is disabled. Analog input path active. (default) |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

General Purpose I/O Ports (PORTS)
26.8.4 Port Output Register

The port output register determines the value of a GPIO pin when it is selected by Pn_IOC Rx as output. Writing a 0 to a Pn_OUT.Px (x = 0-15) bit position delivers a low level at the corresponding output pin. A high level is output when the corresponding bit is written with a 1. Note that the bits of Pn_OUT.Px can be individually set/reset by writing appropriate values into the port output modification register Pn_OMR, avoiding read-modify-write operations on the Pn_OUT, which might affect other pins of the port.

The Pn_OUT is also used to store/drive a defined value for the input in Deep Sleep mode. For details on this see the [Port Pin Power Save Register](#). That is also the only use of the Pn_OUT register in the analog and digital input ports P14 and P15.

Pn_OUT (n=0-9)

Port n Output Register (4802 8000_H + n*100_H) **Reset Value: 0000 0000_H**

Pn_OUT (n=14-15)

Port n Output Register (4802 8000_H + n*100_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------------------|---------|------|--|
| Px (x = 0-15) | x | rwh | Port n Output Bit x This bit determines the level at the output pin Pn.x if the output is selected as GPIO output. 0 _B The output level of Pn.x is 0. 1 _B The output level of Pn.x is 1. Pn.x can also be set/reset by control bits of the Pn_OMR register. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

26.8.5 Port Output Modification Register

The port output modification register contains control bits that make it possible to individually set, reset, or toggle the logic state of a single port line by manipulating the output register.

Pn_OMR (n=0-9)

Port n Output Modification Register

(4802 8004_H + n*100_H)

Reset Value: 0000 0000_H

Pn_OMR (n=14-15)

Port n Output Modification Register

(4802 8004_H + n*100_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

| W | W | W | W | W | W | W | W | W | W | W | W | W | W | W | W |

| Field | Bits | Type | Description |
|--------------------------|--------|------|--|
| PSx (x = 0-15) | x | w | Port n Set Bit x Setting this bit will set or toggle the corresponding bit in the port output register Pn_OUT. The function of this bit is shown in Table 26-7 . |
| PRx (x = 0-15) | x + 16 | w | Port n Reset Bit x Setting this bit will reset or toggle the corresponding bit in the port output register Pn_OUT. The function of this bit is shown in Table 26-7 . |

Note: Register Pn_OMR is virtual and does not contain any flip-flop. A read action delivers the value of 0. A 8 or 16-bits write behaves like a 32-bit write padded with zeros.

Table 26-7 Function of the Bits PRx and PSx

| PRx | PSx | Function |
|-----|-----|-------------------------------|
| 0 | 0 | Bit Pn_OUT.Px is not changed. |
| 0 | 1 | Bit Pn_OUT.Px is set. |
| 1 | 0 | Bit Pn_OUT.Px is reset. |
| 1 | 1 | Bit Pn_OUT.Px is toggled. |

26.8.6 Port Input Register

The logic level of a GPIO pin can be read via the read-only port input register Pn_IN. Reading the Pn_IN register always returns the current logical value at the GPIO pin, synchronized to avoid meta-stabilities, independently whether the pin is selected as input or output.

Pn_IN (n=0-9)

Port n Input Register (4802 8024_H + n*100_H) **Reset Value: 0000 XXXX_H**

Pn_IN (n=14-15)

Port n Input Register (4802 8024_H + n*100_H) **Reset Value: 0000 XXXX_H**

| Field | Bits | Type | Description |
|--------------------------------|---------|------|--|
| Px (x = 0-15) | x | rh | Port n Input Bit x This bit indicates the level at the input pin Pn.x. 0 _B The input level of Pn.x is 0. 1 _B The input level of Pn.x is 1. |
| 0 | [31:16] | r | Reserved Read as 0. |

General Purpose I/O Ports (PORTS)

26.8.7 Port Pin Power Save Register

When the XMC4[78]00 enters Deep Sleep mode, pins with enabled Pin Power Save option are set to a defined state and the input Schmitt-Trigger as well as the output driver stage are switched off.

Note: Do not enable the Pin Power Save function for pins configured for Hardware Control ($Pn_HWSEL.HWx \neq 00_B$). Doing so may result in an undefined behavior of the pin when the device enters the Deep Sleep state.

Pn_PPS (n=0-9)

Port n Pin Power Save Register

$$(4802\ 8070_H + n \cdot 100_H)$$

Reset Value: 0000 0000_H

Pn_PPS (n=14-15)

Port n Pin Power Save Register

$$(4802\ 8070_H + n \cdot 100_H)$$

Reset Value: 0000 0000_H

| 0 | [31:16] | r | Reserved Read as 0. |

Deep Sleep Pin Power Save behavior

The actual behavior in Deep Sleep mode with enabled Pin Power Save is controlled by the Pn_IOCry.PCx bit field ([Page 26-14](#)) of the respective pin. [Table 26-8](#) shows the coding.

Table 26-8 PCx Coding in Deep Sleep mode

| PCx[4:0] | I/O | Normal Operation or PPSx=0 _B | Deep Sleep mode and PPSx=1 _B |
|--------------------|-------------------|--|---|
| 0X000 _B | Direct Input | See Table 26-5 | Input value=Pn_OUTx |
| 0X001 _B | | | Input value=0 _B ; pull-down deactivated |
| 0X010 _B | | | Input value=1 _B ; pull-up deactivated |
| 0X011 _B | | | Input value=Pn_OUTx, storing the last sampled input value |
| 0X100 _B | Inverted Input | See Table 26-5 | Input value= $\overline{\text{Pn_OUTx}}$ |
| 0X101 _B | | | Input value=1 _B ; pull-down deactivated |
| 0X110 _B | | | Input value=0 _B ; pull-up deactivated |
| 0X111 _B | | | Input value= $\overline{\text{Pn_OUTx}}$, storing the last sampled input value |
| 1XXXX _B | Output | See Table 26-5 | Output driver off, Input Schmitt-Trigger off, no pull device active, Input value=Pn_OUTx |

26.8.8 Port Pin Hardware Select Register

Some peripherals require direct hardware control of their I/Os. As on some pins multiple such peripheral I/Os are mapped, the register Pn_HWSEL is used to select which peripheral has the control over the pin.

Note: Pn_HWSEL.HWx just pre-assigns the hardware-control of the pin to a certain peripheral, but the peripheral itself decides to actually take control over it. As long as the peripheral does not take control of a given pin via HWx_EN, the configuration of this pin is still defined by the configuration registers and it is available as GPIO or for other alternate functions. This might be because the selected peripheral has controls to just activate a subset of its pins, or because the peripheral is not active at all.

This mechanism can also be used to prohibit the hardware control of certain pins to a peripheral, in case the application does not need the respective functionality and the peripheral has no controls to disable the hardware control selectively.

The shared analog and digital input ports P14 and P15 do not support the hardware select feature.

General Purpose I/O Ports (PORTS)

P0_HWSEL

Port 0 Pin Hardware Select Register (0074_H)

Reset Value: 0001 4000_H

P1_HWSEL

Port 1 Pin Hardware Select Register (0074_H)

Reset Value: 0000 0000_H

P2_HWSEL

Port 2 Pin Hardware Select Register (0074_H)

Reset Value: 0000 0004_H

Pn_HWSEL (n=3-9)

Port n Pin Hardware Select Register

(4802 8074_H + n*100_H)

Reset Value: 0000 0000_H

| HWx (x = 0-15) | [2*x+1: 2*x] | rw | Port n Pin Hardware Select Bit x 00 _B Software control only. 01 _B HWI0/HWO0 control path can override the software configuration. 10 _B HWI1/HWO1 control path can override the software configuration. 11 _B Reserved. |

26.9 Package Pin Summary

The following general building block is used to describe each pin:

Table 26-9 Package Pin Mapping Description

| Function | Package A | Package B | ... | Pad Type | Notes |
|----------|-----------|-----------|-----|----------|-------|
| Name | N | Ax | ... | A2 | |

The table is sorted by the “Function” column, starting with the regular Port pins (Px.y), followed by the dedicated pins (i.e. PORST) and supply pins.

The following columns, titled with the supported package variants, lists the package pin number to which the respective function is mapped in that package.

The “Pad Type” indicates the employed pad type (A1, A1+, A2, special=special pad, In=input pad, AN/DIG_IN=analog and digital input, Power=power supply). Details about the pad properties are defined in the Data Sheet.

In the “Notes”, special information to the respective pin/function is given, i.e. deviations from the default configuration after reset. Per default the regular Port pins are configured as direct input with no internal pull device active.

Table 26-10 Package Pin Mapping

| Function | LFBGA-196 | LQFP-144 | LQFP-100 | Pad Type | Notes |
|----------|-----------|----------|----------|----------|--|
| P0.0 | E4 | 2 | 2 | A1+ | |
| P0.1 | E3 | 1 | 1 | A1+ | |
| P0.2 | C3 | 144 | 100 | A2 | |
| P0.3 | C4 | 143 | 99 | A2 | |
| P0.4 | D5 | 142 | 98 | A2 | |
| P0.5 | C5 | 141 | 97 | A2 | |
| P0.6 | C6 | 140 | 96 | A2 | |
| P0.7 | D7 | 128 | 89 | A2 | After a system reset, via HWSEL this pin selects the DB.TDI function. |
| P0.8 | C8 | 127 | 88 | A2 | After a system reset, via HWSEL this pin selects the DB.TRST function, with a weak pull-down active. |
| P0.9 | F4 | 4 | 4 | A2 | |
| P0.10 | D4 | 3 | 3 | A1+ | |

26.10 Port I/O Functions

The following general building block is used to describe each PORT pin:

Table 26-11 Port I/O Function Description

| Function | Outputs | | | Inputs | | |
|----------|----------|----------|----------|----------|----------|----------|
| | ALT1 | ALTn | HWO0 | HWI0 | Input | Input |
| P0.0 | | MODA.OUT | MODB.OUT | MODB.INA | MODC.INA | |
| Pn.y | MODA.OUT | | | | MODA.INA | MODC.INB |

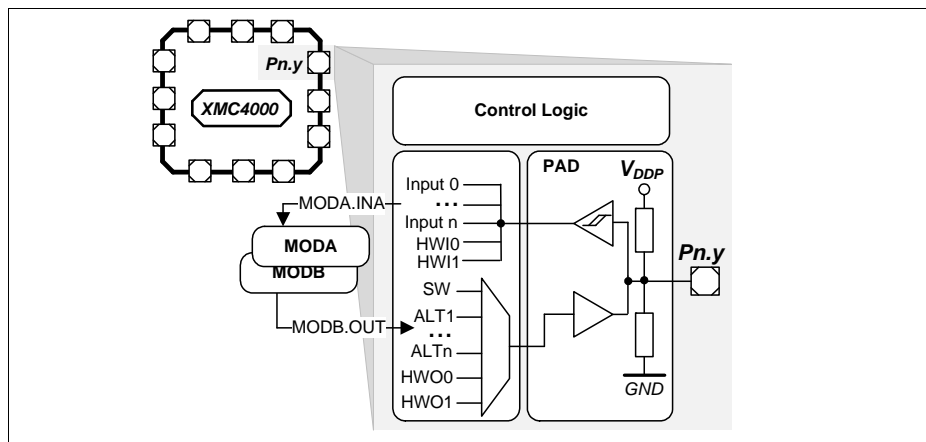

Figure 26-4 Simplified Port Structure

Pn.y is the port pin name, defining the control and data bits/registers associated with it. As GPIO, the port is under software control. Its input value is read via Pn_IN.y, Pn_OUT defines the output value.

