Legal Disclaimer

The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office.

Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Revision History: V1.1 2015-10

Previous Versions:

V1.0 2015-06

| Page | Subjects (major changes since last revision) |
|---|---|
| 2-83, 2-108ff. | Updated CPU chapter <ul style="list-style-type: none"> Bit field names of AFSR and MVFRx registers corrected to match CMSIS SVD format ruling |
| 4-35ff., 4-38ff. | Updated Service Request Processing chapter <ul style="list-style-type: none"> ERU0 outputs not connected directly to NVIC but routed through SCU. Corrected in ERU0 tables. Added ECAT0 connections in both ERU0 and ERU1 tables |
| 11-1ff. | Updated SCU chapter for consistence with ECAT0 |
| 16-1ff. | Updated ECAT chapter to V1.0 revision tracking starts with this version |
| 18-83ff. 18-247 | Updated USIC chapter <ul style="list-style-type: none"> Description on the case where the slave generates PDL as the parity bit is added Wrong USIC2_CH1.DX0E assignment is fixed, from CAN1INS to P4.6 in the interconnects table |
| 19-15ff., 19-31f., 19-67, 19-75f., 19-87, 19-102, 19-114 | Updated MultiCAN+ chapter <ul style="list-style-type: none"> Clarified usage of fractional divider for high baud rates Corrected f_{CAN} to f_{CLC} in section on automatic baudrate detection Removed f_{CANB} as source for MCR.CLKSEL bit field Corrected that only NCRx.INIT is affected by NCRx.CANSDIS bit field Corrected f_{CAN} to f_{CLC} in NFCRx.CFC bit field Removed MOFCRn.RXTOE bit field Corrected access modes for write access |
| 20-133 | Updated VADC chapter <ul style="list-style-type: none"> Corrected number of channels with alternate reference |
| 26-30ff., 26-39ff. | Updated PORTS chapter <ul style="list-style-type: none"> Swapped RTC_XTAL pins |
| 27-1ff. | Updated Startup Modes chapter for clarity, improved figures |

Trademarks

C166™, TriCore™, XMCTM and DAVE™ are trademarks of Infineon Technologies AG.
ARM®, ARM Powered®, Cortex®, Thumb® and AMBA® are registered trademarks of ARM, Limited.

CoreSight™, ETM™, Embedded Trace Macrocell™ and Embedded Trace Buffer™ are trademarks of ARM, Limited.

Synopsys™ is a trademark of Synopsys, Inc.

We Listen to Your Comments

Is there any information in this document that you feel is wrong, unclear or missing?
Your feedback will help us to continuously improve the quality of this document.

Table of Contents

| | | |
|----------|--|------|
| 1 | Introduction | 1-1 |
| 1.1 | Architectural Overview | 1-1 |
| 1.1.1 | Block Diagram | 1-3 |
| 1.2 | System Core Components | 1-3 |
| 1.3 | On-Chip System Resources | 1-5 |
| 1.3.1 | Memories | 1-5 |
| 1.4 | Bus System | 1-6 |
| 1.4.1 | Bus Matrix | 1-6 |
| 1.4.2 | Bus Interfaces | 1-7 |
| 1.5 | Communication | 1-8 |
| 1.6 | Analog Frontend | 1-10 |
| 1.7 | Industrial Control | 1-10 |
| 1.8 | On-Chip Debug Support | 1-11 |
| 2 | Central Processing Unit (CPU) | 2-1 |
| 2.1 | Overview | 2-1 |
| 2.1.1 | Features | 2-2 |
| 2.1.2 | Block Diagram | 2-2 |
| 2.2 | Programmers Model | 2-4 |
| 2.2.1 | Processor Mode and Privilege Levels for Software Execution | 2-4 |
| 2.2.2 | Stacks | 2-4 |
| 2.2.3 | Core Registers | 2-6 |
| 2.2.4 | Exceptions and Interrupts | 2-17 |
| 2.2.5 | Data Types | 2-17 |
| 2.2.6 | The Cortex Microcontroller Software Interface Standard | 2-17 |
| 2.2.7 | CMSIS functions | 2-18 |
| 2.3 | Memory Model | 2-20 |
| 2.3.1 | Memory Regions, Types and Attributes | 2-20 |
| 2.3.2 | Memory System Ordering of Memory Accesses | 2-21 |
| 2.3.3 | Behavior of Memory Accesses | 2-22 |
| 2.3.4 | Software Ordering of Memory Accesses | 2-23 |
| 2.3.5 | Memory Endianness | 2-24 |
| 2.3.6 | Synchronization Primitives | 2-24 |
| 2.3.7 | Programming Hints for the Synchronization Primitives | 2-26 |
| 2.4 | Instruction Set | 2-26 |
| 2.5 | Exception Model | 2-26 |
| 2.5.1 | Exception States | 2-26 |
| 2.5.2 | Exception Types | 2-27 |
| 2.5.3 | Exception Handlers | 2-29 |
| 2.5.4 | Vector Table | 2-30 |
| 2.5.5 | Exception Priorities | 2-31 |

Table of Contents

| | | |
|----------|--|------------|
| 2.5.6 | Interrupt Priority Grouping | 2-31 |
| 2.5.7 | Exception Entry and Return | 2-32 |
| 2.6 | Fault Handling | 2-36 |
| 2.6.1 | Fault Types | 2-37 |
| 2.6.2 | Fault Escalation and Hard Faults | 2-38 |
| 2.6.3 | Fault Status Registers and Fault Address Registers | 2-39 |
| 2.6.4 | Lockup | 2-39 |
| 2.7 | Power Management | 2-40 |
| 2.7.1 | Entering Sleep Mode | 2-40 |
| 2.7.2 | Wakeup from Sleep Mode | 2-41 |
| 2.7.3 | The External Event Input | 2-41 |
| 2.7.4 | Power Management Programming Hints | 2-42 |
| 2.8 | Private Peripherals | 2-42 |
| 2.8.1 | About the Private Peripherals | 2-42 |
| 2.8.2 | System control block | 2-42 |
| 2.8.2.1 | System control block design hints and tips | 2-43 |
| 2.8.3 | System timer, SysTick | 2-43 |
| 2.8.3.1 | SysTick design hints and tips | 2-43 |
| 2.8.4 | Nested Vectored Interrupt Controller (NVIC) | 2-43 |
| 2.8.4.1 | Level-sensitive and pulse interrupts | 2-44 |
| 2.8.4.2 | NVIC design hints and tips | 2-45 |
| 2.8.4.3 | Using CMSIS functions to access NVIC | 2-45 |
| 2.8.5 | Memory Protection Unit (MPU) | 2-46 |
| 2.8.5.1 | MPU Access Permission Attributes | 2-48 |
| 2.8.5.2 | MPU Mismatch | 2-50 |
| 2.8.5.3 | Updating an MPU Region | 2-50 |
| 2.8.5.4 | MPU Design Hints and Tips | 2-53 |
| 2.8.6 | Floating Point Unit (FPU) | 2-53 |
| 2.8.6.1 | Enabling the FPU | 2-54 |
| 2.9 | PPB Registers | 2-54 |
| 2.9.1 | SCS Registers | 2-58 |
| 2.9.2 | SysTick Registers | 2-84 |
| 2.9.3 | NVIC Registers | 2-87 |
| 2.9.4 | MPU Registers | 2-93 |
| 2.9.5 | FPU Registers | 2-101 |
| 3 | Bus System | 3-1 |
| 3.1 | Bus Interfaces | 3-1 |
| 3.2 | Bus Matrix | 3-1 |
| 4 | Service Request Processing | 4-1 |
| 4.1 | Overview | 4-1 |
| 4.1.1 | Features | 4-1 |
| 4.1.2 | Block Diagram | 4-2 |

Table of Contents

| | | |
|----------|---|------------|
| 4.2 | Service Request Distribution | 4-3 |
| 4.3 | Interrupt Service Requests | 4-4 |
| 4.4 | DMA Line Router (DLR) | 4-7 |
| 4.4.1 | Functional Description | 4-7 |
| 4.4.2 | DMA Service Request Source Selection | 4-10 |
| 4.5 | Event Request Unit (ERU) | 4-15 |
| 4.5.1 | Event Request Select Unit (ERS) | 4-16 |
| 4.5.2 | Event Trigger Logic (ETLx) | 4-17 |
| 4.5.3 | Cross Connect Matrix | 4-19 |
| 4.5.4 | Output Gating Unit (OGUy) | 4-20 |
| 4.6 | Service Request Generation | 4-23 |
| 4.7 | Debug Behavior | 4-23 |
| 4.8 | Power, Reset and Clock | 4-23 |
| 4.9 | Initialization and System Dependencies | 4-23 |
| 4.10 | Registers | 4-24 |
| 4.10.1 | DLR Registers | 4-25 |
| 4.10.2 | ERU Registers | 4-29 |
| 4.11 | Interconnects | 4-34 |
| 4.11.1 | ERU0 Connections | 4-35 |
| 4.11.2 | ERU1 Connections | 4-38 |
| 5 | General Purpose DMA (GPDMA) | 5-1 |
| 5.1 | Overview | 5-1 |
| 5.1.1 | Features | 5-1 |
| 5.1.2 | Block Diagram | 5-3 |
| 5.2 | Functional Description | 5-4 |
| 5.2.1 | Terminology | 5-4 |
| 5.2.2 | Variable Definitions | 5-7 |
| 5.2.3 | Flow Controller and Transfer Type | 5-8 |
| 5.2.4 | Handshaking Interface | 5-9 |
| 5.2.4.1 | Hardware Handshaking | 5-10 |
| 5.2.4.2 | Software Handshaking | 5-10 |
| 5.2.4.3 | Handshaking with GPDMA as Flow Controller | 5-11 |
| 5.2.4.4 | Handshaking with Peripheral as Flow Controller | 5-13 |
| 5.2.5 | FIFO Usage | 5-14 |
| 5.2.6 | Bus and Channel Locking | 5-15 |
| 5.2.7 | Scatter/Gather | 5-17 |
| 5.2.8 | Abnormal Transfer Termination | 5-20 |
| 5.3 | Basic Transfers | 5-21 |
| 5.3.1 | Block transfer with GPDMA as the flow controller | 5-22 |
| 5.3.2 | Effect of maximum AMBA burst length on a block transfer | 5-23 |
| 5.4 | Multi Block Transfers | 5-27 |
| 5.4.1 | Block Chaining Using Linked Lists | 5-27 |

Table of Contents

| | | |
|----------|--|------------|
| 5.4.2 | Auto-Reloading of Channel Registers | 5-32 |
| 5.4.3 | Contiguous Address Between Blocks | 5-32 |
| 5.4.4 | Suspension of Transfers Between Blocks | 5-32 |
| 5.4.5 | Ending Multi-Block Transfers | 5-33 |
| 5.4.6 | Programing Examples | 5-34 |
| 5.4.6.1 | Single-block Transfer | 5-34 |
| 5.4.6.2 | Multi-Block Transfer with Source Address Auto-Reloaded and Contiguous Destination Address 5-35 | |
| 5.4.6.3 | Multi-Block Transfer with Source and Destination Address Auto- Reloaded 5-39 | |
| 5.4.6.4 | Multi-Block Transfer with Source Address Auto-Reloaded and Linked List Destination Address 5-43 | |
| 5.4.6.5 | Multi-Block DMA Transfer with Linked List for Source and Contiguous Destination Address 5-48 | |
| 5.4.6.6 | Multi-Block Transfer with Linked List for Source and Destination . | 5-51 |
| 5.5 | Service Request Generation | 5-57 |
| 5.6 | Power, Reset and Clock | 5-58 |
| 5.7 | Initialization and System Dependencies | 5-58 |
| 5.8 | Registers | 5-59 |
| 5.8.1 | Configuration and Channel Enable Registers | 5-63 |
| 5.8.2 | Channel Registers | 5-65 |
| 5.8.3 | Interrupt Registers | 5-99 |
| 5.8.4 | Software Handshaking Registers | 5-114 |
| 5.8.5 | Miscellaneous GPDMA Registers | 5-124 |
| 6 | Flexible CRC Engine (FCE) | 6-1 |
| 6.1 | Overview | 6-1 |
| 6.1.1 | Features | 6-1 |
| 6.1.2 | Application Mapping | 6-2 |
| 6.1.3 | Block Diagram | 6-2 |
| 6.2 | Functional Description | 6-3 |
| 6.2.1 | Basic Operation | 6-5 |
| 6.2.2 | Automatic Signature Check | 6-5 |
| 6.2.3 | Register protection and monitoring methods | 6-6 |
| 6.3 | Service Request Generation | 6-8 |
| 6.4 | Debug Behavior | 6-9 |
| 6.5 | Power, Reset and Clock | 6-9 |
| 6.6 | Initialization and System Dependencies | 6-9 |
| 6.7 | Registers | 6-11 |
| 6.7.1 | System Registers description | 6-12 |
| 6.7.2 | CRC Kernel Control/Status Registers | 6-13 |
| 6.8 | Interconnects | 6-24 |
| 6.9 | Properties of CRC code | 6-24 |

Table of Contents

| | | |
|----------|--|------------|
| 7 | Memory Organization | 7-1 |
| 7.1 | Overview | 7-1 |
| 7.1.1 | Features | 7-1 |
| 7.1.2 | Cortex-M4 Address Space | 7-1 |
| 7.2 | Memory Regions | 7-3 |
| 7.3 | Memory Map | 7-3 |
| 7.4 | Service Request Generation | 7-7 |
| 7.5 | Debug Behavior | 7-9 |
| 7.6 | Power, Reset and Clock | 7-9 |
| 7.7 | Initialization and System Dependencies | 7-9 |
| 7.8 | Registers | 7-10 |
| 8 | Flash and Program Memory Unit (PMU) | 8-1 |
| 8.1 | Overview | 8-1 |
| 8.1.1 | Block Diagram | 8-1 |
| 8.2 | Boot ROM (BROM) | 8-2 |
| 8.2.1 | BROM Addressing | 8-2 |
| 8.3 | Prefetch Unit | 8-2 |
| 8.3.1 | Overview | 8-2 |
| 8.3.2 | Operation | 8-3 |
| 8.3.2.1 | Instruction Buffer | 8-3 |
| 8.3.2.2 | Data Buffer | 8-3 |
| 8.3.2.3 | PMU Interface | 8-4 |
| 8.4 | Program Flash (PFLASH) | 8-5 |
| 8.4.1 | Overview | 8-5 |
| 8.4.1.1 | Features | 8-5 |
| 8.4.2 | Definition of Terms | 8-6 |
| 8.4.3 | Flash Structure | 8-7 |
| 8.4.4 | Flash Read Access | 8-8 |
| 8.4.5 | Flash Write and Erase Operations | 8-9 |
| 8.4.6 | Modes of Operation | 8-9 |
| 8.4.7 | Command Sequences | 8-10 |
| 8.4.7.1 | Command Sequence Definitions | 8-10 |
| 8.4.7.2 | Flash Page Programming Example | 8-15 |
| 8.4.8 | Flash Protection | 8-17 |
| 8.4.8.1 | Configuring Flash Protection in the UCB | 8-17 |
| 8.4.8.2 | Flash Read Protection | 8-18 |
| 8.4.8.3 | Flash Write and OTP Protection | 8-20 |
| 8.4.8.4 | System Wide Effects of Flash Protection | 8-22 |
| 8.4.9 | Data Integrity and Safety | 8-22 |
| 8.4.9.1 | Error-Correcting Code (ECC) | 8-22 |
| 8.4.9.2 | Margin Checks | 8-23 |
| 8.5 | Service Request Generation | 8-23 |

Table of Contents

| | | |
|----------|---|------------|
| 8.5.1 | Interrupt Control | 8-24 |
| 8.5.2 | Trap Control | 8-24 |
| 8.5.3 | Handling Errors During Operation | 8-25 |
| 8.5.3.1 | SQER "Sequence Error" | 8-25 |
| 8.5.3.2 | PFOPER "Operation Error" | 8-26 |
| 8.5.3.3 | PROER "Protection Error" | 8-26 |
| 8.5.3.4 | VER "Verification Error" | 8-27 |
| 8.5.3.5 | PFSBER/DFSBER "Single-Bit Error" | 8-28 |
| 8.5.3.6 | Handling Flash Errors During Startup | 8-29 |
| 8.6 | Power, Reset and Clock | 8-29 |
| 8.6.1 | Power Supply | 8-29 |
| 8.6.2 | Power Reduction | 8-29 |
| 8.6.3 | Reset Control | 8-31 |
| 8.6.3.1 | Resets During Flash Operation | 8-31 |
| 8.6.4 | Clock | 8-33 |
| 8.7 | Registers | 8-33 |
| 8.7.1 | PMU Registers | 8-33 |
| 8.7.1.1 | PMU ID Register | 8-34 |
| 8.7.2 | Prefetch Registers | 8-35 |
| 8.7.2.1 | Prefetch Configuration Register | 8-35 |
| 8.7.3 | Flash Registers | 8-37 |
| 8.7.3.1 | Flash Status Definition | 8-38 |
| 8.7.3.2 | Flash Configuration Control | 8-43 |
| 8.7.3.3 | Flash Identification Register | 8-48 |
| 8.7.3.4 | Margin Check Control Register | 8-49 |
| 8.7.3.5 | Protection Configuration Indication | 8-49 |
| 9 | Window Watchdog Timer (WDT) | 9-1 |
| 9.1 | Overview | 9-1 |
| 9.1.1 | Features | 9-1 |
| 9.1.2 | Block Diagram | 9-2 |
| 9.2 | Time-Out Mode | 9-3 |
| 9.3 | Pre-warning Mode | 9-4 |
| 9.4 | Bad Service Operation | 9-5 |
| 9.5 | Service Request Processing | 9-7 |
| 9.6 | Debug Behavior | 9-7 |
| 9.7 | Power, Reset and Clock | 9-7 |
| 9.8 | Initialization and Control Sequence | 9-7 |
| 9.8.1 | Initialization & Start of Operation | 9-8 |
| 9.8.2 | Reconfiguration & Restart of Operation | 9-8 |
| 9.8.3 | Software Stop & Resume Operation | 9-9 |
| 9.8.4 | Enter Sleep/Deep Sleep & Resume Operation | 9-9 |
| 9.8.5 | Prewarning Alarm Handling | 9-9 |

Table of Contents

| | | |
|-----------|--|-------|
| 9.9 | Registers | 9-11 |
| 9.9.1 | Registers Description | 9-11 |
| 9.10 | Interconnects | 9-16 |
| 10 | Real Time Clock (RTC) | 10-1 |
| 10.1 | Overview | 10-1 |
| 10.1.1 | Features | 10-1 |
| 10.1.2 | Block Diagram | 10-1 |
| 10.2 | RTC Operation | 10-2 |
| 10.3 | Register Access Operations | 10-3 |
| 10.4 | Service Request Processing | 10-4 |
| 10.4.1 | Periodic Service Request | 10-4 |
| 10.4.2 | Timer Alarm Service Request | 10-4 |
| 10.5 | Wake-up From Hibernation Trigger | 10-4 |
| 10.5.1 | Periodic Wake-up Trigger Generation | 10-4 |
| 10.5.2 | Timer Alarm Wake-up Trigger Generation | 10-4 |
| 10.6 | Debug behavior | 10-5 |
| 10.7 | Power, Reset and Clock | 10-5 |
| 10.8 | Initialization and Control Sequence | 10-5 |
| 10.8.1 | Initialization & Start of Operation | 10-5 |
| 10.8.2 | Re-configuration & Re-start of Operation | 10-6 |
| 10.8.3 | Configure and Enable Periodic Event | 10-6 |
| 10.8.4 | Configure and Enable Timer Event | 10-6 |
| 10.9 | Registers | 10-8 |
| 10.9.1 | Registers Description | 10-8 |
| 10.10 | Interconnects | 10-20 |
| 11 | System Control Unit (SCU) | 11-1 |
| 11.1 | Overview | 11-1 |
| 11.1.1 | Features | 11-1 |
| 11.1.2 | Block Diagram | 11-2 |
| 11.2 | Miscellaneous Control Functions | 11-5 |
| 11.2.1 | Startup Software Support | 11-5 |
| 11.2.2 | Service Requests | 11-6 |
| 11.2.2.1 | Service Request Sources | 11-6 |
| 11.2.3 | Memory Parity Protection | 11-7 |
| 11.2.3.1 | Parity Error Handling | 11-7 |
| 11.2.4 | Trap Generation | 11-9 |
| 11.2.4.1 | Trap Sources | 11-9 |
| 11.2.5 | Die Temperature Measurement | 11-10 |
| 11.2.5.1 | Temperature Measurement | 11-10 |
| 11.2.5.2 | Offset Adjustment | 11-11 |
| 11.2.5.3 | Gain Adjustment | 11-12 |
| 11.2.6 | Retention Memory | 11-13 |

Table of Contents

| | | |
|----------|---|-------|
| 11.2.7 | Out of Range Comparator Control | 11-14 |
| 11.3 | Power Management | 11-14 |
| 11.3.1 | Functional Description | 11-14 |
| 11.3.2 | System States | 11-15 |
| 11.3.3 | Hibernate Domain Operating Modes | 11-17 |
| 11.3.4 | Embedded Voltage Regulator (EVR) | 11-19 |
| 11.3.5 | Power-on Reset | 11-19 |
| 11.3.6 | Supply Watchdog (SWD) | 11-20 |
| 11.3.7 | Power Validation | 11-20 |
| 11.3.8 | Supply Voltage Brown-out Detection | 11-20 |
| 11.3.9 | Hibernate Domain Power Management | 11-21 |
| 11.3.10 | Flash Power Control | 11-21 |
| 11.4 | Hibernate Control | 11-21 |
| 11.4.1 | Hibernate Mode | 11-21 |
| 11.4.2 | Hibernate Domain Pin Functions | 11-22 |
| 11.4.3 | System Level Integration | 11-23 |
| 11.5 | Reset Control | 11-25 |
| 11.5.1 | Supported Reset types | 11-25 |
| 11.5.2 | Peripheral Reset Control | 11-27 |
| 11.5.3 | EtherCAT Reset | 11-27 |
| 11.5.4 | Reset Status | 11-28 |
| 11.6 | Clock Control | 11-28 |
| 11.6.1 | Block Diagram | 11-28 |
| 11.6.2 | Clock Sources | 11-29 |
| 11.6.3 | Clock System Overview | 11-31 |
| 11.6.3.1 | Clock System Architecture | 11-33 |
| 11.6.4 | High Precision Oscillator Circuit (OSC_HP) | 11-37 |
| 11.6.5 | Backup Clock Source | 11-38 |
| 11.6.6 | Main PLL | 11-39 |
| 11.6.6.1 | Features | 11-39 |
| 11.6.6.2 | System PLL Functional Description | 11-39 |
| 11.6.6.3 | Configuration and Operation of the Prescaler Mode | 11-43 |
| 11.6.6.4 | Bypass Mode | 11-45 |
| 11.6.6.5 | System Oscillator Watchdog (OSC_WDG) | 11-45 |
| 11.6.6.6 | VCO Power Down Mode | 11-46 |
| 11.6.6.7 | PLL Power Down Mode | 11-46 |
| 11.6.6.8 | Application Hints | 11-46 |
| 11.6.7 | Internally Generated System Clock Calibration | 11-47 |
| 11.6.7.1 | Factory Calibration | 11-47 |
| 11.6.7.2 | Automatic Calibration | 11-47 |
| 11.6.7.3 | Alternative Internal Clock Calibration | 11-47 |

About this Document

This Reference Manual is addressed to embedded hardware and software developers. It provides the reader with detailed descriptions about the behavior of the XMC4[78]00 series functional units and their interaction.

The manual describes the functionality of the superset device of the XMC4[78]00 microcontroller series. For the available functionality (features) of a specific XMC4[78]00 derivative (derivative device), please refer to the respective Data Sheet. For simplicity, the various device types are referenced by the collective term XMC4[78]00 throughout this manual.

XMC4000 Family User Documentation

The set of user documentation includes:

- **Reference Manual**
 - describes the functionality of the superset device.
- **Data Sheets**
 - list the complete ordering information, available features and electrical characteristics of derivative devices.
- **Errata Sheets**
 - list deviations from the specifications given in the related Reference Manual or Data Sheets. Errata Sheets are provided for the superset of devices.

Attention: Please consult all parts of the documentation set to attain consolidated knowledge about your device.

Application related guidance is provided by **Users Guides** and **Application Notes**.

Please refer to <http://www.infineon.com/xmc4000> to get access to the latest versions of those documents.

Text Conventions

This document uses the following naming conventions:

- Functional units of the device are given in plain UPPER CASE. For example: “The USIC0 unit supports...”.
- Pins using negative logic are indicated by an overline. For example: “The $\overline{\text{WAIT}}$ input has...”.
- Bit fields and bits in registers are generally referenced as “Module_RegisterName.BitField” or “Module_RegisterName.Bit”. For example: “The USIC0_PCR.MCLK bit enables the...”. Most of the register names contain a module name prefix, separated by an underscore character “_” from the actual register name (for example, “USIC0_PCR”, where “USIC0” is the module name prefix, and “PCR” is the kernel register name). In chapters describing the kernels of the peripheral modules, the registers are mainly referenced with their kernel register names. The peripheral module implementation sections mainly refer to the actual register names with module prefixes.
- Variables used to describe sets of processing units or registers appear in mixed upper and lower cases. For example, register name “MOFCRn” refers to multiple “MOFCR” registers with variable n. The bounds of the variables are always given where the register expression is first used (for example, “n = 0-31”), and are repeated as needed in the rest of the text.
- The default radix is decimal. Hexadecimal constants are suffixed with a subscript letter “H”, as in 100_H. Binary constants are suffixed with a subscript letter “B”, as in: 111_B.
- When the extent of register fields, groups register bits, or groups of pins are collectively named in the body of the document, they are represented as “NAME[A:B]”, which defines a range for the named group from B to A. Individual bits, signals, or pins are given as “NAME[C]” where the range of the variable C is given in the text. For example: CFG[2:0] and SRPN[0].
- Units are abbreviated as follows:
 - **MHz** = Megahertz
 - **μs** = Microseconds
 - **kBaud, kbit/s** = 1000 characters/bits per second
 - **MBaud, Mbit/s, Mbps** = 1,000,000 characters/bits per second
 - **Kbyte, KB** = 1024 bytes of memory
 - **Mbyte, MB** = 1048576 bytes of memory

In general, the k prefix scales a unit by 1000 whereas the K prefix scales a unit by 1024. Hence, the Kbyte unit scales the expression preceding it by 1024. The kBaud unit scales the expression preceding it by 1000. The M prefix scales by 1,000,000 or 1048576. For example, 1 Kbyte is 1024 bytes, 1 Mbyte is

About this Document

1024 × 1024 bytes, 1 kBaud/kbit are 1000 characters/bits per second, 1 MBaud/Mbit are 1000000 characters/bits per second, and 1 MHz is 1,000,000 Hz.

- Data format quantities are defined as follows:
 - **Byte** = 8-bit quantity
 - **Half-word** = 16-bit quantity
 - **Word** = 32-bit quantity
 - **Double-word** = 64-bit quantity

Bit Function Terminology

In tables where register bits or bit fields are defined, the following conventions are used to indicate the access types.

Table 1 Bit Function Terminology

| Bit Function | Description |
|--------------|---|
| rw | The bit or bit field can be read and written. |
| rwh | As rw, but bit or bit field can be also set or reset by hardware. If not otherwise documented the software takes priority in case of a write conflict between software and hardware. |
| r | The bit or bit field can only be read (read-only). |
| w | The bit or bit field can only be written (write-only). A read to this register will always give a default value back. |
| rh | This bit or bit field can be modified by hardware (read-hardware, typical example: status flags). A read of this bit or bit field give the actual status of this bit or bit field back. Writing to this bit or bit field has no effect to the setting of this bit or bit field. |

Register Access Modes

Read and write access to registers and memory locations are sometimes restricted. In memory and register access tables, the following terms are used.

Table 2 Register Access Modes

| Symbol | Description |
|-----------|---|
| U | Access permitted when software executes on Unprivileged level. |
| PV | Access permitted when software executes on Privileged level. |
| 32 | Only 32-bit word accesses are permitted to this register/address range. |
| NC | No change, indicated register is not changed. |

Table 2 Register Access Modes (cont'd)

| Symbol | Description |
|--------|---|
| BE | Indicates that an access to this address range generates a Bus Error. |
| nBE | Indicates that no Bus Error is generated when accessing this address range. |

Reserved Bits

Register bit fields named **Reserved** or **0** indicate unimplemented functions with the following behavior:

- Reading these bit fields returns 0.
- These bit fields should be written with 0 if the bit field is defined as r or rh.
- These bit fields must to be written with 0 if the bit field is defined as rw.

Abbreviations and Acronyms

Introduction

1 Introduction

The XMC4[78]00 devices are members of the XMC4000 family of microcontrollers based on the ARM Cortex-M4 processor core. The XMC4000 is a family of high performance and energy efficient microcontrollers optimized for Industrial Connectivity, Industrial Control, Power Conversion, Sense & Control.

The growing complexity of today's energy efficient embedded control applications are demanding microcontroller solutions with higher performance CPUs along with DSC (Digital Signal Control) and FPU (Floating Point Unit) capabilities to handle complex control algorithms and integrated peripherals that are optimized for performance. Combined with a development environment designed to shorten product development time and increase productivity, the XMC4[78]00 family of microcontrollers take advantage of Infineon's decades of experience in the industrial market to provide an optimized solution to meet the performance challenges of today's embedded control applications.

1.1 Architectural Overview

The XMC4[78]00 combines the extended functionality and performance of the ARM Cortex-M4 core with powerful on-chip peripheral subsystems and on-chip memory units. The following key features are available in the XMC4700 / XMC4800 devices:

- CPU Subsystem
 - High Performance 32-bit ARM Cortex-M4 CPU
 - 16-bit and 32-bit Thumb2 instruction set
 - DSP/MAC instructions
 - Floating Point Unit
 - Memory Protection Unit
 - Low power consumption
 - Low latency interrupt processing
 - Nested Vectored Interrupt Controller
 - 3 Bus interfaces
 - Little Endian
 - On-chip debug support
 - System timer (SysTick) for Operating System support
- Integrated On-Chip Memories
 - 16 KB on-chip boot ROM
 - 96 KB on-chip high-speed program memory
 - 128 KB on-chip high speed data memory
 - 128 KB on-chip high-speed communication
 - 2 MB on-chip Flash Memory with 8 KB instruction cache
- Serial Interfaces
 - Three Universal Serial Interface Channel Units (USIC), providing UART, double-SPI, quad-SPI, IIC, IIS and LIN interfaces

Introduction

- Controller Area Network interface (MultiCAN), Full-CAN/Basic-CAN
- Universal Serial Bus, USB 2.0 host, Full-SpeedOTG, with internal PHY
- Ethernet MAC module capable of 10/100 Mbit/s transfer rates
- EtherCat MAC module (ECAT0), capable of 100 Mbit/s transfer rates supporting different external PHYs, enables a host to transmit and receive data over Ethernet, IEEE 802.3-2002 compliant
- External Memory Interfaces
 - Multi-Media Card and SD interface (SDMMC) for data storage memory cards
 - External Bus interface (EBU) enabling communication with external memories and off-chip peripherals
- On-Chip Peripheral Subsystems
 - General Purpose DMA up-to 12 channels
 - Two Capture/Compare Units 8 (CCU8) for Motor Control and Power Conversion.
 - Four Capture/Compare Units 4 (CCU4) for use as general purpose timers
 - Two Position Interfaces (POSIF) for servo motor positioning
 - Die Temperature Sensor (DTS)
 - Window Watchdog Timer (WDT) for safety sensitive applications
 - Flexible CRC Engine (FCE) for multiple bit error detection
 - Real Time Clock module with alarm support
 - LED and Touch-Sense Controller (LEDTS) for Human-Machine interface
 - System Control Unit for system configuration and control
- Analog Frontend
 - Digital-Analogue Converter (DAC) with two channels of 12-bit resolution
 - Four Versatile Analog-Digital Converters (VADC) of 12-bit resolution, 8 channels each
 - Delta Sigma Demodulator, digital input stage for A/D signal conversion
- On-Chip Debug Support
 - standard ARM-JTAG support with boundary scan board level support
 - dual wire I/O source level debugging with up to 8 breakpoints on code and data
 - one wire serial output for instrumentation data trace
 - Flash Patch and Breakpoint Unit
- Input/Output Lines
 - Programmable port driver control module (PORTS)
 - Individual Bit Addressability
 - Tri-stated in input mode
 - Push/pull or open drain output mode
- Packages
 - PG-LQFP-144
 - PG-LQFP-100
 - PG-LFBGA-196

1.1.1 Block Diagram

The diagram below shows the functional blocks and their basic connectivity within the XMC4700 / XMC4800 System.

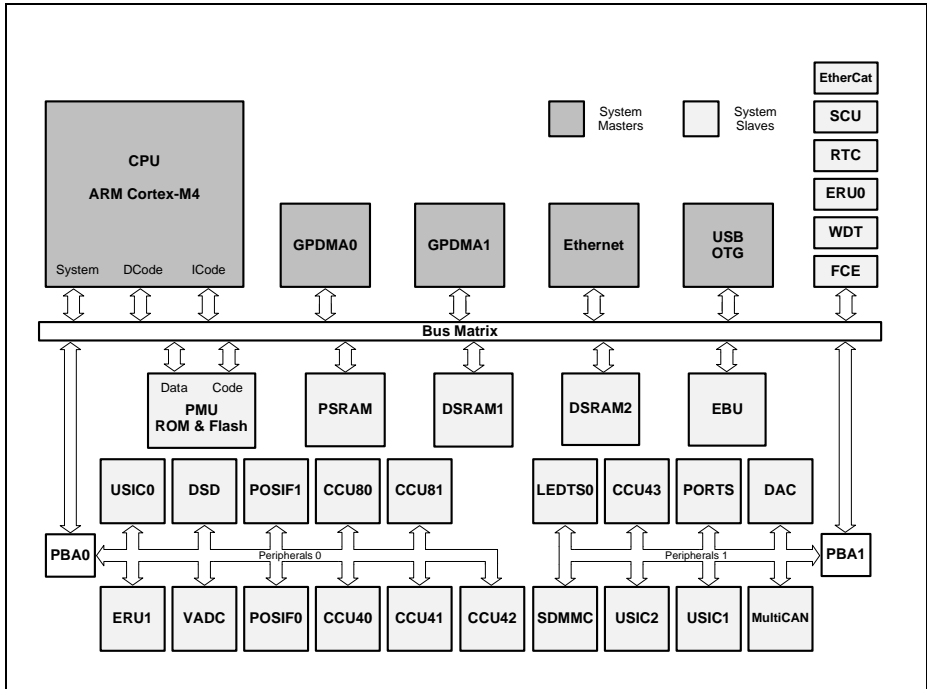

Figure 1-1 System Block Diagram

1.2 System Core Components

The XMC4[78]00 system core consists of the CPU (including FPU and MPU) and the memory interface blocks for program and data memories - PMU.

Central Processing Unit (CPU)

The Cortex-M4 processor is built on a high-performance processor core with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and a design optimized for energy efficient control applications. To address the growing complexity of embedded control it also includes a IEEE754-compliant single-precision

Introduction

floating-point computation and a range of single-cycle/SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4 processor implements tightly-coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities.

To ensure high code density and reduced program memory requirements the processor also implements a version of the Thumb® instruction set based on Thumb-2 technology. The instruction set provides the exceptional performance expected of a modern 32-bit architecture with the high code density of 8-bit and 16-bit microcontrollers.

Floating Point Unit (FPU)

The Floating-point unit (FPU) provides IEEE754-compliant operations on single-precision, 32-bit, floating-point values.

Memory Protection Unit (MPU)

The MPU improves system reliability by defining the memory attributes for different memory regions. It provides fine grain memory control, enabling applications to utilize multiple privilege levels, separating and protecting code, data and stack on a task-by-task basis. Up to eight different regions are supported as well as an optional predefined background region. These features are becoming critical to support safety requirements in many Industrial embedded applications.

Programmable Multiple Priority Interrupt System (NVIC)

The XMC4[78]00 provides separate interrupt nodes that may be assigned to 64 priority levels. Most interrupt sources are connected to a dedicated interrupt node. In some cases, multi-source interrupt nodes are incorporated for efficient use of system resources. These nodes can be activated by several source requests and are controlled via interrupt subnode control registers.

Direct Memory Access (GPDMA)

The GPDMA is a highly configurable DMA controller that allows high-speed data transfers between peripherals and memory, memory to memory and peripheral to peripheral. Complex data transfers can be done with minimal intervention of the processor, keeping the CPU resources free for other operations.

Flexible CRC Engine (FCE)

The FCE provides a parallel implementation of Cyclic Redundancy Code (CRC) algorithms. The FCE implements the IEEE 802.3 ethernet CRC32, the CCITT CRC16 and the SAE J1850 CRC8 polynomials. FCE's generic structure enables it to be extended with multiple independent CRC polynomials. The primary target of FCE is to

be used as a hardware acceleration engine for software applications or operating systems services using CRC signatures.

1.3 On-Chip System Resources

The XMC4[78]00 controllers provide a number of system resources designed around the CPU. The combination of CPU and these resources results in the high performance of the members of this controller family.

The on-chip memories provide zero-waitstate accesses to code and data. The memories can be accessed concurrently from various system masters.

In order to meet the needs of applications where more peripherals are required the External Bus Unit also provides means to optionally attach external devices.

1.3.1 Memories

Various types of dedicated memories are available on-chip. The suggested use of the memories aims to improve performance and system stability in most typical application cases. However, the user has the flexibility to use the memories in any other way in order to fulfill application specific requirements.

Boot ROM (BROM)

The Boot ROM memory contains boot code and exception vector table. The basic system initialization sequence code, also referred to as firmware, is executed immediately after reset release.

Flash memory

The Flash is for non volatile code or constant data storage. The Flash module implements protected and efficient writing algorithms for programming and erasing as well as dynamic error correction providing high read data security for all read accesses.

Code RAM (PSRAM)

The Code RAM is intended for user code or Operating System data storage. The memory is accessed via the Bus Matrix and provides zero-wait-state access for the CPU for code execution or data access.

System RAM (DSRAM1)

The System RAM is intended for general user data storage. The System RAM is accessed via the Bus Matrix and provides zero-wait-state access for data.

Communication RAM (DSRAM2)

The Communication RAM is intended for use with communication interface units like the USB and ETH modules.

1.4 Bus System

The XMC4[78]00 is targeted for use in embedded systems. Therefore the key features are timing determinism and low latency on real time events. Bus bandwidth is required particularly for communication peripherals.

The bus system will therefore provide:

- Timing Determinism
- Low Latency
- Performance
- Throughput

1.4.1 Bus Matrix

The central part of the bus system is built up around a multilayer AHB-lite compliant matrix. By means of this technique the bus masters and bus slaves can be connected in a flexible way while maintaining high bus performance.

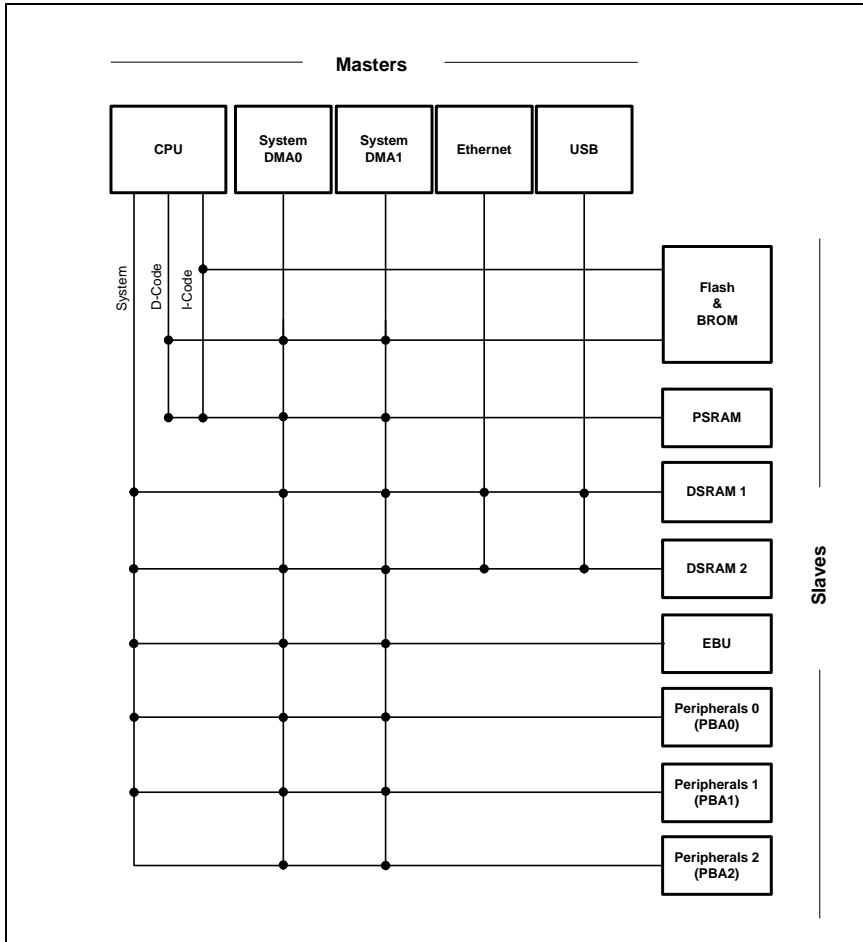

Figure 1-2 Multilayer Bus Matrix

The Bus Matrix depicted in **Figure 1-2** implements an optimized topology enabling zero wait state data accesses between the Masters and Slaves connected to it. Dedicated arbitration scheme enables optimal access conflicts resolution resulting in improved system stability and real time behavior.

1.4.2 Bus Interfaces

This chapter describes the features for the two kinds of interfaces.

- **Memory Interface**
- **Peripheral Interface**

All on-chip peripherals and memories are attached to the Bus Matrix, in some cases via peripheral bridges. All on-chip modules implement Little Endian data organization. The following types of transfer are supported:

- Locked Transfers
- Burst Operation
- Protection Control

Pipelining is also supported for bandwidth critical transfers.

Memory Interface

The on-chip memories capable to accept a transfer request with each bus clock cycle.

The memory interface data bus width is 32-bit. Each memory slave support 32-bit, 16-bit and 8-bit access types.

Peripheral Interface

Each slave supports 32-bit accesses. Some slaves also support 8-bit and/or 16-bit accesses.

1.5 Communication

Communication features are key requirements in today's industrial systems. The XMC4[78]00 offers units to realize Ethernet or CAN network or USB access. Further various memory interfaces and a unit to implement a Human Machine Interface (HMI) are provided.

LED and Touch Sense (LEDTS)

The LEDTS drives LEDs and controls touch pads used as human-machine interface (HMI) in an application. The LEDTS can measure the capacitance of up to 8 touch pads using the relaxation oscillator (RO) topology. The module can also drive up to 64 LEDs in an LED matrix. Touch pads and LEDs can share pins to minimize the number of pins needed for such applications.

SD/MMC interface (SDMMC)

The Secure Digital/ MultiMediaCard interface (SDMMC) provides an interface between SD/SDIO/MMC cards and the AHB bus. The CPU is programmed to support SD, SDIO, SDHC and MMC cards, and can operate up to 48 MHz. The SDMMC module is able to transfer a maximum of 24 MB/sec for SD cards and 48 MB/sec for MMC cards.

The SDMMC Host Controller handles SDIO/SD protocol at transmission level, packing data, adding cyclic redundancy check (CRC), start/end bit, and checking for transaction

Introduction

format correctness. Some useful applications of the SDMMC includes memory extension, data logging, and firmware update.

External Bus Unit (EBU)

The EBU controls the transactions between external memories or peripheral units, and the internal memories and peripheral units.

Ethernet MAC (ETH)

The Ethernet MAC (ETH) is a major communication peripheral that supports 10/100 MBit/s data transfer rates in compliance with the IEEE 802.3-2002 standard.

The ETH may be used to implement Internet connected applications using IPv4 and IPv6. The ETH also includes support for IEEE1588 time synchronisation to allow implementation of Real Time Ethernet protocols.

EtherCat (ECAT)

An EtherCAT Slave Controller (ECAT) takes care of the EtherCAT communication as an interface between the EtherCAT fieldbus and the slave application. EtherCAT was invented by Beckhoff Automation and is standardized in IEC 61158.

Universal Serial Bus (USB)

The USB module is a Dual-Role Device (DRD) controller that supports both device and host functions and complies fully with the On-The-Go Supplement to the USB 2.0 Specification, Revision 1.3. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification.

The USB core's USB 2.0 configurations support full-speed (12-Mbps) transfers.

The USB core is optimized for the following applications and systems:

- Portable electronic devices
- Point-to-point applications (direct connection to FS device)

Universal Serial Interface Channel (USIC)

The USIC is a flexible interface module covering several serial communication protocols. A USIC module contains two independent communication channels. The user can program during run-time which protocol will be handled by each communication channel and which pins are used.

Controller Area Network (CAN)

The MultiCAN module contains independently operating CAN nodes with Full-CAN functionality that are able to exchange Data and Remote Frames via a gateway function. Transmission and reception of CAN frames is handled in accordance with CAN

Introduction

specification V2.0 B (active). Each CAN node can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

All CAN nodes share a common set of message objects. Each message object can be individually allocated to one of the CAN nodes. Besides serving as a storage container for incoming and outgoing frames, message objects can be combined to build gateways between the CAN nodes or to setup a FIFO buffer.

1.6 Analog Frontend

XMC4[78]00's interfaces from and to the analog world.

Versatile Analog-to Digital Convertor (VDAC)

The 12-bit VADC is a set of converter blocks that can be operated either independently or via a common request source that emulates a background converter. Each converter block is equipped with a dedicated input multiplexer and dedicated request sources, which together build separate groups.

This basic structure supports application-oriented programming and operating while still providing general access to all resources. The almost identical converter groups allow a flexible assignment of functions to channels.

Delta- Sigma Demodulator (DSD)

The Delta-Sigma Demodulator provides a series of digital input channels accepting data streams from external modulators using the Delta/Sigma (DS) conversion principle.

The on-chip demodulator channels convert these inputs to discrete digital values.

Digital to Analog Convertor (DAC)

The module consists of two separate 12-bit digital to analog converters (DACs). It converts two digital input signals into two analog voltage signal outputs at a maximum conversion rate of 1MHz. The chosen design structure is based on a current steering architecture with internal reference generation and provides buffered voltage outputs. In order to reduce power consumption during inactive periods, a power down mode is available.

1.7 Industrial Control

Core components needed for motion and motor control, power conversion and other time based applications.

Capture/Compare Unit 4 (CCU4)

The CCU4 peripheral is a major component for systems that need general purpose timers for signal monitoring/conditioning and Pulse Width Modulation (PWM) signal

Introduction

generation. Power electronic control systems like switched mode power supplies or uninterruptible power supplies can easily be implemented with the functions inside the CCU4 peripheral.

The internal modularity of CCU4, translates into a software friendly system for fast code development and portability between applications

Capture/Compare Unit 8 (CCU8)

The CCU8 peripheral functions play a major role in applications that need complex Pulse Width Modulation (PWM) signal generation, with complementary high side and low side switches, multi phase control or output parity checking. The CCU8 is optimized for state of the art motor control, multi phase and multi level power electronics systems.

The internal modularity of CCU8, translates into a software friendly system for fast code development and portability between applications.

Position Interface Unit (POSIF)

The POSIF unit is a flexible and powerful component for motor control systems that use Rotary Encoders or Hall Sensors as feedback loop. The configuration schemes of the module target a very large number of motor control application requirements.

This enables the build of simple and complex control feedback loops for industrial and automotive motor applications, targeting high performance motion and position monitoring.

1.8 On-Chip Debug Support

The On-Chip Debug Support system based on the ARM CoreSight™ provides a broad range of debug and emulation features built into the XMC4[78]00. The user software running on the XMC4[78]00 can thus be debugged within the target system environment.

The On-Chip Debug Support is controlled by an external debugging device via the debug interface and an optional break interface. The debugger controls the On-Chip Debug Support via a set of dedicated registers accessible via the debug interface. Additionally, the On-Chip Debug Support system can be controlled by the CPU, e.g. by a monitor program.

CPU Subsystem

2 Central Processing Unit (CPU)

The XMC4[78]00 features the ARM Cortex-M4 processor. A high performance 32-bit processor designed for the microcontroller market. This CPU offers significant benefits to users, including:

- outstanding processing performance combined with fast interrupt handling
- enhanced system debug with extensive breakpoint and trace capabilities
- platform security robustness, with integrated memory protection unit (MPU).
- ultra-low power consumption with integrated sleep modes

2.1 Overview

The Cortex-M4 processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including IEEE754-compliant single-precision floating-point computation, a range of single-cycle and SIMD multiplication and multiply-with-accumulate capabilities, saturating arithmetic and dedicated hardware division.

To facilitate the design of cost-sensitive devices, the Cortex-M4 processor implements tightly-coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M4 processor implements a version of the Thumb® instruction set based on Thumb-2 technology, ensuring high code density and reduced program memory requirements. The Cortex-M4 instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M4 processor closely integrates a configurable NVIC, to deliver industry-leading interrupt performance. The NVIC includes a non-maskable interrupt (NMI), and provides up to 64 interrupt priority levels. The tight integration of the processor core and

Central Processing Unit (CPU)

NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing the interrupt latency. This is achieved through the hardware stacking of registers, and the ability to suspend load-multiple and store-multiple operations. Interrupt handlers do not require wrapping in assembler code, removing any code overhead from the ISRs. A tail-chain optimization also significantly reduces the overhead when switching from one ISR to another.

To optimize low-power designs, the NVIC integrates with the sleep modes, that include a deep sleep function that enables the entire device to be rapidly powered down while still retaining program state.

2.1.1 Features

The XMC4[78]00 CPU features comprise

- Thumb2 instruction set combines high code density with 32-bit performance
- IEEE754-compliant single-precision FPU
- power control optimization of system components
- integrated sleep modes for low power consumption
- fast code execution permits slower processor clock or increases sleep mode time
- hardware division and fast digital-signal-processing orientated multiply accumulate
- saturating arithmetic for signal processing
- deterministic, high-performance interrupt handling for time-critical applications
- memory protection unit (MPU) for safety-critical applications
- extensive debug and trace capabilities:
 - Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging, tracing, and code profiling.

2.1.2 Block Diagram

The Cortex-M4 core components comprise:

Processor Core

The CPU provides 16-bit and 32-bit Thumb2 instruction set and DSP/MAC instructions.

Floating-point unit

The FPU provides IEEE754-compliant operations on single-precision, 32-bit, floating-point values.

Nested Vectored Interrupt Controller

The NVIC is an embedded interrupt controller that supports low latency interrupt processing.

Memory Protection Unit

The MPU improves system reliability by defining the memory attributes for different memory regions. It provides up to eight different regions, and an optional predefined background region.

Debug Solution

The XMC4[78]00 implements a complete hardware debug solution.

- Embedded Trace Macrocell
- Traditional JTAG port or a 2-pin Serial Wire Debug Access Port
- Trace port or Serial Wire Viewer
- Flash breakpoints and Data watchpoints

This provides high system control and visibility of the processor and memory even in small package devices.

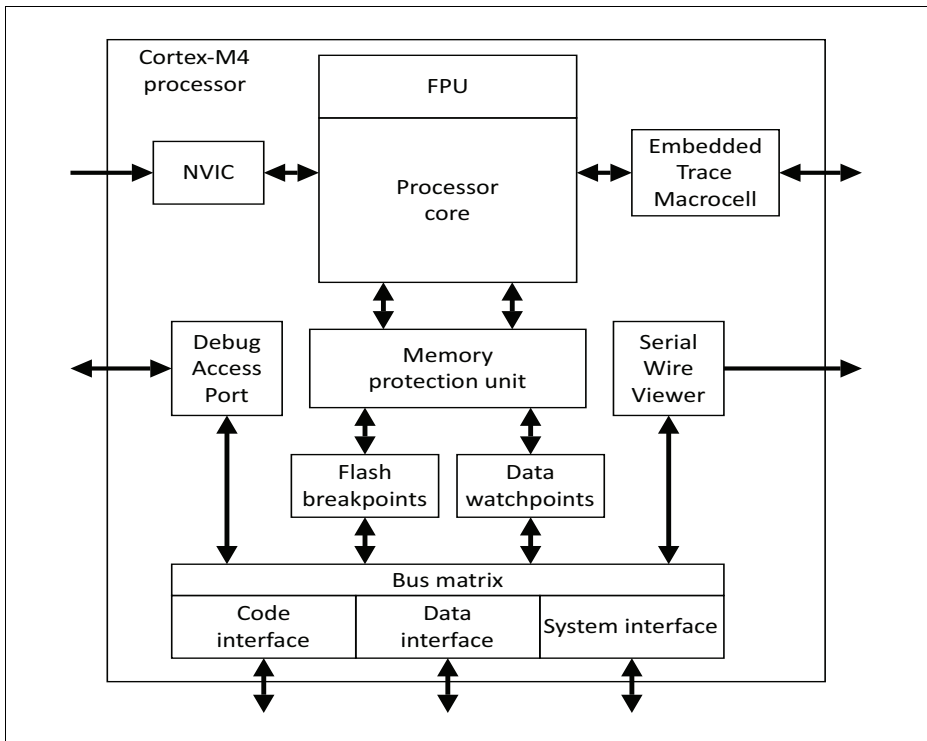

Figure 2-1 Cortex-M4 Block Diagram

System Level Interfaces

The Cortex-M4 processor provides a code, data and system interface using AMBA[®] technology to provide high speed, low latency accesses.

2.2 Programmers Model

This section describes the Cortex-M4 programmers model. In addition to the individual core register descriptions, it contains information about the processor modes and privilege levels for software execution and stacks.

2.2.1 Processor Mode and Privilege Levels for Software Execution

The processor modes are:

- **Thread mode**
Used to execute application software. The processor enters Thread mode when it comes out of reset.
- **Handler mode**
Used to handle exceptions. The processor returns to Thread mode when it has finished all exception processing.

The privilege levels for software execution are:

- **Unprivileged**
Unprivileged software executes at the unprivileged level.
The software:
 - has limited access to the MSR and MRS instructions, and cannot use the CPS instruction
 - cannot access the system timer, NVIC, or system control block
 - might have restricted access to memory or peripherals.
- **Privileged**
Privileged software executes at the privileged level.
The software can use all the instructions and has access to all resources.

In Thread mode, the CONTROL register controls whether software execution is privileged or unprivileged, see CONTROL register on [Page 2-15](#). In Handler mode, software execution is always privileged.

Only privileged software can write to the CONTROL register to change the privilege level for software execution in Thread mode. Unprivileged software can use the SVC instruction to make a supervisor call to transfer control to privileged software.

2.2.2 Stacks

The processor uses a full descending stack. This means the stack pointer holds the address of the last stacked item in memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory

Central Processing Unit (CPU)

location. The processor implements two stacks, the main stack and the process stack, with a pointer for each held in independent registers, see Stack Pointer on [Page 2-8](#).

In Thread mode, the CONTROL register controls whether the processor uses the main stack or the process stack, see CONTROL register on [Page 2-15](#). In Handler mode, the processor always uses the main stack. The options for processor operations are:

Table 2-1 Summary of processor mode, execution privilege level, and stack use options

| Processor mode | Used to execute | Privilege level for software execution | Stack used |
|----------------|--------------------|--|---|
| Thread | Applications | Privileged or unprivileged ¹⁾ | Main stack or process stack ¹⁾ |
| Handler | Exception handlers | Always privileged | Main stack |

1) See CONTROL register on [Page 2-15](#).

2.2.3 Core Registers

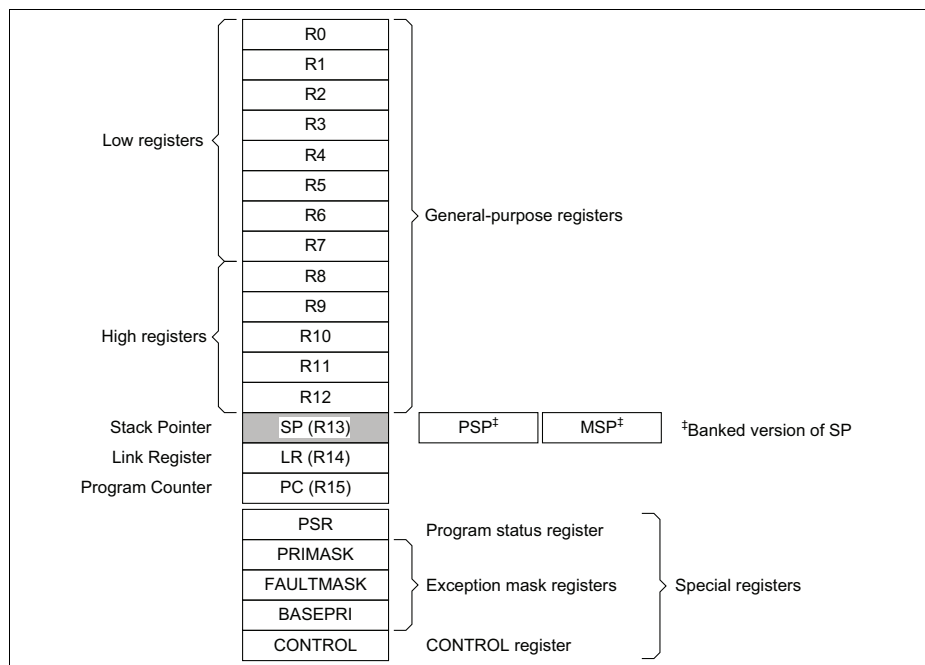

Figure 2-2 Core registers

The processor core registers are:

Table 2-2 Core register set summary

| Name | Type ¹⁾ | Required privilege ²⁾ | Reset value | Description |
|--------|--------------------|----------------------------------|----------------------|---|
| R0-R12 | rw | Either | Unknown | General-purpose registers on Page 2-7 |
| MSP | rw | Privileged | See description | Stack Pointer on Page 2-8 |
| PSP | rw | Either | Unknown | Stack Pointer on Page 2-8 |
| LR | rw | Either | FFFFFFF _H | Link Register on Page 2-8 |
| PC | rw | Either | See description | Program Counter on Page 2-8 |

Central Processing Unit (CPU)
Table 2-2 Core register set summary (cont'd)

| Name | Type ¹⁾ | Required privilege ²⁾ | Reset value | Description |
|-----------|--------------------|----------------------------------|-----------------------|---|
| PSR | rw | Privileged | 01000000 _H | Program Status Register on Page 2-9 |
| ASPR | rw | Either | Unknown | Application Program Status Register on Page 2-9 |
| IPSR | r | Privileged | 00000000 _H | Interrupt Program Status Register on Page 2-10 |
| EPSR | r | Privileged | 01000000 _H | Execution Program Status Register on Page 2-11 |
| PRIMASK | rw | Privileged | 00000000 _H | Priority Mask Register on Page 2-13 |
| FAULTMASK | rw | Privileged | 00000000 _H | Fault Mask Register on Page 2-14 |
| BASEPRI | rw | Privileged | 00000000 _H | Base Priority Mask Register on Page 2-14 |
| CONTROL | rw | Privileged | 00000000 _H | CONTROL register on Page 2-15 |

1) Describes access type during program execution in thread mode and Handler mode. Debug access can differ.

2) An entry of Either means privileged and unprivileged software can access the register.

General-purpose registers

R0-R12 are 32-bit general-purpose registers for data operations

Rx (x=0-12)
General Purpose Register Rx
Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| VALUE | [31:0] | rw | Content of Register |

Stack Pointer

The Stack Pointer (SP) is register R13. In Thread mode, bit[1] of the CONTROL register indicates the stack pointer to use:

- 0 = Main Stack Pointer (MSP). This is the reset value.
- 1 = Process Stack Pointer (PSP).

On reset, the processor loads the MSP with the value from address 00000000_H.

SP

Stack Pointer

Reset Value: 2000 FF3C_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| VALUE | [31:0] | rw | Content of Register |

Link Register

The Link Register (LR) is register R14. It stores the return information for subroutines, function calls, and exceptions. On reset, the processor sets the LR value to FFFFFFFF_H.

LR

Link Register

Reset Value: FFFF FFFF_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| VALUE | [31:0] | rw | Content of Register |

Program Counter

The Program Counter (PC) is register R15. It contains the current program address. On reset, the processor loads the PC with the value of the reset vector, which is at address 00000004_H. Bit[0] of the value is loaded into the EPSR T-bit at reset and must be 1.

PC

Program Counter

Reset Value: 0000 0004_H

| Field | Bits | Type | Description |
|-------|--------|------|---------------------|
| VALUE | [31:0] | rw | Content of Register |

Program Status Register

The Program Status Register (PSR) combines:

- Application Program Status Register (APSR)
- Interrupt Program Status Register (IPSR)
- Execution Program Status Register (EPSR)

These registers are mutually exclusive bit fields in the 32-bit PSR.

Access these registers individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example:

- read all of the registers using PSR with the MRS instruction
- write to the APSR N, Z, C, V, and Q bits using APSR_nzcvq with the MSR instruction.

The PSR combinations and attributes are:

Table 2-3 PSR register combinations

| Register | Type | Combination |
|----------|--------------------|----------------------|
| PSR | rw ¹⁾²⁾ | APSR, EPSR, and IPSR |
| IEPSR | r | EPSR and IPSR |
| IAPSR | rw ¹⁾ | APSR and IPSR |
| EAPSR | rw ²⁾ | APSR and EPSR |

1) The processor ignores writes to the IPSR bits.

2) Reads of the EPSR bits return zero, and the processor ignores writes to the these bits

Application Program Status Register

The APSR contains the current state of the condition flags from previous instruction executions. See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

APSR

Application Program Status Register

Reset Value: XXXX XXXX_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| N | Z | C | V | Q | 0 | | | | | | | GE[3:0] | | | | 0 | | | | | | | | | | | | | | | |
| rw | rw | rw | rw | rw | r | | | | | | | rw | | | | r | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|----------------|--------------------|------|---|
| GE[3:0] | [19:16] | rw | Greater than or Equal flags Please refer also to SEL instruction. |
| Q | 27 | rw | DSP overflow and saturation flag |
| V | 28 | rw | Overflow flag |
| C | 29 | rw | Carry or borrow flag |
| Z | 30 | rw | Zero flag |
| N | 31 | rw | Negative flag |
| 0 | [26:20], [15:0] | r | Reserved Read as 0; should be written with 0. |

Interrupt Program Status Register

The IPSR contains the exception type number of the current Interrupt Service Routine (ISR). See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

IPSR

Interrupt Program Status Register

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | | | | | | ISR_NUMBER | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | | r | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------------------|--------|------|---|
| ISR_NUMBER | [8:0] | r | Number of the current exception 0 _D Thread mode 1 _D Reserved 2 _D NMI 3 _D HardFault 4 _D MemManage 5 _D BusFault 6 _D UsageFault 7 _D Reserved 8 _D Reserved 9 _D Reserved 10 _D Reserved 11 _D SVCall 12 _D Reserved for Debug 13 _D Reserved 14 _D PendSV 15 _D SysTick 16 _D IRQ0 ... 127 _D IRQ111 Values > 127 _D undefined. See Exception types on Page 2-26 for more information. |
| 0 | [31:9] | r | Reserved Read as 0; should be written with 0. |

Execution Program Status Register

The EPSR contains the Thumb state bit, and the execution state bits for either the:

- If-Then (IT) instruction
- Interruptible-Continuable Instruction (ICI) field for an interrupted load multiple or store multiple instruction.

See the register summary in [Table 2-2](#) on [Page 2-6](#) for the EPSR attributes.

Attempts to read the EPSR directly through application software using the MSR instruction always return zero. Attempts to write the EPSR using the MSR instruction in application software are ignored.

EPSR

Execution Program Status Register

Reset Value: 0100 0000_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|--------|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | ICI/IT | | T | 0 | | | | ICI/IT | | | | 0 | | | | | | | | | | | | | | | | |
| r | | | | r | | r | r | | | | r | | | | r | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------|-------------------------------|------|--|
| IC/IT | [26:25], [15:10] | r | Interruptible-continuable instruction bits/Execution state bits of the IT instruction Please refer also to IT instruction. |
| T | 24 | r | Thumb state bit Thumb state. |
| 0 | [31:27], [23:16], [9:0] | r | Reserved Read as 0; should be written with 0. |

Interruptible-continuable instructions

When an interrupt occurs during the execution of an LDM, STM, PUSH, POP, VLDM, VSTM, VPOP, or VPOP instruction, the processor:

- stops the load multiple or store multiple instruction operation temporarily
- stores the next register operand in the multiple operation to EPSR bits[15:12]

After servicing the interrupt, the processor:

- returns to the register pointed to by bits[15:12]
- resumes execution of the multiple load or store instruction.

When the EPSR holds ICI execution state, bits[26:25,11:10] are zero.

If-Then block

The If-Then block contains up to four instructions following an IT instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some can be the inverse of others. See IT on page 3-122 for more information.

Thumb state

The Cortex-M4 processor only supports execution of instructions in Thumb state. The following can clear the T bit to 0:

- instructions BLX, BX and POP{PC}

Central Processing Unit (CPU)

- restoration from the stacked xPSR value on an exception return
- bit[0] of the vector value on an exception entry or reset.

Attempting to execute instructions when the T bit is 0 results in a fault or lockup. See Lockup on [Page 2-39](#) for more information.

Exception mask registers

The exception mask registers disable the handling of exceptions by the processor. Disable exceptions where they might impact on timing critical tasks.

To access the exception mask registers use the MSR and MRS instructions, or the CPS instruction to change the value of PRIMASK or FAULTMASK.

Priority Mask Register

The PRIMASK register prevents activation of all exceptions with configurable priority. See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

PRIMASK

Priority Mask Register

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| PRIMASK | 0 | rw | Priority Mask 0 _B No effect 1 _B Prevents the activation of all exceptions with configurable priority. |
| 0 | [31:1] | r | Reserved Read as 0; should be written with 0. |

Central Processing Unit (CPU)

Fault Mask Register

The FAULTMASK register prevents activation of all exceptions except for Non-Maskable Interrupt (NMI). See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

FAULTMASK

Fault Mask Register

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| FAULTMASK | 0 | rw | Fault Mask 0_B no effect 1_B prevents the activation of all exceptions except for NMI. |
| 0 | [31:1] | r | Reserved Read as 0; should be written with 0. |

The processor clears the FAULTMASK bit to 0 on exit from any exception handler except the NMI handler.

Base Priority Mask Register

The BASEPRI register defines the minimum priority for exception processing. When BASEPRI is set to a nonzero value, it prevents the activation of all exceptions with the same or lower priority level as the BASEPRI value. See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

Central Processing Unit (CPU)

BASEPRI

Base Priority Mask Register

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------------|--------|------|---|
| BASEPRI¹⁾ | [7:0] | rw | Priority mask bits 0_H no effect others , defines the base priority for exception processing. The processor does not process any exception with a priority value greater than or equal to BASEPRI. |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

1) This field is similar to the priority fields in the interrupt priority registers. The XMC4[78]00 implements only bits[7:2] of this field, bits[1:0] read as zero and ignore writes. See [Interrupt Priority Registers](#) on [Page 2-90](#) for more information. Remember that higher priority field values correspond to lower exception priorities.

CONTROL register

The CONTROL register controls the stack used and the privilege level for software execution when the processor is in Thread mode and indicates whether the FPU state is active. See the register summary in [Table 2-2](#) on [Page 2-6](#) for its attributes.

CONTROL

CONTROL register

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| nPRIV | 0 | rh | Thread mode privilege level 0 _B Privileged 1 _B Unprivileged |
| SPSEL | 1 | rh | Currently active stack pointer In Handler mode this bit reads as zero and ignores writes. The Cortex-M4 updates this bit automatically on exception return. 0 _B MSP is the current stack pointer 1 _B PSP is the current stack pointer |
| FPCA | 2 | rh | Floating-point context currently active 0 _B No floating-point context active 1 _B Floating-point context active The Cortex-M4 uses this bit to determine whether to preserve floating-point state when processing an exception. |
| 0 | [31:3] | r | Reserved Read as 0; should be written with 0. |

Handler mode always uses the MSP, so the processor ignores explicit writes to the active stack pointer bit of the CONTROL register when in Handler mode. The exception entry and return mechanisms automatically update the CONTROL register based on the EXC_RETURN value, see [Table 2-9](#) on [Page 2-36](#).

In an OS environment, ARM recommends that threads running in Thread mode use the process stack and the kernel and exception handlers use the main stack.

Central Processing Unit (CPU)

By default, Thread mode uses the MSP. To switch the stack pointer used in Thread mode to the PSP, either:

- use the MSR instruction to set the Active stack pointer bit to 1.
- perform an exception return to Thread mode with the appropriate EXC_RETURN value, see [Table 2-9](#) on [Page 2-36](#).

Note: When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction. This ensures that instructions after the ISB instruction execute using the new stack pointer.

2.2.4 Exceptions and Interrupts

The Cortex-M4 processor supports interrupts and system exceptions. The processor and the NVIC prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses Handler mode to handle all exceptions except for reset. See Exception entry on [Page 2-33](#) and Exception return on [Page 2-36](#) for more information.

The NVIC registers control interrupt handling. See [Page 2-43](#) for more information.

2.2.5 Data Types

The processor:

- supports the following data types:
 - 32-bit words
 - 16-bit halfwords
 - 8-bit bytes
- manages all data memory accesses as little-endian. See Memory regions, types and attributes on [Page 2-20](#) for more information.

2.2.6 The Cortex Microcontroller Software Interface Standard

For a Cortex-M4 microcontroller system, the Cortex Microcontroller Software Interface Standard (CMSIS) [\[2\]](#) defines:

- a common way to:
 - access peripheral registers
 - define exception vectors
- the names of:
 - the registers of the core peripherals
 - the core exception vectors
- a device-independent interface for RTOS kernels, including a debug channel.

The CMSIS includes address definitions and data structures for the core peripherals in the Cortex-M4 processor.

Central Processing Unit (CPU)

CMSIS simplifies software development by enabling the reuse of template code and the combination of CMSIS-compliant software components from various middleware vendors. Software vendors can expand the CMSIS to include their peripheral definitions and access functions for those peripherals.

This document includes the register names defined by the CMSIS, and gives short descriptions of the CMSIS functions that address the processor core and the core peripherals.

Note: This document uses the register short names defined by the CMSIS. In a few cases these differ from the architectural short names that might be used in other documents.

The following sections give more information about the CMSIS:

- Power management programming hints on [Page 2-42](#)
- CMSIS functions on [Page 2-18](#)
- Using CMSIS functions to access NVIC on [Page 2-45](#)

For additional information please refer to <http://www.onarm.com/cmsis>

2.2.7 CMSIS functions

ISO/IEC C code cannot directly access some Cortex-M4 instructions. This section describes intrinsic functions that can generate these instructions, provided by the CMSIS and that might be provided by a C compiler. If a C compiler does not support an appropriate intrinsic function, you might have to use inline assembler to access some instructions.

The CMSIS provides the following intrinsic functions to generate instructions that ISO/IEC C code cannot directly access:

Table 2-4 CMSIS functions to generate some Cortex-M4 instructions

| Instruction | CMSIS function |
|-------------|---|
| CPSIE I | <code>void __enable_irq(void)</code> |
| CPSID I | <code>void __disable_irq(void)</code> |
| CPSIE F | <code>void __enable_fault_irq(void)</code> |
| CPSID F | <code>void __disable_fault_irq(void)</code> |
| ISB | <code>void __ISB(void)</code> |
| DSB | <code>void __DSB(void)</code> |
| DMB | <code>void __DMB(void)</code> |
| REV | <code>uint32_t __REV(uint32_t int value)</code> |
| REV16 | <code>uint32_t __REV16(uint32_t int value)</code> |

Central Processing Unit (CPU)

Table 2-4 CMSIS functions to generate some Cortex-M4 instructions (cont'd)

| Instruction | CMSIS function |
|-------------|--------------------------------------|
| REVSH | uint32_t __REVSH(uint32_t int value) |
| RBIT | uint32_t __RBIT(uint32_t int value) |
| SEV | void __SEV(void) |
| WFE | void __WFE(void) |
| WFI | void __WFI(void) |

The CMSIS also provides a number of functions for accessing the special registers using MRS and MSR instructions:

Table 2-5 CMSIS functions to access the special registers

| Special register | Access | CMSIS function |
|------------------|--------|--|
| PRIMASK | Read | uint32_t __get_PRIMASK (void) |
| | Write | void __set_PRIMASK (uint32_t value) |
| FAULTMASK | Read | uint32_t __get_FAULTMASK (void) |
| | Write | void __set_FAULTMASK (uint32_t value) |
| BASEPRI | Read | uint32_t __get_BASEPRI (void) |
| | Write | void __set_BASEPRI (uint32_t value) |
| CONTROL | Read | uint32_t __get_CONTROL (void) |
| | Write | void __set_CONTROL (uint32_t value) |
| MSP | Read | uint32_t __get_MSP (void) |
| | Write | void __set_MSP (uint32_t TopOfMainStack) |
| PSP | Read | uint32_t __get_PSP (void) |
| | Write | void __set_PSP (uint32_t TopOfProcStack) |

Central Processing Unit (CPU)

2.3 Memory Model

This section describes the processor memory map and the behavior of memory accesses. The processor has a fixed default memory map that provides up to 4GB of addressable memory. The memory map is:

| | | |
|------------------------|-------|--------------------------|
| Vendor-specific memory | 511MB | 0xFFFFFFFF |
| Private peripheral bus | 1.0MB | 0xE0100000 0xE00FFFFF |
| External device | 1.0GB | 0xE0000000 0xDFFFFFFF |
| External RAM | 1.0GB | 0xA0000000 0x9FFFFFFF |
| Peripheral | 0.5GB | 0x60000000 0x5FFFFFFF |
| SRAM | 0.5GB | 0x40000000 0x3FFFFFFF |
| Code | 0.5GB | 0x20000000 0x1FFFFFFF |
| | | 0x00000000 |

Figure 2-3 Memory map

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers, see About the Private Peripherals on [Page 2-42](#).

2.3.1 Memory Regions, Types and Attributes

The memory map and the programming of the MPU splits the memory map into regions. Each region has a defined memory type, and some regions have additional memory

Central Processing Unit (CPU)

attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

| | |
|-------------------------|--|
| Normal | The processor can re-order transactions for efficiency, or perform speculative reads. |
| Device | The processor preserves transaction order relative to other transactions to Device or Strongly-ordered memory. |
| Strongly-ordered | The processor preserves transaction order relative to all other transactions. |

The different ordering requirements for Device and Strongly-ordered memory mean that the memory system can buffer a write to Device memory, but must not buffer a write to Strongly-ordered memory.

The additional memory attributes include:

Execute Never (XN) Means the processor prevents instruction accesses. A fault exception is generated only on execution of an instruction executed from an XN region.

2.3.2 Memory System Ordering of Memory Accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing this does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions. See Software ordering of memory accesses on [Page 2-23](#).

However, the memory system does guarantee some ordering of accesses to Device and Strongly-ordered memory. For two memory access instructions A1 and A2, if A1 occurs before A2 in program order, the ordering of the memory accesses caused by two instructions is:

| A1 \ A2 | Normal access | Device access | Strongly-ordered access |
|-------------------------|---------------|---------------|-------------------------|
| Normal access | - | - | - |
| Device access | - | < | < |
| Strongly-ordered access | - | < | < |

Figure 2-4 Ordering of Memory Accesses

Where:

- “-” Means that the memory system does not guarantee the ordering of the accesses.
- “<” Means that accesses are observed in program order, that is, A1 is always observed before A2.

2.3.3 Behavior of Memory Accesses

The behavior of accesses to each region in the memory map is:

Table 2-6 Memory access behavior

| Address range | Memory region | Memory type ¹⁾ | XN ¹⁾ | Description |
|-----------------------|------------------------|---------------------------|------------------|--|
| 0x00000000-0x1FFFFFFF | Code | Normal | - | Executable region for program code. You can also put data here. |
| 0x20000000-0x3FFFFFFF | SRAM | Normal | - | Executable region for data. You can also put code here. |
| 0x40000000-0x5FFFFFFF | Peripheral | Device | XN | Peripherals region. |
| 0x60000000-0x9FFFFFFF | External RAM | Normal | - | Executable region for data. |
| 0xA0000000-0xDFFFFFFF | External device | Device | XN | External Device memory. |
| 0xE0000000-0xE00FFFFF | Private Peripheral Bus | Strongly-ordered | XN | This region includes the NVIC, System timer, and system control block. |
| 0xE0100000-0xFFFFFFFF | Vendor-specific device | Device | XN | Accesses to this region are to vendor-specific peripherals. |

1) See Memory regions, types and attributes on [Page 2-20](#) for more information.

The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region. This is because the processor has separate buses that enable instruction fetches and data accesses to occur simultaneously.

The MPU can override the default memory access behavior described in this section. For more information, see Memory protection unit on [Page 2-46](#).

Instruction prefetch and branch prediction

The Cortex-M4 processor:

- prefetches instructions ahead of execution
- speculatively prefetches from branch target addresses.

2.3.4 Software Ordering of Memory Accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions. This is because:

- the processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces
- memory or devices in the memory map have different wait states
- some memory accesses are buffered or speculative.

Memory system ordering of memory accesses on [Page 2-21](#) describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The processor provides the following memory barrier instructions:

| | |
|------------|--|
| DMB | The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions. |
| DSB | The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute. |
| ISB | The Instruction Synchronization Barrier (ISB) ensures that the effect of all completed memory transactions is recognizable by subsequent instructions. |

MPU programming

Use a DSB followed by an ISB instruction or exception return to ensure that the new MPU configuration is used by subsequent instructions.

2.3.5 Memory Endianness

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. The XMC4[78]00 stores information “Little-endian” format.

Little-endian format

In little-endian format, the processor stores the least significant byte of a word at the lowest-numbered byte, and the most significant byte at the highest-numbered byte. For example:

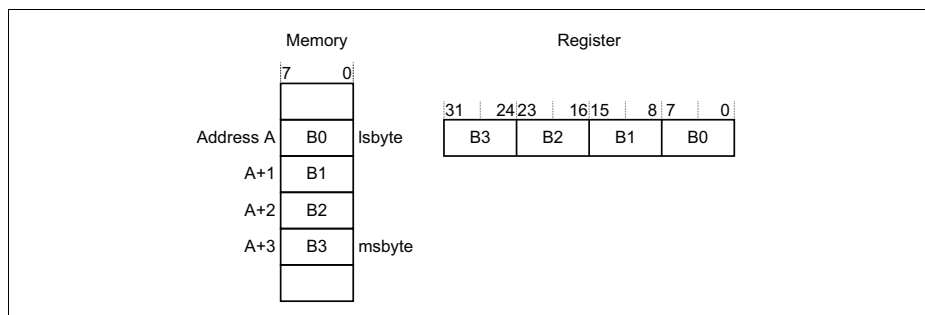

Figure 2-5 Little-endian format

2.3.6 Synchronization Primitives

The Cortex-M4 instruction set includes pairs of synchronization primitives. These provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use them to perform a guaranteed read-modify-write memory update sequence, or for a semaphore mechanism.

A pair of synchronization primitives comprises:

A Load-Exclusive instruction

Used to read the value of a memory location, requesting exclusive access to that location.

A Store-Exclusive instruction

Used to attempt to write to the same memory location, returning a status bit to a register. If this bit is:

- 0 it indicates that the thread or process gained exclusive access to the memory, and the write succeeds,
- 1 it indicates that the thread or process did not gain exclusive access to the memory, and no write was performed.

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- the word instructions LDREX and STREX
- the halfword instructions LDREXH and STREXH
- the byte instructions LDREXB and STREXB.

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform an exclusive read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Modify the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location.
4. Test the returned status bit. If this bit is:
 - 0 The read-modify-write completed successfully.
 - 1 No write was performed. This indicates that the value returned at step 1 might be out of date. The software must retry the entire read-modify-write sequence.

Software can use the synchronization primitives to implement a semaphores as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.
2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.
3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M4 includes an exclusive access monitor, that tags the fact that the processor has executed a Load-Exclusive instruction.

The processor removes its exclusive access tag if:

- It executes a CLREX instruction.
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs. This means the processor can resolve semaphore conflicts between different threads.

2.3.7 Programming Hints for the Synchronization Primitives

ISO/IEC C cannot directly generate the exclusive access instructions. CMSIS provides intrinsic functions for generation of these instructions:

Table 2-7 CMSIS functions for exclusive access instructions

| Instruction | CMSIS function |
|-------------|---|
| LDREX | <code>uint32_t __LDREXW (uint32_t *addr)</code> |
| LDREXH | <code>uint16_t __LDREXH (uint16_t *addr)</code> |
| LDREXB | <code>uint8_t __LDREXB (uint8_t *addr)</code> |
| STREX | <code>uint32_t __STREXW (uint32_t value, uint32_t *addr)</code> |
| STREXH | <code>uint32_t __STREXH (uint16_t value, uint16_t *addr)</code> |
| STREXB | <code>uint32_t __STREXB (uint8_t value, uint8_t *addr)</code> |
| CLREX | <code>void __CLREX (void)</code> |

For example:

```
uint16_t value;
uint16_t *address = 0x20001002;
value = __LDREXH (address);    // load 16-bit value from memory
address 0x20001002
```

2.4 Instruction Set

The Cortex-M4 instruction set reference is available through [\[1\]](#)

2.5 Exception Model

This section describes the exception model. It describes:

- Exception states
- Exception types
- Exception handlers on [Page 2-27](#)
- Vector table on [Page 2-30](#)
- Exception priorities on [Page 2-31](#)
- Interrupt priority grouping on [Page 2-31](#)
- Exception entry and return on [Page 2-32](#)

2.5.1 Exception States

Each exception is in one of the following states:

| | |
|---------------------------|--|
| Inactive | The exception is not active and not pending. |
| Pending | The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending. |
| Active | An exception that is being serviced by the processor but has not completed. <i>Note: An exception handler can interrupt the execution of another exception handler. In this case both exceptions are in the active state.</i> |
| Active and pending | The exception is being serviced by the processor and there is a pending exception from the same source. |

2.5.2 Exception Types

The exception types are:

| | |
|------------------|--|
| Reset | Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode. |
| NMI | A NonMaskable Interrupt (NMI) can be signalled by a peripheral or triggered by software. This is the highest priority exception other than reset. It is permanently enabled and has a fixed priority of -2. NMIs cannot be: <ul style="list-style-type: none"> masked or prevented from activation by any other exception preempted by any exception other than Reset. |
| HardFault | A HardFault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. HardFaults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority. |
| MemManage | A MemManage fault is an exception that occurs because of a memory protection related fault. The MPU or the fixed memory protection constraints determines this fault, for both instruction and data memory transactions. This fault is always used to abort instruction accesses to Execute Never (XN) memory regions. |

Central Processing Unit (CPU)

| | |
|------------------------|---|
| BusFault | A BusFault is an exception that occurs because of a memory related fault for an instruction or data memory transaction. This might be from an error detected on a bus in the memory system. |
| UsageFault | <p>A UsageFault is an exception that occurs because of a fault related to instruction execution. This includes:</p> <ul style="list-style-type: none"> • an undefined instruction • an illegal unaligned access • invalid state on instruction execution • an error on exception return. <p>The following can cause a UsageFault when the core is configured to report them:</p> <ul style="list-style-type: none"> • an unaligned address on word and halfword memory access • division by zero. |
| SVCall | A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers. |
| PendSV | PendSV is an interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active. |
| SysTick | A SysTick exception is an exception the system timer generates when it reaches zero. Software can also generate a SysTick exception. In an OS environment, the processor can use this exception as system tick. |
| Interrupt (IRQ) | An interrupt, or IRQ, is an exception signalled by a peripheral, or generated by a software request. All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor. |

Table 2-8 Properties of the different exception types

| Exception number¹⁾ | IRQ number¹⁾ | Exception type | Priority | Vector address or offset²⁾ | Activation |
|--------------------------------------|--------------------------------|-----------------------|----------------------------|--|-------------------|
| 1 | - | Reset | -3, the highest | 0x00000004 | Asynchronous |
| 2 | -14 | NMI | -2 | 0x00000008 | Asynchronous |
| 3 | -13 | HardFault | -1 | 0x0000000C | - |
| 4 | -12 | MemManage | Configurable ³⁾ | 0x00000010 | Synchronous |

Central Processing Unit (CPU)
Table 2-8 Properties of the different exception types (cont'd)

| Exception number ¹⁾ | IRQ number ¹⁾ | Exception type | Priority | Vector address or offset ²⁾ | Activation |
|--------------------------------|--------------------------|-----------------|----------------------------|--|---|
| 5 | -11 | BusFault | Configurable ³⁾ | 0x00000014 | Synchronous when precise, asynchronous when imprecise |
| 6 | -10 | UsageFault | Configurable ³⁾ | 0x00000018 | Synchronous |
| 7-10 | - | Reserved | - | - | - |
| 11 | -5 | SVCall | Configurable ³⁾ | 0x0000002C | Synchronous |
| 12-13 | - | Reserved | - | - | - |
| 14 | -2 | PendSV | Configurable ³⁾ | 0x00000038 | Asynchronous |
| 15 | -1 | SysTick | Configurable ³⁾ | 0x0000003C | Asynchronous |
| 16 and above | 0 and above | Interrupt (IRQ) | Configurable ⁴⁾ | 0x00000040 and above ⁵⁾ | Asynchronous |

1) To simplify the software layer, the CMSIS only uses IRQ numbers and therefore uses negative values for exceptions other than interrupts. The IPSR returns the Exception number, see Interrupt Program Status Register on [Page 2-10](#).

2) See Vector table for more information.

3) See System Handler Priority Registers on [Page 2-70](#)

4) See Interrupt Priority Registers on [Page 2-90](#).

5) Increasing in steps of 4.

For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that [Table 2-8](#) on [Page 2-28](#) shows as having configurable priority, see:

- System Handler Control and State Register on [Page 2-72](#)
- Interrupt Clear-enable Registers on [Page 2-88](#).

For more information about HardFaults, MemManage faults, BusFaults, and UsageFaults, see Fault handling on [Page 2-36](#).