Up to four alternate output functions (ALT1/2/3/4) can be mapped to a single port pin, selected by Pn_IOC.R.PC. The output value is directly driven by the respective module, with the pin characteristics controlled by the port registers (within the limits of the connected pad).

The port pin input can be connected to multiple peripherals. Most peripherals have an input multiplexer to select between different possible input sources.

The input path is also active while the pin is configured as output. This allows to feedback an output to on-chip resources without wasting an additional external pin.

By Pn_HWSEL (Section 26.8.8) it is possible to select between different hardware “masters” (HWO0/HWI0, HWO1/HWI1). The selected peripheral can take control of the pin(s). Hardware control overrules settings in the respective port pin registers.

26.10.1 Port I/O Function Table

Table 26-12 Port I/O Functions

| Function | Outputs | | | | | | Inputs | | | | | | | |
|----------|-----------------------|------------------|-------------------|-----------------|----------------|----------------|----------------|--------------|----------------|-------------------|--------------|-----------------|----------------|--|

Startup Modes

27 Startup modes

This chapter describes the various startup modes supported by the device along with actions that must be performed by the end user.

27.1 Overview

The on-chip firmware resides in a non volatile memory namely the BootROM and is the first software of any kind to be executed by the CPU right after reset.

The on-chip firmware has two parts:

- Startup Software in BootROM (SSW) which provisions the various boot modes selectable by the user and is the main thread of execution.
- Test Firmware (Testware, not described in this document) which deals with test related routines that can be invoked during chip test in test mode only is not intended to be executed by the user.

The terms startup mode and boot mode mean the same and are used interchangeably throughout this chapter.

27.1.1 Features

Supported boot modes are summarized briefly. Desired boot mode can be enabled by driving the boot mode pins (JTAG TCK and TMS) with appropriate logic levels and issuing a power on reset (PORST). The actual value of these pins is latched into register STCON.HWCON. Some boot modes can only be selected by configuring STCON.SWCON bit field (of SCU module) and applying a system reset (such as a watchdog reset or CPU software reset).

Normal Boot mode

Startup type: *Internal start*

Required Reset type: *PORST or System reset*

An application located at the start of flash is given control after SSW has finished its execution. In case of an erased flash, the SSW will remain in BootROM.

Alternative Boot mode (ABM-0/ABM-1)

Startup type: *Internal start*

Required Reset type: *System reset*

An application located at user defined location on the flash is given control by SSW. The SSW after completing its execution evaluates a header hereafter known as ABM header kept at a well known address on the flash which in turn provides the location of application placed at user defined address. Two such applications can be programmed into the flash and thus two ABMs are supported. An invalid header results in the SSW

Startup modes

aborting further execution and launching the CPU into safe mode which is Diagnostics Monitor Mode (DMM). A PORST is required to exit the safe mode of operation.

Fallback ABM

Startup type: *Internal start*

Required Reset type: *System reset*

SSW evaluates the two ABM headers in succession. The first ABM header found valid by SSW results in application referenced by that header given control to. Should both the headers be found unusable, SSW aborts further execution and places the CPU into a safe mode which is Diagnostics Monitor Mode (DMM). A PORST is required to exit the safe mode of operation.

PSRAM boot

Startup type: *Internal start*

Required Reset type: *System reset*

An application loaded into PSRAM is given control after SSW finishes its execution. The start address of this application is deduced from an ABM like header placed in the last 32 bytes of PSRAM. An invalid header results in the SSW aborting further execution and launching the CPU into safe mode which is Diagnostics Monitor Mode (DMM). A PORST is required to exit the safe mode of operation.

ASC BSL (UART Bootstrap loading)

Startup type: *External start*

Required Reset type: *PORST or System reset*

An application can be downloaded into the start of PSRAM over the USIC ASC interface and executed. The size of the application downloaded is limited to the size of PSRAM on the device.

CAN BSL (CAN Bootstrap loading)

Startup type: *External start*

Required Reset type: *PORST or System reset*

An application can be downloaded into the start of PSRAM over the MultiCAN interface and executed. The size of the application downloaded is limited to the size of PSRAM on the device.

Boot mode Index (BMI)

Startup type: *Internal or External start*

Required Reset type: *PORST or System reset*

Startup modes

A user defined bootmode is offered via following mechanism. With initial factory programming (at customer site), a so called BMI string can be programmed into user configuration block (UCB). The BMI string describes actions that must be performed by SSW before lending into one of the internal or external startup modes.

The firmware can be triggered to initialize the parity of the SRAMs when starting in BMI boot mode, as depicted in [Figure 27-14](#). For other boot modes, the initialization needs to be done in the user start-up code.

27.2 Boot and Startup

This section describes the startup sequence of the XMC4[78]00 as a process taking place before user application software takes control of the system.

27.2.1 Initial boot sequence

There are several tasks which the SSW performs before it gets to the point where the user requested boot mode must be identified and launched. This is to ensure that user applications have a stable execution environment when program control is hand over to them.

The SSW ensures that the flash subsystem has initialized before any user program can be executed out of flash memory.

It identifies the user requested boot mode and launches the same. It is important to state at this point that a few DSRAM1 locations are used by SSW for staging information read out of Flash Configuration Sector. [Figure 27-1](#) depicts usage of DSRAM1 used by SSW. In addition at every reset Device Information Data is reloaded at start of the DSRAM1. Detailed information about the content can be found in [Chapter 27.2.4](#).

Debugger access is prohibited if the global flash read protection is enabled. Before program control is hand over to user application (described next), SSW turns on the Startup protection feature. This restricts access to certain registers (described as startup protected registers) and memories such as the Flash Configuration Sector (FCS).

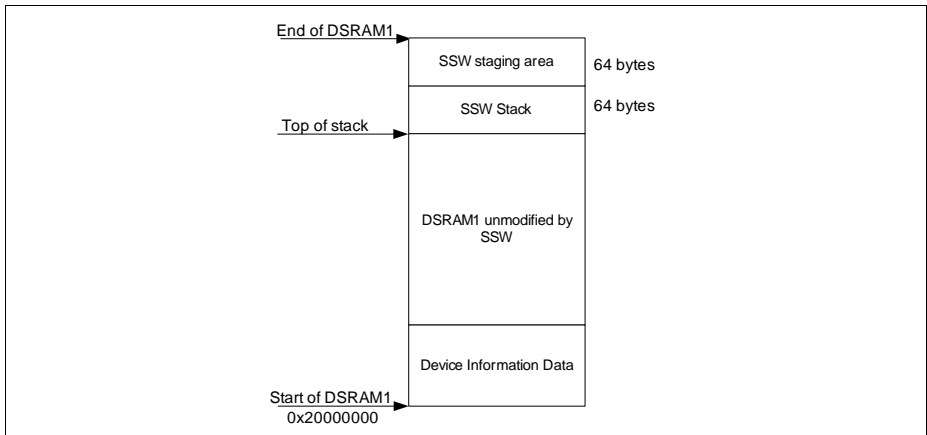

Figure 27-1 DSRAM1 usage by SSW

27.2.2 Reset types and corresponding boot modes

The XMC4000 family supports 2 categories of reset namely Power On Reset (PORST) and System Reset. Every cause of reset which is not a PORST is a System Reset.

27.2.2.1 Power On Reset (PORST)

When the SSW executes after a PORST as the reset type, it gets to choose from one of Normal boot mode, ASC BSL, CAN BSL and BMI based on what is read off the boot pins (JTAG TCK and TMS).

Pins TCK and TMS are stored into the HWCON[1:0] bit field of the SCU.STCON register after PORST and are mirrored into STCON.SWCON[1:0]. STCON.HWCON content can only be modified by PORST as reset source. HWCON bits are read by the SSW upon emergence from PORST.

Following table enlists the boot mode pin encoding and associated boot modes.

Table 27-1 Boot mode pin encoding for PORST

| TCK | TMS | HWCON[1:0] | Boot mode |
|-----|-----|-----------------|-----------|
| 0 | 1 | 00 _B | Normal |
| 0 | 0 | 01 _B | ASC BSL |
| 1 | 1 | 10 _B | BMI |
| 1 | 0 | 11 _B | CAN BSL |

27.2.2.2 System Reset

When the SSW executes after a System Reset, it chooses one of the following boot modes - Normal, ASC BSL, BMI, CAN BSL, PSRAM boot, ABM-0, ABM-1 and Fallback ABM. Since the Reset Status Information in register SCU.RSTSTAT is the accumulated reset type, it is necessary to clean the bitfield using the SCU register RSTCLR.RSCLR before issuing a System Reset, else SSW will enter the boot mode reflected in STCON.HWCON.

The following table enlists the encoding of the SWCON bitfield and boot modes. In the event when software does not explicitly program SWCON and a system reset is experienced, values on TCK and TMS decide the boot mode.

Table 27-2 System reset boot modes

| SWCON[3:0] | Boot mode |
|-------------------|------------------|
| 0000 _B | Normal |
| 0001 _B | ASC BSL |
| 0010 _B | BMI |
| 0011 _B | CAN BSL |
| 0100 _B | PSRAM boot |
| 1000 _B | ABM-0 |
| 1100 _B | ABM-1 |
| 1110 _B | Fallback ABM |

27.2.3 Boot mode selection

HWCON bit field is read only for PORST (Power ON Reset). For every other reset type (available in SCU_RSTSTAT) register, the SWCON field is assessed.

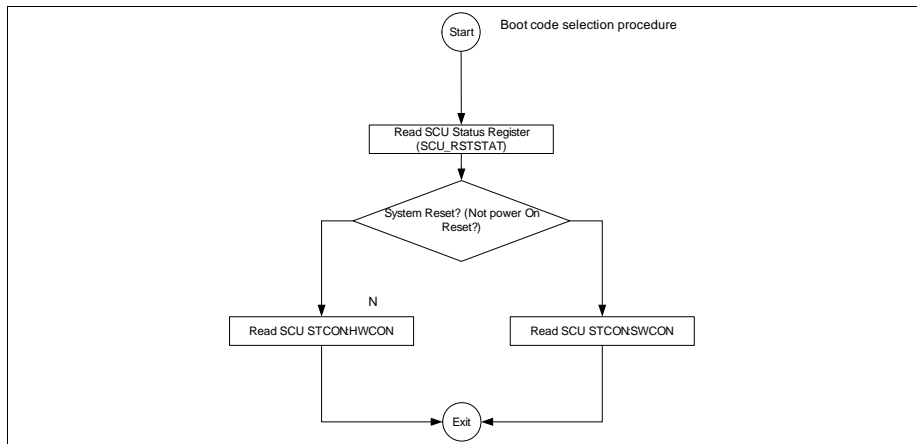

Figure 27-2 Reading Bootcode

Figure 27-3 depicts the decision tree that the SSW has to traverse in order to select the desired boot mode.

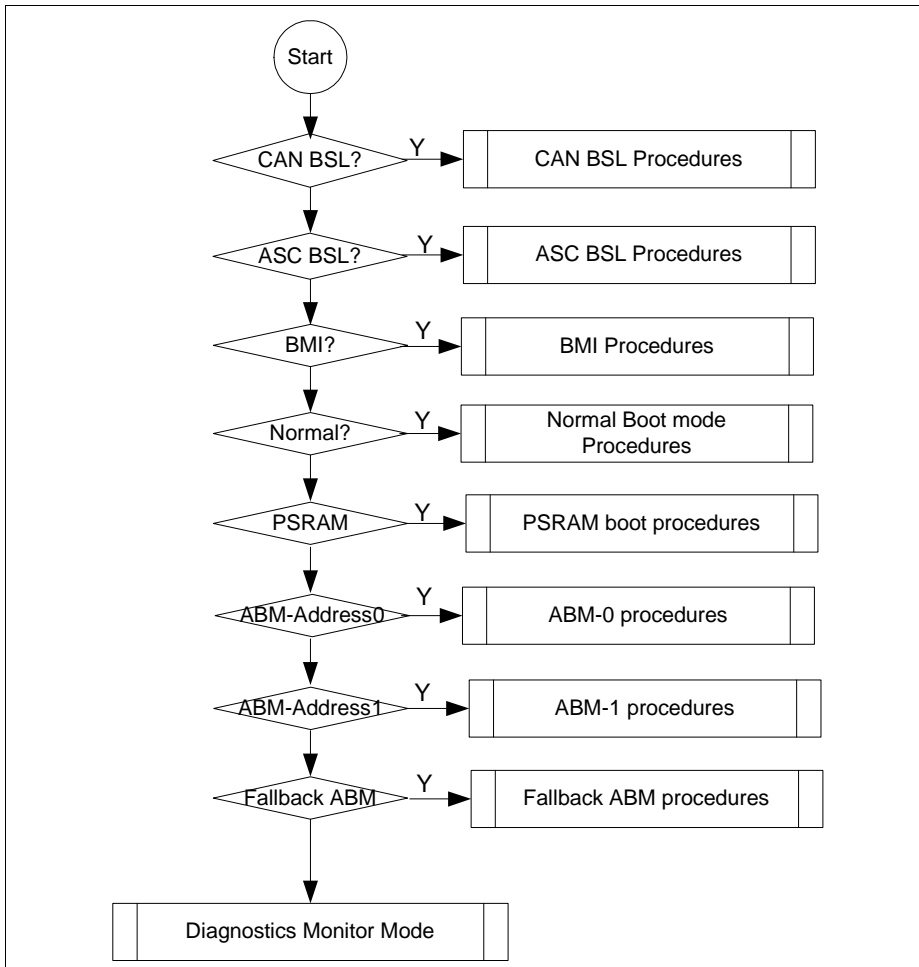

Figure 27-3 Boot mode identification

27.2.4 Unique Chip ID and Device Information Data

The XMC4[78]00 provides device specific information stored at begin of DSRAM1. The first value is a Unique Chip ID. This ID is a 16 Byte value absolute unique for every XMC4000. Following is the DTS calibration data 128 Byte and the BMI string 64 Byte. The last values is the JTAG-ID 4 Byte. More information about the BMI can be found in [Chapter 27.3.8](#).

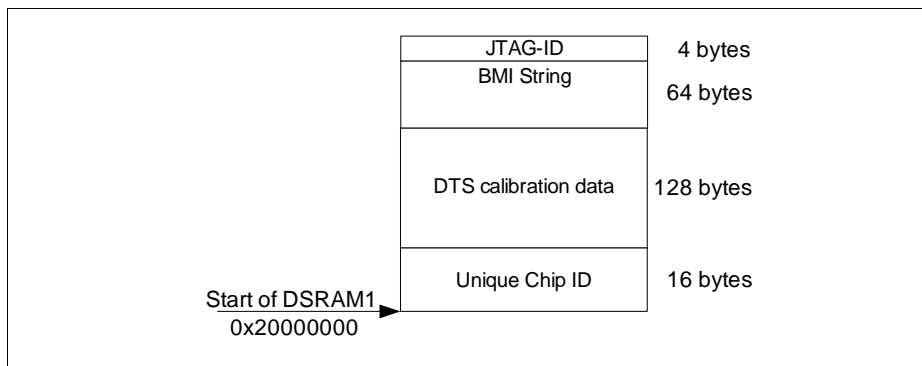

Figure 27-4 Device Information Data

27.3 Boot mode details

This chapter describes the Boot modes more in detail, explaining the Bootstrap Loaders (BSL) for UART and CAN, provide informations about setting up and handling the BMI.

27.3.1 Normal boot mode

This is a boot mode in which user application available at the start of flash (0C000000_H) is given control to after SSW execution.

SSW enables access to coresight system before passing control to the first user instruction. If the HALT after RESET feature were requested for by a connected hardware debugger, SSW configures a breakpoint on the first user instruction.

It is expected that the vector table of user application is available at the start of the flash. Firmware essentially reprograms the Cortex M4's SCB.VTOR register with the start address of flash (0C000000_H) and passes control to user application by programing register R15 (Program Counter) with reset vector contents. The reset vector contents point to a routine that could be in either the cached or the uncached address space of the flash.

User actions for normal boot mode

User must:

- Flash the application at the start of flash
- Drive TCK and TMS as per [Table 27-1](#)
- Issue a PORST

Alternatively

- A currently running program can setup SWCON bit field in the SCU.STCON register
- Clear Reset Source in SCU.RSTSTAT using the register RSTCLR.RSCLR
- Issue a system reset

27.3.2 Boot from PSRAM

This boot mode option requires user code to be downloaded into Program SRAM (PSRAM) first.

The SWCON bit field of the SCU.STCON register is then expected to be programmed with the Boot from PSRAM boot code. Second the reset status must be cleared followed by initiation of any of the system resets.

PORST leaves SRAM contents undefined. With a System Reset previous PSRAM contents retained intact. Application initiated software reset or a watchdog reset are two examples of System Reset.

For SSW to branch to user application in PSRAM, it must first be assured of integrity of user application. This is done by means of a magic key (A5C3E10F_H) and CRC audit. It

Startup modes

is therefore required that the PSRAM boot header be placed at the last 32 bytes of the PSRAM. The layout of the header is depicted in **Figure 27-5**. Polynomial used for checksum calculation is of CRC-32 type (04C11DB7_μ) with a initial value of 0x0H.

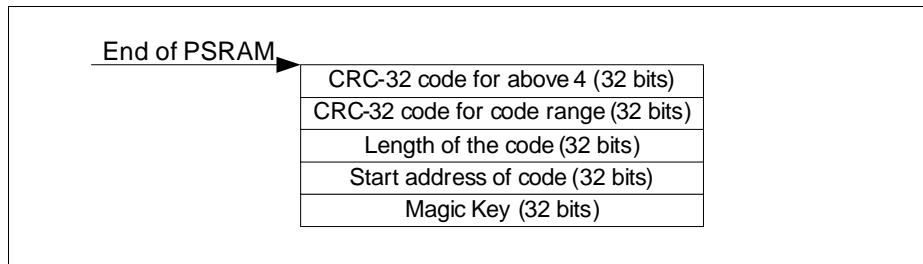

Figure 27-5 PSRAM header layout

This layout is reused in the ABM boot modes. A pictorial representation PSRAM usage for this boot mode is presented in **Figure 27-6**.

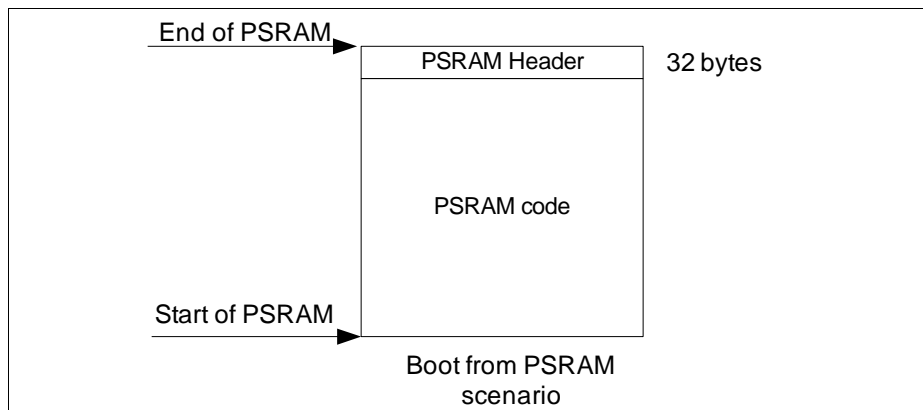

Figure 27-6 PSRAM layout for PSRAM boot

After audits confirm integrity of the code, SSW installs startup protection and cedes control to user application. SCB VTOR is programmed with PSRAM start address and CPU register R15 with application reset vector.

User actions for PSRAM boot mode

User must:

- Download application (Vector table + code) into PSRAM (Currently running program launched by any of the other internal boot modes can do this)

Startup modes

- Create PSRAM header and program the last 32 bytes of PSRAM with this header (Currently running program can either download header from host or create a header after application has been downloaded)
- Program SWCON bit field in the SCU.STCON register
- Clear Reset Source in SCU.RSTSTAT using the register RSTCLR.RSCLR
- Issue a system reset

27.3.3 Alternative boot mode - Address0 (ABM-0)

SSW can cede control to user application residing at an user defined flash address. As described in [Figure 27-5](#), an identical header is expected to be present at a fixed location in the flash. This fixed address for the header is the last 32 bytes (0C00FFE0_H on XMC4[78]00) of the first 64 KB physical sector.

Should the SSW find a corrupted header, execution is aborted and a diagnostics monitor mode (DMM) is entered.

As a norm, the address range of an application is typically linear without any holes. As an exception, an application may be scattered in the flash (with the help of scatter linker scripts) thus leaving holes on the flash. In such as cases, SSW only audits the ABM header and decides if control may be ceded to the reset vector. Distinction between linear and scattered application is made by evaluating application CRC and application length fields of the header. Both of these fields are set to FFFFFFFF_H in the case of scattered application. Polynomial used for CRC calculations is CRC-32 (04C11DB7_H) with a initial value of 0_H. A pictorial representation of this concept is presented in [Figure 27-7](#).

Figure 27-7 ABM concept

User actions

User must:

- Program flash with application and ABM header
- Drive TCK and TMS to launch Normal boot mode
- Configure STCON.SWCON per [Table 27-2](#)
- Clear Reset Source in SCU.RSTSTAT using the register RSTCLR.RSCLR
- Issue a system reset (Example: Watchdog reset, Software reset)

Alternatively

- program the flash with application and ABM header
- Encode the SWCON field in the BMI word with ABM boot code and program into the flash User Configuration Block-2 (UCB2-Page1)
- Drive TCK and TMS for BMI and issue PORST

27.3.4 Alternative boot mode - Address1 (ABM-1)

This is same as ABM-Address0. Address for the header is the last 32 bytes (0C01FFE0_H for XMC4[78]00) of the second 64 KB physical sector.