2.5.3 Exception Handlers

The processor handles exceptions using:

| | |
|--|--|
| Interrupt Service Routines (ISRs) | Interrupts IRQ0 to IRQ111 are the exceptions handled by ISRs. |
| Fault handlers | HardFault, MemManage fault, UsageFault, and BusFault are fault exceptions handled by the fault handlers. |
| System handlers | NMI, PendSV, SVCall SysTick, and the fault exceptions are all system exceptions that are handled by system handlers. |

2.5.4 Vector Table

The vector table contains the reset value of the stack pointer, and the start addresses, also called exception vectors, for all exception handlers. [Figure 2-6](#) on [Page 2-30](#) shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code, see Thumb state on [Page 2-12](#).

| Exception number | IRQ number | Offset | Vector |
|------------------|------------|--------|-------------------------|
| 127 | 111 | 0x01FC | IRQ111 |
| . | | . | . |
| . | | . | . |
| . | | . | . |
| | | 0x004C | |
| 18 | 2 | 0x0048 | IRQ2 |
| 17 | 1 | 0x0044 | IRQ1 |
| 16 | 0 | 0x0040 | IRQ0 |
| 15 | -1 | 0x003C | Systick |
| 14 | -2 | 0x0038 | PendSV |
| 13 | | | Reserved |
| 12 | | | Reserved for Debug |
| 11 | -5 | 0x002C | SVCall |
| 10 | | | Reserved |
| 9 | | | |
| 8 | | | |
| 7 | | | |
| 6 | -10 | 0x0018 | Usage fault |
| 5 | -11 | 0x0014 | Bus fault |
| 4 | -12 | 0x0010 | Memory management fault |
| 3 | -13 | 0x000C | Hard fault |
| 2 | -14 | 0x0008 | NMI |
| 1 | | 0x0004 | Reset |
| | | 0x0000 | Initial SP value |

Figure 2-6 Vector table

On system reset, the vector table is fixed at address 0x00000000. Privileged software can write to the VTOR to relocate the vector table start address to a different memory location, in the range 0x00000400 to 0x3FFFC00, see Vector Table Offset Register on [Page 2-63](#).

2.5.5 Exception Priorities

As [Table 2-8](#) on [Page 2-28](#) shows, all exceptions have an associated priority, with:

- a lower priority value indicating a higher priority
- configurable priorities for all exceptions except Reset, HardFault, and NMI.

If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities see

- System Handler Priority Registers on [Page 2-70](#)
- Interrupt Priority Registers on [Page 2-90](#).

Note: Configurable priority values are in the range 0-63. This means that the Reset, HardFault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

2.5.6 Interrupt Priority Grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This divides each interrupt priority register entry into two fields:

- an upper field that defines the group priority
- a lower field that defines a subpriority within the group.

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler,

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

Central Processing Unit (CPU)

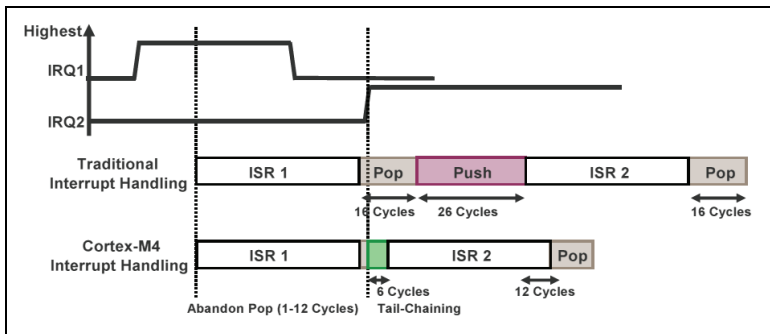

For information about splitting the interrupt priority fields into group priority and subpriority, see Application Interrupt and Reset Control Register on [Page 2-64](#).

2.5.7 Exception Entry and Return

Descriptions of exception handling use the following terms:

Preemption When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See Interrupt priority grouping for more information about preemption by an interrupt.

When one exception preempts another, the exceptions are called nested exceptions. See Exception entry on [Page 2-33](#) more information.

Source of figure [\[3\]](#).

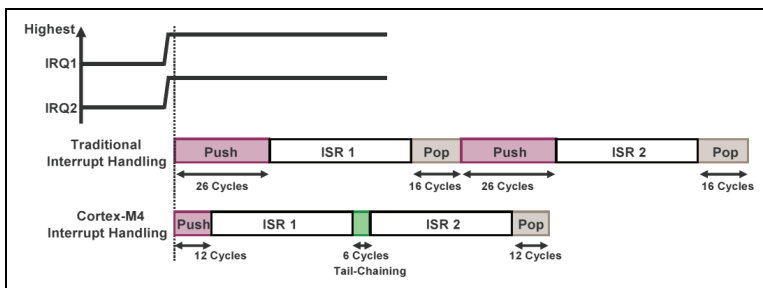

Return

This occurs when the exception handler is completed, and:

- there is no pending exception with sufficient priority to be serviced
- the completed exception handler was not handling a late-arriving exception.

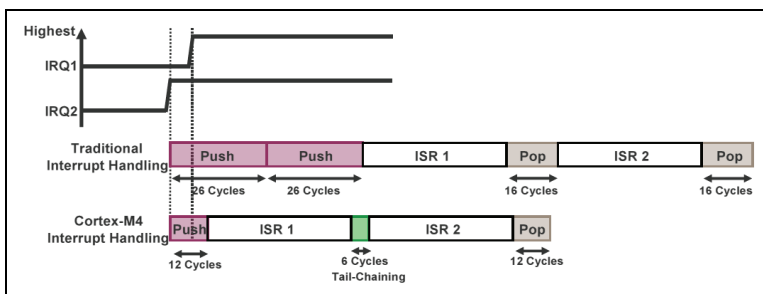

The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See Exception return on [Page 2-36](#) for more information.

Tail-chaining This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.

Source of figure [3].

Late-arriving This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

Source of figure [3].

Exception entry

Exception entry occurs when there is a pending exception with sufficient priority and either:

Central Processing Unit (CPU)

- the processor is in Thread mode
- the new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has more priority than any limits set by the mask registers, see Exception mask registers on [Page 2-13](#). An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as stacking and the structure of eight data words is referred to as the stack frame.

When using floating-point routines, the Cortex-M4 processor automatically stacks the architected floating-point state on exception entry. [Figure 2-7](#) on [Page 2-35](#) shows the Cortex-M4 stack frame layout when floating-point state is preserved on the stack as the result of an interrupt or an exception.

Note: Where stack space for floating-point state is not allocated, the stack frame is the same as that of ARMv7-M implementations without an FPU. [Figure 2-7](#) on [Page 2-35](#) shows this stack frame also.

Figure 2-7 Exception stack frame

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame. The alignment of the stack frame is controlled via the STKALIGN bit of the Configuration Control Register (CCR).

The stack frame includes the return address. This is the address of the next instruction in the interrupted program. This value is restored to the PC at exception return so that the interrupted program resumes.

In parallel to the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an EXC_RETURN value to the LR. This indicates which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

Central Processing Unit (CPU)

If another higher priority exception occurs during exception entry, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception. This is the late arrival case.

Exception return

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the EXC_RETURN value into the PC:

- an LDM or POP instruction that loads the PC
- an LDR instruction with PC as the destination
- a BX instruction using any register.

EXC_RETURN is the value loaded into the LR on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest five bits of this value provide information on the return stack and processor mode. [Table 2-9](#) shows the EXC_RETURN values with a description of the exception return behavior.

All EXC_RETURN values have bits[31:5] set to one. When this value is loaded into the PC it indicates to the processor that the exception is complete, and the processor initiates the appropriate exception return sequence.

Table 2-9 Exception return behavior

| EXC_RETURN[31:0] | Description |
|------------------|--|
| 0xFFFFFFFF1 | Return to Handler mode, exception return uses non-floating-point state from the MSP and execution uses MSP after return. |
| 0xFFFFFFFF9 | Return to Thread mode, exception return uses non-floating-point state from MSP and execution uses MSP after return. |
| 0xFFFFFFFFD | Return to Thread mode, exception return uses non-floating-point state from the PSP and execution uses PSP after return. |
| 0xFFFFFEE1 | Return to Handler mode, exception return uses floating-point-state from MSP and execution uses MSP after return. |
| 0xFFFFFEE9 | Return to Thread mode, exception return uses floating-point state from MSP and execution uses MSP after return. |
| 0xFFFFFEEF | Return to Thread mode, exception return uses floating-point state from PSP and execution uses PSP after return. |

2.6 Fault Handling

Faults are a subset of the exceptions, see Exception model on [Page 2-26](#). Faults are generated by:

- a bus error on:

Central Processing Unit (CPU)

- an instruction fetch or vector table load
- a data access.
- an internally-detected error such as an undefined instruction
- attempting to execute an instruction from a memory region marked as Non-Executable (XN).
- a privilege violation or an attempt to access an unmanaged region causing an MPU fault

2.6.1 Fault Types

Table 2-10 shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates that the fault has occurred. See Configurable Fault Status Register on page 4-24 for more information about the fault status registers.

Table 2-10 Faults

| Fault | Handler | Bit name | Fault status register |
|---|-----------|------------------------|---|
| Bus error on a vector read | HardFault | VECTTBL | HardFault Status Register on Page 2-81 |
| Fault escalated to a hard fault | | FORCED | |
| MPU or default memory map mismatch: | MemManage | - | - |
| on instruction access | | IACCVIOL ¹⁾ | MemManage Fault Address Register on Page 2-82 |
| on data access | | DACCVIOL | |
| during exception stacking | | MSTKERR | |
| during exception unstacking | | MUNSKERR | |
| during lazy floating-point state preservation | | MLSPERR | |

Central Processing Unit (CPU)

Table 2-10 Faults (cont'd)

| Fault | Handler | Bit name | Fault status register |
|---|----------------|-----------------|---|
| Bus error: | BusFault | - | - |
| during exception stacking | | STKERR | BusFault Status Register on Page 2-74 |
| during exception unstacking | | UNSTKERR | |
| during instruction prefetch | | IBUSERR | |
| during lazy floating-point state preservation | | LSPERR | |
| Precise data bus error | | PRECISERR | |
| Imprecise data bus error | | IMPRECISERR | |
| Attempt to access a coprocessor | UsageFault | NOCP | UsageFault Status Register on Page 2-74 |
| Undefined instruction | | UNDEFINSTR | |
| Attempt to enter an invalid instruction set state ²⁾ | | INVSTATE | |
| Invalid EXC_RETURN value | | INVPC | |
| Illegal unaligned load or store | | UNALIGNED | |
| Divide By 0 | | DIVBYZERO | |

1) Occurs on an access to an XN region even if the processor does not include an MPU or the MPU is disabled.

2) Attempting to use an instruction set other than the Thumb instruction set or returns to a non load/store-multiple instruction with ICI continuation.

2.6.2 Fault Escalation and Hard Faults

All faults exceptions except for HardFault have configurable exception priority, see System Handler Priority Registers on page 4-21. Software can disable execution of the handlers for these faults, see System Handler Control and State Register on page 4-23.

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler. as described in Exception model on [Page 2-26](#).

In some situations, a fault with configurable priority is treated as a HardFault. This is called priority escalation, and the fault is described as escalated to HardFault. Escalation to HardFault occurs when:

Central Processing Unit (CPU)

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to HardFault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This is because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a BusFault occurs during a stack push when entering a BusFault handler, the BusFault does not escalate to a HardFault. This means that if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

Note: Only Reset and NMI can preempt the fixed priority HardFault. A HardFault can preempt any exception other than Reset, NMI, or another HardFault.

2.6.3 Fault Status Registers and Fault Address Registers

The fault status registers indicate the cause of a fault. For BusFaults and MemManage faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in [Table 2-11](#).

Table 2-11 Fault status and fault address registers

| Handler | Status register name | Address register name | Register description |
|------------|----------------------|-----------------------|---|
| HardFault | HFSR | - | HardFault Status Register on Page 2-81 |
| MemManage | MMFSR | MMFAR | MemManage Fault Status Register Page 2-74 MemManage Fault Address Register Page 2-82 |
| BusFault | BFSR | BFAR | BusFault Status Register on Page 2-74 BusFault Address Register on Page 2-83 |
| UsageFault | UFSR | - | UsageFault Status Register on Page 2-74 |

2.6.4 Lockup

The processor enters a lockup state if a fault occurs when executing the NMI or HardFault handlers. When the processor is in lockup state it does not execute any instructions. The processor remains in lockup state until either:

- it is reset

- an NMI occurs
- it is halted by a debugger

Note: If lockup state occurs from the NMI handler a subsequent NMI does not cause the processor to leave lockup state.

2.7 Power Management

The Cortex-M4 processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock.
- Deep sleep mode stops the system clock and switches off the PLL and flash memory.

The SLEEPDEEP bit of the SCR selects which sleep mode is used, see System Control Register on [Page 2-67](#). For more information about the behavior of the sleep modes see section “Power Management” in SCU chapter.

The following section describes the mechanisms for entering sleep mode, and the conditions for waking up from sleep mode.

2.7.1 Entering Sleep Mode

This section describes the mechanisms software can use to put the processor into sleep mode

The system can generate spurious wakeup events, for example a debug operation wakes up the processor. Therefore software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

Wait for interrupt

The wait for interrupt instruction, WFI, causes immediate entry to sleep mode unless the wake-up condition is true, see Wakeup from WFI or sleep-on-exit on [Page 2-41](#). When the processor executes a WFI instruction it stops executing instructions and enters sleep mode.

Wait for event

The wait for event instruction, WFE, causes entry to sleep mode depending on the value of a one-bit event register. When the processor executes a WFE instruction, it checks the value of the event register:

- 0 The processor stops executing instructions and enters sleep mode.
- 1 The processor clears the register to 0 and continues executing instructions without entering sleep mode.

If the event register is 1, this indicate that the processor must not enter sleep mode on execution of a WFE instruction. Typically, this is because an external event signal is

Central Processing Unit (CPU)

asserted, or a processor in the system has executed an SEV instruction, see SEV on page 3-166. Software cannot access this register directly.

Sleep-on-exit

If the SLEEPONEXIT bit of the SCR is set to 1, when the processor completes the execution of all exception handlers it returns to Thread mode and immediately enters sleep mode. Use this mechanism in applications that only require the processor to run when an exception occurs.

2.7.2 Wakeup from Sleep Mode

The conditions for the processor to wakeup depend on the mechanism that cause it to enter sleep mode.

Wakeup from WFI or sleep-on-exit

Normally, the processor wakes up only when it detects an exception with sufficient priority to cause exception entry. Some embedded systems might have to execute system restore tasks after the processor wakes up, and before it executes an interrupt handler. To achieve this set the PRIMASK bit to 1 and the FAULTMASK bit to 0. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor sets PRIMASK to zero. For more information about PRIMASK and FAULTMASK see Exception mask registers on [Page 2-13](#).

Wakeup from WFE

The processor wakes up if:

- it detects an exception with sufficient priority to cause exception entry
- it detects an external event signal, see The external event input

In addition, if the SEVONPEND bit in the SCR is set to 1, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about the SCR see System Control Register on [Page 2-67](#).

2.7.3 The External Event Input

The processor provides an external event input signal. Peripherals can drive this signal, either to wake the processor from WFE, or to set the internal WFE event register to one to indicate that the processor must not enter sleep mode on a later WFE instruction. See Wait for event on [Page 2-40](#) for more information.

2.7.4 Power Management Programming Hints

ISO/IEC C cannot directly generate the WFI and WFE instructions. The CMSIS provides the following functions for these instructions:

```
void __WFE(void)    // Wait for Event
void __WFI(void)    // Wait for Interrupt
```

2.8 Private Peripherals

The following sections are the reference material for the ARM Cortex-M4 core peripherals.

2.8.1 About the Private Peripherals

The address map of the Private Peripheral Bus (PPB) is:

Table 2-12 Core peripheral register regions

| Address | Core peripheral | Description |
|-----------------------|--------------------------------------|---|
| 0xE000E008-0xE000E00F | System control block | Section 2.8.2 and Section 2.9.1 |
| 0xE000E010-0xE000E01F | System timer | Section 2.8.3 and Section 2.9.2 |
| 0xE000E100-0xE000E4EF | Nested Vectored Interrupt Controller | Section 2.8.4 and Section 2.9.3 |
| 0xE000ED00-0xE000ED3F | System control block | Section 2.8.2 and Section 2.9.1 |
| 0xE000ED90-0xE000EDB8 | Memory protection unit | Section 2.8.5 and Section 2.9.4 |
| 0xE000EF00-0xE000EF03 | Nested Vectored Interrupt Controller | Section 2.8.4 and Section 2.9.3 |
| 0xE000EF30-0xE000EF44 | Floating Point Unit | Section 2.8.6 and Section 2.9.5 |

2.8.2 System control block

The System control block (SCB) provides system implementation information, and system control. This includes configuration, control, and reporting of the system exceptions. The system control block registers are:

2.8.2.1 System control block design hints and tips

Ensure software uses aligned accesses of the correct size to access the system control block registers:

- except for the CFSR and SHPR1-SHPR3, it must use aligned word accesses
- for the CFSR and SHPR1-SHPR3 it can use byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to system control block registers.

In a fault handler, to determine the true faulting address:

1. Read and save the MMFAR or BFAR value.
2. Read the MMARVALID bit in the MMFSR, or the BFARVALID bit in the BFSR. The MMFAR or BFAR address is valid only if this bit is 1.

Software must follow this sequence because another higher priority exception might change the MMFAR or BFAR value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the MMFAR or BFAR value.

2.8.3 System timer, SysTick

The processor has a 24-bit system timer, SysTick, that counts down from the reload value to zero, reloads, that is wraps to, the value in the **SYST_RVR** register on the next clock edge, then counts down on subsequent clocks.

Note: When the processor is halted for debugging the counter does not decrement.

2.8.3.1 SysTick design hints and tips

The SysTick counter runs on the clock selected by **SYST_CSR.CLKSOURCE**. If the selected clock signal is stopped, the SysTick counter stops.

Ensure software uses aligned word accesses to access the SysTick registers.

The SysTick counter reload and current value are undefined at reset, the correct initialization sequence for the SysTick counter is:

1. Program reload value.
2. Clear current value.
3. Program Control and Status register.

2.8.4 Nested Vectored Interrupt Controller (NVIC)

This section describes the NVIC and the registers it uses. The XMC4[78]00 NVIC supports:

- 112 interrupts.
- A programmable priority level of 0-63 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Level and pulse detection of interrupt signals.

- Dynamic reprioritization of interrupts.
- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- An external Non-maskable interrupt (NMI)

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead. This provides low latency exception handling. The hardware implementation of the NVIC registers is:

2.8.4.1 Level-sensitive and pulse interrupts

The processor supports both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt, see next section. For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. This means that the peripheral can hold the interrupt signal asserted until it no longer requires servicing.

See section “Service Request Distribution” in the “Service Request Processing” chapter for details about which interrupts are level-based and which are pulsed.

Hardware and software control of interrupts

The Cortex-M4 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- the NVIC detects that the interrupt signal is HIGH and the interrupt is not active
- the NVIC detects a rising edge on the interrupt signal
- software writes to the corresponding interrupt set-pending register bit, see Interrupt Set-pending Registers on [Page 2-89](#) or to the STIR to make an interrupt pending, see Software Trigger Interrupt Register on [Page 2-92](#).

A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt. This changes the state of the interrupt from pending to active. Then:
 - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.

Central Processing Unit (CPU)

- For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.
 If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.
- Software writes to the corresponding interrupt clear-pending register bit.
 For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
 For a pulse interrupt, state of the interrupt changes to:
 - inactive, if the state was pending
 - active, if the state was active and pending.

2.8.4.2 NVIC design hints and tips

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers. See the individual register descriptions for the supported access sizes.

A interrupt can enter pending state even if it is disabled. Disabling an interrupt only prevents the processor from taking that interrupt.

Before programming VTOR to relocate the vector table, ensure the vector table entries of the new vector table are setup for fault handlers, NMI and all enabled exception like interrupts. For more information see Vector Table Offset Register on [Page 2-63](#).

2.8.4.3 Using CMSIS functions to access NVIC

CMSIS functions enable software portability between different Cortex-M profile processors. To ensure Cortex-M portability, use the functions marked for Cortex-M portability in the table below.

CMSIS provides a number of functions for NVIC control, including:

Table 2-13 CMSIS functions for NVIC control

| CMSIS interrupt control function | Description | Cortex-M Portable |
|---|----------------------------|-------------------|
| <code>void NVIC_SetPriorityGrouping(uint32_t priority_grouping)</code> | Set the priority grouping. | No |
| <code>uint32_t NVIC_GetPriorityGrouping(void)</code> | Get the priority grouping. | No |
| <code>void NVIC_EnableIRQ(IRQn_t IRQn)</code> | Enables IRQn. | Yes |

Central Processing Unit (CPU)

Table 2-13 CMSIS functions for NVIC control (cont'd)

| CMSIS interrupt control function | Description | Cortex-M Portable |
|--|--|--------------------------|
| <code>void NVIC_DisableIRQ(IRQn_t IRQn)</code> | Disables IRQn. | Yes |
| <code>uint32_t NVIC_GetPendingIRQ(IRQn_t IRQn)</code> | Return IRQ-Number (true) if IRQn is pending. | Yes |
| <code>void NVIC_SetPendingIRQ(IRQn_t IRQn)</code> | Set IRQn pending. | Yes |
| <code>void NVIC_ClearPendingIRQ(IRQn_t IRQn)</code> | Clear IRQn pending. | Yes |
| <code>uint32_t NVIC_GetActive(IRQn_t IRQn)</code> | Return the IRQ number of the active interrupt. | No |
| <code>void NVIC_SetPriority(IRQn_t IRQn, uint32_t priority)</code> | Set priority for IRQn. | Yes |
| <code>uint32_t NVIC_GetPriority(IRQn_t IRQn)</code> | Read priority of IRQn. | Yes |
| <code>uint32_t NVIC_EncodePriority(uint32_t PriorityGroup, uint32_t PreemptPriority, uint32_t SubPriority)</code> | Encodes the priority for an interrupt with the given priority group, preemptive priority value and sub priority value. | No |
| <code>void NVIC_DecodePriority(uint32_t Priority, uint32_t PriorityGroup, uint32_t* pPreemptPriority, uint32_t* pSubPriority)</code> | Decodes an interrupt priority value with the given priority group to preemptive priority value and sub priority value. | No |
| <code>void NVIC_SystemReset(void)</code> | Reset the system | Yes |

The parameter IRQn is the IRQ number, see [Table 2-8](#) on [Page 2-28](#). For more information about these functions see the CMSIS documentation [\[4\]](#).

2.8.5 Memory Protection Unit (MPU)

The MPU divides the memory map into a number of regions, and defines the location, size, access permissions, and memory attributes of each region. It supports:

- independent attribute settings for each region
- overlapping regions
- export of memory attributes to the system

Central Processing Unit (CPU)

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M4 MPU defines:

- eight separate memory regions, 0-7
- a background region

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.

The Cortex-M4 MPU memory map is unified. This means instruction accesses and data accesses have same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a MemManage fault. This causes a fault exception, and might cause termination of the process in an OS environment.

In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types, see Memory regions, types and attributes on [Page 2-20](#).

Table 2-14 shows the possible MPU region attributes.

Note: The shareability and cache attributes are not relevant to the XMC4[78]00.

Table 2-14 Memory attributes summary

| Address | Shareability | Other attributes | Description |
|------------------|--------------|---|--|
| Strongly-ordered | - | - | All accesses to Strongly-ordered memory occur in program order. All Strongly-ordered regions are assumed to be shared. |
| Device | Shared | - | Memory-mapped peripherals that several processors share. |
| | Non-shared | - | Memory-mapped peripherals that only a single processor uses. |
| Normal | Shared | Non-cacheable Write-through or Write-back Cacheable | Normal memory that is shared between several processors. |
| | Non-shared | Non-cacheable Write-through or Write-back Cacheable | Normal memory that only a single processor uses. |

2.8.5.1 MPU Access Permission Attributes

This section describes the MPU access permission attributes. The access permission bits, TEX, C, B, S, AP, and XN, of the RASR, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault. [Table 2-15](#) shows encodings for the TEX, C, B, and S access permission bits.

Table 2-15 TEX, C, B, and S encoding

| TEX | C | B | S | Memory type | Shareability | Other attributes |
|-------|--------|---|-----------------|------------------------------------|---------------|--|
| 0b000 | 0 | 0 | x | Strongly-ordered | Shareable | - |
| | | 1 | x | Device | Shareable | - |
| | 1 | 0 | 0 | Normal | Not shareable | Outer and inner write-through. No write allocate. |
| | | | 1 | | Shareable | |
| | | 1 | 0 | Normal | Not shareable | Outer and inner write-back. No write allocate. |
| | | | 1 | | Shareable | |
| 0b001 | 0 | 0 | 0 | Normal | Not shareable | Outer and inner noncacheable. |
| | | | 1 | | Shareable | |
| | | 1 | x ¹⁾ | Reserved encoding | | - |
| | 1 | 0 | x ¹⁾ | Implementation defined attributes. | | |
| | | 1 | 0 | Normal | Not shareable | Outer and inner write-back. Write and read allocate. |
| | | | 1 | | Shareable | |
| 0b010 | 0 | 0 | x ¹⁾ | Device | Not shareable | Nonshared Device. |
| | | 1 | x ¹⁾ | Reserved encoding | | - |
| | 1 | x | x ¹⁾ | Reserved encoding | | - |
| 0b1BB | A A | | 0 | Normal | Not shareable | Cached memory, BB = outer policy, AA = inner policy. See Table 2-16 on Page 2-49 for the encoding of the AA and BB bits. |
| | | | 1 | | Shareable | |

1) The MPU ignores the value of this bit.

Central Processing Unit (CPU)

Table 2-16 shows the cache policy for memory attribute encodings with a TEX value is in the range 4-7.

Table 2-16 Cache policy for memory attribute encoding

| Encoding, AA or BB | Corresponding cache policy |
|--------------------|-------------------------------------|
| 00 | Non-cacheable |
| 01 | Write back, write and read allocate |
| 10 | Write through, no write allocate |
| 11 | Write back, no write allocate |

MPU configuration for the XMC4[78]00

The XMC4[78]00 has only a single processor and no caches. However to enable portability it is recommended to program the MPU as follows:

Table 2-17 Memory region attributes for a microcontroller

| Memory region | TEX | C | B | S | Memory type and attributes |
|------------------------|-------|---|---|---|--|
| Internal Flash memory | 0b000 | 1 | 0 | 0 | Normal memory, Non-shareable, write-through |
| Internal SRAM memories | 0b000 | 1 | 0 | 1 | Normal memory, Shareable, write-through |
| External memories | 0b000 | 1 | 1 | 1 | Normal memory, Shareable, write-back, write-allocate |
| Peripherals | 0b000 | 0 | 1 | 1 | Device memory, Shareable |

Table 2-18 shows the AP encodings that define the access permissions for privileged and unprivileged software.

Table 2-18 AP encoding

| AP[2:0] | Privileged permissions | Unprivileged permissions | Description |
|---------|------------------------|--------------------------|---|
| 000 | No access | No access | All accesses generate a permission fault |
| 001 | rw | No access | Access from privileged software only |
| 010 | rw | r | Writes by unprivileged software generate a permission fault |
| 011 | rw | rw | Full access |

Table 2-18 AP encoding (cont'd)

| AP[2:0] | Privileged permissions | Unprivileged permissions | Description |
|---------|------------------------|--------------------------|---|
| 100 | Unpredictable | Unpredictable | Reserved |
| 101 | r | No access | Reads by privileged software only |
| 110 | r | r | Read only, by privileged or unprivileged software |
| 111 | r | r | Read only, by privileged or unprivileged software |

2.8.5.2 MPU Mismatch

When an access violates the MPU permissions, the processor generates a MemManage fault, see Exceptions and interrupts on [Page 2-17](#). The MMFSR indicates the cause of the fault. See MemManage Fault Status Register on [Page 2-74](#) for more information.

2.8.5.3 Updating an MPU Region

To update the attributes for an MPU region, update the MPU_RNR, MPU_RBAR and MPU_RASR registers. You can program each register separately, or use a multiple-word write to program all of these registers. You can use the MPU_RBAR and MPU_RASR aliases to program up to four regions simultaneously using an STM instruction.

Updating an MPU region using separate words

Simple code to configure one region:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0, MPU_RNR           ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]        ; Region Number
STR R4, [R0, #0x4]        ; Region Base Address
STRH R2, [R0, #0x8]       ; Region Size and Enable
STRH R3, [R0, #0xA]       ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
```

Central Processing Unit (CPU)

```
LDR R0, =MPU_RNR           ; 0xE000ED98, MPU region number
register
STR R1, [R0, #0x0]         ; Region Number
BIC R2, R2, #1             ; Disable
STRH R2, [R0, #0x8]        ; Region Size and Enable
STR R4, [R0, #0x4]         ; Region Base Address
STRH R3, [R0, #0xA]        ; Region Attribute
ORR R2, #1                 ; Enable
STRH R2, [R0, #0x8]        ; Region Size and Enable
```

Software must use memory barrier instructions:

- before MPU setup if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings
- after MPU setup if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not require any memory barrier instructions during MPU setup, because it accesses the MPU through the PPB, which is a Strongly-Ordered memory region.

For example, if you want all of the memory access behavior to take effect immediately after the programming sequence, use a DSB instruction and an ISB instruction. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then you do not require an ISB.

Updating an MPU region using multi-word writes

You can program directly using multi-word writes, depending on how the information is divided. Consider the following reprogramming:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPU_RNR           ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]         ; Region Number
STR R2, [R0, #0x4]         ; Region Base Address
STR R3, [R0, #0x8]         ; Region Attribute, Size and Enable
```

Use an STM instruction to optimize this:

```
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPU_RNR           ; 0xE000ED98, MPU region number register
```

Central Processing Unit (CPU)

STM R0, {R1-R3} ; Region Number, address, attribute, size and enable

You can do this in two words for pre-packed information. This means that the MPU_RBAR contains the required region number and had the VALID bit set to 1, see MPU Region Base Address Register on [Page 2-96](#). Use this when the data is statically packed, for example in a boot loader:

```
; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPU_RBAR ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0] ; Region base address and
                    ; region number combined with VALID (bit 4)
set to 1
STR R2, [R0, #0x4] ; Region Attribute, Size and Enable
```

Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the SRD field of the MPU_RASR to disable a subregion, see MPU Region Attribute and Size Register on [Page 2-98](#). The least significant bit of SRD controls the first subregion, and the most significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions, With regions of these sizes, you must set the SRD field to 0x00, otherwise the MPU behavior is Unpredictable.

Example of SRD use

Two regions with the same base address overlap. Region one is 128KB, and region two is 512KB. To ensure the attributes from region one apply to the first 128KB region, set the SRD field for region two to 0b00000011 to disable the first two subregions, as the figure shows.

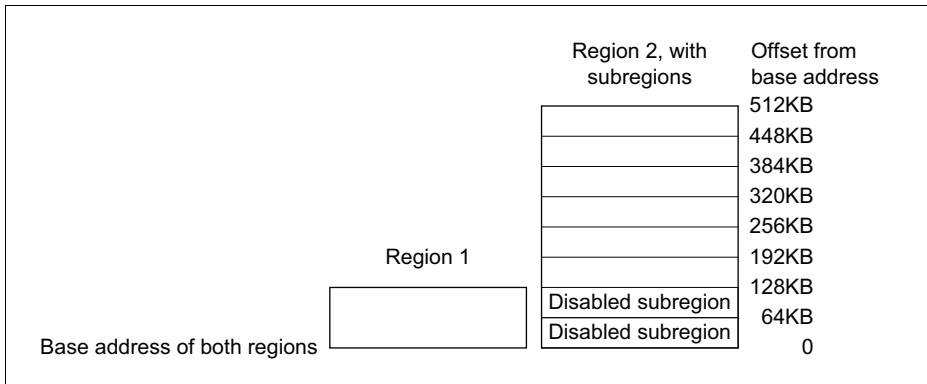

Figure 2-8 Example of SRD use

2.8.5.4 MPU Design Hints and Tips

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- except for the MPU_RASR, it must use aligned word accesses
- for the MPU_RASR it can use byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

In the XMC4[78]00 the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable.

2.8.6 Floating Point Unit (FPU)

The Cortex-M4 FPU implements the FPUv4-SP floating-point extension.

The FPU fully supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. It also provides conversions between fixed-point and floating-point data formats, and floating-point constant instructions.

The FPU provides floating-point computation functionality that is compliant with the ANSI/IEEE Std 754-2008, IEEE Standard for Binary Floating-Point Arithmetic, referred to as the IEEE 754 standard [4].

The FPU contains 32 single-precision extension registers, which you can also access as 16 doubleword registers for load, store, and move operations.

2.8.6.1 Enabling the FPU

The FPU is disabled from reset. You must enable it before you can use any floating-point instructions. The Example shows an example code sequence for enabling the FPU in both privileged and user modes. The processor must be in privileged mode to read from and write to the CPACR.

Example: Enabling the FPU

```
; CPACR is located at address 0xE000ED88
LDR.W   R0, =0xE000ED88
; Read CPACR
LDR     R1, [R0]
; Set bits 20-23 to enable CP10 and CP11 coprocessors
ORR     R1, R1, #(0xF << 20)
; Write back the modified value to the CPACR
STR     R1, [R0]; wait for store to complete
DSB
;reset pipeline now the FPU is enabled
ISB
```

2.9 PPB Registers

The CPU private peripherals registers base address is E000E000_H.

2) See the register description for more information.

2.9.1 SCS Registers

Auxiliary Control Register

The ACTLR provides disable bits for the following processor functions:

- IT folding
- write buffer use for accesses to the default memory map
- interruption of multi-cycle instructions.

By default this register is set to provide optimum performance from the Cortex-M4 processor, and does not normally require modification.

ACTLR

Auxiliary Control Register

(E000 E008_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|-------------|-------------|----|----|----|----|----|-------------|--------------------|--------------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | DISO OFF | DISF PCA | 0 | | | | | DISF OLD | DISD EFW BUF | DIS MCY CINT |
| r | | | | | | rw | rw | r | | | | | rw | rw | rw |

| Field | Bits | Type | Description |
|------------|------|------|---|
| DISMCYCINT | 0 | rw | Disable load/store multiple When set to 1, disables interruption of load multiple and store multiple instructions. This increases the interrupt latency of the processor because any LDM or STM must complete before the processor can stack the current state and enter the interrupt handler. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-------------------|-------------------|------|--|
| DISDEFWBUF | 1 | rw | Disable write buffer When set to 1, disables write buffer use during default memory map accesses. This causes all BusFaults to be precise BusFaults but decreases performance because any store to memory must complete before the processor can execute the next instruction. <i>Note: This bit only affects write buffers implemented in the Cortex-M4 processor.</i> |
| DISFOLD | 2 | rw | Disable IT folding When set to 1, disables IT folding. |
| DISFPCA | 8 | rw | Disable FPCA update Disable automatic update of CONTROL.FPCA. |
| DISOOF | 9 | rw | Disable out of order FP execution Disables floating point instructions completing out of order with respect to integer instructions. |
| 0 | [31:10], [7:3] | r | Reserved Read as 0; should be written with 0. |

About IT folding

In some situations, the processor can start executing the first instruction in an IT block while it is still executing the IT instruction. This behavior is called IT folding, and improves performance. However, IT folding can cause jitter in looping. If a task must avoid jitter, set the DISFOLD bit to 1 before executing the task, to disable IT folding.

Central Processing Unit (CPU)

CPUID Base Register

The CPUID register contains the processor part number, version, and implementation information.

CPUID

CPUID Base Register

(E000 ED00_H)

Reset Value: 410F C241_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Implementer | [31:24] | r | Implementer code 41 _H ARM |

Interrupt Control and State Register

The ICSR:

- provides:
 - a set-pending bit for the Non-Maskable Interrupt (NMI) exception
 - set-pending and clear-pending bits for the PendSV and SysTick exceptions
- indicates:
 - the exception number of the exception being processed
 - whether there are preempted active exceptions
 - the exception number of the highest priority pending exception
 - whether any interrupts are pending.

ICSR

Interrupt Control and State Register

(E000 ED04_H)

Reset Value: 0000 0000_H

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| VECTPENDING | | | | RET TOB ASE | 0 | VECTACTIVE | | | | | | | | | |
| r | | | | r | r | r | | | | | | | | | |

| Field | Bits | Type | Description |
|--------------------------|-------|------|---|
| VECTACTIVE ¹⁾ | [8:0] | r | Active exception number 00 _H Thread mode Nonzero = The exception number of the currently active exception. <i>Note: Subtract 16 from this value to obtain the CMSIS IRQ number required to index into the Interrupt Clear-Enable, Set-Enable, Clear-Pending, Set-Pending, or Priority Registers.</i> |
| RETTOBASE | 11 | r | Return to Base Indicates whether there are preempted active exceptions: 0 _B there are preempted active exceptions to execute 1 _B there are no active exceptions, or the currently-executing exception is the only active exception. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|--------------------|---------|------|--|
| VECTPENDING | [17:12] | r | Vector Pending Indicates the exception number of the highest priority pending enabled exception: 0 _H no pending exceptions Nonzero = the exception number of the highest priority pending enabled exception. The value indicated by this field includes the effect of the BASEPRI and FAULTMASK registers, but not any effect of the PRIMASK register. |
| ISRPENDING | 22 | r | Interrupt pending flag excluding NMI and Faults: 0 _B interrupt not pending 1 _B interrupt pending. |
| Res | 23 | r | Reserved This bit is reserved for Debug use and reads-as-zero when the processor is not in Debug. |
| PENDSTCLR | 25 | w | SysTick exception clear-pending bit 0 _B no effect 1 _B removes the pending state from the SysTick exception. <i>Note: This bit is w. On a register read its value is Unknown.</i> |
| PENDSTSET | 26 | rw | SysTick exception set-pending bit 0 _B Write: no effect Read: SysTick exception is not pending 1 _B Write: changes SysTick exception state to pending Read: SysTick exception is pending |
| PENDSVCLR | 27 | w | PendSV clear-pending bit 0 _B no effect 1 _B removes the pending state from the PendSV exception. <i>Note: This bit is w. On a register read its value is Unknown.</i> |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-------------------|---------------------------------------|------|---|
| PENDSVSET | 28 | rw | PendSV set-pending bit 0 _B Write: no effect Read: PendSV exception is not pending 1 _B Write: changes PendSV exception state to pending Read: PendSV exception is pending Writing 1 to this bit is the only way to set the PendSV exception state to pending. |
| NMIPENDSET | 31 | rw | NMI set-pending bit 0 _B Write: no effect Read: NMI exception is not pending 1 _B Write: changes NMI exception state to pending Read: NMI exception is pending Because NMI is the highest-priority exception, normally the processor enter the NMI exception handler as soon as it registers a write of 1 to this bit, and entering the handler clears this bit to 0. A read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler. |
| 0 | [30:29], 24, [21:18], [10:9] | r | Reserved Read as 0; should be written with 0. |

1) This is the same value as IPSR bits[8:0], see Interrupt Program Status Register on page 2-6.

When you write to the ICSR, the effect is Unpredictable if you:

*Note: write 1 to the PENDSVSET bit and write 1 to the PENDSVCLR bit
 write 1 to the PENDSTSET bit and write 1 to the PENDSTCLR bit.*

Vector Table Offset Register

The VTOR indicates the offset of the vector table base address from memory address 0x00000000.

VTOR

Vector Table Offset Register

(E000 ED08_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|---------|------|---|
| TBLOFF | [31:10] | rw | Vector table base offset field It contains bits[29:10] of the offset of the table base from the bottom of the memory map. <i>Note: Bit[29] determines whether the vector table is in the code or SRAM memory region:</i> 0 = code 1 = SRAM Bit[29] is sometimes called the TBLBASE bit. |
| 0 | [9:0] | r | Reserved Read as 0; should be written with 0. |

When setting TBLOFF, you must align the offset to the number of exception entries in the vector table. The XMC4[78]00 provides 112 interrupt nodes - minimum alignment is therefore 256 words, enough for up to 128 interrupts.

Notes

1. XMC4[78]00 implements 112 interrupts, the remaining nodes to 128 are not used.
2. Table alignment requirements mean that bits[9:0] of the table offset must always be zero.

Application Interrupt and Reset Control Register

The AIRCR provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system.

To write to this register, you must write 0x5FA to the VECTKEY field, otherwise the processor ignores the write.

Central Processing Unit (CPU)

AIRCR

Application Interrupt and Reset Control Register
(E000 ED0C_H)

Reset Value: FA05 0000_H

| Field | Bits | Type | Description |
|----------------------|--------|------|---|
| VECTRESET | 0 | w | Reserved for Debug use. This bit reads as 0. When writing to the register you must write 0 to this bit, otherwise behavior is Unpredictable |
| VECTCLRACTIVE | 1 | w | Reserved for Debug use. This bit reads as 0. When writing to the register you must write 0 to this bit, otherwise behavior is Unpredictable. |
| SYSRESETREQ | 2 | w | System reset request <div> <div>0_B</div> <div>no system reset request</div> </div> <div> <div>1_B</div> <div>asserts a signal to the outer system that requests a reset.</div> </div> This is intended to force a large system reset of all major components except for debug. This bit reads as 0. |
| PRIGROUP | [10:8] | rw | Interrupt priority grouping field This field determines the split of group priority from subpriority, see Binary point on Page 2-66 . |
| ENDIANNESS | 15 | r | Data endianness bit <div> <div>0_B</div> <div>Little-endian</div> </div> <div> <div>1_B</div> <div>Big-endian.</div> </div> |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|----------------|-------------------|------|---|
| VECTKEY | [31:16] | rw | Register key Read: = VECTKEY, reads as 0xFA05 Write: = VECTKEYSTAT, On writes, write 0x5FA to VECTKEY, otherwise the write is ignored. |
| 0 | [14:11], [7:3] | r | Reserved Read as 0; should be written with 0. |

Binary point

The PRIGROUP field indicates the position of the binary point that splits the PRI_n fields in the Interrupt Priority Registers into separate group priority and subpriority fields. **Table 2-20** shows how the PRIGROUP value controls this split.

Table 2-20 Priority grouping

| Interrupt priority level value, PRI_N[7:0] | | | | Number of | |
|--|----------------------------|---------------------|------------------|------------------|----------------|
| PRIGROUP | Binary point ¹⁾ | Group priority bits | Subpriority bits | Group priorities | Sub-priorities |
| 0b000 | bxxxxxx0.0 | [7:2] | None | 64 | 1 |
| 0b001 | bxxxxxx.00 | [7:2] | None | 64 | 1 |
| 0b010 | bxxxxx.y00 | [7:3] | [2] | 32 | 2 |
| 0b011 | bxxxx.yy00 | [7:4] | [3:2] | 16 | 4 |
| 0b100 | bxxx.yyy00 | [7:5] | [4:2] | 8 | 8 |
| 0b101 | bxx.yyyy00 | [7:6] | [5:2] | 4 | 16 |
| 0b110 | bx.yyyyy00 | 7 | [6:2] | 2 | 32 |
| 0b111 | b.yyyyyy00 | None | [7:2] | 1 | 64 |

1) PRI_n[7:0] field showing the binary point. x denotes a group priority field bit, and y denotes a subpriority field bit.

Note: Determining preemption of an exception uses only the group priority field, see Interrupt Priority Grouping on [Page 2-31](#).

Central Processing Unit (CPU)

System Control Register

The SCR controls features of entry to and exit from low power state.

| Field | Bits | Type | Description |
|--------------------|------|------|---|
| SLEEPONEXIT | 1 | rw | Sleep on Exit Indicates sleep-on-exit when returning from Handler mode to Thread mode: 0 _B do not sleep when returning to Thread mode. 1 _B enter sleep, or deep sleep, on return from an ISR. Setting this bit to 1 enables an interrupt driven application to avoid returning to an empty main application. |
| SLEEPDEEP | 2 | rw | Sleep or Deep Sleep Controls whether the processor uses sleep or deep sleep as its low power mode: 0 _B sleep 1 _B deep sleep |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|-----------------|------|--|
| SEVONPEND | 4 | rw | Send Event on Pending bit: 0_B only enabled interrupts or events can wakeup the processor, disabled interrupts are excluded 1_B enabled events and all interrupts, including disabled interrupts, can wakeup the processor. When an event or interrupt enters pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE. The processor also wakes up on execution of an SEV instruction or an external event. |

Configuration and Control Register

The CCR controls entry to Thread mode and enables:

- the handlers for NMI, hard fault and faults escalated by FAULTMASK to ignore BusFaults
- trapping of divide by zero and unaligned accesses
- access to the STIR by unprivileged software, see [Software Trigger Interrupt Register](#) on [Page 2-92](#)

| r | | | | | | rw | rw | r | | | rw | rw | r | rw | rw |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|----------------------------|------|------|---|
| NONBASETHR DENA | 0 | rw | Non Base Thread Mode Enable Indicates how the processor enters Thread mode: 0 _B processor can enter Thread mode only when no exception is active. 1 _B processor can enter Thread mode from any level under the control of an EXC_RETURN value, see Exception return . |
| USERSETMPE ND | 1 | rw | User Set Pending Enable Enables unprivileged software access to the STIR, see Software Trigger Interrupt Register . 0 _B disable 1 _B enable |
| UNALIGN_TRP | 3 | rw | Unaligned Access Trap Enable Enables unaligned access traps: 0 _B do not trap unaligned halfword and word accesses 1 _B trap unaligned halfword and word accesses. If this bit is set to 1, an unaligned access generates a UsageFault. Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of whether UNALIGN_TRP is set to 1. |
| DIV_0_TRP | 4 | rw | Divide by Zero Trap Enable Enables faulting or halting when the processor executes an SDIV or UDIV instruction with a divisor of 0: 0 _B do not trap divide by 0 1 _B trap divide by 0. When this bit is set to 0, a divide by zero returns a quotient of 0. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-----------------|-------------------|------|--|
| BFHFNMI | 8 | rw | Bus Fault Hard Fault and NMI Ignore Enables handlers with priority -1 or -2 to ignore data BusFaults caused by load and store instructions. This applies to the hard fault, NMI, and FAULTMASK escalated handlers: 0 _B data bus faults caused by load and store instructions cause a lock-up 1 _B handlers running at priority -1 and -2 ignore data bus faults caused by load and store instructions. Set this bit to 1 only when the handler and its data are in absolutely safe memory. The normal use of this bit is to probe system devices and bridges to detect control path problems and fix them. |
| STKALIGN | 9 | rw | Stack Alignment Indicates stack alignment on exception entry: 0 _B 4-byte aligned 1 _B 8-byte aligned. On exception entry, the processor uses bit[9] of the stacked PSR to indicate the stack alignment. On return from the exception it uses this stacked bit to restore the correct stack alignment. |
| 0 | [31:10], [7:5], 2 | r | Reserved Read as 0; should be written with 0. |

System Handler Priority Registers

The SHPR1-SHPR3 registers set the priority level, 0 to 63 of the exception handlers that have configurable priority.

SHPR1-SHPR3 are byte accessible.

The system fault handlers and the priority field and register for each handler are:

Table 2-21 System fault handler priority fields

| Handler | Field | Register description |
|------------|--------|---|
| MemManage | PRI_4 | System Handler Priority Register 1 on Page 2-71 |
| BusFault | PRI_5 | |
| UsageFault | PRI_6 | |
| SVC | PRI_11 | System Handler Priority Register 2 on Page 2-71 |

Central Processing Unit (CPU)

Table 2-21 System fault handler priority fields (cont'd)

| Handler | Field | Register description |
|---------|--------|---|
| PendSV | PRI_14 | System Handler Priority Register 3 on Page 2-72 |
| SysTick | PRI_15 | |

Each PRI_N field is 8 bits wide, but the XMC4[78]00 implements only bits[7:2] of each field, and bits[1:0] read as zero and ignore writes.

| 0 | [31:19], 9, [6:4], 2 | r | Reserved Read as 0; should be written with 0. |

Notes

1. Active bits, read as 1 if the exception is active, or as 0 if it is not active. You can write to these bits to change the active status of the exceptions, but see the Caution in this section.
2. Pending bits, read as 1 if the exception is pending, or as 0 if it is not pending. You can write to these bits to change the pending status of the exceptions.
3. Enable bits, set to 1 to enable the exception, or set to 0 to disable the exception.

If you disable a system handler and the corresponding fault occurs, the processor treats the fault as a hard fault.

You can write to this register to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

Note: Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.

Note: After you have enabled the system handlers, if you have to change the value of a bit in this register you must use a read-modify-write procedure to ensure that you change only the required bit.

Configurable Fault Status Register

The CFSR indicates the cause of a MemManage fault, BusFault, or UsageFault.

The flags in the MMFSR indicate the cause of memory access faults.

Central Processing Unit (CPU)

The flags in the BFSR indicate the cause of a bus access fault.

The UFSR indicates the cause of a UsageFault.

Figure 2-9 CFSR

The CFSR is byte accessible. You can access the CFSR or its subregisters as follows:

- access the complete CFSR with a word access to 0xE000ED28
- access the MMFSR with a byte access to 0xE000ED28
- access the MMFSR with a byte access to 0xE000ED28
- access the MMFSR and BFSR with a halfword access to 0xE000ED28
- access the BFSR with a byte access to 0xE000ED29
- access the UFSR with a halfword access to 0xE000ED2A

Note: The UFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset.

CFSR

Configurable Fault Status Register

(E000 ED28_H)

Reset Value: 0000 0000_H

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|------|------|---|
| IACCVIOL | 0 | rw | Instruction access violation flag 0_B no instruction access violation fault 1_B the processor attempted an instruction fetch from a location that does not permit execution. This fault occurs on any access to an XN region, even when the MPU is disabled or not present. When this bit is 1, the PC value stacked for the exception return points to the faulting instruction. The processor has not written a fault address to the MMAR. |
| DACCVIOL | 1 | rw | Data access violation flag 0_B no data access violation fault 1_B the processor attempted a load or store at a location that does not permit the operation. When this bit is 1, the PC value stacked for the exception return points to the faulting instruction. The processor has loaded the MMAR with the address of the attempted access. |
| MUNSTKERR | 3 | rw | MemManage fault on unstacking for a return from exception 0_B no unstacking fault 1_B unstack for an exception return has caused one or more access violations. This fault is chained to the handler. This means that when this bit is 1, the original return stack is still present. The processor has not adjusted the SP from the failing return, and has not performed a new save. The processor has not written a fault address to the MMAR. |
| MSTKERR | 4 | rw | MemManage fault on stacking for exception entry 0_B no stacking fault 1_B stacking for an exception entry has caused one or more access violations. When this bit is 1, the SP is still adjusted but the values in the context area on the stack might be incorrect. The processor has not written a fault address to the MMAR. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|------|------|---|
| MLSPERR | 5 | rw | MemManage fault during floating point lazy state preservation 0_B No MemManage fault occurred during floating-point lazy state preservation 1_B A MemManage fault occurred during floating-point lazy state preservation |
| MMARVALID | 7 | rw | MemManage Fault Address Register (MMFAR) valid flag 0_B value in MMAR is not a valid fault address 1_B MMAR holds a valid fault address. If a MemManage fault occurs and is escalated to a HardFault because of priority, the HardFault handler must set this bit to 0. This prevents problems on return to a stacked active MemManage fault handler whose MMAR value has been overwritten. |
| IBUSERR | 8 | rw | Instruction bus error 0_B no instruction bus error 1_B instruction bus error. The processor detects the instruction bus error on prefetching an instruction, but it sets the IBUSERR flag to 1 only if it attempts to issue the faulting instruction. When the processor sets this bit is 1, it does not write a fault address to the BFAR. |
| PRECISERR | 9 | rw | Precise data bus error 0_B no precise data bus error 1_B a data bus error has occurred, and the PC value stacked for the exception return points to the instruction that caused the fault. When the processor sets this bit is 1, it writes the faulting address to the BFAR. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|--------------------|------|------|--|
| IMPRECISERR | 10 | rw | <p>Imprecise data bus error</p> <p>0_B no imprecise data bus error 1_B a data bus error has occurred, but the return address in the stack frame is not related to the instruction that caused the error.</p> <p>When the processor sets this bit to 1, it does not write a fault address to the BFAR.</p> <p>This is an asynchronous fault. Therefore, if it is detected when the priority of the current process is higher than the BusFault priority, the BusFault becomes pending and becomes active only when the processor returns from all higher priority processes. If a precise fault occurs before the processor enters the handler for the imprecise BusFault, the handler detects both IMPRECISERR set to 1 and one of the precise fault status bits set to 1.</p> |
| UNSTKERR | 11 | rw | <p>BusFault on unstacking for a return from exception</p> <p>0_B no unstacking fault 1_B stacking for an exception entry has caused one or more BusFaults.</p> <p>This fault is chained to the handler. This means that when the processor sets this bit to 1, the original return stack is still present. The processor does not adjust the SP from the failing return, does not performed a new save, and does not write a fault address to the BFAR.</p> |
| STKERR | 12 | rw | <p>BusFault on stacking for exception entry</p> <p>0_B no stacking fault 1_B stacking for an exception entry has caused one or more BusFaults.</p> <p>When the processor sets this bit to 1, the SP is still adjusted but the values in the context area on the stack might be incorrect. The processor does not write a fault address to the BFAR.</p> |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-------------------|------|------|---|
| LSPERR | 13 | rw | BusFault during floating point lazy state preservation 0_B No bus fault occurred during floating-point lazy state preservation. 1_B A bus fault occurred during floating-point lazy state preservation |
| BFARVALID | 15 | rw | BusFault Address Register (BFAR) valid flag 0_B value in BFAR is not a valid fault address 1_B BFAR holds a valid fault address. The processor sets this bit to 1 after a BusFault where the address is known. Other faults can set this bit to 0, such as a MemManage fault occurring later. If a BusFault occurs and is escalated to a hard fault because of priority, the hard fault handler must set this bit to 0. This prevents problems if returning to a stacked active BusFault handler whose BFAR value has been overwritten. |
| UNDEFINSTR | 16 | rw | Undefined instruction UsageFault 0_B no undefined instruction UsageFault 1_B the processor has attempted to execute an undefined instruction. When this bit is set to 1, the PC value stacked for the exception return points to the undefined instruction. An undefined instruction is an instruction that the processor cannot decode. |
| INVSTATE | 17 | rw | Invalid state UsageFault 0_B no invalid state UsageFault 1_B the processor has attempted to execute an instruction that makes illegal use of the EPSR. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that attempted the illegal use of the EPSR. This bit is not set to 1 if an undefined instruction uses the EPSR. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|----------------------------------|------|---|
| INVPC | 18 | rw | Invalid PC load UsageFault caused by an invalid PC load by EXC_RETURN: 0 _B no invalid PC load UsageFault 1 _B the processor has attempted an illegal load of EXC_RETURN to the PC, as a result of an invalid context, or an invalid EXC_RETURN value. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that tried to perform the illegal load of the PC. |
| NOCP | 19 | rw | No coprocessor UsageFault 0 _B no UsageFault caused by attempting to access a coprocessor 1 _B the processor has attempted to access a coprocessor. |
| UNALIGNED | 24 | rw | Unaligned access UsageFault 0 _B no unaligned access fault, or unaligned access trapping not enabled 1 _B the processor has made an unaligned memory access. Enable trapping of unaligned accesses by setting the UNALIGN_TRP bit in the CCR to 1, see Configuration and Control Register on Page 2-68 . Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of the setting of UNALIGN_TRP. |
| DIVBYZERO | 25 | rw | Divide by zero UsageFault 0 _B no divide by zero fault, or divide by zero trapping not enabled 1 _B the processor has executed an SDIV or UDIV instruction with a divisor of 0 When the processor sets this bit to 1, the PC value stacked for the exception return points to the instruction that performed the divide by zero. Enable trapping of divide by zero by setting the DIV_0_TRP bit in the CCR to 1, see Configuration and Control Register on Page 2-68 . |

| 0 | | | | | | | | | | | | | VEC TTB L | 0 | |
| r | | | | | | | | | | | | | rw | r | |

| Field | Bits | Type | Description |
|--------|------|------|---|
| VECTBL | 1 | rw | BusFault on vector table read Indicates a BusFault on a vector table read during exception processing: 0 _B no BusFault on vector table read 1 _B BusFault on vector table read This error is always handled by the hard fault handler. When this bit is set to 1, the PC value stacked for the exception return points to the instruction that was preempted by the exception. |
| FORCED | 30 | rw | Forced HardFault Indicates a forced hard fault, generated by escalation of a fault with configurable priority that cannot be handles, either because of priority or because it is disabled: 0 _B no forced HardFault 1 _B forced HardFault. When this bit is set to 1, the HardFault handler must read the other fault status registers to find the cause of the fault. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-----------------|--------------|------|---|
| DEBUGEVT | 31 | rw | Reserved for Debug use When writing to the register you must write 0 to this bit, otherwise behavior is Unpredictable |
| 0 | [29:2], 0 | r | Reserved Read as 0; should be written with 0. |

Note: The HFSR bits are sticky. This means as one or more fault occurs, the associated bits are set to 1. A bit that is set to 1 is cleared to 0 only by writing 1 to that bit, or by a reset.

MemManage Fault Address Register

The MMFAR contains the address of the location that generated a MemManage fault.

MMFAR

MemManage Fault Address Register

(E000 ED34_H)

Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| ADDRESS | [31:0] | rw | Address causing the fault When the MMARVALID bit of the MMFSR is set to 1, this field holds the address of the location that generated the MemManage fault |

When an unaligned access faults, the address is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size.

Flags in the MMFSR indicate the cause of the fault, and whether the value in the MMFAR is valid. See MemManage Fault Status Register on [Page 2-74](#).

Central Processing Unit (CPU)

BusFault Address Register

The BFAR contains the address of the location that generated a BusFault.

BFAR

BusFault Address Register (E000 ED38_H) Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|---------|--------|------|--|
| ADDRESS | [31:0] | rw | Address causing the fault When the BFARVALID bit of the BFSR is set to 1, this field holds the address of the location that generated the BusFault |

When an unaligned access faults the address in the BFAR is the one requested by the instruction, even if it is not the address of the fault.

Flags in the BFSR indicate the cause of the fault, and whether the value in the BFAR is valid. See BusFault Status Register on [Page 2-74](#).

Auxiliary Fault Status Register

The AFSR contains additional system fault information.

This register is read, write to clear. This means that bits in the register read normally, but writing 1 to any bit clears that bit to 0.

AFSR

Auxiliary Fault Status Register (E000 ED3C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| VALUE | [31:0] | rw | Reserved Read as 0; should be written with 0. |

Central Processing Unit (CPU)

Each AFSR bit maps directly to an AUXFAULT input of the processor, and a single-cycle HIGH signal on the input sets the corresponding AFSR bit to one. It remains set to 1 until you write 1 to the bit to clear it to zero.

When an AFSR bit is latched as one, an exception does not occur. Use an interrupt if an exception is required.

2.9.2 SysTick Registers

SysTick Control and Status Register

The SysTick SYST_CSR register enables the SysTick features.

SYST_CSR

SysTick Control and Status Register

(E000 E010_H)

Reset Value: 0000 0004_H

| Field | Bits | Type | Description |
|---------|------|------|--|
| ENABLE | 0 | rw | Enable Enables the counter: 0 _B counter disabled 1 _B counter enabled. |
| TICKINT | 1 | rw | Tick Interrupt Enable Enables SysTick exception request: 0 _B counting down to zero does not assert the SysTick exception request 1 _B counting down to zero to asserts the SysTick exception request. Software can use COUNTFLAG to determine if SysTick has ever counted to zero. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|------------------|--------------------|------|---|
| CLKSOURCE | 2 | rw | Clock source $0_B \quad f_{STDBY} / 2$ $1_B \quad f_{CPU}$ |
| COUNTFLAG | 16 | rw | Counter Flag Returns 1 if timer counted to 0 since last time this was read. |
| 0 | [31:17], [15:3] | r | Reserved Read as 0; should be written with 0. |

When ENABLE is set to 1, the counter loads the RELOAD value from the SYST_RVR register and then counts down. On reaching 0, it sets the COUNTFLAG to 1 and optionally asserts the SysTick depending on the value of TICKINT. It then loads the RELOAD value again, and begins counting.

SysTick Reload Value Register

The SYST_RVR register specifies the start value to load into the SYST_CVR register.

SYST_RVR

SysTick Reload Value Register (E000 E014_H) **Reset Value: XXXX XXXX_H**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | RELOAD | | | | | | | | | | | | | | | | | | | | | | | |
| r | | | | | | | | rw | | | | | | | | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| RELOAD | [23:0] | rw | Reload Value Value to load into the SYST_CVR register when the counter is enabled and when it reaches 0, see Calculating the RELOAD value. |
| 0 | [31:24] | r | Reserved Read as 0; should be written with 0. |

Notes on calculating the RELOAD value

1. The RELOAD value can be any value in the range 0x00000001-0x00FFFFFF. A start value of 0 is possible, but has no effect because the SysTick exception request and COUNTFLAG are activated when counting from 1 to 0.

Central Processing Unit (CPU)

2. The RELOAD value is calculated according to its use. For example, to generate a multi-shot timer with a period of N processor clock cycles, use a RELOAD value of N-1. If the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

SysTick Current Value Register

The SYST_CVR register contains the current value of the SysTick counter.

SYST_CVR

SysTick Current Value Register (E000 E018_H) **Reset Value: XXXX XXXX_H**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|--|--|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | |
| 0 | | | | | | | | CURRENT | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| r | | | | | | | | rw | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| CURRENT | [23:0] | rw | Current Value Reads return the current value of the SysTick counter. A write of any value clears the field to 0, and also clears the SYST_CSR COUNTFLAG bit to 0. |
| 0 | [31:24] | r | Reserved Read as 0; should be written with 0. |

SysTick Calibration Value Register

The SYST_CALIB register indicates the SysTick calibration properties.

SYST_CALIB

SysTick Calibration Value Register
r **(E000 E01C_H)** **Reset Value: C000 0000_H**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------------|------------------|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| N O R E F | S K E W | 0 | | | | | | | | TENMS | | | | | | | | | | | | | | | | | | | | | |
| | | r | | | | | | | | rw | | | | | | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| TENMS | [23:0] | rw | Ten Milliseconds Reload Value Reload value for 10ms (100Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known. |
| SKEW | 30 | rw | Ten Milliseconds Skewed Indicates whether the TENMS value is exact: 0_B TENMS value is exact 1_B TENMS value is inexact, or not given. An inexact TENMS value can affect the suitability of SysTick as a software real time clock. |
| NOREF | 31 | rw | No Reference Clock Indicates whether the device provides a reference clock to the processor: 0_B reference clock provided 1_B no reference clock provided. If your device does not provide a reference clock, the SYST_CSR.CLKSOURCE bit reads-as-one and ignores writes. |
| 0 | [29:24] | r | Reserved Read as 0; should be written with 0. |

2.9.3 NVIC Registers

Interrupt Set-enable Registers

The NVIC_ISERx (x=0-3) registers enable interrupts, and show which interrupts are enabled.

NVIC_ISERx (x=0-3)

Interrupt Set-enable Register x

(E000 E100_H + 4*x)

Reset Value: 0000 0000_H

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| SETENA | [31:0] | rw | Interrupt set-enable bits 0_B Write: no effect Read: interrupt disabled 1_B Write: enable interrupt Read: interrupt enabled |

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.

Interrupt Clear-enable Registers

The NVIC_ICERx registers disable interrupts, and show which interrupts are enabled.

NVIC_ICERx (x=0-3)

Interrupt Clear-enable Register x

(E000 E180_H + 4*x)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| CLRENA | [31:0] | rw | Interrupt clear-enable bits. 0_B Write: no effect Read: interrupt disabled 1_B Write: disable interrupt Read: interrupt enabled |

Interrupt Set-pending Registers

The NVIC_ISPRx registers force interrupts into the pending state, and show which interrupts are pending.

NVIC_ISPRx (x=0-3)

Interrupt Set-pending Register x

(E000 E200_H + 4*x)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------|--------|------|---|
| SETPEND | [31:0] | rw | Interrupt set-pending bits. 0 _B Write: no effect Read: interrupt is not pending 1 _B Write: changes interrupt state to pending Read: interrupt is pending |

Writing 1 to the ISPR bit corresponding to:

- an interrupt that is pending has no effect
- a disabled interrupt sets the state of that interrupt to pending

Interrupt Clear-pending Registers

The NVIC_ICPRx registers remove the pending state from interrupts, and show which interrupts are pending.

NVIC_ICPRx (x=0-3)

Interrupt Clear-pending Register x

(E000 E280_H + 4*x)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|---|
| CLRPEND | [31:0] | rw | Interrupt set-pending bits. 0_B Write: no effect Read: interrupt is not pending 1_B Write: removes pending state an interrupt Read: interrupt is pending |

Note: Writing 1 to an ICPR bit does not affect the active state of the corresponding interrupt.

Interrupt Active Bit Registers

The NVIC_IABRx registers indicate which interrupts are active.

NVIC_IABRx (x=0-3)

Interrupt Active Bit Register x

(E000 E300_H + 4*x)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| ACTIVE | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| rw | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| ACTIVE | [31:0] | rw | Interrupt active flags: 0_B interrupt not active 1_B interrupt active |

A bit reads as one if the status of the corresponding interrupt is active or active and pending.

Interrupt Priority Registers

The NVIC_IPRx (x=0-27) registers provide an 8-bit priority field for each interrupt. These registers are byte-accessible. Each register holds four priority fields as shown:

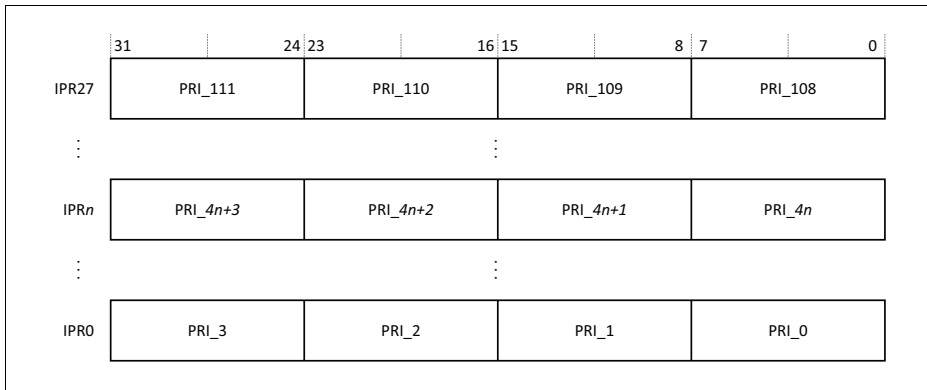

Figure 2-10 Interrupt Priority Register

NVIC_IPRx (x=0-27)

Interrupt Priority Register x

(E000 E400_H + 4*x)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| PRI_0 | [7:0] | rw | Priority value 0 |
| PRI_1 | [15:8] | rw | Priority value 1 |
| PRI_2 | [23:16] | rw | Priority value 2 |
| PRI_3 | [31:24] | rw | Priority value 3 The lower the value, the greater the priority of the corresponding interrupt. The processor implements only bits[7:n] of each field, bits[n-1:0] read as zero and ignore writes. |

See “Using CMSIS functions to access NVIC” on [Page 2-45](#) for more information about the access to the interrupt priority array, which provides the software view of the interrupt priorities.

Find the IPR number and byte offset for interrupt m as follows:

Central Processing Unit (CPU)

- the corresponding IPR number n , see [Figure 2-10](#) on [Page 2-917](#), is given by $n = m \text{ DIV } 4$
- the byte offset of the required Priority field in this register is $m \text{ MOD } 4$, where:
 - byte offset 0 refers to register bits[7:0]
 - byte offset 1 refers to register bits[15:8]
 - byte offset 2 refers to register bits[23:16]
 - byte offset 3 refers to register bits[31:24].

Software Trigger Interrupt Register

Write to the STIR to generate an interrupt from software.

When the USERSETMPEND bit in the SCR is set to 1, unprivileged software can access the STIR, see System Control Register on [Page 2-67](#).

Note: Only privileged software can enable unprivileged access to the STIR.

STIR

Software Trigger Interrupt Register

(E000 EF00_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| INTID | [8:0] | w | Interrupt ID of the interrupt to trigger in the range 0-111. For example, a value of 0x03 specifies interrupt IRQ3. |
| 0 | [31:9] | r | Reserved Read as 0; should be written with 0. |

2.9.4 MPU Registers

MPU Type Register

The MPU_TYPE register indicates whether the MPU is present, and if so, how many regions it supports.

MPU_TYPE

MPU Type Register

(E000 ED90_H)

Reset Value: 0000 0800_H

| Field | Bits | Type | Description |
|----------|----------------|------|---|
| SEPARATE | 0 | r | Support for unified or separate instruction and data memory maps 0 _B unified |
| DREGION | [15:8] | r | Number of supported MPU data regions 08 _H Eight MPU regions |
| IREGION | [23:16] | r | Number of supported MPU instruction regions Always contains 0x00. The MPU memory map is unified and is described by the DREGION field. |
| 0 | [31:24], [7:1] | r | Reserved Read as 0; should be written with 0. |

MPU Control Register

The MPU_CTRL register:

- enables the MPU
- enables the default memory map background region
- enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and FAULTMASK escalated handlers.

Central Processing Unit (CPU)

MPU_CTRL

MPU Control Register

(E000 ED94_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|------|------|--|
| ENABLE | 0 | rw | Enable MPU 0 _B MPU disabled 1 _B MPU enabled. |
| HFNMIENA | 1 | rw | Enable the operation of MPU during hard fault, NMI, and FAULTMASK handlers When the MPU is enabled: 0 _B MPU is disabled during hard fault, NMI, and FAULTMASK handlers, regardless of the value of the ENABLE bit 1 _B the MPU is enabled during hard fault, NMI, and FAULTMASK handlers. When the MPU is disabled, if this bit is set to 1 the behavior is Unpredictable. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|-------------------|--------|------|--|
| PRIVDEFENA | 2 | rw | Enables privileged software access to the default memory map 0 _B If the MPU is enabled, disables use of the default memory map. Any memory access to a location not covered by any enabled region causes a fault. 1 _B If the MPU is enabled, enables use of the default memory map as a background region for privileged software accesses. When enabled, the background region acts as if it is region number -1. Any region that is defined and enabled has priority over this default map. If the MPU is disabled, the processor ignores this bit. |
| 0 | [31:3] | r | Reserved Read as 0; should be written with 0. |

When ENABLE and PRIVDEFENA are both set to 1:

- For privileged accesses, the default memory map is as described in Memory model on [Page 2-20](#). Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a MemManage fault.

XN and Strongly-ordered rules always apply to the System Control Space regardless of the value of the ENABLE bit.

When the ENABLE bit is set to 1, at least one region of the memory map must be enabled for the system to function unless the PRIVDEFENA bit is set to 1. If the PRIVDEFENA bit is set to 1 and no regions are enabled, then only privileged software can operate.

When the ENABLE bit is set to 0, the system uses the default memory map. This has the same memory attributes as if the MPU is not implemented, see [Table 2-6](#) on [Page 2-22](#). The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether PRIVDEFENA is set to 1.

Unless HFNMIENA is set to 1, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception, or when FAULTMASK is enabled. Setting the HFNMIENA bit to 1 enables the MPU when operating with these two priorities.

Central Processing Unit (CPU)

MPU Region Number Register

The MPU_RNR selects which memory region is referenced by the MPU_RBAR and MPU_RASR registers.

MPU_RNR

MPU Region Number Register (E000 ED98_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| REGION | [7:0] | rw | Region Indicates the MPU region referenced by the MPU_RBAR and MPU_RASR registers. The MPU supports 8 memory regions, so the permitted values of this field are 0-7. |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

Normally, you write the required region number to this register before accessing the MPU_RBAR or MPU_RASR. However you can change the region number by writing to the MPU_RBAR with the VALID bit set to 1, see MPU Region Base Address Register. This write updates the value of the REGION field.

MPU Region Base Address Register

The MPU_RBAR defines the base address of the MPU region selected by the MPU_RNR, and can update the value of the MPU_RNR.

Central Processing Unit (CPU)

MPU_RBAR

MPU Region Base Address Register

(E000 ED9C_H)

Reset Value: 0000 0000_H

MPU_RBAR_A1

MPU Region Base Address Register A1

(E000 EDA4_H)

Reset Value: 0000 0000_H

MPU_RBAR_A2

MPU Region Base Address Register A2

(E000 EDAC_H)

Reset Value: 0000 0000_H

MPU_RBAR_A3

MPU Region Base Address Register A3

(E000 EDB4_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|-------|------|---|
| REGION | [3:0] | rw | MPU region field For the behavior on writes, see the description of the VALID field. On reads, returns the current region number, as specified by the RNR. |

Central Processing Unit (CPU)

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| VALID | 4 | rw | MPU Region Number valid bit Write: 0 _B MPU_RNR not changed, and the processor: - updates the base address for the region specified in the MPU_RNR - ignores the value of the REGION field 1 _B the processor: - updates the value of the MPU_RNR to the value of the REGION field - updates the base address for the region specified in the REGION field. Always reads as zero. |
| ADDR | [31:9] | rw | Region base address field The value of N (N = 9 for bit definition) depends on the region size. For more information see The ADDR field. |
| 0 | [8:5] | r | Reserved Read as 0; should be written with 0. |

The ADDR field

The ADDR field is bits[31:N] of the MPU_RBAR. The region size, as specified by the SIZE field in the MPU_RASR, defines the value of N:

$$N = \text{Log2}(\text{Region size in bytes}),$$

If the region size is configured to 4GB, in the MPU_RASR, there is no valid ADDR field. In this case, the region occupies the complete memory map, and the base address is 0x00000000.

The base address is aligned to the size of the region. For example, a 64KB region must be aligned on a multiple of 64KB, for example, at 0x00010000 or 0x00020000.

MPU Region Attribute and Size Register

The MPU_RASR defines the region size and memory attributes of the MPU region specified by the MPU_RNR, and enables that region and any subregions.

MPU_RASR is accessible using word or halfword accesses:

- the most significant halfword holds the region attributes
- the least significant halfword holds the region size and the region and subregion enable bits.

| S | 18 | rw | Shareable bit see Table 2-15 on Page 2-48 . |
| TEX | [21:19] | rw | Memory access attribute see Table 2-15 on Page 2-48 . |
| AP | [26:24] | rw | Access permission field see Table 2-18 on Page 2-49 . |
| XN | 28 | rw | Instruction access disable bit 0 _B instruction fetches enabled 1 _B instruction fetches disabled. |
| 0 | [31:29, 27, [23:22], [7:6] | r | Reserved Read as 0; should be written with 0. |

For information about access permission, see [MPU Access Permission Attributes](#) on [Page 2-48](#).

SIZE field values

The SIZE field defines the size of the MPU memory region specified by the RNR. as follows:

$$(\text{Region size in bytes}) = 2(\text{SIZE}+1)$$

The smallest permitted region size is 32B, corresponding to a SIZE value of 4. [Table 2-22](#) gives example SIZE values, with the corresponding region size and value of N in the MPU_RBAR.

Table 2-22 Example SIZE field values

| SIZE value | Region size | Value of N ¹⁾ | Note |
|--------------|-------------|--------------------------|------------------------|
| 0b00100 (4) | 32B | 5 | Minimum permitted size |
| 0b01001 (9) | 1KB | 10 | - |
| 0b10011 (19) | 1MB | 20 | - |
| 0b11101 (29) | 1GB | 30 | - |
| 0b11111 (31) | 4GB | 32 | Maximum possible size |

1) In the MPU_RBAR, see MPU Region Base Address Register on [Page 2-96](#).

2.9.5 FPU Registers

Coprocessor Access Control Register

The CPACR register specifies the access privileges for coprocessors.

CPACR

Coprocessor Access Control Register

(E000 ED88_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|-----------------|------|---|
| CP10 | [21:20] | rw | Access privileges for coprocessor 10 The possible values of each field are: 00 _B Access denied. Any attempted access generates a NOCP UsageFault. 01 _B Privileged access only. An unprivileged access generates a NOCP fault. 10 _B Reserved. The result of any access is Unpredictable. 11 _B Full access. |
| CP11 | [23:22] | rw | Access privileges for coprocessor 11 The possible values of each field are: 00 _B Access denied. Any attempted access generates a NOCP UsageFault. 01 _B Privileged access only. An unprivileged access generates a NOCP fault. 10 _B Reserved. The result of any access is Unpredictable. 11 _B Full access. |
| 0 | [31:24], [19:0] | r | Reserved Read as 0; should be written with 0. |

Floating-point Context Control Register

The FPCCR register sets or returns FPU control data.

FPCCR

Floating-point Context Control Register

(E000 EF34_H)

Reset Value: C000 0000_H

3 Bus System

The XMC4[78]00 is targeted for use in embedded systems. Therefore the key features are timing determinism and low latency on real time events. Bus bandwidth is required particularly for communication peripherals.

The bus system will therefore provide:

- Timing Determinism
- Low Latency
- Performance
- Throughput

3.1 Bus Interfaces

This chapter describes the features for the two kinds of interfaces.

- **Memory Interface**
- **Peripheral Interface**

All on-chip peripherals and memories are attached to the Bus Matrix, in some cases via peripheral bridges. All on-chip modules implement Little Endian data organization. The following types of transfer are supported:

- Locked Transfers
- Burst Operation
- Protection Control

Pipelining is also supported for bandwidth critical transfers.

Memory Interface

The on-chip memories capable to accept a transfer request with each bus clock cycle.

The memory interface data bus width is 32-bit. Each memory slave support 32-bit, 16-bit and 8-bit access types.

Peripheral Interface

Each slave supports 32-bit accesses. Some slaves also support 8-bit and/or 16-bit accesses.

3.2 Bus Matrix

The central part of the bus system is built up around a multilayer AHB-lite compliant matrix. By means of this technique the bus masters and bus slaves can be connected in a flexible way while maintaining high bus performance.

The Bus Matrix depicted in [Figure 3-1](#) implements an optimized topology enabling zero wait state data accesses between the Masters and Slaves connected to it. Dedicated

Bus System

arbitration scheme enables optimal access conflicts resolution resulting in improved system stability and real time behavior.

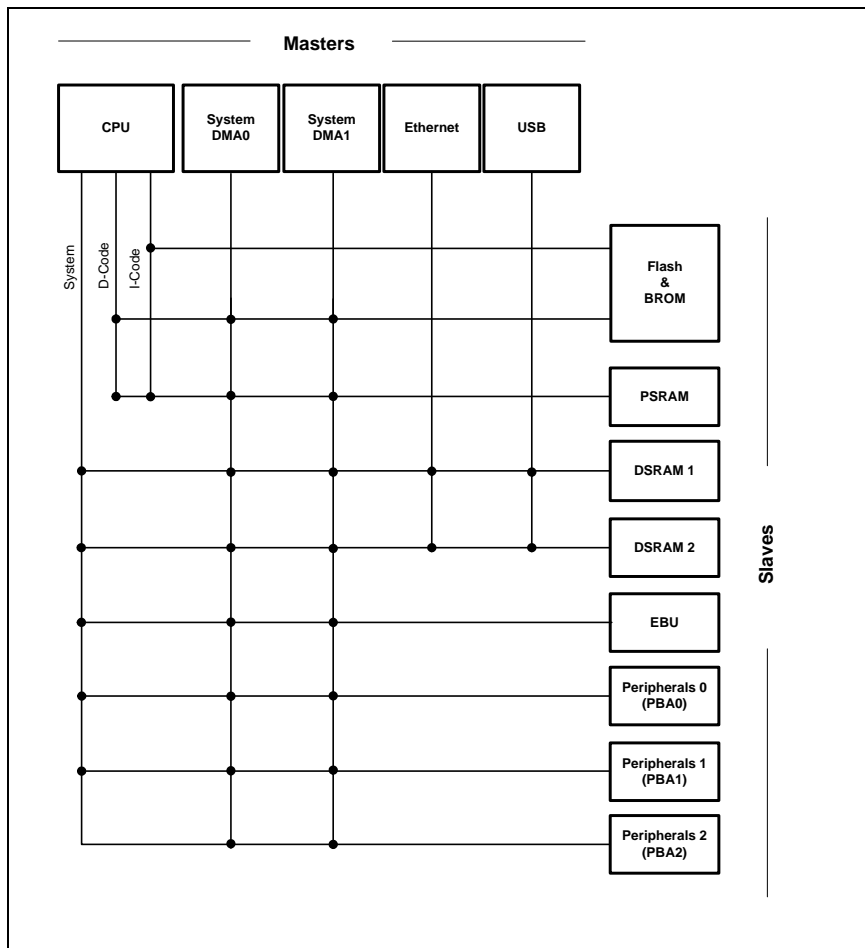

Figure 3-1 Multilayer Bus Matrix

Arbitration Priorities

In case of concurring access to the same slave the master with the highest priority is granted the bus.

Table 3-1 Access Priorities per Slave¹⁾

| | CPU | GPDMA0 | GPDMA1 | ETH | USB |
|-----------|------------|---------------|---------------|------------|------------|
| PMU/FLASH | 1 | 2 | 3 | - | - |
| PSRAM | 1 | 2 | 3 | - | - |
| DSRAM1 | 1 | 2 | 3 | 4 | 5 |
| DSRAM2 | 1 | 4 | 5 | 2 | 3 |
| EBU | 1 | 2 | 3 | - | - |
| PBA0 | 1 | 2 | 3 | - | - |
| PBA1 | 1 | 2 | 3 | - | - |
| PBA2 | 1 | 2 | 3 | - | - |

1) Lower number means higher priority

The DSRAM priorities are chosen to support the application dependance of the data memories:

- DSRAM1: general purpose data storage
- DSRAM2: Ethernet and USB data storage

4 Service Request Processing

A hardware pulse or level change is called Service Request (SR) in an XMC4[78]00 system. Service Requests are the fastest way to send trigger “messages” between connected on-chip resources.

An SR can generate any of the following requests

- Interrupt
- DMA
- Peripheral action

This chapter describes the available Service Requests and the different ways to select and process them.

Notes

1. *The CPU exception model and interrupt processing (by NVIC unit) are described in the CPU chapter.*
2. *General Purpose DMA request processing is described in the GPDMA chapter*

Table 4-1 Abbreviations

| | |
|------|--------------------------------------|
| DLR | DMA Line Router |
| ERU | Event Request Unit |
| NVIC | Nested Vectored Interrupt Controller |
| SR | Service Request |

4.1 Overview

Efficient Service Request Processing is based on the interconnect between the request sources and the request processing units. XMC4[78]00 provides both fixed and programmable interconnect.

4.1.1 Features

The following features are provided for Service Request processing:

- Connectivity matrix between Service Requests and request processing units
 - Fixed connections
 - Programmable connections using ERU
- Event Request Unit (ERU)
 - Flexible processing of external and internal service requests
 - Programmable for edge and/or level triggering
 - Multiple inputs per channel
 - Triggers combinable from multiple inputs
 - Input and output gating

- DMA Line Router (DLR)
 - Routing and processing of DMA requests

4.1.2 Block Diagram

The shaded components shown in **Figure 4-1** are described in this chapter.

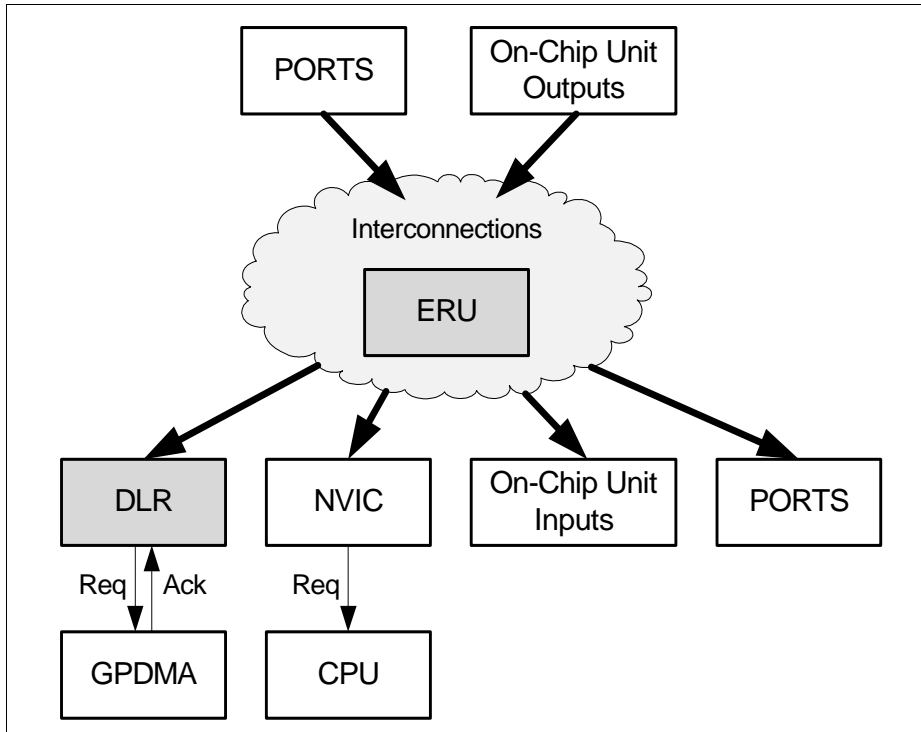

Figure 4-1 Block Diagram on Service Request Processing

4.2 Service Request Distribution

The following figure shown an example of how a service request can be distributed concurrently. To support the concurrent distribution to multiple receivers, the receiving modules are capable to enable/disable incoming requests.

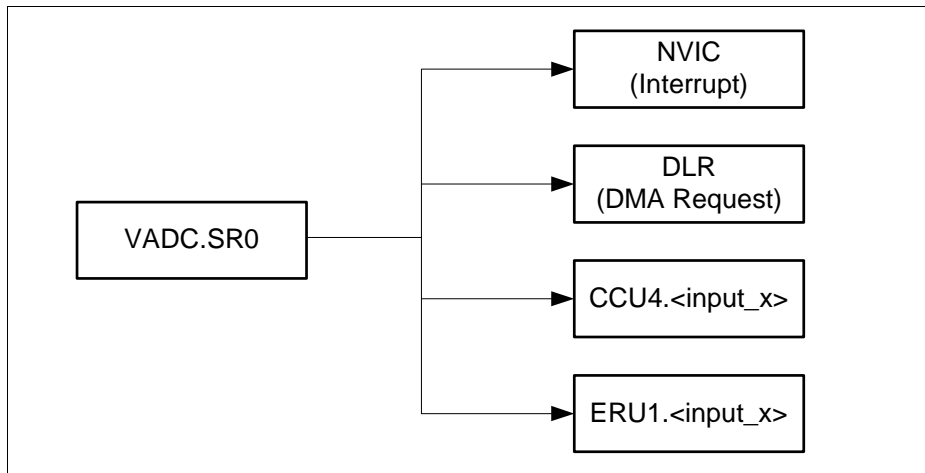

Figure 4-2 Example for Service Request Distribution

The units involved in Service Request distribution can be subdivided into

- Embedded real time services
- Interrupt and DMA services

Embedded real time services

Connectivity between On-Chip Units and PORTS is real time application and also chip package dependant. Related connectivity and availability of pins can be looked up in the

- “Interconnects” Section of the respective module(s) chapters
- “Parallel Ports” chapter and Data Sheet for PORTS
- Event Request Unit ([Section 4.5](#))

Interrupt and DMA services

The following table gives an overview on the number of service requests per module and how the service requests are assigned to NVIC Interrupt and DLR/GPDMA service providers.