27.3.5 Fallback ABM

When this boot mode is selected, ABM Address-0 header is audited first. A positive audit results in SSW passing control to user application pointed to by the header. A negative audit results in evaluation of ABM Address-1. Should the audit of ABM-Address1 header fail, SSW launched diagnostics monitor mode (DMM).

27.3.6 ASC BSL mode

SSW supports bootstrap loader modes. When configured, any user application limited to the size of PSRAM on the device can be downloaded into PSRAM over the USIC0 channel 0 (U0C0) and immediately executed.

As an example, this application may be a secondary flash loader that can download a larger application and write the latter into program flash.

Data and code fetches are disabled if the global flash read protection is installed. Initial preparation and generic procedures are described next.

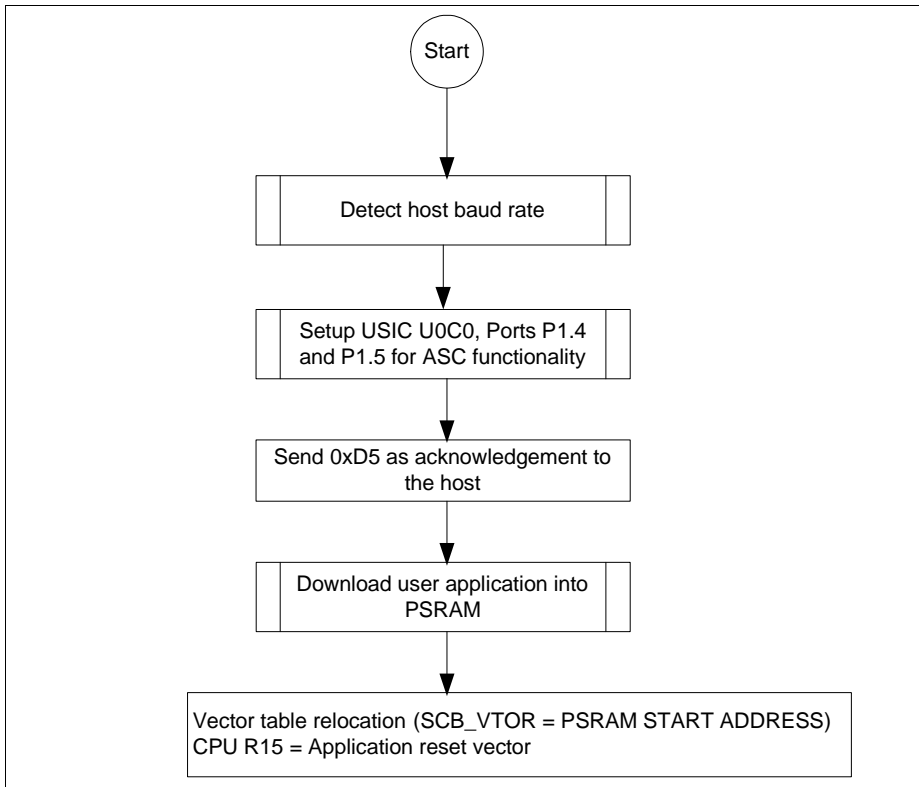

Figure 27-8 ASC BSL mode procedures

Full duplex ASC functionality of U0C0 is used for the BSL mode.

Port pins used are P1.4 (U0C0_DX0B) for USIC RX and P1.5 (U0C0_DOUT0) for USIC TX functionality.

The host starts by transmitting a zero byte to help the device detect the baud rate. After the baud rate has been detected by the device, a download protocol specified next helps download of application of any size only limited by the size of PSRAM on the device.

After the baud rate has been detected, SSW transmits an acknowledgement byte D5_H back to the host. It then awaits 4 bytes describing the length of the application from the host. The least significant byte is received first.

If application length is found acceptable by SSW, an OK (1_H) byte is sent to the host. Then the host will start to send the byte stream of the application. After the byte stream has been received, SSW terminates the protocol by sending a final OK (1_H) byte and then cedes control to the downloaded application.

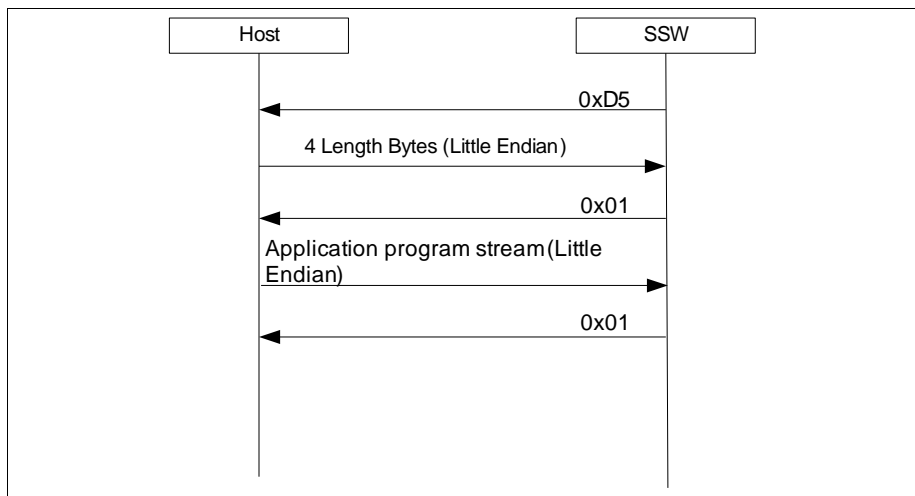

Figure 27-9 Application download protocol

If application length is found to be in error (application length greater than device PSRAM size), a N_OK (2_H) byte is transmitted back to the host and the SSW resumes awaiting the length bytes.

Figure 27-10 Application download protocol FAIL

User actions for ASC BSL mode

User must:

- Configure boot mode pins as described in [Table 27-1](#)
- Reset the device
- Ensure host sends 00_H to the device (used to capture the baud rate)
- Ensure host receives D5_H as acknowledgement from device
- Ensure host sends data length of application and receive a positive acknowledgement
- Ensure host sends the complete application byte stream

Alternatively

- A currently running program can setup SWCON bit field in the SCU.STCON register
- Clear Reset Source in SCU.RSTSTAT using the register RSTCLR.RSCLR
- Issue a system reset
- Ensure host sends 00_H to the device (used to capture the baud rate)
- Ensure host receives D5_H as acknowledgement from device
- Ensure host then sends data length of application and receive a positive acknowledgement
- Ensure host sends the complete application byte stream

27.3.7 CAN BSL mode

The CAN bootstrap loader mode transfers user application via Node-0 or Node-1 of the CAN module into PSRAM.

A stable external clock is mandatory. SSW uses an iterative algorithm to determine the external clock frequency and switches to it. For transfer rates of 1 Mbps it must be ensured by the end user that the external clock is at least 10 MHz.

A protocol comprising three phases described next leads to user application downloaded into PSRAM. Size of downloaded application is only limited by the size of PSRAM on the device.

[Figure 27-11](#) depicts CAN BSL mode procedures.

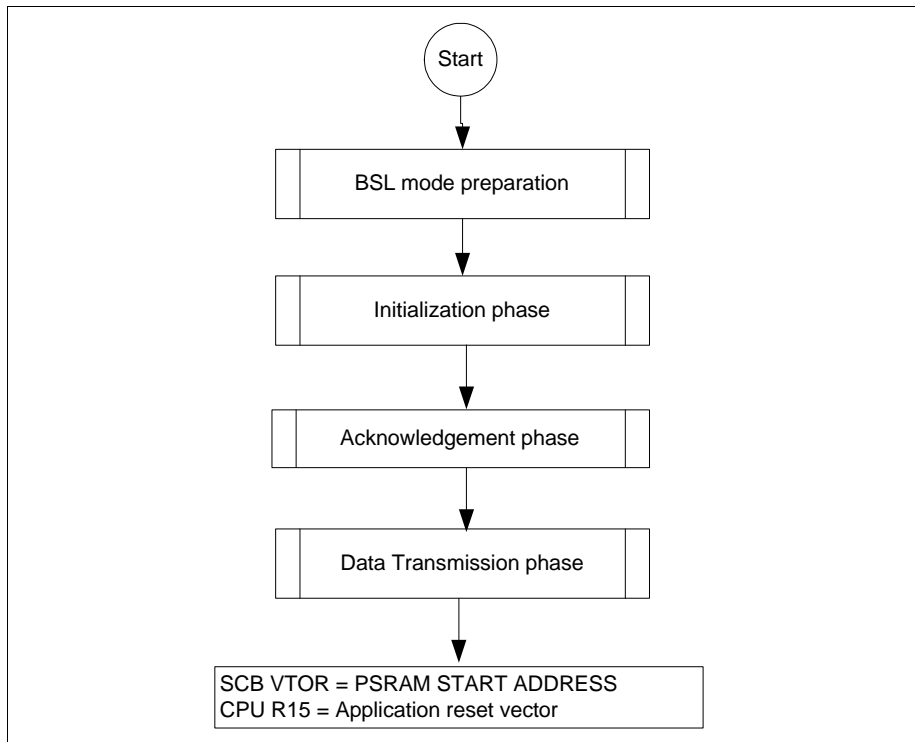

Figure 27-11 CAN BSL procedures

Initialization phase

The baud rate of the host is determined.

SSW switches to external clock source. PLL is brought out of power down mode and configured for pre-scalar mode of operation. The VCO is bypassed and powered down.

A standard CAN base frame comprising eight data bytes is transmitted continuously by the host. The LSB-aligned 11 bit message ID of the frame (555_H) is used by SSW for baud rate detection. Data bytes 0 and 1 contain 'don't care' bytes. Data bytes 2 and 3 contain the acknowledgement identifier which the SSW must use for acknowledging the completion of initialization phase to the host. The next two bytes (4 and 5) indicate the number of eight byte data frames of user application which must be received by SSW and placed into PSRAM, where the total size of the data frames should be selected to be smaller or equal than the available PSRAM size. The last two bytes (6 and 7) indicate the message identifier that would be used by the host while transmitting the user application.

Figure 27-12 Data field of CAN BSL Initialization frame

At start of the BSL port pins P1.4 and P1.5 are used as receive inputs. If the SSW detects initialization frame on P1.4, it would configure P1.5 for TX functionality. If SSW detects initialization frame on P1.5, it configures P1.4 for TX functionality.

Acknowledgement phase

An acknowledgement frame is sent to the host indicating completion of initialization phase.

After SSW computes the baud rate of the host and reconfigures the NBTR register of node-0, it waits until the initialization frame is correctly and fully received. SSW signals its intent to use the bus by transmitting a dominant (0) bit in its ACK slot.

After the dominant bit has been transmitted, an acknowledgement frame using the ACK-ID extracted from the initialization frame is sent to the host. This ACK-ID is used as the LSB-aligned 11-bit message ID and for data bytes 2 and 3. The configured NBTR register value is captured through data bytes 0 and 1. If the size of application intended to be downloaded is greater than the size of PSRAM on the device, a negative acknowledgement as depicted below is sent, where data bytes 4-7 contains the error code of 0xDEADBEEF. SSW enters acknowledgement phase again. If the size of the application is smaller or equal to the PSRAM size, then data byte 4 to 7 of the frame is a direct copy of the equivalent data bytes of the initialization frame. [Figure 27-13](#) depicts data part of acknowledgement frame.

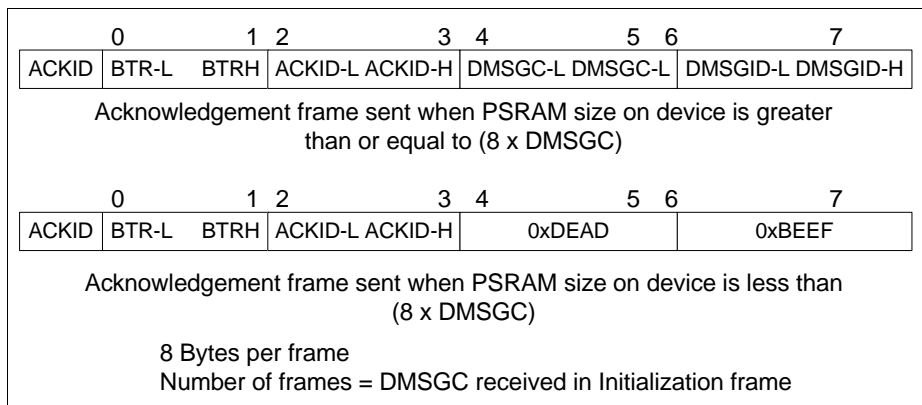

Figure 27-13 CAN Acknowledgement frame

Data transmission phase

Host transmits user application in several CAN frames to the device.

After the SSW transmits the acknowledgement frame, it prepares to receive user application over several CAN frames. Each CAN frame carries eight data bytes and the number of CAN frames is limited to the value retrieved from the DMSGC (Data Message Count) field of the initialization frame. Message identifier is essentially the DMSGID extracted from the initialization frame.

Data received in a frame is placed into PSRAM sequentially. After all frames have been received, SSW cedes control to the first user instruction at the start of PSRAM.

User actions for CAN BSL mode

User must:

- Configure the boot mode pins as described in [Table 27-1](#)
- Reset the device
- Ensure CAN host continuously transmits initial frame described in [Figure 27-12](#)
- Ensure host receives acknowledgement frame and transmits the application stream

27.3.8 Boot Mode Index (BMI)

BMI provides a provision for end user to customize boot sequence. A 32 bit BMI word describes a set of activities that must be performed by SSW. The BMI word must be programmed into page-1 of User Configuration Block-2 (UCB2-Page1).

BMI word along with associated parameters is known as the BMI string. [Figure 27-14](#) depicts this pictorially.

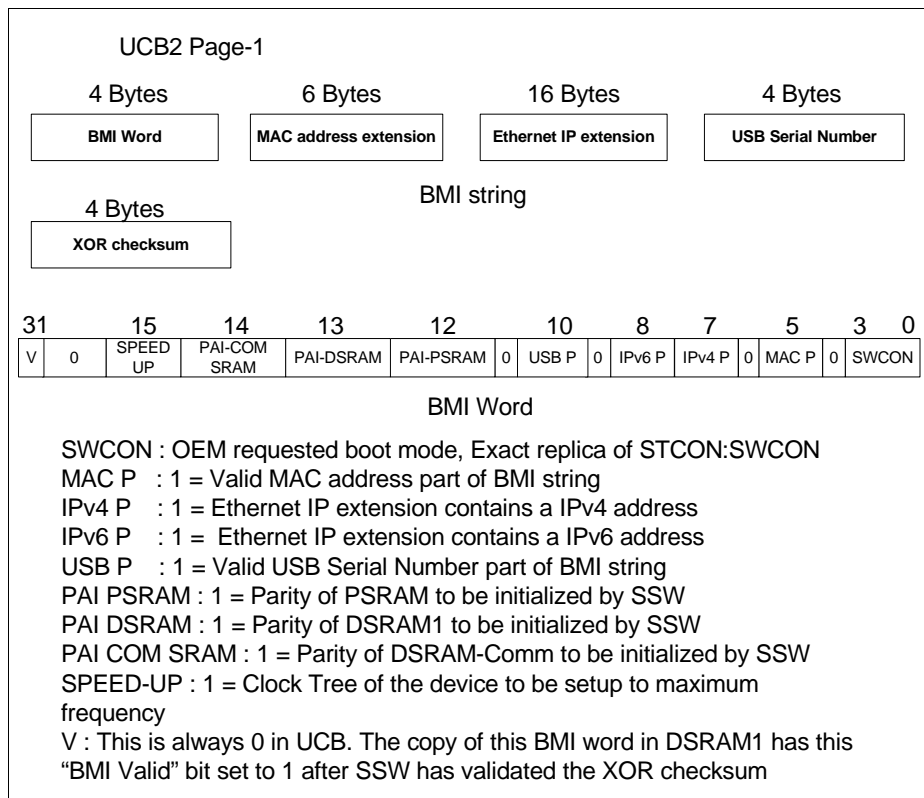

Figure 27-14 BMI String layout

The BMI string is written into UCB2-Page1 by the customer. SSW upon a any reset copies the BMI string into a 64 byte location on DSRAM-1([Figure 27-4](#)). A 4 byte XOR checksum is appended to the string.

Of the 64 bytes, the BMI string is stored starting from the lowest address with the BMI word stored first followed by the MAC address, IP address and USB serial number.

All elements of the BMI string and the XOR checksum are stored in little-endian format. SSW performs byte wise XOR checksum over the 30 bytes BMI string. The checksum variable is initialized with zero and then XOR-ed with the first byte of the BMI string. The resulting checksum is then XOR-ed again with the second byte, and the operation continues until the last byte of the BMI string.

All elements of BMI string are stored linearly without any holes. Following table provides details of the layout.

Table 27-3 BMI string layout offset table

| Element | Offset |
|---------------------------|---------------|
| BMI Word (LSB) | 0 |
| MAC (LSB) | 4 |
| IP address (LSB) | 10 |
| IP address (MSB) for IPv4 | 13 |
| IP address (MSB) for IPv6 | 25 |
| USB serial number (LSB) | 26 |
| XOR checksum | 33 |

Details of actions taken by SSW are listed in the [Figure 27-15](#).

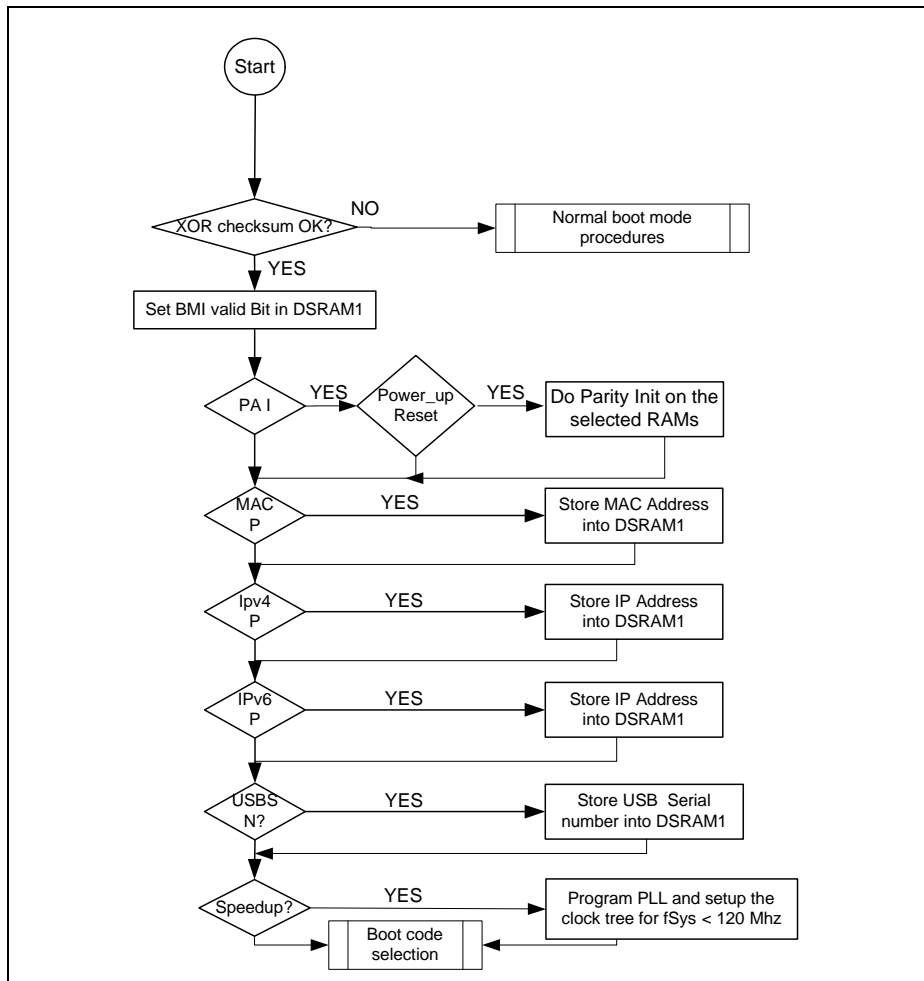

Figure 27-15 BMI Actions

The BMI Speedup feature yields a frequency which is never guaranteed to be maximum system frequency. This is due to the fact that the source clock provided as input to PLL is the fast internal clock f_{OFI} which is never an accurate 24 MHz. SSW programs PLL to ensure that f_{sys} is lower than maximum system frequency.

User actions for BMI

User must:

- Flash BMI string into the User Configuration Block (UCB2-Page1)
- Configure boot mode pins as described in [Table 27-1](#)
- Reset the device

Alternatively

- A currently running program can setup SWCON bit field in the SCU.STCON register
- Clear Reset Source in SCU.RSTSTAT using the register RSTCLR.RSCLR
- Issue a system reset

27.4 Debug behavior

This section describes the Halt after reset (HAR), flash protection, debugger access and diagnostics monitor mode features.

27.4.1 Boot modes and hardware debugger support

The SSW cannot be debugged. It is not possible to halt the CPU after a reset until the SSW has finished its execution. The SSW disables the coresight module thus inhibiting installation of breakpoints and watchpoints. All memory accesses that can otherwise be requested over the debug bus are also inhibited. The coresight module is enabled subject to certain conditions at the time when SSW has finished its activities and is about to cede control to user applications.

Halt after reset feature

Halt after reset feature results in halting of the CPU when the first instruction from the user program enters the CPU pipeline. This is implemented only for Normal boot mode, ABM-0 and ABM-1. It is further applicable only for a PORST case. A breakpoint is installed at the address retrieved from reset vector location of the application exception vector table. However for this to happen, the hardware debugger is expected to have registered its request with coresight for halting the CPU.