Service Requests can be of type “Level” or “Pulse”. The DLR/GPDMA can only process “Pulse” type of requests while the NVIC can process both. The type of Service Requests generated is listed in column “Type” in [Table 4-2](#).

Table 4-2 Interrupt and DMA services per Module

| Modules | Request Sources | NVIC | DLR/GPDMA | Type |
|------------|-----------------|------|-----------|-------|
| VADC | 20 | 20 | 20 | Pulse |
| DSD | 8 | 8 | 4 | Pulse |
| DAC | 2 | 2 | 2 | Pulse |
| CCU40-3 | 16 | 16 | 8 | Pulse |
| CCU80-1 | 8 | 8 | 4 | Pulse |

| ETH0 | 1 | 1 | - | Level |
| ECAT0 | 1 | 1 | - | Level |
| Totals | 103 | 103 | 54 | - |

4.3 Interrupt Service Requests

The NVIC is an integral part of the Cortex M4 processor unit. Due to a tight coupling with the CPU it allows to achieve lowest interrupt latency and efficient processing of late arriving interrupts.

NVIC Features

- 112 interrupt nodes
- Programmable priority level of 0-63 for each interrupt node. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority
- Request source can be level or edge signal type
- Dynamic reprioritization of interrupts.

Service Request Processing

- Grouping of priority values into group priority and subpriority fields.
- Interrupt tail-chaining.
- One external Non-maskable interrupt (NMI)
- Relocatable vector table
- Software interrupt generation

Level-sensitive and pulse interrupts

The NVIC is capable to capture both level-sensitive and pulse interrupts.

- A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Deassertion is typically triggered by the interrupt service routine (ISR). It is
 - used for less frequent requests and
 - the ISR is often more complex and longer.
- A pulse interrupt is asserted and after a fixed period of time automatically deasserted. The period of time depends on the peripheral, please refer to the “Service Request Generation” section of the respective peripheral. It is
 - used for more frequent requests and
 - the ISR is often more simple and shorter.

The way to process both types of requests differs and is described in section “Level-sensitive and pulse interrupts” in the CPU chapter.

Service Request to IRQ Number Assignment

Table 4-3 lists the service request sources per on-chip unit and their assignment to NVIC IRQ numbers. The resulting exception number is calculated by adding 16 to the IRQ Number. The first 16 exception numbers are used by the Cortex M4 CPU. For calculation of the resulting exception routine address please refer to the CPU chapter.

Table 4-3 Interrupt Node assignment

| Service Request | IRQ Number | Description |
|----------------------------|------------|--|
| SCU.SR0 | 0 | System Control |
| ERU0.SR0 ERU0.SR3 | 1...4 | External Request Unit 0 |
| ERU1.SR0 ERU1.SR3 | 5...8 | External Request Unit 1 |

4.4 DMA Line Router (DLR)

The DMA line router provides the following functionality:

- Selection of DMA request sources
- Handling of the DMA request and acknowledge handshake
- Detection of service request overruns

4.4.1 Functional Description

This unit enables the user to select 12 DMA service requests out of the set of DMA capable service request sources. It handles the Request and Acknowledge handshake to the GPDMA units. Furthermore it detects service request overruns.

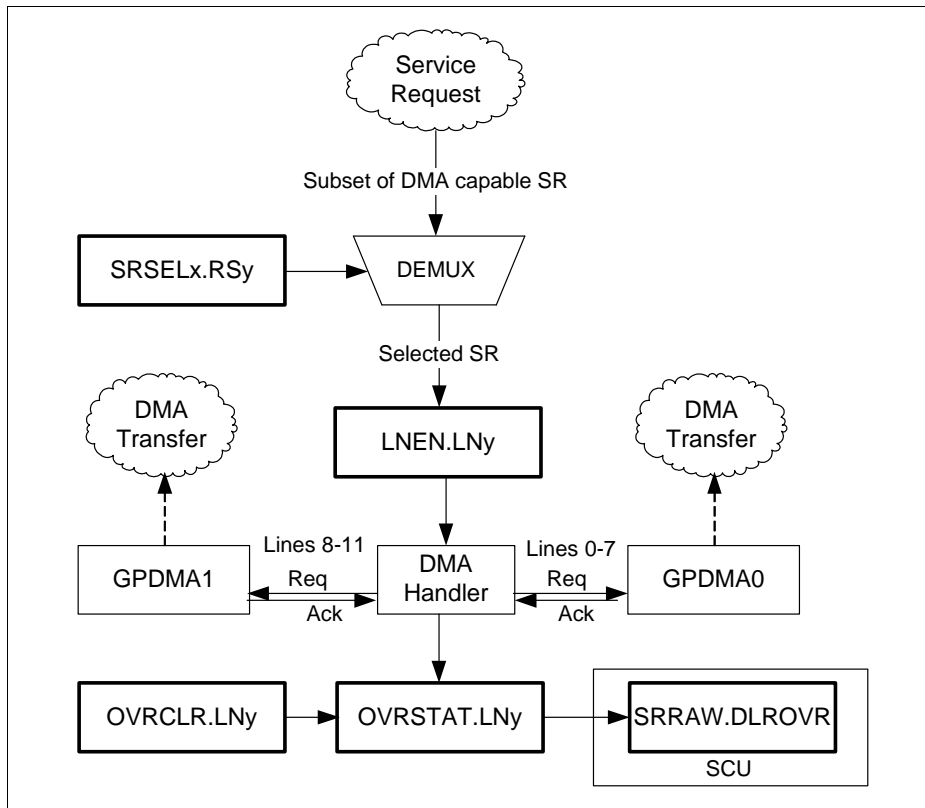

Figure 4-3 DMA Line Handler

For each DMA line the user can assign one service request source from the subset of DMA capable XMC4[78]00 service request sources. The assignment is done by programming the SRSx bit field of register [DLR_SRSELx](#). The DLR lines 0-7 are connected to GPDMA0 and the lines 8-11 are connected to GPDMA1.

If the selected service request pulse occurs and if the according line is enabled by the [DLR_LNEN](#) register, then the DMA handler forwards the request and stores it until the GPDMA responds with an acknowledge. A request pulse occurring while another transfer is ongoing is ignored and the according overrun status bit is set in the [DLR_OVRSTAT](#) register.

Once the overrun condition is entered the user can clear the overrun status bits by writing to the [DLR_OVRCLR](#) register. Additionally the pending request must be reset by successively disabling and enabling the respective line.

Service Request Processing

If any bit within the **DLR_OVRSTAT** register is set, a service request is flagged by setting the SCU_SRRAW.DLROVR bit.

The DLR unit has the following inputs:

Table 4-4 DMA Handler Service Request inputs

| Service Request | # of Inputs | Description |
|----------------------------|-------------|--|
| ERU0.SR1 - ERU0.SR4 | 4 | ERU0 (System Control) requests |
| VADC.C0SR0 - VADC.C0SR3 | 4 | Analog to Digital Converter Common Block 0 |
| VADC.G0SR0 - VADC.G0SR3 | 4 | Analog to Digital Converter Group 0 |
| VADC.G1SR0 - VADC.G1SR3 | 4 | Analog to Digital Converter Group 1 |
| VADC.G2SR0 - VADC.G2SR3 | 4 | Analog to Digital Converter Group 2 |
| VADC.G3SR0 - VADC.G3SR3 | 4 | Analog to Digital Converter Group 3 |
| DSD.SR0 - DSD.SR3 | 4 | Delta Sigma Demodulator |
| DAC.SR0 - DAC.SR1 | 2 | Digital to Analog Converter |
| CCU40.SR0 - CCU40.SR1 | 2 | Capture Compare Unit 4 (Module 0) |
| CCU41.SR0 - CCU41.SR1 | 2 | Capture Compare Unit 4 (Module 1) |
| CCU42.SR0 - CCU42.SR1 | 2 | Capture Compare Unit 4 (Module 2) |
| CCU43.SR0 - CCU43.SR1 | 2 | Capture Compare Unit 4 (Module 3) |
| CCU80.SR0 - CCU80.SR1 | 2 | Capture Compare Unit 8 (Module 0) |
| CCU81.SR0 - CCU81.SR1 | 2 | Capture Compare Unit 8 (Module 1) |
| CAN.SR0 - CAN.SR3 | 4 | MultiCAN |

Service Request Processing
Table 4-4 DMA Handler Service Request inputs (cont'd)

| Service Request | # of Inputs | Description |
|--------------------------|-------------|---|
| USIC0.SR0 - USIC0.SR1 | 2 | Universal Serial Interface Channel (Module 0) |
| USIC1.SR0 - USIC1.SR1 | 2 | Universal Serial Interface Channel (Module 1) |
| USIC2.SR0 - USIC2.SR3 | 4 | Universal Serial Interface Channel (Module 2) |

4.4.2 DMA Service Request Source Selection

The selection of the request sources is done according to the following table by programming the **DLR_SRSELx** register. Please note that each service request source can be assigned to 2 different lines to provide maximum flexibility. For example VADC.SR0 can be assigned to line 0 and 4.

Table 4-5 DMA Request Source Selection

| DMA Line | DMA Request Line | Selected by DLR_SRSEL bit field |
|----------|------------------|---------------------------------|
| 0 | ERU0.SR0 | RS0 = 0000 _B |
| | VADC.C0SR0 | RS0 = 0001 _B |
| | VADC.G0SR3 | RS0 = 0010 _B |
| | VADC.G2SR0 | RS0 = 0011 _B |
| | VADC.G2SR3 | RS0 = 0100 _B |
| | DSD.SRM0 | RS0 = 0101 _B |
| | CCU40.SR0 | RS0 = 0110 _B |
| | CCU80.SR0 | RS0 = 0111 _B |
| | Reserved | RS0 = 1000 _B |
| | CAN.SR0 | RS0 = 1001 _B |
| | USIC0.SR0 | RS0 = 1010 _B |
| | USIC1.SR0 | RS0 = 1011 _B |
| | Reserved | RS0 = 1100 _B |
| | VADC.G3SR3 | RS0 = 1101 _B |
| 1 | CCU42.SR0 | RS0 = 1110 _B |
| | Reserved | RS0 = 1111 _B |
| | ERU0.SR3 | RS1 = 0000 _B |
| | | |

Service Request Processing
Table 4-5 DMA Request Source Selection (cont'd)

| DMA Line | DMA Request Line | Selected by DLR_SRSEL bit field |
|----------|------------------|---------------------------------|

4.5 Event Request Unit (ERU)

The Event Request Unit (ERU) is a versatile multiple input event detection and processing unit. The XMC4[78]00 provides two units - ERU0 and ERU1.

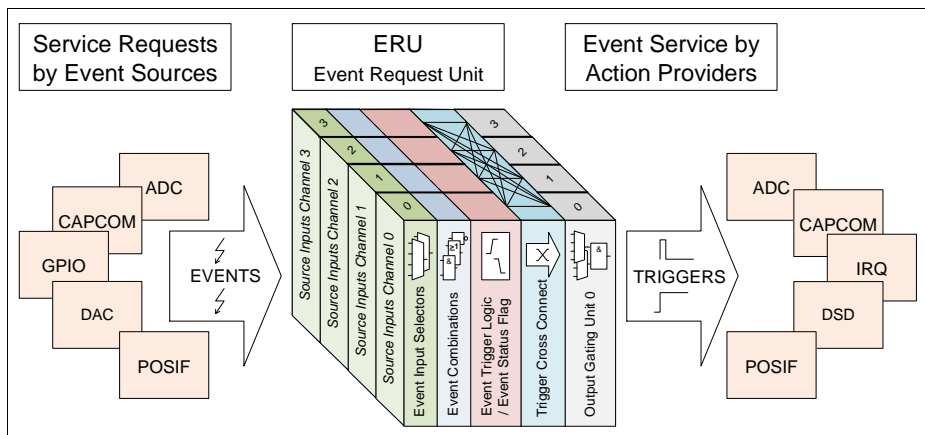

Figure 4-4 Event Request Unit Overview

Each ERU unit consists of the following blocks:

- An **Event Request Select (ERS)** unit.
 - Event Input Selectors allow the selection of one out of two inputs. For each of these two inputs, an vector of 4 possible signals is available.
 - Event Combinations allow a logical combination of two input signals to a common trigger.
- An **Event Trigger Logic (ETL)** per Input Channel allows the definition of the transition (edge selection, or by software) that lead to a trigger event and can also store this status. Here, the input levels of the selected signals are translated into events.
- The Trigger **Cross Connect Matrix** distributes the events and status flags to the Output Channels. Additionally, trigger signals from other modules are made available and can be combined with the local triggers.
- An **Output Gating Unit (OGU)** combines the trigger events and status information and gates the Output depending on a gating signal.

Note: An event of one Input can lead to reactions on several Outputs, or also events on several Inputs can be combined to a reaction on one Output.

4.5.1 Event Request Select Unit (ERS)

For each Input Channel x ($x = 0-3$), an ERS_x unit handles the input selection for the associated ETL_x unit. Each ERS_x performs a logical combination of two signals (A_x , B_x) to provide one combined output signal ERS_xO to the associated ETL_x . Input A_x can be selected from 4 options of the input vector $ERU_xA[3:0]$ and can be optionally inverted. A similar structure exists for input B_x (selection from $ERU_xB[3:0]$).

Service Request Processing

In addition to the direct choice of either input Ax or Bx or their inverted values, the possible logical combinations for two selected inputs are a logical AND or a logical OR.

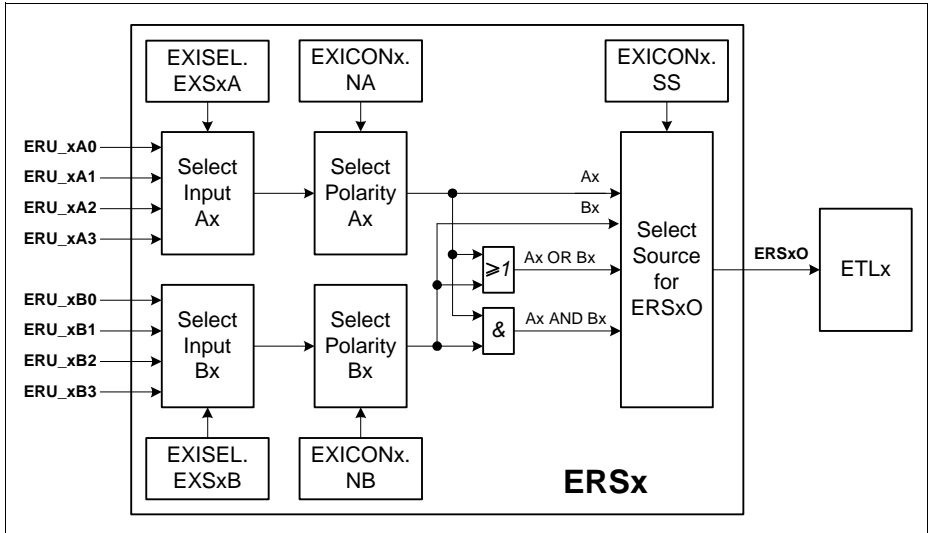

Figure 4-5 Event Request Select Unit Overview

The ERS units are controlled via register **ERU0_EXISEL** (one register for all four ERSx units) and registers EXICONx (one register for each ERSx and associated ETLx unit, e.g. **ERU0_EXICONx (x=0-3)** for Input Channel 0).

4.5.2 Event Trigger Logic (ETLx)

For each Input Channel x (x = 0-3), an event trigger logic ETLx derives a trigger event and related status information from the input ERSxO. Each ETLx is based on an edge detection block, where the detection of a rising or a falling edge can be individually enabled. Both edges lead to a trigger event if both enable bits are set (e.g. to handle a toggling input).

Each of the four ETLx units has an associated EXICONx register, that controls all options of an ETLx (the register also holds control bits for the associated ERSx unit, e.g. **ERU0_EXICONx (x=0-3)** to control ERS0 and ETL0).

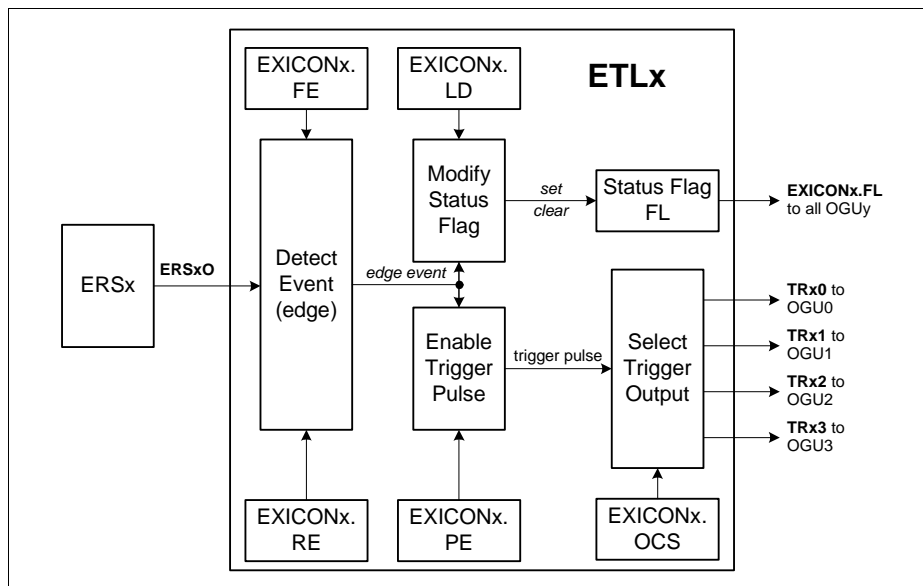

Figure 4-6 Event Trigger Logic Overview

When the selected event (edge) is detected, the status flag EXICONx.FL becomes set. This flag can also be modified by software. Two different operating modes are supported by this status flag.

It can be used as “sticky” flag, which is set by hardware when the desired event has been detected and has to be cleared by software. In this operating mode, it indicates that the event has taken place, but without indicating the actual status of the input.

In the second operating mode, it is cleared automatically if the “opposite” event is detected. For example, if only the falling edge detection is enabled to set the status flag, it is cleared when the rising edge is detected. In this mode, it can be used for pattern detection where the actual status of the input is important (enabling both edge detections is not useful in this mode).

The output of the status flag is connected to all following Output Gating Units (OGUy) in parallel (see [Figure 4-7](#)) to provide **pattern detection capability of all OGUy** units based on different or the same status flags.

In addition to the modification of the status flag, a trigger pulse output TRxy of ETLx can be enabled (by bit EXICONx.PE) and selected to **trigger actions in one of the OGUy** units. The target OGUy for the trigger is selected by bit field EXICONx.OCS.

The trigger becomes active when the selected edge event is detected, independently from the status flag EXICONx.FL.

4.5.3 Cross Connect Matrix

The matrix shown in **Figure 4-7** distributes the trigger signals (TRxy) and status signals (EXICONx.FL) from the different ETLx units between the OGUy units. In addition, it receives peripheral trigger signals that can be OR-combined with the ETLx trigger signals in the OGUy units.

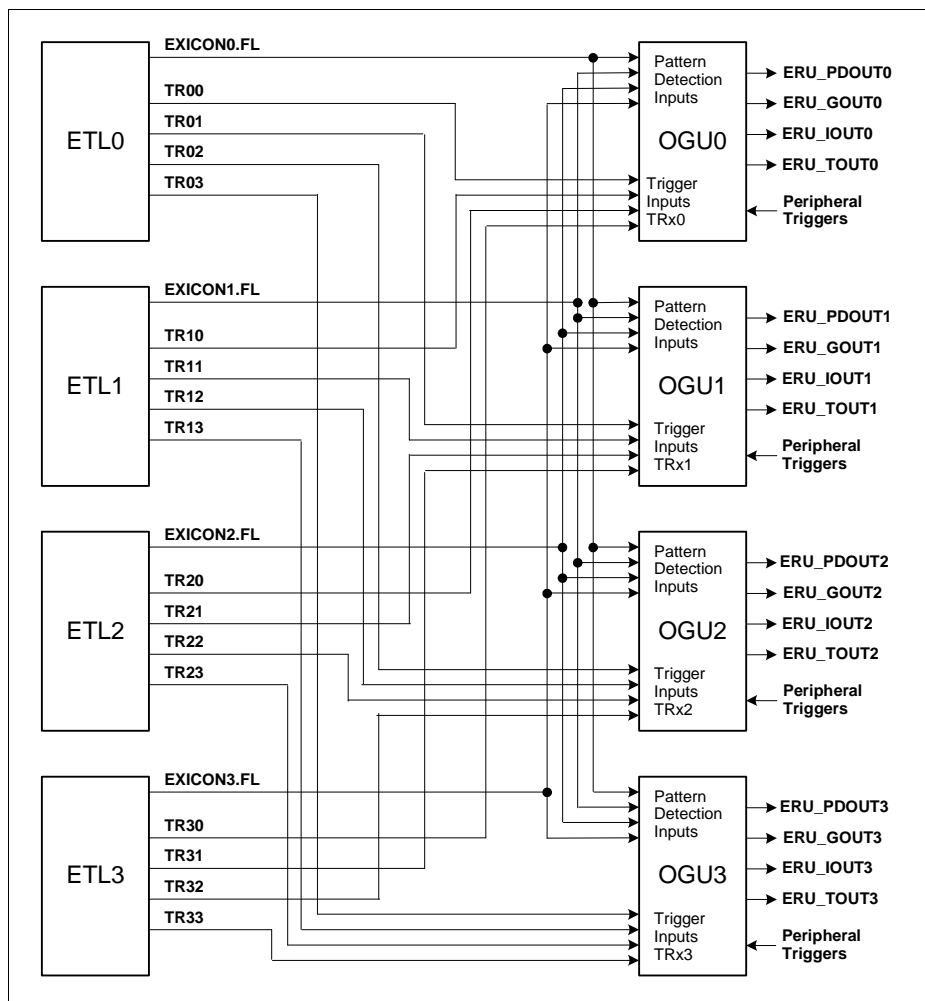

Figure 4-7 ERU Cross Connect Matrix

4.5.4 Output Gating Unit (OGUy)

Each OGUy (y = 0-3) unit combines the available trigger events and status flags from the Input Channels and distributes the results to the system. **Figure 4-8** illustrates the logic blocks within an OGUy unit. All functions of an OGUy unit are controlled by its associated EXOCONy register, e.g. **ERU0_EXOCONx (x=0-3)** for OGU0. The function of an OGUy unit can be split into two parts:

- **Trigger Combination:**
All trigger signals TRxy from the Input Channels that are enabled and directed to OGUy, a selected peripheral-related trigger event, and a pattern change event (if enabled) are logically OR-combined.
- **Pattern Detection:**
The status flags EXICONx.FL of the Input Channels can be enabled to take part in the pattern detection. A pattern match is detected while all enabled status flags are set.

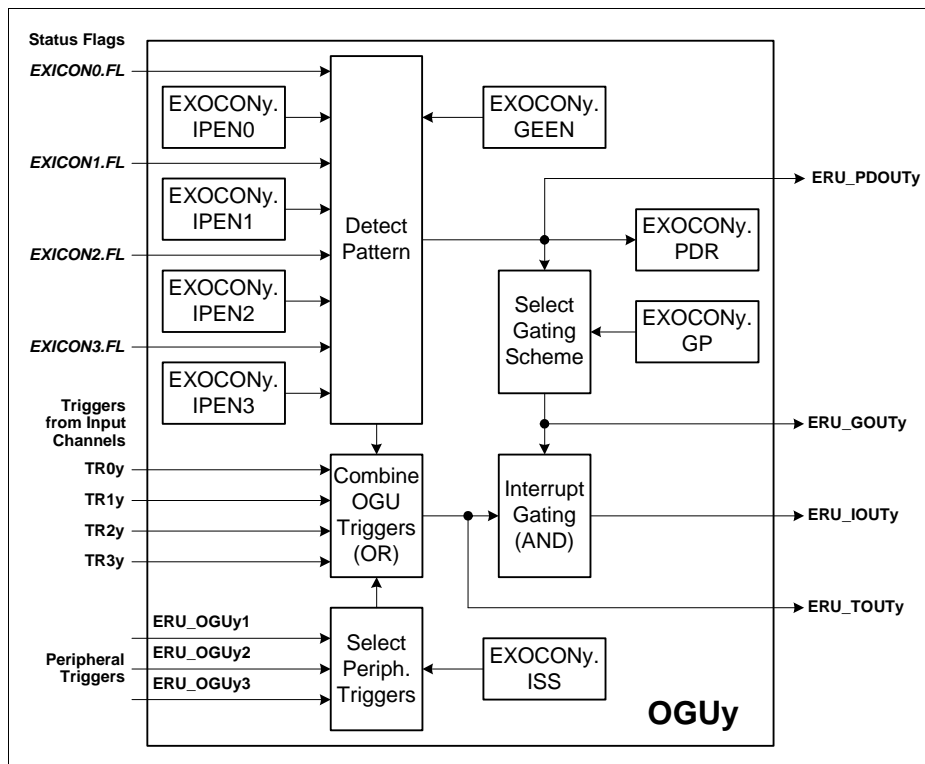

Figure 4-8 Output Gating Unit for Output Channel y

Service Request Processing

Each OGUy unit generates 4 output signals that are distributed to the system (not all of them are necessarily used):

- **ERU_PDOUTy** to directly output the pattern match information for gating purposes in other modules (pattern match = 1).
- **ERU_GOUTy** to output the pattern match or pattern miss information (inverted pattern match), or a permanent 0 or 1 under software control for gating purposes in other modules.
- **ERU_TOUTy** as combination of a peripheral trigger, a pattern detection result change event, or the ETLx trigger outputs TRxy to trigger actions in other modules.
- **ERU_IOUTy** as gated trigger output (ERU_GOUTy logical AND-combined with ERU_TOUTy) to trigger service requests (e.g. the service request generation can be gated to allow service request activation during a certain time window).

Trigger Combination

The trigger combination logically OR-combines different trigger inputs to form a common trigger ERU_TOUTy. Possible trigger inputs are:

- In each ETLx unit of the **Input Channels**, the trigger output TRxy can be enabled and the trigger event can be directed to one of the OGUy units.
- One out of three **peripheral trigger** signals per OGUy can be selected as additional trigger source. These peripheral triggers are generated by on-chip peripheral modules, such as capture/compare or timer units. The selection is done by bit field EXOCONy.ISS.
- In the case that at least one **pattern detection** input is enabled (EXOCONy.IPENx) and a change of the pattern detection result from pattern match to pattern miss (or vice-versa) is detected, a trigger event is generated to indicate a pattern detection result event (if enabled by ECOCONy.GEEN).

The trigger combination offers the possibility to program different trigger criteria for several input signals (independently for each Input Channel) or peripheral signals, and to combine their effects to a single output, e.g. to generate an service request or to start an ADC conversion. This combination capability allows the generation of a service request per OGU that can be triggered by several inputs (multitude of request sources results in one reaction).

The selection is defined by the bit fields ISS in registers **ERU0_EXOCONx (x=0-3)** (for ERU0.OGUx) and **ERU1_EXOCONy (y=0-3)** (for ERU1.OGUy).

Pattern Detection

The pattern detection logic allows the combination of the status flags of all ETLx units. Each status flag can be individually included or excluded from the pattern detection for each OGUy, via control bits EXOCONy.IPENx. The pattern detection block outputs the following pattern detection results:

Service Request Processing

- **Pattern match** (EXOCONy.PDR = 1 and ERU_PDOUTy = 1):
A pattern match is indicated while all status flags FL that are included in the pattern detection are 1.
- **Pattern miss** (EXOCONy.PDR = 0 and ERU_PDOUTy = 0):
A pattern miss is indicated while at least one of the status flags FL that are included in the pattern detection is 0.

In addition, the pattern detection can deliver a trigger event if the pattern detection result changes from match to miss or vice-versa (if enabled by EXOCONy.GEEN = 1). The pattern result change event is logically OR-combined with the other enabled trigger events to support service request generation or to trigger other module functions (e.g. in the ADC). The event is indicated when the pattern detection result changes and EXOCONy.PDR becomes updated.

The service request generation in the OGUy is based on the trigger ERU_TOUTy that can be gated (masked) with the pattern detection result ERU_PDOUTy. This allows an automatic and reproducible generation of service requests during a certain time window, where the request event is elaborated by the trigger combination block and the time window information (gating) is given by the pattern detection. For example, service requests can be issued on a regular time base (peripheral trigger input from capture/compare unit is selected) while a combination of input signals occurs (pattern detection based on ETLx status bits).

A programmable gating scheme introduces flexibility to adapt to application requirements and allows the generation of service requests ERU_IOUTy under different conditions:

- **Pattern match** (EXOCONy.GP = 10_B):
A service request is issued when a trigger event occurs while the pattern detection shows a pattern match.
- **Pattern miss** (EXOCONy.GP = 11_B):
A service request is issued when the trigger event occurs while the pattern detection shows a pattern miss.
- **Independent** of pattern detection (EXOCONy.GP = 01_B):
In this mode, each occurring trigger event leads to a service request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy with service requests on trigger events).
- **No service requests** (EXOCONy.GP = 00_B, default setting)
In this mode, an occurring trigger event does not lead to a service request. The pattern detection output can be used independently from the trigger combination for gating purposes of other peripherals (independent use of ERU_TOUTy and ERU_PDOUTy without service requests on trigger events).

4.6 Service Request Generation

If any bit within the DLR.**DLR_OVRSTAT** register is set, a service request is flagged by setting the SCU_SRRAW.DLROVR bit.

To clear a request user must program the corresponding bit in the DLR.**DLR_OVRCLR** register. Then also clear SCU_SRRAW.DLROVR bit as described in the SCU chapter.

It is possible to mask out promotion of the service request by setting SCU_SRMSK.DLROVR bit.

4.7 Debug Behavior

Service request processing behavior is unchanged in debug mode.

4.8 Power, Reset and Clock

Service request processing is

- consuming power in all operating modes.
- running on f_{CPU} .
- asynchronously initialized by the system reset.

4.9 Initialization and System Dependencies

Service Requests must always be enabled at the source and at the destination. Additionally it must be checked whether it is necessary to program the ERU process and route a request.

Enabling Peripheral SRx Outputs

- Peripherals SRx outputs must be selectively enabled. This procedure depends on the individual peripheral. Please look up the section “Service Request Generation” within a peripherals chapter for details.
- Optionally ERUx must be programmed to process and route the request

Enabling External Requests

- Selected PORTS must be programmed for input
- ERUx must be programmed to process and route the external request

Note: The number of external service request inputs may be limited by the package used.

Enabling NVIC and GPDMA

Interrupt and DMA service request processing must be enabled. Please refer to the CPU and GPDMA chapters for details.

4.10 Registers

Registers Overview

The absolute register address is calculated by adding:
Module Base Address + Offset Address

Table 4-6 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| DLR | 5000 4900 _H | 5000 49FF _H | |
| ERU0 | 5000 4800 _H | 5000 48FF _H | |
| ERU1 | 4004 4000 _H | 4004 7FFF _H | |

4.10.1 DLR Registers

DLR_OVRSTAT

The DLR_OVRSTAT register is used to track status of GPDMA service request overruns. Upon overrun detection, additionally a service request flag is set in the SCU_SRRAW.DLROVR bit.

DLR_OVRSTAT

Overrun Status (00_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|------|------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |

| r | | | | rh | rh | rh | rh | rh | rh | rh | rh | rh | rh | rh | rh |

| Field | Bits | Type | Description |
|--------------------------|---------|------|--|
| LNx (x = 0-11) | x | rh | Line x Overrun Status Set if an overrun occurred on this line. |
| 0 | [31:12] | r | Reserved Read as 0; should be written with 0. |

DLR_OVRCLR

The DLR_OVRCLR register is used to clear the DLR_OVRSTAT register bits.

DLR_OVRCLR

Overflow Clear

(04_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------------------------|---------|------|---|
| LNx (x = 0-11) | x | w | Line x Overrun Status Clear Clears the corresponding bit in the DLR_OVRSTAT register when set to 1. |
| 0 | [31:12] | r | Reserved Read as 0; should be written with 0. |

DLR_LNEN

The DLR_LNEN register is used to enable each individual DLR line and to reset a previously stored and pending service request.

DLR_LNEN

Line Enable

(10_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------------------------|---------|------|--|
| LNx (x = 0-11) | x | rw | Line x Enable 0 _B Disables the line 1 _B Enables the line and resets a pending request |
| 0 | [31:12] | r | Reserved Read as 0; should be written with 0. |

DLR_SRSELx

The DLR_SRSELx registers are used to select the service request source used to trigger a DMA transfer.

DLR_SRSEL0

Service Request Selection 0

(08_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------------------------|-----------------|------|---|
| RSx (x = 0-7) | [x*4+3: x*4] | rw | Request Source for Line x The request source according to Table 4-5 is selected for DMA line x. These lines are connected to GPDMA0 |

DLR_SRSEL1

Service Request Selection 1

(0C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| RS8 | [3:0] | rw | Request Source for Line 8 The request source according to Table 4-5 is selected for DMA line x. This line is connected to GPDMA1. |
| RS9 | [7:4] | rw | Request Source for Line 9 The request source according to Table 4-5 is selected for DMA line x. This line is connected to GPDMA1. |
| RS10 | [11:8] | rw | Request Source for Line 10 The request source according to Table 4-5 is selected for DMA line x. This line is connected to GPDMA1. |
| RS11 | [15:12] | rw | Request Source for Line 11 The request source according to Table 4-5 is selected for DMA line x. This line is connected to GPDMA1. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

4.10.2 ERU Registers

ERU0_EXISEL

Event Input Select

(00_H)

Reset Value: 0000 0000_H

ERU1_EXISEL

Event Input Select

(0000_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|-------|------|--|
| EXS0A | [1:0] | rw | Event Source Select for A0 (ERS0) This bit field defines which input is selected for A0. 00 _B Input ERU_0A0 is selected 01 _B Input ERU_0A1 is selected 10 _B Input ERU_0A2 is selected 11 _B Input ERU_0A3 is selected |
| EXS0B | [3:2] | rw | Event Source Select for B0 (ERS0) This bit field defines which input is selected for B0. 00 _B Input ERU_0B0 is selected 01 _B Input ERU_0B1 is selected 10 _B Input ERU_0B2 is selected 11 _B Input ERU_0B3 is selected |
| EXS1A | [5:4] | rw | Event Source Select for A1 (ERS1) This bit field defines which input is selected for A1. 00 _B Input ERU_1A0 is selected 01 _B Input ERU_1A1 is selected 10 _B Input ERU_1A2 is selected 11 _B Input ERU_1A3 is selected |

Service Request Processing

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| EXS1B | [7:6] | rw | Event Source Select for B1 (ERS1) This bit field defines which input is selected for B1. 00 _B Input ERU_1B0 is selected 01 _B Input ERU_1B1 is selected 10 _B Input ERU_1B2 is selected 11 _B Input ERU_1B3 is selected |
| EXS2A | [9:8] | rw | Event Source Select for A2 (ERS2) This bit field defines which input is selected for A2. 00 _B Input ERU_2A0 is selected 01 _B Input ERU_2A1 is selected 10 _B Input ERU_2A2 is selected 11 _B Input ERU_2A3 is selected |
| EXS2B | [11:10] | rw | Event Source Select for B2 (ERS2) This bit field defines which input is selected for B2. 00 _B Input ERU_2B0 is selected 01 _B Input ERU_2B1 is selected 10 _B Input ERU_2B2 is selected 11 _B Input ERU_2B3 is selected |
| EXS3A | [13:12] | rw | Event Source Select for A3 (ERS3) This bit field defines which input is selected for A3. 00 _B Input ERU_3A0 is selected 01 _B Input ERU_3A1 is selected 10 _B Input ERU_3A2 is selected 11 _B Input ERU_3A3 is selected |
| EXS3B | [15:14] | rw | Event Source Select for B3 (ERS3) This bit field defines which input is selected for B3. 00 _B Input ERU_3B0 is selected 01 _B Input ERU_3B1 is selected 10 _B Input ERU_3B2 is selected 11 _B Input ERU_3B3 is selected |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

ERU0_EXICONx (x=0-3)

Event Input Control x

$(10_H + 4 \cdot x)$

Reset Value: 0000 0000_H

ERU1_EXICONy (y=0-3)

Event Input Control y

$(0010_H + 4 \cdot y)$

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| PE | 0 | rw | Output Trigger Pulse Enable for ETLx This bit enables the generation of an output trigger pulse at TRxy when the selected edge is detected (set condition for the status flag FL). 0 _B The trigger pulse generation is disabled 1 _B The trigger pulse generation is enabled |
| LD | 1 | rw | Rebuild Level Detection for Status Flag for ETLx This bit selects if the status flag FL is used as “sticky” bit or if it rebuilds the result of a level detection. 0 _B The status flag FL is not cleared by hardware and is used as “sticky” bit. Once set, it is not influenced by any edge until it becomes cleared by software. 1 _B The status flag FL rebuilds a level detection of the desired event. It becomes automatically set with a rising edge if RE = 1 or with a falling edge if FE = 1. It becomes automatically cleared with a rising edge if RE = 0 or with a falling edge if FE = 0. |

Service Request Processing

| Field | Bits | Type | Description |
|------------|-------|------|---|
| RE | 2 | rw | Rising Edge Detection Enable ETLx This bit enables/disables the rising edge event as edge event as set condition for the status flag FL or as possible trigger pulse for TRxy. 0 _B A rising edge is not considered as edge event 1 _B A rising edge is considered as edge event |
| FE | 3 | rw | Falling Edge Detection Enable ETLx This bit enables/disables the falling edge event as edge event as set condition for the status flag FL or as possible trigger pulse for TRxy. 0 _B A falling edge is not considered as edge event 1 _B A falling edge is considered as edge event |
| OCS | [6:4] | rw | Output Channel Select for ETLx Output Trigger Pulse This bit field defines which Output Channel OGUy is targeted by an enabled trigger pulse TRxy. 000 _B Trigger pulses are sent to OGU0 001 _B Trigger pulses are sent to OGU1 010 _B Trigger pulses are sent to OGU2 011 _B Trigger pulses are sent to OGU3 Others: Reserved, do not use this combination |
| FL | 7 | rwh | Status Flag for ETLx This bit represents the status flag that becomes set or cleared by the edge detection. 0 _B The enabled edge event has not been detected 1 _B The enabled edge event has been detected |
| SS | [9:8] | rw | Input Source Select for ERSx This bit field defines which logical combination is taken into account as ERSxO. 00 _B Input A without additional combination 01 _B Input B without additional combination 10 _B Input A OR input B 11 _B Input A AND input B |
| NA | 10 | rw | Input A Negation Select for ERSx This bit selects the polarity for the input A. 0 _B Input A is used directly 1 _B Input A is inverted |

Service Request Processing

| Field | Bits | Type | Description |
|-----------|---------|------|--|
| NB | 11 | rw | Input B Negation Select for ERSx This bit selects the polarity for the input B. 0 _B Input B is used directly 1 _B Input B is inverted |
| 0 | [31:12] | r | Reserved Read as 0; should be written with 0. |

ERU0_EXOCONx (x=0-3)

Event Output Trigger Control x

$$(20_H + 4 \cdot x)$$

Reset Value: 0000 0008_H

ERU1_EXOCONy (y=0-3)

Event Output Trigger Control y

$$(0020_H + 4 \cdot y)$$

Reset Value: 0000 0008_H

| Field | Bits | Type | Description |
|-------------|-------|------|--|
| ISS | [1:0] | rw | Internal Trigger Source Selection This bit field defines which input is selected as peripheral trigger input for OGUy. 00 _B The peripheral trigger function is disabled 01 _B Input ERU_OGUy1 is selected 10 _B Input ERU_OGUy2 is selected 11 _B Input ERU_OGUy3 is selected |
| GEEN | 2 | rw | Gating Event Enable Bit GEEN enables the generation of a trigger event when the result of the pattern detection changes from match to miss or vice-versa. 0 _B The event detection is disabled 1 _B The event detection is enabled |

Service Request Processing

| Field | Bits | Type | Description |
|----------------------------|---------------------|------|---|
| PDR | 3 | rh | Pattern Detection Result Flag This bit represents the pattern detection result. 0 _B A pattern miss is detected 1 _B A pattern match is detected |
| GP | [5:4] | rw | Gating Selection for Pattern Detection Result This bit field defines the gating scheme for the service request generation (relation between the OGU output ERU_PDOUTy and ERU_GOUTy). 00 _B ERU_GOUTy is always disabled and ERU_IOUTy can not be activated 01 _B ERU_GOUTy is always enabled and ERU_IOUTy becomes activated with each activation of ERU_TOUTy 10 _B ERU_GOUTy is equal to ERU_PDOUTy and ERU_IOUTy becomes activated with an activation of ERU_TOUTy while the desired pattern is detected (pattern match PDR = 1) 11 _B ERU_GOUTy is inverted to ERU_PDOUTy and ERU_IOUTy becomes activated with an activation of ERU_TOUTy while the desired pattern is not detected (pattern miss PDR = 0) |
| IPENx (x = 0-3) | 12+x | rw | Pattern Detection Enable for ETLx Bit IPENx defines whether the trigger event status flag EXICONx.FL of ETLx takes part in the pattern detection of OGUy. 0 _B Flag EXICONx.FL is excluded from the pattern detection 1 _B Flag EXICONx.FL is included in the pattern detection |

5 General Purpose DMA (GPDMA)

The GPDMA is a highly configurable DMA controller, that allows high-speed data transfers between peripherals and memories. Complex data transfers can be done with minimal intervention of the processor, keeping this way the CPU resources free for other operations.

Extensive support for the microcontroller peripherals, like A/D and D/A converters, Timers, Communication Interfaces (USIC) via the GPDMA, unload the CPU and increase the efficiency and parallelism, for a high arrangement of real-time applications.

Table 5-1 Abbreviations table

| | |
|-----------|--------------------------------|
| GPDMAx | General Purpose DMA instance x |
| SCU | System Control Unit |
| DLR | DMA Line Router |
| f_{DMA} | GPDMA clock frequency |

5.1 Overview

The GPDMA module enables hardware or software controlled data transfers between all microcontroller modules with the exclusion of those modules which provide built-in DMA functionality (USB and Ethernet).

Each GPDMA module contains a dedicated set of highly programmable channels, that can accommodate several type of peripheral-to-peripheral, peripheral-to-memory and memory-to-memory transfers.

The link between a highly programmable channel allocation and channel priority, gives a high benefit for applications that need high efficiency and parallelism.

The built-in fast DMA request handling together with the flexible peripheral configuration, enables the implementation of very demanding application software loops.

5.1.1 Features

The GPDMA component includes the following features.

General

- Bus interfaces
 - 1 Bus master interface per DMA unit
 - 1 Bus slave interface per DMA unit
- Channels
 - One GPDMA0 unit with 8 channels
 - One GPDMA1 unit with 4 channels
 - Programmable channel priority

General Purpose DMA (GPDMA)

- Transfers
 - Support for memory-to-memory, memory-to-peripheral, peripheral-to-memory, and peripheral-to-peripheral DMA transfers

Channels

All channels can be programmed for the following transfer modes

- DMA triggered by software or selectable from hardware service request sources
- Programmable source and destination addresses
- Address increment, decrement, or no change

Channels 0 and 1 of GPDMA0 can be programmed for the following transfer modes

- Multi-block transfers achieved through:
 - Linked Lists (block chaining)
 - Auto-reloading of channel registers
 - Contiguous address between blocks
- Independent source and destination selection of multi-block transfer type
- Scatter/Gather - source and destination areas do not need to be in a contiguous memory space

The GPDMA0 channels 0 and 1 provide a FIFO of 32 Bytes (eight 32-bit entries). These channels can be used to execute burst transfers up to a fixed length burst size of 8. The remaining channels FIFO size is 8 Bytes.

Channel Control

- Programmable source and destination for each channel
- Programmable burst transaction size for each channel
- Programmable enable and disable of DMA channel
- Support for disabling channel without data loss
- Support for suspension of DMA operation
- Support for ERROR response
- Bus locking - programmable over transaction, block, or DMA transfer level
- Channel locking - programmable over transaction, block, or DMA transfer level
- Optional writeback of the Channel Control register at the end of every block transfer

Interrupts

- Combined and separate interrupt service requests
- Request generation on:
 - DMA transfer completion
 - Block transfer completion
 - Single and burst transaction completion
 - Error condition
- Support of interrupt enabling and masking

5.1.2 Block Diagram

Figure 5-1 shows the following functional groupings of the main interfaces to the GPDMA block:

- DMA hardware request interface (DLR)
- Up to twelve channels
- Arbiter
- Bus Master and Slave interfaces

One channel of the GPDMA is required for each source/destination pair. The master interface reads the data from a source peripheral and writes it to a destination peripheral. Two physical transfers are therefore required for each DMA transaction.

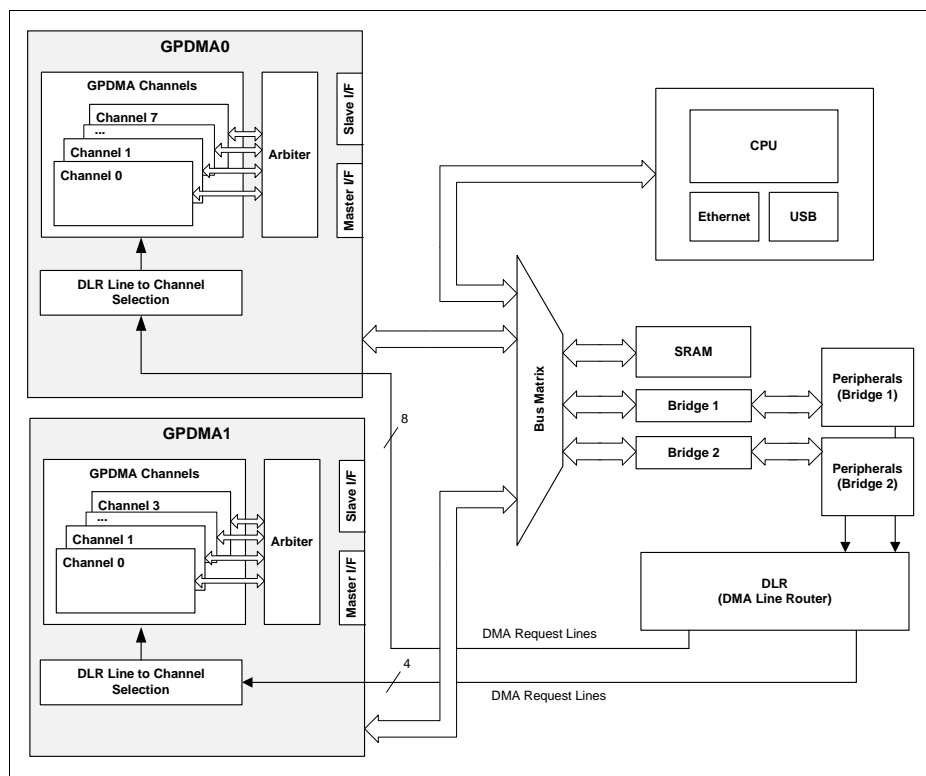

Figure 5-1 GPDMA Block Diagram

5.2 Functional Description

This chapter describes the functional details of the GPDMA.

5.2.1 Terminology

The following terms are concise definitions of the DMA concepts are used throughout this chapter:

Service Partner Terms

- **Source peripheral** - Device from which the GPDMA reads data; the GPDMA then stores the data in the channel FIFO. The source peripheral teams up with a destination peripheral to form a channel.
- **Destination peripheral** - Device to which the GPDMA writes the stored data from the FIFO (previously read from the source peripheral).
- **Memory** - Source or destination that is always "ready" for a DMA transfer and does not require a handshaking interface to interact with the GPDMA. Note that
- **Channel** - Read/write data path between a source peripheral and a destination peripheral, that occurs through the channel FIFO. If the source peripheral is not memory, then a source handshaking interface is assigned to the channel. If the destination peripheral is not memory, then a destination handshaking interface is assigned to the channel. Source and destination handshaking interfaces can be assigned dynamically by programming the channel registers.

Interface Terms

- **Master interface** - GPDMA is a master on the AHB, reading data from the source and writing it to the destination over the bus. Each channel has to arbitrate for the master interface.
- **Slave interface** - The AHB interface over which the GPDMA is programmed.
- **Handshaking interface** - A set of signals or software registers that conform to a protocol and handshake between the GPDMA and source or destination peripheral in order to control transferring a single or burst transaction between them. This interface is used to request, acknowledge, and control a GPDMA transaction. A channel can receive a request through one of two types of handshaking interface: software, or peripheral trigger.
 - **Software handshaking interface** - Software uses registers to control transferring a single or burst transaction between the GPDMA and the source or destination peripheral. This mode is useful if the total block size is unknown at the beginning of a transfer. For more information about this interface, refer to [Section 5.2.4.2](#).
 - **Peripheral trigger interface** - In this mode, a DLR service request line is used to trigger single or burst transactions. For using this mode, the total block size must be known at the beginning of a transfer. For more information about this interface, refer to [Section 5.2.4](#).

Flow Control Terms

- **Flow controller** - Device that determines the length of a DMA block transfer and terminates it.
 - If you know the length of a block before enabling the channel, then GPDMA should be programmed as the flow controller.
 - If the length of a block is not known prior to enabling the channel, the source or destination peripheral needs to control and terminate a transfer. In this mode, the peripheral, using the software handshaking interface, is the flow controller.
- **Flow control mode (CFG.FCMODE)** - Special mode that only applies when the destination peripheral is the flow controller. It controls the data pre-fetching from the source peripheral.

Transfer Terms

- **Transfer hierarchy** - **Figure 5-2** illustrates the hierarchy between GPDMA transfers, block transfers, transactions (single or burst), and AHB transfers (single or burst) for peripherals. **Figure 5-3** shows the transfer hierarchy for memory.

Note: For memory type transfers, there is no “Transaction Level”.

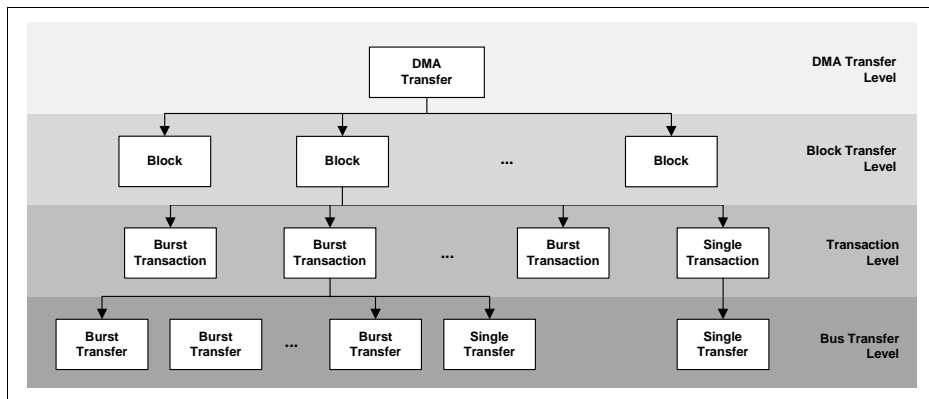

Figure 5-2 Transfer Hierarchy for Peripherals

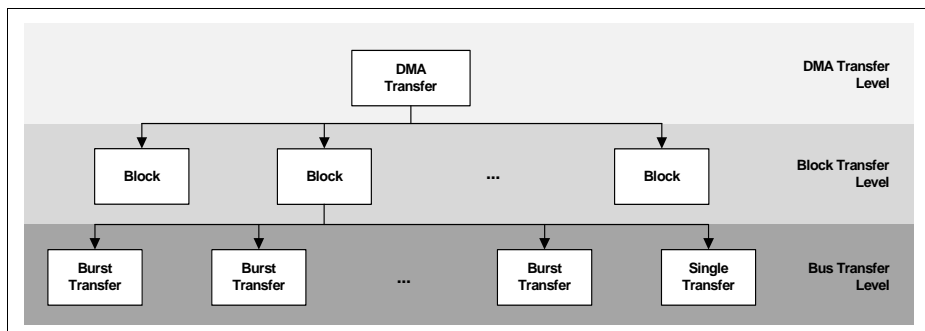

Figure 5-3 Transfer Hierarchy for Memory

- **DMA transfer** - Can be programmed to single or multiple blocks (depends on channel features). Once a DMA transfer has finished, the hardware within the GPDMA disables the channel and can generate an interrupt to signal the DMA transfer completion. You can then reprogram the channel for a new DMA transfer.
 - **Single-block DMA transfer** - Consists of a single block.
 - **Multi-block DMA transfer** - DMA transfer may consist of multiple GPDMA blocks. Multi-block DMA transfers are supported through **Linked lists (block chaining)**, **Auto-reloading** and **Contiguous blocks**. The source and destination can independently select which method to use.
- **Block** - Block of GPDMA data, the amount of which is the block length and is determined by the flow controller. For transfers between the GPDMA and memory, a block is broken directly into a sequence of bursts and single transfers. For transfers between the GPDMA and a peripheral, a block is broken into a sequence of GPDMA transactions (single and bursts). These are in turn broken into a sequence of AHB transfers.
- **Transaction** - Basic unit of a GPDMA transfer, as determined by either the hardware or software handshaking interface. A transaction is relevant only for transfers between the GPDMA and a source or destination peripheral. There are two types of transactions:
 - **Single transaction** - is always converted to a single AHB transfer.
 - **Burst transaction** - Length of a burst transaction is programmed into the GPDMA. The burst transaction is converted into a sequence of AHB fixed length bursts and AHB single transfers. GPDMA executes each burst transfer by performing incremental bursts that are no longer than the maximum burst size set; the only type of burst in this kind of transaction is incremental. The burst transaction length is under program control and normally bears some relationship to the FIFO sizes in the GPDMA and in the source and destination peripherals.

Specific Transfer Mode Terms

- **Scatter** - Relevant to destination transfers within a block. The destination address is incremented or decremented by a programmed amount when a scatter boundary is reached. The number of AHB transfers between successive scatter boundaries is under software control.
- **Gather** - Relevant to source transfers within a block. The source address is incremented or decremented by a programmed amount when a gather boundary is reached. The number of AHB transfers between successive gather boundaries is under software control.
- **Channel locking** - Software can program a channel to keep the AHB master interface by locking arbitration of the master AHB interface for the duration of a DMA transfer, block, or transaction (single or burst).
- **Bus locking** - Software can program a channel to maintain control of the AHB bus for the duration of a DMA transfer, block, or transaction (single or burst). At minimum, channel locking is asserted during bus locking.
- **FIFO mode** - Special mode to improve bandwidth. When enabled, the channel waits until the FIFO is less than half full to fetch the data from the source peripheral, and waits until the FIFO is greater than or equal to half full in order to send data to the destination peripheral. Because of this, the channel can transfer the data using bursts, which eliminates the need to arbitrate for the AHB master interface in each single AHB transfer. When this mode is not enabled, the channel waits only until the FIFO can transmit or accept a single AHB transfer before it requests the master bus interface.

5.2.2 Variable Definitions

The following variable definitions are used in this chapter:

Source single transaction size in bytes

```
src_single_size_bytes = CTLL.SRC_TR_WIDTH/8
```

Source burst transaction size in bytes

```
src_burst_size_bytes = CTLL.SRC_MSIZE * src_single_size_bytes
```

Destination single transaction size in bytes

```
dst_single_size_bytes = CTLL.DST_TR_WIDTH/8
```

Destination burst transaction size in bytes

```
dst_burst_size_bytes = CTLL.DEST_MSIZE * dst_single_size_bytes
```

Block size in bytes

- GPDMA is the flow controller:
 With the GPDMA as the flow controller, the processor programs the GPDMA with the number of data items (block size) of source transfer width (**CTL.SRC_TR_WIDTH**) to be transferred by the GPDMA in a block transfer; this is programmed into the **CTL.BLOCK_TS** field. Therefore, the total number of bytes to be transferred in a block is defined by:

$$\text{blk_size_bytes_dma} = \text{CTL.BLOCK_TS} * \text{src_single_size_bytes}$$

- Source peripheral is block flow controller:

$$\text{blk_size_bytes_src} = (\text{Number of source burst transactions in block} * \text{src_burst_size_bytes}) + (\text{Number of source single transactions in block} * \text{src_single_size_bytes})$$
- Destination peripheral is block flow controller:

$$\text{blk_size_bytes_dst} = (\text{Number of destination burst transactions in block} * \text{dst_burst_size_bytes}) + (\text{Number of destination single transactions in block} * \text{dst_single_size_bytes})$$

*Note: In the above equations, references to **CTL.SRC_MSIZ**, **CTL.DEST_MSIZ**, **CTL.SRC_TR_WIDTH**, and **CTL.DST_TR_WIDTH** refer to the decoded values of the parameters; for example, **CTL.SRC_MSIZ** = 001₂ decodes to 4, and **CTL.SRC_TR_WIDTH** = 010₂ decodes to 32 bits.*

5.2.3 Flow Controller and Transfer Type

The device that controls the length of a block is known as the flow controller. Either the GPDMA, the source peripheral, or the destination peripheral must be assigned as the flow controller.

- If the block size is known prior to when the channel is enabled, then the GPDMA must be programmed as the flow controller. The block size is programmed into the **CTL.BLOCK_TS** field.
- If the block size is unknown when the GPDMA channel is enabled, either the source or destination peripheral must be the flow controller.

Attention: If a peripheral is assigned as the flow controller then hardware handshaking is not supported.

The **CTL.TT_FC** field indicates the transfer type and flow controller for that channel.

Table 5-2 lists valid transfer types and flow controller combinations.

Table 5-2 Transfer Type, Flow Control and Handshake Combinations

| Transfer Type | Flow Controller | Handshaking |
|--------------------------|------------------------|----------------------|
| Memory to Memory | GPDMA | - |
| Memory to Peripheral | GPDMA | Hardware or Software |
| Peripheral to Memory | GPDMA | Hardware or Software |
| Peripheral to Peripheral | GPDMA | Hardware or Software |
| Peripheral to Memory | Peripheral | Software |
| Peripheral to Peripheral | Source Peripheral | Software |
| Memory to Peripheral | Peripheral | Software |
| Peripheral to Peripheral | Destination Peripheral | Software |

5.2.4 Handshaking Interface

Handshaking interfaces are used at the transaction level to control the flow of single or burst transactions. The operation of the handshaking interface depends on whether the peripheral or the GPDMA is the flow controller.

The peripheral uses the handshaking interface to indicate to the GPDMA that it is ready to transfer data over the AHB bus.

A peripheral can request a DMA transaction through the GPDMA using one of two types of handshaking interfaces:

- Hardware
- Software

The user selects between the hardware or software handshaking interface on a per-channel basis. Software handshaking is accomplished through memory-mapped registers, while hardware handshaking is accomplished using a dedicated handshaking interface.

Notes

1. *Throughout the remainder of this chapter, references to both source and destination hardware handshaking interfaces assume an active-high interface (refer to **CFG.SRC(DST)_HS_POL** bits in the Channel Configuration register, **CFG**). When active-low handshaking interfaces are used, then the active level and edge are reversed from that of an active-high interface.*
2. *Source and destination peripherals can independently select the handshaking interface type; that is, hardware or software handshaking. For more information, refer to the **CFG.HS_SEL_SRC** and **CFG.HS_SEL_DST** parameters in the **CFG** register.*

5.2.4.1 Hardware Handshaking

Before the transfer can begin the GPDMA and DLR units must be set up according to the user requirements (shown as step 1 in [Figure 5-4](#)).

Once the peripheral (source or destination) is ready for a transaction it sends a service request. This request is taken by the DLR which in turn forwards it to the GPDMA (step 2). The GPDMA finally executes the transaction (step 3).

Steps 2 and 3 repeat until the programmed transfer is complete.

Note: Optionally interrupts can be generated after block or transaction completion as described in [Section 5.5](#)

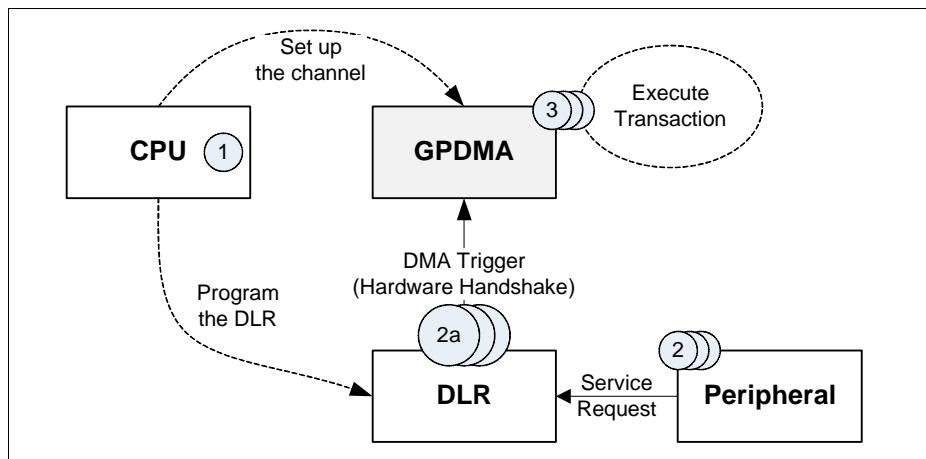

Figure 5-4 Hardware Handshaking Interface

5.2.4.2 Software Handshaking

Before the transfer can begin the GPDMA and NVIC units must be set up according to the user requirements (shown as step 1 in [Figure 5-5](#)).

Once the peripheral (source or destination) is ready for a transaction it sends a service request to the CPU. The interrupt service routine then uses the software registers, detailed in [Section 5.8.4](#), to initiate and control a DMA transaction (step 2). The GPDMA finally executes the transaction (step 3).

Steps 2 and 3 repeat until the programmed transfer is complete.

Note: Optionally interrupts can be generated after block or transaction completion as described in [Section 5.5](#)

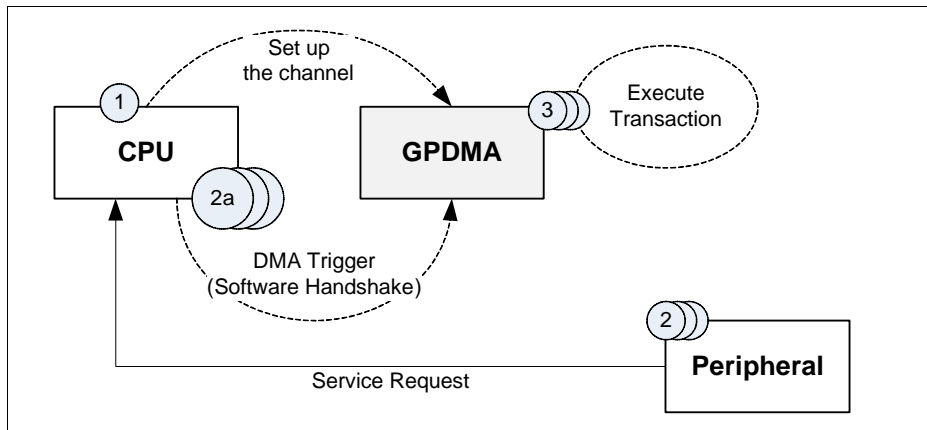

Figure 5-5 Software Handshaking Interface

5.2.4.3 Handshaking with GPDMA as Flow Controller

The GPDMA tries to efficiently transfer the data using as little of the bus bandwidth as possible. Generally, the GPDMA tries to transfer the data using burst transactions and, where possible, fill or empty the channel FIFO in single bursts - provided that the software has not limited the burst length.

The GPDMA can also lock the arbitration for the master bus interface so that a channel is permanently granted the master bus interface. Additionally, the GPDMA can assert the lock signal to lock the system arbiter. For more information, refer to [Section 5.2.6](#).

Before describing the handshaking interface operation, the following sections define the terms "Single Transaction Region" and "Early-Terminated Burst Transaction".

Single Transaction Region

The single transaction region is the time interval where the GPDMA can no longer use full burst transactions to complete the block transfer.

There are cases where a DMA block transfer cannot be completed using only burst transactions. Typically this occurs when the block size is not a multiple of the burst transaction length. In these cases, the block transfer uses burst transactions up to the point where the amount of data left to complete the block is less than the amount of data in a burst transaction. At this point, the GPDMA completes the block transfer using single or early-terminated burst transactions.

Early-Terminated Burst Transaction

When a source or destination peripheral is in the Single Transaction Region, a burst transaction can still be requested when using Software Handshaking. In this case, the burst transaction is started and "early-terminated" at block completion without transferring the programmed amount of data, that is, `src_burst_size_bytes` or `dst_burst_size_bytes`, but only the amount required to complete the block transfer.

Hardware Handshaking

Works as described above in [Chapter 5.2.4.1](#).

Software Handshaking

When the GPDMA is the flow controller, then the last transaction registers - **LSTSRCREG** and **LSTDSTREG** - are not used, and the values in these registers are ignored.

- Operation - Peripheral Not In Single Transaction Region

Writing a 1 to the **REQSRCREG[x]**, **REQDSTREG[x]** bit fields is always interpreted as a burst transaction request, where x is the channel number. However, in order for a burst transaction request to start, software must write a 1 to the **SGLREQSRCREG[x]**, **SGLREQDSTREG[x]** register.

You can write a 1 to the **SGLREQSRCREG[x]**, **SGLREQDSTREG[x]** and **REQSRCREG[x]**, **REQDSTREG[x]** registers in any order, but both registers must be asserted in order to initiate a burst transaction. Upon completion of the burst transaction, the hardware clears the **SGLREQSRCREG[x]**, **SGLREQDSTREG[x]** and **REQSRCREG[x]**, **REQDSTREG[x]** registers.

- Operation - Peripheral In Single Transaction Region

Writing a 1 to the **SGLREQSRCREG**, **SGLREQDSTREG** initiates a single transaction. Upon completion of the single transaction, both the **SGLREQSRCREG**, **SGLREQDSTREG** and **REQSRCREG**, **REQDSTREG** bits are cleared by hardware. Therefore, writing a 1 to the **REQSRCREG**, **REQDSTREG** is ignored while a single transaction has been initiated, and the requested burst transaction is not serviced.

Again, writing a 1 to the **REQSRCREG**, **REQDSTREG** register is always a burst transaction request. However, in order for a burst transaction request to start, the corresponding channel bit in the **SGLREQSRCREG**, **SGLREQDSTREG** must be asserted. Therefore, to ensure that a burst transaction is serviced in this region, you must write a 1 to the **REQSRCREG**, **REQDSTREG** before writing a 1 to the **SGLREQSRCREG**, **SGLREQDSTREG** register. If the programming order is reversed, a single transaction is started instead of a burst transaction. The hardware clears both the **REQSRCREG**, **REQDSTREG** and the **SGLREQSRCREG**, **SGLREQDSTREG** registers after the burst transaction request completes. When a burst transaction is initiated in the

General Purpose DMA (GPDMA)

Single Transaction Region, then the block completes using an Early-Terminated Burst Transaction.

Software can poll the relevant channel bit in the SGLREQSRCREG, SGLREQDSTREG and REQSRCREG, REQDSTREG registers. When both are 0, then either the requested burst or single transaction has completed. Alternatively, the IntSrcTran or IntDstTran interrupts can be enabled and unmasked in order to generate an interrupt when the requested source or destination transaction has completed.

Note: The transaction-complete interrupts are triggered when both single and burst transactions are complete. The same transaction-complete interrupt is used for both single and burst transactions.

5.2.4.4 Handshaking with Peripheral as Flow Controller

When the peripheral is the flow controller, it controls the length of the block and must communicate to the GPDMA when the block transfer is complete. The peripheral does this by telling the GPDMA that the current transaction - burst or single - is the last transaction in the block. When the peripheral is the flow controller and the block size is not a multiple of the CTL.SRC_MSIZ, CTL.DEST_MSIZ, then the peripheral must use single transactions to complete a block transfer.

Note: Since the peripheral can terminate the block on a single transaction, there is no notion of a Single Transaction Region such as there is when the GPDMA is the flow controller.

When the peripheral is the flow controller, it indicates to the GPDMA which type of transaction - single or burst - to perform by using **Software Handshaking**. Where possible, the GPDMA uses the maximum possible burst length. It can also lock the arbitration for the master bus so that a channel is permanently granted the master bus interface. The GPDMA can also assert the hlock signal to lock the system arbiter. For more information, refer to **Section 5.2.6**.

Hardware Handshaking

This mode is not supported in the XMC4[78]00.

Software Handshaking

Writing a 1 to the Source/Destination Software Transaction Request initiates a transaction (refer to **REQSRCREG** and **REQDSTREG**, respectively). The type of transaction - single or burst - depends on the state of the corresponding channel bit in the Single Source/Destination Transaction Request register (refer to **SGLREQSRCREG** or **SGLREQDSTREG**, respectively)

If SGLREQSRCREG[n], SGLREQDSTREG[n] = 1 when a 1 is written to the REQSRCREG[n], REQDSTREG[n] register, this means that software is requesting a single transaction on channel n, or a burst transaction otherwise.

General Purpose DMA (GPDMA)

The request is the last in the block if the corresponding channel bit in the Last Source/Destination Request register is asserted; refer to **LSTSRCREG** and **LSTDSTREG**, respectively.

If **LSTSRCREG[n]**, **LSTDSTREG[n]** = 1 when a 1 is written to the **REQSRCREG[n]**, **REQDSTREG[n]** register, this means that software is requesting that this transaction is the last transaction in the block. The **SGLREQSRCREG**, **SGLREQDSTREG** and **LSTSRCREG**, **LSTDSTREG** registers must be written to before the **REQSRCREG**, **REQDSTREG** registers.

On completion of the transaction - single or burst - the relevant channel bit in the **REQSRCREG**, **REQDSTREG** register is cleared by hardware. Software can therefore poll this bit in order to determine when the requested transaction has completed. Alternatively, the **IntSrcTran** or **IntDstTran** interrupts can be enabled and unmasked in order to generate an interrupt when the requested transaction - single or burst - has completed.

When the peripheral is the flow controller and the block size is not a multiple of the **CTL.SRC_MSIZ**, **CTL.DEST_MSIZ**, then software must use single transactions to complete the block transfer.

5.2.5 FIFO Usage

Each channel has a source state machine and destination state machine running in parallel. These state machines generate the request inputs to the arbiter, which arbitrates for the master bus interface (one arbiter per master bus interface).

When the source/destination state machine is granted control of the master bus interface, then AHB transfers between the peripheral and the GPDMA (on behalf of the granted state machine) can take place.

AHB transfers from the source peripheral or to the destination peripheral cannot proceed until the channel FIFO is ready. For burst transaction requests and for transfers involving memory peripherals, the criterion for "FIFO readiness" is controlled by the **FIFO_MODE** field of the **CFG** register.

The definition of FIFO readiness is the same for:

- Single transactions
- Burst transactions, where **CFG.FIFO_MODE** = 0
- Transfers involving memory peripherals, where **CFG.FIFO_MODE** = 0

The channel FIFO is deemed ready when the space/data available is sufficient to complete a single AHB transfer of the specified transfer width. FIFO readiness for source transfers occurs when the channel FIFO contains enough room to accept at least a single transfer of **CTL.SRC_TR_WIDTH** width. FIFO readiness for destination transfers occurs when the channel FIFO contains data to form at least a single transfer of **CTL.DST_TR_WIDTH** width.

General Purpose DMA (GPDMA)

*Note: An exception to FIFO readiness for destination transfers occurs in "FIFO flush mode". In this mode, FIFO readiness for destination transfers occurs when the channel FIFO contains data to form at least a single transfer of **CTL.SRC_TR_WIDTH** width (and not **CTL.DST_TR_WIDTH** width, as is the normal case).*

When **CFG.FIFO_MODE** = 1, then the criteria for FIFO readiness for burst transaction requests and transfers involving memory peripherals are as follows:

- A FIFO is ready for a source burst transfer when the FIFO is less than half empty.
- A FIFO is ready for a destination burst transfer when the FIFO is greater than or equal to half full.

Exceptions to this "readiness" occur. During these exceptions, a value of **CTL.FIFO_MODE** = 0 is assumed. The following are the exceptions:

- Near the end of a burst transaction or block transfer - The channel source state machine does not wait for the channel FIFO to be less than half empty if the number of source data items left to complete the source burst transaction or source block transfer is less than FIFO DEPTH/2. Similarly, the channel destination state machine does not wait for the channel FIFO to be greater than or equal to half full, if the number of destination data items left to complete the destination burst transaction or destination block transfer is less than FIFO DEPTH/2.
- In FIFO flush mode
- When a channel is suspended - The destination state machine does not wait for the FIFO to become half empty to flush the FIFO, regardless of the value of the **FIFO_MODE** field.

When the source/destination peripheral is not memory, the source/destination state machine waits for a single/burst transaction request. Upon receipt of a transaction request and only if the channel FIFO is "ready" for source/destination AHB transfers, a request for the master bus interface is made by the source/destination state machine.

*Note: There is one exception to this, which occurs when the destination peripheral is the flow controller and **CFG.FCMODE** = 1 (data pre-fetching is disabled). Then the source state machine does not generate a request for the master bus interface (even if the FIFO is "ready" for source transfers and has received a source transaction request) until the destination requests new data.*

When the source/destination peripheral is memory, the source/destination state machine must wait until the channel FIFO is "ready". A request is then made for the master bus interface. There is no handshaking mechanism employed between a memory peripheral and the GPDMA.

5.2.6 Bus and Channel Locking

It is possible to program the GPDMA for:

- Bus locking

General Purpose DMA (GPDMA)

- Channel locking - Locks the arbitration for the AHB master interface, which grants ownership of the master bus interface to one of the requesting channel state machines (source or destination).

Bus and channel locking can proceed for the duration of a DMA transfer, a block transfer, or a single or burst transaction.

Bus Locking

If the LOCK_B bit in the channel configuration register (**CFG**) is set, then the AHB bus is locked for the duration specified in the LOCK_B_L field.

Channel Locking

If the LOCK_CH field is set, then the arbitration for the master bus interface is exclusively reserved for the source and destination peripherals of that channel for the duration specified in the LOCK_CH_L field.

If bus locking is activated for a certain duration, then it follows that the channel is also automatically locked for that duration. Three cases arise:

- **CFG.LOCK_B** = 0 - Programmed values of **CFG.LOCK_CH** and **CFG.LOCK_CH_L** are used.
- **CFG.LOCK_B** = 1 and **CFG.LOCK_CH** = 0 - DMA transfer proceeds as if **CFG.LOCK_CH** = 1 and **CFG.LOCK_CH_L** = **CFG.LOCK_B_L**. The programmed values of **CFG.LOCK_CH** and **CFG.LOCK_CH_L** are ignored.
- **CFG.LOCK_B** = 1 and **CFG.LOCK_CH** = 1 - Two cases arise:
 - **CFG.LOCK_B_L** <= **CFG.LOCK_CH_L** - In this case, the DMA transfer proceeds as if **CFG.LOCK_CH_L** = **CFG.LOCK_B_L** and the programmed value of **CFG.LOCK_CH_L** is ignored. Thus, if bus locking is enabled over the DMA transfer level, then channel locking is enabled over the DMA transfer level, regardless of the programmed value of **CFG.LOCK_CH_L**.
 - **LOCK_B_L** > **CFG.LOCK_CH_L** - The programmed value of **CFG.LOCK_CH_L** is used. Thus, if bus locking is enabled over the DMA block transfer level and channel locking is enabled over the DMA transfer level, then channel locking is performed over the DMA transfer level.

Locking Levels

If locking is enabled for a channel, then locking of the AHB master bus interface at a programmed locking transfer level is activated when the channel is first granted the AHB master bus interface at the start of that locking transfer level. It continues until the locking transfer level has completed; that is, if channel 0 has enabled channel level locking at the block transfer level, then this channel locks the master bus interface when it is first granted the master bus interface at the start of the block transfer, and continues to lock the master bus interface until the block transfer has completed.

General Purpose DMA (GPDMA)

Source and destination block transfers occur successively in time, and a new source block cannot commence until the previous destination block has completed.

Block and DMA transfer level locking are both terminated on completion of the block or DMA transfer to the destination.

Transaction-level locking is different due to the fact that source and destination transactions occur independently in time, and the number of source and destination transactions in a DMA block or DMA transfer do not have to match. Transaction-level locking is cleared at the end of a source or destination transaction only if the opposing peripheral is not currently in the middle of a transaction.

If channel-level or bus-level locking is enabled for a channel at the transaction level, and either the source or destination of the channel is a memory device, then the locking is ignored and the channel proceeds as if locking (bus or channel) is disabled.

Note: Since there is no notion of a transaction level for a memory peripheral, then transaction-level locking is not allowed when either source or destination is memory.

5.2.7 Scatter/Gather

Scatter is relevant to a destination transfer. The destination address is incremented or decremented by a programmed amount - the scatter increment - when a scatter boundary is reached. [Figure 5-6](#) shows an example destination scatter transfer. The destination address is incremented or decremented by the value stored in the destination scatter increment (DSRx.DSI) field (refer to [DSR](#)), multiplied by the number of bytes in a single AHB transfer to the destination s (decoded value of [CTL.DST_TR_WIDTH](#))/8 - when a scatter boundary is reached. The number of destination transfers between successive scatter boundaries is programmed into the Destination Scatter Count (DSC) field of the DSR register.

Scatter is enabled by writing a 1 to the [CTL.DST_SCATTER_EN](#) field. The [CTL.DINC](#) field determines if the address is incremented, decremented, or remains fixed when a scatter boundary is reached. If the [CTL.DINC](#) field indicates a fixed-address control throughout a DMA transfer, then the [CTL.DST_SCATTER_EN](#) field is ignored, and the scatter feature is automatically disabled.

Gather is relevant to a source transfer. The source address is incremented or decremented by a programmed amount when a gather boundary is reached. The number of source transfers between successive gather boundaries is programmed into the Source Gather Count (SGRx.SGC) field. The source address is incremented or decremented by the value stored in the source gather increment (SGRx.SGI) field (refer to [SGR](#)), multiplied by the number of bytes in a single AHB transfer from the source - (decoded value of [CTL.SRC_TR_WIDTH](#))/8 - when a gather boundary is reached.

Gather is enabled by writing a 1 to the [CTL.SRC_GATHER_EN](#) field. The [CTL.SINC](#) field determines if the address is incremented, decremented, or remains fixed when a

General Purpose DMA (GPDMA)

gather boundary is reached. If the **CTL.SINC** field indicates a fixed-address control throughout a DMA transfer, then the **CTL.SRC_GATHER_EN** field is ignored, and the gather feature is automatically disabled.

Note: For multi-block transfers, the counters that keep track of the number of transfers left to reach a gather/scatter boundary are re-initialized to the source gather count (SGRx.SGC) and destination scatter count (DSC), respectively, at the start of each block transfer.

Figure 5-6 Example of Destination Scatter Transfer

As an example of gather increment, consider the following:

```
SRC_TR_WIDTH = 3'b010 (32 bits)
SGR.SGC = 0x04 (source gather count)
CTL.SRC_GATHER_EN = 1 (source gather enabled)
SAR = A0 (starting source address)
```

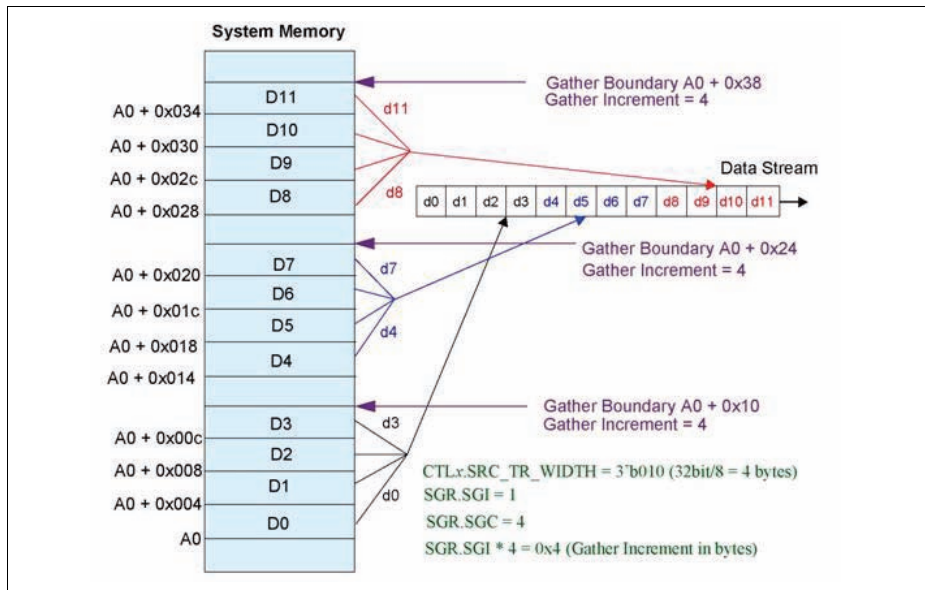

Figure 5-7 Source Gather when $\text{SGR.SGI} = 0x1$

In general, if the starting address is $A0$ and $\text{CTL.SINC} = 00_B$ (increment source address control), then the transfer will be:

$$A0, A0 + \text{TWB}, A0 + 2 * \text{TWB} \quad (A0 + (\text{SGR.SGC} - 1) * \text{TWB})$$

$$<\text{-scatter_increment-}> (A0 + (\text{SGR.SGC} * \text{TWB}) + (\text{SGR.SGI} * \text{TWB}))$$

where TWB is the transfer width in bytes, decoded value of $\text{CTL.SRC_TR_WIDTH}/8 = \text{src_single_size_bytes}$.

5.2.8 Abnormal Transfer Termination

A GPDMA DMA transfer may be terminated abruptly by software by clearing the channel enable bit, **CHENREG.CH_EN** or by clearing the global enable bit in the GPDMA Configuration Register (**DMACFGREG[0]**).

If a transfer is in progress while a channel is disabled, abnormal transfer termination and data corruption occurs. Also the transfer acknowledge may be lost. Therefore this must be avoided.

Attention: *Disabling a channel via software prior to completing a transfer is not supported.*

5.3 Basic Transfers

From a users perspective DMA transfers can be grouped into

- software triggered transfers and
- hardware triggered transfers.

The setup procedure for both kinds of transfers is identical to a large extent and is described in more detail later in this section after highlighting the differences of the trigger types.

Software triggered transfers

are set up as memory-to-memory types and start automatically when the channel is enabled. After transfer completion the channel is disabled. There is no way to trigger the transactions by on-chip hardware.

Hardware triggered transfers

are set up as peripheral-to-memory, memory-to-peripheral or peripheral-to-peripheral types. Additionally the trigger source, signal routing and trigger generation must be programmed. Details on trigger generation are found in the “Service Request Generation” section of each peripherals chapter. Signal routing options (ERU) and trigger generation (DLR) are described in the “Service Request Processing” chapter.

GPDMA set up

Transfers are set up by programming fields of the **CTL** and **CFG** registers for that channel. As shown in **Figure 5-2**, a single block is made up of numerous transactions - single and burst - which are in turn composed of AHB transfers.

Note: There are references to software parameters throughout this chapter. The software parameters are the field names in each register description table and are prefixed by the register name; for example, the Block Transfer Size field in the Control Register is designated as "CTL.BLOCK_TS."

Table 5-3 lists the parameters that are investigated in the following examples. The effects of these parameters on the flow of the block transfer are highlighted.

Table 5-3 Parameters Used in Transfer Examples

| Parameter | Description |
|-------------------------|--------------------------------|
| CTL.TT_FC | Transfer type and flow control |
| CTL.BLOCK_TS | Block transfer size |
| CTL.SRC_TR_WIDTH | Source transfer width |
| CTL.DST_TR_WIDTH | Destination transfer width |

Table 5-3 Parameters Used in Transfer Examples (cont'd)

| Parameter | Description |
|------------------------|--------------------------------------|
| CTL.SRC_MSIZ E | Source burst transaction length |
| CTL.DEST_MSIZ E | Destination burst transaction length |
| CFG.MAX_ABRST | Maximum AMBA burst length |
| CFG.FIFO_MODE | FIFO mode select |
| CFG.FC MODE | Flow-control mode |

The GPDMA is programmed with the number of data items that are to be transferred for each burst transaction request, **CTL.SRC_MSIZ**E and **CTL.DEST_MSIZ**E. Similarly, the width of each data item in the transaction is set by the **CTL.SRC_TR_WIDTH** and **CTL.DST_TR_WIDTH** fields.

5.3.1 Block transfer with GPDMA as the flow controller

Table 5-4 lists the DMA parameters for this example (the FIFO depth is taken as 16 bytes).

Table 5-4 Parameters in Transfer Operation

| Parameter | Description |
|--|---|
| CTL.TT_FC = 011 _B | Peripheral-to-peripheral transfer with GPDMA as flow controller |
| CTL.BLOCK_TS = 12 | - |
| CTL.SRC_TR_WIDTH = 010 _B | 32 bits |
| CTL.DST_TR_WIDTH = 010 _B | 32 bits |
| CTL.SRC_MSIZ E = 001 _B | Source burst transaction length = 4 |
| CTL.DEST_MSIZ E = 001 _B | Destination burst transaction length = 4 |
| CFG.MAX_ABRST = 0 _B | No limit on maximum AMBA burst length |

A total of 48 bytes are transferred in the block (that is blk_size_bytes_dma = 48). As shown in **Figure 5-8**, this block transfer consists of three bursts of length 4 from the source, interleaved with three bursts, again of length 4, to the destination.

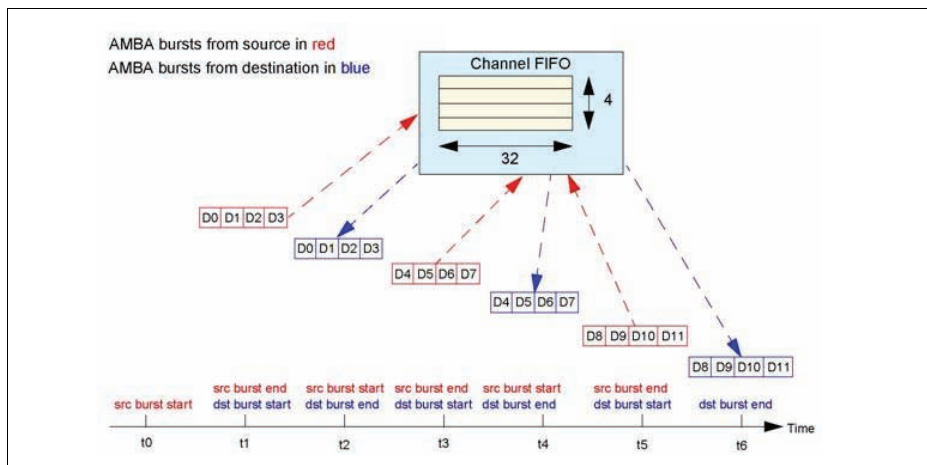

Figure 5-8 Breakdown of Block Transfer

The channel FIFO is alternatively filled by a burst from the source and emptied by a burst to the destination until the block transfer has completed, as shown in [Figure 5-9](#).

| | | | | | |
|---------|---------|---------|---------|---------|---------|
| D3 | Empty | D7 | Empty | D11 | Empty |
| D2 | Empty | D6 | Empty | D10 | Empty |
| D1 | Empty | D5 | Empty | D9 | Empty |
| D0 | Empty | D4 | Empty | D8 | Empty |
| Time t1 | Time t2 | Time t3 | Time t4 | Time t5 | Time t6 |

Figure 5-9 Channel FIFO Contents

Burst transactions are completed in one burst. Additionally neither the source or destination peripherals enter their Single Transaction Region at any stage throughout the DMA transfer, and the block transfer from the source and to the destination consists of burst transactions only.

5.3.2 Effect of maximum AMBA burst length on a block transfer

If the [CFG.MAX_ABRST](#) = 2 parameter and all other parameters are left unchanged from previous example, then the block transfer would look like that shown in [Figure 5-10](#).

Figure 5-10 Breakdown of Block Transfer where max_abrst = 2, Case 1

The channel FIFO is alternatively half filled by a burst from the source, and then emptied by a burst to the destination until the block transfer has completed; this is illustrated in [Figure 5-11](#).

| | | | | | | |
|---------|---------|---------|---------|-----|----------|----------|
| Empty | Empty | Empty | Empty | ... | Empty | Empty |
| Empty | Empty | Empty | Empty | | Empty | Empty |
| D1 | Empty | D3 | Empty | | D10 | Empty |
| D0 | Empty | D2 | Empty | | D11 | Empty |
| Time t1 | Time t2 | Time t3 | Time t4 | | Time t11 | Time t12 |

Figure 5-11 Channel FIFO Contents

In this example block transfer, each source or destination burst transaction is made up of two bursts, each of length 2. As [Figure 5-11](#) illustrates, the top two channel FIFO locations are redundant for this block transfer. However, this is not the general case. The block transfer could proceed as indicated in [Figure 5-12](#).

General Purpose DMA (GPDMA)

Figure 5-12 Breakdown of Block Transfer where max_abrst = 2, Case 2

This depends on the timing of the source and destination transaction requests, relative to each other. **Figure 5-13** illustrates the channel FIFO status for **Figure 5-12**.

| | | | | | |
|---------|---------|---------|---------|----------|----------|
| D3 | Empty | D7 | Empty | D11 | Empty |
| D2 | Empty | D6 | Empty | D10 | Empty |
| D1 | Empty | D5 | Empty | D9 | Empty |
| D0 | Empty | D4 | Empty | D8 | Empty |
| Time t2 | Time t4 | Time t6 | Time t8 | Time t10 | Time t12 |

Figure 5-13 Channel FIFO Contents

Recommendation

To allow a burst transaction to complete in a single burst, the following should be true:

$$\text{CFGL.MAX_ABRST} \geq \max(\text{src_burst_size_bytes}, \text{dst_burst_size_bytes})$$

Adhering to the above recommendation results in a reduced number of bursts per block, which in turn results in improved bus utilization and lower latency for block transfers.

General Purpose DMA (GPDMA)

Limiting a burst to a maximum length prevents the GPDMA from saturating the AHB bus when the system arbiter is configured to only allow changing of the grant signals to bus masters at the end of an undefined length burst. It also prevents a channel from saturating a GPDMA master bus interface.

5.4 Multi Block Transfers

A DMA transfer may consist of

- single block transfer, supported by all channels.
- multi-block transfers, supported by channels 0 and 1 of GPDMA0.

On successive blocks of a multi-block transfer, the **SAR**, **DAR** register in the GPDMA is reprogrammed using either of the following methods:

- Block chaining using linked lists
- Auto-reloading
- Contiguous address between blocks

On successive blocks of a multi-block transfer, the **CTL** register in the GPDMA is reprogrammed using either of the following methods:

- Block chaining using linked lists
- Auto-reloading

When block chaining, using Linked Lists is the multi-block method of choice. On successive blocks, the **LLP** register in the GPDMA is reprogrammed using block chaining with linked lists.

A block descriptor consists of six registers: **SAR**, **DAR**, **LLP**, **CTL**, **SSTAT** and **DSTAT**. The first four registers, along with the **CFG** register, are used by the GPDMA to set up and describe the block transfer.

Note: The term Link List Item (LLI) and block descriptor are synonymous.

5.4.1 Block Chaining Using Linked Lists

In this case, the GPDMA reprograms the channel registers prior to the start of each block by fetching the block descriptor for that block from system memory. This is known as an LLI update.

GPDMA block chaining uses a Linked List Pointer register (**LLP**) that stores the address in memory of the next linked list item. Each LLI contains the corresponding block descriptors:

1. **SAR**
2. **DAR**
3. **LLP**
4. **CTL**
5. **SSTAT**
6. **DSTAT**

To set up block chaining, you program a sequence of Linked Lists in memory.

LLI accesses are always 32-bit accesses aligned to 32-bit boundaries and cannot be changed or programmed to anything other than 32-bit, even if the AHB master interface of the LLI supports more than a 32-bit data width.

General Purpose DMA (GPDMA)

The **SAR**, **DAR**, **LLP**, and **CTL** registers are fetched from system memory on an LLI update. The updated contents of the **CTL**, **SSTAT**, and **DSTAT** registers are optionally written back to memory on block completion. **Figure 5-14** and **Figure 5-15** show how you use chained linked lists in memory to define multi-block transfers using block chaining.

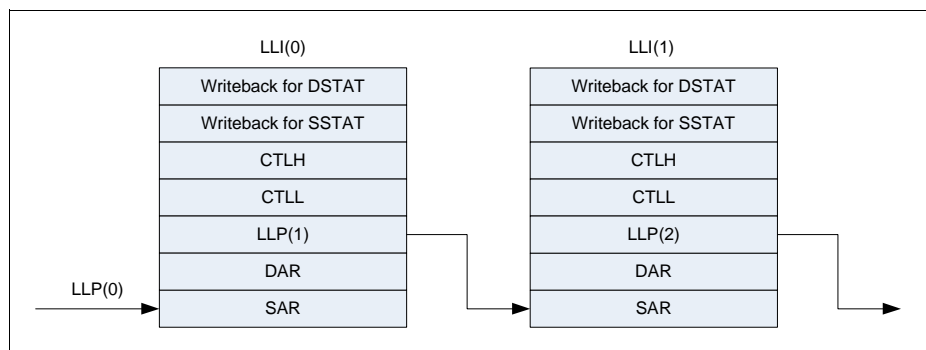

Figure 5-14 Multi-Block Transfer Using Linked Lists When **CFG.SS_UPD_EN is set to '1'**

It is assumed that no allocation is made in system memory for the source status when the parameter **CFG.SS_UPD_EN** is set to '0'. In this case, then the order of a Linked List item is as follows:

1. **SAR**
2. **DAR**
3. **LLP**
4. **CTL**
5. **DSTAT**

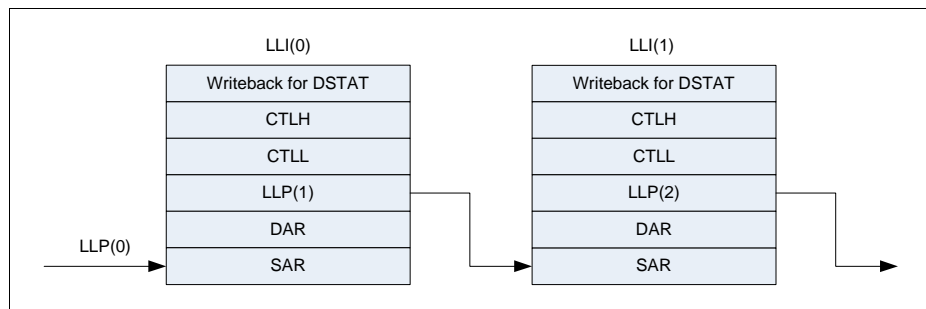

Figure 5-15 Multi-Block Transfer Using Linked Lists When **CFG.SS_UPD_EN is set to '0'**

General Purpose DMA (GPDMA)

*Note: In order to not confuse the **SAR**, **DAR**, **LLP**, **CTL**, **SSTAT** and **DSTAT** register locations of the LLI with the corresponding GPDMA memory mapped register locations, the LLI register locations are prefixed with LLI; that is, LLI.SAR, LLI.DAR, LLI.LLP, LLI.CTLH/L, LLI.SSTATx, and LLI.DSTATx.*

Figure 5-14 and **Figure 5-15** show the mapping of a Linked List Item stored in memory to the channel registers block descriptor.

Rows 6 through 10 of **Table 5-5** show the required values of **LLP**, **CTL**, and **CFG** for multi-block DMA transfers using block chaining.

*Note: For rows 6 through 10 of **Table 5-5**, the LLI.CTLH/L, LLI.LLP, LLI.SAR, and LLI.DAR register locations of the LLI are always affected at the start of every block transfer. The LLI.LLP and LLI.CTLH/L locations are always used to reprogram the GPDMA **LLP** and **CTL** registers. However, depending on the **Table 5-5** row number, the LLI.SAR, LLI.DAR address may or may not be used to reprogram the GPDMA **SAR**, **DAR** registers.*

Table 5-5 Programming of Transfer Types and Channel Register Update Method

| Transfer Type | LLP. LOC = 0 | CTL.LLP_SRC EN | CFG.RELOAD_SRC | CTL.LLPDST_EN | CFG.RELOAD_DST | CTL, LLP UpdateMethod | SAR UpdateMethod | DAR UpdateMethod | Write Back |
|--|--------------|----------------|----------------|---------------|----------------|---|------------------|------------------|------------|
| 1. Single-block or last transfer of multi-block. | Yes | 0 | 0 | 0 | 0 | None, user reprograms | None (single) | None (single) | No |
| 2. Auto-reload multi-block transfer with contiguous SAR | Yes | 0 | 0 | 0 | 1 | CTL , LLP are reloaded from initial values. | Contiguous | Auto-Reload | No |
| 3. Auto-reload multi-block transfer with contiguous DAR . | Yes | 0 | 1 | 0 | 0 | CTL , LLP are reloaded from initial values | Auto-Reload | Contiguous | No |
| 4. Auto-reload multi-block transfer | Yes | 0 | 1 | 0 | 1 | CTL , LLP are reloaded from initial values | Auto-reload | Auto-Reload | No |

Table 5-5 Programming of Transfer Types and Channel Register Update Method (cont'd)

| Transfer Type | LLP. LOC = 0 | CTL.LLP_SRC EN | CFG.RELOAD_SRC | CTL.LLPDST_EN | CFG.RELOAD_DST | CTL, LLP UpdateMethod | SAR UpdateMethod | DAR UpdateMethod | Write Back |
|--|--------------|----------------|----------------|---------------|----------------|---|---------------------|---------------------|------------|
| 5. Single-block or last transfer of multi-block. | No | 0 | 0 | 0 | 0 | None, user reprograms | None (single) | None (single) | Yes |
| 6. Linked list multi-block transfer with contiguous SAR | No | 0 | 0 | 1 | 0 | CTL, LLP loaded from next Linked List item. | Contiguous | Linked List | Yes |
| 7. Linked list multi-block transfer with auto-reload SAR | No | 0 | 1 | 1 | 0 | CTL, LLP loaded from next Linked List item. | Auto-Reload | Linked List | Yes |
| 8. Linked list multi-block transfer with contiguous DAR | No | 1 | 0 | 0 | 0 | CTL, LLP loaded from next Linked List item. | Linked List | Contiguous | Yes |
| 9. Linked list multi-block transfer with auto-reload DAR | No | 1 | 0 | 0 | 1 | CTL, LLP loaded from next Linked List item. | Linked List | Auto-Reload | Yes |
| 10. Linked list multi-block transfer | No | 1 | 0 | 1 | 0 | CTL, LLP loaded from next Linked List item. | Linked List | Linked List | Yes |

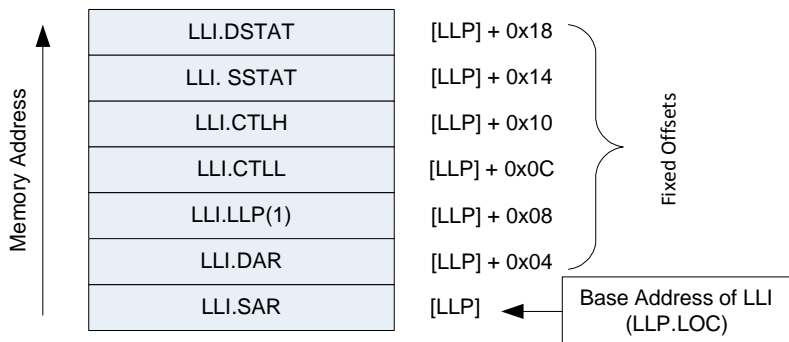

Figure 5-16 Mapping of Block Descriptor (LLI) in Memory to Channel Registers When $\text{CFG.SS_UPD_EN} = 1$

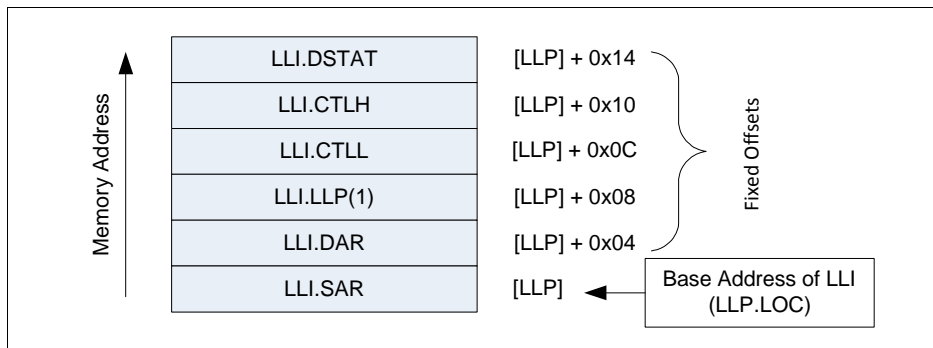

Figure 5-17 Mapping of Block Descriptor (LLI) in Memory to Channel Registers When $\text{CFG.SS_UPD_EN} = 0$

Notes

1. Throughout this chapter, there are descriptions about fetching the LLI.CTLH/L register from the location pointed to by the **LLP** register. This exact location is the LLI base address (stored in **LLP** register) plus the fixed offset. For example, in **Figure 5-16** the location of the LLI.CTLH/L register is **LLP.LOC** + 0xc.
2. Referring to **Table 5-5**, if the Write Back column entry is "Yes" and the channel is 0 or 1, then the CTLH register is always written to system memory (to LLI.CTLH) at the end of every block transfer.
3. The source status is fetched and written to system memory at the end of every block transfer if the Write Back column entry is "Yes" and **CFG.SS_UPD_EN** is enabled.

General Purpose DMA (GPDMA)

4. The destination status is fetched and written to system memory at the end of every block transfer if the Write Back column entry is "Yes" and **CFG.DS_UPD_EN** is enabled.

5.4.2 Auto-Reloading of Channel Registers

During auto-reloading, the channel registers are reloaded with their initial values at the completion of each block and the new values used for the new block. Depending on the row number in **Table 5-5**, some or all of the **SAR**, **DAR**, and **CTL** channel registers are reloaded from their initial value at the start of a block transfer.

5.4.3 Contiguous Address Between Blocks

In this case, the address between successive blocks is selected as a continuation from the end of the previous block.

Enabling the source or destination address to be contiguous between blocks is a function of the **CTL.LLP_SRC_EN**, **CFG.RELOAD_SRC**, **CTL.LLP_DST_EN**, and **CTL.RELOAD_DST** registers (see **Table 5-5**).

*Note: You cannot select both **SAR** and **DAR** updates to be contiguous. If you want this functionality, you should increase the size of the Block Transfer (**CTL.BLOCK_TS**), or if this is at the maximum value, use Row 10 of **Table 5-5** and set up the **LLI.SAR** address of the block descriptor to be equal to the end **SAR** address of the previous block. Similarly, set up the **LLI.DAR** address of the block descriptor to be equal to the end **DAR** address of the previous block.*

5.4.4 Suspension of Transfers Between Blocks

At the end of every block transfer, an end-of-block interrupt is asserted if:

1. Interrupts are enabled, **CTL.INT_EN** = 1, and
2. The channel block interrupt is unmasked, **MASKBLOCK[n]** = 1, where n is the channel number.

Note: The block-complete interrupt is generated at the completion of the block transfer to the destination.

For rows 6, 8, and 10 of **Table 5-5**, the DMA transfer does not stall between block transfers. For example, at the end-of-block N, the GPDMA automatically proceeds to block N + 1.

For rows 2, 3, 4, 7, and 9 of **Table 5-5** (**SAR** and/or **DAR** auto-reloaded between block transfers), the DMA transfer automatically stalls after the end-of-block interrupt is asserted, if the end-of-block interrupt is enabled and unmasked.

The GPDMA does not proceed to the next block transfer until a write to the **CLEARBLOCK[n]** block interrupt clear register, done by software to clear the channel block-complete interrupt, is detected by hardware.

General Purpose DMA (GPDMA)

For rows 2, 3, 4, 7, and 9 of **Table 5-5** (**SAR** and/or **DAR** auto-reloaded between block transfers), the DMA transfer does not stall if either:

- Interrupts are disabled, **CTL.INT_EN** = 0, or
- The channel block interrupt is masked, **MASKBLOCK[n]** = 0, where n is the channel number.

Channel suspension between blocks is used to ensure that the end-of-block ISR (interrupt service routine) of the next-to-last block is serviced before the start of the final block commences. This ensures that the ISR has cleared the **CFG.RELOAD_SRC** and/or **CFG.RELOAD_DST** bits before completion of the final block. The reload bits **CFG.RELOAD_SRC** and/or **CFG.RELOAD_DST** should be cleared in the end-of-block ISR for the next-to-last block transfer.

5.4.5 Ending Multi-Block Transfers

All multi-block transfers must end as shown in either Row 1 or Row 5 of **Table 5-5**. At the end of every block transfer, the GPDMA samples the row number, and if the GPDMA is in the Row 1 or Row 5 state, then the previous block transferred was the last block and the DMA transfer is terminated.

Note: Row 1 and Row 5 are used for single-block transfers or terminating multi-block transfers. Ending in the Row 5 state enables status fetch and write-back for the last block. Ending in the Row 1 state disables status fetch and write-back for the last block.

For rows 2, 3, and 4 of **Table 5-5**, (**LLP.LOC** = 0 and **CFG.RELOAD_SRC** and/or **CFG.RELOAD_DST** is set), multi-block DMA transfers continue until both the **CFG.RELOAD_SRC** and **CFG.RELOAD_DST** registers are cleared by software. They should be programmed to 0 in the end-of-block interrupt service routine that services the next-to-last block transfer; this puts the GPDMA into the Row 1 state.

For rows 6, 8, and 10 of **Table 5-5** (both **CFG.RELOAD_SRC** and **CFG.RELOAD_DST** cleared), the user must set up the last block descriptor in memory so that both **LLI.CTLH/L.LLP_SRC_EN** and **LLI.CTLH/L.LLP_DST_EN** are 0. If the **LLI.LLP** register of the last block descriptor in memory is non-zero, then the DMA transfer is terminated in Row 5. If the **LLI.LLP** register of the last block descriptor in memory is 0, then the DMA transfer is terminated in Row 1.

*Note: The only allowed transitions between the rows of **Table 5-5** are from any row into Row 1 or Row 5. As already stated, a transition into row 1 or row 5 is used to terminate the DMA transfer; all other transitions between rows are not allowed. Software must ensure that illegal transitions between rows do not occur between blocks of a multi-block transfer. For example, if block N is in row 10, then the only allowed rows for block N + 1 are rows 10, 5, or 1.*

5.4.6 Programing Examples

Three registers - **LLP**, **CTL**, and **CFG** - need to be programmed to determine whether single- or multi-block transfers occur, and which type of multi-block transfer is used. The different transfer types are shown in **Table 5-5**.

The GPDMA can be programmed to fetch the status from the source or destination peripheral; this status is stored in the **SSTAT** and **DSTAT** registers. When the GPDMA is programmed to fetch the status from the source or destination peripheral, it writes this status and the contents of the **CTL** register back to memory at the end of a block transfer. The Write Back column of **Table 5-5** shows when this occurs.

The "Update Method" columns indicate where the values of **SAR**, **DAR**, **CTL**, and **LLP** are obtained for the next block transfer when multi-block GPDMA transfers are enabled.

*Note: In **Table 5-5**, all other combinations of **LLP.LOC** = 0, **CTL.LLP_SRC_EN**, **CFG.RELOAD_SRC**, **CTL.LLP_DST_EN**, and **CFG.RELOAD_DST** are illegal, and will cause indeterminate or erroneous behavior.*

Generic Setup of Transfer Type and Characteristics

This generic sequence is referenced by the examples further below in this section.

1. Set up the transfer type (memory or non-memory peripheral for source and destination) and flow control device by programming the TT_FC of the **CTL** register. **Table 5-10** lists the decoding for this field.
2. Set up the transfer characteristics, such as:
 - a) Transfer width for the source in the SRC_TR_WIDTH field.
Table 5-9 lists the decoding for this field.
 - b) Transfer width for the destination in the DST_TR_WIDTH field.
Table 5-9 lists the decoding for this field.
 - c) Incrementing/decrementing or fixed address for the source in the SINC field.
 - d) Incrementing/decrementing or fixed address for the destination in the DINC field.

5.4.6.1 Single-block Transfer

This section is an example for the transfer listed in row 1 in **Table 5-5**.

*Note: Row 5 in **Table 5-5** is also a single-block transfer with write-back of control and status information enabled at the end of the single-block transfer.*

1. Read the Channel Enable register to choose a free (disabled) channel.
2. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEARDSTTRAN**, and **CLEARERR**. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
3. Program the following channel registers:
 - a) Write the starting source address in the **SAR** register for channel x.

General Purpose DMA (GPDMA)

- b) Write the starting destination address in the **DAR** register for channel x.
- c) Program **CTL** and **CFG** according to Row 1, as shown in **Table 5-5**. Program the **LLP** register with 0.
- d) Write the control information for the DMA transfer in the **CTL** register for channel x.
- e) Write the channel configuration information into the **CFG** register for channel x.
 1. Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
 This step requires programming the **CFG.HS_SEL_SRC** or **CFG.HS_SEL_DST** bits, respectively. Writing a 0 activates the hardware handshaking interface to handle source/destination requests. Writing a 1 activates the software handshaking interface to handle source and destination requests.
 2. If the hardware handshaking interface is activated for the source or destination peripheral, assign a handshaking interface to the source and destination peripheral; this requires programming the **CFG.SRC_PER** and **CFG.DEST_PER** bits, respectively.
- f) If gather is enabled (**CTL.SRC_GATHER_EN** = 1), program the **SGR** register for channel x.
- g) If scatter is enabled (**CTL.DST_SCATTER_EN** = 1), program the **DSR** register for channel x.
4. After the GPDMA-selected channel has been programmed, enable the channel by writing a 1 to the **GPDMA0_CHENREG.CH_EN** bit. Ensure that bit 0 of the **GPDMA0_DMACFGREG** register is enabled.
5. Source and destination request single and burst DMA transactions in order to transfer the block of data (assuming non-memory peripherals). The GPDMA acknowledges at the completion of every transaction (burst and single) in the block and carries out the block transfer.
6. Once the transfer completes, hardware sets the interrupts and disables the channel. At this time, you can respond to either the Block Complete or Transfer Complete interrupts, or poll for the transfer complete raw interrupt status register (**RAWTFR[n]**, n = channel number) until it is set by hardware, in order to detect when the transfer is complete. Note that if this polling is used, the software must ensure that the transfer complete interrupt is cleared by writing to the Interrupt Clear register, **CLEARTFR[n]**, before the channel is enabled.

5.4.6.2 Multi-Block Transfer with Source Address Auto-Reloaded and Contiguous Destination Address

This section is an example for the transfer listed in row 3 in **Table 5-5**.

Note: This type of transfer is supported by GPDMA0 channels 0 and 1 only.

1. Read the Channel Enable register (see **GPDMA0_CHENREG**) to choose a free (disabled) channel.

General Purpose DMA (GPDMA)

2. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEAR DSTTRAN**, and **CLEARERR**. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
3. Program the following channel registers:
 - a) Write the starting source address in the **SAR** register for channel x.
 - b) Write the starting destination address in the **DAR** register for channel x.
 - c) Program **CTL** and **CFG** according to Row 3, shown in **Table 5-5**. Program the **LLP** register with 0.
 - d) Write the control information for the DMA transfer in the **CTL** register for channel x.
 - e) If gather is enabled (**CTL.SRC_GATHER_EN** = 1), program the **SGR** register for channel x.
 - f) If scatter is enabled (**CTL.DST_SCATTER_EN** = 1), program the **DSR** register for channel x.
 - g) Write the channel configuration information into the **CFG** register for channel x.
 1. Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
 This step requires programming the **HS_SEL_SRC**, **HS_SEL_DST** bits, respectively. Writing a 0 activates the hardware handshaking interface to handle source/destination requests for the specific channel. Writing a 1 activates the software handshaking interface to handle source/destination requests.
 2. If the hardware handshaking interface is activated for the source or destination peripheral, assign the handshaking interface to the source and destination peripheral. This requires programming the **SRC_PER** and **DEST_PER** bits, respectively.
4. After the GPDMA channel has been programmed, enable the channel by writing a 1 to the **GPDMA0_CHENREG.CH_EN** bit. Ensure that bit 0 of the **GPDMA0_DMACFGREG** register is enabled.
5. Source and destination request single and burst GPDMA transactions to transfer the block of data (assuming non-memory peripherals). The GPDMA acknowledges at the completion of every transaction (burst and single) in the block and carries out the block transfer.
6. When the block transfer has completed, the GPDMA reloads the **SAR** register; the **DAR** register remains unchanged. Hardware sets the block-complete interrupt. The GPDMA then samples the row number, as shown in **Table 5-5**. If the GPDMA is in Row 1, then the DMA transfer has completed. Hardware sets the transfer-complete interrupt and disables the channel. You can either respond to the Block Complete or Transfer Complete interrupts, or poll for the transfer complete raw interrupt status register (**RAWTFR[n]**, n = channel number) until it is set by hardware, in order to detect when the transfer is complete. Note that if this polling is used, software must ensure that the transfer complete interrupt is cleared by writing to the Interrupt Clear register, **CLEARTRF[n]**, before the channel is enabled. If the GPDMA is not in Row 1, the next step is performed.

General Purpose DMA (GPDMA)

7. The DMA transfer proceeds as follows:
- If interrupts are enabled (**CTL.INT_EN** = 1) and the block-complete interrupt is unmasked (**MASKBLOCK[x]** = 1_B, where x is the channel number), hardware sets the block-complete interrupt when the block transfer has completed. It then stalls until the block-complete interrupt is cleared by software. If the next block is to be the last block in the DMA transfer, then the block-complete ISR (interrupt service routine) should clear the source reload bit, **CFG.RELOAD_SRC**. This puts the GPDMA into Row 1, as shown in [Table 5-5](#). If the next block is not the last block in the DMA transfer, then the source reload bit should remain enabled to keep the GPDMA in Row 3, as shown in [Table 5-5](#).
 - If interrupts are disabled (**CTL.INT_EN** = 0) or the block-complete interrupt is masked (**MASKBLOCK[x]** = 0_B, where x is the channel number), then hardware does not stall until it detects a write to the block-complete interrupt clear register; instead, it starts the next block transfer immediately. In this case, software must clear the source reload bit, **CFG.RELOAD_SRC**, to put the device into Row 1 of [Table 5-5](#) before the last block of the DMA transfer has completed.

The transfer is similar to that shown in [Figure 5-18](#).

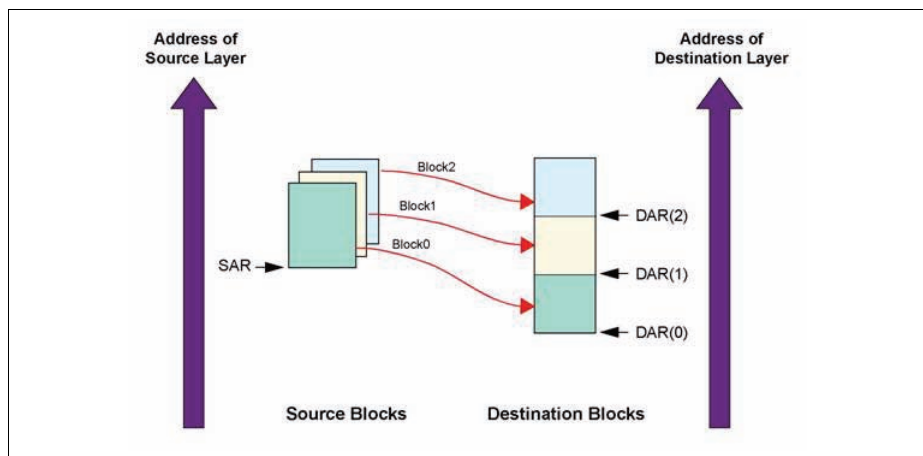

Figure 5-18 Multi-Block DMA Transfer with Source Address Auto-Reloaded and Contiguous Destination Address

The DMA transfer flow is shown in **Figure 5-19**.

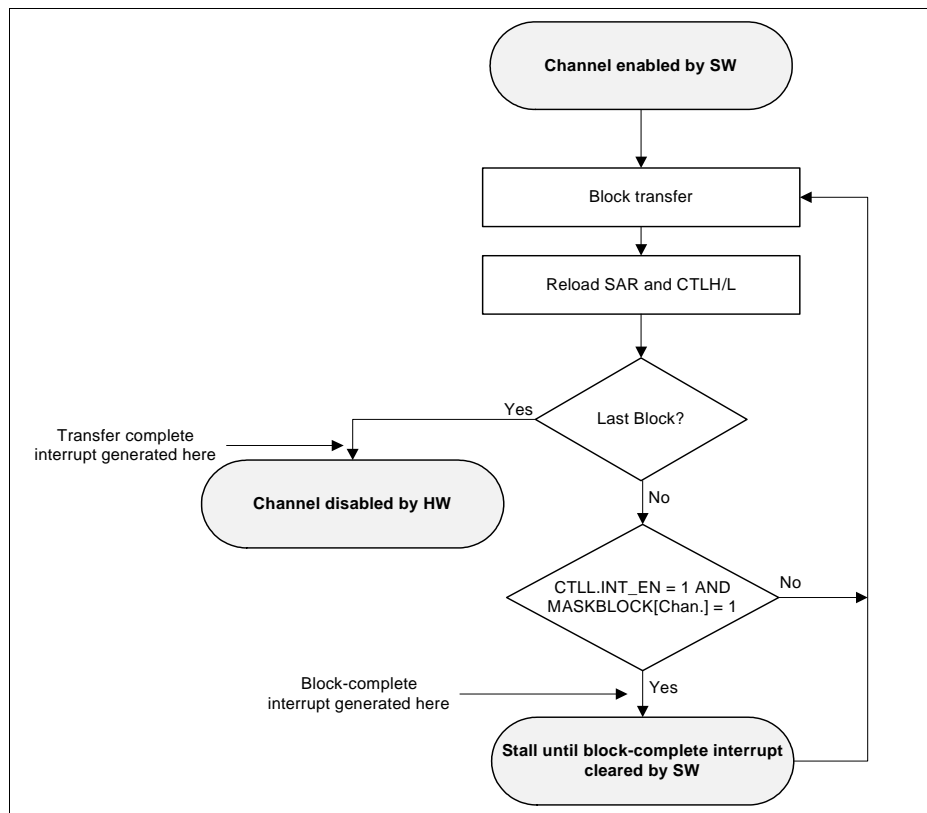

Figure 5-19 DMA Transfer Flow for Source Address Auto-Reloaded and Linked List Destination Address

5.4.6.3 Multi-Block Transfer with Source and Destination Address Auto-Reloaded

This section is an example for the transfer listed in row 4 in [Table 5-5](#).

Note: This type of transfer is supported by GPDMA0 channels 0 and 1 only.

1. Read the Channel Enable register (see [GPDMA0_CHENREG](#)) to choose an available (disabled) channel.
2. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: CLEARTRF, CLEARBLOCK, CLEARSRCTRAN, CLEARSTTRAN, and CLEARERR. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
3. Program the following channel registers:
 - a) Write the starting source address in the [SAR](#) register for channel x.
 - b) Write the starting destination address in the [DAR](#) register for channel x.
 - c) Program [CTL](#) and [CFG](#) according to Row 4, as shown in [Table 5-5](#). Program the [LLP](#) register with 0.
 - d) Write the control information for the DMA transfer in the [CTL](#) register for channel x.
 - e) If gather is enabled ([CTL.SRC_GATHER_EN](#) = 1), program the [SGR](#) register for channel x.
 - f) If scatter is enabled ([CTL.DST_SCATTER_EN](#) = 1), program the [DSR](#) register for channel x.
 - g) Write the channel configuration information into the [CFG](#) register for channel x. Ensure that the reload bits, [CFG.RELOAD_SRC](#) and [CFG.RELOAD_DST](#), are enabled.
 1. Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
 This step requires programming the [HS_SEL_SRC](#), [HS_SEL_DST](#) bits, respectively. Writing a 0 activates the hardware handshaking interface to handle source/destination requests for the specific channel. Writing a 1 activates the software handshaking interface to handle source/destination requests.
 2. If the hardware handshaking interface is activated for the source or destination peripheral, assign the handshaking interface to the source and destination peripheral. This requires programming the [SRC_PER](#) and [DEST_PER](#) bits, respectively.
4. After the GPDMA selected channel has been programmed, enable the channel by writing a 1 to the [GPDMA0_CHENREG.CH_EN](#) bit. Ensure that bit 0 of the [GPDMA0_DMACFGREG](#) register is enabled.
5. Source and destination request single and burst GPDMA transactions to transfer the block of data (assuming non-memory peripherals). The GPDMA acknowledges on completion of each burst/single transaction and carries out the block transfer.
6. When the block transfer has completed, the GPDMA reloads the [SAR](#), [DAR](#), and [CTL](#) registers. Hardware sets the block-complete interrupt. The GPDMA then

General Purpose DMA (GPDMA)

samples the row number, as shown in [Table 5-5](#). If the GPDMA is in Row 1, then the DMA transfer has completed. Hardware sets the transfer complete interrupt and disables the channel. You can either respond to the Block Complete or Transfer Complete interrupts, or poll for the transfer complete raw interrupt status register (RAWTFR[n], where n is the channel number) until it is set by hardware, in order to detect when the transfer is complete. Note that if this polling is used, software must ensure that the transfer complete interrupt is cleared by writing to the Interrupt Clear register, CLEARTFR[n], before the channel is enabled. If the GPDMA is not in Row 1, the next step is performed.

7. The DMA transfer proceeds as follows:

- a) If interrupts are enabled (**CTL.INT_EN** = 1) and the block-complete interrupt is unmasked (**MASKBLOCK[x]** = 1_B, where x is the channel number), hardware sets the block-complete interrupt when the block transfer has completed. It then stalls until the block-complete interrupt is cleared by software. If the next block is to be the last block in the DMA transfer, then the block-complete ISR (interrupt service routine) should clear the reload bits in the **CFG.RELOAD_SRC** and **CFG.RELOAD_DST** registers. This puts the GPDMA into Row 1, as shown in [Table 5-5](#). If the next block is not the last block in the DMA transfer, then the reload bits should remain enabled to keep the GPDMA in Row 4.
- b) If interrupts are disabled (**CTL.INT_EN** = 0) or the block-complete interrupt is masked (**MASKBLOCK[x]** = 0_B, where x is the channel number), then hardware does not stall until it detects a write to the block-complete interrupt clear register; instead, it immediately starts the next block transfer. In this case, software must clear the reload bits in the **CFG.RELOAD_SRC** and **CFG.RELOAD_DST** registers to put the GPDMA into Row 1 of [Table 5-5](#) before the last block of the DMA transfer has completed.

The transfer is similar to that shown in [Figure 5-20](#).

Figure 5-20 Multi-Block DMA Transfer with Source and Destination Address Auto-Reloaded

General Purpose DMA (GPDMA)

The DMA transfer flow is shown in **Figure 5-21**.

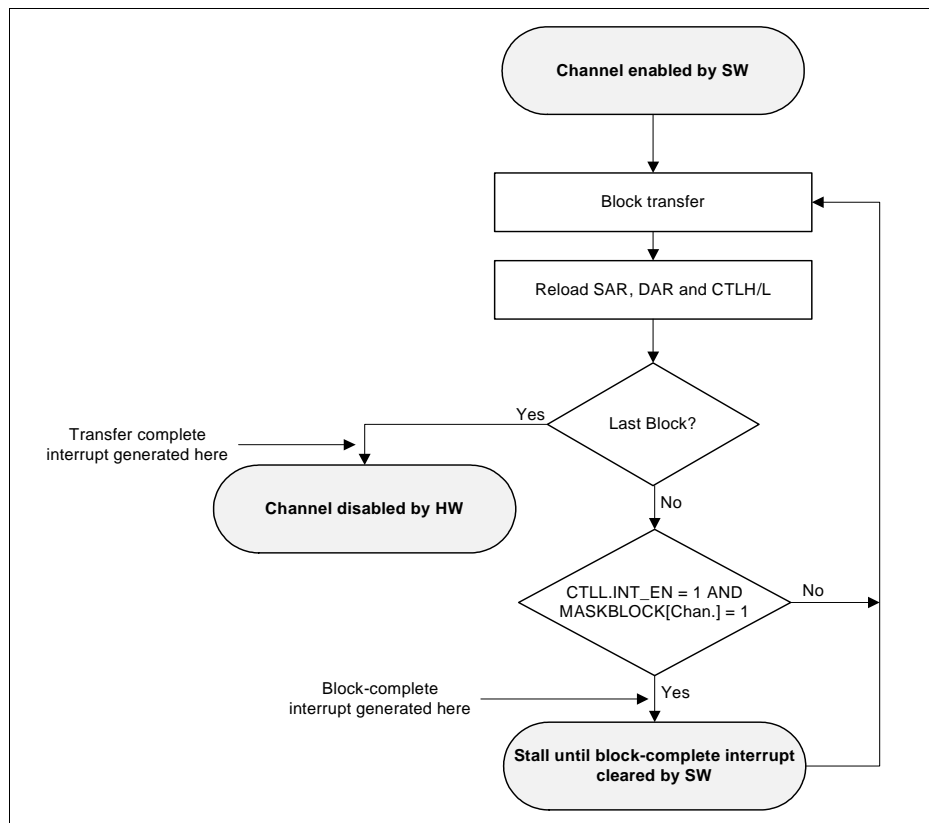

Figure 5-21 DMA Transfer Flow for Source and Destination Address Auto-Reloaded

5.4.6.4 Multi-Block Transfer with Source Address Auto-Reloaded and Linked List Destination Address

This section is an example for the transfer listed in row 7 in [Table 5-5](#).

Note: This type of transfer is supported by GPDMA0 channels 0 and 1 only.

1. Read the Channel Enable register (see [GPDMA0_CHENREG](#)) in order to choose a free (disabled) channel.
2. Set up the chain of linked list items (otherwise known as block descriptors) in memory. Write the control information in the LLI.CTL register location of the block descriptor for each LLI in memory (see [Figure 5-14](#)) for channel x.
3. Write the starting source address in the [SAR](#) register for channel x.

Note: The values in the LLI.SAR register locations of each of the Linked List Items (LLIs) set up in memory, although fetched during an LLI fetch, are not used.

4. Write the channel configuration information into the [CFG](#) register for channel x.
 - a) Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
This step requires programming the HS_SEL_SRC, HS_SEL_DST bits. Writing a 0 activates the hardware handshaking interface to handle source/destination requests for the specific channel. Writing a 1 activates the software handshaking interface source/destination requests.
 - b) If the hardware handshaking interface is activated for the source or destination peripheral, assign the handshaking interface to the source and destination peripheral; this requires programming the SRC_PER and DEST_PER bits, respectively.
5. Make sure that the LLI.CTLH/L register locations of all LLIs in memory (except the last) are set as shown in Row 7 of [Table 5-5](#), while the LLI.CTLH/L register of the last Linked List item must be set as described in Row 1 or Row 5 of [Table 5-5](#). Figure 7-1 shows a Linked List example with two list items.
6. Ensure that the LLI.LLP register locations of all LLIs in memory (except the last) are non-zero and point to the next Linked List item.
7. Ensure that the LLI.DAR register location of all LLIs in memory point to the start destination block address preceding that LLI fetch.
8. Ensure that the LLI.CTLH/L.DONE fields of the LLI.CTLH/L register locations of all LLIs in memory are cleared.
9. If source status fetching is enabled ([CFG.SS_UPD_EN](#) is enabled), program the [SSTATAR](#) register so that the source status information can be fetched from the location pointed to by the [SSTATAR](#). For conditions under which the source status information is fetched from system memory, refer to the Write Back column of [Table 5-5](#).
10. If destination status fetching is enabled ([CFG.DS_UPD_EN](#) is enabled), program the [DSTATAR](#) register so that the destination status information can be fetched from the location pointed to by the [DSTATAR](#) register. For conditions under which the

General Purpose DMA (GPDMA)

destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

11. If gather is enabled (**CTL.SRC_GATHER_EN** = 1), program the **SGR** register for channel x.
12. If scatter is enabled (**CTL.DST_SCATTER_EN** = 1), program the **DSR** register for channel x.
13. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEARDSTTRAN**, and **CLEARERR**. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
14. Program the **CTL** and **CFG** registers according to Row 7, as shown in **Table 5-5**.
15. Program the **LLP** register with **LLP(0)**, the pointer to the first Linked List item.
16. Finally, enable the channel by writing a 1 to the **GPDMA0_CHENREG.CH_EN** bit; the transfer is performed. Ensure that bit 0 of the **GPDMA0_DMACFGREG** register is enabled.
17. The GPDMA fetches the first LLI from the location pointed to by **LLP(0)**.

Note: *The **LLI.SAR**, **LLI.DAR**, **LLI.LLP**, and **LLI.CTLH/L** registers are fetched. The **LLI.SAR** register - although fetched - is not used.*

18. Source and destination request single and burst GPDMA transactions in order to transfer the block of data (assuming non-memory peripherals). The GPDMA acknowledges at the completion of every transaction (burst and single) in the block and carries out the block transfer.
19. Once the block of data is transferred, the source status information is fetched from the location pointed to by the **SSTATAR** register and stored in the **SSTAT** register if **CFG.SS_UPD_EN** is enabled. For conditions under which the source status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

The destination status information is fetched from the location pointed to by the **DSTATAR** register and stored in the **DSTAT** register if **CFG.DS_UPD_EN** is enabled. For conditions under which the destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

20. The **CTLH** register is written out to system memory. For conditions under which the **CTLH** register is written out to system memory, refer to the Write Back column of **Table 5-5**.

The **CTLH** register is written out to the same location where it was originally fetched; that is, the location of the **CTL** register of the linked list item fetched prior to the start of the block transfer. Only the **CTLH** register is written out, because only the **CTL.BLOCK_TS** and **CTL.DONE** fields have been updated by hardware within the GPDMA. The **LLI.CTLH/L.DONE** bit is asserted to indicate block completion. Therefore, software can poll the **LLI.CTL.DONE** bit field of the **CTL** register in the LLI to ascertain when a block transfer has completed.

Note: *Do not poll the **CTL.DONE** bit in the GPDMA memory map. Instead, poll the **LLI.CTLH/L.DONE** bit in the LLI for that block. If the polled **LLI.CTLH/L.DONE** bit is*

General Purpose DMA (GPDMA)

asserted, then this block transfer has completed. This LLI.CTLH/L.DONE bit was cleared at the start of the transfer (Step 8).

21. The **SSTAT** register is now written out to system memory if **CFG.SS_UPD_EN** is enabled. It is written to the SSTAT register location of the LLI pointed to by the previously saved **LLP.LOC** register.

The **DSTAT** register is now written out to system memory if **CFG.DS_UPD_EN** is enabled. It is written to the DSTAT register location of the LLI pointed to by the previously saved **LLP.LOC** register.

The end-of-block interrupt, **int_block**, is generated after the write-back of the control and status registers has completed.

Note: The write-back location for the control and status registers is the LLI pointed to by the previous value of the **LLP.LOC** register, not the LLI pointed to by the current value of the **LLP.LOC** register.

22. The GPDMA reloads the **SAR** register from the initial value. Hardware sets the block-complete interrupt. The GPDMA samples the row number, as shown in **Table 5-5**. If the GPDMA is in Row 1 or Row 5, then the DMA transfer has completed. Hardware sets the transfer complete interrupt and disables the channel. You can either respond to the Block Complete or Transfer Complete interrupts, or poll for the transfer complete raw interrupt status register (**RAWTFR[n]**, $n = \text{channel number}$) until it is set by hardware, in order to detect when the transfer is complete. Note that if this polling is used, software must ensure that the transfer complete interrupt is cleared by writing to the Interrupt Clear register, **CLEARTR[n]**, before the channel is enabled. If the GPDMA is not in Row 1 or Row 5 as shown in **Table 5-5**, the following steps are performed.

23. The DMA transfer proceeds as follows:

- a) If interrupts are enabled (**CTL.INT_EN** = 1) and the block-complete interrupt is unmasked (**MASKBLOCK[x]** = 1_B, where x is the channel number), hardware sets the block-complete interrupt when the block transfer has completed. It then stalls until the block-complete interrupt is cleared by software. If the next block is to be the last block in the DMA transfer, then the block-complete ISR (interrupt service routine) should clear the **CFG.RELOAD_SRC** source reload bit. This puts the GPDMA into Row 1, as shown in **Table 5-5**. If the next block is not the last block in the DMA transfer, then the source reload bit should remain enabled to keep the GPDMA in Row 7, as shown in **Table 5-5**.
- b) If interrupts are disabled (**CTL.INT_EN** = 0) or the block-complete interrupt is masked (**MASKBLOCK[x]** = 0_B, where x is the channel number), then hardware does not stall until it detects a write to the block-complete interrupt clear register; instead, it immediately starts the next block transfer. In this case, software must clear the source reload bit, **CFG.RELOAD_SRC** in order to put the device into Row 1 of **Table 5-5** before the last block of the DMA transfer has completed.

24. The GPDMA fetches the next LLI from memory location pointed to by the current **LLP** register and automatically reprograms the **DAR**, **CTL**, and **LLP** channel registers. Note that the **SAR** is not reprogrammed, since the reloaded value is used for the next

General Purpose DMA (GPDMA)

DMA block transfer. If the next block is the last block of the DMA transfer, then the **CTL** and **LLP** registers just fetched from the LLI should match Row 1 or Row 5 of **Table 5-5**.

The DMA transfer might look like that shown in **Figure 5-22**.

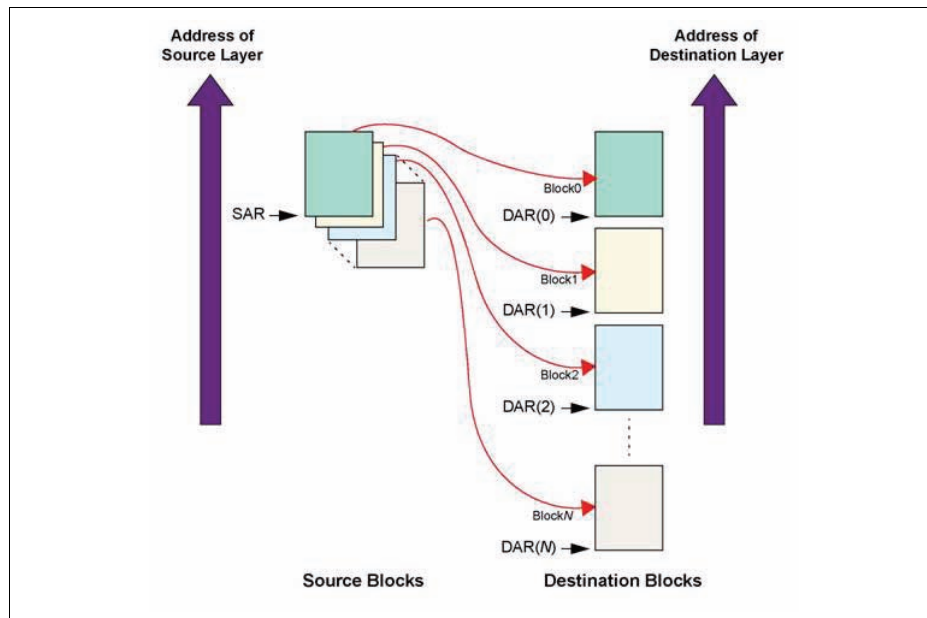

Figure 5-22 Multi-Block DMA Transfer with Source Address Auto-Reloaded and Linked List Destination Address

General Purpose DMA (GPDMA)

The DMA transfer flow is shown in **Figure 5-23**.

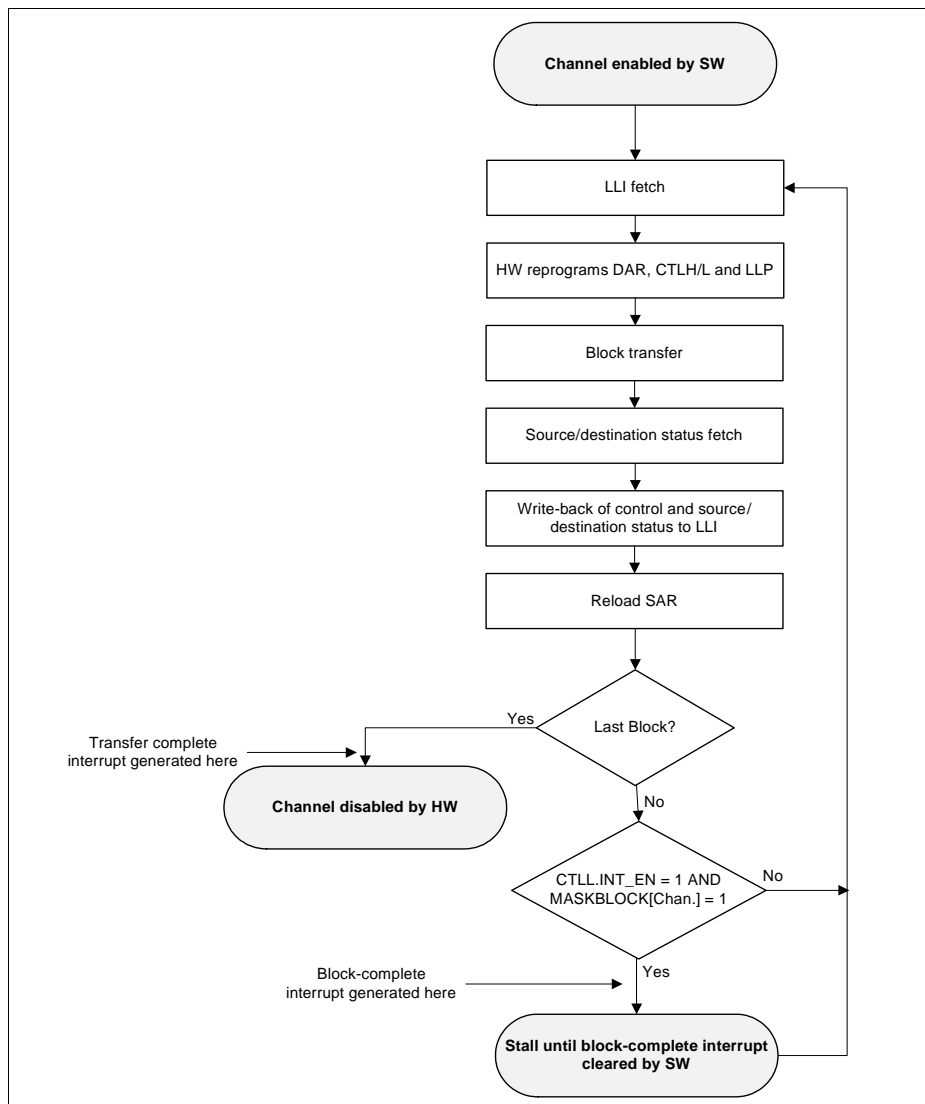

Figure 5-23 DMA Transfer Flow for Source Address Auto-Reloaded and Linked List Destination Address

5.4.6.5 Multi-Block DMA Transfer with Linked List for Source and Contiguous Destination Address

This section is an example for the transfer listed in row 8 in [Table 5-5](#).

Note: This type of transfer is supported by GPDMA0 channels 0 and 1 only.

1. Read the Channel Enable register (see [GPDMA0_CHENREG](#)) to choose a free (disabled) channel.
2. Set up the linked list in memory. Write the control information in the LLI.[CTL](#) register location of the block descriptor for each LLI in memory (see [Figure 5-14](#)) for channel x.
3. Write the starting destination address in the [DAR](#) register for channel x.
Note: *The values in the LLI.DAR register location of each Linked List Item (LLI) in memory, although fetched during an LLI fetch, are not used.*
4. Write the channel configuration information into the [CFG](#) register for channel x.
 1. Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
This step requires programming the HS_SEL_SRC, HS_SEL_DST bits. Writing a 0 activates the hardware handshaking interface to handle source/destination requests for the specific channel. Writing a 1 activates the software handshaking interface to handle source/destination requests.
 2. If the hardware handshaking interface is activated for the source or destination peripheral, assign the handshaking interface to the source and destination peripherals. This requires programming the SRC_PER and DEST_PER bits, respectively.
5. Ensure that all LLI.[CTLH/L](#) register locations of the LLI (except the last) are set as shown in Row 8 of [Table 5-5](#), while the LLI.[CTLH/L](#) register of the last Linked List item must be set as described in Row 1 or Row 5 of [Table 5-5](#). [Figure 5-14](#) shows a Linked List example with two list items.
6. Ensure that the LLI.[LLP](#) register locations of all LLIs in memory (except the last) are non-zero and point to the next Linked List item.
7. Ensure that the LLI.[SAR](#) register location of all LLIs in memory point to the start source block address preceding that LLI fetch.
8. Ensure that the LLI.[CTLH/L](#).DONE fields of the LLI.[CTLH/L](#) register locations of all LLIs in memory are cleared.
9. If source status fetching is enabled ([CFG](#).SS_UPD_EN is enabled), program the [SSTATAR](#) register so that the source status information can be fetched from the location pointed to by [SSTATAR](#). For conditions under which the source status information is fetched from system memory, refer to the Write Back column of [Table 5-5](#).
10. If destination status fetching is enabled ([CFG](#).DS_UPD_EN is enabled), program the [DSTATAR](#) register so that the destination status information can be fetched from the location pointed to by the [DSTATAR](#) register. For conditions under which the

General Purpose DMA (GPDMA)

destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

11. If gather is enabled (**CTL.SRC_GATHER_EN** = 1), program the **SGR** register for channel x.
12. If scatter is enabled (**CTL.DST_SCATTER_EN** = 1), program the **DSR** register for channel x.
13. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEARDSTTRAN**, and **CLEARERR**. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
14. Program the **CTL** and **CFG** registers according to Row 8, as shown in **Table 5-5**.
15. Program the **LLP** register with **LLP(0)**, the pointer to the first Linked List item.
16. Finally, enable the channel by writing a 1 to the **GPDMA0_CHENREG.CH_EN** bit; the transfer is performed. Ensure that bit 0 of the **GPDMA0_DMACFGREG** register is enabled.
17. The GPDMA fetches the first LLI from the location pointed to by **LLP(0)**.
Note: *The **LLI.SAR**, **LLI.DAR**, **LLI.LLP**, and **LLI.CTLH/L** registers are fetched. The **LLI.DAR** register location of the LLI - although fetched - is not used. The **DAR** register in the GPDMA remains unchanged.*
18. Source and destination request single and burst GPDMA transactions to transfer the block of data (assuming non-memory peripherals). The GPDMA acknowledges at the completion of every transaction (burst and single) in the block and carries out the block transfer.
19. Once the block of data is transferred, the source status information is fetched from the location pointed to by the **SSTATAR** register and stored in the **SSTAT** register if **CFG.SS_UPD_EN** is enabled. For conditions under which the source status information is fetched from system memory, refer to the Write Back column of **Table 5-5**. The destination status information is fetched from the location pointed to by the **DSTATAR** register and stored in the **DSTAT** register if **CFG.DS_UPD_EN** is enabled. For conditions under which the destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.
20. The **CTLH** register is written out to system memory. For conditions under which the **CTLH** register is written out to system memory, refer to the Write Back column of **Table 5-5**. The **CTLH** register is written out to the same location where it was originally fetched; that is, the location of the **CTL** register of the linked list item fetched prior to the start of the block transfer. Only the second word of the **CTL** register is written out, **CTLH**, because only the **CTL.BLOCK_TS** and **CTL.DONE** fields have been updated by hardware within the GPDMA. Additionally, the **CTL.DONE** bit is asserted to indicate block completion. Therefore, software can poll the **LLI.CTL.DONE** bit field of the **CTL** register in the LLI to ascertain when a block transfer has completed.

Note: Do not poll the **CTL.DONE** bit in the GPDMA memory map. Instead, poll the **LLI.CTLH/L.DONE** bit in the LLI for that block. If the polled **LLI.CTLH/L.DONE** bit is

General Purpose DMA (GPDMA)

asserted, then this block transfer has completed. This LLI.CTLH/L.DONE bit was cleared at the start of the transfer (Step 8).

21. The **SSTAT** register is now written out to system memory if **CFG.SS_UPD_EN** is enabled. It is written to the **SSTAT** register location of the LLI pointed to by the previously saved **LLP.LOC** register. The **DSTAT** register is now written out to system memory if **CFG.DS_UPD_EN** is enabled. It is written to the **DSTAT** register location of the LLI pointed to by the previously saved **LLP.LOC** register. The end-of-block interrupt, **int_block**, is generated after the write-back of the control and status registers has completed.

Note: The write-back location for the control and status registers is the LLI pointed to by the previous value of the **LLP.LOC** register, not the LLI pointed to by the current value of the **LLP.LOC** register.

22. The GPDMA does not wait for the block interrupt to be cleared, but continues and fetches the next LLI from the memory location pointed to by the current **LLP** register and automatically reprograms the **SAR**, **CTL**, and **LLP** channel registers. The **DAR** register is left unchanged. The DMA transfer continues until the GPDMA samples that the **CTL** and **LLP** registers at the end of a block transfer match those described in Row 1 or Row 5 of **Table 5-5** (as discussed earlier). The GPDMA then knows that the previously transferred block was the last block in the DMA transfer.

The GPDMA transfer might look like that shown in **Figure 5-24**. Note that the destination address is decrementing.

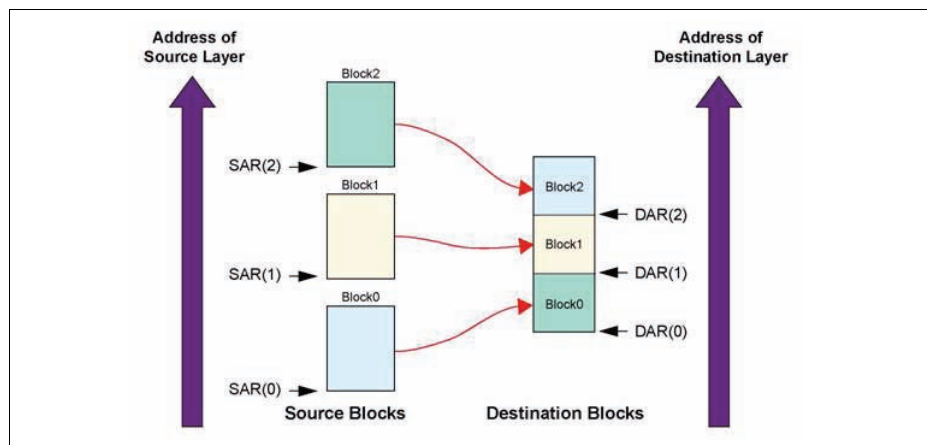

Figure 5-24 Multi-Block DMA Transfer with Linked List Source Address and Contiguous Destination Address

The DMA transfer flow is shown in **Figure 5-25**.

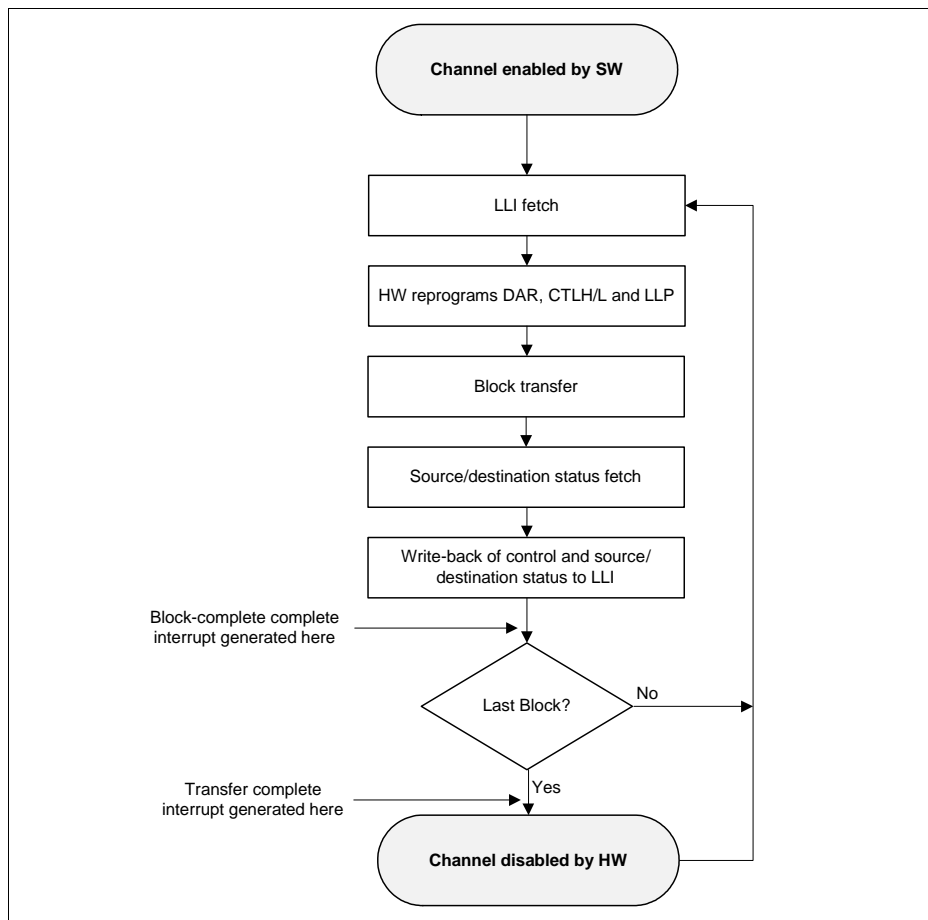

Figure 5-25 DMA Transfer Flow for Source Address Auto-Reloaded and Linked List Destination Address

5.4.6.6 Multi-Block Transfer with Linked List for Source and Destination

This section is an example for the transfer listed in row 10 in **Table 5-5**.

Note: This type of transfer is supported by GPDMA0 channels 0 and 1 only.

1. Read the Channel Enable register (see **GPDMA0_CHENREG**) to choose a free (disabled) channel.

General Purpose DMA (GPDMA)

2. Set up the chain of Linked List Items (otherwise known as block descriptors) in memory. Write the control information in the LLI.**CTL** register location of the block descriptor for each LLI in memory (see **Figure 5-14**) for channel x.
3. Write the channel configuration information into the **CFG** register for channel x.
 - a) Designate the handshaking interface type (hardware or software) for the source and destination peripherals; this is not required for memory.
 This step requires programming the **CFG.HS_SEL_SRC** or **CFG.HS_SEL_DST** bits, respectively. Writing a 0 activates the hardware handshaking interface to handle source/destination requests for the specific channel. Writing a 1 activates the software handshaking interface to handle source/destination requests.
 - b) If the hardware handshaking interface is activated for the source or destination peripheral, assign the handshaking interface to the source and destination peripheral. This requires programming the **CFG.SRC_PER** and **CFG.DEST_PER** bits, respectively.
4. Make sure that the LLI.**CTLH/L** register locations of all LLI entries in memory (except the last) are set as shown in Row 10 of **Table 5-5**. The LLI.**CTLH/L** register of the last Linked List Item must be set as described in Row 1 or Row 5 of **Table 5-5**. **Figure 5-14** shows a Linked List example with two list items.
5. Make sure that the LLI.**LLP** register locations of all LLI entries in memory (except the last) are non-zero and point to the base address of the next Linked List Item.
6. Make sure that the LLI.**SAR**, LLI.**DAR** register locations of all LLI entries in memory point to the start source/destination block address preceding that LLI fetch.
7. Ensure that the LLI.**CTLH/L.DONE** field of the LLI.**CTLH/L** register locations of all LLI entries in memory is cleared.
8. If source status fetching is enabled (**CFG.SS_UPD_EN** is enabled), program the **SSTATAR** register so that the source status information can be fetched from the location pointed to by the **SSTATAR**. For conditions under which the source status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.
9. If destination status fetching is enabled (**CFG.DS_UPD_EN** is enabled), program the **DSTATAR** register so that the destination status information can be fetched from the location pointed to by the **DSTATAR** register. For conditions under which the destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.
10. If gather is enabled (**CTL.SRC_GATHER_EN** = 1), program the **SGR** register for channel x.
11. If scatter is enabled (**CTL.DST_SCATTER_EN** = 1), program the **DSR** register for channel x.
12. Clear any pending interrupts on the channel from the previous DMA transfer by writing to the Interrupt Clear registers: **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEAR DSTTRAN**, and **CLEARERR**. Reading the Interrupt Raw Status and Interrupt Status registers confirms that all interrupts have been cleared.
13. Program the **CTL** and **CFG** registers according to Row 10, as shown in **Table 5-5**.

General Purpose DMA (GPDMA)

14. Program the **LLP** register with LLP(0), the pointer to the first linked list item.
15. Finally, enable the channel by writing a 1 to the **GPDMA0_CHENREG.CH_EN** bit; the transfer is performed.
16. The GPDMA fetches the first LLI from the location pointed to by LLP(0). The LLI.SAR, LLI.DAR, LLI.LLP, and LLI.CTL registers are fetched and the GPDMA automatically reprograms the according **SAR**, **DAR**, **LLP**, and **CTL** channel registers.
17. Source and destination request single and burst DMA transactions to transfer the block of data (assuming non-memory peripheral). The GPDMA acknowledges at the completion of every transaction (burst and single) in the block and carries out the block transfer.

18. Once the block of data is transferred, the source status information is fetched from the location pointed to by the **SSTATAR** register and stored in the **SSTAT** register if **CFG.SS_UPD_EN** is enabled. For conditions under which the source status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

The destination status information is fetched from the location pointed to by the **DSTATAR** register and stored in the **DSTAT** register if **CFG.DS_UPD_EN** is enabled. For conditions under which the destination status information is fetched from system memory, refer to the Write Back column of **Table 5-5**.

19. The **CTLH** register is written out to system memory. For conditions under which the **CTLH** register is written out to system memory, refer to the Write Back column of **Table 5-5**.

The **CTLH** register is written out to the same location where it was originally fetched; that is, the location of the **CTL** register of the linked list item fetched prior to the start of the block transfer. Only the **CTLH** register is written out, because only the **CTL.BLOCK_TS** and **CTL.DONE** fields have been updated by the GPDMA hardware. Additionally, the **CTL.DONE** bit is asserted to indicate block completion. Therefore, software can poll the LLI.CTLH/L.DONE bit of the **CTL** register in the LLI to ascertain when a block transfer has completed.

Note: Do not poll the **CTL.DONE** bit in the GPDMA memory map; instead, poll the LLI.CTLH/L.DONE bit in the LLI for that block. If the polled LLI.CTLH/L.DONE bit is asserted, then this block transfer has completed. This LLI.CTLH/L.DONE bit was cleared at the start of the transfer (Step 7).

20. The **SSTAT** register is now written out to system memory if **CFG.SS_UPD_EN** is enabled. It is written to the **SSTAT** register location of the LLI pointed to by the previously saved **LLP.LOC** register.

The **DSTAT** register is now written out to system memory if **CFG.DS_UPD_EN** is enabled. It is written to the **DSTAT** register location of the LLI pointed to by the previously saved **LLP.LOC** register.

The end-of-block interrupt, **int_block**, is generated after the write-back of the control and status registers has completed.

Note: The write-back location for the control and status registers is the LLI pointed to

General Purpose DMA (GPDMA)

by the previous value of the **LLP.LOC** register, not the LLI pointed to by the current value of the **LLP.LOC** register.

21. The GPDMA does not wait for the block interrupt to be cleared, but continues fetching the next LLI from the memory location pointed to by the current **LLP** register and automatically reprograms the **SAR**, **DAR**, **CTL**, and **LLP** channel registers. The DMA transfer continues until the GPDMA determines that the **CTL** and **LLP** registers at the end of a block transfer match the ones described in Row 1 or Row 5 of **Table 5-5** (as discussed earlier). The GPDMA then knows that the previously transferred block was the last block in the DMA transfer.

The DMA transfer might look like that shown in **Figure 5-26**.

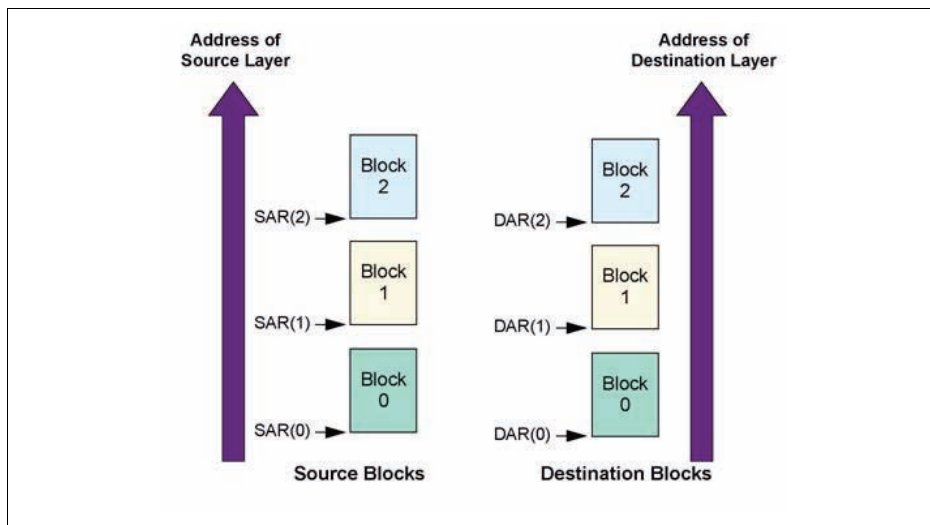

Figure 5-26 Multi-Block with Linked Address for Source and Destination

If the user needs to execute a DMA transfer where the source and destination address are contiguous, but where the amount of data to be transferred is greater than the maximum block size **CTL.BLOCK_TS**, then this can be achieved using the type of multi-block transfer shown in **Figure 5-27**.

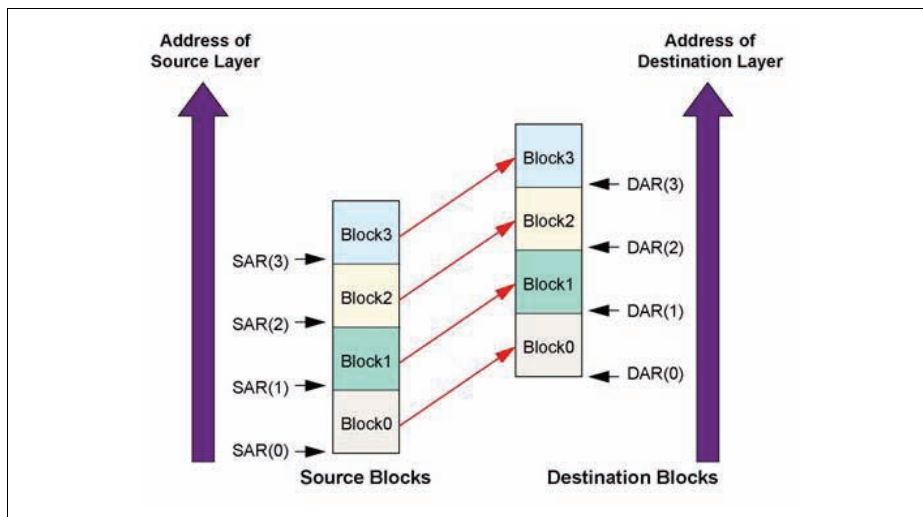

Figure 5-27 Multi-Block with Linked Address for Source and Destination Where SAR and DAR Between Successive Blocks are Contiguous

The DMA transfer flow is shown in **Figure 5-28**.

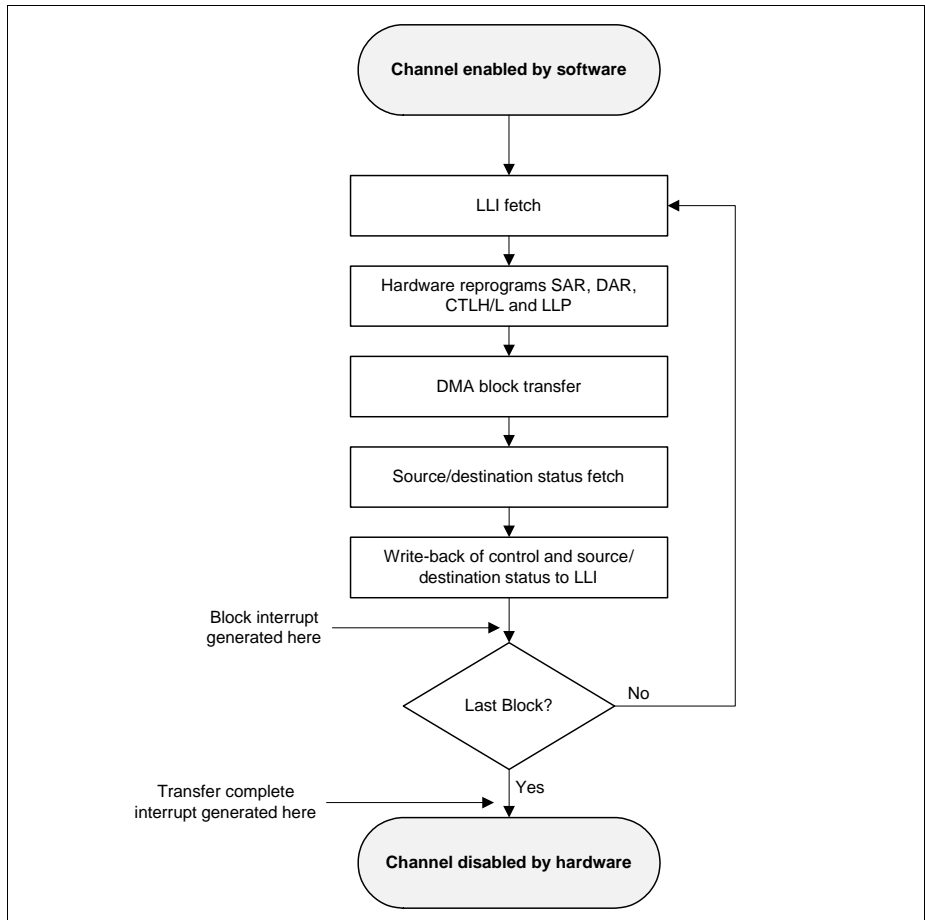

Figure 5-28 DMA Transfer Flow for Source and Destination Linked List Address

5.5 Service Request Generation

Each GPDMA block provides a number of registers (see [Section 5.8.3](#)) to control the request behavior and to provide an interface for software to check for request occurrence.

The following DMA Events can be generated for each channel due to DMA activity:

- IntSrcTran - Source Transaction Complete
- IntDstTran - Destination Transaction Complete
- IntBlock - Block Transfer Complete
- IntTfr - DMA Transfer Complete
- IntErr - Error

DMA Event processing per channel

Each DMA Event for each channel is directly stored in the according “RAW Status” bit shown in [Figure 5-29](#). The user software can control the processing by writing to the according “Mask” and “Clear” bits.

Note: Request forwarding is disabled by default setting of the “Mask” register.

Once the event is forwarded to the “Status” bit its occurrence is registered in the [Combined Interrupt Status Register](#) and a service request is triggered to the NVIC.

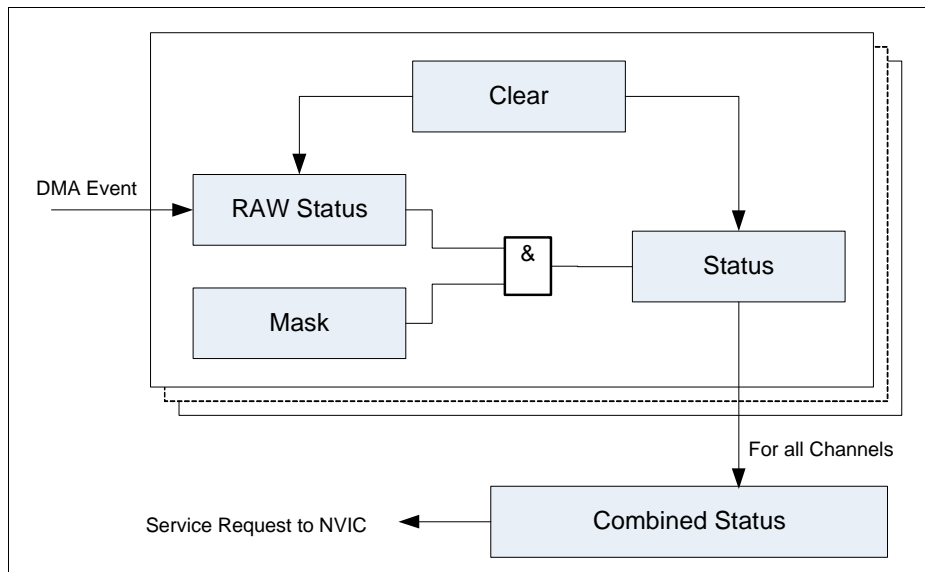

Figure 5-29 DMA Event to Service Request Flow

5.6 Power, Reset and Clock

The GPDMA unit is inside the core power domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) chapter.

Additionally, if a GPDMA unit is not needed, it can be held in reset via the PRSET2.DMAyRS bitfield (address the SCU chapter for a full description).

The clock used for the GPDMA unit is described on the SCU chapter as f_{DMA} . Please address the specific section under the SCU chapter for a detailed description on the clock configuration schemes.

5.7 Initialization and System Dependencies

The generic initialization sequence for an application that is using the GPDMA, should be the following:

1st Step: Release reset of the GPDMA, via the specific SCU bitfield on the PRCLR2 register.

2nd Step: If the GPDMA is already under use (step 1 was not performed) do the following steps:

- read the channel Enable register to choose a free channel, **CHENREG**. Clear also any pending requests of the specific channel, by writing into the **CLEARTRF**, **CLEARBLOCK**, **CLEARSRCTRAN**, **CLEAR DSTTRAN** and **CLEARERR**
- confirm that all the interrupts have been cleared via the Status and RAW registers.

3rd Step: Configure the GPDMA channels accordingly with the wanted transfer type:

- Configure the starting source address and starting destination address, on the **SAR** and **DAR**, respectively.
- Configure the type of transfer that are going to be used via the **LLP**, **CTL** and **CFG** registers.

4th Step: Enable the GPDMA channel, by setting the specific bitfield on the **CHENREG**.

5th Step: Configure the DLR (DMA Line Router) block to map the DMA requests from the peripherals to the wanted DMA request lines (if not previously done).

6th Step: Configure the peripherals that are linked with DMA requests.

7th Step: Enable the specific Service requests on the peripheral blocks.

8th Step: Start the peripheral(s)

*Note: This is a generic channel initialization example. Please refer to **Section 5.3** and **Section 5.4** for a complete description and examples of how to control the complete flow for a GPDMA channel.*

5.8 Registers

This chapter includes information on how to program the GPDMA.

Register references

There are references to software parameters throughout this chapter. The software parameters are the field names in each register description table and are prefixed by the register name; for example, the Block Transfer Size field in the Control register for channel x of GPDMA0 is designated as "GPDMA0_CHx_CTLH.BLOCK_TS"

Illegal Register Access

An illegal access can be any of the following:

1. A write to the **SAR**, **DAR**, **LLP**, **CTL**, **SSTAT**, **DSTAT**, **SSTATAR**, **DSTATAR**, **SGR**, or **DSR** registers occurs when the channel is enabled.
2. A read from the Interrupt Clear Registers is attempted.
3. A write to the Interrupt Status Registers, **GPDMA0_STATUSINT**, **ID** or **VERSION** is attempted.

An illegal access (read/write) returns an AHB error response.

Table 5-6 Registers Address Space

| Module | Base Address | End Address | Note |
|------------|------------------------|------------------------|------|
| GPDMA0_CH0 | 5001 4000 _H | 5001 4054 _H | |

1) x = channel number

5.8.1 Configuration and Channel Enable Registers

DMACFGREG

This register is used to enable the GPDMA, which must be done before any channel activity can begin.

GPDMA0_DMACFGREG

GPDMA Configuration Register (398_H)

Reset Value: 0000 0000_H

GPDMA1_DMACFGREG

GPDMA Configuration Register (398_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|--------|------|--|
| DMA_EN | 0 | rw | GPDMA Enable bit. 0 _B GPDMA Disabled 1 _B GPDMA Enabled. |
| 0 | [31:1] | r | Reserved |

If the global channel enable bit is cleared while any channel is still active, then DMACFGREG.DMA_EN still returns 1 to indicate that there are channels still active until hardware has terminated all activity on all channels, at which point the DMACFGREG.DMA_EN bit returns 0.

CHENREG

This is the GPDMA “Channel Enable Register”. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive; it can then enable an inactive channel with the required priority.

All bits of this register are cleared to 0 when the global GPDMA channel enable bit, **DMACFGREG**[0], is 0. When the global channel enable bit is 0, then a write to the **CHENREG** register is ignored and a read will always read back 0.

General Purpose DMA (GPDMA)

The channel enable bit, **CHENREG.CH_EN**, is written only if the corresponding channel write enable bit, **CHENREG.CH_EN_WE**, is asserted on the same AHB write transfer. For example, writing hex 01x1 writes a 1 into **CHENREG[0]**, while **CHENREG[7:1]** remains unchanged. Writing hex 00xx leaves **CHENREG[7:0]** unchanged. Note that a read-modified write is not required.

GPDMA0_CHENREG

GPDMA Channel Enable Register (3A0_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|

| Field | Bits | Type | Description |
|--------------|-------------------|------|---|
| CH | [3:0] | rw | Enables/Disables the channel Setting this bit enables a channel; clearing this bit disables the channel. 0 _B Disable the Channel 1 _B Enable the Channel The CHENREG.CH_EN bit is automatically cleared by hardware to disable the channel after the last AMBA transfer of the DMA transfer to the destination has completed. Software can therefore poll this bit to determine when this channel is free for a new DMA transfer. |
| WE_CH | [11:8] | w | Channel enable write enable |
| 0 | [31:12], [7:4] | r | Reserved |

5.8.2 Channel Registers

The **SAR**, **DAR**, **LLP**, **CTL**, and **CFG** channel registers should be programmed prior to enabling the channel. However, if an LLI update occurs before commencing data transfer, **SAR** and **DAR** may not need to be programmed prior to enabling the channel; refer to rows 6 to 10 in **Table 5-5**. It is an illegal register access when a write to the **SAR**, **DAR**, **LLP**, **CTL**, **SSTAT**, **DSTAT**, **SSTATAR**, **DSTATAR**, **SGR**, or **DSR** registers occurs when the channel is enabled.

General Purpose DMA (GPDMA)

SAR

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current AHB transfer.

*Note: You must program the SAR address to be aligned to **CTL.SRC_TR_WIDTH**.*

For information on how the **SAR** is updated at the start of each DMA block for multi-block transfers, refer to **Table 5-5**.

GPDMA0_CHx_SAR (x=0-7)

Source Address Register for Channel x

$$(00_H + x * 58_H)$$

Reset Value: 0000 0000_H

GPDMA1_CHx_SAR (x=0-3)

Source Address Register for Channel x

$$(00_H + x * 58_H)$$

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|---|
| SAR | [31:0] | rw | Current Source Address of DMA transfer Updated after each source transfer. The SINC field in the CTL register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer. Reset: 0 _D |

General Purpose DMA (GPDMA)

DAR

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current AHB transfer.

*Note: You must program the DAR to be aligned to **CTL.DST_TR_WIDTH**.*

GPDMA0_CHx_DAR (x=0-7)

Destination Address Register for Channel x

$(08_H + x * 58_H)$

Reset Value: 0000 0000_H

GPDMA1_CHx_DAR (x=0-3)

Destination Address Register for Channel x

$(08_H + x * 58_H)$

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| DAR | [31:0] | rw | Current Destination address of DMA transfer Updated after each destination transfer. The DINC field in the CTL register determines whether the address increments, decrements, or is left unchanged on every destination transfer throughout the block transfer. Reset: 0 _D |

Hardware Realignment of SAR/DAR Registers

In a particular circumstance, during contiguous multi-block DMA transfers, the destination address can become misaligned between the end of one block and the start of the next block. When this situation occurs, GPDMA re-aligns the destination address before the start of the next block.

Consider the following example. If the block length is 9, the source transfer width is 16 (halfword), and the destination transfer width is 32 (word) — the destination is programmed for contiguous block transfers — then the destination performs four word transfers followed by a halfword transfer to complete the block transfer to the destination. At the end of the destination block transfer, the address is aligned to a 16-bit transfer as the last AMBA transfer is halfword. This is misaligned to the programmed transfer size of 32 bits for the destination. However, for contiguous destination multi-block transfers, GPDMA re-aligns the DAR address to the nearest 32-bit address (next 32-bit address

General Purpose DMA (GPDMA)

upwards if address control is incrementing or next address downwards if address control is decrementing).

The destination address is automatically realigned by the GPDMA in the following DMA transfer setup scenario:

- Contiguous multi-block transfers on destination side, AND
- $\text{DST_TR_WIDTH} > \text{SRC_TR_WIDTH}$, AND
- $(\text{BLOCK_TS} * \text{SRC_TR_WIDTH}) / \text{DST_TR_WIDTH} \neq \text{integer}$ (where SRC_TR_WIDTH , DST_TR_WIDTH is byte width of transfer)

LLP

You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled.