The CPU simply cannot be halted while the SSW executes. The hardware debugger can only register a halt request with the coresight while the SSW is executing. This request is picked up by SSW towards the end of its execution resulting in installation of breakpoint on the first user application instruction.

Debugger support after SSW execution

Debugger support is enabled after SSW execution. But this is subject to the state of flash protection. As long as the user flash is not protected, user programs can be debugged. Should the SSW detect that flash has been password protected, it disables the coresight (ARM debug) interface. Hence debugging is not possible on flash protected devices.

Flash access after SSW execution

Special attention must be paid to the table below. Flash access is unconditionally provided for Normal and ABM boot modes regardless of flash protection. CPU can fetch CODE and RO-DATA from the program flash for the two boot modes. Flash access is however only conditionally permitted for BSL and PSRAM boot modes. [Table 27-4](#) lists the criteria for flash and debugger accesses.

Table 27-4 Flash and Debug access policy

| HWCON/SWCON | Flash protected | Flash access | Debugger access |
|-----------------|-----------------|--------------|-----------------|
| UART/CAN BSL | N | Y | Y |
| UART/CAN BSL | Y | N | N |
| Normal/ABM | N | Y | Y |
| Normal/ABM | Y | Y | N |
| Boot from PSRAM | N | Y | Y |
| Boot from PSRAM | Y | N | N |

Empty flash and debugger behavior

A value of 00000000_H at 0C000004_H (Reset vector) indicates empty flash. In case the SSW detects this values a safe loop in SSW is entered. A hardware debugger can be attached in that situation to program the flash with a user application.

27.4.2 Failures and handling

It is possible to find out the progress made by SSW during its execution and also the reason for boot failures.

Diagnostics Monitor Mode (DMM)

During its course of execution, SSW has either something normal to trace or an error to report. Access to the Coresight system is disabled during SSW execution.

The SCU provides a dedicated register SCU_TSW0 which the SSW can write to. SCU_TSW0 is mirrored by the TCU (Test Control Unit) and the latter's contents can be conveniently scanned out.

This register is known as the TRACE_ERROR_REG and the JTAG instruction for accessing it is the FW_TRACE_ERR (63_H).

Errors classified as recoverable result in a watchdog reset. Fatal errors require a PORST. The power consumption is reduced to a minimum level.

[Figure 27-16](#) represents this concept.

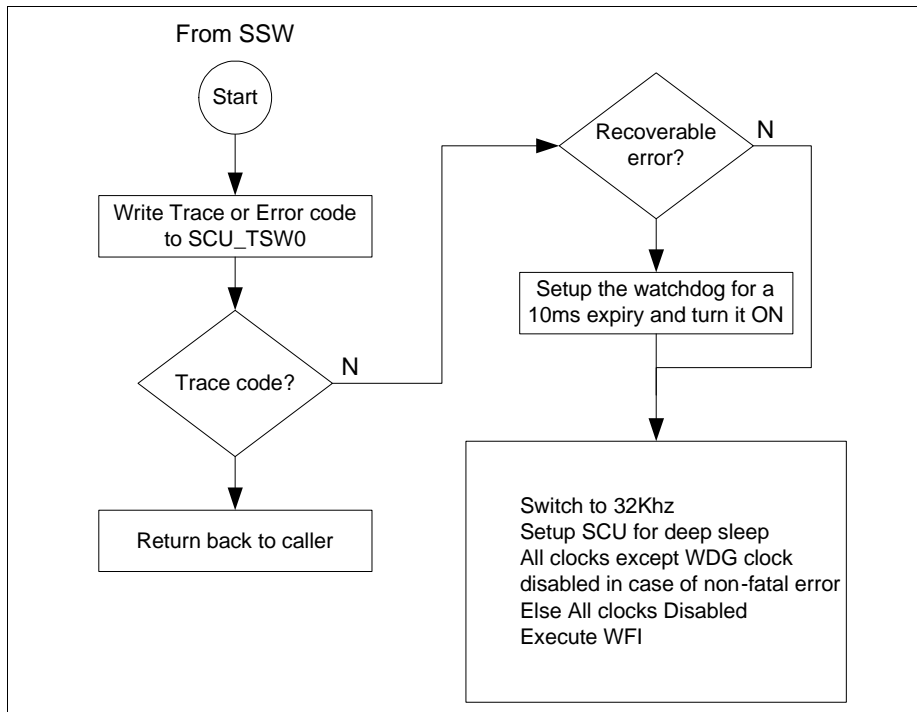

Figure 27-16 Diagnostics monitor mode

Encoding of the trace word

SSW can write a 32 bit word representing either a trace code or an error code. TSW0[15:0] represents the code. TSW0[17:16] represent the code type.

A code type of 0b00 represents invalid code contents, 0b01 represents a trace code, 0b10 represents a fatal error and 0b11 represents a non fatal error.

TSW0[31:18] bits are currently reserved.

List of errors and their classification

Table 27-5 lists errors that lead to SSW launching DMM.

Table 27-5 Error events and codes

| Event | Severity | 16 bit Code |
|--------------------------------|----------|-----------------|
| Flash rampup error | Fatal | 1 _H |
| FCS CRC mismatch | Fatal | 2 _H |
| Invalid SWCON | Fatal | 3 _H |
| MBIST error | Fatal | 4 _H |
| PSRAM boot header CRC mismatch | Fatal | 5 _H |
| ABM header CRC mismatch | Fatal | 6 _H |
| Invalid bootcode | Fatal | 7 _H |
| NMI exception | Fatal | 8 _H |
| Hardfault exception | Fatal | 9 _H |
| Memory management exception | Fatal | A _H |
| Busfault exception | Fatal | B _H |
| Usage fault exception | Fatal | C _H |
| ASC baudrate calculation error | Fatal | D _H |
| Invalid BMI password error | Fatal | E _H |
| EVR rampup error | Fatal | F _H |
| ASC BSL receive error | Fatal | 10 _H |
| CAN BSL errors | Fatal | 11 _H |

27.5 Power, Reset and Clock

SSW operates at 24 MHz. The fast internal oscillator provides the system clock frequency (f_{OFI}). Frequency scaling is conditionally performed in BMI boot mode of operation based on the BMI word.

Registers modified by SSW

SSW during its course of execution modifies default register settings of a few registers. They are listed in [Table 27-6](#).

Table 27-6 Registers modified by SSW

| Startup mode | Register | Bitfield | Value |
|--------------|-------------|----------------------------|---|

Debug and Trace System

28 Debug and Trace System (DBG)

The XMC4[78]00 Series Microcontrollers provide a large variety of debug, trace and test features. They are implemented with a standard configuration of the ARM CoreSight™ module together with a daisy chained standard TAP controller. Debug and trace functions are integrated into the ARM Cortex-M4. The debug system supports serial wire debug (SWD) and trace functions in addition to standard JTAG debug and parallel trace.

28.1 Overview

The Debug and Trace System implements ARM CoreSight™ debug and trace features with the objective of debugging the entire SoC. The CoreSight™ infrastructure includes a debug subsystem and a trace subsystem. The debug functionality includes processor halt, single-step, processor core register access, Vector Catch, unlimited software break points and full system memory access. The debug function includes a breakpoint unit supporting 2 literal comparators and 6 instruction comparators and a watchpoint unit supporting 4 watchpoints. The processing element (CPU) is paired with an instruction/data ETM (ETM-M4). CoreSight™ enables different trace sources to be enabled into one stream. The unique trace stream, marked with suitable identifiers and timestamps. Trace can be done using either a 4-bit parallel or a Serial Wire interface. Less data can be traced with Serial Wire interface, but only one output pin is required for application. Parallel trace has a greater bandwidth, but uses 5 more pins.

Features

The accurate Debug and Trace System provides the following functionality:

- Serial Wire Debug Port (SW-DP)
- JTAG Debug Port (SWJ-DP)
- Flash Patch Breakpoint (FPB)
- Data Watchpoint and Trace (DWT)
- Embedded Trace Module (ETM)

Debug and Trace System (DBG)

- Instrumentation Trace Macrocell (ITM)
- Trace Port Interface Unit (TPIU)
- Halt after reset (HAR)

Note: Please refer to ARM Reference Documentation Cortex-M4-r0p0 for more detailed information on the debug and trace functionality.

Application Mapping

Table 28-1 Debug System available features mapped to functions

| | |
|--------|--|
| SW-DP | Provides Serial Wire Debug, which allows to debug via 2 pins. Instrumentation Trace is provided via a third pin. |
| SWJ-DP | This debug port provides native JTAG debug capabilities. |
| FPB | The FPB implements hardware breakpoints and patches code and data from code space to system space. |
| DWT | Implemented watch points, trigger resources, and system profiling. The DWT contains four comparators that can be configured as a hardware watchpoint, an ETM trigger, a PC sampler event trigger or a data address sampler event trigger, data sampler, interrupt trace and CPU statistics |
| ETM | The ETM provides Instruction Trace capabilities |
| ITM | Application driven trace source, supports printf style debugging. The ITM generates trace information as packets out of four sources (Software Trace, Hardware Trace, Time Stamping and Global System Time Stamping). |
| TPIU | The TPIU encodes and provides trace information to the debugger. As ports the single wire viewer (TRACESWO) or 4-bit Trace Port (TRACEDATA[3:0], TRACECLK) can be used. |
| HAR | Allows to halt the CPU before application code is entered. |

Debug and Trace System (DBG)

Block Diagram

The Debug and Trace system block diagram is shown in [Figure 28-1](#).

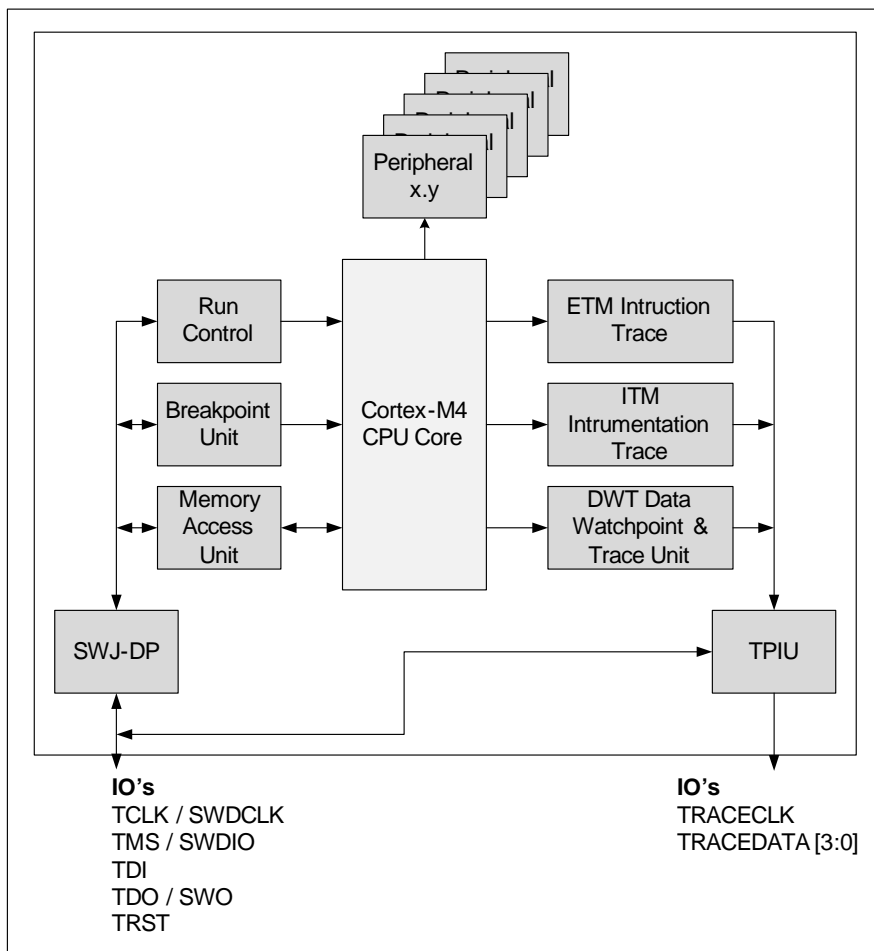

Figure 28-1 Debug and Trace System block diagram

28.2 Debug System Operation

The Debug System provides general debug options and additional trace functions. Debug options are based on break points and CPU halt. The trace capability supports data access trace and instruction execution trace.