GPDMA0_CHx_LLDP (x = 0-1)

Linked List Pointer Register for Channel x

($10_H + x * 58_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| LOC | [31:2] | rw | Starting Address In Memory of next LLI if block chaining is enabled. Note that the two LSBs of the starting address are not stored because the address is assumed to be aligned to a 32-bit boundary. |
| 0 | [1:0] | r | Reserved |

The LLP register has two functions:

- The logical result of the equation $LLP.LOC \neq 0$ is used to set up the type of DMA transfer — single or multi-block. [Table 5-5](#) shows how the method of updating the channel registers is a function of $LLP.LOC \neq 0$. If $LLP.LOC$ is set to 0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type.
- $LLP.LOC \neq 0$ contains the pointer to the next LLI for block chaining using linked lists. The [LLP](#) register can also point to the address where write-back of the control and source/destination status information occur after block completion.

General Purpose DMA (GPDMA)

CTL

These registers contain fields that control the DMA transfer.

The CTLH and CTLL registers are part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

If status write-back is enabled, the upper control register, CTLH, is written to the control register location of the LLI in system memory at the end of the block transfer.

Note: You need to program these registers prior to enabling the channel.

CTLH

Control Register High.

GPDMA0_CHx_CTLH (x=0-7)

Control Register High for Channel x

$(1C_H + x*58_H)$

Reset Value: 0000 0002_H

GPDMA1_CHx_CTLH (x=0-3)

Control Register High for Channel x

$(1C_H + x*58_H)$

Reset Value: 0000 0002_H

General Purpose DMA (GPDMA)

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| BLOCK_TS | [11:0] | rw | <p>Block Transfer Size</p> <p>When the GPDMA is the flow controller, the user writes this field before the channel is enabled in order to indicate the block size. The number programmed here indicates the total number of single transactions to perform for every block transfer.</p> <p>Once the transfer starts, the read-back value is the total number of data items already read from the source peripheral.</p> <p><i>Note: The width of the single transaction is determined by CTL.SRC_TR_WIDTH.</i></p> |
| DONE | 12 | rw | <p>Done bit</p> <p>If this bit is set and status write-back is enabled then CTLH is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer.</p> <p>Software can poll the LLI CTLH.DONE bit to see when a block transfer is complete. The LLI CTLH.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel.</p> |
| 0 | [31:13] | r | Reserved |

CTLL

Control Register Low.

GPDMA0_CHx_CTLL (x=0-1)

Control Register Low for Channel x

($18_H + x * 58_H$)

Reset Value: 0030 4801_H

| | | | | | | | | | | | | | | | |

General Purpose DMA (GPDMA)

SSTAT

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the **SSTATAR** register. This status information is then stored in the SSTAT register and written out to the SSTAT register location of the LLI before the start of the next block.

Note: This register is a temporary placeholder for the source status information on its way to the SSTAT register location of the LLI. The source status information should be retrieved by software from the SSTAT register location of the LLI, and not by a read of this register over the GPDMA slave interface.

GPDMA0_CHx_SSTAT (x=0-1)

Source Status Register for Channel x

($20_H + x * 58_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|---|
| SSTAT | [31:0] | rw | Source Status retrieved by hardware from the address pointed to by the contents of the SSTATAR register. |

General Purpose DMA (GPDMA)

DSTAT

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the **DSTATAR** register. This status information is then stored in the DSTAT register and written out to the DSTAT register location of the LLI before the start of the next block. This register does only exist for channels 0 and 1, for other channels the read-back value is always 0.

Note: This register is a temporary placeholder for the destination status information on its way to the DSTAT register location of the LLI. The destination status information should be retrieved by software from the DSTAT register location of the LLI and not by a read of this register over the GPDMA slave interface.

GPDMA0_CHx_DSTAT (x=0-1)

Destination Status Register for Channel x

($28_H + x * 58_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| DSTAT | [31:0] | rw | Destination Status retrieved by hardware from the address pointed to by the contents of the DSTATAR register. |

General Purpose DMA (GPDMA)

SSTATAR

After the completion of each block transfer, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATAR register.

GPDMA0_CHx_SSTATAR (x=0-1)

Source Status Address Register for Channel x

($30_H + x * 58_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------|--------|------|---|
| SSTATAR | [31:0] | rw | Source Status Address Pointer from where hardware can fetch the source status information, which is registered in the SSTAT register and written out to the SSTAT register location of the LLI before the start of the next block. |

General Purpose DMA (GPDMA)

DSTATAR

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATAR register.

GPDMA0_CHx_DSTATAR (x=0-1)

Destination Status Address Register for Channel x

(38_H + x*58_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------|--------|------|---|
| DSTATAR | [31:0] | rw | Destination Status Address Pointer from where hardware can fetch the destination status information, which is registered in the DSTAT register and written out to the DSTAT register location of the LLI before the start of the next block. |

General Purpose DMA (GPDMA)

CFG

These registers contain fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer.

Note: You need to program this register prior to enabling the channel.

GPDMA0_CHx_CFGH (x=0-1)

Configuration Register High for Channel x

(44_H + x*58_H)

Reset Value: 0000 0004_H

| Field | Bits | Type | Description |
|-------------------|-------|------|---|
| CH_PRIOR | [7:5] | rw | Channel priority A priority of 7 is the highest priority, and 0 is the lowest. The value programmed to this field must be within 0 and 7. A programmed value outside this range will cause erroneous behavior. Reset: Channel Number For example: Chan0 = 000 _B Chan1 = 001 _B |
| CH_SUSP | 8 | rw | Channel Suspend Suspends all DMA data transfers from the source until this bit is cleared. There is no guarantee that the current transaction will complete. Can also be used in conjunction with CFGLx.FIFO_EMPTY to cleanly disable a channel without losing any data. 0 _B Not suspended. 1 _B Suspend DMA transfer from the source. |
| FIFO_EMPTY | 9 | r | Indicates if there is data left in the channel FIFO Can be used in conjunction with CFGLx.CH_SUSP to cleanly disable a channel. 1 _B Channel FIFO empty 0 _B Channel FIFO not empty |

General Purpose DMA (GPDMA)

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| HS_SEL_DST | 10 | rw | Destination Software or Hardware Handshaking Select This register selects which of the handshaking interfaces - hardware or software - is active for destination requests on this channel. 0 _B Hardware handshaking interface. Software-initiated transaction requests are ignored. 1 _B Software handshaking interface. Hardware-initiated transaction requests are ignored. If the destination peripheral is memory, then this bit is ignored. |
| HS_SEL_SRC | 11 | rw | Source Software or Hardware Handshaking Select This register selects which of the handshaking interfaces - hardware or software - is active for source requests on this channel. 0 _B Hardware handshaking interface. Software-initiated transaction requests are ignored. 1 _B Software handshaking interface. Hardware-initiated transaction requests are ignored. If the source peripheral is memory, then this bit is ignored. |
| LOCK_CH_L | [13:12] | rw | Channel Lock Level Indicates the duration over which CFGLx.LOCK_CH bit applies. 00 _B Over complete DMA transfer 01 _B Over complete DMA block transfer 1x _B Over complete DMA transaction |
| LOCK_B_L | [15:14] | rw | Bus Lock Level Indicates the duration over which CFGLx.LOCK_B bit applies. 00 _B Over complete DMA transfer 01 _B Over complete DMA block transfer 1x _B Over complete DMA transaction |

General Purpose DMA (GPDMA)

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| LOCK_CH | 16 | rw | Channel Lock Bit When the channel is granted control of the master bus interface and if the CFGLx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGLx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGLx.LOCK_CH_L. |
| LOCK_B | 17 | rw | Bus Lock Bit When active, the AHB bus master signal hlock is asserted for the duration specified in CFGLx.LOCK_B_L. For more information, refer to Section 5.2.6 . |
| DST_HS_POL | 18 | rw | Destination Handshaking Interface Polarity 0 _B Active high 1 _B Active low For information on this, refer to Section 5.2.4 . |
| SRC_HS_POL | 19 | rw | Source Handshaking Interface Polarity 0 _B Active high 1 _B Active low For information on this, refer to Section 5.2.4 . |
| MAX_ABRST | [29:20] | rw | Maximum AMBA Burst Length Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel. |
| RELOAD_SRC | 30 | rw | Automatic Source Reload The SAR register can be automatically reloaded from its initial value at the end of every block for multi-block transfers. A new block transfer is then initiated. For conditions under which this occurs, refer to Table 5-5 . |
| RELOAD_DST | 31 | rw | Automatic Destination Reload The DAR register can be automatically reloaded from its initial value at the end of every block for multi-block transfers. A new block transfer is then initiated. For conditions under which this occurs, refer to Table 5-5 . |

General Purpose DMA (GPDMA)

SGR

The Source Gather register contains two fields:

- Source gather count field (SGRx.SGC) - Specifies the number of contiguous source transfers of **CTL.SRC_TR_WIDTH** between successive gather intervals. This is defined as a gather boundary.
- Source gather interval field (SGRx.SGI) - Specifies the source address increment/decrement in multiples of **CTL.SRC_TR_WIDTH** on a gather boundary when gather mode is enabled for the source transfer.

The **CTL.SINC** field controls whether the address increments or decrements. When the **CTL.SINC** field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGR register is ignored. For more information, see [Section 5.2.7](#).

GPDMA0_CHx_SGR (x=0-1)

Source Gather Register for Channel x

(48_H + x*58_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| SGI | [19:0] | rw | Source gather interval |
| SGC | [31:20] | rw | Source gather count Source contiguous transfer count between successive gather boundaries. |

DSR

The Destination Scatter register contains two fields:

- Destination scatter count field (DSRx.DSC) - Specifies the number of contiguous destination transfers of **CTL.DST_TR_WIDTH** between successive scatter boundaries.
- Destination scatter interval field (DSRx.DSI) - Specifies the destination address increment/decrement in multiples of **CTL.DST_TR_WIDTH** on a scatter boundary when scatter mode is enabled for the destination transfer.

The **CTL.DINC** field controls whether the address increments or decrements. When the **CTL.DINC** field indicates a fixed address control, then the address remains constant throughout the transfer and the DSR register is ignored. For more information, see [Section 5.2.7](#).

GPDMA0_CHx_DSR (x=0-1)

Destination Scatter Register for Channel x

(50_H + x*58_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|---------|------|--|
| DSI | [19:0] | rw | Destination scatter interval |
| DSC | [31:20] | rw | Destination scatter count Destination contiguous transfer count between successive scatter boundaries. |

5.8.3 Interrupt Registers

The following sections describe the registers pertaining to interrupts, their status, and how to clear them. For each channel, there are five types of interrupt sources:

- **IntBlock** - Block Transfer Complete Interrupt. This interrupt is generated on DMA block transfer completion to the destination peripheral.
- **IntDstTran** - Destination Transaction Complete Interrupt
 This interrupt is generated after completion of the last AHB transfer of the requested single/burst transaction from the handshaking interface (either the hardware or software handshaking interface) on the destination side.

Note: If the destination for a channel is memory, then that channel will never generate the IntDstTran interrupt. Because of this, the corresponding bit in this field will not be set.

- **IntErr** - Error Interrupt
 This interrupt is generated when an ERROR response is received from an AHB slave on the HRESP bus during a DMA transfer. In addition, the DMA transfer is cancelled and the channel is disabled.
- **IntSrcTran** - Source Transaction Complete Interrupt
 This interrupt is generated after completion of the last AHB transfer of the requested single/burst transaction from the handshaking interface (either the hardware or software handshaking interface) on the source side.

Note: If the source or destination is memory, then IntSrcTran/IntDstTran interrupts should be ignored, as there is no concept of a "DMA transaction level" for memory.

- **IntTfr** - DMA Transfer Complete Interrupt
 This interrupt is generated on DMA transfer completion to the destination peripheral.

There are several groups of interrupt-related registers:

- **Interrupt Raw Status Registers**
- **Interrupt Status Registers**
- **Interrupt Mask Registers**
- **Interrupt Clear Registers**
- **Combined Interrupt Status Register**

When a channel has been enabled to generate interrupts, the following is true:

- Interrupt events are stored in the Raw Status registers.
- The contents of the Raw Status registers are masked with the contents of the Mask registers.
- The masked interrupts are stored in the Status registers.
- The contents of the Status registers are used to drive the int_* port signals.
- Writing to the appropriate bit in the Clear registers clears an interrupt in the Raw Status registers and the Status registers on the same clock cycle.

General Purpose DMA (GPDMA)

The contents of each of the five Status registers is ORed to produce a single bit for each interrupt type in the Combined Status register; that is, STATUSINT.

Note: For interrupts to propagate past the raw interrupt register stage, **CTL.INT_EN** must be set to 1_B, and the relevant interrupt must be unmasked in the mask* interrupt register.*

Interrupt Raw Status Registers

Interrupt events are stored in these Raw Interrupt Status registers before masking: RAWBLOCK, RawDstTran, RawErr, RawSrcTran, and RAWTFR. Each Raw Interrupt Status register has a bit allocated per channel; for example, RAWTFR[2] is the Channel 2 raw transfer complete interrupt.

Each bit in these registers is cleared by writing a 1 to the corresponding location in the CLEARTRF, CLEARBLOCK, CLEARSRCTRAN, CLEARDSTTRAN, CLEARERR registers.

Note: Write access is available to these registers for software testing purposes only. Under normal operation, writes to these registers are not recommended.

RAWTFR

Raw DMA Transfer Complete Interrupt Status.

RAWBLOCK

Raw Block Transfer Complete Interrupt Status.

RAWSRCTRAN

Raw Source Transaction Complete Interrupt Status.

RAWDSTTRAN

Raw Destination Transaction Complete Interrupt Status.

RAWERR

Raw Error Interrupt Status.

|------------------------------|--------|------|---|
| CHx (x=0-3) | x | rw | Raw Interrupt Status for channel x |
| 0 | [31:4] | r | Reserved |

Interrupt Status Registers

All interrupt events from all channels are stored in these Interrupt Status registers after masking: STATUSBLOCK, STATUSDSTTRAN, STATUSERR, STATUSSRCTRAN, and STATUSTFR. Each Interrupt Status register has a bit allocated per channel; for example, STATUSTFR[2] is the Channel 2 status transfer complete interrupt. The contents of these registers are used to generate the interrupt signals (int or int_n bus, depending on interrupt polarity) leaving the GPDMA.

STATUSTFR

DMA Transfer Complete Interrupt Status.

STATUSBLOCK

Block Transfer Complete Interrupt Status.

STATUSSRCTRAN

Source Transaction Complete Interrupt Status.

STATUSDSTTRAN

Block Transfer Complete Interrupt Status.

STATUSERR

Error Interrupt Status.

Interrupt Mask Registers

The contents of the Raw Status registers are masked with the contents of the Mask registers: MASKBLOCK, MASKDSTTRAN, MASKERR, MASKSRCTRAN, and MASKTFR. Each Interrupt Mask register has a bit allocated per channel; for example, MASKTFR[2] is the mask bit for the Channel 2 transfer complete interrupt.

When the source peripheral of DMA channel *i* is memory, then the source transaction complete interrupt, MASKSRCTRAN[*z*], must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel *i* is memory, then the destination transaction complete interrupt, MASKDSTTRAN[*i*], must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal.

A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same AHB write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MASKTFR register writes a 1 into MASKTFR[0], while MASKTFR[7:1] remains unchanged. Writing hex 00xx leaves MASKTFR[7:0] unchanged.

Writing a 1 to any bit in these registers unmask the corresponding interrupt, thus allowing the GPDMA to set the appropriate bit in the Status registers and int_* port signals.

MASKTFR

Mask for Raw DMA Transfer Complete Interrupt Status.

MASKBLOCK

Mask for Raw Block Transfer Complete Interrupt Status.

MASKSRCTRAN

Mask for Raw Source Transaction Complete Interrupt Status.

MASKDSTTRAN

Mask for Raw Block Transfer Complete Interrupt Status.

MASKERR

Interrupt Clear Registers

Each bit in the Raw Status and Status registers is cleared on the same cycle by writing a 1 to the corresponding location in the Clear registers: CLEARBLOCK, CLEARSTTRAN, CLEARERR, CLEARSRCTAN, and CLEARTFR. Each Interrupt Clear register has a bit allocated per channel; for example, CLEARTFR[2] is the clear bit for the Channel 2 transfer complete interrupt. Writing a 0 has no effect. These registers are not readable.

CLEARTFR

Clear DMA Transfer Complete Interrupt Status and Raw Status.

CLEARBLOCK

Clear Block Transfer Complete Interrupt Status and Raw Status.

CLEARSRCTAN

Clear Source Transaction Complete Interrupt Status and Raw Status.

CLEARSTTRAN

Clear Block Transfer Complete Interrupt Status and Raw Status.

CLEARERR

| DSTT | 3 | r | OR of the contents of STATUSDSTTRAN register |
| ERR | 4 | r | OR of the contents of STATUSERR register |
| 0 | [31:5] | r | Reserved |

5.8.4 Software Handshaking Registers

The registers that comprise the software handshaking registers allow software to initiate single or burst transaction requests in the same way that handshaking interface signals do in hardware.

Setting **CFG.HS_SEL_SRC** to 1 enables software handshaking on the source of channel x. Setting **CFG.HS_SEL_DST** to 1 enables software handshaking on the destination of channel x.

REQSRCREG

A bit is assigned for each channel in this register. REQSRCREG[n] is ignored when software handshaking is not enabled for the source of channel n.

A channel SRC_REQ bit is written only if the corresponding channel write enable bit in the SRC_REQ_WE field is asserted on the same AHB write transfer, and if the channel is enabled in the **CHENREG** register. For example, writing hex 0101 writes a 1 into REQSRCREG[0], while REQSRCREG[7:1] remains unchanged. Writing hex 00xx leaves REQSRCREG[7:0] unchanged. This allows software to set a bit in the REQSRCREG register without performing a read-modified write operation.

The functionality of this register depends on whether the source is a flow control peripheral or not.

GPDMA0_REQSRCREG

Source Software Transaction Request Register

| WE_CHx (x=0-3) | 8+x | w | Source request write enable for channel x 0 _B write disabled 1 _B write enabled |
| 0 | [31:12], [7:4] | r | Reserved |

SGLREQDSTREG

A bit is assigned for each channel in this register. SGLREQDSTREG[n] is ignored when software handshaking is not enabled for the destination of channel n.

A channel DST_SGLREQ bit is written only if the corresponding channel write enable bit in the DST_SGLREQ_WE field is asserted on the same AHB write transfer, and if the channel is enabled in the **CHENREG** register.

The functionality of this register depends on whether the destination is a flow control peripheral or not.

VERSION

This is the GPDMA Component Version register, which is a read-only register that specifies the version of the packaged component.

GPDMA0_VERSION

DMA Component Version (3FC_H) **Reset Value: 3231 342A_H**

GPDMA1_VERSION

DMA Component Version (3FC_H) **Reset Value: 3231 342A_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| VALUE | [31:0] | r | Version number of the component |

6 Flexible CRC Engine (FCE)

The FCE provides a parallel implementation of Cyclic Redundancy Code (CRC) algorithms. The current FCE version for the XMC4[78]00 microcontroller implements the IEEE 802.3 ethernet CRC32, the CCITT CRC16 and the SAE J1850 CRC8 polynomials. The primary target of FCE is to be used as an hardware acceleration engine for software applications or operating systems services using CRC signatures.

The FCE operates as a standard peripheral bus slave and is fully controlled through a set of configuration and control registers. The different CRC algorithms are independent from each other, they can be used concurrently by different software tasks.

Note: The FCE kernel register names described in “Registers” on Page 6-11 are referenced in a product Reference Manual by the module name prefix “FCE_”.

6.1 Overview

This section provides an overview of the features, applications and architecture of the FCE module.

6.1.1 Features

The FCE provides the following features:

- The FCE implements the following CRC polynomials:

Flexible CRC Engine (FCE)

- CRC kernel 0 and 1: IEEE 802.3 CRC32 ethernet polynomial: $0x04C11DB7^{1)}$ - $x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$
- CRC kernel 2: CCITT CRC16 polynomial: $0x1021$ - $x^{16}+x^{12}+x^5+1$
- CRC kernel 3: SAE J1850 CRC8 polynomial: $0x1D$ - $x^8+x^4+x^3+x^2+1$
- Parallel CRC implementation
 - Data blocks to be computed by FCE shall be a multiple of the polynomial degree
 - Start address of Data blocks to be computed by FCE shall be aligned to the polynomial degree
- Register Interface:
 - Input Register
 - CRC Register
 - Configuration Registers enabling to control the CRC operation and perform automatic checksum checks at the end of a message.
 - Extended register interface to control reliability of FCE execution in safety applications.
- Error notification scheme via dedicated interrupt node for:
 - Transient error detection: error interrupt generation (maskable) with local status register (cleared by software)
 - Checksum failure: error interrupt generation (maskable) with local status register (cleared by software)
- FCE provides one interrupt line to the interrupt system. Each CRC engine has its own set of flag registers.

6.1.2 Application Mapping

Among other applications, CRC algorithms are commonly used to calculate message signatures to:

- Check message integrity during transport over communication channels like internal buses or interfaces between microcontrollers
- Sign blocks of data residing in variable or invariable storage elements
- Compute signatures for program flow monitoring

One important property to be taken into account by the application when choosing a polynomial is the hamming distance: see [Section 6.9](#).

6.1.3 Block Diagram

The FCE is a standard peripheral slave module which is controlled over a set of memory mapped registers. The FCE is fully synchronous with the CPU clock and runs with a 1:1 clock ratio.

1) The polynomial hexadecimal representation covers the coefficients (degree - 1) down to 0.

Flexible CRC Engine (FCE)

Depending on the hardware configuration the FCE may implement more CRC kernels with different CRC polynomials. The specific configuration for the XMC4[78]00 microcontroller is shown in the **Figure 6-1 “FCE Block Diagram” on Page 6-3**.

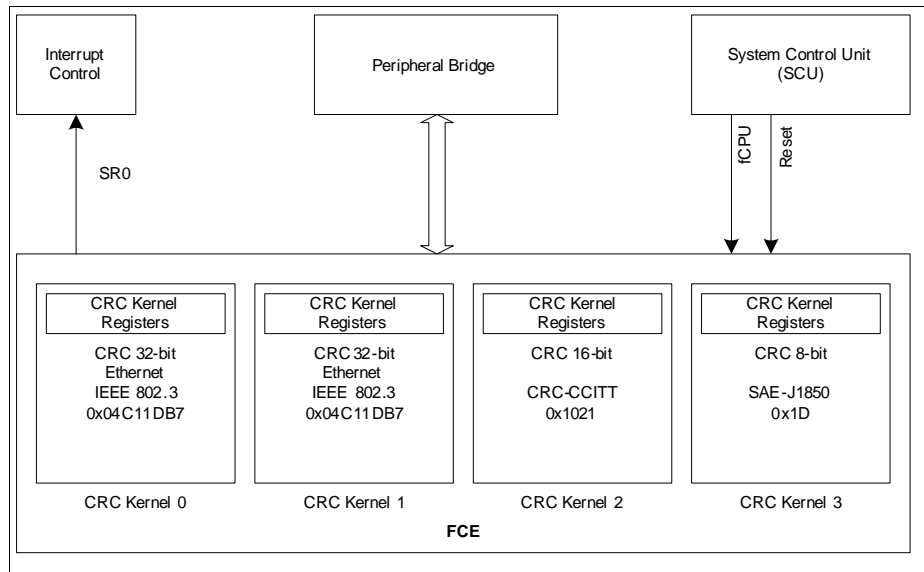

Figure 6-1 FCE Block Diagram

Every CRC kernel will present the same hardware and software architecture. The rest of this document will focus only on the description of the generic CRC kernel architecture.

In a multi-kernel implementation the interrupt lines are ored together, the FCE only presents a single interrupt node to the system. Each CRC kernel implements a status register that enables the software to identify which interrupt source is active. Please refer to the **STSm (m = 0-3)** register for a detailed description of the status and interrupt handling.

6.2 Functional Description

A checksum algorithm based on CRC polynomial division is characterized by the following properties:

1. polynomial degree (e.g. 32, that represents the highest power of two of the polynomial)
2. polynomial (e.g. 0x04C11DB7: the 33rd bit is omitted because always equal to 1)
3. init value: the initial value of the CRC register

Flexible CRC Engine (FCE)

4. input data reflected: indicates if each byte of the input parallel data is reflected before being used to compute the CRC
5. result data reflected: indicates if the final CRC value is reflected or not
6. XOR value: indicates if a final XOR operation is done before returning the CRC result

All the properties are fixed once a polynomial has been chosen. However the FCE provides the capability to control the two reflection steps and the final XOR through the CFG register. The reset values are compatible with the implemented algorithm. The final XOR control enables to select either 0xFFFFFFFF or 0x00000000 to be XORed with the POST_CRC1 value. These two values are those used by the most common CRC polynomials.

Note: The reflection steps and final XOR do not modify the properties of the CRC algorithm in terms of error detection, only the CRC final signature is affected.

The next two figures provides an overview of the control and status features of a CRC kernel.

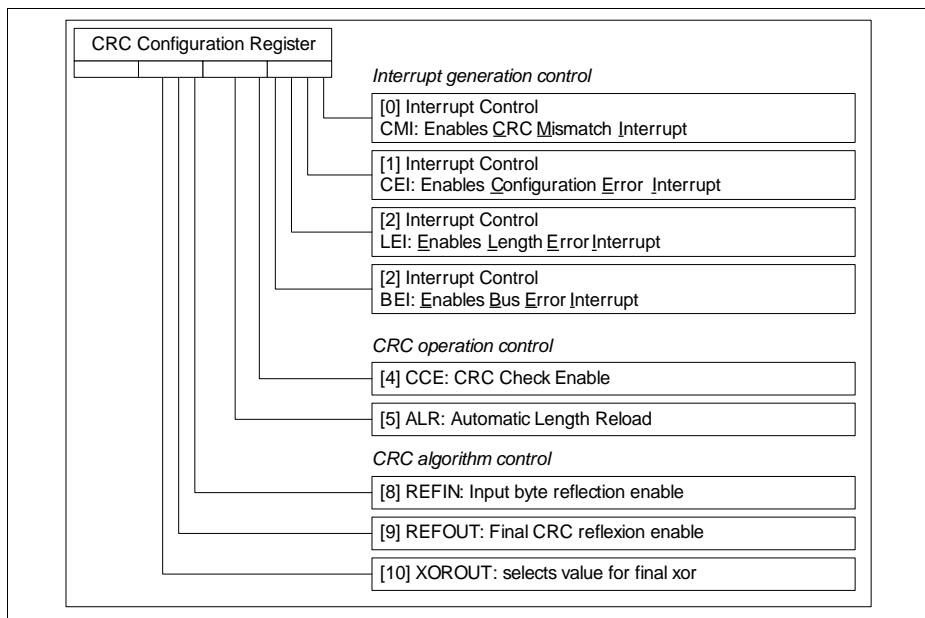

Figure 6-2 CRC kernel configuration register

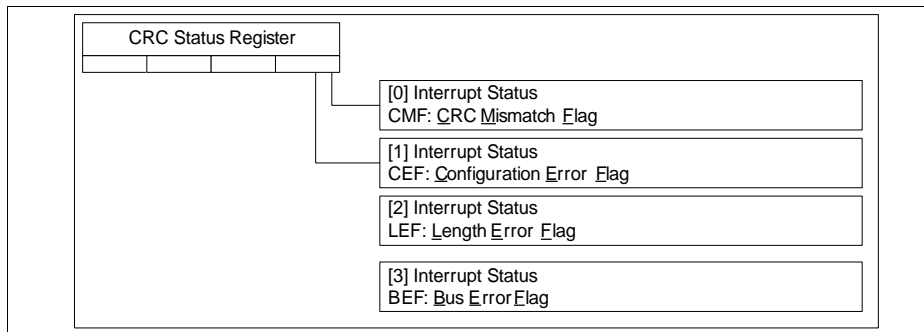

Figure 6-3 CRC kernel status register

6.2.1 Basic Operation

The software must first ensure that the CRC kernel is properly configured, especially the initial CRC value written via the **CRC** register. Then, it writes as many times as necessary into the **IR** register according to the length of the message. The resulting signature is stored in the CRC engine result register, **RESm**, which can be read by the software.

Depending on the CRC kernel accesses by software the following rules apply:

- When accessing a CRC kernel of degree <N> only the bits N-1 down to 0 are used by the CRC kernel. The upper bits are ignored on write. When reading from a CRC kernel register the non-used upper bits are set to 0.

6.2.2 Automatic Signature Check

The automatic signature check compares the signature at the end of a message with the expected signature configured in the **CHECK** register. In case of a mismatch, an event is generated (see [Section 6.3](#)). This feature is enabled by the **CFG.CCE** bit field (see **CFGm (m = 0-3)** register).

If the software wishes to use this feature, the **LENGTH** register and **CHECK** registers must be configured with respectively the length as number of words of the message and the expected signature (**CHECK**). The word length is defined by the degree of the polynomial used. The **CHECK** value takes into account the final CRC reflection and XOR operation.

When the **CFG.CCE** bit field is set, every time the **IR** register is written, the **LENGTH** register is decremented by one until it reaches zero. The hardware monitors the transition of the **LENGTH** register from 1 to 0 to detect the end of the message and proceed with the comparison of the result register **RESvalue** with the **CHECK** register value. If the automatic length reload feature is enabled by the **CFG.ALR** bit field (see

Flexible CRC Engine (FCE)

CFGm (m = 0-3)), the LENGTH register is reinitialized with the previously configured value. This feature is especially suited when the FCE is used in combination with a DMA engine.

In the case the automatic length reload feature is not enabled, if LENGTH is already at zero but software still writes to IR (by mistake) every bit of the LENGTH should be set to 1 and hold this value until software initializes it again for the processing of a new message. In such case the STS.LEF (Length Error Flag) should be set and an interrupt generated if the CFG.LEI (Length Error Interrupt) is set.

Usually, the CRC signature of a message M0 is computed and appended to M0 to form the message M1 which is transmitted. One interesting property of CRCs is that the CRC signature of M1 shall be zero. This property is particularly useful when automatically checking the signature of data blocks of fixed length with the automatic length reload enabled. LENGTH should be loaded with the length of M1 and CHECK with 0.

6.2.3 Register protection and monitoring methods

Register Monitoring: applied to CFG and CHECK registers

Because CFG and CHECK registers are critical to the CRC operation, some mechanisms to detect and log transient errors are provided. Early detection of transient failures enables to improve the failure detection time and assess the severity of the failure. The monitoring mechanisms are implemented using two redundant instances as presented in [Figure 6-4](#).

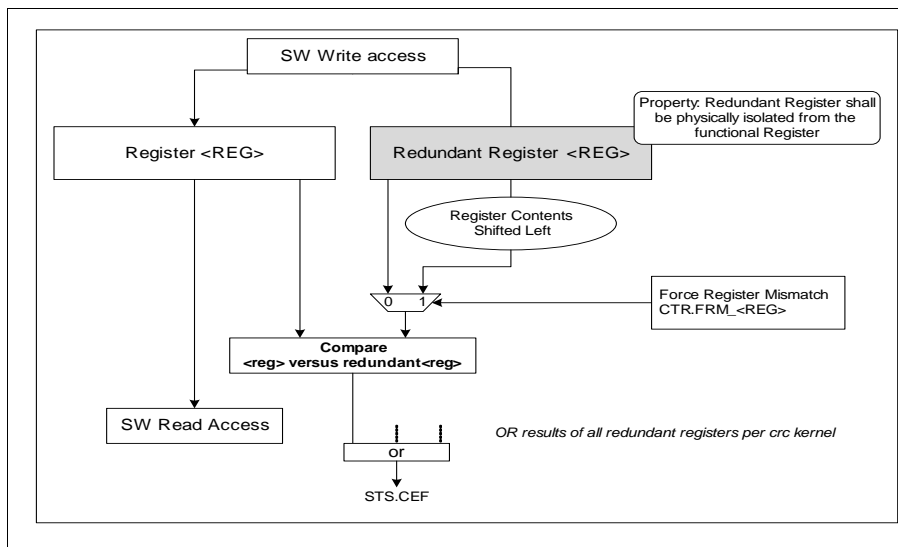

Figure 6-4 Register monitoring scheme

Let <REG> designate either CFG or CHECK registers. When a write to <REG> takes place the redundant register is also updated. **Redundant registers are not visible to software.** Bits of <REG> reserved have no storage and are not used for redundancy. A compare logic continuously compares the two stored values and provides a signal that indicates if the compare is successful or not. The result of all compare blocks are or'd together to provide a single flag information. If a mismatch is detected the **STS.CEF** (Configuration Error Flag) bit is set. For run-time validation of the compare logic a Force Register Mismatch bit field (**CTR.FRM_<REG>**) is provided. When set to 1 by software the contents of the redundant register is shifted left by one bit position (redundant bit 0 position is always replaced by a logical 0 value) and is given to the compare logic instead of the redundant register value. This enables to check the compare logic is functional. Using a walking bit pattern, the software can completely check the full operation of the compare logic. Software needs to clear the **CTR.FRM_<REG>** bit to '0' to be able to trigger again a new comparison error interrupt.

Register Access Protection: applies to LENGTH and CHECK registers

In order to reduce the probability of a mis-configuration of the CHECK and LENGTH registers (in the case the automatic check is used), the write access to the CHECK and LENGTH registers must follow a procedure:

Let <REG> designate **CHECK** or **LENGTH** registers. Before being able to configure a new <value> value into the <REG> register of a CRC kernel, software must first write the

Flexible CRC Engine (FCE)

0xFACECAFE value to the <REG> address. The 0xFACECAFE is not written into the <REG> register. The next write access will proceed as a normal bus write access. The write accesses shall use full 32-bit access only. This procedure will then be repeated every time software wants to configure a new <REG> value. If software reads the CHECK register just after writing 0xFACECAFE it returns the current <REG> contents and not 0xFACECAFE. **A read access to <REG> has no effect on the protection mechanism.**

The following C-code shows write accesses to the CHECK and LENGTH registers following this procedure:

```
//set CHECK register
FCE_CHECK0.U = 0xFACECAFE;
FCE_CHECK0.U = 0;

//set LENGTH register
FCE_LENGTH0.U = 0xFACECAFE;
FCE_LENGTH0.U = 256;
```

6.3 Service Request Generation

Each FCE CRC kernel provides one internal interrupt source. The interrupt lines from each CRC kernel are ored together to be sent to the interrupt system. The system interrupt is an active high pulse with the duration of one cycle (of the peripheral clock). The FCE interrupt handler can use the status information located within the **STS** status register of each CRC kernel.

Each CRC kernel provides the following interrupt sources:

- CRC Mismatch Interrupt controlled by **CFG.CMI** bit field and observable via the status bit field **STS.CMF** (CRC Mismatch Flag).
- Configuration Error Interrupt controlled by **CFG.CEI** bit field and observable via the status bit field **STS.CEF** (Configuration Error Flag).
- Length Error Interrupt controlled by **CFG.LEI** bit field and observable via the status bit field **STS.LEF** (Length Error Flag).
- Bus Error Interrupt controlled by **CFG.BEI** bit field and observable via the status bit field **STS.BEF** (Bus Error Flag).

Interrupt generation rules

- A status flag shall be cleared by software by writing a **1** to the corresponding bit position.
- If an status flag is set and a new hardware condition occurs, no new interrupt is generated by the kernel: the STS.<FLAG> bit field masks the generation of a new

Flexible CRC Engine (FCE)

interrupt from the same source. If a SW access to clear the interrupt status bit takes place and in the same cycle the hardware wants to set the bit, the hardware condition wins the arbitration.

As all the interrupts are caused by an error condition, the interrupt shall be handled by a Error Management software layer. The software services using the FCE as acceleration engine may not directly deal with error conditions but let the upper layer using the service to deal with the error handling.

6.4 Debug Behavior

The FCE has no specific debug feature.

6.5 Power, Reset and Clock

The FCE is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) section.

A power down mode can be achieved by disabling the module using the **Clock Control Register (CLC)**.

The FCE module has one reset source. This reset source is handled at system level and it can be generated independently via a system control register (address SCU section for full description).

After release, the complete IP is set to default configuration. The default configuration for each register field is addressed on **Section 6.7**.

The FCE uses the CPU clock, fCPU (address SCU section for more details on clocking).

6.6 Initialization and System Dependencies

The FCE may have dependencies regarding the bus clock frequency. This dependencies should be addressed in the SCU and System Architecture sections.

Initialization:

The FCE is enabled by writing 0x0 to the CLC register. Software must first ensure that the CRC kernel is properly configured, especially the initial CRC register value written via the CRC register, the input and result reflection as well as the final xored value via the CFG register. The following source code is an example of initialization for the basic operation of the FCE kernel 0:

```
//enable FCE
FCE_CLC.U = 0x0;
//final result to be xored with 0xFFFFFFFF, no reflection
```

```
FCE_CFG0.U = 0x400;  
//set CRC initial value (seed)  
FCE_CRC0.U = 0xFFFFFFFF;
```

6.7 Registers

Table 6-3 show all registers associated with a FCE CRC-kernel. All FCE kernel register names are described in this section. They should get the prefix "FCE_" when used in the context of a product specification.

The registers are numbered by one index to indicate the related FCE CRC Kernel ($m = 0-3$). Some kernel registers are adapted to the degree of the polynomial implemented by the kernel.

Table 6-2 Registers Address Space - FCE Module

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| FCE | 5002 0000 _H | 5002 3FFF _H | |

- 1) The absolute register byte address for each CRC kernel m is calculated as follows:
CRC kernel register base Address (Table 6-2) + $m \times 20H$, $m = 0-3$

Disabling the FCE

The FCE module can be disabled using the **CLC** register.

When the disable state is requested all pending transactions running on the bus slave interface must be completed before the disabled state is entered. The CLC Register Module Disable Bit Status CLC.DISS indicates whether the module is currently disabled (DISS == 1). Any attempt to write any register with the exception of the CLC Register will generate a bus error. A read operation is allowed and does not generate a bus error.

6.7.1 System Registers description

This section describes the registers related to the product system architecture.

Clock Control Register (CLC)

The Clock Control Register allows the programmer to adapt the functionality and power consumption of the module to the requirements of the application.

CLC

Clock Control Register (00_H) **Reset Value: 0000 0003_H**

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| DISR | 0 | rw | Module Disable Request Bit Used for enable/disable control of the module. |
| DISS | 1 | rh | Module Disable Status Bit Bit indicates the current status of the module. |
| 0 | [31:2] | r | Reserved Read as 0; should be written with 0. |

Module Identification Register

ID

Module Identification Register (08_H) **Reset Value: 00CA C001_H**

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number This bit field defines the module revision number. The value of a module revision starts with 01 _H (first revision). The current revision number is 01 _H . |
| MOD_TYPE | [15:8] | r | Module Type The bit field is set to C0 _H which defines the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines a module identification number. The value for the FCE module is 00CA _H . |

6.7.2 CRC Kernel Control/Status Registers

CRC Engine Input Register

IRm (m = 0-1)

Input Register m (20_H + m*20_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| IR | [31:0] | rw | Input Register This bit field holds the 32-bit data to be computed |

A write to IRm triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Only 32-bit write transactions are allowed to this IRm registers, any other bus write transaction will lead to a Bus Error.

CRC Engine Input Register

IRm (m = 2-2)

Input Register m

(20_H + m*20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| IR | [15:0] | rw | Input Register This bit field holds the 16-bit data to be computed |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

A write to IRm triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Only 32-bit or 16-bit write transactions are allowed to this IRm register, any other bus write transaction will lead to a Bus Error. Only the lower 16-bit of the write transactions will be used.

CRC Engine Input Register

IRm (m = 3-3)

Input Register m

(20_H + m*20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|---|
| IR | [7:0] | rw | Input Register This bit field holds the 8-bit data to be computed |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

A write to IR_m triggers the CRC kernel to update the message checksum according to the IR contents and to the current CRC register contents. Any write transaction is allowed to this IR_m register. Only the lower 8-bit of the write transactions will be used.

CRC Engine Result Register

RES_m (m = 0-1)

CRC Result Register m (24_H + m*20_H) **Reset Value: FFFF FFFF_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| RES | [31:0] | rh | Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect. |

CRC Engine Result Register

RES_m (m = 2-2)

CRC Result Register m (24_H + m*20_H) **Reset Value: 0000 FFFF_H**

| Field | Bits | Type | Description |
|------------|---------|------|---|
| RES | [15:0] | rh | Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Result Register

RESm (m = 3-3)

CRC Result Register m $(24_H + m \cdot 20_H)$ **Reset Value: 0000 00FF_H**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|--|--|--|--|--|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | | | |
| 0 | | | | | | | | | | | | | | | | | | | | | | | | RES | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | | | | | | | | | | rh | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|------------|--------|------|---|
| RES | [7:0] | rh | Result Register Returns the final CRC value including CRC reflection and final XOR according to the CFG register configuration. Writing to this register has no effect. |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Configuration Register

CFGm (m = 0-3)

CRC Configuration Register m

(28_H + m*20_H)

Reset Value: 0000 0700_H

| Field | Bits | Type | Description |
|-------|------|------|---|
| CMI | 0 | rw | CRC Mismatch Interrupt 0 _B CRC Mismatch Interrupt is disabled 1 _B CRC Mismatch Interrupt is enabled |
| CEI | 1 | rw | Configuration Error Interrupt When enabled, a Configuration Error Interrupt is generated whenever a mismatch is detected in the CFG and CHECK redundant registers. 0 _B Configuration Error Interrupt is disabled 1 _B Configuration Error Interrupt is enabled |
| LEI | 2 | rw | Length Error Interrupt When enabled, a Length Error Interrupt is generated if software writes to IR register with LENGTH equal to 0 and CFG.CCE is set to 1. 0 _B Length Error Interrupt is disabled 1 _B Length Error Interrupt is enabled |
| BEI | 3 | rw | Bus Error Interrupt When enabled, an interrupt is generated if a bus write transaction with an access width smaller than the kernel width is issued to the input register. 0 _B Bus Error Interrupt is disabled 1 _B Bus Error Interrupt is enabled |

Flexible CRC Engine (FCE)

| Field | Bits | Type | Description |
|---------------|-------------------|------|---|
| CCE | 4 | rw | CRC Check Comparison 0 _B CRC check comparison at the end of a message is disabled 1 _B CRC check comparison at the end of a message is enabled |
| ALR | 5 | rw | Automatic Length Reload 0 _B Disables automatic reload of the LENGTH field. 1 _B Enables automatic reload of the LENGTH field at the end of a message. |
| REFIN | 8 | rw | IR Byte Wise Reflection 0 _B IR Byte Wise Reflection is disabled 1 _B IR Byte Wise Reflection is enabled |
| REFOUT | 9 | rw | CRC 32-Bit Wise Reflection 0 _B CRC 32-bit wise is disabled 1 _B CRC 32-bit wise is enabled |
| XSEL | 10 | rw | Selects the value to be xored with the final CRC 0 _B 0x00000000 1 _B 0xFFFFFFFF |
| 0 | [7:6], [31:11] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Status Register

STSm (m = 0-3)

CRC Status Register m

($2C_H + m \cdot 20_H$)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|--|
| CMF | 0 | rwh | CRC Mismatch Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. |
| CEF | 1 | rwh | Configuration Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. |
| LEF | 2 | rwh | Length Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. |
| BEF | 3 | rwh | Bus Error Flag This bit is set per hardware only. To clear this bit, software must write a 1 to this bit field location. Writing 0 per software has no effect. |
| 0 | [31:4] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Length Register

LENGTH_m (m = 0-3)

CRC Length Register m

(30_H + m*20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|---------|------|---|
| LENGTH | [15:0] | rwh | Message Length Register Number of words building the message over which the CRC checksum is calculated. This bit field is modified by the hardware: every write to the IR register decrements the value of the LENGTH bit field. If the CFG.ALAR field is set to 1, the LENGTH field shall be reloaded with its configuration value at the end of the cycle where LENGTH reaches 0. |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Check Register

CHECK_m (m = 0-1)

CRC Check Register m

(34_H + m*20_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| CHECK | [31:0] | rw | CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field |

CRC Engine Check Register
CHECK_m (m = 2-2)
CRC Check Register m
(34_H + m*20_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| CHECK | [15:0] | rw | CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Check Register
CHECK_m (m = 3-3)
CRC Check Register m
(34_H + m*20_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| CHECK | [7:0] | rw | CHECK Register Expected CRC value to be checked by the hardware upon detection of a 1 to 0 transition of the LENGTH register. The comparison is enabled by the CFG.CCE bit field |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Initialization Register

CRCm (m = 0-1)

CRC Register m $(38_H + m*20_H)$ **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| CRC | [31:0] | rwh | CRC Register This register enables to directly access the internal CRC register |

CRC Engine Initialization Register

CRCm (m = 2-2)

CRC Register m $(38_H + m*20_H)$ **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|---------|------|---|
| CRC | [15:0] | rwh | CRC Register This register enables to directly access the internal CRC register |
| 0 | [31:16] | r | Reserved Read as 0; should be written with 0. |

CRC Engine Initialization Register

CRCm (m = 3-3)

CRC Register m (38_H + m*20_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| CRC | [7:0] | rwh | CRC Register This register enables to directly access the internal CRC register |
| 0 | [31:8] | r | Reserved Read as 0; should be written with 0. |

CRC Test Register

CTRM (m = 0-3)

CRC Test Register m (3C_H + m*20_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|------|------|--|
| FCM | 0 | rw | Force CRC Mismatch Forces the CRC compare logic to issue an error regardless of the CHECK and CRC values. The hardware detects a 0 to 1 transition of this bit field and triggers a CRC Mismatch interrupt |

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| FRM_CFG | 1 | rw | Force CFG Register Mismatch This field is used to control the error injection mechanism used to check the compare logic of the redundant CFG registers. This is a one shot operation. When the hardware detects a 0 to 1 transition of this bit field it triggers a Configuration Mismatch interrupt (if enabled by the corresponding CFGm register). |
| FRM_CHECK | 2 | rw | Force Check Register Mismatch This field is used to control the error injection mechanism used to check the compare logic of the redundant CHECK registers. This is a one shot operation. The hardware detects a 0 to 1 transition of this bit field and triggers a Check Register Mismatch interrupt (if enabled by the corresponding CFGm register). |
| 0 | [31:3] | r | Reserved Read as 0; should be written with 0. |

6.8 Interconnects

The interfaces of the FCE module shall be described in the module design specification. The [Table 6-4](#) shows the services requests of the FCE module.

Table 6-4 FCE Service Requests

| Inputs/Outputs | I/O | Connected To | Description |
|----------------|-----|--------------|----------------------|
| FCE.SR0 | O | NVIC | Service request line |

6.9 Properties of CRC code

Hamming Distance

The Hamming distance defines the error detection capability of a CRC polynomial. A cyclic code with a Hamming Distance of D can detect all D-1 bit errors. [Table 6-5 “Hamming Distance as a function of message length \(bits\)” on Page 6-25](#) shows the dependency of the Hamming Distance with the length of the message.

Table 6-5 Hamming Distance as a function of message length (bits)¹⁾

| Hamming Distance | IEEE-802.3 CRC32 | CCITT CRC16 | J1850 CRC8 |
|------------------|------------------|---------------------------|---------------------------|
| 15 | 8 - 10 | Information not available | Information not available |

On-Chip Memories

7 Memory Organization

This chapter provides description of the system Memory Organization and basic information related to Parity Testing and Parity Error handling.

References

[8] Cortex™-M4 User Guide, ARM DUI 0508B (ID062910)

7.1 Overview

The Memory Map is intended to balance decoding cost at various level of the system bus infrastructure.

7.1.1 Features

The Memory Map implements the following features:

- Compatibility with standard ARM Cortex-M4 CPU [\[8\]](#)
- Compatibility across entire XMC4000 Family
- Optimal functional module address spaces grouping

7.1.2 Cortex-M4 Address Space

The system memory map defines several regions. Address boundaries of each of the regions are determined by the Cortex-M4 core architecture.

7.2 Memory Regions

The XMC4[78]00 device specific address map assumes presence of internal and external memories and peripherals. The memory regions for XMC4[78]00 are described in [Table 7-1](#).

Table 7-1 Memory Regions

| Start | End | Size (hex) | Space name | Usage |
|----------|-----------|------------|---------------------------|------------------------------------|
| 00000000 | 1FFFFFFF | 20000000 | Code | Boot ROM Flash Program SRAM |
| 20000000 | 3FFFFFFF | 20000000 | SRAM | Fast internal SRAMs |
| 40000000 | 47FFFFFFF | 08000000 | Peripheral 0 | Internal Peripherals group 0 |
| 48000000 | 4FFFFFFF | 08000000 | Peripheral 1 | Internal Peripherals group 1 |
| 50000000 | 57FFFFFFF | 08000000 | Peripheral 2 | Internal Peripherals group 2 |
| 58000000 | 5FFFFFFF | 08000000 | Peripheral 3 | Internal Peripherals group 3 |
| 60000000 | 9FFFFFFF | 40000000 | External SRAM | External Memories |
| A0000000 | DFFFFFFF | 40000000 | External Device | External Devices |
| E0000000 | E0FFFFFFF | 00100000 | Private Peripheral Bus | CPU |
| E0100000 | FFFFFFF | 0FF00000 | Vedor specific 1 | reserved |
| F0000000 | FFFFFFF | 10000000 | Vedor specific 2 | reserved |

7.3 Memory Map

[Table 7-2](#) defines detailed system memory map of XMC4[78]00 where each individual peripheral or memory instance implement its own address spaces. For detailed register description of the system components and peripherals please refer to respective chapters of this document.

Table 7-2 Memory Map

| Addr space | Start Address (hex) | End Address (hex) | Modules |
|------------|---------------------|-------------------|----------------------|

7.4 Service Request Generation

Memory modules and other system components are capable of generating error responses indicated to the CPU as bus error exceptions or interrupts.

Types of error causes

- Unsupported Access Mode
- Access to Invalid Address
- Parity Error (memories only)
- Bufferable Write Access to Peripheral

Errors that cannot be indicated with bus errors get indicated with service requests that get propagated to the CPU as interrupts. Typically lack of bus error response capability applies to memory modules that lack of direct access from the system bus This applies to memories that serve the purpose of internal FIFOs and local storage buffers.

Unsupported Access Modes

Unsupported access modes can be classified in various ways and are usually specific to the module that access is performed to. The typical examples of unsupported access modes are read access to write-only or write access to read-only type of address mapped resources, unsupported access data widths, protected memory regions. For module specific limitations please refer to individual module chapters.

Invalid Address

Accesses to invalid addresses result in error responses. Invalid addresses are defined as those that do not mapped to any valid resources. This applies to single addresses and to wider address ranges. Some invalid addresses within valid module address ranges may not produce error responses and this is specific to individual modules.

Parity Errors

Parity test is performed on the XMC4[78]00 memories in normal functional mode. Parity errors are generated in case of failure of parity test performed inside of each of the memory module. The mechanism of parity testing depends on memory data width and access mode, i.e. memory modules that are accessible byte-wise implement parity check for each data byte individually while for memory modules that are accessible double-word-wise it is sufficient to perform joint check for all bits.

The occurrence of a parity error gets signaled to the system with system bus error or an interrupt (parity trap). For details on parity error generation control and handling please refer to the SCU chapter. For more details please refer to [Table 7-3](#).

Table 7-3 Parity Test Enabled Memories and Supported Parity Error Indication

| Memory | Number of Parity Bits | Parity Test Granularity | Bus Error | Parity Trap |
|-----------------------------|-----------------------|-------------------------|-----------|-------------|
| Program SRAM (PSRAM) | 1 | 4 bytes | yes | yes |
| System SRAM (DSRAM1) | 4 | 1 byte | yes | yes |
| Communication SRAM (DSRAM2) | 4 | 1 byte | yes | yes |
| USIC 0 Buffer Memory | 1 | 4 bytes | no | yes |
| USIC 1 Buffer Memory | 1 | 4 bytes | no | yes |
| USIC 2 Buffer Memory | 1 | 4 bytes | no | yes |
| USIC 3 Buffer Memory | 1 | 4 bytes | no | yes |
| MultiCAN Buffer Memory | 1 | 4 bytes | no | yes |
| PMU Prefetch Buffer Memory | 1 | 4 bytes | no | yes |

Table 7-3 Parity Test Enabled Memories and Supported Parity Error Indication
 (cont'd)

| Memory | Number of Parity Bits | Parity Test Granularity | Bus Error | Parity Trap |
|-------------------------|-----------------------|-------------------------|-----------|-------------|
| USB Buffer Memory | 1 | 4 bytes | no | yes |
| ETH 0 TX Buffer Memory | 1 | 4 bytes | no | yes |
| ETH 0 RX Buffer Memory | 1 | 4 bytes | no | yes |
| ECAT 0 RX Buffer Memory | 1 | 1 byte | yes | yes |
| SDMMC Buffer Memory 0 | 1 | 4 bytes | no | yes |
| SDMMC Buffer Memory 1 | 1 | 4 bytes | no | yes |

Bufferable Write Access to Peripheral

Bufferable writes to peripheral may result in error responses as described above. Bus error responses from modules attached to peripheral bridges PBA0 and PBA1 trigger service request from the respective bridge that will result in NMI to the CPU. Error status and access address that caused the service request get stored in dedicated registers of the peripheral bridges. For detail please refer to [Registers](#).

7.5 Debug Behavior

The bus system in debug mode allows debug probe access to all system resources except for the Flash sectors protected with a dedicated protection mechanism (for more details please refer to Flash Memory chapter). No special handling of HALT mode is implemented and all interfaces respond with a valid bus response upon accesses.

7.6 Power, Reset and Clock

The bus system clocking scheme enables stable system operation and accesses to system resources for all valid system clock rates. Some parts of the system may also run at a half of the system clock rate and no special handling is required as appropriate alignment of the bus system protocol is provided on the clock domain boundary (for details please refer to clocking system description in SCU chapter).

7.7 Initialization and System Dependencies

No initialization is required for the memory system from user point of view. All valid memories are available after reset. Some peripherals may need to be initialized (e.g. released from reset state) before accessed. For details please refer to individual peripheral chapters.

7.8 Registers

This section describes registers of the Peripheral Bridges. The purpose of the registers is handling of errors signaled during bufferable accesses to peripherals connected to the respective bridges. Active errors on bufferable writes trigger interrupt requests generated from the Peripheral Bridges that can be monitored and cleared in the register defined in this chapter.

Table 7-4 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|---------------------|
| PBA0 | 4000 0000 _H | 4000 3FFF _H | Peripheral Bridge 0 |
| PBA1 | 4800 0000 _H | 4800 3FFF _H | Peripheral Bridge 1 |

Table 7-5 Registers Overview

| Register Short Name | Register Long Name | Offset Address | Access Mode | | Description |
|---------------------|---------------------------|-------------------|-------------|-------|---------------------------|
| | | | Read | Write | |
| PBA0_STS | PBA 0 Status Register | 0000 _H | U, PV | PV | Page 7-10 |
| PBA0_WADDR | PBA 0 Write Error Address | 0004 _H | U, PV | | Page 7-11 |
| PBA1_STS | PBA 1 Status Register | 0000 _H | U, PV | PV | Page 7-12 |
| PBA1_WADDR | PBA 1 Write Error Address | 0004 _H | U, PV | | Page 7-12 |

PBA0_STS

The status register of PBA0 bridge indicates bus error occurrence for write access. Is meant to be used for errors triggered upon buffered writes. The bit gets set and interrupt request has been generated to the SCU.

Write one to clear, writing zero has no effect.

PBA0_STS

Peripheral Bridge Status Register (0000_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| WERR | 0 | rw | Bufferable Write Access Error 0 _B no write error occurred. 1 _B write error occurred, interrupt request is pending. |
| 0 | [31:1] | r | Reserved bits. Write zeros |

PBA0_WADDR

The Write Error Address Register keeps write access address that caused a bus error upon bufferable write attempt to a peripheral connected to PBA0 bridge. This register store the address that of the bufferable write access attempt that caused error resulting in setting WERR bit of the [PBA0_STS](#) register.

This register value remains unchanged when WERR bit of [PBA0_STS](#) register is set.

PBA0_WADDR

PBA Write Error Address Register (0004_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| WADDR | [31:0] | rh | Write Error Address Address of the write access that caused a bus error on the bridge Master port. |

PBA1_STS

The status register of PBA1 bridge indicates bus error occurrence for write access. Is meant to be used for errors triggered upon buffered writes. The bit gets set and interrupt request has been generated to the SCU.

Write one to clear, writing zero has no effect.

PBA1_STS

Peripheral Bridge Status Register (0000_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| 0 | | | | | | | | | | | | | | | |
| r | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | | | | | | | | WERR |
| r | | | | | | | | | | | | | | | rw |

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| WERR | 0 | rw | Bufferable Write Access Error 0 _B no write error occurred. 1 _B write error occurred, interrupt request is pending. |
| 0 | [31:1] | r | Reserved bits. Write zeros |

PBA1_WADDR

The Write Error Address Register keeps write access address that caused a bus error upon bufferable write attempt to a peripheral connected to PBA1 bridge. This register store the address that of the bufferable write access attempt that caused error resulting in setting WERR bit of the **PBA1_STS** register.

This register value remains unchanged when WERR bit of **PBA1_STS** register is set.

PBA1_WADDR

PBA Write Error Address Register (0004_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| WADDR | [31:0] | rh | Write Error Address Address of the write access that caused a bus error on the bridge Master port. |

8 Flash and Program Memory Unit (PMU)

The Program Memory Unit (PMU) controls the Flash memory and the BROM and connects these to the system. The Prefetch unit maximizes system performance with higher system frequencies, by buffering instruction and data accesses to the Flash.

8.1 Overview

In the XMC4[78]00, the PMU controls the following interfaces:

- The Flash command and fetch control interface for Program Flash
- The Boot ROM interface
- The PMU interfaces via the Prefetch unit to the Bus Matrix

Following memories are controlled by and belong to the PMU:

- 2.0 Mbyte of Program Flash memory (PFLASH)
- 16 Kbyte of BROM (BROM)
- 8 Kbyte of Instruction Cache memory in the Prefetch unit
- 256-bit Data Buffer in the Prefetch unit

8.1.1 Block Diagram

The PMU block diagram is shown in [Figure 8-1](#).

Figure 8-1 PMU Block Diagram

8.2 Boot ROM (BROM)

The Boot ROM in PMU0 has a capacity of 16 KB. The BROM contains the Firmware with:

- startup routines
- bootstrap loading software.

Details on the operations of the BROM are given in the chapter “Startup Modes”.

8.2.1 BROM Addressing

The BROM is visible at one location, as can be seen in the memory map:

- (non-cached space) starting at location 0000 0000_H

After any reset, the hardware-controlled start address is 0000 0000_H. At this location, the startup procedure is stored and started. As no other start location after reset is supported, the startup software within the BROM is always executed first after any reset.

8.3 Prefetch Unit

The purpose of the Prefetch unit is to reduce the Flash latency gap at higher system frequencies to increase the instruction per cycle performance.

8.3.1 Overview

The Prefetch unit separates between instruction and data accesses to the Flash with the following configuration:

- 8 Kbyte Instruction Buffer
 - 2-way set associative
 - Least-Recently-Used (LRU) replacement policy
 - Cache line size: 256 bits
 - Critical word first
 - Streaming¹⁾
 - Line wrap around
 - Parity, 32-bit granularity
 - Buffer can be bypassed
 - Buffer can be globally invalidated
- 256-bit Data Buffer
 - Single line
 - Critical word first
 - Streaming¹⁾
 - Line Wrap around
 - Buffer can be bypassed

1) The first 32-bit data from Flash gets immediately forwarded to the CPU

Flash and Program Memory Unit (PMU)

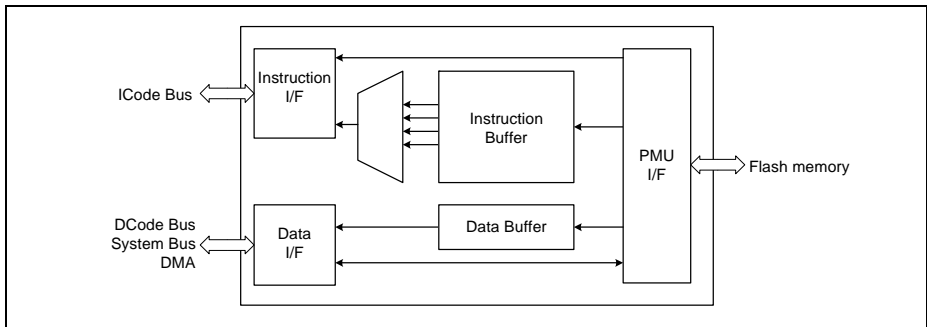

Figure 8-2 Prefetch Unit

8.3.2 Operation

8.3.2.1 Instruction Buffer

The instruction buffer acts like a regular instruction cache with the characteristics described in the overview, optimized for minimum latency via the dedicated instruction interface. Instruction fetches to the non-cacheable address space bypass the instruction buffer. For software development and benchmarking purposes the cacheable accesses can also bypass the instruction buffer by setting **PREF_PCON.IBYP** to 1_B.

Prefetch buffer hits are without any penalty i.e. single cycle access rate. This ensures a minimized latency.

The instruction buffer may be invalidated by writing a 1_B to **PREF_PCON.IINV**. After system reset, the instruction buffer is automatically invalidated.

A parity error during a buffer read operation is automatically turned into a buffer miss, triggering a refill operation of the cache line.

Note: The complete invalidation operation is performed in a single cycle.

Note: The parity information is generated on the fly during the cache refill operation. Parity is checked for each read operation targeting the instruction buffer.

The streaming operation is on the fly - it does not cause any additional latency.

8.3.2.2 Data Buffer

The characteristics of the data buffer are described in the overview. It is used for data read requests from the CPU using the DCode interface and for data read requests from

Flash and Program Memory Unit (PMU)

the DMA. CPU read accesses to the prefetch buffer are without any penalty i.e. single cycle access rate. The miss latency is minimized.

The data interface is shared between DMA requests, CPU DCode bus requests and CPU System bus requests. The CPU System bus is attached to the Prefetch unit to access configuration and status registers within the Prefetch unit and the PMU and Flash. All read requests outside the cacheable address space and all write accesses bypass the data buffer. For software development and benchmarking purposes the cacheable accesses can also bypass the data buffer by setting **PREF_PCON.DBYP** to 1_B.

Note: The streaming operation is on the fly - it does not cause any additional latency.

Note: An erase and/or program operation to the Flash does not clear/invalidate the data buffer and may result in inconsistent data buffer content (no data coherence between data buffer and the updated Flash).

A (dummy) read operation to a cacheable Flash address that has not been updated restores the data coherency.

8.3.2.3 PMU Interface

Each Flash read access returns 256 bits, intermediately stored in a “global read buffer” in the Flash (**Section 8.4.4**). The Prefetch unit reads from this buffer via a 64-bit interface. Cacheable read accesses that are not yet stored in the Prefetch buffer (cache miss) trigger a refill operation by a 4x64-bit burst transfer. By that burst transfer the data from the global buffer is copied, refilling the instruction buffer (code fetch) or data buffer (data fetch) respectively.

Only the initial Flash read access is affected by the Flash latency. The subsequent read accesses of the burst transfer are serviced by the global read buffer with no additional delay. An additional prefetch mechanism in the PFLASH further reduces the latency for linear Flash accesses (**Section 8.4.4**).

Non-cacheable accesses benefit from the global read buffer in the same way, as long as its content is not “trashed” by a new Flash read access (e.g. from a different bus master).

Accesses to the BROM and register address spaces and write operations are ignored by the Prefetch buffers.

8.4 Program Flash (PFLASH)

This chapter describes the embedded Flash module of the XMC4[78]00 and its software interface.

8.4.1 Overview

The embedded Flash module of XMC4[78]00 includes 2.0 MB of Flash memory for code or constant data (called Program Flash).

8.4.1.1 Features

The following list gives an overview of the features implemented in the Program Flash. Absolute values can be found in the “Data Sheet”.

- Consists of one bank.
- Commonly used for instructions and constant data.
- High throughput burst read based on a 256-bit Flash access.
- Application optimized sector structure with sectors ranging from 16 Kbytes to 256 Kbytes.
- High throughput programming of a 256 byte page (see Data Sheet t_{PRP}).
- Sector-wise erase on logical and physical sectors (see Data Sheet t_{ERP}).
- Write protection separately configurable for groups of sectors.
- Hierarchical write protection control with 3 levels of which 2 are password based and 1 is a one-time programmable one.
- Password based read protection combined with write protection for the whole Flash.
- Separate configuration sector containing the protection configuration and boot configuration (BMI).
- All Flash operations initiated by command sequences as protection against unintended operation.
- Erase and program performed by a Flash specific control logic independent of the CPU.
- End of erase and program operations reported by interrupt.
- Dynamic Error Correcting Code (ECC) with Single-bit Error Correction and Double-bit Error Detection (“SEC-DED”).
- Error reporting by bus error, interrupts and status flags.
- Margin reads for quality assurance.
- Delivery in the erased state.
- Configurable wait state configuration for optimum read performance depending on CPU frequency (see [FCON.WSPFLASH](#)).
- High endurance and long retention.
- Pad supply voltage used for program and erase.

8.4.2 Definition of Terms

The description of Flash memories uses a specific terminology for operations and the hierarchical structure.

Flash Operation Terms

- **Erasing:** The erased state of a Flash cell is logical '0'. Forcing a cell to this state is called "erasing". Depending on the Flash area and command sequence complete logical or physical sectors are erased. All Flash cells in this area incur one "cycle" that counts for the "endurance".
- **Programming:** The programmed state of a cell is logical '1'. Changing an erased Flash cell to this state is called "programming". The 1-bits of a page are programmed concurrently.
- **Retention:** This is the time during which the data of a Flash cell can be read reliably. The retention time is a statistical figure that depends on the operating conditions of the device (e.g. temperature profile) and is affected by operations on other Flash cells in the same word-line and physical sector. With an increasing number of program/erase cycles (see endurance) the retention is lowered. Figures are documented in the Data Sheet separately for physical sectors (t_{RET}) and UCBs (t_{RTU}).
- **Endurance:** The maximum number of program/erase cycles of each Flash cell is called "endurance". The endurance is a statistical figure that depends on operating conditions and the use of the flash cells and also on the required quality level. The endurance is documented in the Data Sheet as a condition to the retention parameters.

Flash Structure Terms

- **Flash Module:** The PMU contains one "Flash module" with its own operation control logic.
- **Bank:** A "Flash module" may contain separate "banks". "Banks" support concurrent operations (read, program, erase) with some limitations due to common logic.
- **Physical Sector:** A Flash "bank" consists of "physical sectors" ranging from 64 Kbytes to 256 Kbytes. The Flash cells of different "physical sectors" are isolated from each other. Therefore cycling Flash cells in one physical sectors does not affect the retention of Flash cells in other physical sectors. A "physical sector" is the largest erase unit.
- **Logical Sector:** A "logical sector" is a group of word-lines of one physical sector. They can be erased with a single operation but other Flash cells in the same physical sector are slightly disturbed.
- **Sector:** The plain term "sector" means "logical sector" when a physical sector is divided in such, else it means the complete physical sector.
- **User Configuration Block "UCB":** A "UCB" is a specific logical sector contained in the configuration sector. It contains the protection settings and other data configured

Flash and Program Memory Unit (PMU)

by the user. The “UCBs” are the only part of the configuration sector that can be programmed and erased by the user.

- **Word-Line:** A “word-line” consists of two pages, an even one and an odd one. In the PFLASH a word-line contains aligned 512 bytes.
- **Page:** A “page” is a part of a word-line that is programmed at once. In PFLASH a page is an aligned group of 256 bytes.

8.4.3 Flash Structure

The PMU contains one PFLASH bank, accessible via the cacheable or non-cacheable address space. The offset address of each sector is relative to the base address of its bank which is given in [Table 8-1](#).

Derived devices (see Data Sheet) can have less Flash memory. The PFLASH bank shrinks by cutting-off higher numbered physical sectors.

Table 8-1 Flash Memory Map

| Range Description | Size | Start Address |
|---|-----------|------------------------|
| PMU0 Program Flash Bank non-cached | 2.0 Mbyte | 0C00 0000 _H |
| PMU0 Program Flash Bank cached space (different address space for the same physical memory, mapped in the non- cached address space) | 2.0 Mbyte | 0800 0000 _H |
| PMU0 UCB User Configuration Blocks | 3 Kbyte | 0C00 0000 _H |
| PMU0 Flash Registers | 1 Kbyte | 5800 2000 _H |

PFLASH

All addresses offset to the start addresses given in [Table 8-1](#). All sectors from S9 on have a size of 256 Kbyte.

Table 8-2 Sector Structure of PFLASH

| Sector | Phys. Sector | Size | Offset Address |
|--------|--------------|-------|----------------------|
| S0 | PS0 | 16 KB | 00'0000 _H |
| S1 | | 16 KB | 00'4000 _H |
| S2 | | 16 KB | 00'8000 _H |
| S3 | | 16 KB | 00'C000 _H |

Flash and Program Memory Unit (PMU)
Table 8-2 Sector Structure of PFLASH (cont'd)

| Sector | Phys. Sector | Size | Offset Address |
|--------|--------------|--------|----------------------|
| S4 | PS4 | 16 KB | 01'0000 _H |
| S5 | | 16 KB | 01'4000 _H |
| S6 | | 16 KB | 01'8000 _H |
| S7 | | 16 KB | 01'C000 _H |
| S8 | – | 128 KB | 02'0000 _H |
| S9 | – | 256 KB | 04'0000 _H |
| S10 | – | 256 KB | 08'0000 _H |
| S11 | – | 256 KB | 0C'0000 _H |
| S12 | – | 256 KB | 10'0000 _H |
| S13 | – | 256 KB | 14'0000 _H |
| S14 | – | 256 KB | 18'0000 _H |
| S15 | – | 256 KB | 1C'0000 _H |

UCB

All addresses offset to the start addresses given in [Table 8-1](#). As explained before the UCBx are logical sectors.

Table 8-3 Structure of UCB Area

| Sector | Size | Offset Address |
|--------|------|----------------------|
| UCB0 | 1 KB | 00'0000 _H |
| UCB1 | 1 KB | 00'0400 _H |
| UCB2 | 1 KB | 00'0800 _H |

8.4.4 Flash Read Access

Flash banks that are active and in read mode can be directly read like a ROM.

The wait cycles for the Flash read access must be configured based on the CPU frequency f_{CPU} (incl. PLL jitter) in relation to the Flash access time t_a defined in the Data Sheet. The following formula applies for **FCON.WSPFLASH** > 0_H¹⁾:

$$\text{WSPFLASH} \times (1 / f_{\text{CPU}}) \geq t_a \quad (8.1)$$

1) WSPFLASH = 0_H deviates from this formula and results in the same timing as WSPFLASH = 1_H.

Flash and Program Memory Unit (PMU)

The PFLASH delivers 256 bits per read access. All read data from the PFLASH passes through a 256-bit “global read buffer”.

The PMU allows 4x64-bit burst accesses to the cached address space and single 32-bit read accesses to the non-cached address space of the PFLASH.

The Prefetch generates the 4x64-bit bursts for code and data fetches from the cached address range in order to fill one cache line or the data buffer respectively. Data reads from the non-cached address range are performed with single 32-bit transfers.

Following an initial Flash access, the PFLASH automatically starts a prefetch of the next linear address (even before it has been requested). Has the content of the global read buffer been read completely (e.g. by a burst from the Prefetch unit), the new prefetched data is copied to the read buffer and another prefetch to the PFLASH is started. This significantly reduces the Flash latency for mostly linearly accessed code or data sections. To avoid additional wait states due to these prefetches, they can be aborted in case a new (initial) read access is requested from a different address. For power saving purposes these prefetch operations can be disabled by **FCON.IDLE (Idle Read Path)**.

Read accesses from Flash can be blocked by the read protection (see **Section 8.4.8**).

ECC errors can be detected and corrected (see **Section 8.4.9**).

8.4.5 Flash Write and Erase Operations

Flash write and erase operations are triggered by **Command Sequences** to avoid harm to the stored data by “accidental” accesses from faulty code. Erase operations are executed on sectors, write operations on pages.

Attention: Flash write and erase operations must be executed to the non-cacheable address space.

8.4.6 Modes of Operation

A Flash module can be in one of the following states:

- Active (normal) mode.
- Sleep mode (see **Section 8.6.2**).

In sleep mode write and read accesses to all Flash ranges of this PMU are refused with a bus error.

When the Flash module is in active mode the Flash bank can be in one of these modes:

- Read mode.
- Command mode.

In read mode a Flash bank can be read and command sequences are interpreted. In read mode a Flash bank can additionally enter page mode which enables it to receive data for programming.

Flash and Program Memory Unit (PMU)

In command mode an operation is performed. During its execution the Flash bank reports BUSY in **FSR**. In this mode read accesses to this Flash bank are refused with a bus error. At the end of an operation the Flash bank returns to read mode and BUSY is cleared. Only operations with a significant duration (shown in the command documentation) set BUSY.

Register read and write accesses are not affected by these modes.

8.4.7 Command Sequences

All Flash operations except read are performed with command sequences. When a Flash bank is in read mode or page mode all write accesses to its reserved address range are interpreted as command cycle belonging to a command sequence. Write accesses to a busy bank cause a sequence error (SQER).

Attention: *For the proper execution of the command sequences and the triggered operations f_{CPU} must be equal or above 1 MHz.*

Command sequences consist of 1 to 6 command cycles. The command interpreter checks that a command cycle is correct in the current state of command interpretation. Else a SQER is reported.

When the command sequence is accepted the last command cycle finishes read mode and the Flash bank transitions into command mode.

These write accesses must be single transfers and must address the non-cacheable address range.

Generally when the command interpreter detects an error it reports a sequence error by setting **FSR.SQER**. Then the command interpreter is reset and a page mode is left. The next command cycle must be the 1st cycle of a command sequence. The only exception is "Enter Page Mode" when a bank is already in page mode (see below).

8.4.7.1 Command Sequence Definitions

Table 8-4 gives an overview of the supported command sequence, with the following nomenclature:

The parameter "addr" can be one of the following:

- **CCCC_H**: The "addr" must point into the bank that performs the operation. The last 16 address bits must match CCCCC_H. It is recommended to use as address the base address of the bank incremented by CCCCC_H.
- **PA**: Absolute start address of the Flash page.
- **UCPA**: Absolute start address of a user configuration block page.
- **SA**: Absolute start address of a Flash sector. Allowed are the PFLASH sectors Sx.
- **PSA**: Absolute start address of a physical sector. Allowed are the PFLASH physical sectors PSx.
- **UCBA**: Absolute start address of a user configuration block.

Flash and Program Memory Unit (PMU)

The parameter “data” can be one of the following:

- **WD**: 32-bit write data to be loaded into the page assembly buffer.
- **xxYY**: 8-bit write data as part of a command cycle. Only the byte “YY” is used for command interpretation. The higher order bytes “xx” are ignored.
 - **xx5y**: Specific case for “YY”. The “y” can be “0_H” for selecting the PFLASH bank.
- **UL**: User protection level (xxx0_H or xxx1_H for user levels 0 and 1).
- **PWx**: 32-bit password.

Command Sequence Overview Table

The **Table 8-4** summarizes all commands sequences. The following sections describe each command sequence in detail.

Table 8-4 Command Sequences for Flash Control

| Command Sequence | | 1. Cycle | 2. Cycle | 3. Cycle | 4. Cycle | 5. Cycle | 6. Cycle |
|---|-----------------|--------------------|--------------------|--------------------|-----------------------|----------------------|-----------------------|
| Reset to Read | Address Data | .5554 ..xxF0 | | | | | |
| Enter Page Mode | Address Data | .5554 ..xx5y | | | | | |
| Load Page | Address Data | .55F0 WD | .55F4 WD | | | | |
| Write Page | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xxA0 | PA ..xxAA | | |
| Write User Configuration Page | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xxC0 | UCPA ..xxAA | | |
| Erase Sector | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xx80 | .5554 ..xxAA | .AAA8 ..xx55 | SA ..xx30 |
| Erase Physical Sector 1) | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xx80 | .5554 ..xxAA | .AAA8 ..xx55 | PSA ..xx40 |
| Physical Sector Repair ¹⁾ | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xx80 | .5554 ..xxAA | .AAA8 ..xx55 | PSA ..xx40 |
| Erase User Configuration Block | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .5554 ..xx80 | .5554 ..xxAA | .AAA8 ..xx55 | UCBA ..xxC0 |
| Disable Sector Write Protection | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .553C UL | .AAA8 PW 0 | .AAA8 PW 1 | .5558 ..xx05 |
| Disable Read Protection | Address Data | .5554 ..xxAA | .AAA8 ..xx55 | .553C ..xx00 | .AAA8 PW 0 | .AAA8 PW 1 | .5558 ..xx08 |

Flash and Program Memory Unit (PMU)
Table 8-4 Command Sequences for Flash Control (cont'd)

| Command Sequence | | 1. Cycle | 2. Cycle | 3. Cycle | 4. Cycle | 5. Cycle | 6. Cycle |
|--------------------------|---------|----------------|-------------|-------------|-------------|-------------|-------------|
| Resume Protection | Address | .5554 | | | | | |
| | Data | ..xx 5E | | | | | |
| Clear Status | Address | .5554 | | | | | |
| | Data | ..xx F5 | | | | | |

1) Alternate operation as Erase Physical Sector or Sector Soft Repair, depending on the configuration of PROCON1.PSR.

Reset to Read

This function resets the command interpreter to its initial state (i.e. the next command cycle must be the 1st cycle of a sequence). A page mode is aborted.

This command is the only one that is accepted without generating a SQER when the command interpreter has already received command cycles of a different sequence but is still not in command mode. Thus “Reset to Read” can cancel every command sequence before its last command cycle has been received.

The error flags of **FSR** (PFOPER, SQER, PROER, PFDBER, ORIER, VER) are cleared. The flags can be also cleared in the status registers without command sequence.

If any Flash bank is busy this command is executed but the flag SQER is set.

Enter Page Mode

The PFLASH enters page mode. The selection of the PFLASH assembly buffer (256 bytes) is additionally done by the parameter “y_H = 0_H”.

The write pointer of the page assembly buffer is set to 0, its previous content is maintained.

The page mode is signalled by the flag PAGEx in the FSR.

If a new “Enter Page Mode” command sequence is received while any Flash bank is already in page mode SQER is set but this sequence is correctly executed (i.e. in this case the command interpreter is not reset).

Load Page

Loads the data “WD” into the page assembly buffer. It is required to transfer 64-bit with two consecutive 32-bit data transfers, first addressing the low word with 55F0_H, followed by the high word with 55F4_H. The 64-bit are then transferred to the assembly buffer and the write pointer is incremented to the next position.

32 “Load Page” operations are required to fill the assembly buffer for one 256 byte page. The addressed bank must be in page mode, else SQER is issued.

Flash and Program Memory Unit (PMU)

If “Load Page” is called more often than necessary for filling the page SQER is issued and if configured an interrupt is triggered. The overflow data is discarded. The page mode is not left.

Write Page

This function starts the programming process for one page with the data transferred previously by “Load Page” commands. Upon entering command mode the page mode is finished (indicated by clearing the corresponding PAGE flag) and the BUSY flag of the bank is set.

This command is refused with SQER when the addressed Flash bank is not in page mode.

SQER is also issued when PA addresses an unavailable Flash range or when PA does not point to a legal page start address.

If after “Enter Page Mode” too few data or no data was transferred to the assembly buffer with “Load Page” then “Write Page” programs the page but sets SQER. The missing data is programmed with the previous content of the assembly buffer.

When the page “PA” is located in a sector with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

Write User Configuration Page

As for “Write Page”, except that the page “UCPA” is located in a user configuration block. This changes the Flash module’s protection configuration.

When the page “UCPA” is located in an UCB with active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

When UCPA is not the start address of a page in a valid UCB the command fails with SQER.

Erase Sector

The sector “SA” is erased.

SQER is returned when SA does not point to the base address of a correct sector (as specified at the beginning of this section) or to an unavailable sector.

When SA has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

Erase Physical Sector

The physical sector “PSA” is erased.

SQER is returned when PSA does not point to the base address of a correct sector (as specified at the beginning of this section) or an unavailable sector.

Flash and Program Memory Unit (PMU)

When PSA has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

*Note: The same command sequence can alternatively be used as Erase Physical Sector or Sector Soft Repair, depending on the configuration of **PROCON1.PSR**.*

Physical Sector Repair

The physical sector “PSA = PS4” is repaired.

This command sequence must be used when an erase operation on a logical sector inside the physical sector PS4 has been aborted by a reset - this may render parts or the whole physical sector unreadable. This command sequence repairs the corrupted logical sector.

This command sequence is required to run an EEPROM emulation algorithm that cycles the logical sectors S4..S7 of PS4.

The Physical Sector Repair command sequence will be ignored if any other sector than “PSA4” is addressed. No SQER is triggered in this case.

*Note: The same command sequence can alternatively be used as Erase Physical Sector or Sector Soft Repair, depending on the configuration of **PROCON1.PSR**.*

Erase User Configuration Block

The addressed user configuration block “UCB” is erased.

When the UCB has an active write protection or the Flash module has an active global read protection the execution fails and PROER is set.

The command fails with SQER when UCBA is not the start address of a valid UCB.

Disable Sector Write Protection

The sector write protection belonging to user level “UL” is temporarily disabled by setting FSR.WPRODIS when the passwords PW0 and PW1 match their configured values in the corresponding UCB.

The command fails by setting PROER when any of PW0 and PW1 does not match. In this case until the next application reset all further calls of “Disable Sector Write Protection” and “Disable Read Protection” fail with PROER independent of the supplied password.

Disable Read Protection

The Flash module read protection including the derived module wide write protection are temporarily disabled by setting FSR.RPRODIS when the passwords PW0 and PW1 match their configured values in the UCB0.

The command fails by setting PROER when any of PW0 and PW1 does not match. In this case until the next application reset all further calls of “Disable Sector Write

Flash and Program Memory Unit (PMU)

Protection" and "Disable Read Protection" fail with PROER independent of the supplied password.

Resume Protection

This command clears all FSR.WPRODISx and the FSR.RPRODIS effectively enabling again the Flash protection as it was configured.

A FSR.WPRODISx is not cleared when corresponding UCBx is not in the "confirmed" state (see [Section 8.4.8.1](#)).

Clear Status

The flags FSR.PROG and FSR.ERASE and the error flags of **FSR** (PFOPER, SQER, PROER, PFDBER, ORIER, VER) are cleared. These flags can be also cleared in the status registers without command sequence.

When any Flash bank is busy this command fails by setting additionally SQER.

8.4.7.2 Flash Page Programming Example

Figure 8-3 shows the basic flow of command sequences to program a Flash page. All commands are write accesses to the non-cached Flash address space. E.g. the "Enter Page Mode" command can be executed by a write access to the address 0C00 5554_H with the data 0000 0050_H.

In the first step the Flash bank is switched to Page Mode. Only in this mode the other command sequences are accepted.

Then the data is loaded in the assembly buffer with a series of "Load Page" commands.

The "Write Page" command triggers the actual write operation, transferring the 256 bytes data from the assembly buffer to the addressed page in the Flash.

FSR.PROG is set with the last cycle of the "Write Page" command sequence, indicating that a program operation is started.

While this write operation is processed the Flash bank is not accessible, indicated by the **FSR.PBUSY** flag.

In every step the **FSR.SQER** flag provides a direct feedback on the successful execution of the command sequence.

After the program operation has been completed successfully, the "sticky" status flags like **FSR.PROG** can be cleared by the "Clear Status" sequence, before the next operation is started.

Flash and Program Memory Unit (PMU)

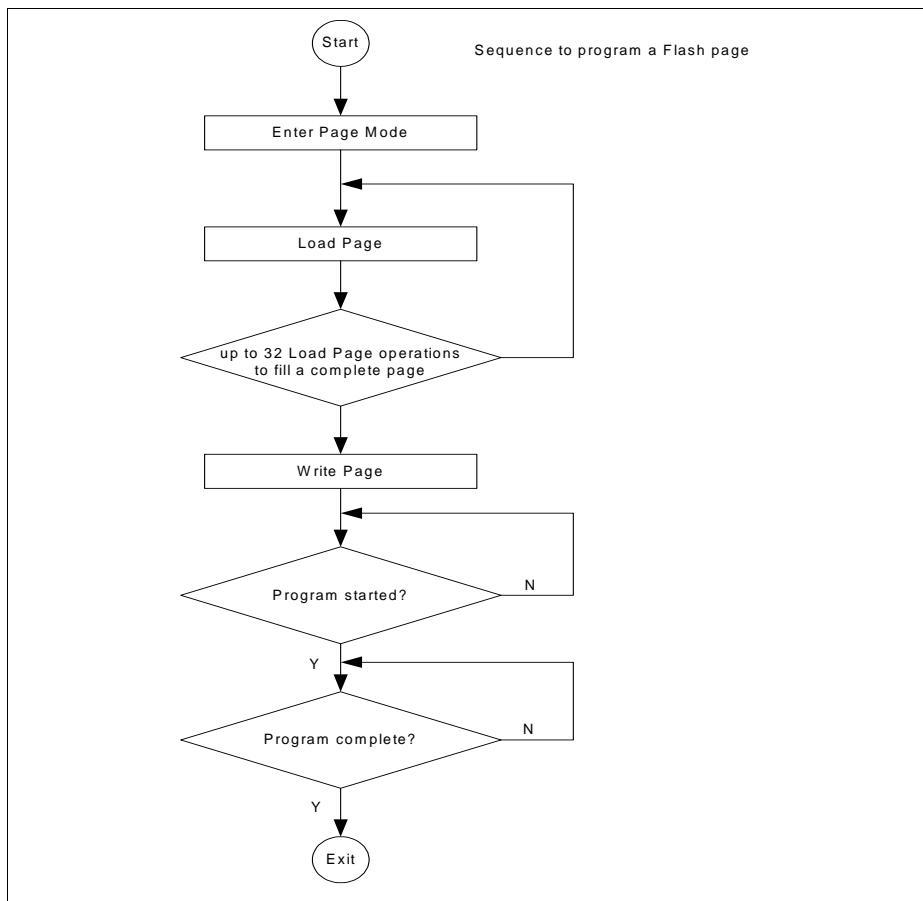

Figure 8-3 Basic Flash Program Sequence

Flash and Program Memory Unit (PMU)

8.4.8 Flash Protection

The Flash memory can be read and write protected. The protection is configured by programming the User Configuration Blocks "UCB".

For an effective IP protection the Flash read protection must be activated. This ensures system wide that the Flash cannot be read from external or changed without authorization.

8.4.8.1 Configuring Flash Protection in the UCB

As indicated above the effective protection is determined by the content of the **Protection Configuration Indication** PROCON0–2 registers. These are loaded during startup from the UCB0–2. Each UCB comprises 1 Kbyte of Flash organized in 4 UC pages of 256 bytes. The UCBs have the following structure:

Table 8-5 UCB Content

| UC Page | Bytes | UCB0 | UCB1 | UCB2 |
|---------|---------|--------------------------|--------------------------|--|
| 0 | [1:0] | PROCON0 | PROCON1 | PROCON2 |
| | [7:2] | unused | unused | unused |
| | [9:8] | PROCON0 (copy) | PROCON1 (copy) | PROCON2 (copy) |
| | [15:10] | unused | unused | unused |
| | [19:16] | PW0 of User 0 | PW0 of User 1 | unused |
| | [23:20] | PW1 of User 0 | PW1 of User 1 | unused |
| | [27:24] | PW0 of User 0 (copy) | PW0 of User 1 (copy) | unused |
| | [31:28] | PW1 of User 0 (copy) | PW1 of User 1 (copy) | unused |
| | others | unused | unused | unused |
| 1 | | unused | unused | BMI and configuration data (details in Startup Mode chapter) |
| 2 | [3:0] | confirmation code | confirmation code | confirmation code |
| | [11:8] | confirmation code (copy) | confirmation code (copy) | confirmation code (copy) |
| | others | unused | unused | unused |
| 3 | unused | unused | unused | unused |

Flash and Program Memory Unit (PMU)

If the confirmation code field is programmed with 8AFE 15C3_H the UCB content is “confirmed” otherwise it is “unconfirmed”. The status flags **FSR.PROIN**, **FSR.RPROIN** and **FSR.WPROIN0–2** indicate this confirmation state:

- **FSR.PROIN**: set when any UCB is in the confirmed state.
- **FSR.RPROIN**: set when **PROCON0.RPRO** is ‘1’ and the UCB0 is in “confirmed” state.
- **FSR.WPROIN0–2**: set when their UCB0–2 is in “confirmed” state.

An UCB can be erased with the command “Erase User Configuration Block”. An UCB page can be programmed with the command “Write User Configuration Page”. These commands fail with PROER when the UCB is write-protected.

An UCB is write-protected if:

- UCB0: (**FSR.RPROIN** and not **FSR.RPRODIS**) or (**FSR.WPROIN0** and not **FSR.WPRODIS0**)
- UCB1: **FSR.WPROIN1** and not **FSR.WPRODIS1**.
- UCB2: **FSR.WPROIN2**

So when the UCB2 is in the “confirmed” state its protection can not be changed anymore. Therefore this realizes a one-time programmable protection.

Changing UCBs

The protection installation is modified by erasing and programming the UCBs with dedicated command sequences, described in [Section 8.4.7.1](#). These operations need to be performed with care as described in the following.

Aborting an “Erase UC Block” operation (e.g. due to reset or power failure) must be avoided at all means, as it can result in an unusable device.

UCBs are logical sectors, and as such the allowed number of program/erase cycles of the UCBs must not be exceeded. Over-cycling the UCBs can also lead to an unusable device.

The installation of the protection and its confirmation on different pages of the UCB offers the possibility to check the installation before programming the confirmation. First the protection needs to be programmed, then an application reset must be triggered to trigger the reading of the UCBs by the PMU and after that the protection can be verified (e.g. “Disable ... Protection” to check the password and by checking **PROCONs** and **FCON**). The application reset is inevitable because the PMU reads the UCBs only during the startup phase.

8.4.8.2 Flash Read Protection

Read protection can be activated for the whole Flash module.

Read Protection Status

A read access to PFLASH fails with bus error under the following conditions:

- Code fetch: **FCON**.DCF and **FCON**.RPA.
- Data read: **FCON**.DDF and **FCON**.RPA.

The read protection bit **FCON**.RPA is determined during startup by the protection configuration of UCB0. It can be temporarily modified by the command sequences “Disable Read Protection” and “Resume Protection” which modify **FSR**.RPRODIS. **FCON**.RPA is determined by the following equation:

- **FCON**.RPA = **PROCON0**.RPRO and not **FSR**.RPRODIS.

The bits **FCON**.DDF and **FCON**.DCF are initialized by the startup software depending on the configured protection and the startup mode. They can also be directly modified by the user software under conditions noted in the description of **FCON**.

Initializing Read Protection

Installation of read protection is performed with the “Write User Configuration Page” operation, controlled by the user 0. With this command, user 0 writes the protection configuration bits RPRO, and the two 32-bit keywords into the UCB0 page 0. Additionally, with a second “Write User Configuration Page” command, a special 32-bit confirmation (lock-) code is written into the UCB0 page 2. Only this confirmation code enables the protection and thus the keywords. The confirmation write operation to the second wordline of the User Configuration Block shall be executed only after check of keyword-correctness (with command “Disable Read Protection” after next reset). The confirmed state and thus the installation of protection is indicated with the FSR-bit PROIN in Flash Status Register FSR and for read protection with bit RPROIN in FSR. If read protection is not correctly confirmed and thus not enabled, the bits PROIN and RPROIN in the FSR are not set. The configured read protection as fetched from UCB0 is indicated in the protection configuration register **PROCON0**.

For safety of the information stored in the UCB pages, all keywords, lock bits and the confirmation code are stored two-times in the two wordlines. In case of a disturbed original data detected during ramp up, its copy is used **FSR**. Layout of the four UC pages belonging to the user's UC block is shown in **Table 8-5**, the command “Write User Configuration Page” is described in **Section 8.4.7.1**.

Disabling Read Protection

With the command sequence “Disable Read Protection” short-term disabling of read protection is possible. This command disables the Flash protection (latest until next reset) for user controlled erase and re-program operations as well as for clearing of DCF and DDF control bits after external program execution. The “Disable Read Protection” command sequence is a protected command, which is only processed by the command state machine, if the included two passwords are identical to the two keywords of user 0.

Flash and Program Memory Unit (PMU)

The disabled state of read protection is controlled with the **FCON**.RPA='0' and indicated in the Flash Status Register **FSR** with the RPRODIS bit (see [Section 8.7.3.1](#)). As long as read protection is disabled (and thus not active), the **FCON**-bits DDF and DCF can be cleared.

Resumption of read protection after disablement is performed with the "Resume Read/Write Protection" command. After execution of this single cycle command, read protection (if installed) is again active, indicated by the **FCON** bit RPA='1'.

Generally, Flash read protection will remain installed as long as it is confirmed (locked) in the User Configuration Block 0. Erase of UC block and re-program of UC pages can be performed up to 4 times. But note, after execution of the Erase UC block command (which is protected and therefore requires the preceding disable command with the user's specific passwords), all keywords and all protection installations of user 0 are erased; thus, the Flash is no more read protected (beginning with next reset) until re-programming the UC pages. But the division and separation of the protection configuration data and of the confirmation data into two different UCB-wordlines guarantees, that a disturb of keywords can be discovered and corrected before the protection is confirmed. For this reason, the command sequence "Disable Read Protection" can also be used when protection is programmed (configured) but not confirmed; wrong keywords are then indicated by the error flag PROER.

Read protection can be combined with sector specific write protection. In this case, after execution of the command 'Disable Read Protection' only those sectors are unlocked for write accesses, which are not separately write protected.

8.4.8.3 Flash Write and OTP Protection

A range of Flash can be write protected by several means:

- The complete PFLASH can be write protected by the read protection.
- Groups of sectors of PFLASH can be write-protected by three different "users", i.e. UCBs:
 - UCB0: Write protection that can be disabled with the password of UCB0.
 - UCB1: Write protection that can be disabled with the password of UCB1.
 - UCB2: Write protection that can not be disabled anymore (ROM or OTP function: "One-Time Programmable").

Write and OTP Protection Status

An active write protection is indicated by WPROIN bits in **FSR** register. It causes the program and erase command sequences to fail with a PROER.

A range "x" (i.e. a group of sectors, see [PROCON0](#)) of the PFLASH is write protected if any of the following conditions is true:

- **FCON**.RPA
- **PROCON2**.SxROM

Flash and Program Memory Unit (PMU)

- **PROCON0**.SxL and not(**FSR**.WPRODIS0)
- **PROCON1**.SxL and not(**PROCON0**.SxL) and not(**FSR**.WPRODIS1)

Thus with the password of UCB0 the write protection of sectors protected by user 0 and user 1 can be disabled, however with the password of UCB1 only those sectors that are only protected by user 1. The write protection of user 2 (OTP) can be obviously not disabled. The global write protection caused by the read protection can be disabled as described above by using the password of UCB0 to disable the read protection.

Initialization of Write and OTP Protection

Installation of write protection is performed with the “Write User Configuration Page” operation, controlled by the user. With this command, the user defines and writes into the UCBx page 0 the write protection configuration bits for all sectors, which shall be locked by the specific user, and the user-specific two keywords (not necessary for user 2). The position of sector lock bits is identical as defined for the PROCON registers (**Section 8.7.3.5**). The correctness of keywords shall then (after next reset) be checked with the command ‘Disable Sector Write Protection’, which delivers a protection error PROER in case of wrong passwords. Only if the keywords are correct, the special 32-bit confirmation code must be written into the page 2 of UCBx with a second “Write User Configuration Page” command. Only this confirmation code enables the write protection of the User Control Block UCBx, and only in this case the installation bit(s) in **FSR** is (are) set during ramp up.

Note: If the write protection is configured in the user's UCB page 0 but not confirmed via page 2 (necessary for check of keywords), the state after next reset is as follows:

- The selected sector(s) are protected (good for testing of protection, but not OTP!)
- The respective PROCON register is set accordingly (also for OTP!)
- The UCBx is not protected, thus it can be erased without passwords
- The related WPROINx bit in **FSR** is not set
- The Disable Write Protection command sets the WPRODISx bit
- The Resume command does not clear the WPRODISx bit.

The structure and layout of the three UC blocks is shown in **Table 8-3** below, the command “Write User Configuration Page” is described in **Section 8.4.7.1**.

Disabling Write Protection (not applicable to OTP)

With the command sequence “Disable Sector Write Protection” short-term disabling of write protection for user 0 or user 1 is possible. This command unlocks temporarily all locked sectors belonging to the user. The “Disable Sector Write Protection” command sequence is a protected command, which is only processed by the command state machine, if the included two passwords are correct. The disabled state of sector protection is indicated in the Flash Status Register **FSR** with the WPRODIS bit of the user 0 or/and user 1 (see **Section 8.7.3.1**). For user 2 who owns the sectors with ROM functionality, a disablement of write protection and thus re-programming is not possible.

Flash and Program Memory Unit (PMU)

Resumption of write protection after disablement is performed with the “Resume Read/Write Protection” command, which is identical for user 0 and user 1.

Generally, sector write protection will remain installed as long as it is configured and confirmed in the User Configuration Block belonging to the user. Erase of UC block and re-program of UC pages can be performed up to 4 times, for user 0 and user 1 only. But note, after execution of the Erase UC block command (which is still protected and therefore requires the preceding disablement of write protection with the user’s passwords), the complete protection configuration including the keywords of the specific user (not user 2) is erased; thus, the sectors belonging to the user are unprotected until the user’s UC pages are re-programmed. Only exception: sectors protected by user 2 are locked for ever because the UCB2 can no more be erased after installation of write protection in UCB2.

8.4.8.4 System Wide Effects of Flash Protection

An active Flash read protection needs to be respected in the complete system.

The startup software (SSW) checks if the Flash read protection is active in the PMU, if yes:

- If the selected boot mode executes from internal PFLASH.
 - The SSW clears the DCF and DDF.
 - The SSW leaves the debug interface locked.
- If the selected boot mode does not execute from internal PFLASH:
 - The SSW either leaves DCF and DDF set or actively sets them again in the PMU after evaluating the configuration sector.
 - The debug interface is unlocked.

If the read protection is inactive in the PMU the DCF and DDF flags are cleared by the SSW and the debug interface is unlocked.

Note: Full Flash analysis of an FAR device is only possible when the customer has removed all installed protections or delivers the necessary passwords with the device. As the removal of an OTP protection in UCB2 is not possible the OTP protection inevitably limits analysis capabilities.

8.4.9 Data Integrity and Safety

The data in Flash is stored with error correcting codes “ECC” in order to protect against data corruption. The healthiness of Flash data can be checked with margin checks.

8.4.9.1 Error-Correcting Code (ECC)

The data in the PFLASH is stored with ECC codes. These are automatically generated when the data is programmed. When data is read these codes are evaluated. Data in

Flash and Program Memory Unit (PMU)

PFLASH uses an ECC code with SEC-DED (Single Error Correction, Double Error Detection) capabilities. Each block of 64 data bits is accompanied with 8 ECC bits.

Standard PFLASH ECC

In the standard PFLASH ECC the 8-bit ECC value is calculated over 64 data bits. An erased data block (all bits '0') has an ECC value of 00_H. Therefore an erased sector is free of ECC errors. A data block with all bits '1' has an ECC value of FF_H.

The ECC is automatically generated when programming the PFLASH.

The ECC is automatically evaluated when reading data.

This algorithm has the following capabilities:

- Single-bit error:
 - Is noted in **FSR**.PFSBER.
 - Data and ECC value are corrected.
 - Interrupt is triggered if enabled with **FCON**.PFSBERM.
- Double-bit error:
 - Is noted in **FSR**.PFDBER.
 - Causes a bus error if not disabled by **MARP**.TRAPDIS.
 - Interrupt is triggered if enabled with **FCON**.PFDBERM. This interrupt shall only be used for margin check, when the bus error is disabled.

8.4.9.2 Margin Checks

The Flash memory offers a "margin check feature": the limit which defines if a Flash cell is read as logic '0' or logic '1' can be shifted. This is controlled by the register **MARP**. The Margin Control Register **MARP** is used to change the margin levels for read operations to find problematic array bits. The array area to be checked is read with more restrictive margins. "Problematic" bits will result in a single or double-bit error that is reported to the CPU by an error interrupt or a bus error trap. The double-bit error trap can be disabled for margin checks and also redirected to an error interrupt.

After changing the read margin at least $t_{FL_MarginDel}$ have to be waited before reading the affected Flash module. During erase or program operation only the standard (default) margins are allowed.

8.5 Service Request Generation

Access and/or operational errors (e.g. wrong command sequences) may be reported to the user by interrupts, and they are indicated by flags in the Flash Status Register **FSR**. Additionally, bus errors may be generated resulting in CPU traps.

8.5.1 Interrupt Control

The PMU and Flash module supports immediate error and status information to the user by interrupt generation. One CPU interrupt request is provided by the Flash module.

The Flash interrupt can be issued because of following events:

- End of busy state: program or erase operation finished
- Operational error (OPER): program or erase operation aborted
- Verify error (VER): program or erase operation not correctly finished
- Protection error
- Sequence error
- Single-bit error: corrected read data from PFLASH delivered
- Double-bit error in Program Flash.

Note: In case of an OPER or VER error, the error interrupt is issued not before the busy state of the Flash is deactivated.

The source of interrupt is indicated in the Flash Status Register **FSR** by the error flags or by the PROG or ERASE flag in case of end of busy interrupt. An interrupt is also generated for a new error event, even if the related error flag is still set from a previous error interrupt.

Every interrupt source is masked (disabled) after reset and can be enabled via dedicated mask bits in the Flash Configuration Register **FCON**.

8.5.2 Trap Control

CPU traps are triggered because of bus errors, generated by the PMU in case of erroneous Flash accesses. Bus errors are generated synchronously to the bus cycle requesting the not allowed Flash access or the disturbed Flash read data. Bus errors are issued because of following events:

- Not correctable double-bit error of 64-bit read data from PFLASH (if not disabled for margin check)
- Not allowed write access to read only register (see [Table 8-11](#))
- Not allowed write access to Privileged Mode protected register (see [Table 8-11](#))
- Not allowed data or instruction read access in case of active read protection
- Access to not implemented addresses within the register or array space.
- Read-modify-write access to the Flash array.

Write accesses to the Flash array address space are interpreted as command cycles and initiate not a bus error but a sequence error if the address or data pattern is not correct. However, command sequence cycles, which address a busy Flash bank, are serviced with busy cycles, not with a sequence error.

If the trap event is a double-bit error in PFLASH, it is indicated in the **FSR**. With exception of this error trap event, all other trap sources cannot be disabled within the PMU.

Flash and Program Memory Unit (PMU)

*Note: A double-bit error trap during margin check can be disabled (via **MARP** register) and redirected to an interrupt request.*

8.5.3 Handling Errors During Operation

The previous sections described shortly the functionality of “error indicating” bits in the flash status register **FSR**. This section elaborates on this with more in-depth explanation of the error conditions and recommends how these should be handled by customer software. This first part handles error conditions occurring during operation (i.e. after issuing command sequences) and the second part (**Section 8.5.3.6**) error conditions detected during startup.

8.5.3.1 SQER “Sequence Error”

Fault conditions:

- Improper command cycle address or data, i.e. incorrect command sequence.
- New “Enter Page” in Page Mode.
- “Load Page” and not in Page Mode.
- “Load Page” results in buffer overflow.
- First “Load Page” addresses 2. word.
- “Write Page” with buffer underflow.
- “Write Page” and not in Page Mode.
- “Write Page” to wrong Flash type.
- Byte transfer to password or data.
- “Clear Status” or “Reset to Read” while busy¹⁾.
- Erase UCB with wrong UCBA.

New state:

Read mode is entered with following exceptions:

- “Enter Page” in Page Mode re-enters Page Mode.
- “Write Page” with buffer underflow is executed.
- After “Load Page” causing a buffer overflow the Page Mode is not left, a following “Write Page” is executed.

Proposed handling by software:

Usually this bit is only set due to a bug in the software. Therefore in development code the responsible error tracer should be notified. In production code this error should not occur. It is however possible to clear this flag with “Clear Status” or “Reset to Read” and simply issue the corrected command sequence again.

With a SQER after the “Write Page” sequence it is possible to verify the written data in the Flash. It is sufficient to clear the flag with the “Clear Status” command if the written

1) When the command addresses the busy Flash bank, the access is serviced with busy cycles.

Flash and Program Memory Unit (PMU)

data is correct. If the written data is wrong, the whole sector must be erased and reprogrammed.

8.5.3.2 PFOPER “Operation Error”Fault conditions:

ECC double-bit error detected in Flash module internal SRAM during a program or erase operation in PFLASH. This can be a transient event due to alpha-particles or illegal operating conditions or it is a permanent error due to a hardware defect. This situation will practically not occur.

Attention: these bits can also be set during startup (see [Section 8.5.3.6](#)).

New state:

The Flash operation is aborted, the BUSY flag is cleared and read mode is entered.

Proposed handling by software:

The flag should be cleared with “Clear Status”. The last operation can be determined from the PROG and ERASE flags. In case of an erase operation the affected physical sector must be assumed to be in an invalid state, in case of a program operation only the affected page. Other physical sectors can still be read. New program or erase commands must not be issued before the next reset.

Consequently a reset must be performed. This performs a new Flash ramp up with initialization of the microcode SRAM. The application must determine from the context which operation failed and react accordingly. Mostly erasing the addressed sector and re-programming its data is most appropriate. If a “Program Page” command was affected and the sector can not be erased the wordline could be invalidated if needed by marking it with all-one data and the data could be programmed to another empty wordline.

Only in case of a defective microcode SRAM the next program or erase operation will incur again this error.

Note: Although this error indicates a failed operation it is possible to ignore it and rely on a data verification step to determine if the Flash memory has correct data. Before re-programming the Flash the flow must ensure that a new reset is applied.

Note: Even when the flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see [Section 8.5.1](#), interrupt because of operational error).

8.5.3.3 PROER “Protection Error”Fault conditions:

- Password failure.
- Erase/Write to protected sector.
- Erase UCB and protection active.

Flash and Program Memory Unit (PMU)

- Write UC-Page to protected UCB.

Attention: a protection violation can even occur when a protection was not explicitly installed by the user. This is the case when the Flash startup detects an error and starts the user software with read-only Flash (see [Section 8.5.3.6](#)). Trying to change the Flash memory will then cause a PROER.

New state:

Read mode is entered. The protection violating command is not executed.

Proposed handling by software:

Usually this bit is only set during runtime due to a bug in the software. In case of a password failure a reset must be performed in the other cases the flag can be cleared with "Clear Status" or "Reset to Read". After that the corrected sequence can be executed.

8.5.3.4 VER "Verification Error"Fault conditions:

This flag is a warning indication and not an error. It is set when a program or erase operation was completed but with a suboptimal result. This bit is already set when only a single bit is left over-erased or weakly programmed which would be corrected by the ECC anyhow.

However, excessive VER occurrence can be caused by operating the Flash out of the specified limits, e.g. incorrect voltage or temperature. A VER after programming can also be caused by programming a page whose sector was not erased correctly (e.g. aborted erase due to power failure).

Under correct operating conditions a VER after programming will practically not occur. A VER after erasing is not unusual.

Attention: this bit can also be set during startup (see [Section 8.5.3.6](#)).

New state:

No state change. Just the bit is set.

Proposed handling by software:

This bit can be ignored. It should be cleared with "Clear Status" or "Reset to Read". In-spec operation of the Flash memory must be ensured.

If the application allows (timing and data logistics), a more elaborate procedure can be used to get rid of the VER situation:

- VER after program: erase the sector and program the data again. This is only recommended when there are more than 3 program VERs in the same sector. When programming the Flash in field ignoring program VER is normally the best solution because its most likely cause are violated operating conditions. Take care that never a sector is programmed in which the erase was aborted.

Flash and Program Memory Unit (PMU)

- VER after erase: the erase operation can be repeated until VER disappears. Repeating the erase more than 3 times consecutively for the same sector is not recommended. After that it is better to ignore the VER, program the data and check its readability. Again its most likely cause are violated operating conditions. Therefore it is recommended to repeat the erase at most once or ignore it altogether.

For optimizing the quality of Flash programming see the following section about handling single-bit ECC errors.

Note: Even when this flag is ignored it is recommended to clear it. Otherwise all following operations — including “sleep” — could trigger an interrupt even when they are successful (see [Section 8.5.1](#), interrupt because of verify error).

8.5.3.5 PFSBER/DFSBER “Single-Bit Error”Fault conditions:

When reading data or fetching code from PFLASH the ECC evaluation detected a single-bit error (“SBE”) which was corrected.

This flag is a warning indication and not an error. A certain amount of single-bit errors must be expected because of known physical effects.

New state:

No state change. Just the bit is set.

Proposed handling by software:

This flag can be used to analyze the state of the Flash memory. During normal operation it should be ignored. In order to count single-bit errors it must be cleared by “Clear Status” or “Reset to Read” after each occurrence¹⁾.

Usually it is sufficient after programming data to compare the programmed data with its reference values ignoring the SBE bits. When there is a comparison error the sector is erased and programmed again.

When programming the PFLASH (end-of-line programming or SW updates) customers can further reduce the probability of future read errors by performing the following check after programming:

- Change the read margin to “high margin 0”.
- Verify the data and count the number of SBEs.
- When the number of SBEs exceeds a certain limit (e.g. 10 in 2 Mbyte) the affected sectors could be erased and programmed again.
- Repeat the check for “high margin 1”.

¹⁾ Further advice: remember that the ECC is evaluated when the data is read from the PMU. When counting single-bit errors use always the non-cached address range otherwise the error count can depend on cache hit or miss and it refers to the complete cache line. As the ECC covers a block of 64 data bits take care to evaluate the [FSR](#) only once per 64-bit block.

Flash and Program Memory Unit (PMU)

- Each sector should be reprogrammed at most once, afterwards SBEs can be ignored.

Due to the specificity of each application the appropriate usage and implementation of these measures (together with the more elaborate VER handling) must be chosen according to the context of the application.

8.5.3.6 Handling Flash Errors During Startup

During startup, a fatal error during Flash ramp up forces the Firmware to terminate the startup process and to end in the Debug Monitor Mode (see Firmware chapter).

The reason for a failed Flash startup can be a hardware error or damaged configuration data.

FSR bits set after startup are of informative warning nature.

FSR.PFOPER can indicate a problem of a program/erase operation before the last system reset or an error when restoring the Flash module internal SRAM content after the last reset. In both cases it is advised to clear the flag with the command sequence "Clear Status" and trigger a system reset. If the error shows up again it is an indication for a permanent fault which will limit the Flash operation to read accesses. Under this condition program and erase operations are forbidden (but not blocked by hardware!).

8.6 Power, Reset and Clock

The following chapters describe the required power supplies, the power consumption and its possible reduction, the control of Flash Sleep Mode and the basic control of Reset.

8.6.1 Power Supply

The Flash module uses the standard V_{DDP} I/O power supply to generate the voltages for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations as well as for read operations. The standard V_{DDC} is used for all digital control functions.

8.6.2 Power Reduction

The "Flash Sleep Mode" can be used to drastically reduce power consumption while the Flash is not accessed for longer periods of time.

The "Idle Read Path" slightly reduces the dynamic power consumption during normal operation with marginal impact on the Flash read performance.

Flash Sleep Mode

As power reduction feature, the Flash module provides the Flash Sleep mode which can be selected by the user individually for the Flash. The Sleep mode can be requested by:

- Programming 1_B to the bit **FCON.SLEEP**.
- “External” sleep mode by the SCU (see “Flash Power Control” in the SCU). Only executed by the Flash when **FCON.ESLDIS** = 0_B.

Attention: ***f_{CPU} must be equal or above 1 MHz when Sleep mode is requested until the Sleep mode is indicated in **FSR.SLM**, and when a wake-up request is triggered, until **FSR.PBUSY** is cleared.***

The requested Sleep mode is only taken if the Flash is in idle state and when all pending or active requests are processed and terminated. Only then, the Flash array performs the ramp down into the Sleep mode: the sense amplifiers are switched off and the voltages are ramped down.

During ramp down to Sleep mode **FSR.PBUSY** is set.

As long as the Flash is in Sleep mode, this state is indicated by the bit **FSR.SLM**. The **FSR.PBUSY** stays set as well.

Wake-up from sleep is controlled with clearing of bit **FCON.SLEEP**, if selected via this bit, or wake-up is initiated by releasing the “external” sleep signal from SCU. After wake-up, the Flash enters read mode and is available again after the wake-up time t_{WU} . During the wake-up phase the **FSR.PBUSY** is set until the wake-up process is completed.

Note: During sleep and wake-up, the Flash is reported to be busy. Thus, read and write accesses to the Flash in Sleep mode are acknowledged with busy’ and should therefore be avoided; those accesses make sense only during wake-up, when waiting for the Flash read mode.

3. The wake-up time t_{WU} is documented in the Data Sheet. This time may fully delay the interrupt response time in Sleep mode.
4. Note: A wake-up is only accepted by the Flash if it is in Sleep mode. The Flash will first complete the ramp down to Sleep mode before reacting to a wake-up trigger.

Idle Read Path

An additional power saving feature is enabled by setting **FCON.IDLE**. In this case the PFLASH read path (**Flash Read Access**) is switched off when no read access is pending. System performance for sequential accesses is slightly reduced because internal linear prefetches of the PFLASH are disabled. Non-sequential read accesses requested by the CPU or any other bus master see no additional delay.

8.6.3 Reset Control

All PMU and Flash functionality is reset with the system reset with the exception of the register bits: **FSR.PROG**, **FSR.ERASE**, **FSR.PFOPER**. These bits are reset with the power-on reset.

The flash will be automatically reset to the read mode after every reset.

8.6.3.1 Resets During Flash Operation

A reset or power failure during an ongoing Flash operation (i.e. program or erase) must be considered as violation of stable operating conditions. However the Flash was designed to prevent damage to non-addressed Flash ranges when the reset is applied as defined in the data sheet. The exceptions are erasing logical sectors and UCBs. Aborting an erase process of a logical sector can leave the complete physical sector unreadable. When an UCB erase is aborted the complete Flash can become unusable. So UCBs must be only erased in a controlled environment. The addressed Flash range is left in an undefined state.

When an erase operation is aborted the addressed logical or physical sector can contain any data. It can even be in a state that doesn't allow this range to be programmed.

When a page programming operation is aborted the page can still appear as erased (but contain slightly programmed bits), it can appear as being correctly programmed (but the data has a lowered retention) or the page contains garbage data. It is also possible that the read data is instable so that depending on the operating conditions different data is read.

For the detection of an aborted Flash process the flags **FSR.PROG** and **FSR.ERASE** could be used as indicator but only when the reset was a System Reset. Power-on resets can not be determined from any flags. It is not possible to detect an aborted operation simply by reading the Flash range. Even the margin reads don't offer a reliable indication.

When erasing or programming the PFLASH usually an external instance can notice the reset and simply restart the operation by erasing the Flash range and programming it again.

However, in cases where this external instance is not existing, a common solution is detecting an abort by performing two operations in sequence and determine after reset from the correctness of the second the completeness of the first operation.

E.g. after erasing a sector a page is programmed. After reset the existence of this page proves that the erase process was performed completely.

The detection of aborted programming processes can be handled similarly. After programming a block of data an additional page is programmed as marker. When after reset the block of data is readable and the marker is existent it is ensured that the block of data was programmed without interruption.

Flash and Program Memory Unit (PMU)

If a complete page can be spent as marker, the following recipe allows to reduce the marker size to 8 bytes. This recipe violates the rule that a page may be programmed only once. This violation is only allowed for this purpose and only when the algorithm is robust against disturbed pages (see also recommendations for handling single-bit errors) by repeating a programming step when it detects a failure.

Robust programming of a page of data with an 8 byte marker:

1. After reset program preferably always first to an even page ("Target Page").
2. If the Other Page on the same wordline contains active data save it to SRAM (the page can become disturbed because of the 4 programming operations per wordline).
3. Program the data to the Target Page.
4. Perform strict check of the Target Page (see below).
5. Program 8 byte marker to Target Page.
6. Perform strict check of the Target Page.
7. In case of any error of the strict check go to the next wordline and program the saved data and the target data again following the same steps.
8. Ensure that the algorithm doesn't repeat unlimited in case of a violation of operating conditions.

Strict checking of programmed data:

1. Ignore single-bit errors and the VER flag.
2. Switch to tight margin 0.
3. If the data (check the complete page) is not equal to the expected data report an error.
4. If a double-bit error is detected report an error.

After reset the algorithm has to check the last programmed page if it was programmed completely:

1. Read with normal read level. Ignore single-bit errors.
2. Read 8-byte marker and check for double-bit error.
3. Read data part and verify its consistency (e.g. by evaluating a CRC). Check for double-bit error.
4. If the data part is defective don't use it (e.g. by invalidating the page).
5. If the data part is ok:
 - a) If the marker is erased the data part could have been programmed incompletely. Therefore the data part should not be used or alternatively it could be programmed again to a following page.
 - b) If the marker contains incorrect data the data part was most likely programmed correctly but the marker was programmed incompletely. The page could be used as is or alternatively the data could be programmed again to a following page.
 - c) If the marker is ok the data part was programmed completely and has the full retention. However this is not ensured for the marker part itself. Therefore the algorithm must be robust against the case that the marker becomes unreadable later.

Flash and Program Memory Unit (PMU)

8.6.4 Clock

The Flash interface is operating at the same clock speed as the CPU, f_{CPU} . Depending on the frequency, wait states must be inserted in the Flash accesses. Further details on the wait states configuration are given in [Section 8.4.4](#).

For proper operation of command sequences and when entering or waking up from Sleep mode, f_{CPU} must be equal or above 1 MHz.

8.7 Registers

The register set consists of the PMU ID register ([Section 8.7.1](#)), the Prefetch Control register ([Section 8.7.2](#)). The other registers control Flash functionality ([Section 8.7.3](#)).

All accesses prevented due to access mode restrictions fail with a bus error.

Also accesses to unoccupied register addresses fail with a bus error.

8.7.1 PMU Registers

The PMU only contains the ID register.

Table 8-6 Registers Address Space

| Module | Base Address | End Address | Note |
|----------|------------------------|------------------------|-----------|
| reserved | 5800 0000 _H | 5800 04FF _H | Bus Error |
| PMU0 | 5800 0500 _H | 5800 05FF _H | |
| reserved | 5800 0600 _H | 5800 0FFF _H | Bus Error |
| reserved | 5800 2400 _H | 5800 3FFF _H | Bus Error |

Table 8-7 Registers Overview

| Short Name | Description | Offset Addr. ¹⁾ | Access Mode | | Reset Class | Page Number |
|------------|-----------------------|----------------------------|-------------|-------|--------------|----------------------|
| | | | Read | Write | | |
| ID | Module Identification | 08 _H | U, PV | BE | System Reset | 8-34 |

1) The absolute register address is calculated as follows:

Module Base Address ([Table 8-6](#)) + Offset Address (shown in this column)

Flash and Program Memory Unit (PMU)

8.7.1.1 PMU ID Register

The PMU0_ID register is a read-only register, thus write accesses lead to a bus error trap. Read accesses are permitted in Privileged Mode PV and in User Mode. The PMU0_ID register is defined as follows:

PMU0_ID

PMU0 Identification Register

(5800 0508_H)

Reset Value: 0091 C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|---|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first rev.). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the module identification number for PMU0. |

8.7.2 Prefetch Registers

This section describes the register of the Prefetch unit.

Table 8-8 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|---------------------------|
| PREF | 5800 4000 _H | 5800 7FFF _H | Prefetch Module Registers |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|-------------|-----------------------------|------|---|
| IBYP | 0 | rw | Instruction Prefetch Buffer Bypass 0_B Instruction prefetch buffer not bypassed. 1_B Instruction prefetch buffer bypassed. |
| IINV | 1 | w | Instruction Prefetch Buffer Invalidate Write Operation: 0_B No effect. 1_B Initiate invalidation of entire instruction cache. |
| DBYP | 4 | rw | Data Buffer Bypass 0_B Prefetch Data buffer not bypassed. 1_B Prefetch Data buffer bypassed. |
| 0 | 16 | rw | Reserved Must be written with 0. |
| 0 | [15:5], 3, 2, [31:17] | r | Reserved returns 0 if read; should be written with 0. |

Flash and Program Memory Unit (PMU)

8.7.3 Flash Registers

All register addresses are word aligned, independently of the register width. Besides word-read/write accesses, also byte or half-word read/write accesses are supported.

The absolute address of a Flash register is calculated by the base address from [Table 8-10](#) plus the offset address of this register from [Table 8-11](#).

Table 8-10 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|-------------------------|
| FLASH0 | 5800 1000 _H | 5800 23FF _H | Flash registers of PMU0 |

The following table shows the addresses, the access modes and reset types for the Flash registers in PMU0:

Table 8-11 Addresses of Flash0 Registers

| Short Name | Description | Address | Access Mode | | Reset | See |

Flash and Program Memory Unit (PMU)
8.7.3.1 Flash Status Definition

The Flash Status Register FSR reflects the overall status of the Flash module after Reset and after reception of the different commands. Sector specific protection states are not indicated in the FSR, but in the registers PROCON0, PROCON1 and PROCON2. The status register is a read-only register. Only the error flags and the two status flags (PROG, ERASE) are affected with the "Clear Status" command. The error flags are also cleared with the "Reset to Read" command.

The FSR is defined as follows:

FSR
Flash Status Register
(1010_H)
Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |
|-----|----------|----|----------|--------|------------|------------|----------|-----------|-----------|-----------|-------|-----------|----------|----------|---------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| VER | X | 0 | SLM | 0 | W PRO DIS1 | W PRO DIS0 | 0 | W PRO IN2 | W PRO IN1 | W PRO IN0 | 0 | R PRO DIS | R PRO IN | 0 | PRO IN |
| rh | rh | r | rh | r | rh | rh | r | rh | rh | rh | r | rh | rh | r | rh |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | PF DB ER | 0 | PF SB ER | PRO ER | SQ ER | 0 | PF OP ER | 0 | PF PAG E | ERA SE | PRO G | 0 | 0 | FA BUS Y | P BUS Y |
| r | rh | r | rh | rh | rh | r | rh | r | rh | rh | rh | r | r | rh | rh |

| Field | Bits | Type | Description |
|----------------------|------|------|---|
| PBUSY ¹⁾ | 0 | rh | Program Flash Busy HW-controlled status flag. 0 _B PFLASH ready, not busy; PFLASH in read mode. 1 _B PFLASH busy; PFLASH not in read mode. Indication of busy state of PFLASH because of active execution of program or erase operation; PFLASH busy state is also indicated during Flash recovery (after reset) and in power ramp-up state or in sleep mode; while in busy state, the PFLASH is not in read mode. |
| FABUSY ¹⁾ | 1 | rh | Flash Array Busy Internal busy flag for testing purposes. Must be ignored by application software, which must use PBUSY instead. |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|---------------------------------|------|------|---|
| PROG ³⁾⁴⁾ | 4 | rh | Programming State HW-controlled status flag. 0 _B There is no program operation requested or in progress or just finished. 1 _B Programming operation (write page) requested (from FIM) or in action or finished. Set with last cycle of Write Page command sequence, cleared with Clear Status command (if not busy) or with power-on reset. If one BUSY flag is coincidentally set, PROG indicates the type of busy state. If xOPER is coincidentally set, PROG indicates the type of erroneous operation. Otherwise, PROG indicates, that operation is still requested or finished. |
| ERASE ³⁾⁴⁾ | 5 | rh | Erase State HW-controlled status flag. 0 _B There is no erase operation requested or in progress or just finished 1 _B Erase operation requested (from FIM) or in action or finished. Set with last cycle of Erase command sequence, cleared with Clear Status command (if not busy) or with power-on reset. Indications are analogous to PROG flag. |
| PFPAGE ¹⁾²⁾ | 6 | rh | Program Flash in Page Mode HW-controlled status flag. 0 _B Program Flash not in page mode 1 _B Program Flash in page mode; assembly buffer of PFLASH (256 byte) is in use (being filled up) Set with Enter Page Mode for PFLASH, cleared with Write Page command <i>Note: Concurrent page and read modes are allowed</i> |
| PFOPER ²⁾³⁾⁴⁾ | 8 | rh | Program Flash Operation Error 0 _B No operation error reported by Program Flash 1 _B Flash array operation aborted, because of a Flash array failure, e.g. an ECC error in microcode. This bit is not cleared with System Reset, but with power-on reset. Registered status bit; must be cleared per command |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|--------------------------------|------|------|---|
| SQER¹⁾²⁾³⁾ | 10 | rh | Command Sequence Error 0_B No sequence error 1_B Command state machine operation unsuccessful because of improper address or command sequence. A sequence error is not indicated if the Reset to Read command aborts a command sequence. Registered status bit; must be cleared per command |
| PROER¹⁾²⁾³⁾ | 11 | rh | Protection Error 0_B No protection error 1_B Protection error. A Protection Error is reported e.g. because of a not allowed command, for example an Erase or Write Page command addressing a locked sector, or because of wrong password(s) in a protected command sequence such as "Disable Read Protection" Registered status bit; must be cleared per command |
| PFSBER¹⁾²⁾³⁾ | 12 | rh | PFLASH Single-Bit Error and Correction 0_B No Single-Bit Error detected during read access to PFLASH 1_B Single-Bit Error detected and corrected Registered status bit; must be cleared per command |
| PFDBER¹⁾²⁾³⁾ | 14 | rh | PFLASH Double-Bit Error 0_B No Double-Bit Error detected during read access to PFLASH 1_B Double-Bit Error detected in PFLASH Registered status bit; must be cleared per command |
| PROIN | 16 | rh | Protection Installed 0_B No protection is installed 1_B Read or/and write protection for one or more users is configured and correctly confirmed in the User Configuration Block(s). HW-controlled status flag |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|-------------------------------|------|------|--|
| RPROIN | 18 | rh | Read Protection Installed 0_B No read protection installed 1_B Read protection and global write protection is configured and correctly confirmed in the User Configuration Block 0. Supported only for the master user (user zero). HW-controlled status flag |
| RPRODIS¹⁾⁵⁾ | 19 | rh | Read Protection Disable State 0_B Read protection (if installed) is not disabled 1_B Read and global write protection is temporarily disabled. Flash read with instructions from other memory, as well as program or erase on not separately write protected sectors is possible. HW-controlled status flag |
| WPROIN0 | 21 | rh | Sector Write Protection Installed for User 0 0_B No write protection installed for user 0 1_B Sector write protection for user 0 is configured and correctly confirmed in the User Configuration Block 0. HW-controlled status flag |
| WPROIN1 | 22 | rh | Sector Write Protection Installed for User 1 0_B No write protection installed for user 1 1_B Sector write protection for user 1 is configured and correctly confirmed in the User Configuration Block 1. HW-controlled status flag |
| WPROIN2 | 23 | rh | Sector OTP Protection Installed for User 2 0_B No OTP write protection installed for user 2 1_B Sector OTP write protection with ROM functionality is configured and correctly confirmed in the UCB2. The protection is locked for ever. HW-controlled status flag |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|--------------------------------|------|------|--|
| WPRODISO¹⁾⁵⁾ | 25 | rh | Sector Write Protection Disabled for User 0 0_B All protected sectors of user 0 are locked if write protection is installed 1_B All write-protected sectors of user 0 are temporarily unlocked, if not coincidentally locked by user 2 or via read protection. Hierarchical protection control: User-0 sectors are also unlocked, if coincidentally protected by user 1. But not vice versa. HW-controlled status flag |
| WPRODISO¹⁾⁵⁾ | 26 | rh | Sector Write Protection Disabled for User 1 0_B All protected sectors of user 1 are locked if write protection is installed 1_B All write-protected sectors of user 1 are temporarily unlocked, if not coincidentally locked by user 0 or user 2 or via read protection. HW-controlled status flag |
| SLM¹⁾ | 28 | rh | Flash Sleep Mode HW-controlled status flag. Indication of Flash sleep mode taken because of global or individual sleep request; additionally indicates when the Flash is in shut down mode. 0_B Flash not in sleep mode 1_B Flash is in sleep or shut down mode |
| X | 30 | rh | Reserved Value undefined |
| VER¹⁾³⁾ | 31 | rh | Verify Error 0_B The page is correctly programmed or the sector correctly erased. All programmed or erased bits have full expected quality. 1_B A program verify error or an erase verify error has been detected. Full quality (retention time) of all programmed ("1") or erased ("0") bits cannot be guaranteed. See Section 8.5.3 and Section 8.5.3.6 for proper reaction. Registered status bit; must be cleared per command |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|----------|---|------|--|
| 0 | 2,3,7, 9,13, 15,17, 20,24, 27, 29 | r | Reserved Read zero, no write |

Note: The footnote numbers of FSR bits describe the specific reset conditions:

- 1)Cleared with System Reset
- 2)Cleared with command “Reset to Read”
- 3)Cleared with command “Clear Status”
- 4)Cleared with power-on reset (PORST)
- 5)Cleared with command “Resume Protection”

Note: The xBUSY flags as well as the protection flags cannot be cleared with the “Clear Status” command or with the “Reset to Read” command. These flags are controlled by HW.

Note: The reset value above is indicated after correct execution of Flash ramp up. Additionally, errors are possible after ramp up (see [Section 8.5.3.6](#)).

8.7.3.2 Flash Configuration Control

The Flash Configuration Register FCON reflects and controls the following general Flash configuration functions:

- Number of wait states for Flash accesses.
- Indication of installed and active read protection.
- Instruction and data access control for read protection.
- Interrupt mask bits.
- Power reduction and shut down control.

FCON is a Privileged Mode protected register. It is defined as follows:

Flash and Program Memory Unit (PMU)

FCON

Flash Configuration Register

(1014_H)

Reset value: 000X 0006_H

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| SL EEP | ESL DIS | IDLE | 0 | | | | | | | | | WSEC PF | WSPFLASH | | |
| rw | rw | rw | r | | | r | | | | r | | rw | | rw | |

| Field | Bits | Type | Description |
|-----------------|-------|------|--|
| WSPFLASH | [3:0] | rw | Wait States for read access to PFLASH This bit field defines the number of wait states n, which are used for an initial read access to the Program Flash memory area, with $WSPFLASH \times (1 / f_{CPU}) \geq t_a^{(1)}$. 0000 _B PFLASH access in one clock cycle 0001 _B PFLASH access in one clock cycle 0010 _B PFLASH access in two clock cycles 0011 _B PFLASH access in three clock cycles PFLASH access in four up to fourteen clock cycles. 1111 _B PFLASH access in fifteen clock cycles. |
| WSECPF | 4 | rw | Wait State for Error Correction of PFLASH 0 _B No additional wait state for error correction 1 _B One additional wait state for error correction during read access to Program Flash. If enabled, this wait state is only used for the first transfer of a burst transfer. Set this bit only when requested by Infineon. |
| IDLE | 13 | rw | Dynamic Flash Idle 0 _B Normal/standard Flash read operation 1 _B Dynamic idle of Program Flash enabled for power saving; static prefetching disabled |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|---------------|------|------|--|
| ESLDIS | 14 | rw | External Sleep Request Disable 0_B External sleep request signal input is enabled 1_B Externally requested Flash sleep is disabled The 'external' signal input is connected with a global power-down/sleep request signal from SCU. |
| SLEEP | 15 | rw | Flash SLEEP 0_B Normal state or wake-up 1_B Flash sleep mode is requested Wake-up from sleep is started with clearing of the SLEEP-bit. |
| RPA | 16 | rh | Read Protection Activated This bit monitors the status of the Flash-internal read protection. This bit can only be '0' when read protection is not installed or while the read protection is temporarily disabled with password sequence. 0_B The Flash-internal read protection is not activated. Bits DCF, DDF are not taken into account. Bits DCF, DDFx can be cleared 1_B The Flash-internal read protection is activated. Bits DCF, DDF are enabled and evaluated. |
| DCF | 17 | rwh | Disable Code Fetch from Flash Memory This bit enables/disables the code fetch from the internal Flash memory area. Once set, this bit can only be cleared when RPA='0'. This bit is automatically set with reset and is cleared during ramp up, if no RP installed, and during startup (BROM) in case of internal start out of Flash. 0_B Code fetching from the Flash memory area is allowed. 1_B Code fetching from the Flash memory area is not allowed. This bit is not taken into account while RPA='0'. |

Flash and Program Memory Unit (PMU)

| Field | Bits | Type | Description |
|----------------|-------------------------------|------|--|
| DDF | 18 | rwh | Disable Any Data Fetch from Flash This bit enables/disables the data read access to the Flash memory area (Program Flash and Data Flash). Once set, this bit can only be cleared when RPA='0'. This bit is automatically set with reset and is cleared during ramp up, if no RP installed, and during startup (BROM) in case of internal start out of Flash. 0 _B Data read access to the Flash memory area is allowed. 1 _B Data read access to the Flash memory area is not allowed. This bit is not taken into account while RPA='0'. |
| VOPERM | 24 | rw | Verify and Operation Error Interrupt Mask 0 _B Interrupt not enabled 1 _B Flash interrupt because of Verify Error or Operation Error in Flash array (FSI) is enabled |
| SQERM | 25 | rw | Command Sequence Error Interrupt Mask 0 _B Interrupt not enabled 1 _B Flash interrupt because of Sequence Error is enabled |
| PROERM | 26 | rw | Protection Error Interrupt Mask 0 _B Interrupt not enabled 1 _B Flash interrupt because of Protection Error is enabled |
| PFSBERM | 27 | rw | PFLASH Single-Bit Error Interrupt Mask 0 _B No Single-Bit Error interrupt enabled 1 _B Single-Bit Error interrupt enabled for PFLASH |
| PFDBERM | 29 | rw | PFLASH Double-Bit Error Interrupt Mask 0 _B Double-Bit Error interrupt for PFLASH not enabled 1 _B Double-Bit Error interrupt for PFLASH enabled. Especially intended for margin check |
| EOBM | 31 | rw | End of Busy Interrupt Mask 0 _B Interrupt not enabled 1 _B EOB interrupt is enabled |
| 0 | [12:5], [23:19], 28, 30 | r | Reserved Always read/write zero |

Flash and Program Memory Unit (PMU)

1) WSPFLASH = 0_H deviates from this formula and results in the same timing as WSPFLASH = 1_H.

Note: The default numbers of wait states represent the slow cases. This is a general proceeding and additionally opens the possibility to execute higher frequencies without changing the configuration.

Note: After reset and execution of Firmware, the read protection control bits are coded as follows:

DDF, DCF, RPA = "110": No read protection installed

DDF, DCF, RPA = "001": Read protection installed; start in internal Flash

DDF, DCF, RPA = "111": Read protection installed; start not in internal Flash.

Flash and Program Memory Unit (PMU)

8.7.3.3 Flash Identification Register

The module identification register of Flash module is directly accessible by the CPU via PMU access. This register is mapped into the space of the Flash Interface Module's registers (see [Table 8-11](#)).

FLASH0_ID

Flash Module Identification Register (1008_H)

Reset Value: 0092 C0XX_H

| Field | Bits | Type | Description |
|------------|---------|------|---|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the module revision number. The value of a module revision starts with 01 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines a module identification number. For the XMC4[78]00 Flash0 this number is 0092 _H . |

Flash and Program Memory Unit (PMU)

8.7.3.4 Margin Check Control Register

MARP

Margin Control Register PFLASH (1018_H) **Reset Value: 0000 0000_H**

| TRAPDIS | 15 | rw | PFLASH Double-Bit Error Trap Disable 0 _B If a double-bit error occurs in PFLASH, a bus error trap is generated ¹⁾ . 1 _B The double-bit error trap is disabled. Shall be used only during margin check |
| 0 | [14:4], [31:16] | r | Reserved Always read as 0; should be written with 0. |

1) After Boot ROM exit, double-bit error traps are enabled (TRAPDIS = 0).

8.7.3.5 Protection Configuration Indication

The configuration of read/write/OTP protection is indicated with registers PROCON0, PROCON1 and PROCON2, thus separately for every user, and it is generally indicated in the status register FSR.

If write protection is installed for user 0 or 1 or OTP protection for user 2, for each sector of the Program Flash it is indicated in the user-specific Protection Configuration register PROCONx, if it is locked or unlocked for program or erase operations.

Flash and Program Memory Unit (PMU)

The Flash Protection Configuration registers PROCONx are loaded out of the user's configuration block directly after reset during ramp up. For software the three PROCONx registers are read-only registers.

PROCON0

System Control

9 Window Watchdog Timer (WDT)

Purpose of the Window Watchdog Timer module is improvement of system integrity. WDT triggers the system reset or other corrective action like e.g. non-maskable interrupt if the main program, due to some fault condition, neglects to regularly service the watchdog (also referred to as “kicking the dog”, “petting the dog”, “feeding the watchdog” or “waking the watchdog”). The intention is to bring the system back from unresponsive state into normal operation.

References

[9] Cortex-M4 User Guide, ARM DUI 0508B (ID062910)

9.1 Overview

A successful servicing of the WDT results in a pulse on the signal `wdt_service`. The signal is offered also as an alternate function output. It can be used to show to an external watchdog that the system is alive.

The WDT timer is a 32-bit counter, which counts up from 0_H . It can be serviced while the counter value is within the window boundary, i.e. between the lower and the upper boundary value. Correct servicing results in a reset of the counter to 0_H . A so called “Bad Service” attempt results in a system reset request.

The timer block is running on the f_{WDT} clock which is independent from the bus clock. The timer value is updated in the corresponding register **TIM**, whenever the timer value increments. This mechanism enables immediate response on a read access from the bus.

The WDT module provides register interface for configuration. A write to writable registers is only allowed, when the access is in privileged mode. A write access in user mode results in a bus error response.

9.1.1 Features

The watchdog timer (WDT) is an independent window watchdog timer.

The features are:

- Triggers system reset when not serviced on time or serviced in a wrong way
- Servicing restricted to be within boundaries of a user definable refresh window
- Can run from an independent clock
- Provides service indication to an external pin
- Can be suspended in HALT mode
- Provides optional pre-warning alarm before reset

Table 9-1 Application Features

| Feature | Purpose/Application |
|--|---|
| System reset upon Bad Servicing | Triggered to restore system stable operation and ensure system integrity |
| Servicing restricted to be within defined boundaries of refresh window | Allows to consider minimum and maximum software timing |
| Independent clocks | To ensure that WDT counts even in case of the system clock failure |
| Service indication on external pin | For dual-channel watchdog solution, additional external control of system integrity |
| Suspending in HALT mode | Enables safe debugging with productive code |
| Pre-warning alarm | Software recovery to allow corrective action via software recovery routine bringing system back from the unresponsive state into normal operation |

9.1.2 Block Diagram

The WDT block diagram is shown in [Figure 9-1](#).

Window Watchdog Timer (WDT)

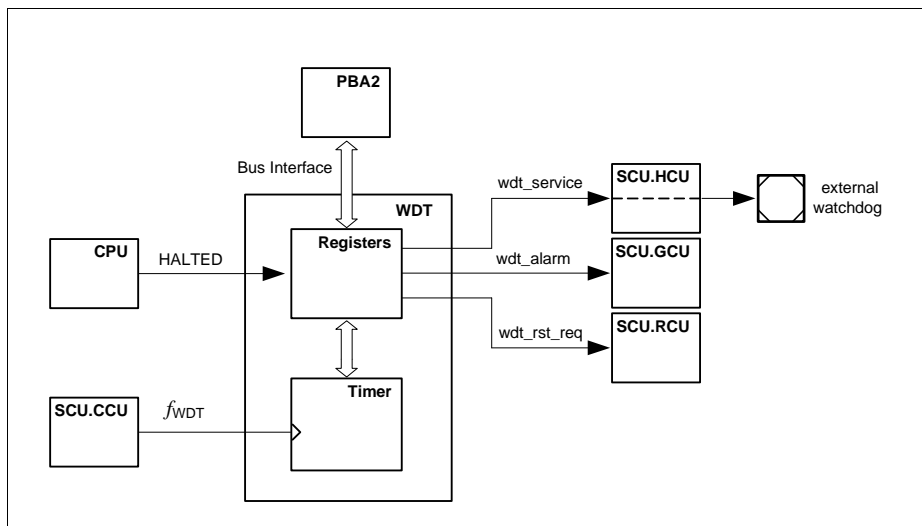

Figure 9-1 Watchdog Timer Block Diagram

9.2 Time-Out Mode

An overflow results in an immediate reset request going to the RCU of the SCU via the signal `wdt_rst_req` whenever the counter crosses the upper boundary it triggers an overflow event pre-warning is not enabled with **CTR** register. A successful servicing performed with writing a unique value, referred to as “Magic Word” to the **SRV** register of the WDT within the valid servicing window, results in a pulse on the signal `wdt_service` and reset of the timer counter.

Window Watchdog Timer (WDT)

Figure 9-2 Reset without pre-warning

The example scenario depicted in [Figure 9-2](#) shows two consecutive service pulses generated from WDT module as the result of successful servicing within valid time windows. The situation where no service has been performed immediately triggers generation of reset request on the `wdt_rst_req` output after the counter value has exceeded window upper bound value.

9.3 Pre-warning Mode

While in pre-warning mode the effect of the overflow event is different with and without pre-warning enabled. The first crossing of the upper bound triggers the outgoing alarm signal `wdt_alarm` when pre-warning is enabled. Only the next overflow results a reset request. The alarm status is shown via register [WDTSTS](#) and can be cleared via register [WDTCLR](#). A clear of the alarm status will bring the WDT back to normal state. The alarm signal is routed as request to the SCU, where it can be promoted to NMI.

Window Watchdog Timer (WDT)

Figure 9-3 Reset after pre-warning

The example scenario depicted in [Figure 9-3](#) shows service pulse generated from WDT module as the result of successful servicing within valid time window. WDT generates alarm pulse on `wdt_alarm` upon first missing servicing. The alarm signal is routed as interrupt request to the SCU, where it can be promoted to NMI. Within this alarm service request the user can clear the WDT status bit and give a proper WDT service before it overflows next time. Otherwise WDT generates reset request on `wdt_rst_req` upon the second missing service.

9.4 Bad Service Operation

A bad service attempt results in a reset request. A bad service attempt can be due to servicing outside the window boundaries or servicing with an invalid Magic Word.

Window Watchdog Timer (WDT)

Figure 9-4 Reset upon servicing in a wrong window

The example in **Figure 9-4** shows servicing performed outside of valid servicing window. Attempt to service WDT while counter value remains below the Window Lower Bound results in immediate reset request on wdt_rst_req signal.

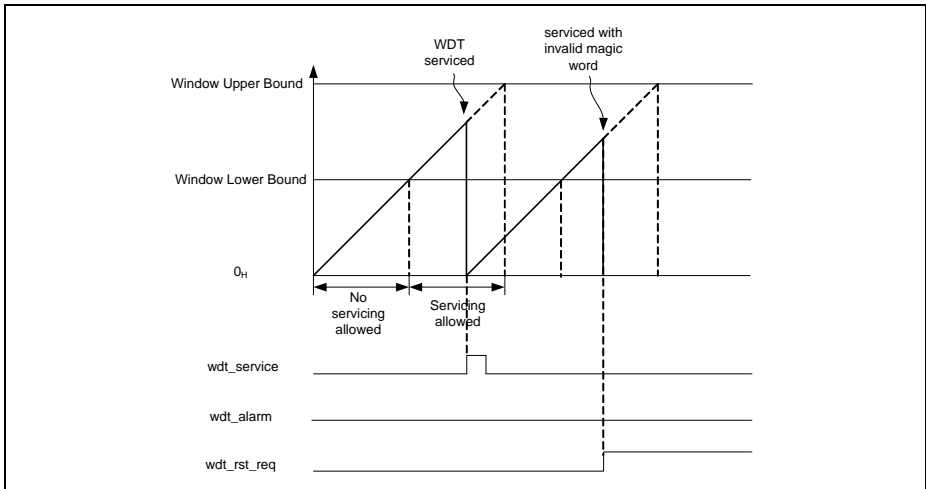

Figure 9-5 Reset upon servicing with a wrong magic word

Window Watchdog Timer (WDT)

The example in **Figure 9-5** shows servicing performed within a valid servicing window but with an invalid Magic Word. Attempt to write a wrong word to the **SRV** register results in immediate reset request on wdt_rst_req signal.

9.5 Service Request Processing

The WDT generates watchdog alarm service requests via wdt_alarm output signal upon first counter overflow over Watchdog Upper Bound when pre-warning mode is enabled. The alarm service request may be promoted by the SCU in two alternative modes:

- service request
- trap request causing NMI interrupt

Service requests can be disabled i SCU with service request mask or trap request disable registers respectively.

9.6 Debug Behavior

The WDT function can be suspended when the CPU enters HALT mode. WDT debug function is controlled by DSP bit field in **CTR** register.

9.7 Power, Reset and Clock

The WDT module is a part of the core domain and supplied with VDDC voltage.

All WDT registers get reset with the system reset.

A sticky bit in the RSSTAT register of SCU/RCU module indicates whether the last system reset has been triggered by the WDT module. This bit does not get reset with system reset.

The input clock of the WDT counter can be selected by the user between system PLL output, direct output of the internal system oscillator or 32kHz clock of hibernate domain, independently from the AHB interface clock. Selection of the WDT input clock is performed in SCU using WDTCLKCR register (for details please refer to the SCU/CCU chapter).

9.8 Initialization and Control Sequence

The programming model of the WDT module assumes several scenarios where different control sequences apply.

Note: Some of the scenarios described in this chapter require operations on system level the that are not in the scope of the WDT module description, therefore for detailed information please refer to relevant chapters of this document.

Window Watchdog Timer (WDT)**9.8.1 Initialization & Start of Operation**

Complete WDT module initialization is required after system reset.

- check reason for last system reset in order to determine power state
 - read out SCU_RSTSTAT.RSTSTAT register bit field to determine last system reset cause
 - perform appropriate operations dependent on the last system reset cause
- WDT software initialization sequence
 - enable WDT clock with SCU_CLKSET.WDTCEN register bit field
 - release WDT reset with SCU_PRCLR2.WDTRS register bit field
 - set lower window bound with WDT_WLB register
 - set upper window bound with WDT_WUB register
 - configure external watchdog service indication (optional, please refer to SCU/HCU chapter)
 - select and enable WDT input clock with SCU_WDTCLKCR register
 - enable system trap for pre-warning alarm on system level with SCU_NMIREQEN register (optional, used in WDT pre-warning mode only)
- software start sequence
 - select mode (Time-Out or Pre-warning) and enable WDT module with WDT_CTRL register
- service the watchdog
 - check current timer value in WDT_TIM register against programmed time window
 - write magic word to WDT_SRV register within valid time window

9.8.2 Reconfiguration & Restart of Operation

Reset and initialization of the WDT module is required in order to update its settings.

- software initialization sequence
 - assert WDT reset with SCU_PRSET2.WDTCEN register bit field
 - release WDT reset with SCU_PRCLR2.WDTRS register bit field register
 - set lower window bound with WDT_WLB register
 - set upper window bound with WDT_WUB register
 - configure external watchdog service indication (optional, please refer to SCU/HCU chapter)
 - select and enable WDT input clock (if change of the clock settings required) with SCU_WDTCLKCR register
 - enable system trap for pre-warning alarm on system level with SCU_NMIREQEN register (optional, used in WDT pre-warning mode only)
- software start sequence
 - select mode (Time-Out or Pre-warning) and enable WDT module with WDT_CTRL register

Window Watchdog Timer (WDT)

- service the watchdog
 - check current timer value in WDT_TIM register against programmed time window
 - write magic word to WDT_SRV register within valid time window

9.8.3 Software Stop & Resume Operation

The WDT module can be stopped and re-started at any point of time for e.g. debug purpose using software sequence.

- software stop sequence
 - disable WDT module with WDT_CTR register
- perform any user operations
- software start (resume) sequence
 - enable WDT module with WDT_CTR register with WDT_CTR register
- service the watchdog
 - check current timer value in WDT_TIM register against programmed time window
 - write magic word to WDT_SRV register within valid time window

9.8.4 Enter Sleep/Deep Sleep & Resume Operation

The WDT counter clock can be configured to stop while in sleep or deep-sleep mode. No direct software interaction with the WDT is required in those modes and no watchdog time-out will fire if the WDT clock is configured to stop while CPU is sleeping.

- software configuration sequence for sleep/deep-sleep mode
 - configure WDT behavior with SCU register SLEEPSCR or DSLEEPSCR
- enter sleep/deep-sleep mode software sequence
 - select sleep or deep-sleep mode in CPU (for details please refer to Cortex-M4 documentation [\[9\]](#))
 - enter selected mode (for details please refer to Cortex-M4 documentation [\[9\]](#))
- wait for a wake-up event (no software interaction, CPU stopped)
- resume operation (CPU clock restarted automatically on an event)
- service the watchdog
 - check current timer value in WDT_TIM register against programmed time window
 - write magic word to WDT_SRV register within valid time window

9.8.5 Prewarning Alarm Handling

The WDT will fire prewarning alarm before requesting system reset while in pre-warning mode and not serviced within valid time window. The WDT status register indicating alarm must be cleared before the timer counter value crosses the upper bound for the second time after firing the alarm. After clearing of the alarm status regular watchdog servicing must be performed within valid time window.

Window Watchdog Timer (WDT)

- alarm event
 - exception routine (system trap or service request) clearing WDT_WDTSTAT register with WDT_WDTCLR register
- service the watchdog
 - check current timer value in WDT_TIM register against programmed time window
 - write magic word to WDT_SRV register within valid time window

Window Watchdog Timer (WDT)

9.9 Registers

Registers Overview

All these registers can be read in User Mode, but can only be written in Supervisor Mode.
The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 9-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|--------------------------|
| WDT | 5000 8000 _H | 5000 BFFF _H | Watchdog Timer Registers |

Table 9-3 Register Overview

| Short Name | Register Long Name | Offset Addr. | Access Mode | | Description |
|----------------------|--------------------------------|-----------------|-------------|-------|---------------------------|
| | | | Read | Write | |

| WDTCLR | Watchdog Status Clear Register | 1C _H | U, PV | PV | Page 9-16 |

9.9.1 Registers Description

ID

The module ID register.

Window Watchdog Timer (WDT)

ID

WDT ID Register

(00_H)

Reset Value: 00AD C0XX_H

| Field | Bits | Type | Description |
|-------------------|---------|------|---|
| MOD_REV | [7:0] | r | Module Revision Indicates the revision number of the implementation. This information depends on the design step. |
| MOD_TYPE | [15:8] | r | Module Type This internal marker is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Indicates the module identification number |

CTR

The operation mode control register.

CTR

WDT Control Register

(04_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|------|------|---|
| ENB | 0 | rw | Enable 0 _B disables watchdog timer, 1 _B enables watchdog timer |

Window Watchdog Timer (WDT)

| Field | Bits | Type | Description |
|------------|-----------------------------|------|---|
| PRE | 1 | rw | Pre-warning 0 _B disables pre-warning 1 _B enables pre-warning, |
| DSP | 4 | rw | Debug Suspend 0 _B watchdog timer is stopped during halting mode debug, 1 _B watchdog timer is not stopped during halting mode debug |
| SPW | [15:8] | rw | Service Indication Pulse Width Pulse width (SPW+1) of service indication in f _{WDT} cycles |
| 0 | [3:2], [7:5], [31:16] | r | Reserved |

SRV

The WDT service register. Software must write a magic word while the timer value is within the valid window boundary. Writing the magic word while the timer value is within the window boundary will service the watchdog and result a reload of the timer with 0H.

Upon writing data different than the magic word within valid time window or writing even correct Magic Word but outside of the valid time window no servicing will be performed. Instead will request an immediate system reset request.

SRV

WDT Service Register (08_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| SRV | [31:0] | w | Service Writing the magic word ABADCAFE _H while the timer value is within the window boundary will service the watchdog. |

Window Watchdog Timer (WDT)

TIM

The actual watchdog timer register count value. This register can be read by software in order to determine current position in the WDT time window.

TIM

WDT Timer Register (0C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TIM | [31:0] | rh | Timer Value Actual value of watchdog timer value. |

WLB

The Window Lower Bound register defines the lower bound for servicing window. Servicing of the watchdog has only effect within the window boundary

WLB

WDT Window Lower Bound Register (10_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| WLB | [31:0] | rw | Window Lower Bound Lower bound for servicing window. Setting the lower bound to 0 _H disables the window mechanism. |

WUB

The Window Upper Bound register defines the upper bound for servicing window. Servicing of the watchdog has only effect within the window boundary.

Window Watchdog Timer (WDT)

WUB

WDT Window Upper Bound Register (14_H)

Reset Value: FFFF FFFF_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| WUB | [31:0] | rw | Window Upper Bound Upper Bound for servicing window. The WDT triggers an reset request when the timer is crossing the upper bound value without pre-warning enabled. With pre-warning enabled the first crossing triggers a watchdog alarm and the second crossing triggers a system reset. |

WDTSTS

The status register contains sticky bit indicating occurrence of alarm condition.

WDTSTS

WDT Status Register

(0018_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------|------|------|--|
| ALMS | 0 | rh | Pre-warning Alarm 1 _B pre-warning alarm occurred, 0 _B no pre-warning alarm occurred |

Window Watchdog Timer (WDT)

| Field | Bits | Type | Description |
|----------|--------|------|-----------------|
| 0 | [31:1] | r | Reserved |

WDTCLR

The status register contains sticky bitfield indicating occurrence of alarm condition.

WDTCLR

WDT Clear Register (001C_H) Reset Value: 00000000_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| ALMC | 0 | w | Pre-warning Alarm 1 _B clears pre-warning alarm 0 _B no-action |
| 0 | [31:1] | r | Reserved |

9.10 Interconnects

Table 9-4 Pin Table

| Input/Output | I/O | Connected To | Description |
|-------------------------|-----|--------------|---|
| Clock and Reset Signals | | | |
| f_{WDT} | I | SCU.CCU | timer clock |
| Timer Signals | | | |
| wdt_service | O | SCU.HCU | service indication to external watchdog |

Window Watchdog Timer (WDT)

Table 9-4 Pin Table (cont'd)

| Input/Output | I/O | Connected To | Description |
|------------------------------|-----|--------------|---|
| HALTED | I | CPU | In halting mode debug. HALTED remains asserted while the core is in debug. |
| Service Request Connectivity | | | |
| wdt_alarm | O | SCU.GCU | pre-warning alarm |
| wdt_rst_req | O | SCU.RCU | reset request |

10 Real Time Clock (RTC)

Real-time clock (RTC) is a clock that keeps track of the current time. RTCs are present in almost any electronic device which needs to keep accurate time in a digital format for clock displays and real-time actions.

10.1 Overview

The RTC module tracks time with separate registers for hours, minutes, and seconds. The calendar registers track date, day of the week, month and year with automatic leap year correction.

The RTC is capable of running from an alternate source of power, so it can continue to keep time while the primary source of power is off or unavailable. The timer remains operational when the core domain is in power-down. The kernel part of the RTC keeps running as long as the hibernate domain is powered with an alternate supply source. The alternate source can be for example a lithium battery or a supercapacitor.

10.1.1 Features

The features of the Real Time Clock (RTC) module are:

- Precise real time keeping with
 - 32.768 kHz external crystal clock
 - 32.768 kHz high precision internal clock
- Periodic time-based interrupt
- Programmable alarm interrupt on time match
- Supports wake-up mechanism from hibernate state

Table 10-1 Application Features

| Feature | Purpose/Application |
|---|---|
| Precise real-time keeping | Reduced need for time adjustments |
| Periodic time-based interrupt | Scheduling of operations performed on precisely defined intervals |
| Programmable alarm interrupt on time match | Scheduling of operations performed on precisely defined times |
| Supports wake-up mechanism from hibernate state | Autonomous wake up from hibernate for system state control and maintenance routine operations |

10.1.2 Block Diagram

The RTC block diagram is shown in [Figure 10-1](#).

Real Time Clock (RTC)

The main building blocks of the RTC is Time Counter implementing real time counter and RTC registers containing multi-field registers for the time counter and alarm programming register. Dedicated fields represent values for elapsing second, minutes, hours, days, days of week, months and years.

The kernel of the RTC module is instantiated in the hibernate domain.

The RTC registers are instantiated in hibernate domain and mirrored in SCU. Access to the RTC registers is performed via register mirror updated over serial interface.

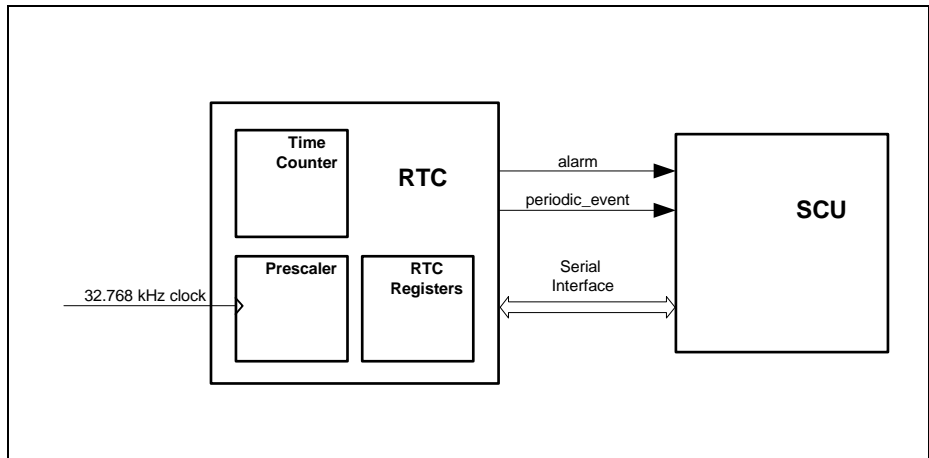

Figure 10-1 Real-Time Clock Block Diagram Structure

10.2 RTC Operation

The RTC timer counts seconds, minutes, hours, days of month, days of week, months and years each in a separate field (see [Figure 10-2](#)). Individual bit fields of the RTC counter can be programmed and read with software over serial interface via mirror registers in SCU module. For details of the serial communication please refer to SCU chapter.

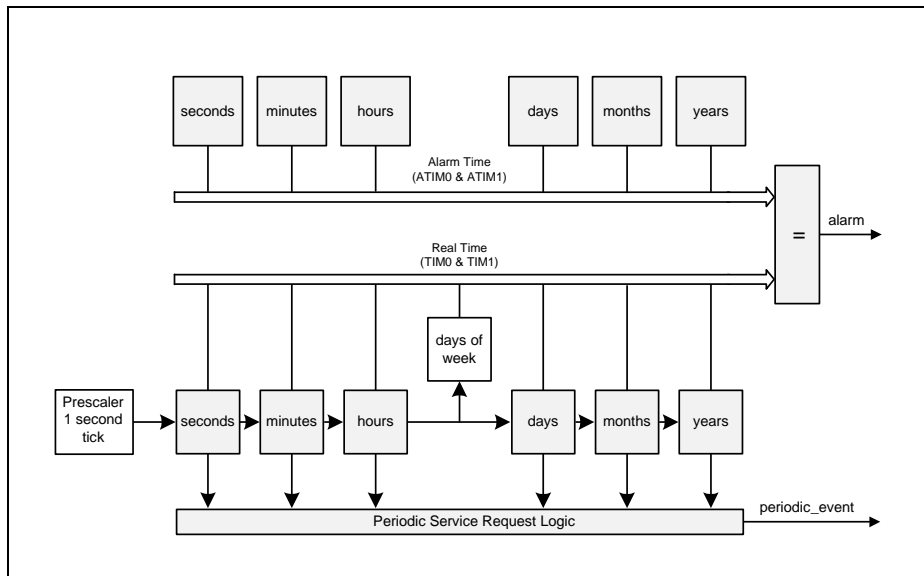

Figure 10-2 Block Diagram of RTC Time Counter

Occurrence of an internal timer event is stored in the service request raw status register **RAWSTAT**. The values of the status register **RAWSTAT** drive the outgoing service request lines alarm and periodic_event.

10.3 Register Access Operations

The RTC module is a part of SCU from programming model perspective and shares register address space for configuration with other sub-modules of SCU. RTC registers are instantiated in hibernate domain and are mirrored in SCU. The registers get updated in both clock domains over serial interface running at 32kHz clock rate.

Any update of the registers is performed with some delay required for data to propagate to and from the mirror registers over serial interface. Accesses to the RTC registers in core domain must not block the bus interface of SCU module. For details of the register mirror and serial communication handling please refer to SCU chapter.

A write to writable registers is only allowed, when the access is in privileged mode. A write access in user mode results in a bus error response.

For consistent write to the timer registers **TIM0** and **TIM1**, the register **TIM0** has to be written before the register **TIM1**. Transfer of the new values from the register mirror starts only after both registers have been written.

After wake-up from hibernate state the content of the mirror registers **TIMO** and **TIM1** is undefined until the first update of the corresponding RTC timers occurs and is propagated to the registers.

10.4 Service Request Processing

The RTC generates service requests upon:

- periodic timer events
- configured alarm condition

The service requests can be processed in the core domain as regular service requests.

10.4.1 Periodic Service Request

The periodic timer service request is raised whenever a non-masked field of the timer counter gets updated. The Periodic Service requests can be enabled/disabled with the **MSKSR** register.

10.4.2 Timer Alarm Service Request

The alarm interrupt is triggered when **TIMO** and **TIM1** bit fields values match all corresponding bit fields values of **ATIMO**, **ATIM1** registers. The Timer Alarm Service requests can be enabled/disabled with the **MSKSR** register.

10.5 Wake-up From Hibernation Trigger

The RTC generates wake-up triggers upon:

- periodic timer events
- configured alarm condition

The timer events can be processed in the hibernate domain as wake-up triggers from hibernate mode, in the HCU module of hibernate domain (for more details please refer to hibernate control description in SCU chapter).

10.5.1 Periodic Wake-up Trigger Generation

The periodic timer wake-up trigger gets generated whenever a non-masked field of the timer counter gets updated. The Periodic Wake-up Trigger generation can be enabled/disabled with the **CTR** register.

10.5.2 Timer Alarm Wake-up Trigger Generation

The alarm wake-up gets trigger gets generated when **TIMO** and **TIM1** bit fields values match all corresponding bit fields values of **ATIMO**, **ATIM1** registers. Timer Alarm Wake-up Trigger generation can be enabled/disabled with the **CTR** register.

10.6 Debug behavior

The RTC clock does not implement dedicated debug mechanisms.

10.7 Power, Reset and Clock

RTC is instantiated entirely in hibernate domain and remains powered up when hibernate domain is powered up. Supply voltage is passed via power switch either from VDDP or VBAT pin as specified in the SCU chapter.

The RTC module remains in reset state along with entire hibernate domain after initial power up of hibernate domain until reset released with software.

The RTC timer is running from ether internal or external 32.768 kHz clock selectable with HDCR control register of SCU/HCU module. The prescaler setting of 7FFF_H results in an once per second update of the RTC timer.

10.8 Initialization and Control Sequence

Programming model of the RTC module assumes several scenarios where different control sequences apply.

Note: Some of the scenarios described in this chapter require operations on system level the that are not in the scope of the RTC module description, therefore for detailed information please refer to relevant chapters of this document.

10.8.1 Initialization & Start of Operation

Complete RTC module initialization is required upon hibernate domain reset. The hibernate domain needs to be enabled before any programming of RTC registers takes place. Accesses to RTC registers are performed via dedicated mirror registers (for more details please refer to SCU chapter)

- enable hibernate domain (if not disabled)
 - write one to SCU_PWRSET.HIB
- release reset of hibernate domain reset (if asserted)
 - write one to SCU_RSTCLR.HIBRS
- enable RTC module to start counting time
 - write one to RTC_CTR.ENB
- program RTC_TIM0 and RTC_TIM1 registers with current time
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_TIM0 register
 - write a new value to the RTC_TIM0 register
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_TIM1 register
 - write a new value to the RTC_TIM1 register

10.8.2 Re-configuration & Re-start of Operation

Reset and re-initialization of the RTC module may be required without complete power up sequence of the hibernate domain.

- apply and release reset of hibernate domain reset
 - write one to SCU_RSTSET.HIBRS
 - write one to SCU_RSTCLR.HIBRS
- enable RTC module to start counting time
 - write one to RTC_CTR.ENB
- program RTC_TIM0 and RTC_TIM1 registers with current time
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_TIM0 register
 - write a new value to the RTC_TIM1 register
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_TIM1 register
 - write a new value to the RTC_TIM1 register

10.8.3 Configure and Enable Periodic Event

The RTC periodic event configuration requires programming in order to enable interrupt request generation out upon a change of value in the corresponding bit fields.

- enable service request for periodic timer events in RTC module
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_MSKSR register
 - set MAI bit field of RTC_MSKSR register in order to enable individual periodic timer events
- enable service request for periodic timer events in RTC module
 - set PI bit field of SCU_SRMSK register in order to enable generation of interrupts upon periodic timer events

10.8.4 Configure and Enable Timer Event

The RTC periodic event configuration requires programming in order to enable interrupt request generation out upon compare match of values in the corresponding bit fields of TIM0 and TIM1 against ATIM0 and ATIM1 respectively.

- program compare values in individual bit fields of ATIM0 and ATIM1 in RTC module
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_ATIM0 register
 - write to RTC_ATIM0 register bit fields
 - check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_ATIM1 register
 - write to RTC_ATIM1 register bit fields
- enable service request for timer alarm events in RTC module

Real Time Clock (RTC)

- check SCU_MIRRSTS to ensure that no transfer over serial interface is pending to the RTC_CTR register
- set TAE bit field of RTC_CTR register in order enable individual periodic timer events
- enable service request for timer alarm events in RTC module
 - write one to AI bit field of SCU_SRMSK register in order enable generation of interrupts upon periodic timer events

10.9 Registers

Registers Overview

The absolute register address is calculated by adding:
Module Base Address + Offset Address

Table 10-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|---------------------------------|
| RTC | 5000 4A00 _H | 5000 4BFF _H | Accessible via Mirror Registers |

Table 10-3 Register Overview

| Short Name | Register Long Name | Offset Addr. | Access Mode | | Description |
|----------------------|---------------------------------|-------------------|-------------|-------|----------------------------|

ATIM0

RTC Alarm Time Register 0 serves purpose of programming single alarm time at a desired point of time reflecting comparison configuration in the **CTR** for individual fields against **TIMO** register. The register contains portion of bit fields for seconds, minutes, hours and days. Upon attempts to write an invalid value to a bit field e.g. exceeding maximum value default value gets programmed as described for each individual bit fields.

TIM0

RTC Time Register 0 contains current time value for seconds, minutes, hours and days. The bit fields get updated in intervals corresponding with their meaning accordingly. The register needs to be programmed to reflect actual time after initial power up and will continue counting time also while in hibernate mode. Upon attempts to write an invalid value to a bit field e.g. exceeding maximum value a default value gets programmed as described for each individual bit fields.

11 System Control Unit (SCU)

The SCU is the SoC power, reset and a clock manager with additional responsibility of providing system stability protection and other auxiliary functions.

11.1 Overview

The functionality of the SCU described in this chapter is organized in the following sub-chapters, representing different aspects of system control:

- Miscellaneous control functions, [Chapter 11.2](#)
- Power Control, [Chapter 11.3](#)
- Hibernate Control, [Chapter 11.4](#)
- Reset Control, [Chapter 11.5](#)
- Clock Control, [Chapter 11.6](#)

11.1.1 Features

The following features are provided for monitoring and controlling the system:

- General Control
 - Boot Mode Detection
 - Memory Parity Protection
 - Trap Generation
 - Die Temperature Measurement
 - Retention Memory Support
- Power Control
 - Power Sequencing
 - EVR Control
 - Supply Watchdog
 - Voltage Monitoring
 - Power Validation
 - Power State Indication
 - Flash Power Control
- Hibernate Control
 - Hibernate Mode Control
 - Wake-up from Hibernate Mode
 - Hibernate Domain Control
- Reset Control
 - Reset assertion on various reset request sources
 - System Reset Generation
 - Inspection of Reset Sources After Reset
 - Selective Module reset
- Clock Control

System Control Unit (SCU)

- Individual peripheral clock gating
- Input clock selection
- Clock Generation
- Clock Distribution
- Clock Supervision
- Power Management
- RTC Clock

11.1.2 Block Diagram

The block diagram shown in **Figure 11-1** reflects logical organization of the System Control Unit.

- Power Control Unit (PCU)
- Hibernate Control Unit (HCU)
- Reset Control Unit (RCU)
- General Control Unit (GCU)
- Clock Control Unit (CCU)

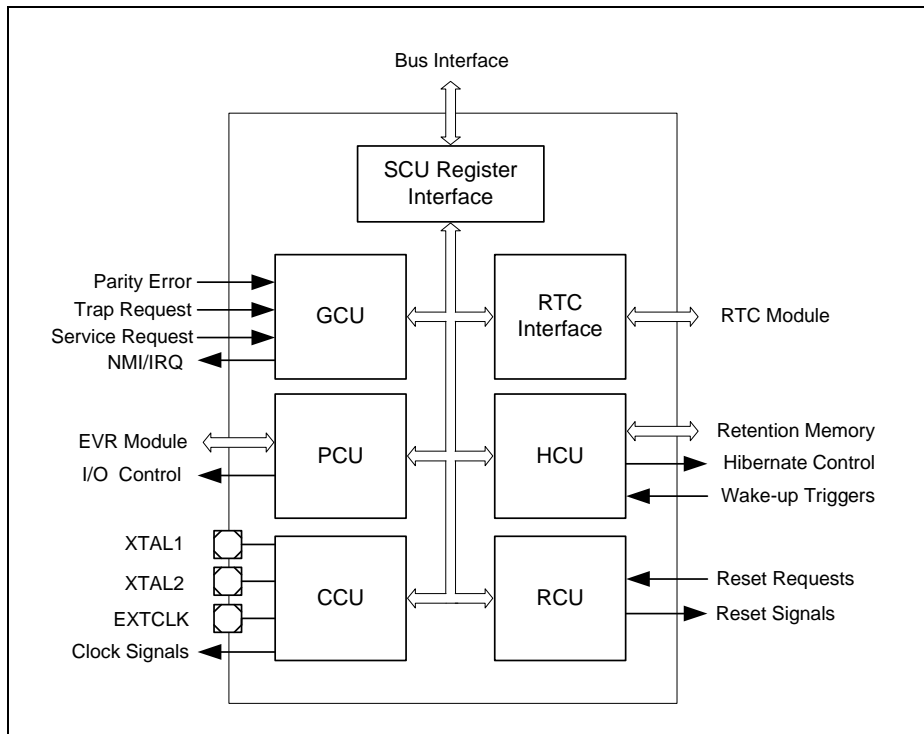

Figure 11-1 SCU Block Diagram

Interface of General Control Unit

The General Control Unit GCU has a memory fault interface to the memory validation logic of each on-chip SRAM and the Flash to receive memory fault events, as parity errors. NMI request are routed to the unit to be gated and combined. The GCU provides the start up protection to all units, which require an additional level of protection.

Interface of Power Control Unit

The Power Control Unit PCU has an interface to the Embedded Voltage Regulator (EVR) and an interface to the PORTS module. The PCU related signals are described in more detail in [Chapter 11.3](#).

Interface of Reset Control Unit

The Reset Control Unit RCU has an interface to the Embedded Voltage Regulator (EVR). The RCU receives from the EVR the power-on reset and the reset information for

System Control Unit (SCU)

each power related reset. Reset requests are coming to the unit from the watchdog, the CPU and the test control unit. The RCU is providing the reset signals to all other units of the chip in the Core power domain. The RCU related signals are described in more detail in [Chapter 11.5](#).

Interface of Clock Control Unit

The Clock Control Unit (CCU) receives the external clock source via the crystal pins XTAL1 and XTAL2. As further clock source the CCU receives the standby clock f_{STDBY} from the Hibernate domain. The CCU drives an external clock output, where internal clocks can be routed out. The CCU provides the clock signals to all other units of the chip.

Interface of Hibernate Power Domain

The interface to the Hibernate domain provides mirror registers updated via a shared serial interface to the Retention Memory, RTC module registers and Hibernate domain control registers. Update of the mirror registers over the serial is controlled using [MIRRSTS](#), [RMDATA](#) and [RMACR](#) registers. End of update can also trigger service requests via [SRSTAT](#) register. Refresh of the Hibernate domain registers in the register mirror is performed continuously, in order to instantly reflect any register state change on both sides. The serial interface is inactivated while in hibernate mode in order to reduce current consumption.

Interface of Retention Memory

Access to the Retention Memory is served over shared serial interface identical to the one used to access Hibernate domain registers, for detail please refer to [“Interface of Hibernate Power Domain” on Page 11-4](#).

Interface of RTC

Access to the RTC module is served over shared serial interface identical to the one used to access Hibernate domain registers, for detail please refer to [“Interface of Hibernate Power Domain” on Page 11-4](#). The RTC module functionality is described in separate RTC chapter.