28.2.1 Flash Patch Breakpoint (FPB)

The FPB implements hardware breakpoints. Six instruction comparators can be configured to generate a breakpoint instruction to the CPU on a match. The original M4 code patch function is not available.

28.2.2 Data Watchpoint and Trace (DWT)

The four DWT comparators can be configured to generate PC sampling packets at defined intervals, PC or Data watch point packets and a Watch point event to halt the CPU. To enable the features, the DWT provides counters with clock cycle, folded instructions, load store unit operation, sleep cycles, clock per instruction and interrupt overhead count.

28.2.3 Instrumentation Trace Macrocell (ITM)

The ITM supports printf style debugging and is an application trace source. The ITM is available to trace application software execution, and allows to emit diagnostic system information. Three different sources are supported to emit trace information as packet, which are software trace, hardware trace and time stamping. The software trace allows software to write directly to ITM stimulus register using printf function. For hardware trace the ITM emits packets generated by the DWT. Relative to packets the ITM emits timestamps, which are generated by a 48-bit counter. The packets emitted by the ITM are output to the trace port interface (TPIU). The TPIU formatter adds some extra packets and then outputs the complete packet sequence to the debugger. The ITM function can be activated by the TRCEN register bit, which is located in the Debug Exception and Monitor control register. ITM data can also be transferred using the Serial Wire interface. The ITM data are the only Trace source data which can be transferred via the Serial Wire interface.

28.2.4 Embedded Trace Macrocell (ETM)

The ETM enables program execution reconstruction. As a short description, data are traced using the DWT component or the ITM, whereas instructions are traced using ETM. The ETM transmits the information as packets and is triggered by internal resources. These internal trigger resources must be programmed independently and the trigger source is selected using the available Trigger Event Register. Available events are address match, provided by an address comparator or a logic equation between two events. The trigger source are one of the DWT module provided comparators (four are

Debug and Trace System (DBG)

available). This allows to monitor clock cycle matching events and data address matching events. The packets which are generated by the ETM are transmitted on the Trace Port output Unit (TPIU). The TPIU adds some extra packets and transmits the complete packet sequence to the debug tool.

28.2.5 Trace Port Interface Unit (TPIU)

The TPIU collects on-chip trace data from ITM and ETM and sends this debug data to the external trace capture hardware. The TPIU uses dedicated trace ports. Maximum available trace ports are four.

28.3 Power, Reset and Clock

For requirements based on power, reset and clock signaling consult CoreSight™ Technology System Design Guide [24] for detailed information. Note, there is no power management implemented for the debug system.

28.3.1 Reset

Reset and implementation is provided according to the ARM reference documentation [22].

28.3.1.1 CoreSight™ resets

The SWJ-DP and SW-DP register are in the power on reset domain. Besides this reset a tool controlled Debug reset can be generated based on a debug register configuration. Activating the reset request in the debug control and status register results in an activation of the CTRL/STAT.CDBGSTREQ. The reset allows a debugger to reset the debug logic in a CoreSight™ system without affecting the functional behavior of the target system. The Debug logic is reset by system reset, if no tool is registered at the debug system.

System Reset (Warm Reset)

A System or warm reset initializes the majority of the processor, excluding NVIC and debug logic, (FPB, DWT, and ITM). The System reset affects the Debug system only, if the tool is not registered (CTRL/STAT.CDBGPWRUPREQ not set).

SWJ-DP reset

nTRST reset initializes the state of the JTAG SWJ-DP TAP controller. Normal processor operation is not affected.

SW-DP reset

Only the PORESETn reset initializes the SW-DP and the other debug logic.

Normal operation

During normal operation the resets PORESETn SYSRESETn and DAPRESETn are deasserted. If the SWJ-DP or SWDP ports are not in use, nTRST must be tied to 0 or 1.

28.3.1.2 Serial Wire interface driven system reset

The CTRL/STAT.SYSRESETREQ allows to reset the CPU core in Serial Wire interface mode. The CTRL/STAT.SYSRESETREQ is asserted when the CTRL/STAT.SYSRESETREQ bit of the Application Interrupt and Reset Control register is set. This causes a reset, intended to force a large system reset of all major components, except for debug logic. [25].

28.4 Initialization and System Dependencies

This chapter provides information about Debug access and Flash protection, Halt After Reset sequences, Halting Debug and Peripheral suspend, Timestamping for Trace and the available tool interfaces and how to enable the tool interface. Additionally the ID Codes and the ROM Table is presented, including the values a debug tool uses to identify the device and available debug functionality. The last section shows the JTAG Debug instruction code definition.

28.4.1 Debug accesses and Flash protection

The Flash has integral measures to protect its content from unauthorized access and modification, see the section Read and Write Protection in the PMU chapter and startup chapter. Special care is taken, that the debugger can't bypass this protection. Because of this, per default and after a system reset the debug interface is disabled. Depending on the boot scenario and the Flash protection setup, the Startup Software enables the debug interface. If it is left disabled, the user can define a protocol, e.g. a password-protected unlock sequence via an SPI port, to enable the debug interface.

28.4.2 Halt after reset

The XMC4[78]00 product supports two different possibilities of halt after reset. One after a power on reset ("Power-on Reset"), which is called Cold Reset Halt situation or Halt after reset (HAR) and the second one after a system reset, which is called Warm Reset Halt situation. For a HAR the debug tool has to register during the start up software (SSW) execution time. The SSW halts at the end of SSW on a successful tool registration, before application code is entered. The Warm Reset Halt is based on break point setting on the very first application code line and is entered by a system reset.

Debug and Trace System (DBG)

For security reasons it is required to prevent a debug access to the processor before and while the boot firmware code from ROM (SSW) is being executed. A bit DAPSA, (DAP has system access) in the SCU is implemented, allowing the access from CoreSight™ debug system to the processor core. The default value of this bit is disabled debug access. The register is reset by System Reset. The System Reset disables the debug access each time SSW is being executed. At the end of the SSW the DAPSA is enabled always (independent of any other register setting or signaling value), to allow debug access to the CPU. A tool accessing the SoC during the SSW execution time reads back a zero and a write is going to a virtual, none existing address.

In a HAR situation the system always comes from a "Power-on Reset". A tool can register for a HAR by sending a pattern enabling the CTRL/STAT.CDBGPWRUPREQ and the DHCSR.C_DEBUGEN [28] register inside the CoreSight™ module. The registration has to be done after the "Power-on Reset" in a time interval smaller then the time the SSW is executed. This registration time is called tssw and the bits must be set before tssw is expired. The timing value for tssw needs to be handled by the debug tool software (no hardware timer available) and informs the tool software during a Cold Reset about the time frame available to set the HAR conditions.

The following figure (**Figure** HAR - Halt After Reset) shows the software flow based on the modules participating to the HAR.

Debug and Trace System (DBG)

The following Figure (Figure Hot Plug and Warm Reset) illustrates the debug tool HOT PLUG situation or the Halt after Warm Reset (system reset) and how to proceed to come to a Halt situation.

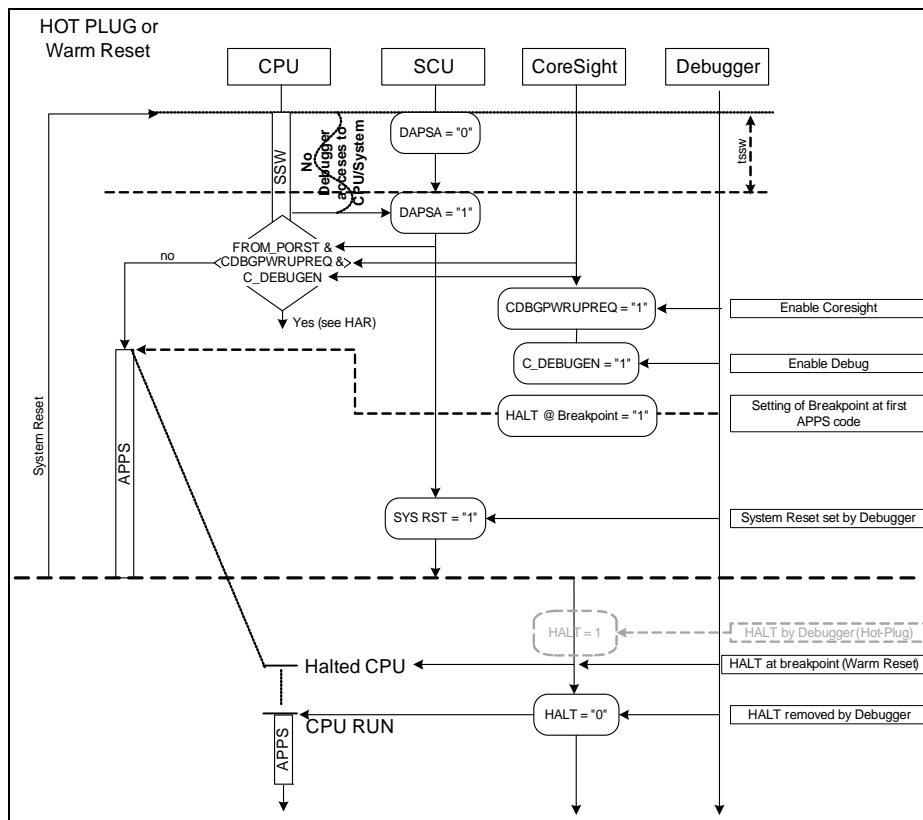

Figure 28-3 HOT PLUG or Warm Reset

28.4.3 Halting Debug and Peripheral Suspend

If the program execution of the CPU is stopped by the debugger, e.g. with a breakpoint, it is possible to suspend the peripherals as well. This allows to debug critical states of the whole microcontroller. It is particularly useful, e.g. to suspend the Watchdog Timer as it can't be serviced by a halted CPU.