11.2 Miscellaneous Control Functions

System Control implements system management functions accessible via GCU registers. General system control including various auxiliary function is performed in General Control Unit (GCU).

11.2.1 Startup Software Support

Externally driven boot mode pins determine the boot mode after a power on reset. It also possible for applications to decide the boot mode. Ability to determine boot mode values on boot mode pins and user application desired boot modes is provided by SCU.

11.2.2 Service Requests

Service request events listed in [Table 11-1](#) can result in assertion of a regular interrupt or an NMI. Please refer to [SRMSK](#) and [NMIREQEN](#) register description.

The interrupt structure is shown in [Figure 11-2](#). The interrupt request or the corresponding interrupt set bit (in register [SRSET](#)) can trigger the interrupt generation at the selected interrupt node x. The service request pulse is generated independently from the interrupt flag in register [SRSTAT](#). The interrupt flag can be cleared by software by writing to the corresponding bit in register [SRCLR](#). In addition several service requests can be promoted to NMI trigger level using [NMIREQEN](#) register

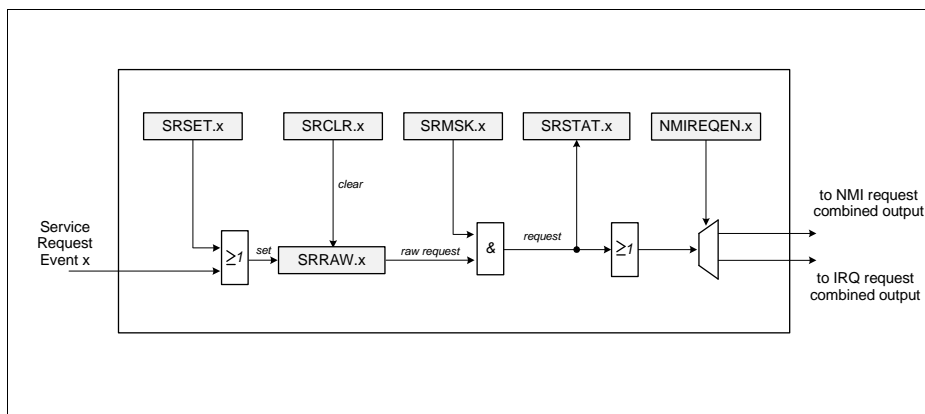

Figure 11-2 Service Request Subsystem

The service request flag in register [SRSTAT](#) can be cleared by software by writing to the corresponding bit in register [SRCLR](#). All service requests are combined to one common line and connected to a regular interrupt node or NMI node of NVIC.

The service requests have a sticky flag in register [SRRAW](#).

Note: When servicing an SCU service request, make sure that all related request flags are cleared after the identified request has been handled.

11.2.2.1 Service Request Sources

The SCU supports service request sources listed in [Table 11-2](#) and reflected in the [SRSTAT](#), [SRRAW](#), [SRMSK](#), [SRCLR](#) and [SRSET](#) registers.

Table 11-1 Service Requests

| Service Request Name | Service Request Short Name |
|--|-----------------------------------|
| WDT pre-warning | PRWARN |
| RTC Periodic Event | PI |
| RTC Alarm | AI |
| DLR Request Overrun | DLROVR |
| HDCLR Mirror Register Updated | HDCLR |
| HDSET Mirror Register Updated | HDSET |
| HDCR Mirror Register Updated | HDCR |
| OSCSICTRL Mirror Register Updated | OSCSICTRL |
| OSCULCTRL Mirror Register Updated | OSCULCTRL |
| RTC CTR Mirror Register Updated | RTC_CTR |
| RTC ATIM0 Mirror Register Updated | RTC_ATIM0 |
| RTC ATIM1 Mirror Register Updated | RTC_ATIM1 |
| RTC TIM0 Mirror Register Updated | RTC_TIM0 |
| RTC TIM1 Mirror Register Updated | RTC_TIM1 |
| Retention Memory Mirror Register Updated | RMX |

11.2.3 Memory Parity Protection

For supervising the content of the on-chip memories, the following mechanism is provided:

All on-chip SRAMs provide protection of integrity via parity checking. The parity logic generates additional parity bits which are stored along with each data word at a write operation. A read operation implies checking of the previous stored parity information.

An occurrence of a parity error is observable at the memory error raw status register. It is configurable whether a memory error should trigger an NMI or System Reset.

11.2.3.1 Parity Error Handling

The on-chip RAM modules check parity information during read accesses and in case of an error a signal can be generated if enabled with **PEEN** register. Two modes of parity error signalling are implemented:

- bus error
- parity error trap (NMI)

The bus error generation applies to memories that can be accessed directly from the bus system level. Apart from that, all memories, including those that are not accessible

System Control Unit (SCU)

directly and are internal to peripherals are capable of generating system traps resulting in NMI. Parity trap requests get enabled with **PETE** register implementing individual control for each memory. Parity error signalling with trap generation is not recommended to be used for memories capable of bus error generation and therefore should be disabled.

Parity error trap generation mechanism can be also used to generate System Reset if enabled with **PERSTEN** register in conjunction with the **PETE** register configuration. For more details of the parity error generation scheme please refer to **Figure 11-3**.

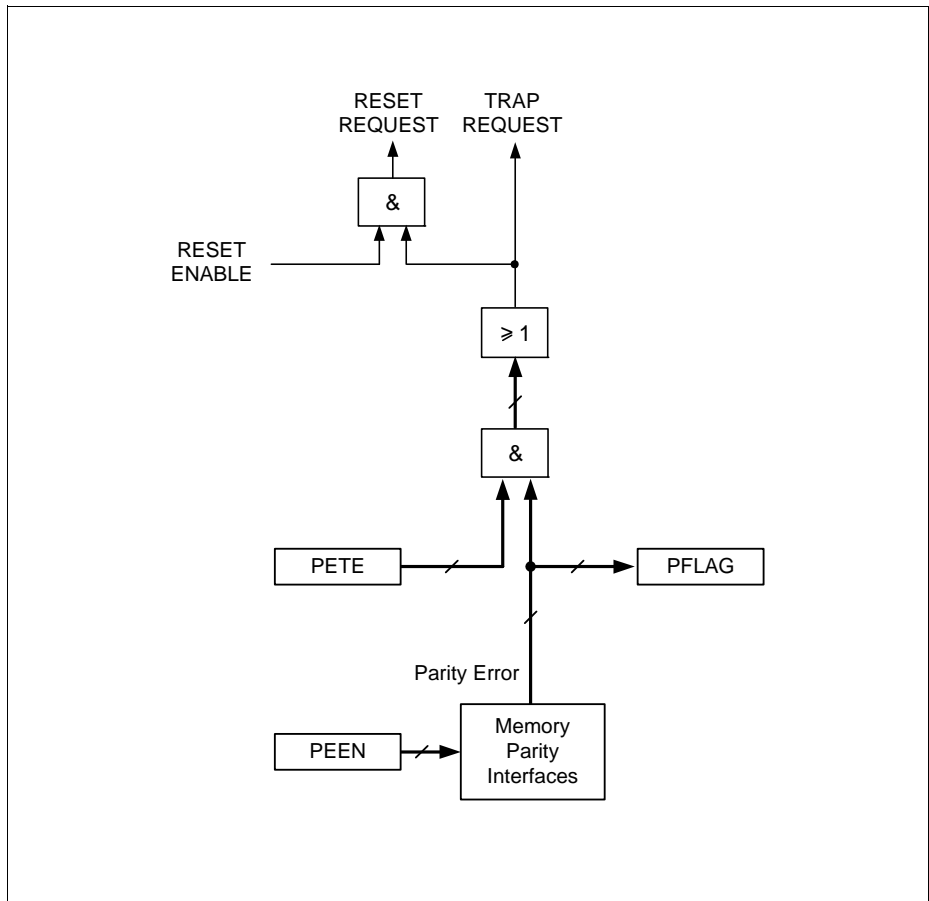

Figure 11-3 Parity Error Control Logic

System Control Unit (SCU)

The logic is controlled by registers **PMTSR** and **PMTPR**. Via bit field **PMTPR.PWR** a parity value can be written to any address of every memory for software driven testing purpose. The parity control software test update has to be enabled with bit **PMTSR** for each memory individually. Otherwise a write to the parity control has no effect. With each read access to a memory the parity from the memory parity control is stored in register **PMTPR** and accessible with software.

11.2.4 Trap Generation

Several abnormal events listed in **Table 11-2** can result in assertion of NMI. Please refer to **TRAPDIS** register description.

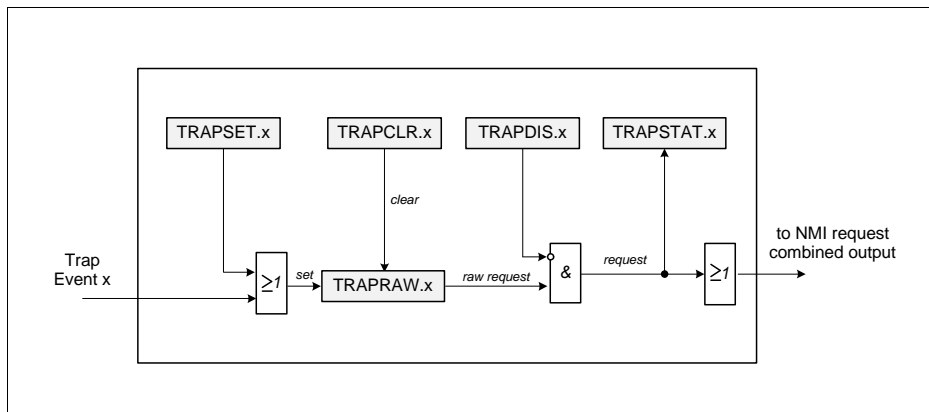

Figure 11-4 Trap Subsystem

The trap flag in register **TRAPSTAT** can be cleared by software by writing to the corresponding bit in register **TRAPCLR**. All trap requests are combined to one common line and connected to NMI node of NVIC.

The trap requests have a sticky flag in register **TRAPRAW**.

Note: When servicing an SCU trap request, make sure that all related request flags are cleared after the identified request has been handled.

11.2.4.1 Trap Sources

The SCU supports trap sources listed in **Table 11-2** and reflected in the **TRAPSTAT**, **TRAPRAW**, **TRAPDIS**, **TRAPCLR** and **TRAPSET** registers.

Table 11-2 SCU Trap Request Overview

| Source of Trap | Short Trap Name |
|-----------------------------------|-----------------|
| OSC_HP Oscillator Watchdog Trap | SOSCDWGT |
| USB VCO Lock Trap | UVCOLCKT |
| System VCO Lock Trap | SVCOLCKT |
| Parity Error Trap | PET |
| Brownout Trap | BRWNT |
| OSC_ULP Oscillator Watchdog Trap | ULPWDGT |
| Peripheral Bus 0 Write Error Trap | BWERR0T |
| Peripheral Bus 1 Write Error Trap | BWERR1T |

11.2.5 Die Temperature Measurement

The Die Temperature Sensor (DTS) generates a measurement result that indicates directly the current temperature. The result of the measurement is displayed via bit field **DTSSTAT.RESULT**. In order to start one measurement bit **DTSCON.START** needs to be set.

The DTS has to be enabled before it can be used via bit **DTSCON.PWD**. When the DTS is powered temperature measurement can be started.

In order to adjust production variations of temperature measurement accuracy bit field **DTSCON.BGTRIM** is provided. **DTSCON.BGTRIM** can be programmed by the user software.

Measurement data is available certain time after measurement started. Register **DTSSTAT.RDY** bit indicated that the DTS is ready to start a measurement. If a started measurement is finished or still in progress is indicated via the status bit **DTSSTAT.BUSY**.

The formula to calculate the die temperature is defined in the Target Data Sheet.

Note: The first measurement after the DTS was powered delivers a result without calibration adjustment and should be ignored.

11.2.5.1 Temperature Measurement

The default formula can be applied in order to calculate the die temperature expressed in °C:

$$T_{DTS} = (\text{RESULT} - 605) / 2.05 [^{\circ}\text{C}]$$

Where RESULT is a value of RESULT bit field in **DTSSTAT** register.

System Control Unit (SCU)

The accuracy of the measurement can be improved with adjustment of the OFFSET and GAIN bit fields in the **DTSCON** register.

The following formula can be applied in order to reflect relation between the actual adjustment settings and the resulting value in the **DTSSTAT** register:

$$\text{RESULT}_{\text{CALIB}} = \text{RESULT}_{\text{UNCALIB}} * (1023 / (1023 - \text{GAIN})) + \text{OFFSET}$$

Where the $\text{RESULT}_{\text{CALIB}}$ is the value read from the RESULT bit field of the **DTSSTAT** register, reflecting the effect of gain and offset calibration.

Hence, the default formula above is a special case with the default calibration values and can be substituted with:

$$T_{\text{DTS}} = (\text{RESULT}_{\text{CALIB}} - 605) / 2.05 [^{\circ}\text{C}]$$

*Note: Please always apply the following values to the bit fields of the **DTSCON** register:*

5. **DTSCON.REFTRIM** = 4_H
6. **DTSCON.BGTRIM** = 8_H

11.2.5.2 Offset Adjustment

Offset Adjustment is defined as a shift of the result. The range of the offset adjustment is 7 bits with a $\frac{1}{2}\text{LSB}$ resolution, which corresponds to $\pm 12.5^{\circ}\text{C}$.

The offset can be adjusted with OFFSET bit field of **DTSCON** register. The range of the result is limited to 1023_D . The bits are in twos complement format, with the MSB as the sign bit.

Figure 11-5 Offset adjustment of the RESULT curve

Offset adjustment has direct effect on the RESULT value in **DTSSTAT** register as illustrated in **Figure 11-5**.

11.2.5.3 Gain Adjustment

The most convenient way to express effect of gain on the result is by a curve, fitted to pass from 0 level point to its maximum value at the highest value in the RESULT bit field of **DTSSTAT** register register as illustrated in **Figure 11-6**. The range of the RESULT is limited to 1023_D.

Figure 11-6 Gain adjustment of the RESULT curve

The gain error can be minimized using 6-bit GAIN bit field of **DTSCON** register where 0 corresponds with a maximum gain and value of 63 corresponds with minimum gain i.e. RESULT value reduced by 63 at the upper imaginary end of the curve.

11.2.6 Retention Memory

Retention memory for context store/restore is available for hibernate mode support. The retention memory is located in Hibernate domain and accessible via regular memory address space. Retention memory content is retained in hibernate mode, while the core might be wpowered off. The user software can store some context critical data in the memory before entering hibernate mode. Access to the data after booting up can be performed at any time with user software. Occurence of a wake-up from hibernate mode is signaled in **RSTSTAT** register.

Access to the 64 Bytes of retention memory is provided via **RMDATA** register, controlled with **RMACR** register. The purpose of **RMACR** register is addressing of the memory cells and issuing read/write command. The **RMDATA** is read or written by software according to the access direction after data transfer has been completed as indicated with RMX bit field in **MIRRSTS**.

11.2.7 Out of Range Comparator Control

The out of range comparator serves the purpose of overvoltage monitoring for analog input pins of the chip. A number of analog channels are associated with dedicated pads connected to inputs of analog modules. They get supervised by dedicated circuits constituted of analog comparator controlled by digital signals as depicted in [Figure 11-7](#).

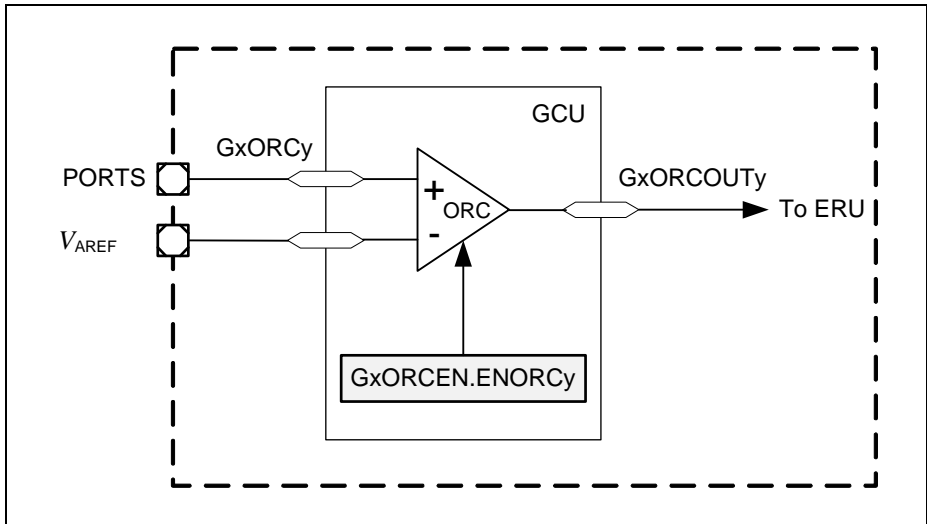

Figure 11-7 Out of Range Comparator Control

Detection of input voltage exceeding V_{AREF} triggers a service request to the ERU. Digital control signals are generated in GCU submodule of SCU. Dedicated registers **G0ORCEN** and **G1ORCEN** provide control means for enabling and disabling monitoring of analog channels.

11.3 Power Management

Power management control is performed with the Power Control Unit (PCU).

The PCU connects to the embedded voltage regulation EVR, the hibernate control unit in the hibernate power domain and the Ports module. The system integration of the PCU is shown in

11.3.1 Functional Description

The XMC4700 / XMC4800 is running from a single external power supply (V_{DDP}). The main supply voltage is supervised by a supply watchdog.

System Control Unit (SCU)

The I/Os and the main part of the flash block are running directly from the external supply voltage. The core voltage (V_{DDC}) is generated by an on-chip Embedded Voltage Regulator (EVR). The safe voltage range of the core voltage is supervised by a power validation circuit, which is part of the EVR.

Logic in the hibernate domain, mainly the real-time clock RTC, hibernate control and retention memory, is supplied by an auxiliary power supply using an additional power pad. The auxiliary V_{BAT} voltage, supplied from e.g. a coin battery, enables the RTC to operate while the main supply is switched off.

11.3.2 System States

The system has the following general system states:

- Active
- Sleep
- Deep Sleep
- Hibernate

Figure 11-8 shows the state diagram and the transitions between these power modes. The additional state power-up is only a transient state which is passed on cold or warm start-up from Off state.

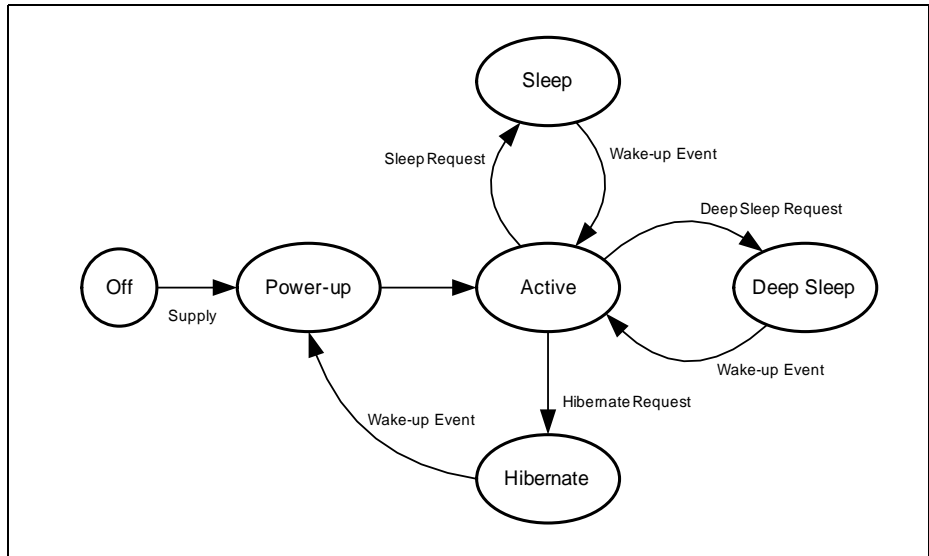

Figure 11-8 System States Diagram

Active State

The Active state is the normal operation state. The system is fully powered. The CPU is usually running from a high-speed clock. Depending on the application the system clock might be slowed down. The PLL output clock or another clock can be selected as clock source. Unused peripherals might be stopped. Stopping a peripheral means that the peripheral is put into reset and the clock to this peripherals is disabled.

After a cold start the hibernate domain stays disabled until activated by user code.

Sleep State

The Sleep state of the system corresponds to the Sleep state of the CPU. The state is entered via WFI or WFE instruction of the CPU. In this state the clock to the CPU is stopped. The source of the system clock may be altered. Peripherals clocks are gated according to the **SLEEP** register.

Peripherals can continue to operate unaffected and eventually generate an event to wake-up the CPU. Any interrupt to the NVIC will bring the CPU back to operation. The clock tree upon exit from SLEEP state is restored to what it was before entry into SLEEP state.

Deep Sleep State

The Deep Sleep state is entered on the same mechanism as the Sleep state. User code configures the Deep Sleep state in **DSLEEP** control register. In Deep Sleep state the OSC_HP and the PLL may be switched off. The wake-up logic in the NVIC is still clocked by a free-running clock. Peripherals are only clocked when configured to stay enabled in the **DSLEEP** register. Configuration of peripherals and any SRAM content is preserved.

The Flash module can be put into low-power mode to achieve a further power reduction. On wake-up Flash module will be restarted again before instructions or data access is possible.

Any interrupt will bring the system back to operation via the NVIC. The clock setup before entering Deep Sleep state is restored upon wake-up.

Hibernate State

In Hibernate mode the power supply to the core is switched off. Additionally the power to the analog domain and the main supply V_{DDP} can be switched off. Only the Hibernate power domain will stay powered. The power supply of the Hibernate domain is switched automatically to the auxiliary supply when the main supply is no longer present.

The Hibernate State is entered using control register **HDCR** of HCU in the Hibernate domain that will drive the external Voltage Regulator with HIBOUT signal to switch off power to the chip (see **System Level Power Control example - externally controlled with two pins**).

Depending on configuration the following wake-up sources will wake-up the system to normal operation:

- Edge detection on external WKUP signal
- RTC Alarm Event
- RTC Periodic Event
- OSC_ULP Watchdog Event

The system can only wake-up from Hibernate if V_{DDP} is present. An external power supply can be switched on by the HIBOUT signal of the Hibernate Control Unit.

All blocks outside of the Hibernate domain will see a complete power-up sequence upon wake-up.

11.3.3 Hibernate Domain Operating Modes

The standard use case of the Hibernate domain is the time keeping function with V_{BAT} available, keeping the Real Time Counter active and data in Retention Memory while the System Supply is off.

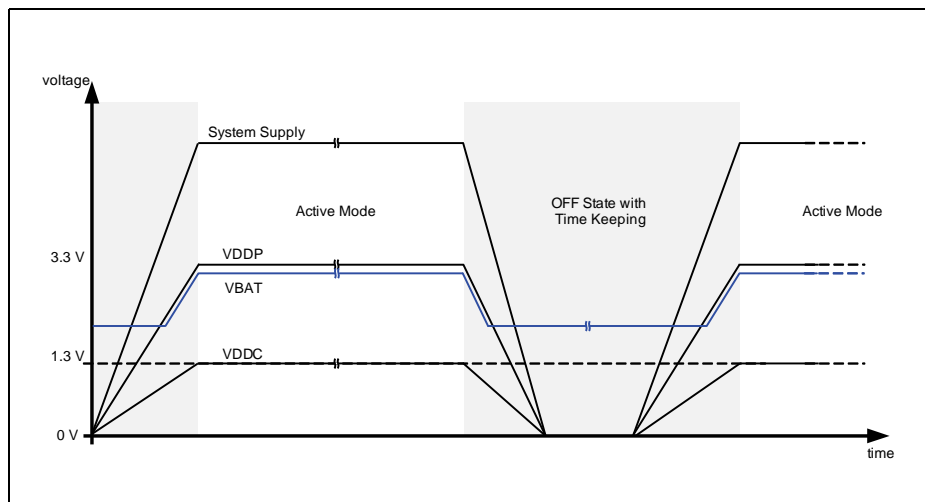

Figure 11-9 Hibernate state in time keeping mode

A special case of the Hibernate domain assumes that the V_{BAT} supply voltage is available only after the core domain power-up. This may occur if, for example, the battery gets plugged in or replaced after the core domain startup, or, if only a capacitor is available to hold V_{BAT} voltage for some limited time in case of absence of the main supply voltage in order to keep the Real Time Counter unaffected. The Hibernate domain requires to be switched on once after core domain power up with the dedicated register

System Control Unit (SCU)

PWRSET.HIB. In this application case even switching off the main supply of the board does not affect availability of the V_{HIB} voltage required to keep RTC running.

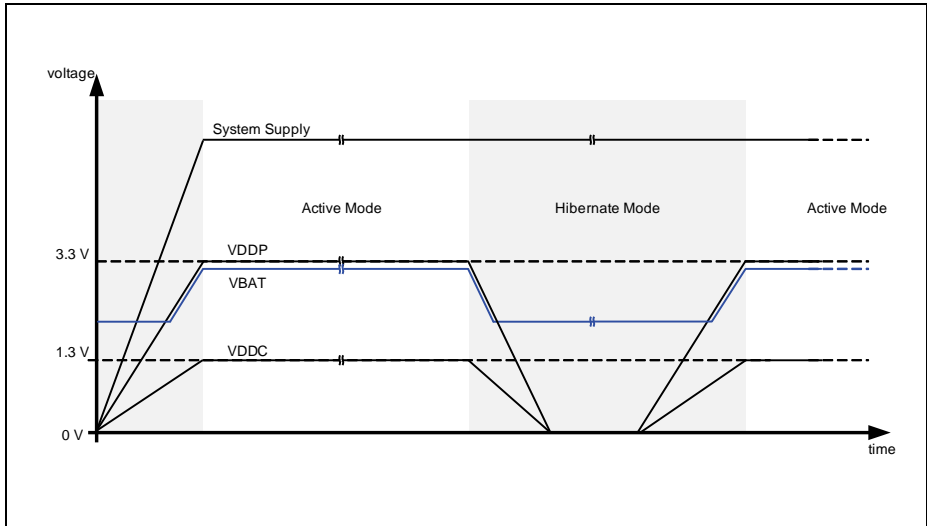

Figure 11-10 Hibernate controlled with external voltage regulator

The externally controlled Hibernate mode is realized with HIB pin and external power supply device. As illustrated in **Figure 11-10** the main supply voltage of the board stays active allowing selective disabling of the XMC4700 / XMC4800 in order to save power while other devices of on the board remain active. At the time HIB pin indicates Hibernate mode the dedicated voltage supply connected to the chip will stop generating V_{DDP} and voltage and in effect complete chip except the Hibernate domain will be powered off. On a wake-up event the Hibernate domain will deactivate the HIB control signal and enable generation of V_{DDP} voltage, hence complete power-up sequence of the core domain.

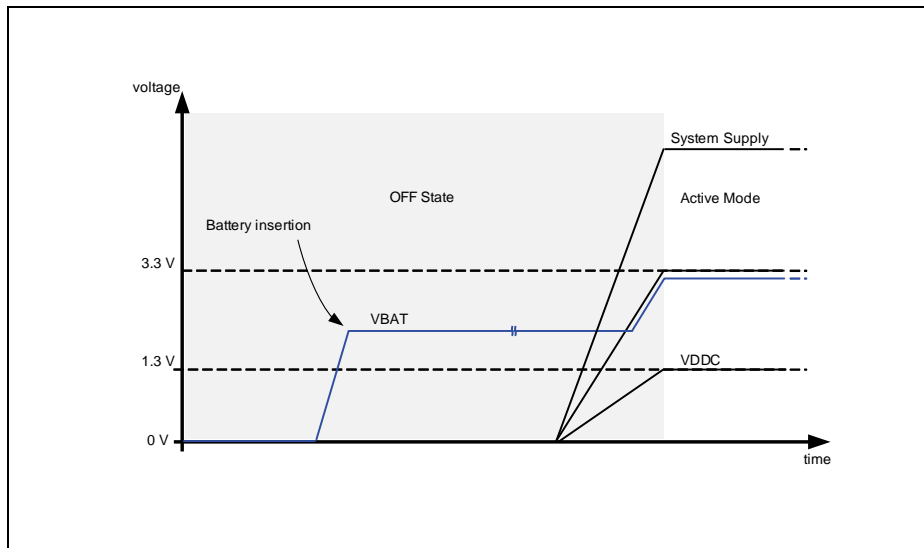

Figure 11-11 Initial power-up sequence

One of the valid power-up scenarios assumes that battery will be installed, possibly soldered, before core supply is available (see [Figure 11-11](#)). That would be a common situation after PCB assembly, before the complete device is installed in the target system. The battery voltage V_{BAT} gets connected before main supply of the board is available and only the Hibernate domain is supplied. No current (only leakage is allowed) is drawn from the battery before explicit switching on Hibernate domain with software after Core domain power up using dedicated register [PWRSET.HIBEN](#). This feature allows to keep the device in a storage for a long time before shipment to the end user, without significant loss of charge in the battery.

11.3.4 Embedded Voltage Regulator (EVR)

The EVR generates the core voltage V_{DDC} out of the external supplied voltage V_{DDP} . The EVR provides a supply watchdog (SWD) for the input voltage V_{DDP} . The generated core voltage V_{DDC} is monitored by a power validation circuit (PV).

11.3.5 Power-on Reset

The EVR starts operation as soon as V_{DDP} is above defined minimum level. It releases the reset, when the external voltage V_{DDP} and the generated voltage V_{DDC} are above the reset thresholds and reaching the nominal values.

11.3.6 Supply Watchdog (SWD)

Figure 11-12 shows the operation of the supply monitor. The supply watchdog compares the supply voltage against the reset threshold V_{POR} . The Data Sheet defines the nominal value and applied hysteresis.

Figure 11-12 Supply Voltage Monitoring

While the supply voltage is below V_{POR} the device is held in reset. As soon as the voltage falls below V_{POR} a power on reset is triggered.

11.3.7 Power Validation

A power validation circuit monitors the internal core supply voltage of the core domain. It monitors that the core voltage is above the voltage threshold V_{PV} which guarantees save operation. Whenever the voltage falls below the threshold level a power-on reset is generated.

11.3.8 Supply Voltage Brown-out Detection

Brown-out detection is an additional voltage monitoring feature that enables the user software to perform some corrective action that bring the chip into safe operation in case a critical supply voltage drop and avoids System Reset generated by the Supply Voltage Monitoring.

System Control Unit (SCU)

A drop of supply voltage to a critical threshold level programmed by the user can be signalized to the CPU with an NMI. An emergency corrective action may involve e.g. reduction of current consumption by switching of some modules or some interaction with external devices that should result in recovery of the supply voltage level.

Automatic monitoring of the voltage against programmed voltage allows efficient operation without a need for software interaction if the supply voltage remains at a safe level. The supply voltage can be monitored also directly by software in register **EVVRADCSTAT**. The threshold value and the inspection interval is configured at **PWRMON**.

11.3.9 Hibernate Domain Power Management

It is strongly recommended to supply Hibernate domain with V_{DDP} when available in order to extend the battery life time. An example of an external supply voltage switching solution based on Schottky diodes is shown in **Figure 11-14** and **Figure 11-15**.

11.3.10 Flash Power Control

The Flash module can be configured to operate in low power mode while the system is in Deep Sleep mode. Control of the Flash power mode it is performed using the **DSLEEP** register prior to entering the Deep Sleep mode. The Flash cannot be accessed while in the lower mode. Upon a wake-up event the Flash gets automatically reactivated. The user needs to trade the reduced leakage current against wake-up time of the Flash.

11.4 Hibernate Control

Hibernate is the operation mode of lowest power consumption. Activity of the microcontroller is limited to real time keeping and wake up functionality.

11.4.1 Hibernate Mode

Hibernate control is performed with Hibernate Control Unit (HCU).

Externally Controlled Hibernate Mode

In this operation mode of the with lowest power consumption only the hibernate domain remains powered up. In this state the hibernate domain enable switching off externally the main power supply (see **Figure 11-14** and **Figure 11-15**).

External Voltage Regulator is controlled from Hibernate domain and V_{DDP} gets switched off when hibernate mode is entered. No reset of hibernate control occurs in hardware upon power-up but the chip will boot up as normal since in this mode no internal state of the chip is affected except for the hibernate control pin from hibernate domain to the External Voltage Regulator. Re-initialization of is possible with software upon boot-up.

Hibernation Support

The entry of the hibernate state is configured via the register **HDCR** by setting of the HIB bit. The HIBOUT bit in conjunction with selected HIBOnPOL bit of **HDCR** register drives HIB_IO_n pad.

The hibernation control signal HIBOUT is connected to an open-drain pad to enable control of an external power regulator for V_{DDP} .

Wake-up from Hibernate Mode

The hibernation control supports multiple wake-up sources. Occurrence of any of the Wake-up from hibernate triggers resets of **HDCR.HIB** bit which results resetting of the HIBOUT signal that controls External Voltage Regulator.

11.4.2 Hibernate Domain Pin Functions

Hibernate domain control register **HDCR** implements fields for alternate pin function selection.

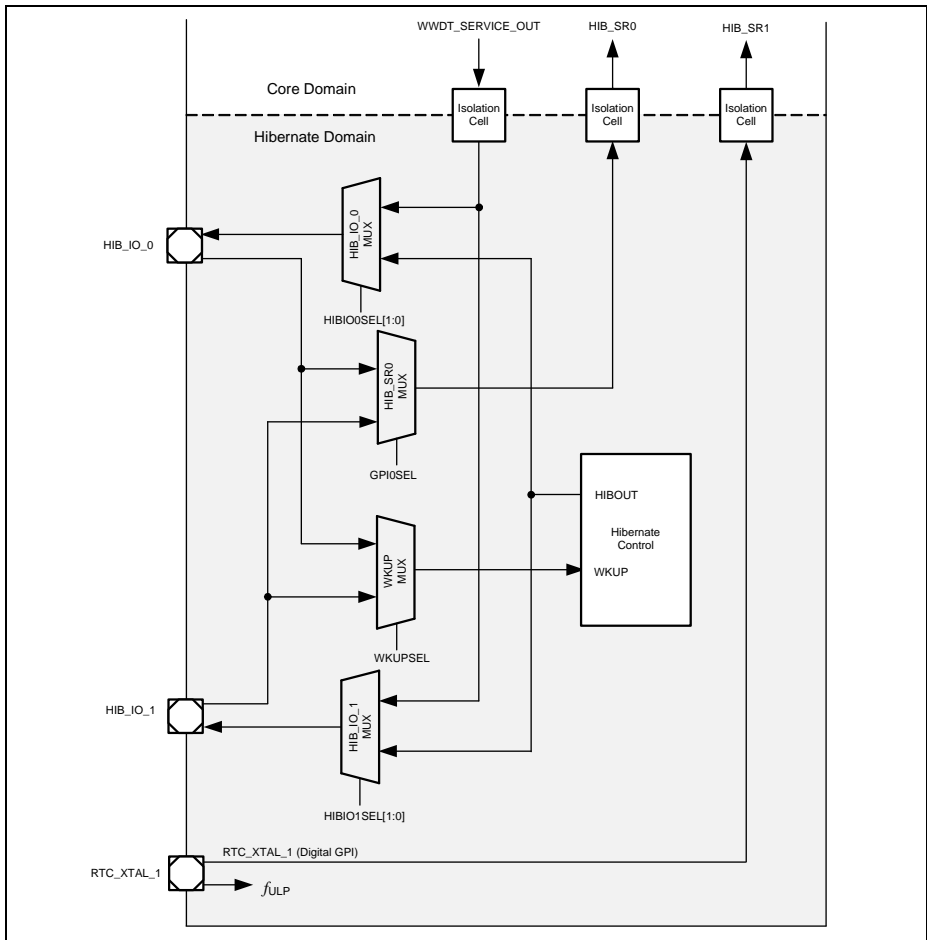

Figure 11-13 Alternate function selection of HIB_IO_0 and HIB_IO_1 pins of Hibernate Domain

11.4.3 System Level Integration

The XMC4700 / XMC4800 enables various system level configuration options for Hibernate mode support, determined by application specific requirements. The examples shown below illustrate functional principles of the hibernate control mechanism in the system level intergration aspect.

Externally Controlled Hibernate mode

The Externally Controlled Power Supply scheme requires external devices in order to fully support power management related functions.

The external power supply needs to support on/off control of the VDDP voltage generation. This scheme enables the XMC4700 / XMC4800 e.g. to control supply voltage for multiple on-board devices.

A simple power control scheme assumes availability of two pins - HIB_IO_0 and HIB_IO_1 as shown in [Figure 11-14](#). If the External Voltage regulator implements low-active (enabled with low) power control then it can be reliably controlled with HIB_IO_0 pin, which by default is set to open-drain and ensures proper driving value from the moment a valid VBAT voltage gets applied. A wake-up signal can be supplied externally via HIB_IO_1 pin or internally generated with from RTC module.

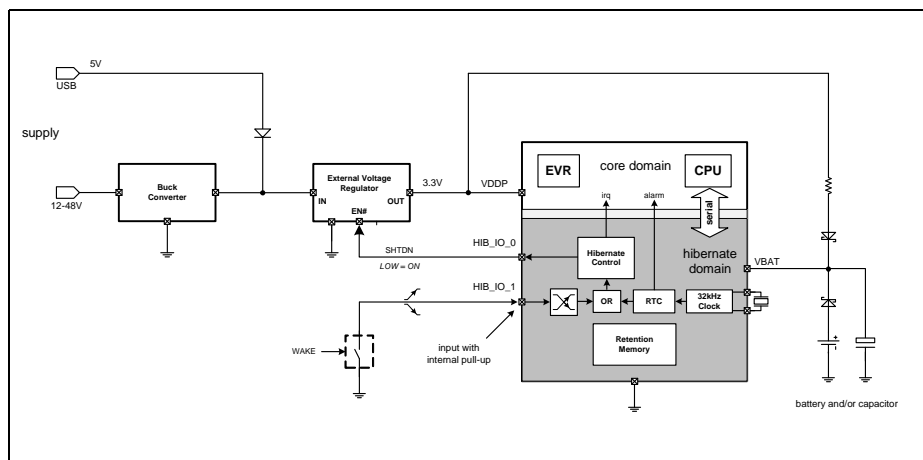

Figure 11-14 System Level Power Control example - externally controlled with two pins

The HIB_IO_0 pad is configured as open drain low and HIB_IO_1 as input after reset. This configuration enables use of low-enabled external voltage regulator as depicted in the [Figure 11-14](#). In case of high-active external voltage regulator and battery presence the pins may be swapped to ensure reliable startup of the system start up of the system from the moment a valid VBAT voltage is applied (additional external pull-up required on HIB_IO_1).

In case of application cases with only one hibernate control pin available for external power control, it is possible to use the same pin for control of the External Voltage Regulator and for an external wake-up trigger signal. The example setup is shown in [Figure 11-15](#), where HIB_IO_0 pin is by default configured to open-drain mode.

System Control Unit (SCU)

- Debug Reset, $\overline{\text{DBGRESET}}$

Power-on Reset ($\overline{\text{PORESET}}$)

A complete reset of the core domain of the device is executed upon power-up. Whenever the supply V_{DDP} is ramped-up and crossing the PORST voltage threshold the power-on reset is released. Additional a power-on reset is triggered by asserting the external PORST pin.

A Power-on reset is asserted again whenever the V_{DDP} voltage or the V_{DDC} voltage falls below defined reset thresholds.

System Reset ($\overline{\text{SYSRESET}}$)

System Reset is triggered by sources:

- Power-on reset
- Software reset via Cortex-M4 Application Interrupt and Reset Control Register (AIRCR)
- Lockup signal from Cortex-M4 when enabled at RCU
- Watchdog reset
- Memory Parity Error
- EtherCAT (ECAT) module triggered by an external master

The System Reset resets almost all logic in the core domain. The only exceptions in the core domain are RCU Registers and Debug Logic.

Standby Reset, ($\overline{\text{STDBYRESET}}$)

The Hibernate domain including the RTC is only reset by a standby reset. A standby reset is triggered by a power-on reset specific to the Hibernate domain. Additionally a standby reset can be activated by software:

- Power-on reset specific to the Hibernate domain
- Software reset via **RSTSET** register

Debug Reset ($\overline{\text{DBGRESET}}$)

Debug reset is triggered by the following sources:

- Debug Reset request from DAP while in mission mode and with debug probe present
- System Reset while in normal mode and debug probe not present

The Debug Reset is triggered by System Reset while in normal operation mode while debug probe is not present.

System Control Unit (SCU)

the system can be performed in NMI service routine according to application specific requirements.

11.5.4 Reset Status

The EVR provides the cause of a power reset to the RCU. The reset cause can be inspected after resuming operation by reading register **RSTSTAT**.

All register of the RCU undergo reset only by a power-on reset **PORESET**.

Table 11-3 shows an overview of the reset signals their source and effects on the various parts of the system.

Table 11-3 Reset Overview

| Name | Source | Core Domain | PAD Domain | Hibernate Domain | Debug & Trace System |
|-------------------|-----------------------------------|-------------|------------|------------------|----------------------|
| PORESET | EVR | yes | yes | no | yes |
| SYSRESET | PORESET Software WDT | yes | no | no | no |
| STDBYRESET | Power-on Software | no | no | yes | no |
| DBGRESET | DAP Software | no | no | no | yes |

11.6 Clock Control

Clock generation and control is performed in the Clock Control Unit (CCU).

11.6.1 Block Diagram

The Clock Control Unit (CCU) consists of two major sub blocks:

- Clock Generation Unit (CGU)
- Clock Selection Unit (CSU)

The CGU provides in parallel three clocks to the CSU:

- USB PLL clock f_{PLLUSB} ,
- System PLL output clock f_{PLL}
- internally generated clock f_{OFI} from the Backup Clock Source.

System Control Unit (SCU)

The f_{STDBY} clock of 32.768 kHz is generated in the Standby Clock Generation Unit (SCGU) of the hibernate domain by either the external crystal oscillator OSC_ULP or by Internal Slow Clock Source.

The module clocks available in the Core Domain get derived from the CGU, passed via CSU module which implements a number of multiplexers and clock dividers enabling clock selection for all system modules and scaling of the frequencies.

The CSU receives in addition a slow standby clock f_{STDBY} from the hibernate domain that can be used in the WDT module for safety sensitive application purpose.

Major clock sources can be selected for driving the external clock pin EXTCLK.

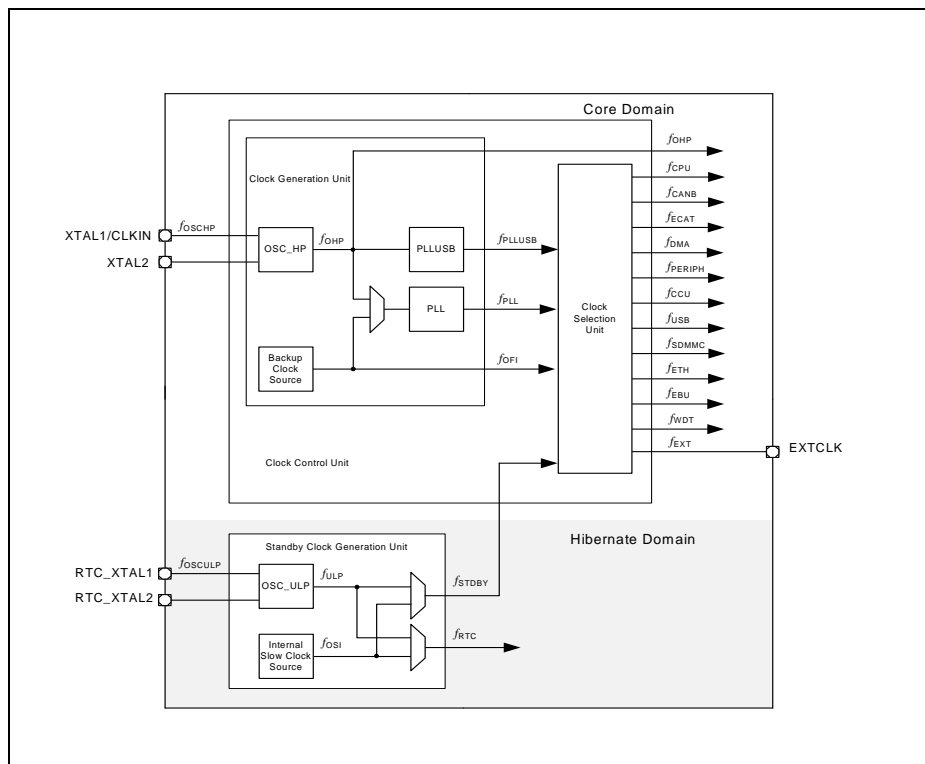

Figure 11-17 Clock Control Unit

11.6.2 Clock Sources

The system has multiple clock sources distributed over the core power domain and the hibernate power domain.

System Control Unit (SCU)

The source clock for CGU can be supplied from:

- internally generate in the Backup Clock Source
- external clock source directly via CLKIN pin
- external crystal High Precision Oscillator (OSC_HP) utilizing XTAL1 and XTAL2 pins

During system start-up the backup clock f_{OFI} is supplied to the system. The f_{OFI} clock may be used during normal or low power operation after the startup.

The high precision oscillator OSC_HP can be used with an external crystal to generate high precision clock via XTAL1 and XTAL2 pins. Either, the OSC_HP or Backup Clock Source can be selected as input clock source for the main PLL. Alternatively, an external clock can also be supplied directly to CGU from CLKIN pin, via the OSC_HP module, bypassing the oscillator circuit.

The clock sources in the hibernate power domain are:

- OSC_ULP, an ultra low power external crystal oscillator 32.768 kHz clock f_{ULP}
- Internal Slow Clock source 32.768 kHz clock f_{OSI}

The clocks drive the logic in the hibernate domain. In addition one of the two can be used as standby clock for low power operation in the core power domain.

To generate the required high precision f_{PLLUSB} clock for operation of the USB and the MMC/SD modules additional PLL can be optionally used if the desired clock frequency cannot be derived from the system PLL output f_{PLL} . The dedicated PLL referred to as PLLUSB, shown the block diagram in **Figure 1-55**.

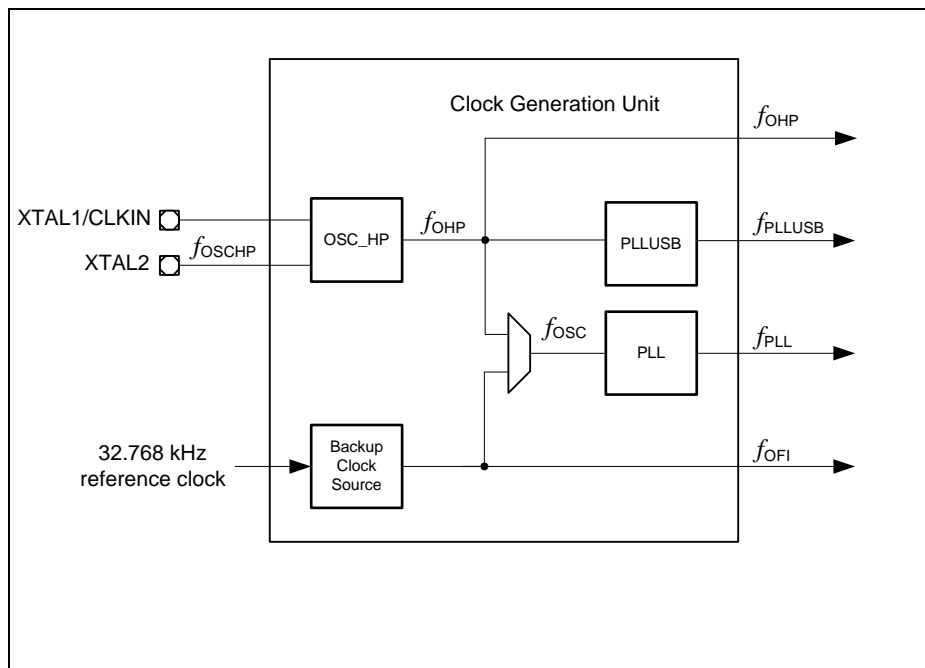

Figure 11-18 Clock Generation Block Diagram

11.6.3 Clock System Overview

The clock selection unit CSU provides the following clocks to the system:

Table 11-4 Clock Signals

| Clock name | From/to module or pin | Description |
|----------------------|-----------------------|--|
| System Clock Signals | | |
| f_{SYS} | SCU.CCU | System master clock |
| f_{CPU} | CPU | CPU and NVIC clock |
| f_{DMA} | DMA0, DMA1 | DMA clock |
| f_{PERIPH} | PBA0 PBA1 | Peripheral clock for modules connected to peripheral bridges PBA0 and PBA1 |

Table 11-4 Clock Signals (cont'd)

| Clock name | From/to module or pin | Description |
|-------------------------------|-----------------------------------|---|
| f_{CCU} | CCU4 CCU8 POSIF | Clock for CCU4, CCU8 and POSIF modules |
| f_{USB} | USB | UTMI clock of USB |
| f_{ETH} | ETH0 | ETH clock |
| f_{ECAT} | ECAT0 | ECAT clock |
| f_{EBU} | EBU | EBU clock |
| f_{WDT} | WDT | Clock for independent watchdog timer |
| Internal Clock Signals | | |
| f_{PLL} | System PLL | System PLL output clock |
| f_{PLLUSB} | USB PLL | USB PLL output clock |
| f_{OHP} | OSC_HP | External crystal oscillator output clock |
| f_{OFI} | Internal Backup Clock Source | System Backup Block |
| f_{ULP} | OSC_ULP | External crystal slow oscillator output clock |
| f_{OSI} | Slow Internal Backup Clock Source | 32.768 kHz backup clock for Hibernate domain |
| f_{OSC} | PLL input | PLL input clock |
| f_{STDBY} | Hibernate Domain | 32.768 kHz clock, optional WDT independent clock |
| f_{FLASH} | FLASH | Internal Flash clock |
| External Clock Signals | | |
| f_{OSCHP} | XTAL1/CLKIN | External crystal input, optionally also direct input clock to system PLL |
| f_{OSCULP} | RTC_XTAL1 | External crystal input, optionally also direct input clock to Hibernate domain and RTC module |
| f_{EXT} | Clock output to pin EXTCLK | Chip output clock |

The clock sources of the clock selection unit are the four clocks from the clock generation unit, i.e. the USB clock f_{USB} , the PLL output clocks f_{PLL} and a fast internal generated clock

System Control Unit (SCU)

f_{OFI} . The clock selection unit receives as additional clocks source a slow standby clock from the hibernate domain.

11.6.3.1 Clock System Architecture

The system clock f_{SYS} drives the CPU clock and all peripheral modules. It can be selected from the following clock sources:

- f_{PLL} , main PLL output clock
- f_{OFI} , fast internal clock, bypassing PLL
- f_{OSCHP} , external clock, bypassing PLL
- f_{OHP} , external crystal oscillator clock, bypassing PLL

Please note that in dependence of the PLL mode setting the PLL output clock f_{PLL} is either a scaled version of the VCO clock in normal mode or a scaled version of one of the input clocks.

In Deep Sleep mode the system clocks can be switched to a clock which does not require PLL and thereby allowing the power down of the system PLL. This is either the fast internal clock or the slow standby clock. The **DSLEEP** register controls the clock settings for Deep Sleep mode.

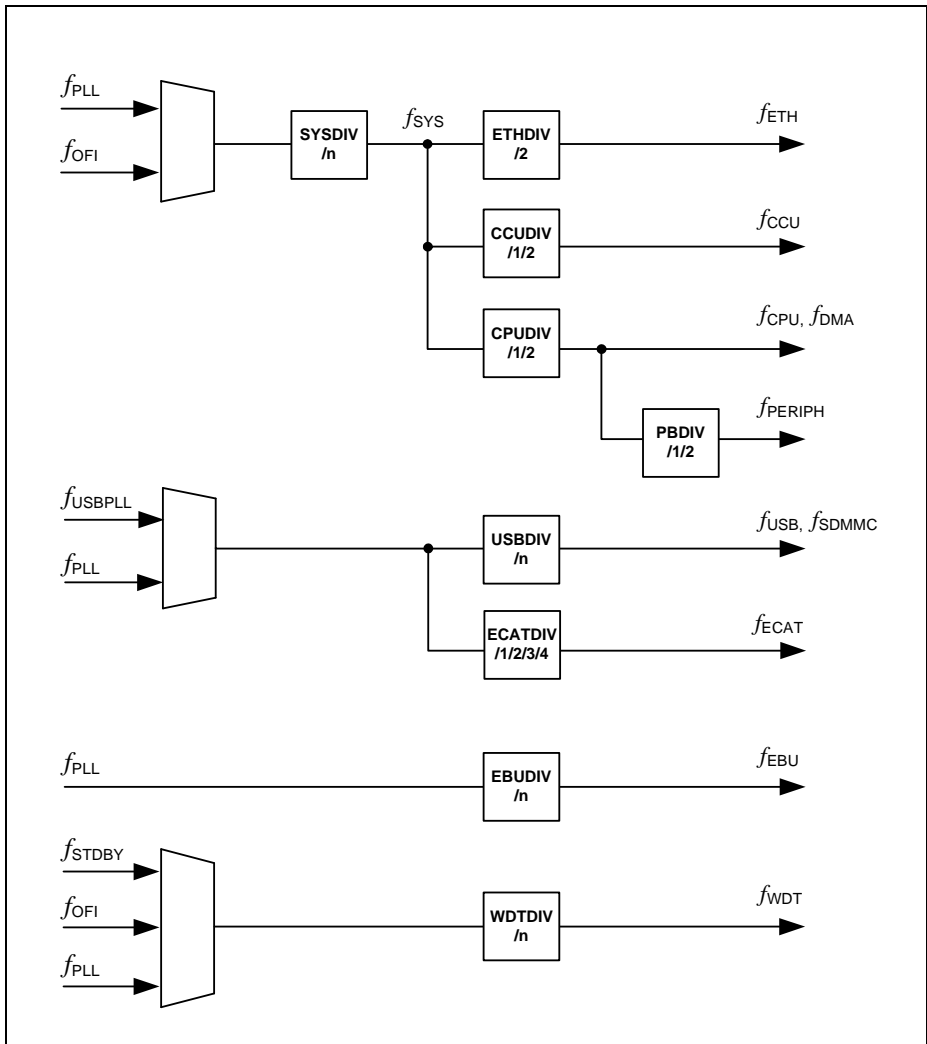

Figure 11-19 Clock Selection Unit

Some limitations apply on clock ratio combinations between f_{CCU} , f_{CPU} and f_{PERIPH} . Only divider setting listed in the table [Table 11-5](#) are allowed for the f_{CCU} , f_{CPU} and f_{PERIPH} clocks. All other clock dividers settings must be prohibited by application software or by hardware when programmed with **MLINKCLKCR** register in order to avoid invalid clock

System Control Unit (SCU)

ratios leading to system malfunctions. The **Table 11-5** table shows also example clock rate values assuming f_{SYS} rate of 144 MHz.

Table 11-5 Valid values of clock divide registers for f_{CCU} , f_{CPU} and f_{PERIPH} clocks

| CCUCLKCR.CCUDIV | CPUCLKCR.CPUDIV | PBCLKCR.PBDIV |
|------------------------|------------------------|----------------------|
| 0 (144 MHz) | 0 (144 MHz) | 0 (144 MHz) |
| 0 (144 MHz) | 0 (144 MHz) | 1 (72 MHz) |
| 0 (144 MHz) | 1 (72 MHz) | 0 (72 MHz) |
| 1 (72 MHz) | 0 (144 MHz) | 1 (72 MHz) |
| 1 (72 MHz) | 1 (72 MHz) | 0 (72 MHz) |

USB and MMC/SD Clock Selection

The clock for the USB module and the clock for the MMC/SD module are both derived from the clock f_{USB} or from the clock f_{PLL} of the main PLL. The later is only feasible, when the main PLL is providing a frequency which allows to generate the 48MHz with a 3-bit divider.

The USB clock is automatically gated and the USB PLL put in power-down by the USB suspend signal.

The clock divider and the MUX must only be configured while the USB and MMC/SD are not enabled.

Ethernet Clock Selection

The Ethernet module receives SRAM clock f_{SYS} which has to be twice the frequency of the ETH MAC internal clock f_{ETH} . The SRAM clock rate must always be above 100 MHz which guarantee that the clock of ETH MAC is of rate above its acceptable minimum of 50 MHz.

Both clocks are disabled with software in Wake-On-Lan mode. The clocks have to be enabled via software when the related interrupt the end of Wake-On-Lan mode.

The clock divider and the clock MUX must only be configured while ETH module is not enabled.

CPU Clock Selection

The CPU clock f_{CPU} may be equal to or a half of the system clock f_{SYS} .

Peripheral Bus Clock Selection

The Peripheral Bus clock is derived from the f_{CPU} clock and may be equal to or a half of the f_{CPU} . There are some limitations imposed on peripheral bus configuration in terms of clock ratio with respect to the f_{CCU} clock. The Peripheral Bus clock rate must never be less than half and more than the f_{CCU} clock.

CAPCOM and POSIF Clock Selection

The capture compare blocks CCU4, CCU8 and POSIF use as timer clock the clock f_{CCU} derived from system f_{SYS} via CCUDIV clock divider. The clock divider allows to adjust clock frequency of the timers with respect to the rest of the system. Relation between f_{CCU} clock and other clocks in the system is constrained as described in the [Table 11-5](#). The f_{CCU} clock frequency must only be configured while all CAPCOM and POSIF modules are not enabled.

Watchdog Clock Selection

The watchdog module uses as independent clock either the internal fast clock f_{OFI} or the slow clock f_{STDBY} . The system clock f_{PLL} is available as additional clock source.

Both the clock divider and the clock MUX must only be configured while the WDT is not enabled.

External Clock Output

An external clock is provided via clock pin EXTCLK. All clock sources can be selected as clock signal for the external clock output. Optionally a divider can be used before bringing the system clock to the outside to stay within the limit of the supported frequencies for the pads.

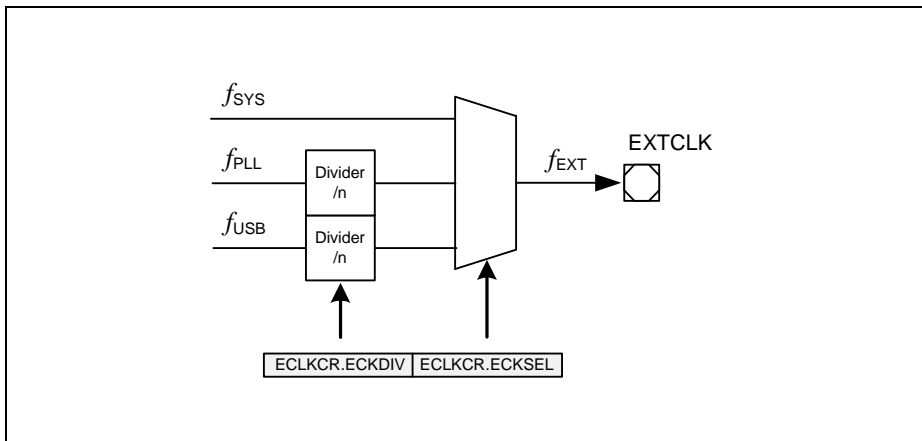

Figure 11-20 External Clock Selection

11.6.4 High Precision Oscillator Circuit (OSC_HP)

The high precision oscillator circuit can drive an external crystal or accepts an external clock source. It consists of an inverting amplifier with XTAL1 as input, and XTAL2 as output.

Figure 11-22 and **Figure 11-21** show the recommended external circuitries for both operating modes, External Crystal Mode and External Input Clock Mode.

External Input Clock Mode

In this usage an external clock signal is supplied directly not using an external crystal and bypassing the amplifier of the oscillator. The input frequency must be in the range from 4 to 40 MHz. When using an external clock signal it must be connected to XTAL1. XTAL2 is left open i.e. unconnected.

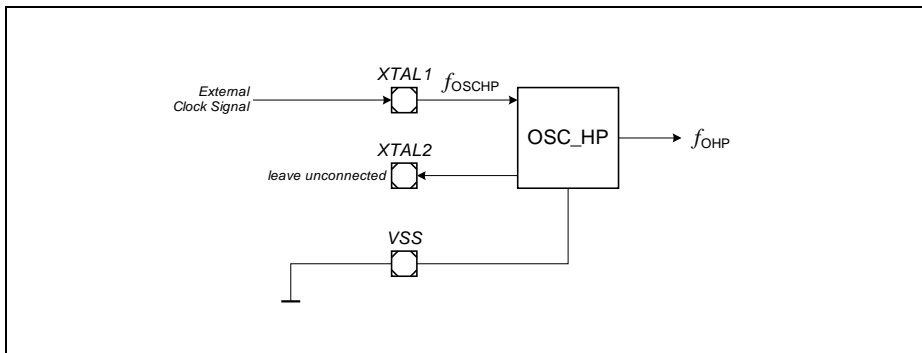

Figure 11-21 External Clock Input Mode for the High-Precision Oscillator

External Crystal Mode

For the external crystal mode an external oscillator load circuitry is required. The circuitry must be connected to both pins, XTAL1 and XTAL2. It consists normally of the two load capacitances C1 and C2. For some crystals a series damping resistor might be necessary. The exact values and related operating range depend on the crystal and have to be determined and optimized together with the crystal vendor using the negative resistance method.

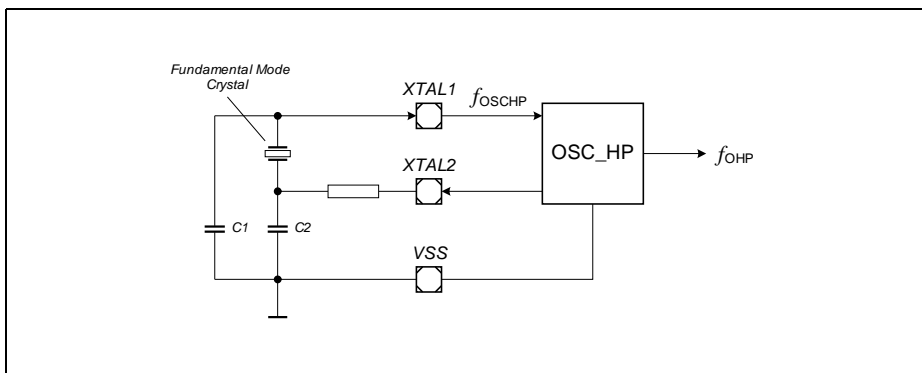

Figure 11-22 External Crystal Mode Circuitry for the High-Precision Oscillator

11.6.5 Backup Clock Source

The backup clock f_{OFI} generated internally is the default clock after start-up. It is used for bypassing the PLL for startup of the system without external clock. Furthermore it can be used as independent clock source for the watchdog module or even as system clock

System Control Unit (SCU)

source during normal operation. While in prescaler mode this clock is automatically used as emergency clock if the external clock failure has been detected.

Clock adjustment is required to reach desired level of f_{OFI} precision. The backup clock source provides two adjustment procedures:

- loading of adjustment value during start-up
- continuous adjustment using the high-precision f_{STDBY} clock as reference

11.6.6 Main PLL

The main PLL converts a low-frequency external clock signal to a high-speed internal clock. The PLL also has fail-safe logic that detects degenerative external clock behavior such as abnormal frequency deviations or a total loss of the external clock. The PLL triggers autonomously emergency action if it loses its lock on the external clock and switches to the Fast Internal Backup Clock.

This module is a phase locked loop for integer frequency synthesis. It allows the use of input and output frequencies of a wide range by varying the different divider factors.

11.6.6.1 Features

- VCO lock detection
- 4-bit input divider **P**: (divide by PDIV+1)
- 7-bit feedback divider **N**: (multiply by NDIV+1)
- 7-bit output dividers **K1 or K2**: (divide by KxDIV+1)
- Oscillator Watchdog
 - Detecting too low input frequencies
 - Detecting too high input frequencies
 - Spike detection for the OSC input frequency
- Different operating modes
 - Bypass Mode
 - Prescaler Mode
 - Normal Mode
- VCO Power Down
- PLL Power Down
- Glitch less switching between K-Dividers
- Switching between Normal Mode and Prescaler Mode

11.6.6.2 System PLL Functional Description

The PLL consists of a Voltage Controlled Oscillator (VCO) with a feedback path. A divider in the feedback path (N-Divider) divides the VCO frequency down. The resulting frequency is then compared with the externally provided and divided frequency (P-Divider). The phase detection logic determines the difference between the two clocks

System Control Unit (SCU)

and accordingly controls the frequency of the VCO (f_{VCO}). A PLL lock detection unit monitors and signals this condition. The phase detection logic continues to monitor the two clocks and adjusts the VCO clock if required.

The following figure shows the PLL block structure.

Clock Source Control

The input clock for the PLL f_{OSC} can be one of the following two clock sources:

- The internal generated fast clock f_{OFI}
- The clock f_{OHP} sourced by the crystal oscillator OSC_HP

The PLL clock f_{PLL} is generated from the input clock in one of two software selectable operation modes:

- Normal Mode, using VCO output clock
- Prescaler Mode, using input clock directly

The PLL output clock f_{PLL} is derived from either

- VCO clock divided by the K2-Divider, Normal Mode
- external oscillator clock divided by the K1-Divider, Prescaler Mode
- backup clock divided by the K1-Divider, Prescaler Mode

The PLL clock f_{PLL} is generated in emergency from one of two sources:

- Free running VCO if Emergency entered from Normal Mode of PLL
- Backup Clock if emergency entered from Prescaler Mode of PLL

Configuration and Operation of the Normal Mode

In Normal Mode, the PLL is running at the frequency f_{OSC} and f_{PLL} is divided down by a factor P, multiplied by a factor N and then divided down by a factor K2.

The output frequency is given by:

(11.1)

$$f_{PLL} = \frac{N}{P \cdot K_2} \cdot f_{OSC}$$

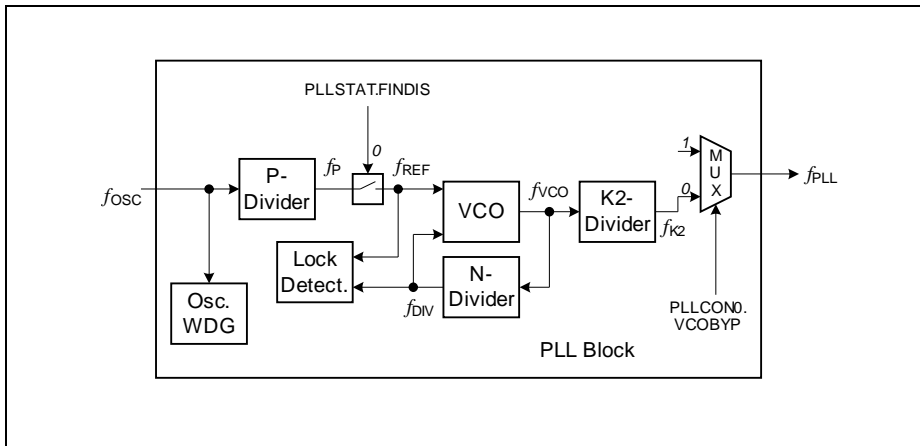

Figure 11-23 PLL Normal Mode

It is strongly recommended to apply even values of P and K2 Divider parameters in order to minimize PLL output clock jitter effect. Please find PLL configuration examples values in [Table 11-6](#).

Table 11-6 PLL example configuration values

| Target Frequency of f_{PLL} [MHz] | External Crystal Frequency [MHz] | P Parameter | N Parameter | K2 Parameter |
|-------------------------------------|----------------------------------|-------------|-------------|--------------|
| 80 | 4 | 1 | 80 | 4 |
| | 8 | 1 | 40 | 4 |
| | 12 | 2 | 80 | 6 |
| | 16 | 1 | 20 | 4 |
| 120 | 4 | 1 | 120 | 4 |
| | 8 | 1 | 60 | 4 |
| | 12 | 1 | 40 | 4 |
| | 16 | 1 | 30 | 4 |
| 140 | 4 | 1 | 70 | 2 |
| | 8 | 1 | 35 | 2 |
| | 12 | 3 | 70 | 2 |
| | 16 | 4 | 70 | 2 |

Table 11-6 PLL example configuration values (cont'd)

| Target Frequency of f_{PLL} [MHz] | External Crystal Frequency [MHz] | P Parameter | N Parameter | K2 Parameter |
|-------------------------------------|----------------------------------|-------------|-------------|--------------|
| 144 | 4 | 1 | 72 | 2 |
| | 8 | 1 | 36 | 2 |
| | 12 | 2 | 48 | 2 |
| | 16 | 1 | 18 | 2 |

Note: The values of P, N and K2 configuration parameters specified in [Table 11-6](#) should must decremented by one before programmed into corresponding registers.

The Normal Mode is selected by the following settings

- Register Setting
 - PLLCON0.VCOBYP = 0
 - PLLCON0.FINDIS = 0

The Normal Mode is entered when the following requirements are all together valid:

- Register Values
 - PLLCON0.FINDIS = 0
 - PLLSTAT.VCOBYST = 0
 - PLLSTAT.VCOLOCK = 1
 - PLLSTAT.PLLLV = 1
 - PLLSTAT.PLLH = 1

Operation on the Normal Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking PLLSTAT.PLLLV. For a better monitoring also the upper frequency can be monitored via PLLSTAT.PLLH.

For the Normal Mode there is the following requirement regarding the frequency of f_{OSC} .

A modification of the two dividers P and N has a direct influence to the VCO frequency and lead to a loss of the VCO Lock status. A modification of the K2-divider has no impact on the VCO Lock status.

When the frequency of the Normal Mode should be modified or entered the following sequence needs to be followed:

- Configure and enter Prescaler Mode
- Disable NMI trap generation for the VCO Lock
- Configure Normal Mode
- Wait for a positive VCO Lock status (PLLSTAT.VCOLOCK = 1).
- Switch to Normal Mode by clearing PLLCON.VCOBYP

The Normal Mode is entered when the status bit PLLSTAT.VCOBYST is cleared.

When the Normal Mode is entered, the NMI status flag for the VCO Lock trap should be cleared and then enabled again. The intended PLL output target frequency can now be configured by changing only the K2-Divider. This can result in multiple changes of the K2-Divider to avoid to big frequency changes. Between the update of two K2-Divider values 6 cycles of f_{PLL} should be waited. For ramping up PLL output frequency in Normal Mode the following steps are required:

- The first target frequency of the Normal Mode should be selected in a way that it matches or is only slightly higher as the one used in the Prescaler Mode. This avoids big changes in the system operation frequency and therefore power consumption when switching later from Prescaler Mode to Normal Mode.
- Selecting P and N in a way that f_{VCO} is in the upper area of its allowed values leads to a slightly increased power consumption but to a slightly reduced jitter
- Selecting P and N in a way that f_{VCO} is in the lower area of its allowed values leads to a slightly reduced power consumption but to a slightly increased jitter
- It is recommended to reset the f_{VCO} Lock detection ($PLLCON0.RESLD = 1$) after the new values of the dividers are configured to get a defined VCO lock check time.

Depending on the selected divider value of the K2-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K2-divider values are defined in the Data Sheet.

PLL VCO Lock Detection

The PLL has a lock detection that supervises the VCO part of the PLL in order to differentiate between stable and unstable VCO circuit behavior. The lock detector marks the VCO circuit and therefore the output f_{VCO} of the VCO as instable if the two inputs f_{REF} and f_{DIV} differ too much. Changes in one or both input frequencies below a level are not marked by a loss of lock because the VCO can handle such small changes without any problem for the system.

PLL VCO Loss-of-Lock Event

The PLL may become unlocked, caused by a break of the crystal or the external clock line. In such a case, an NMI trap is generated if it were enabled. Additionally, the OSC clock input f_{OSC} is disconnected from the PLL VCO to avoid unstable operation due to noise or sporadic clock pulses coming from the oscillator circuit. Without a clock input f_{OSC} , the PLL gradually slows down to its VCO base frequency and remains there. This default feature can be disabled by setting bit $PLLCON0.OSCDISCDIS$. If this bit is set the OSC clock remains connected to the VCO.

11.6.6.3 Configuration and Operation of the Prescaler Mode

In Prescaler Mode, the PLL is running at the external frequency f_{OSC} and f_{PLL1} is derived from f_{OSC} only by the K1-Divider.

The output frequency is given by

$$f_{\text{PLL}} = \frac{f_{\text{OSC}}}{K_1} \quad (11.2)$$

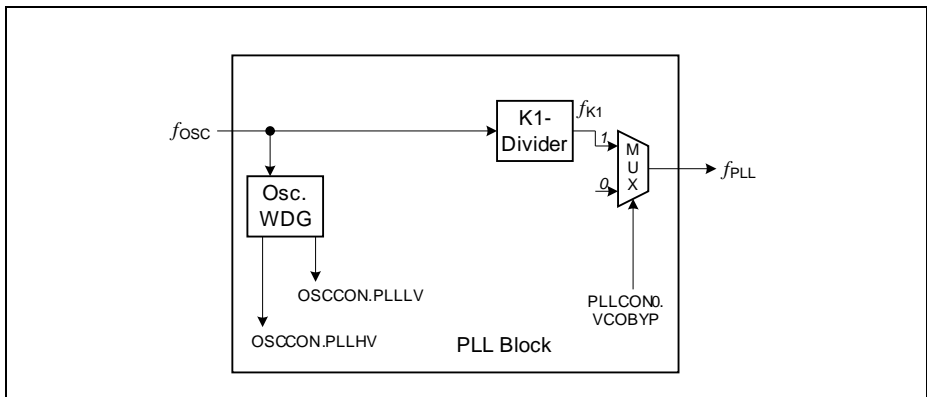

Figure 11-24 PLL Prescaler Mode Diagram

The Prescaler Mode is selected by the following settings

- PLLCON0.VCOBYP = 1

The Prescaler Mode is entered when the following requirements are all together valid:

- PLLSTAT.VCOBYST = 1
- PLLSAT.PLLLV = 1

Operation on the Prescaler Mode does require an input clock frequency of f_{OSC} . Therefore it is recommended to check and monitor if an input frequency f_{OSC} is available at all by checking PLLSAT.PLLLV. For a better monitoring also the upper frequency can be monitored via PLLSAT.PLLHV.

For the Prescaler Mode there are no requirements regarding the frequency of f_{OSC} .

The system operation frequency is controlled in the Prescaler Mode by the value of the K1-Divider. When the value of PLLCON1.DIV was changed the next update of this value should not be done before bit PLLSTAT.K1RDY is set.

Depending on the selected divider value of the K1-Divider the duty cycle of the clock is selected. This can have an impact for the operation with an external communication interface. The duty cycles values for the different K1-divider values are defined in the Data Sheet.

System Control Unit (SCU)

The Prescaler Mode is requested from the Normal Mode by setting bit PLLCON.VCOBYP. The Prescaler Mode is entered when the status bit PLLSTAT.VCOBYST is set. Before the Prescaler Mode is requested the K1-Divider should be configured with a value generating a PLL output frequency f_{PLL} that matches the one generated by the Normal Mode as much as possible. In this way the frequency change resulting out of the mode change is reduced to a minimum.

The Prescaler Mode is requested to be left by clearing bit PLLCON.VCOBYP. The Prescaler Mode is left when the status bit PLLSTAT.VCOBYST is cleared.

11.6.6.4 Bypass Mode

The bypass mode is used only for testing purposes. In Bypass Mode the input clock f_{OSC} is directly connected to the PLL output f_{PLL} .

The output frequency is given by:

(11.3)

$$f_{PLL} = f_{OSC}$$

11.6.6.5 System Oscillator Watchdog (OSC_WDG)

The oscillator watchdog monitors the incoming clock frequency f_{OSC} from the OSC_HP oscillator. A stable and defined input frequency is a mandatory requirement for operation in both Prescaler Mode and Normal Mode. In addition for the Normal Mode it is required that the input frequency f_{OSC} is in a certain frequency range to obtain a stable master clock from the VCO part.

The expected input frequency is selected via the bit field **OSCHPCTRL.OSCVAL**. The OSC_WDG checks for spikes, too low frequencies, and for too high frequencies.

The frequency that is monitored is f_{OSCREF} which is derived from f_{OSC} .

(11.4)

$$f_{OSCREF} = \frac{f_{OSC}}{OSCVAL + 1}$$

The divider value **OSCHPCTRL.OSCVAL** has to be selected in a way that f_{OSCREF} is 2.5 MHz.

Note: f_{OSCREF} has to be within the range of 2 MHz to 3 MHz and should be as close as possible to 2.5 MHz.

The monitored frequency is too low if it is below 1.25 MHz and too high if it is above 7.5 MHz. This leads to the following two conditions:

- Too low: $f_{\text{OSCREF}} < 1.25 \text{ MHz} \times (\text{OSCHPCTRL.OSCVAL}+1)$
- Too high: $f_{\text{OSCREF}} > 7.5 \text{ MHz} \times (\text{OSCHPCTRL.OSCVAL}+1)$

Before configuring the OSC_WDG function all the trap options should be disabled in order to avoid unintended traps. Thereafter the value of **OSCHPCTRL.OSCVAL** can be changed. Then the OSC_WDG should be reset by setting **PLLCON0.OSCVAL**. This requests the start of OSC_WDG monitoring with the new configuration. When the expected positive monitoring results of **PLLSTAT.PLLLV** and / or **PLLSTAT.PLLHV** are set the input frequency is within the expected range. As setting **PLLCON0.OSCVAL** clears all three bits **PLLSTAT.PLLSP**, **PLLSTAT.PLLLV**, and **PLLSTAT.PLLHV** all three trap status flags will be set. Therefore all three flags should be cleared before the trap generation is enabled again. The trap disabling-clearing-enabling sequence should also be used if only bit **PLLCON0.OSCVAL** is set without any modification of **OSCHPCTRL.OSCVAL**.

11.6.6.6 VCO Power Down Mode

The PLL offers a VCO Power Down Mode. This mode can be entered to save power within the PLL. The VCO Power Down Mode is entered by setting bit **PLLCON0.VCOPWD**. While the PLL is in VCO Power Down Mode only the Prescaler Mode is operable. Please note that selecting the VCO Power Down Mode does not automatically switch to the Prescaler Mode. So before the VCO Power Down Mode is entered the Prescaler Mode must be active.

11.6.6.7 PLL Power Down Mode

The PLL offers a Power Down Mode. This mode can be entered to save power if the PLL is not required. The Power Down Mode is entered by setting bit **PLLCON0.PLLPWD**. While the PLL is in Power Down Mode no PLL output frequency is generated.

11.6.6.8 Application Hints

The PLL configuration is a complex module and require a proper configuration sequence. The following application hints are intended to avoid unexpected effects and keep the system in a stable operation state.

Switching from Normal Mode to Prescaler Mode

Switching from Normal Mode to Prescaler Mode can result in generating spikes on the PLL clock output. For setting the Prescaler Mode the following sequence should be applied:

1. Switch from PLL clock (normal mode) to OFI clock using **SYSCCLKCR** register

2. Set the bit **PLLCON0.VCOBYP** to change from normal to prescaler mode
3. Switch back from OFI clock to PLL clock (prescaler mode) using **SYSCLKCR** register

Switching from Prescaler Mode to Normal Mode

Switching from Prescaler Mode to Normal Mode can result in generating spikes on the PLL clock output. For setting the Normal Mode the following sequence should be applied:

1. Switch from OFI clock (prescaler mode) to PLL clock using **SYSCLKCR** register
2. Set the bit **PLLCON0.VCOBYP** to change from prescaler to normal mode
3. Switch back from PLL clock to OFI clock (normal mode) using **SYSCLKCR** register

11.6.7 Internally Generated System Clock Calibration

The internal Backup Clock Source by default generates output clock signal of a frequency parameters as specified in the Data Sheet, referred to as uncalibrated OSC_FI clock. In order to improve accuracy of the Backup Clock Source clock calibration mechanisms are available. For details please refer to the following sub-chapters.

11.6.7.1 Factory Calibration

The Factory Calibration mechanism allows the Backup Clock Source clock output adjustment to parameters specified in the Data Sheet, referred to as OSC_FI factory calibrated clock. The factory calibration can be enabled with user software via bit field FOTR of the **PLLCON0** register. Enabling of this calibration has an immediate effect on the clock output.

11.6.7.2 Automatic Calibration

The Automatic Calibration mechanism enables Backup Clock Source clock output continuous adjustment based on the relation to a high precision reference clock f_{STDBY} . This calibration brings the clock output parameters to the level specified in the Data Sheet as the OSC_FI automatically calibrated clock. The automatic calibration can be enabled with user software via bit field AOTREN of the **PLLCON0** register. It is required that the reference clock f_{STDBY} generated in the Hibernate domain is activated prior to enabling this method of clock calibration.

11.6.7.3 Alternative Internal Clock Calibration

An alternative system clock calibration can be performed by programming of the system PLL with register values reflecting individual chip calibration characteristics determined by the **CLKCALCONST.CALIBCONST** register value. This way of calibration allows to achieve clock of frequency variation comparable with the factory calibration enabled

System Control Unit (SCU)

Internal Backup Clock Source, but with significantly lower output clock jitter as defined for f_{OFI} untrimmed oscillator. For more details please refer to Data Sheet.

The formula describing dependencies between calibration constant and PLL configuration settings that allow to program desired output frequency is provided in **Equation (11.5)**

(11.5)

$$f_{PLL} = 24 \times \left(\frac{CALIBCONST \times 488 + 11651}{11146} \right) \times \left(\frac{N}{P \times K2} \right) [\text{MHz}]$$

It is strongly recommended to apply even value of P and K2 parameters in order to minimize PLL output clock jitter effect. Please find PLL configuration examples for different calibration constant *CALIBCONST* values in **Table 11-7**.

Table 11-7 PLL example configuration values

| Target Frequency of f_{PLL} [MHz] | TRIM Constant | P Parameter | N Parameter | K2 Parameter |
|--|---------------|-------------|-------------|--------------|

| | 13 | 5 | 56 | 3 |
| | 14 | 4 | 29 | 2 |
| | 15 | 8 | 85 | 3 |

Note: The values of P, N and K2 configuration parameters specified in [Table 11-7](#) should must decremented by one before programmed into corresponding registers.

11.6.8 USB PLL

The USB PLL serves the special purpose to provide an accurate clock for USB 2.0 full-speed operation. The basic functionality of the USB PLL is similar to the main PLL (see [Figure 11-25](#)).

Configuration and Operation

The PLLUSB is running at the frequency f_{OHP} and f_{PLLUSB} is divided down by a factor P, multiplied by a factor N and then divided down by the factor of 2.

The output frequency is given by:

(11.6)

$$f_{\text{PLLUSB}} = \frac{N}{P \cdot 2} \cdot f_{\text{OHP}}$$

Operation of the PLLUSB require an input clock frequency of f_{OHP} .

The following requirement must be fulfilled regarding the frequency of f_{OHP} (see).

A modification of the two dividers P and N has a direct influence to the VCO frequency and lead to a loss of the VCO Lock status.

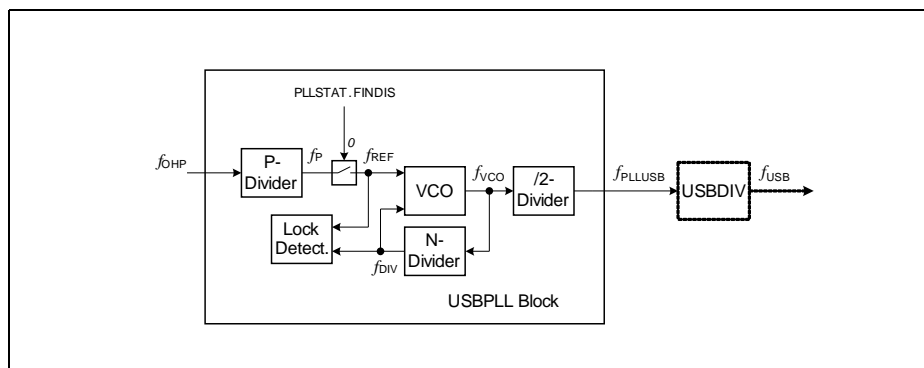

Figure 11-25 PLLUSB Block Diagram

It is strongly recommended to apply even value of P and USB Clock Divider (referred to as USBDIV divider) parameters in order to minimize the PLL output clock jitter effect. Please find PLLUSB configuration examples values in [Table 11-8](#).

Table 11-8 PLLUSB example configuration values

| Crystal frequency [MHz] | P Parameter | N Parameter | USB Divider Parameter |
|-------------------------|-------------|-------------|-----------------------|
| 8 | 2 | 96 | 4 |
| 12 | 2 | 64 | 4 |
| 16 | 2 | 48 | 4 |

Note: The values of P, N and USB Divider configuration parameters specified in [Table 11-8](#) should must decremented by one before programmed into corresponding registers.

The USB PLL is put automatically in power-down by the USB suspend signal, when the clock is not used for SD/MMC operation.

Note: Re-configuration of the P-Divider before the USBPLL has locked must be avoided.

11.6.9 Ultra Low Power Oscillator

The ultra low power oscillator is providing a real time clock source of 32.768 kHz when paired with an external crystal. It operates in the supply voltage range of the Hibernate power domain. The crystal pads are always powered by V_{BAT} or V_{DDP} .

The precise and stable clock can be propagated to Core domain as f_{STDBY} and used for continuous adjustments the fast internal backup clock source f_{OFI} .

11.6.9.1 OSC_ULP Oscillator Watchdog (ULPWDG)

The slow oscillator watchdog monitors the incoming clock frequency f_{ULP} from OSC_ULP. A reliable clock is required in the Hibernate domain in Hibernate state in order to perform system wake-up upon occurrence of configured events. In order to ensure that a clock watchdog is required to continuously monitor the enabled clock sources.

In case of external crystal failure the clock source switches automatically to the Internal Slow Clock Source generating f_{OSI} .

11.6.10 Internal Slow Clock Source

The slow internal clock source provides a clock f_{OSI} of 32.768 kHz. This clock can be used as independent clock source for WDT module and as the clock for periodic wake-up events in power saving modes and for continuous adjustments the fast internal backup clock source f_{OFI} .

11.6.11 Clock Gating Control

The clock to peripherals can be individually gated and parts of the system stopped by these means.

Clock gating in Sleep and Deep Sleep modes

Global power management related to clock generation and selection is supported for the sleep modes of the system. The user has full control on the clock configuration for these modes. The registers **SLEEP**CR and **DSLEEP**CR control which clocks should remain active and which are to be gated by entering the corresponding Sleep or Deep Sleep mode. Furthermore the system clock can be switched to a slow standby clock and the PLLs put into power-down mode in Deep Sleep mode.

11.7 Debug Behavior

The SCU module does not get affected with the HALTED signal from CPU upon debug activities performed using external debug probe.