In other cases it is important to keep some peripherals running, e.g. a PWM or a CAN node, to avoid system errors or even critical damage to the application. Because of this,

Debug and Trace System (DBG)

the peripherals allow to configure how they behave when the CPU enters the halting debug mode.

It can be decided at the peripheral to support a Hard Suspend or a Soft Suspend. At a Hard Suspend situation the clock at the peripheral is switched off immediately, without waiting on acknowledge from the module. At a soft suspend the peripheral can decide when to suspend, usually at the end of the actual active transfer.

A Watchdog timer is only running when the suspend bus is not active. This is particularly useful as it can't be serviced by a halted CPU. A configuration option is available, which allows to enable the Watchdog timer also during suspend. This allows to debug Watchdog behavior, if a debugger is connected.

The user has to ensure, that always only those peripherals are sensitive to suspend, which are intended to be. To address this, each peripheral supporting suspend does have an enable register which allows to enable the suspend feature. The following table (**Table 28-2**) shows the peripherals, supporting or not supporting peripheral suspend or detailed information on the peripheral suspend behavior during soft suspend can be found at the respective peripheral chapter.

Table 28-2 Peripheral Suspend Support

| Peripheral | Supported | Default mode | Hard Suspend | Soft Suspend | Suspend Reset |
|---------------------|-----------|--------------|--------------|--------------|---------------|
| RTC | no | --- | --- | --- | --- |
| WDT ¹⁾ | yes | active | yes | no | system reset |
| LEDTS | yes | not active | yes | no | debug reset |
| SDMMC | no | --- | --- | --- | --- |
| EBU | no | --- | --- | --- | --- |
| ETH | no | --- | --- | --- | --- |
| USB | no | --- | --- | --- | --- |
| ECAT | no | --- | --- | --- | --- |
| USIC | yes | not active | no | yes | debug reset |
| MultiCAN | yes | not active | yes | yes | debug reset |
| VADC | yes | not active | yes | yes | debug reset |
| DSD | yes | not active | yes | yes | debug reset |
| DAC | no | --- | --- | --- | --- |
| CCU4 ¹⁾ | yes | not active | yes | yes | system reset |
| CCU8 ¹⁾ | yes | not active | yes | yes | system reset |
| POSIF ¹⁾ | yes | not active | yes | yes | system reset |

Debug and Trace System (DBG)

- 1) A system reset results in a suspend configuration loss. If it is required to have suspend configuration available after system reset, a HW breakpoint has to be set at the first instruction of use code and reconfiguration of suspend behavior at the peripheral has to be performed again.

28.4.4 Timestamping

A 48-bit timestamping capability is required by the debug system in order to get accurate correlation between the ETM trace and trace data from ITM and DWT. This is also named global timestamping. Timestamp packets encode timestamp information, generic control and synchronization information. The Timestamp counter is a free running global counter.

A synchronization packet is a timestamp packet control. It is emitted at each DWT trigger (DWT must be configured to trigger the ITM).

28.4.5 Debug tool interface access (SWJ-DP)

Debug capabilities can be accessed by a debug tool via Serial Wire (SW) or JTAG interface (JTAG - Debug Port). By default, the JTAG interface is active. The User might switch to SW interface as the full JTAG pins are not available to the user. To enable SW interface a dedicated JTAG sequence on TMS/SWDIO and TCK/SWCLK is required to switch to the Serial Wire Debug interface. A successful sequence disables JTAG interface and enables SW interface.

The sequences to do this are described in [Section 28.4.5.1](#) and [Section 28.4.5.2](#)

28.4.5.1 Switch from JTAG to SWD

The sequence for switching from JTAG to SWD is:

- Send 50 or more TCK cycles with TMS = 1
- Send the 16-bit sequence on TMS = 1110011110011110 (0xE79E LSB first)
- Send 50 or more TCK cycles with TMS = 1

28.4.5.2 Switch from SWD to JTAG

The sequence for switching from SWD to JTAG is:

- Send 50 or more TCK cycles with TMS = 1
- Send the 16-bit sequence on TMS = 1110011100111100 (0xE73C LSB first)
- Send 50 or more TCK cycles with TMS = 1

28.4.6 ID Codes

Available ID Codes are used by a debug tool to identify the available debug components during tool setup.

Table 28-3 ARM CoreSight™ Component ID codes

| ID | Value ¹⁾ | Description |
|-------------|------------------------|---------------------|
| JTAG IDCODE | XXXX X083 _H | The TAP JTAG IDCODE |
| SWJ-DP | 4BA0 0477 _H | The ARM JTAG ID |
| SW_DP | 2BA0 1477 _H | The ARM SW-DP ID |

1) For "X" values please refer to Data Sheet

28.4.7 ROM Table

To identify Infineon as manufacturer and XMC4[78]00 as device, the ROM table has to be read out.

Table 28-4 Peripheral ID Values of XMC4[78]00 ROM Table

| Name | Offset | Value ¹⁾ | Bits | Reference | Infineon JTAG ID Code |
|------|------------------|-----------------------|-----------------------|---|---|
| PID0 | FE0 _H | XXXXXXXX _B | [7:0] | Part Number [7:0] | JTAG IDCODE [19:12] |
| PID1 | FE4 _H | 0001XXXX _B | [7:4] [3:0] | JEP106 ID code [3:0] Part Number [11:8] | JTAG IDCODE [4:1] JTAG IDCODE [23:20] |
| PID2 | FE8 _H | XXXX1100 _B | [7:4] [3] [2:0] | Revision JEDEC assigned ID fields JEP106 ID code [6:4] | JTAG IDCODE [31:28] '1' JTAG IDCODE [7:5] |
| PID3 | FEC _H | 00000000 _B | [7:4] [3:0] | RevAnd, minor revision field Customer-modified block (if non-zero) | |
| PID4 | F00 _H | 00000000 _B | [7:4] [3:0] | 4KB count JEP106 continuation code | 4KB count JTAG IDCODE [11:8] |

1) For "X" values please refer to Data Sheet

28.4.8 JTAG debug port

A standard JTAG IEEE1149 Boundary-Scan statemachine is implemented. It includes all mandatory instructions (SAMPLE/PRELOAD, EXTEST) and also some optional instructions (IDCODE, CLAMP, HIGHZ), and some custom/optional instructions are implemented. The optional RUNBIST instruction is not used and will be treated as BYPASS. No USERCODE-instruction is implemented, it will show only 0 values

Table 28-5 JTAG INSTRUCTIONS

| Opcode | Range | Type | Instruction |
|--------------------------|-------------------------|---------------------------|----------------|
| 0000 0000 | 00H | Reserved | |

JTAG Instruction Definition

BYPASS

The BYPASS instruction bypasses all serial register path, which are accessed over the JTAG TAP port. In the Capture-DR state the rising edge of the TCK clock sets the bypass register to zero. The bypass instruction is primarily used to allow a shorter access path to cascaded devices when the JTAG interface connects a number of devices in series. All unused instructions must connect the TAP controller bypass register output to the Test Access Port output TDO. The BYPASS instruction has no effect on the operation of the device.

28.5 Debug System Registers

For CoreSight™ register overview and detailed register definitions, please refer to ARM documentation CoreSight™ Components Technical Reference Manual [25] and ARMv7-M Architecture Reference Manual [28].

28.6 Debug and Trace Signals

XMC4[78]00 MC Product family provides debug capability using ARM CoreSight™ Debug port SWJ-DP. SWJ-DP includes two debug interfaces namely JTAG Debug Port (JTAG-DP) and Serial Wire Debug Port (SW-DP).

The JTAG-DP interface has 4 (without Reset pin TRST for low pin package) or 5 Pins, see [Table 28-6](#).

The serial wire Debug Port has 2 (Clock + Bidirectional data) or 3 pins (Clock + Bidirectional data + Asynchronous Trace output). They are overlaid on the JTAG-DP pins (TCK, TMS and TDO) for efficient use of package pins, see [Table 28-7](#).

Additionally 5 ETM trace port output signals (TRACECLK, TRACEDATA[3:0]) are available, see [Table 28-8](#).

Sub chapters below additionally describe pull resistors to the IO and the suggested debug connector pin assignment.

Table 28-6 JTAG Debug signal description

| Signal | Direction | Function |
|--------|-----------|---|
| TCK | I | JTAG Test Clock. This pin is the clock for debug module when running in JTAG debug mode. |
| TMS | I | JTAG Test Mode Select. The TMS pin selects the next state in the TAP state machine. |
| TDI | I | JTAG Test Data In. This is the serial data input for the shift register |
| TDO | O | JTAG Test Data Output. This is the serial data output from the shift register. Data is shifted out of the device on the negative edge of the TCK signal |
| TRST | I | JTAG Test reset. |

Table 28-7 Serial Wire Debug signal description

| Signal | Direction | Function |
|--------|-----------|---|
| SWDCLK | I | Serial Wire Clock. This pin is the clock for debug module when running in Serial Wire debug mode. |
| SWDIO | I / O | Serial Wire debug data IO. Used by an external debug tool to communicate with and control the Cortex-M4 CPU. |
| SWO | O | Serial Wire Output. The SWO pin provides data from the ITM and/or ETM for an external debug tool to evaluate the instrumentation trace. |

Table 28-8 ETM Trace Port signal description

| Signal | Direction | Function |
|----------------|-----------|--|
| TRACECLK | O | Trace Clock. Provides the sample clock for trace data on the TRACEDATA pins when tracing is enabled by an external tracing tool. |
| TRACEDATA[3:0] | O | Trace Data bits 3 to 0. Provide ETM trace data when tracing is enabled by an external debug tool. The debug tool can interpret the compressed information and make it available to the user. |

ETM Trace port output enable

The ETM module allows to control the trace port signal on a shared GPIO at the IO port level. The enabling is done by the tool software, by configuring in the ETM main Control register (ETMCR) [23].

28.6.1 Internal pull-up and pull-down on JTAG pins

It is a requirement to ensure none floating JTAG input pins, as they are directly connected to flip-flops controlling the debug function. To avoid any uncontrolled I/O voltage levels internal pull-up and pull-downs on JTAG input pins are provided.

- TRST: Internal pull-down
- TMS/SWDIO: Internal pull-up
- TCK/SWCLK: Internal pull-down

28.6.2 Debug Connector

The suggested connector is the Cortex Debug and ETM connector, which is a 20-pin connector. The connector supports JTAG debug, Serial-Wire debug, Serial Wire viewer (via SWO connection when Serial Wire debug mode is used) and instruction trace operations. The following **Figure 28-4** shows the 20-pin connector for debug and trace.

There may be systems, which required HW to detect debugger presence. This can be enabled by using the GNDDetect pin of the Debug and Trace connector. The pin is driven low by the tool, when the tool connector is plugged into the connector at the PCB. GNDDetect for tool detection requires to have a weak pull-up on the PCB, connected to this pin. At the connector it is suggested not to have the KEY pin available as the KEY is used to identify the correct connector plug-in.