11.8 Power, Reset and Clock

The SCU module consists of sub-modules that interact with different power, clock and reset domains. Some of the sub-modules are controlled via dedicated interfaces across the power, clock and reset boundaries. The sub-modules are considered parts of the SCU in the functional sense therefore the complete SCU module is considered a multi domain circuit.

Power domains

Power domains get separated with appropriate power separation cells.

- Pad domain supplied with V_{DDP} voltage
- Analog domain supplied with V_{DDA} voltage
- Core domain supplied with V_{DDC} voltage
- Hibernate domain supplied with V_{BAT} (optionally with a battery or capacitor) or V_{DDP} voltage

Clock domains

All cross-domain interfaces of SCU implement signal synchronization.

- SCU clock in the core domain is f_{SYS}
- Hibernate Control Unit (HCU) clock is f_{OSI} or f_{ULP} (32.768 kHz)
- The Register Mirror Interface of HCU and RTC clock is clocked with f_{STDBY} (32.768 kHz) and f_{SYS} clocks

Reset domains

All reset signals get synchronized to the respective clocks (please refer to **“Reset Control” on Page 11-25** chapter for more details)

- System Reset ($\overline{SYSRESET}$) resets the core logic and can be triggered from various sources.
- Power-on Reset ($\overline{PORESET}$) resets analog modules and contributes in generation of the System Reset. The reset is controlled from internal power validation circuit or driven externally via the bi-directional \overline{PORST} pin.
- Standby Reset ($\overline{STDBYRESET}$) resets HCU part of SCU. It is triggered by power-up sequence of Hibernate domain and is not affected by power-up sequence of the Core domain. It can also be controlled with software access to **RSTCLR** and **RSTSET** registers.
- Debug Reset ($\overline{DBGRESET}$) is used in debug with an external debug probe.

11.9 Initialization and System Dependencies

The initialization sequence of the XMC4700 / XMC4800 is a process taking place before user application software takes control of the system and is comprising of two major phases (see [Figure 11-26](#)), split in several distinctive steps:

Hardware Controlled Initialization Phase

The hardware controlled initialization phase gets performed automatically after power up of the microcontroller. This part is generic and it ensures basic configuration common to most applications. The hardware setup needs to ensure fulfillment of requirements specified in Data Sheet in order to enable reliable start up of the microcontroller before control is handed over to the user software. The sequence where boot code gets executed is considered a part of the hardware controlled phase of the initialization sequence.

For details of the setup requirements please refer to Data Sheet.

Software Controlled Initialization Phase

The software controlled initialization phase is the part of the complete start-up sequence where the application specific configuration gets applied with user software. It involves several steps that are critical for proper operation of the microcontroller in the application context and may also involve some optional configuration actions in order to improve system performance and stability in the application context.

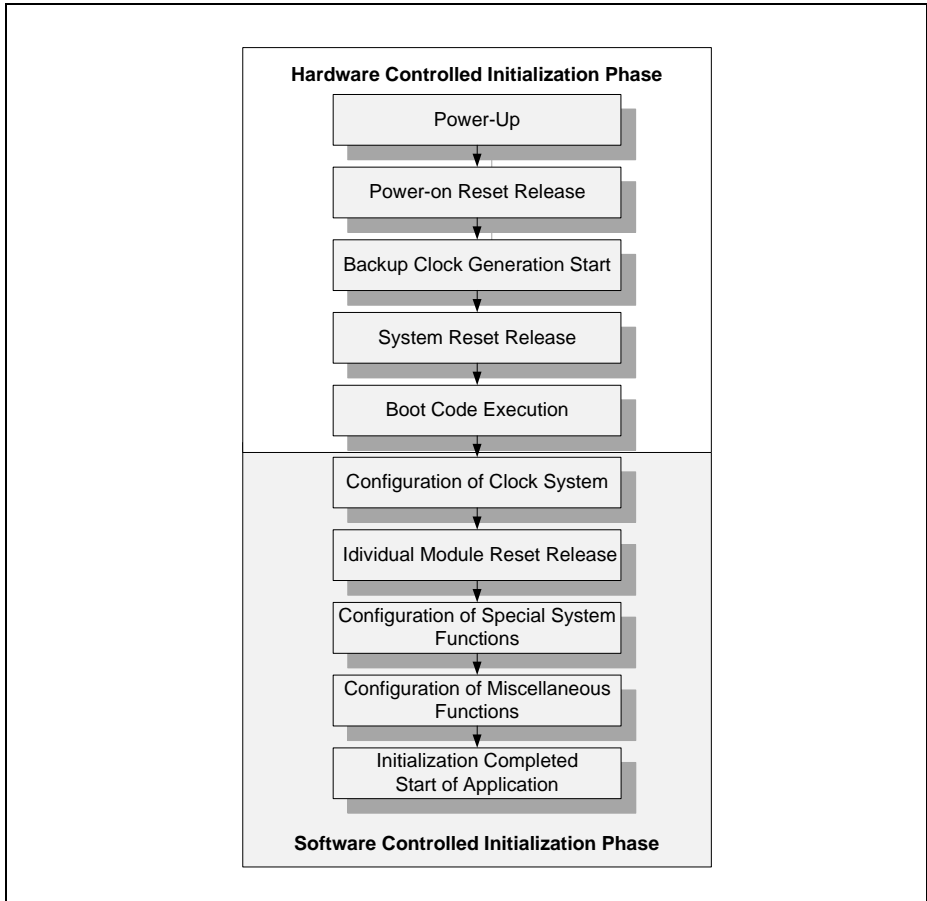

Figure 11-26 Initialization sequence

A more detailed description of the configuration steps is available in the following sub-chapters.

11.9.1 Power-Up

Power up of the microcontroller gets performed by applying VDDP and VDDA supply. Internal voltage generation in the EVR module gets activated automatically after VDDP has been applied (for details of the supply requirements please refer to Data Sheet).

11.9.2 Power-on Reset Release

The XMC4700 / XMC4800 implements bi-directional pin $\overline{\text{PORST}}$ for the Power-on Reset $\overline{\text{PORESET}}$ control. The internal Power-on Reset generation is based on the supply and core voltage validation.

The $\overline{\text{PORST}}$ pin may be used either to control the $\overline{\text{PORESET}}$ from an external source in the system or to control the reset of external components from the XMC4700 / XMC4800. The $\overline{\text{PORST}}$ function, implemented as open drain driver, allows to share the pin between multiple devices in the system.

An example of the system where XMC4700 / XMC4800 may act as the reset control master is shown in [Figure 11-27](#). Any of the devices capable to drive low level of the reset signal is potentially able to assert reset of the system. Release of the reset is effectively performed when devices with output driving capability are not driving low level and the signal is driven high via the pull-up resistance. The driving strength of the pull-up resistance is required to ensure fast release of $\overline{\text{PORST}}$ pin and effectively also fast release of $\overline{\text{PORESET}}$ reset (for details on Power Sequencing please refer to Data Sheet).

Release of the $\overline{\text{PORESET}}$ of XMC4700 / XMC4800 results in start of Backup Clock generation.

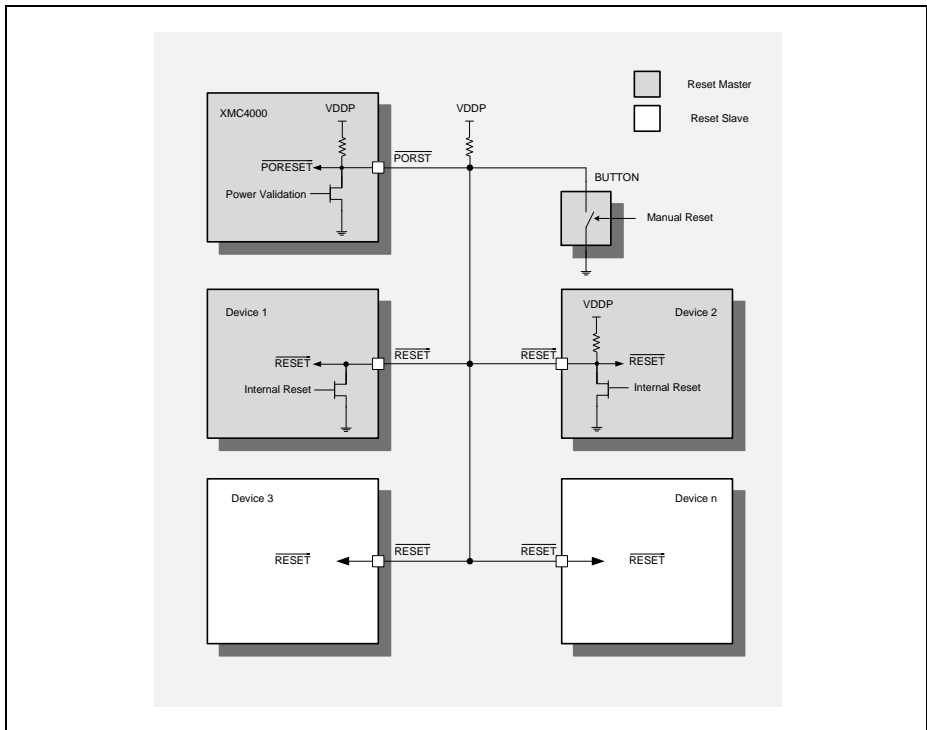

Figure 11-27 System Level Power On Reset Control

11.9.3 System Reset Release

Release of the PORESET and start of the Backup Clock generation results in automatic System Reset SYSRESET release and start of boot code execution.

The System Reset SYSRESET can be triggered from various sources like software controlled CPU reset register, watchdog time-out-triggered reset or a system trap triggered reset. For more details on Reset Control details please refer to **“Reset Control”** on Page 11-25

The cause of the last reset gets automatically stored in the **RSTSTAT** register and can be checked by user software to determine the state of the system and for debug purpose. The reset status in the **RSTSTAT** register shall be reset with **RSTCLR** register after each startup in order to ensure consistent source indication after the next reset.

After SYSRESET release a number of modules clocked with f_{PERIPH} still remain in reset state. Reset release of these modules needs to be released with **PRCLR0**, **PRCLR1**, and **PRCLR2** registers which by default keep the peripheral resets active. It is

System Control Unit (SCU)

recommended to keep the unused modules in reset state in order to reduce power consumption. It is also highly recommended to ensure that clock of the corresponding modules are active before individual peripheral reset release.

11.9.4 Clock System Setup

The following system clocking modes are supported:

- PLL Normal
- PLL Prescaler
- Backup Clock

The default clock signal available after power-up is the internally generated Backup Clock f_{OFI} . The user software starts execution of code clocked with the Backup Clock and can change the clock at any point of time applying a system clock configuration sequence. For details of the clock structure please refer to **“Clock System Overview” on Page 11-31**.

The flowchart in **Figure 11-28** illustrates the recommended system clock configuration sequence. It is strongly recommended to follow the steps in order to ensure proper initialization of the PLL and power sequencing within specified limits (for details on Power Sequencing please refer to Data Sheet). Each of the steps depicted in the diagram may require a sequence of register access actions.

The configuration of the clock system may involve various actions like:

- internal clock trimming configurations, election between Factory or Automatic trimming of the Backup Clock f_{OFI} using **PLLCON0** register
- calibration of the PLL, calculation of the optimal PLL settings using the **Equation (11.5)** on **Page 11-48**
- enabling of external crystal oscillator or direct clock input, configuration of the external clock watchdog with **OSCHPCTRL** register, according to **Equation (11.4)** on **Page 11-45**, selection of the external crystal oscillator or direct clock f_{OSC} using **OSCHPCTRL**
- powering up of the System PLL in **PLLCON0** register
- locking-up of the System PLL, configuration of the System PLL using **PLLCON0**, **PLLCON1** and **PLLCON2** registers
- configuration of clock dividers, switching the system clock to the selected source (please refer to)

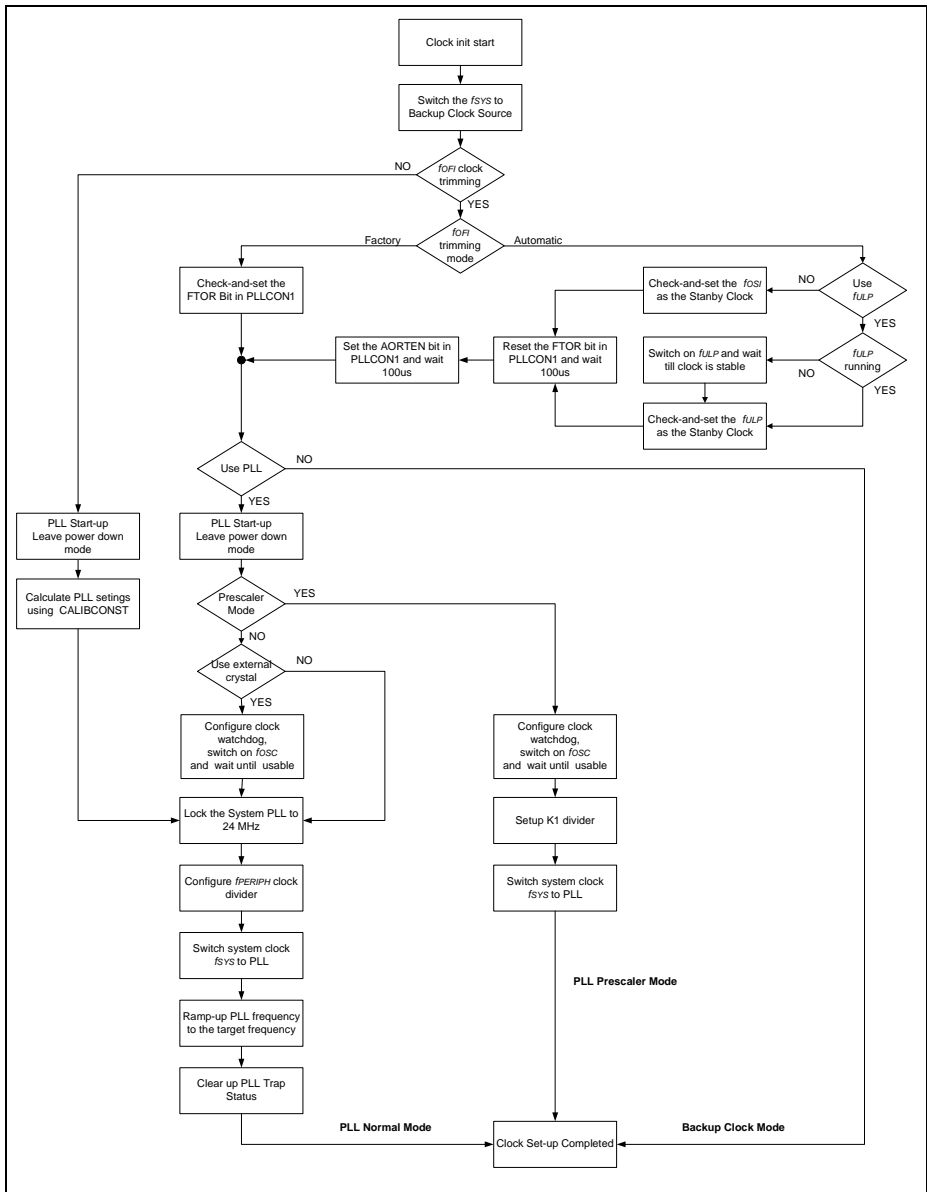

Figure 11-28 Clock initialization sequence

After reset release the system is clocked with a clock derived from the Backup Clock source. If a PLL output clock is required as the system clock source then it is necessary to initialize the respective PLL with a software routine. For details please refer to PLL section in **“Main PLL” on Page 11-39**.

The system relevant and module clocks are configured with the dedicated registers **SYSCLKCR**, **CPUCLKCR** and **PBCLKCR**.

Some peripheral clocks require explicit enable with **CLKSET** register.

11.9.5 Configuration of Special System Functions

Special system functions may be required to perform actions that improve system stability and robustness. The following special system functions or modules require initialization before the actual user application starts:

- Memory Parity Protection
- Supply Voltage Brown-out Detection
- Initialization of the Hibernate Domain
- Watchdog Timer (WDT)
- Real Time Clock (RTC)
- System Trap Initialization

Memory Parity Protection

Memory Parity Protection is performed using memory parity check. The parity check can be enabled individually for each instance of memory with **PEEN** register. A trap generation can be individually enabled with **PETE** register in order to get the trap flag reflected in **TRAPRAW** register or to generate System Reset if enabled in **PERSTEN** register.

For details of the Memory Parity Protection please refer to the **“Memory Parity Protection” on Page 11-7**.

Brown Out Detection

Brown out detection mechanism allow active monitoring of the supply voltage and a corrective reaction in case the voltage level is below a programmed threshold. A trap request will be flagged if a programmed condition is detected. For details please refer to **“Supply Voltage Brown-out Detection” on Page 11-20**

Initialization of the Hibernate Domain

Hibernate Control logic and the RTC module needs to be activated with **PWRSET** register before it can be used. This initialization needs to be performed only once after the V_{BAT} has been applied and it stays enabled if V_{BAT} remains applied. After power off

System Control Unit (SCU)

of the main supply of the chip i.e. VDDP, the hibernate domain will remain intact if V_{BAT} is still supplied. For details of hibernate control please refer to **“Hibernate Control” on Page 11-21**. For details of RTC module control please refer to RTC chapter.

Watchdog Timer

The Watchdog Timer requires a clock source selection and activation. It is highly recommended to use reliable clock source, preferably independent from the system clock source in order to ensure corrective action in case of a system failure which will bring the microcontroller into a safe operation state. For more details please refer to WDT chapter. For details of the WDT module configuration please refer to the “Initialization and Control Sequence” section of the WDT chapter.

Real Time Clock

If the real time clock is required then the initialization must take place after Hibernate domain has been activated. For details of the RTC module configuration please refer to the “Initialization and Control Sequence” section of the RTC chapter.

System Trap Initialization

System Traps are by default disabled and need to be enabled with user software before used. Any active trap flag will be reflected in the **TRAPRAW** register. In order to enable an NMI interrupt generation it needs to be unmasked in **TRAPDIS** register.

For details of the System Trap configuration please refer to the **“Trap Generation” on Page 11-9**.

11.9.6 Configuration of Miscellaneous Functions

A number of miscellaneous functions may be used as a part of the user application, or, e.g. by an Operating System. The following functions are available and require configuration before used:

- Power Saving modes
- Die Temperature Sensor (DTS)
- Out of Range Comparators for analog I/Os

Power Saving modes

Different power modes like Sleep, Deep Sleep and Hibernate mode require configuration of their functions and configuration of wake-up triggers prior to entering the modes. For details of the available modes and configuration please refer to **“Power Management” on Page 11-14**

Die Temperature Sensor

The Die Temperature Sensor allows to perform temperature measurements of the die. The module needs to be enabled with **DTSCON** register before used. For details please refer to **“Die Temperature Measurement” on Page 11-10**

Out of Range Comparators

The out of range comparator serves the purpose of overvoltage monitoring for analog input pins of the chip. This functionality can be enabled with registers **G0ORCEN** and **G1ORCEN**.

11.10 Registers

This section describes the registers of SCU. Most of the registers are reset **SYSRESET** reset signal but some of the registers can be reset only with **PORST** reset.

Table 11-9 Base Addresses of sub-sections of SCU registers

| Short Name | Description | Offset Addr. ¹⁾ |
|---------------|--|----------------------------|
| GCU Registers | Offset address of General Control Unit | 0000 _H |
| PCU Registers | Offset address of Power Control Unit | 0200 _H |
| HCU Registers | Offset address of Hibernate Control Unit | 0300 _H |
| RCU Registers | Offset address of Reset Control Unit | 0400 _H |
| CCU Registers | Offset address of Clock Control Unit | 0600 _H |

1) The absolute register address is calculated as follows:

Module Base Address + Sub-Module Offset Address (shown in this column) + Register Offset Address

Following access result an AHB error response:

- Read or write access to undefined address
- Write access in user mode to registers which allow only privileged mode write
- Write access to read-only registers
- Write access to startup protected registers

Table 11-10 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|-------------------------------|
| SCU | 5000 4000 _H | 5000 7FFF _H | System Control Unit Registers |

1) The absolute register address is calculated as follows:

Module Base Address + Sub-Module Offset Address + Offset Address (shown in this column)

11.10.1 GCU Registers

ID

Register containing unique ID of the module.

System Control Unit (SCU)

ID

SCU Module ID Register

(0000_H)

Reset Value: 0090 C0XX_H

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| MOD_REV | [7:0] | r | Module Revision Indicates the revision number of the implementation. This information depends on the design step. |
| MOD_TYPE | [15:8] | r | Module Type This internal marker is fixed to C0 _H . |
| MOD_NUMBER | [31:16] | r | Module Number Indicates the module identification number |

IDCHIP

Register containing unique ID of the chip.

IDCHIP

Chip ID Register

(0004_H)

Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|---------------|--------|------|----------------|
| IDCHIP | [31:0] | r | Chip ID |

IDMANUF

Register containing unique manufactory ID of the chip.

System Control Unit (SCU)

IDMANUF

Manufactory ID Register

(0008_H)

Reset Value: 0000 1820_H

| Field | Bits | Type | Description |
|-------|---------|------|--|
| DEPT | [4:0] | r | Department Identification Number DEPT indicates department within Infineon Technologies. |
| MANUF | [15:5] | r | Manufacturer Identification Number JEDEC normalized Manufacturer code. MANUF = C1 _H stands for Infineon Technologies. |
| 0 | [31:16] | r | Reserved |

STCON

Startup configuration register determining boot process of the chip.

STCON

Startup Configuration Register

(0010_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|-------------------|------|--|
| HWCON | [1:0] | rh | HW Configuration At PORESET the following values are latched HWCON.0 = not (TMS) HWCON.1 = TCK 00 _B Normal mode, JTAG 01 _B ASC BSL enabled 10 _B BMI customized boot enabled 11 _B CAN BSL enabled |
| SWCON | [11:8] | rw | SW Configuration Bit[9:8] is copy of Bit[1:0] after PORESET 0000 _B Normal mode, boot from Boot ROM 0001 _B ASC BSL enabled 0010 _B BMI customized boot enabled 0011 _B CAN BSL enabled 0100 _B Boot from Code SRAM 1000 _B Boot from alternate Flash Address 0 1100 _B Boot from alternate Flash Address 1 1110 _B Enable fallback Alternate Boot Mode (ABM) <i>Note: Only reset with Power-on Reset</i> |
| 0 | [7:2], [31:12] | r | Reserved Read as 0; should be written with 0. |

GPRx

Software support registers. Can be reset only with PORST reset.

GPRx (x=0-1)

General Purpose Register x **(002C_H + x*4)** **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| DAT | [31:0] | rw | User Data 32-bit data <i>Note: GPRx registers can be reset with PORST reset only</i> |

ETH0_CON

ETH0 module configuration register.

ETH0_CON

Ethernet 0 Port Control Register (50004040_H)

Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| RXD0 | [1:0] | rw | MAC Receive Input 0 This bit field indicates the receive input position of the RXD0 signal. 00 _B Data input RXD0A is selected 01 _B Data input RXD0B is selected 10 _B Data input RXD0C is selected 11 _B Data input RXD0D is selected |
| RXD1 | [3:2] | rw | MAC Receive Input 1 This bit field indicates the receive input position of the RXD1 signal. 00 _B Data input RXD1A is selected 01 _B Data input RXD1B is selected 10 _B Data input RXD1C is selected 11 _B Data input RXD1D is selected |

System Control Unit (SCU)

| Field | Bits | Type | Description |
|-----------------|---------|------|--|
| RXD2 | [5:4] | rw | MAC Receive Input 2 This bit field indicates the receive input position of the RXD2 signal. 00 _B Data input RXD2A is selected 01 _B Data input RXD2B is selected 10 _B Data input RXD2C is selected 11 _B Data input RXD2D is selected |
| RXD3 | [7:6] | rw | MAC Receive Input 3 This bit field indicates the receive input position of the RXD3 signal. 00 _B Data input RXD3A is selected 01 _B Data input RXD3B is selected 10 _B Data input RXD3C is selected 11 _B Data input RXD3D is selected |
| CLK_RMII | [9:8] | rw | RMII clock input This bit field indicates the receive input position of the RMII clock input signal. 00 _B Data input RMIIA is selected 01 _B Data input RMIIB is selected 10 _B Data input RMIIC is selected 11 _B Data input RMIID is selected |
| CRS_DV | [11:10] | rw | CRS_DV input This bit field indicates the receive input position of the CRS_DV input signal. 00 _B Data input CRS_DVA is selected 01 _B Data input CRS_DVB is selected 10 _B Data input CRS_DVC is selected 11 _B Data input CRS_DVD is selected |
| CRS | [13:12] | rw | CRS input This bit field indicates the receive input position of the CRS input signal. 00 _B Data input CRSA 01 _B Data input CRSB 10 _B Data input CRSC 11 _B Data input CRSD |

System Control Unit (SCU)

| Field | Bits | Type | Description |
|---------------|---------------------------------|------|--|
| RXER | [15:14] | rw | RXER Input This bit field indicates the receive input position of the RXER input signal. 00 _B Data input RXERA is selected 01 _B Data input RXERB is selected 10 _B Data input RXERC is selected 11 _B Data input RXERD is selected |
| COL | [17:16] | rw | COL input This bit field indicates the receive input position of the COL clock input signal. 00 _B Data input COLA is selected 01 _B Data input COLB is selected 10 _B Data input COLC is selected 11 _B Data input COLD is selected |
| CLK_TX | [19:18] | rw | CLK_TX input This bit field indicates the receive input position of the CLK_TX input signal. 00 _B Data input CLK_TXA is selected 01 _B Data input CLK_TXB is selected 10 _B Data input CLK_TXC is selected 11 _B Data input CLK_TXD is selected |
| MDIO | [23:22] | rw | MDIO Input Select This bit field selects the input position of the MDI signal. 00 _B Data input MDIA is selected 01 _B Data input MDIB is selected 10 _B Data input MDIC is selected 11 _B Data input MDID is selected |
| INFSEL | 26 | rw | Ethernet MAC Interface Selection This bit selects Ethernet MAC interface to PHY. 0 _B MII 1 _B RMII |
| 0 | [21:20], [25:24], [31:27] | r | Reserved Read as 0; should be written with 0. |

CCUCON

CAPCOM module control register. Individual signals signal is generated with f_{CCU} clock.

System Control Unit (SCU)

CCUCON

CCU Control Register

(004C_H)

Reset Value: 0000 0000_H

| GAIN | | | | | OFFSET | | | | | | | 0 | START | PWD | |
| rw | | | | | rw | | | | | | | r | w | rw | |

System Control Unit (SCU)

| Field | Bits | Type | Description |
|----------------|-------------------|------|--|
| PWD | 0 | rw | Sensor Power Down This bit defines the DTS power state. 0 _B The DTS is powered 1 _B The DTS is not powered |
| START | 1 | w | Sensor Measurement Start This bit starts a measurement of the DTS. 0 _B No DTS measurement is started 1 _B DTS measurement is started If set this bit is automatically cleared. This bit always reads as zero. |
| OFFSET | [10:4] | rw | Offset Calibration Value This bit field interfaces the offset calibration values to the DTS. The calibration values are forwarded to the DTS by setting bit START. |
| GAIN | [16:11] | rw | Gain Calibration Value This bit field interfaces the gain calibration values to the DTS. The calibration values are forwarded to the DTS by setting bit START. |
| REFTRIM | [19:17] | rw | Reference Trim Calibration Value This bit field interfaces the reference trim calibration values to the DTS. The calibration values are forwarded to the DTS by setting bit START. |
| BGTRIM | [23:20] | rw | Bandgap Trim Calibration Value This bit field interfaces the bandgap trim calibration values to the DTS. The calibration values are forwarded to the DTS by setting bit START. |
| 0 | [3:2], [31:24] | r | Reserved Read as 0; should be written with 0. |

DTSSTAT

Die temperature status register

DTSSTAT

Die Temperature Sensor Status Register (0090_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|------------------|------|--|
| RESULT | [9:0] | rh | Result of the DTS Measurement This bit field shows the result of the DTS measurement. The value given is directly related to the die temperature. |
| RDY | 14 | rh | Sensor Ready Status This bit indicate the DTS is ready or not. 0 _B The DTS is not ready 1 _B The DTS is ready |
| BUSY | 15 | rh | Sensor Busy Status This bit indicate if the DTS is currently busy. If the sensor is busy a measurement is still running and the result should not be used. 0 _B not busy 1 _B busy |
| 0 | [13:10], [31:16] | r | Reserved |

SDMMCDEL

Delay control register for SD-MMC module.

System Control Unit (SCU)

SDMMCDEL

SDMMC Delay Control Register

(009C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|------------------|------|---|
| TAPEN | 0 | rw | Enable delay on the CMD/DAT out lines 0 _B Disabled 1 _B Enabled |
| TAPDEL | [7:4] | rw | Number of Delay Elements Select number of delay elements of (TAPDEL+1), |
| 0 | [3:1], [31:8] | r | Reserved Read as 0; should be written with 0. |

GOORCEN

Enable register for out-of-range comparators of group 0 of analog input channels.

GOORCEN

Out of Range Comparator Enable Register 0 (00A0_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|------------------|------|--|
| ENORC6 | 6 | rw | Enable Out of Range Comparator, Channel 6 Each bit (when set) enables the out of range comparator of the associated channel 0 _B Disabled 1 _B Enabled |
| ENORC7 | 7 | rw | Enable Out of Range Comparator, Channel 7 Each bit (when set) enables the out of range comparator of the associated channel 0 _B Disabled 1 _B Enabled |
| 0 | [5:0], [31:8] | r | Reserved returns 0 if read; should be written with 0; |

G1ORCEN

Enable register for out-of-range comparators of group 1 of analog input channels.

G1ORCEN

Out of Range Comparator Enable Register 1 (00A4_H) **Reset Value: 0000 0000_H**

MCHKCON

The following register enables the functional parity check mechanism for testing purpose. MCHKCON register is used to support access to parity bits of SRAM modules for various types of peripherals. The SRAM modules providing direct access natively need to be selected in order to enable direct write to parity bits using **PMTPR** register.

System Control Unit (SCU)

PETE

The following register enables the functional parity error trap generation mechanism. The trap flag gets reflected in **TRAPRAW** register and needs to be enabled with **TRAPDIS** register before can be effectively used to generate an NMI. The same tap flag can be configured with **PERSTEN** register to generate System Reset instead of an NMI.

PEFLAG

The PEFLAG register controls the functional parity check mechanism.

The register bits can only get set by corresponding parity error assertion if enabled and can only be cleared via software. Writing a zero to this bit does not change the content. Writing a one to this bit does clear the bit.

PEFLAG

TRAPSTAT

This register contains the status flags for all trap request trigger sources of the SCU. A trap flag is set when a corresponding emergency event occurs. Trap mechanism supports testing and debug of these status bits by software using registers **TRAPSET** and **TRAPCLR**. This register reflects masking with **TRAPDIS** register.

MLINKCLKCR

Multi-link register for central clock control. This register allows consistent reconfiguration of multiple clocks with a single register access and prevents invalid configurations i.e. clock division combinations are not allowed (see [Table 11-5](#) for more details). An

System Control Unit (SCU)

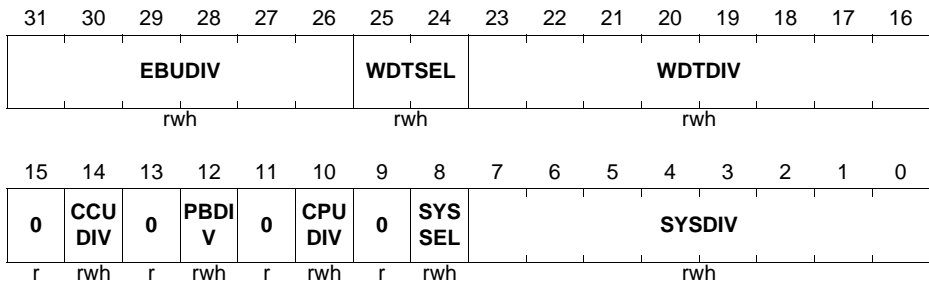

attempt to write invalid value will be rejected and result in generation of bus error response.

MLINKCLKCR

Multi-Link Clock Control

(062C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|-------|------|---|
| SYSDIV | [7:0] | rwh | System Clock Division Value The value the divider operates is (SYSDIV+1). |
| SYSSEL | 8 | rwh | System Clock Selection Value $0_B \quad f_{OFI} \text{ clock}$ $1_B \quad f_{PLL} \text{ clock}$ |
| CPUDIV | 10 | rwh | CPU Clock Divider Enable This bit enables division of f_{SYS} clock to produce f_{CPU} clock. $0_B \quad f_{CPU} = f_{SYS}$ $1_B \quad f_{CPU} = f_{SYS} / 2$ <i>Note: Some clock division combinations are not allowed. See Table 11-5 for more details. This register must ignore the write and generate error response if invalid configuration attempt detected.</i> |

System Control Unit (SCU)

| Field | Bits | Type | Description |
|---------------|--------------------|------|---|
| PBDIV | 12 | rwh | PB Clock Divider Enable This bit enables division of f_{SYS} clock to produce f_{PERIPH} clock. $0_{\text{B}} \quad f_{\text{PERIPH}} = f_{\text{CPU}}$ $1_{\text{B}} \quad f_{\text{PERIPH}} = f_{\text{CPU}} / 2$ <i>Note: Some clock division combinations are not allowed. See Table 11-5 for more details. This register must ignore the write and generate error response if invalid configuration attempt detected.</i> |
| CCUDIV | 14 | rwh | CCU Clock Divider Enable This bit enables division of f_{SYS} clock to produce f_{CCU} clock. $0_{\text{B}} \quad f_{\text{CCU}} = f_{\text{SYS}}$ $1_{\text{B}} \quad f_{\text{CCU}} = f_{\text{SYS}} / 2$ <i>Note: Some clock division combinations are not allowed. See Table 11-5 for more details. This register must ignore the write and generate error response if invalid configuration attempt detected.</i> |
| WDTDIV | [23:16] | rwh | WDT Clock Divider Value WDT is divided by WDTDIV + 1 Must only be programmed, when clock is not used |
| WDTSEL | [25:24] | rwh | WDT Clock Selection Value $00_{\text{B}} \quad f_{\text{OFI}}$ clock $01_{\text{B}} \quad f_{\text{STDBY}}$ clock $10_{\text{B}} \quad f_{\text{PLL}}$ clock $11_{\text{B}} \quad \text{Reserved}$ |
| EBUDIV | [31:26] | rwh | EBU Clock Divider Value PLL clock is divided by EBUDIV + 1 Must only be programmed, when clock is not used |
| 0 | 9, 11,13, 15 | r | Reserved Read as 0; should be written with 0. |

SLEEP_CR

Configuration register that defines some system behavior aspects while in sleep mode. The original clock configuration gets restored upon wake-up from sleep mode.

System Control Unit (SCU)

Note: Switching off a module clock during operation may result in unexpected effects like e.g. clock spikes or protocol violations. Before entering Sleep mode the affected modules should be in reset state. After restoration of the clocks the modules need to be re-initialized in order to ensure proper function.

SLEEP_CR

Sleep Control Register

(0630_H)

DSLEEPCCR

Configuration register that defines some system behavior aspects while in Deep Sleep mode. The original clock configuration gets restored upon wake-up from sleep mode. The PLL re-initialization is required after wake-up from Deep Sleep mode if was enabled before entering Deep Sleep mode and configured to go into power down while in Deep Sleep mode.

Note: Switching off a module clock during operation may result in unexpected effects like e.g. clock spikes or protocol violations. Before entering Sleep mode the affected modules should be in reset state. After re-toration of the clocks the modules need to be re-initialized in order to ensure proper function.

DSLEEPCCR

Deep Sleep Control Register

CLKMXSTAT
Clock Multiplexer Switching Status

This register shows status of clock multiplexing upon switching from one clock source to another. This register should be checked before disabling any of the multiplexer input clock sources after switching. Bits of this registers indicate which of the corresponding input clocks must not be switched off under any circumstances until indicated as inactive. The clocks sources that are indicated as active are still contributing in driving the output clock from respective multiplexer. This is a side effect of glitch-free clock switching mechanism.

Communication Peripherals

12 LED and Touch-Sense (LEDTS)

The LED and Touch-Sense (LEDTS) drives LEDs and controls touch pads used as human-machine interface (HMI) in an application.

Table 12-1 Abbreviations in chapter

| Abbreviation | Meaning |
|--------------|----------------------|
| LEDTS | LED and Touch-sense |
| TSD | time slice duration |
| TFD | time frame duration |
| TPD | time period duration |

12.1 Overview

The LEDTS can measure the capacitance of up to 8 touch pads using the relaxation oscillator (RO) topology. The pad capacitance is measured by generating oscillations on the pad for a fixed time period and counting them. The module can also drive up to 64 LEDs in an LED matrix. Touch pads and LEDs can share pins to minimize the number of pins needed for such applications. This configuration is realized by the module controlling the touch pads and driving the LEDs in a time-division multiplexed manner.

The LEDs in the LED matrix are organized into columns and lines. Every line can be shared between up to 8 LEDs and one touch pad. Certain functions such as column enabling, function selection and control are controlled by hardware. Application software is required to update the LED lines and evaluate the touch pad measurement results.

12.1.1 Features

This device contains 1 LEDTS kernel. Each kernel has an LED driving function and a touch-sensing function.

For the LED driving function, an LEDTS kernel provides these features:

- Selection of up to 8 LED columns; Up to 7 LED columns if touch-sense function is also enabled
- Configurable active time in LED columns to control LED brightness
- Possibility to drive up to 8 LEDs per column, common-anode or common-cathode
- Shadow activation of line pattern for LED column time slice; LED line patterns are updated synchronously to column activation
- Configurable interrupt enable on selected event
- Line and column pins controlled by port SFR setting

For the touch-sensing function, an LEDTS kernel provides these features:

- Up to 8 touch input lines

LED and Touch-Sense (LEDTS)

- Only one pad can be measured at any time; selection of active pad controllable by software or hardware round-robin
- Flexible measurement time on touch pads
- Pin oscillation control circuit with adjustments for oscillation
- 16-bit counter: For counting oscillations on pin.
- Configurable interrupt enable on selected event
- Pin over-rule control for active touch input line (pin)

Note: This chapter refers to the LED or touch-sense pins, e.g. 'pin COL[x]', 'pin TSIN[x]'. In all instances, it refers to the user-configured pin(s) which selects the LED/touch-sense function. Refer to [Section 12.9.5](#) for more elaboration.

Note: This chapter describes the full capability of the LEDTS. The amount of features available on the device is limited by the device pins assigned. Please refer to the [Section 12.11](#) for the pins assigned to the LEDTS.

Table 12-2 LEDTS Applications

| Use Case | Application |
|-----------------------|-------------|
| Non-mechanical switch | HMI |
| LED feedback | HMI |
| Simple PWM | PWM |

12.1.2 Block Diagram

The LEDTS block diagram is shown in [Figure 12-1](#).

LED and Touch-Sense (LEDTS)

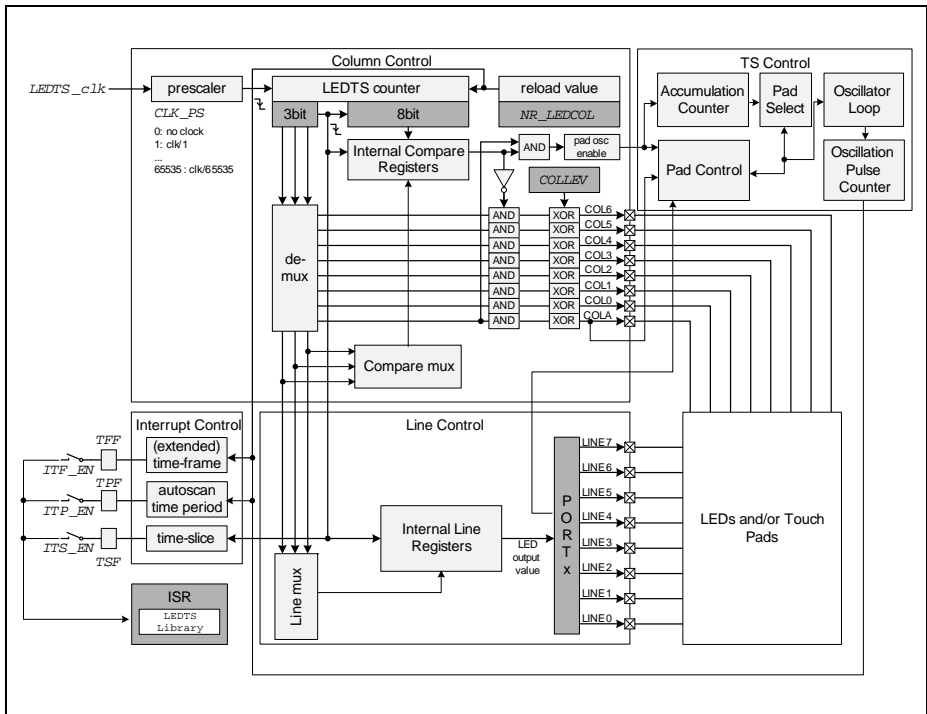

Figure 12-1 LEDTS Block Diagram

12.2 Functional Overview

The same pin can support LED & touch-sense functions in a time-multiplexed manner. LED mode or touch-sense mode can be enabled by hardware for respective function controls.

Time-division multiplexing is done by dividing the time domain into time slots. This basic time slot is called a **time slice**. In one time slice, one LED column is activated or the capacitance of one touch pad is measured.

A **time frame** is composed of 1 or more time slices, up to a maximum of eight. There is one time slice for every LED column enabled. If only LED function is enabled, a time frame can compose up to 8 LED time slices. However, if touch sense function is enabled, the last time slice in every time frame is reserved for touch-sense function. This reduces the maximum number of time slices that can be used for LED function in each time frame to 7. Only one time slice is used for touch sense function in every time frame. This is regardless of the number of touch pads enabled.

In each time slice used for LED function, only one LED column is enabled at a time. In the time slice reserved for touch-sense function, oscillations are enabled and measured on the pin which is activated. No LED column is active during this time slice. A touch pad input line (TSIN[x] pin) is active when its pad turn is enabled. If more than one touch pad input lines are enabled, the enabling and measurement on the touch pads is performed in a round robin manner. Only one touch pad is measured in every time frame.

The resolution of oscillation measurement can be increased by accumulating oscillation counts on each touch input line. When enabled by configuration of "Accumulate Count" (ACCCNT), the pad turn can be extended on consecutive time frames by up to 16 times. This also means that the same touch pad will be measured in consecutive time frames. This control will be handled by hardware. Otherwise it is also possible to enable for software control where the active pad turn is fully under user control.

The number of consecutive time frames, for which a pad turn has been extended, forms an **extended time frame**. When touch-sense function is enabled for automatic hardware pad turn control, several (extended) time frames make up one **autoscan time period** where all pad turns are completed. The time slice duration is configured centrally for the LED and/or touch-sense functions, using the LEDTS-counter. Refer to the description in [Section 12.3](#), [Section 12.9.3](#) and [Figure 12-4](#).

If enabled, a time slice interrupt is triggered on overflow of the 8LSBs of the LEDTS-counter for each new time slice started. The (extended) time frame interrupt may also be enabled. It is triggered on (the configured counts of) overflow of the whole LEDTS-counter. The autoscan time period interrupt may also be enabled. However, this interrupt will require that the hardware pad turn control is enabled. It is triggered when hardware completes the last pad turn on the highest enabled touch input line TSIN[NR_TSIN].

The column activation and pin oscillation duty cycles can be configured for each time slice. This allows the duration of activation of LED columns and/or touch-sense

LED and Touch-Sense (LEDTS)

oscillation counting to be flexible. This is also how the relative brightness of the LEDs can be controlled. In case of touch pads, the activation time is called the oscillation window.

Figure 12-2 shows an example for an LED matrix configuration with touch pads. The configuration in this example is 8 X 4 LED matrix with 4 touch input lines enabled in sequence by hardware. Here no pad turn is extended by ACCCNT, so four time frames complete an autoscan time period.

In the time slice interrupt, software can:

- set up line pattern for next time slice
- set up compare value for next time slice
- evaluate current function in time slice (especially for analysis/debugging)

Refer to **Section 12.9.1** for **Interpretation of Bit Field FNCOL** to determine the currently active time slice.

The (extended) time frame interrupt indicates one touch input line TSIN[x] has been sensed (once or number of times in consecutive frames), application-level software can, for example:

- start touch-sense processing (e.g. filtering) routines and update status
- update LED display data to SFR

In the autoscan time period interrupt which indicates all touch-sense input TSIN[x] have been scanned one round, application-level software can:

- evaluate touch detection result & action
- update LED display data to SFR

LED and Touch-Sense (LEDTS)

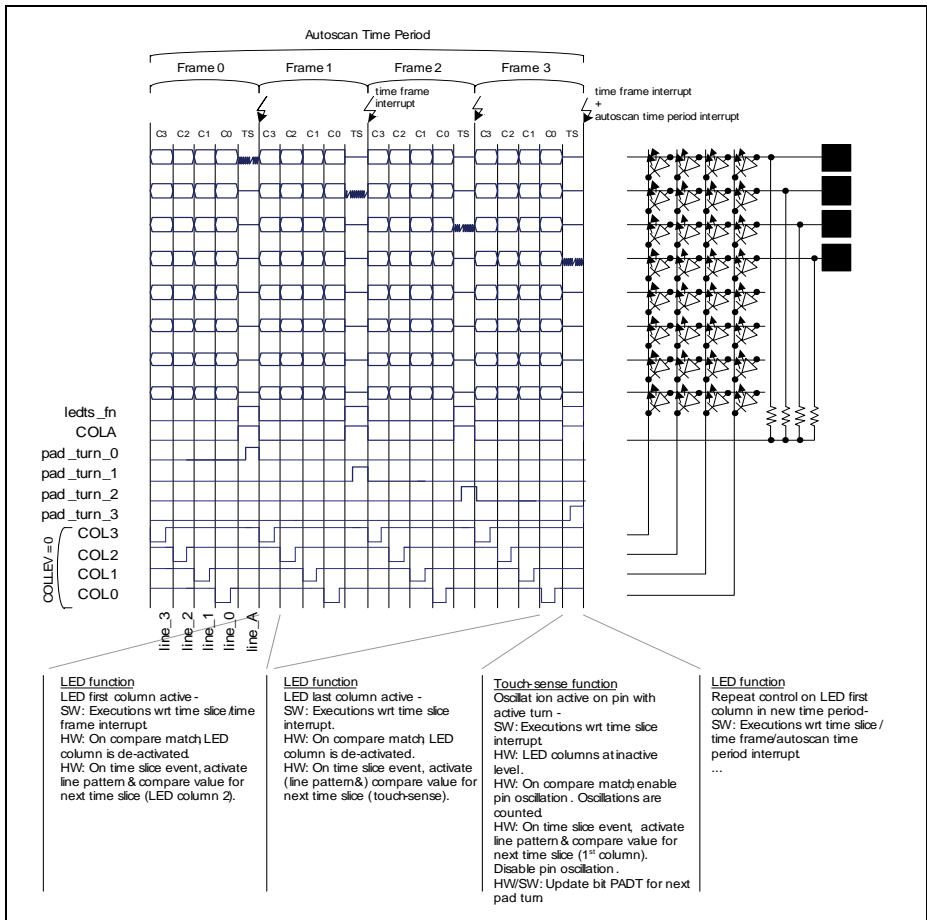

Figure 12-2 Time-Multiplexed LEDTS Functions on Pin (Example)

12.3 LED Drive Mode

LED driving is supported mainly for LED column selection and line control. At one time, only one column is active. The corresponding line level at high or low determines if the associated LED on column is lit or not. Up to eight columns are supported (if only LED function is enabled), and up to eight LEDs can be controlled per column.

With direct LED drive, adjustment of luminence for different types of LEDs with different forward voltages is supported. A compare register for LEDTS-counter is provided so that the duty cycle for column enabling per time slice can be adjusted. The LED column is enabled from the beginning of the time slice until compare match event. For 100% duty cycle for LED column enable in time slice, the compare value should be set to FF_{H-} . If the compare value is set to 00_{H-} , the LED column will stay at passive level during the time slice. The internal compare register for each time slice is updated by shadow transfer from their corresponding compare SFR. This takes place automatically at the beginning of each time slice, refer to **Figure 12-3**.

Updating of LED line pattern (LED enabling) per column (time slice) is performed via a similar shadow transfer mechanism, as illustrated in **Figure 12-3**. This shadow transfer of the corresponding line pattern to the internal line SFR takes place automatically at the beginning of each new time slice.

Note: Any write to any compare or line SFR within the time slice does not affect the internal latched configuration of current time slice.

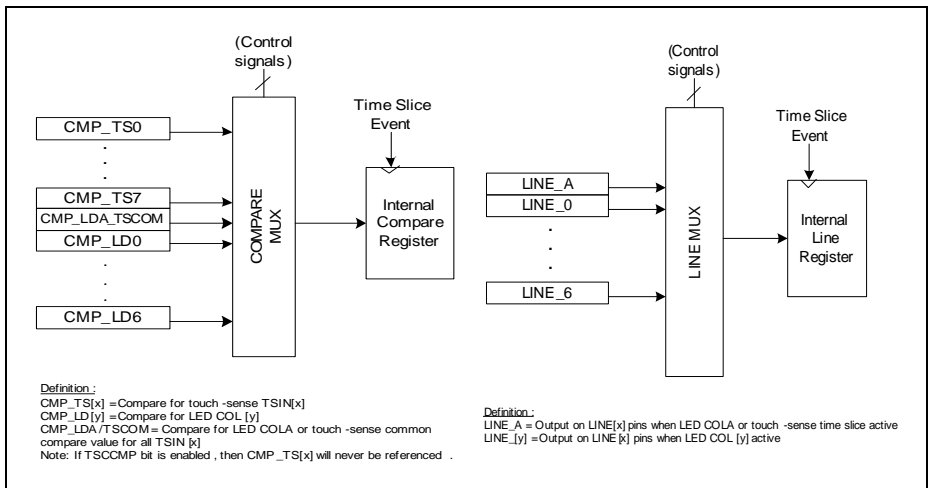

Figure 12-3 Activate Internal Compare/Line Register for New Time Slice

When the LEDTS-counter is first started (enable input clock by CLK_PS), a shadow transfer of line pattern and compare value is activated for the first time slice (column).

LED and Touch-Sense (LEDTS)

A time slice interrupt can be enabled. A new time slice starts on the overflow of the 8LSBs of the LEDTS-counter.

Figure 12-4 shows the LED function control circuit. This circuit also provides the control for enabling the pad oscillator. A 16-bit divider provides pre-scale possibilities to flexibly configure the internal LEDTS-counter count rate, which overflows in one time frame. During a time frame comprising a configurable number of time slices, the configured number of LED columns are activated in sequence. In the last time slice of the time frame, touch-sense function is activated if enabled.

The LEDTS-counter is started when bit CLK_PS is set to any value other than 0 and either the LED or touch-sense function is enabled. It does not run when both functions are disabled. To avoid over-write of function enable which disturbs the hardware control during LEDTS-counter running, the TS_EN and LD_EN bits can only be modified when bit CLK_PS = 0. It is nonetheless possible to set the bits TS_EN and LD_EN in one single write to SFR **GLOBCTL** when setting CLK_PS from 0 to 1, or from 1 to 0.

When started, the counter starts running from a reset/reload value based on enabled function(s): 1) the number of columns (bit-field NR_LEDCOL) when LED function is enabled, 2) add one time slice at end of time frame when touch-sense function is enabled. The counter always counts up and overflows from $7FF_H$ to the reload value which is the same as the reset value. Within each time frame, the sequence of LED column enabling always starts from the most-significant enabled column (column with highest numbering).

To illustrate this point, in the case of four LED columns and one touch pad input enabled, the column enabling sequence will be in as follows:

- Start with COL3,
- followed by COL2,
- followed by COL1,
- followed by COL0,
- then COLA for touch sense function.

If the touch-sense function is not enabled, COLA will be available for LED function as the last LED column time slice of a time frame. The column enabling sequence will then be as follows:

- Start with COL2,
- followed by COL1,
- followed by COL0,
- then COLA.

LED and Touch-Sense (LEDTS)

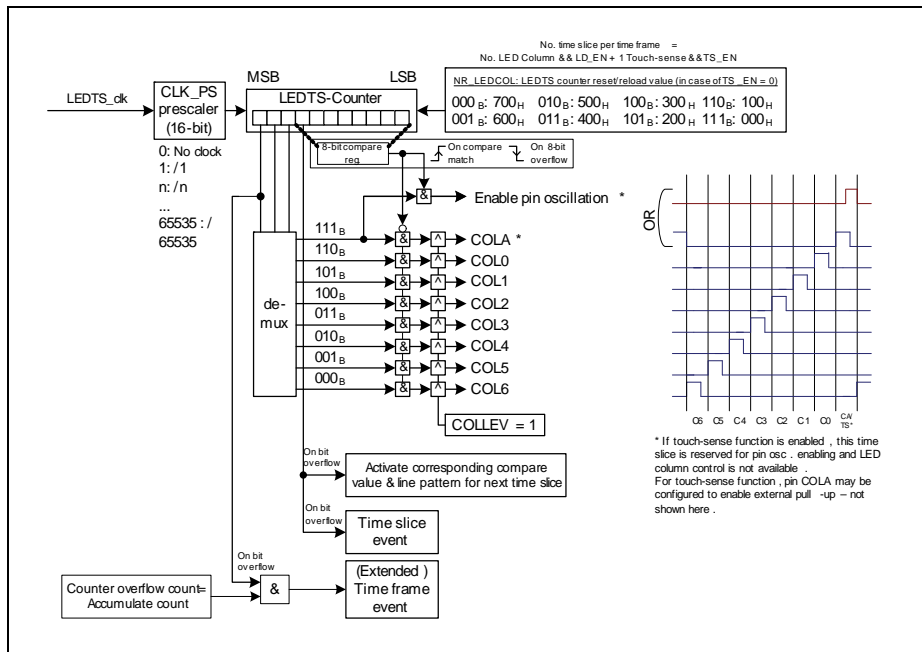

Figure 12-4 LED Function Control Circuit (also provides pad oscillator enable)

In [Section 12.9.3](#), the time slice duration and formulations for LEDTS related timings are provided.

12.3.1 LED Pin Assignment and Current Capability

One LED column pin is enabled within each configured time slice duration to control up to eight LEDs at a time. The assignment of COL[x] to pins is configurable to provide options for application pin usage. The current capability of device pins is also a consideration factor for deciding pin assignment to LED function.

The product data-sheet provides data for all I/O parameters relevant to LED drive.

12.4 Touch-Sense Mode

Figure 12-5 shows the pin oscillation control unit, which is integrated with the standard PORTS pad. The active pad turn (pad_turn_x) for a touch input line is defined as the time duration within the touch-sense time slice (COL A) where the TS-counter is counting oscillations on the TSIN[x] pin. In the case of hardware pad turn control (default), the same TS-counter is connected sequentially on enabled touch input lines to execute a round-robin touch-sensing of TSIN[x] pins.

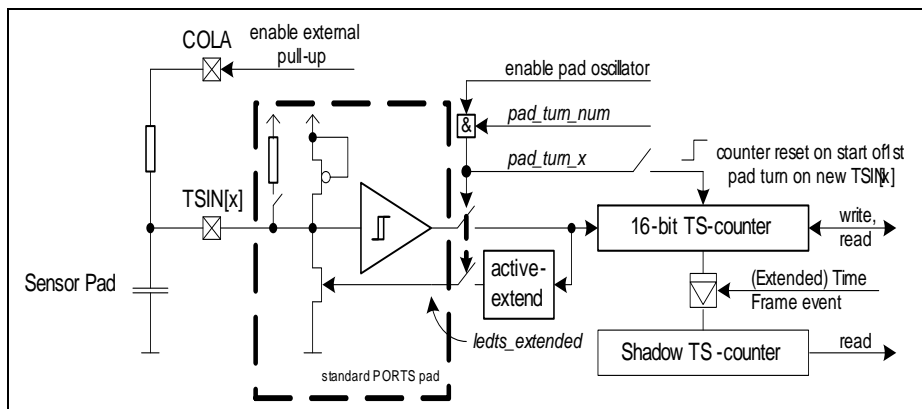

Figure 12-5 Touch-Sense Oscillator Control Circuit

In an example of four touch input lines enabled, the sequence order of touch-sense time slice (COL A) in sequential frames is as follows:

- Always starts with TSIN0,
- followed by TSIN1 in touch-sense time slice of next frame,
- followed by TSIN2 in next touch-sense time slice,
- then TSIN3, and repeat cycle.

It is possible to enable the touch-sense time slice on the same touch input line for consecutive frames (up to 16 times), to accumulate the oscillation count in TS-counter (see **Figure 12-6**). To illustrate this point, in the same case of four touch input lines enabled, and 2 accumulation counts configured, is as follows:

- Always starts with TSIN0,
- followed by TSIN0 again in touch-sense time slice of next frame,
- followed by TSIN1 in touch-sense time slice of next frame,
- followed by TSIN1 again in touch-sense time slice of next frame,
- followed by TSIN2 in touch-sense time slice of next frame,
- followed by TSIN2 again in touch-sense time slice of next frame,
- followed by TSIN3 in touch-sense time slice of next frame,
- then TSIN3 again, and repeat cycle.

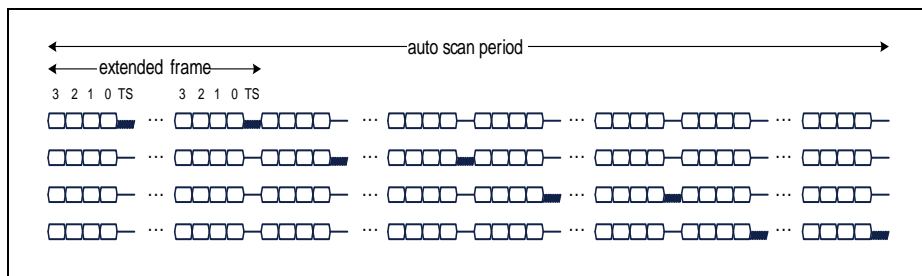

Figure 12-6 Hardware-Controlled Pad Turns for Autoscan of Four TSIN[x] with Extended Frames

There is a 16-bit TS-counter register and there is a 16-bit shadow TS-counter register. The former is both write- and read-accessible, while the latter is only read-accessible. The actual TS-counter counts the latched number of oscillations and can only be written when there is no active pad turn. The content of the TS-counter is latched to the shadow register on every (extended) time frame event. Reading from the shadow register therefore shows the latest valid oscillation count on one TSIN[x] input, ensuring for the application SW there is at least one time slice duration to get the valid oscillation count and meanwhile the actual TS-counter could continually update due to enabled pin oscillations in current time slice.

The TS-counter and shadow TS-counter have another user-enabled function on (extended) time frame event, which is to validate the counter value differences. When this function is enabled by the user and in case the counter values do not differ by 2^n LSB bits ('n' is configurable), the (extended) time frame interrupt request is gated (no interrupt) and the time frame event flag TFF is not set. This gating is on top of the time frame interrupt enable/disable control.

The TS-counter may be enabled for automatic reset (to 00_H) on the start of a new pad turn on the next TSIN[x], i.e. resets in the first touch-sense time slice of each (extended) time frame. Bit TSCTROVF indicates that the counter has overflowed. Alternatively, it can be configured such that the TS-counter stops counting in touch-sense time slice(s) of the same extended frame when the count value saturates, i.e. does not overflow & stops at FFFF_H. In this case, the TS-counter starts running again only in a new (extended) frame on the start of a new pad turn on the next TSIN[x].

A configurable pin-low-level active extension is provided for adjustment of oscillation per user system. The extension is active during the discharge phase of oscillation, and can be configured to be extended by a number of peripheral clocks. This function is very useful if there is a series resistor between the pin and the touch pad which makes the discharge slower. [Figure 12-7](#) illustrates this function.

The configuration of the active touch-sense pin TSIN[x] is over-ruled by hardware in the active duration to enable oscillations, reference [Section 12.9.5](#). In particular, the weak

LED and Touch-Sense (LEDTS)

internal pull-up enable over-rule can be optionally de-activated (correspondingly internal pull-down disable over-rule is also de-activated; PORTS pin SFR setting for pull applies instead), such as when the user system utilize external resistor for pull-up instead. In the whole duration of the touch-sense time slice, COLA is activated high. This activates a pull-up via an external resistor connected to pin COLA. This configuration provides some flexibility to adjust the pin oscillation rate for adaptation to user system.

The touch-sense function is time-multiplexed with the LED function on enabled LINE[x]/TSIN[x] pins. During the touch-sense time slice for the other TSIN pins which are not on active pad turn, the corresponding LINE[x] output remains active. It is recommended that software takes care to set the line bits to 1 to avoid current sink from pin COLA.

The touch-sense function is active in the last time slice of a time frame. Refer to [Section 12.2](#), and [Section 12.3](#) for more details on time slice allocation and configuration.

Figure 12-7 Pin-Low-Level Extension Function

LED and Touch-Sense (LEDTS)

The oscillation is enabled on the pin with valid turn for a configurable duration. A compare value provides the means to adjust the duty cycle within the time slice. The pin oscillation is enabled (TS-counter is counting) only on compare match until the end of the time slice. The time interval, in which the TS-counter is counting, is called the oscillation window. For a 100% duty cycle, the compare value has to be set to 00_H . In this case, the oscillation window fills in the entire time slice. Setting the compare value to FF_H results in no pin oscillation in time slice.

The time slice interrupt, (extended) time frame interrupt and/or autoscan time period interrupt may be enabled as required for touch-sense control.

12.4.1 Finger Sensing

When a finger is placed on the sensor pad, it increases the pin capacitance and frequency of oscillation on pin is reduced. The pin oscillation frequency without finger touch is typically expected to be in the range of 100 kHz to 5 MHz. Various factors affect the oscillation frequency including the size of touch pad, ground planes around and below the pad, the material and thickness of the overlay cover, the trace length and the individual pin itself (every pin has a different pull-up resistance).

In a real-world application, the printed circuit board (PCB) will not be touched directly. Instead, there is usually some sort of a transparent cover material, like a piece of plexiglass sheet, glued onto the PCB. In most of these applications, the oscillation frequency will change by about 2-10% when touched. This change in oscillation frequency can be considered to be very small, and therefore, further signal processing is necessary for reliable detection. Typically, this processing takes the form of a moving average calculation. It is never recommended to try to detect touches based on the raw oscillation count value.

As described in above section, some flexibility is provided to adjust the oscillation frequency in the user system: 1) Configurable pin low-level active extension, 2) Alternative enabling of external pull-up with resistance selectable by user. With a configurable time slice duration, the software can configure the duration of the active pad turn (adjustable within time slice using compare function) and set a count threshold for oscillations to detect if there is a finger touch or not.

To increase touch-sensing oscillation count accuracy, the input clock to LEDTS kernel should be set as high as possible.

12.5 Operating both LED Drive and Touch-Sense Modes

It is possible to enable both LED driving and touch-sense functions in a single time frame. If both functions are enabled, up to 7 time slices are configurable for the LED function, and the last time slice is reserved for touch-sensing function.

The touch-sense function is time-multiplexed with the LED function on enabled LINE[x]/TSIN[x] pins. During the touch-sense time slice (COLA), the corresponding LINE[s] output remains active for the other TSIN pins which are not on active pad turn. In a typical application, COLA is not used and the oscillation is generated by the internal pad structure only. The bits in LINE_A will determine whether the pads, that are not being measured in the given COLA time slice, have a floating or 0V value. This setting usually has a serious effect on the sensitivity and noise robustness of the touch pads.

Refer to [Section 12.2](#) and [Section 12.3](#) for more details on time slice allocation and configuration.

12.6 Service Request Processing

There are three interrupts triggered by LEDTS kernel, all assigned on same node: 1) time slice event, 2) (extended) time frame event, 3) autoscan time period event. The flags are set on event or when CLK_PS is set from 0 regardless of whether the corresponding interrupt is enabled or not. When enabled, the event (including setting of CLK_PS from 0) activates the SR0 interrupt request from the kernel.

[Table 12-3](#) lists the interrupt event sources from the LEDTS, and the corresponding event interrupt enable bit and flag bit.

Table 12-3 LEDTS Interrupt Events

| Event | Event Interrupt Enable Bit | Event Flag Bit |
|--|----------------------------|----------------|
| Start of Time Slice | GLOBCTL.ITS_EN | EVFR.TSF |
| Start of (Extended) Time Frame ¹⁾ | GLOBCTL.ITF_EN | EVFR.TFF |
| Start of Autoscan Time Period | GLOBCTL.ITP_EN | EVFR.TPF |

1) In case of consecutive pad turns enabled on same TSIN[x] pin by ACCCNT bit-field, interrupt is not triggered on a time frame – but on the extended time frame.

[Table 12-4](#) shows the interrupt node assignment for each LEDTS interrupt source.

Table 12-4 LEDTS Events' Interrupt Node Control

| Event | Interrupt Node Enable Bit | Interrupt Node Flag Bit | Node ID |
|--------------------------------|---------------------------|-------------------------|---------|
| Start of Time Slice | LEDTS0.SR0 | LEDTS0.SR0 | 102 |
| Start of (Extended) Time Frame | | | |
| Start of Autoscan Time Period | | | |

12.7 Debug Behavior

The LEDTS timers/counters LEDTS-counter and TS-counter can be enabled (together) for suspend operation when debug mode becomes active (indicated by HALTED signal from CPU).

In debug suspend mode, write and read access are possible. Writing to bit fields that require **GLOBCTL.CLK_PS** = 0 will still be ignored.

At the onset of debug suspend, these counters stop counting (retains the last value) for the duration of the device in debug mode. The function that was active in current time slice on the onset of debug suspend, continues to be active. When debug suspend is revoked, the kernel would resume operation according to latest SFR settings.

12.8 Power, Reset and Clock

The LEDTS kernel is clocked and accessible on the peripheral bus frequency. User should set up consistent time-slice durations for correct function by ensuring a constant frequency input clock when the kernel is in operation. It is recommended to set the input clock **ledts_clk** to highest frequency where possible, for optimal touch-sensing accuracy.

Kernel is in operation in active mode except power-down modes where touch-sensing and LED functions are not available.

12.9 Initialisation and System Dependencies

This section provides hints for enabling the LEDTS functions and using them.

12.9.1 Function Enabling

It is recommended to set up all configuration for the LEDTS in all SFRs before write **GLOBCTL** SFR to enable and start LED and/or touch-sense function(s).

*Note: SFR bits especially affecting the LEDTS-counter configuration for LED/touch-sense function can only be written when the counter is not running i.e. **CLK_PS** = 0. Refer to SFR bit description [Section 12.10](#).*

LED and Touch-Sense (LEDTS)

Enable LED Function Only

To enable LED function only: set LD_EN, clear TS_EN.

Initialization after reset:

```
GLOBCTL = 0bXXXXXXXX XXXXXXXX XXX00000 0000XX10;
//set LD_EN and start LEDTS-counter on prescaled clock
//CLK_PS != 0)
```

Re-configuration during run-time:

```
GLOBCTL &= 0x0000X00X; //stop LEDTS-counter by clearing prescaler
GLOBCTL = 0bXXXXXXXX XXXXXXXX XXX00000 0000XX10;
```

Enable Touch-Sense Function Only

To enable touch-sense function only: clear LD_EN, set TS_EN.

Initialization after reset:

```
GLOBCTL = 0bXXXXXXXX XXXXXXXX XXX00000 0000XX01;
//set TS_EN and start LEDTS-counter on prescaled clock
//(CLK_PS != 0)
```

Re-configuration during run-time:

```
GLOBCTL &= 0x0000X00X; //stop LEDTS-counter by clearing prescaler
GLOBCTL = #0bXXXXXXXX XXXXXXXX XXX00000 0000XX01;
```

Enable Both LED and Touch-Sense Function

To enable both functions: set LD_EN, set TS_EN.

Initialization after reset:

```
GLOBCTL = 0bXXXXXXXX XXXXXXXX XXX00000 0000XX11;
//set TS_EN and start LEDTS-counter on prescaled clock
//(CLK_PS != 0)
```

Re-configuration during run-time:

```
GLOBCTL &= 0x0000X00X; //stop LEDTS-counter by clearing prescaler
GLOBCTL = 0bXXXXXXXX XXXXXXXX XXX00000 0000XX11;
```

12.9.2 Interpretation of Bit Field FNCOL

The interpretation of the FNCOL bit field can be handled by software. The following example where six time slices are enabled (per time frame), with five LED columns and touch-sensing enabled, illustrates this ([Table 12-5](#)).

The FNCOL bit field provides information on the function/column active in the previous time slice. With this information, software can determine the active function/column in

LED and Touch-Sense (LEDTS)

current time slice and prepare the necessary values (to be shadow-transferred) valid for the next time slice.

Referring to the example below, when the FNCOL bit field is 111_B, it can be derived that the touch-sensing function/column was active in the previous time slice and therefore the current active column is LED COL[4]. Hence, the software can update the shadow line and compare registers for LED COL[3] so that these changes will be reflected when LED COL[3] gets activated in the next time slice.

Table 12-5 Interpretation of FNCOL Bit Field

| FNCOL | Active Function / Column in Current Time Slice | SW Prepare via “Shadow” Registers for Function / Column of Next Time Slice |
|------------------|--|--|
| 111 _H | LED COL[4] | LED COL[3] |
| 010 _H | LED COL[3] | LED COL[2] |
| 011 _H | LED COL[2] | LED COL[1] |
| 100 _H | LED COL[1] | LED COL[0] |
| 101 _H | LED COL[0] | Touch Input Line TSIN[PADT] |
| 110 _H | Touch Input Line TSIN[PADT] | LED COL[4] |

12.9.3 LEDTS Timing Calculations

LEDTS main timing or duration formulation are provided in following.

Count-Rate (CR):

$$CR = (fCLK) \div (PREscaler) \quad (12.1)$$

where fCLK = LEDTS module input clock; PREscaler = **GLOBCTL.CLK_PS**

Time slice duration (TSD):

$$TSD = 2^8 \div (CR) \quad (12.2)$$

Time frame duration (TFD):

$$TFD = (\text{Number of time slices}) \times TSD \quad (12.3)$$

Extended TFD:

$$\text{ExtendedTFD} = \text{ACCCNT} \times TFD \quad (12.4)$$

where ACCCNT = **FNCTL.ACCCNT**

Autoscan time period duration (TPD):

$$TPD = (\text{Number of touch-sense inputs TSIN[x]}) \times TFD \quad (12.5)$$

LED and Touch-Sense (LEDTS)

LED drive active duration:

$$\text{LED Drive Active Duration} = \text{TSD} \times \text{Compare_VALUE} \div 2^8 \quad (12.6)$$

Touch-sense drive active duration:

$$\text{Touch-sense Drive Active Duration} = \text{TSD} \times (2^8 - \text{Compare_VALUE}) \div 2^8 \quad (12.7)$$

12.9.4 Time-Multiplexed LED and Touch-Sense Functions on Pin

Some hints are provided regarding the time-multiplexed usage of a pin for LED and touch-sense function:

- The maximum number of LED columns = 7 when touch-sense function is also enabled.
- If enabled by pin, COLA outputs HIGH to enable external R (resistor) as pull-up for touch-sense function.
- During touch-sense time slice, it is recommended to set LED lines to output LOW.
- During LED time slice, COLA outputs LOW and will sink current if connected lines output HIGH.
- The effective capacitance for each TSIN[x] depends largely on what is connected to the pin and the application board layout. All touch-pads for the application should be calibrated for robust touch-detection.

12.9.5 LEDTS Pin Control

The user may flexibly assign pins as provided by PORTS SFRs, for the LEDTS functions:

- COL[x] (for LED column control)
- LINE[x] (for LED line control)
- TSIN[x] (for touch-sensing)

Refer also to [Section 12.3](#) for more considerations with regards to which COL[x] and/or LINE[x]/TSIN[x] will be active based on user configuration.

User code must configure the assigned LED pin PORTS SFR alternate output selection for the LED function, see [Table 12-6](#) and [Figure 12-8](#).

For the touch-sense function, it is also required to configure the PORTS SFRs to enable the hardware function on TSIN[x] pin (similarly alternate output COLA). However, the LEDTS will provide some pin over-rule controls to the assigned touch-sense pin with active pad turn, see [Table 12-6](#) and [Figure 12-8](#).

LED and Touch-Sense (LEDTS)
Table 12-6 LEDTS Pin Control Signals

| Function | ld/ts_en | ledts_fn | Pin | Control of Assigned Pin |
|-------------|-----------|-----------------|--|---|
| LED column | LD_EN = 1 | 0 = LED | Enable COL[x]; Passive level on COL[the rest]. If TS_EN = 1, COLA = 0. | PORTS SFR setting |
| LED line | LD_EN = 1 | 0 = LED | LINE[x] = internal line register value latched from bit field LINE_[x] | PORTS SFR setting |
| Touch-sense | TS_EN = 1 | 1 = Touch-sense | Enable TSIN[x] for oscillation. All other TSIN pins output line value. Passive level on COL[the rest] except COLA = 1. | Hardware over-rule on pad_turn_x ¹⁾ for active duration: - Enable pull-up, disable pull-down (pull over-rule can be disabled by bit EPULL) - Set to output mode (both input, output stages enabled) - Enable open-drain |

1) For the other pad inputs not on turn, there is no HW over-rule which means the PORTS SFR setting is active.

LED and Touch-Sense (LEDTS)

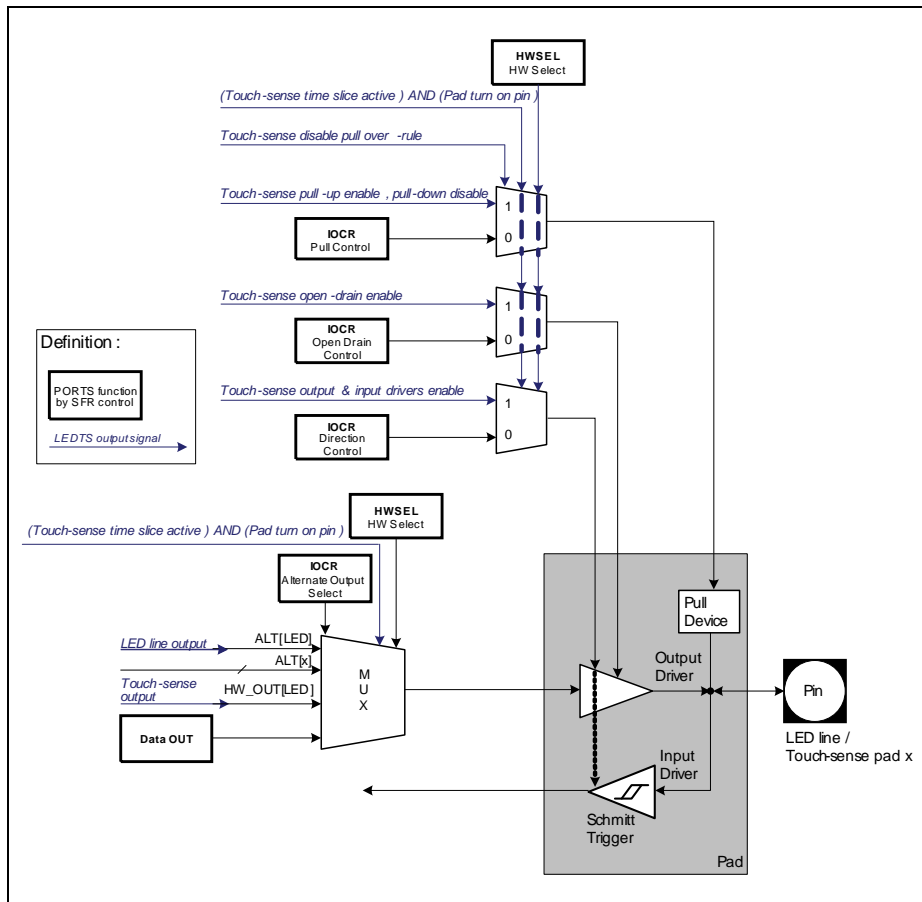

Figure 12-8 Over-rule Control on Pin for Touch-Sense Function

12.9.6 Software Hints

This section provides some useful software hints:

- Compare value 00_H enables oscillation for the full duration of the time slice, whereas FF_H disables oscillation.
- In order to maximize the resolution of the oscillation window, compare value should be selected to maximize the oscillation count without overflowing the TS-counter.
- Valid pad detection period (the time required to detect a valid touch on a pad) can be extended by:

LED and Touch-Sense (LEDTS)

- enabling dummy LED columns (without assigning/setting the LED column pins)
- selecting bigger pre-scale factor (**GLOBCTL.CLK_PS**)
- accumulating the number of pad oscillations (**FNCTL.ACCCNT**)
- Valid pad detection period can be reduced by:
 - selecting smaller pre-scale factor (**GLOBCTL.CLK_PS**)
 - reducing the number of accumulations for pad oscillations (**FNCTL.ACCCNT**)

12.9.7 Hardware Design Hints

This section provides some hardware design hints:

- Touch button oscillation frequency changes when the value of the external pull-up resistor (connected to COLA pin) changes. This results in different sensitivity of the touch button as well as the crosstalk between the adjacent touch buttons.
 - A suitable pull-up resistor should be selected to balance the sensitivity of the touch button and the accuracy of the detection.
- The presence of LEDs modifies the equivalent capacitance for a touch pad. A larger number of LEDs connected to a touch pad will increase the self-capacitance of the pad. This makes the pad less sensitive.
- If possible, LEDs should be located near to the touch pads, to reduce the additional parasitic capacitance introduced by the traces.

12.10 Registers

Registers Overview

The absolute register address is calculated by adding:

Module Base Address + Offset Address

Table 12-7 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| LEDTS0 | 4801 0000 _H | 4801 00FF _H | |

The prefix "**LEDTSx_**" is added to the register names in this table to indicate they belong to the LEDTS kernel.

Note: Register bits marked "w" always deliver 0 when read.

Access rights within the address range of an LEDTS kernel:

- Read or write access to defined register addresses: U, PV
- Accesses to empty addresses: nBE

Table 12-8 Register Overview of LEDTS

| Short Name | Description | Offset Addr. | Access Mode | | Description See |
|------------|--------------------------------|-------------------|-------------|-------|----------------------------|
| | | | Read | Write | |
| ID | Module Identification Register | 0000 _H | U, PV | U, PV | Page 12-23 |

12.10.1 Registers Description

The LEDTS SFRs are organized into registers for global initialization control, functional control comprising TS-counter value, line pattern and compare value registers.

LEDTSx_ID

The module identification register indicate the function and the design step of the peripheral.

ID

Module Identification Register (00_H) **Reset Value: 00AB C0XX_H**

| Field | Bits | Type | Description |
|----------|--------|------|--|
| MOD_REV | [7:0] | r | Module Revision Number MOD_REV defines the revision number. The value of a module revision starts with a 00 _H (first revision). |
| MOD_TYPE | [15:8] | r | Module Type This bit field is C0 _H . It defines the module as a 32-bit module. |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|-------------------|---------|------|--|
| MOD_NUMBER | [31:16] | r | Module Number Value This bit field defines the module identification number. |

GLOBCTL

The GLOBCTL register is used to initialize the LEDTS global controls.

GLOBCTL

Global Control Register (04_H) **Reset Value: 0000 0000_H**

| | | | | | | | | | | | | | | | |
|---------------|---------------|---------------|----------------|----------------|----|----|----------------|----------|----|----|----|----------------|--------------|--------------|--------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| CLK_PS | | | | | | | | | | | | | | | |
| rw | | | | | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| ITP_EN | ITF_EN | ITS_EN | FEN_VAL | MASKVAL | | | SUS_CFG | 0 | | | | ENS_YNC | CMT_R | LD_EN | TS_EN |
| rw | rw | rw | rw | rw | | | rw | r | | | | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|----------------------------|------|------|--|
| TS_EN⁽¹⁾ | 0 | rw | Touch-Sense Function Enable Set to enable the kernel for touch-sense function control when CLK_PS is set from 0. |
| LD_EN⁽¹⁾ | 1 | rw | LED Function Enable Set to enable the kernel for LED function control when CLK_PS is set from 0. |
| CMTR⁽¹⁾ | 2 | rw | Clock Master Disable 0 _B Kernel generates its own clock for LEDTS-counter based on SFR setting 1 _B LEDTS-counter takes its clock from another master kernel If this bit is set, the bit field GLOBCTL.CLK_PS needs to be set to a non-zero value to activate the kernel, even though it is taking its clock from the master kernel. |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|----------------------------|--------|------|--|
| ENSYNC¹⁾ | 3 | rw | Enable Autoscan Time Period Synchronization 0 _B No synchronization 1 _B Synchronization enabled on Kernel0 autoscan time period |
| SUSCFG | 8 | rw | Suspend Request Configuration 0 _B Ignore suspend request 1 _B Enable suspend according to request This bit is restored to default with Debug Reset. |
| MASKVAL | [11:9] | rw | Mask Number of LSB Bits for Event Validation This defines the number of LSB bits to mask for TS-counter and shadow TS-counter comparison when Time Frame validation is enabled. 0 _D Mask LSB bit 1 _D Mask 2 LSB bits ... 7 _D Mask 8 LSB bits |
| FENVAL | 12 | rw | Enable (Extended) Time Frame Validation When enabled, TS-counter and shadow TS-counter values are compared to validate a Time Frame event for set flag and interrupt request. When validation fail, TFF flag does not get set and interrupt is not requested. 0 _B Disable 1 _B Enable |
| ITS_EN | 13 | rw | Enable Time Slice Interrupt 0 _B Disable 1 _B Enable |
| ITF_EN | 14 | rw | Enable (Extended) Time Frame Interrupt 0 _B Disable 1 _B Enable |
| ITP_EN | 15 | rw | Enable Autoscan Time Period Interrupt 0 _B Disable 1 _B Enable (valid only for case of hardware-enabled pad turn control) |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| CLK_PS | [31:16] | rw | LEDTS-Counter Clock Pre-Scale Factor The constant clock input is prescaled according to setting. 0 _D No clock 1 _D Divide by 1 ... 65535 _D Divide by 65535 This bit can only be set to any other value (from 0) provided at least one of touch-sense or LED function is enabled. The LEDTS-counter starts running on the input clock from reset/reload value based on enabled function(s) (and NR_LEDCOL). Refer Section 12.3 for details. When this bit is clear to 0 from other value, the LEDTS-counter stops running and resets. |
| 0 | [7:4] | r | Reserved Read as 0; should be written with 0. |

1) This bit can only be modified when bit CLK_PS = 0.

FNCTL

The FNCTL control register provides control bits for the LED and Touch Sense functions.

FNCTL
Function Control Register
(08_H)
Reset Value: 0000 0000_H

| | | | | | | | | | | | | | | | |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|----------------------------|-------|------|---|
| PADT | [2:0] | rwh | Touch-Sense TSIN Pad Turn This is the TSIN[x] pin that is next or currently active in pad turn. When PADTSW = 0, the value is updated by hardware at the end of touch-sense time slice. Software write is always possible. However, PADT must not be written during an active pad turn. 0 _D TSIN0 ... 7 _D TSIN7 |
| PADTSW¹⁾ | 3 | rw | Software Control for Touch-Sense Pad Turn 0 _B The hardware automatically enables the touch-sense inputs in sequence round-robin, starting from TSIN0. 1 _B Disable hardware control for software control only. The touch-sense input is configured in bit PADT. |
| EPULL | 4 | rw | Enable External Pull-up Configuration on Pin COLA When set, the internal pull-up over-rule on active touch-sense input pin is disabled. 0 _B HW over-rule to enable internal pull-up is active on TSIN[x] for set duration in touch-sense time slice. With this setting, it is not specified to assign the COLA to any pin. 1 _B Enable external pull-up: Output 1 on pin COLA for whole duration of touch-sense time slice. <i>Note: Independent of this setting, COLA always outputs 1 for whole duration of touch-sense time slice.</i> |
| FNCOL | [7:5] | rh | Previous Active Function/LED Column Status Shows the active function / LED column in the previous time slice. Updated on start of new time-slice when LEDTS-counter 8LSB over-flows. Controlled by latched value of the internal DE-MUX, see Figure 12-4 . |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|-----------------------------|---------|------|---|
| ACCCNT¹⁾ | [19:16] | rw | Accumulate Count on Touch-Sense Input Defines the number of times a touch-sense input/pin is enabled in touch-sense time slice of consecutive frames. This provides to accumulate oscillation count on the TSIN[x]. 0 _D 1 time 1 _D 2 times ... 15 _D 16 times |
| TSCCMP | 20 | rw | Common Compare Enable for Touch-Sense 0 _B Disable common compare for touch-sense 1 _B Enable common compare for touch-sense |
| TSOEXT | [22:21] | rw | Extension for Touch-Sense Output for Pin-Low-Level 00 _B Extend by 1 ledts_clk 01 _B Extend by 4 ledts_clk 10 _B Extend by 8 ledts_clk 11 _B Extend by 16 ledts_clk |
| TSCTRR | 23 | rw | TS-Counter Auto Reset 0 _B Disable TS-counter automatic reset 1 _B Enable TS-counter automatic reset to 00H on the first pad turn of a new TSIN[x]. Triggered on compare match in time slice. |
| TSCTRSAT | 24 | rw | Saturation of TS-Counter 0 _B Disable 1 _B Enable. TS-counter stops counting in the touch-sense time slice(s) of the same (extended) frame when it reaches FFH. Counter starts to count again on the first pad turn of a new TSIN[x], triggered on compare match. |
| NR_TSIN¹⁾ | [27:25] | rw | Number of Touch-Sense Input Defines the number of touch-sense inputs TSIN[x]. Used for the hardware control of pad turn enabling. 0 _D 1 ... 7 _D 8 |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|-------------------------------|---------|------|---|
| COLLEV | 28 | rw | Active Level of LED Column 0_B Active low 1_B Active high |
| NR_LEDCOL¹⁾ | [31:29] | rw | Number of LED Columns Defines the number of LED columns. 000_B 1 LED column 001_B 2 LED columns 010_B 3 LED columns 011_B 4 LED columns 100_B 5 LED columns 101_B 6 LED columns 110_B 7 LED columns 111_B 8 LED columns (if bit TS_EN = 1, a maximum number of 7 LED columns is allowed. Combination of TS_EN = 1 and NR_LEDCOL = 111_B is disallowed) <i>Note: LED column is enabled in sequence starting from highest column number. If touch-sense function is not enabled, COLA is activated in last time slice.</i> |
| 0 | [15:8] | r | Reserved Read as 0; should be written with 0. |

1) This bit can only be modified when bit CLK_PS = 0.

EVFR

The EVFR register contains the status flags for events and control bits for requesting clearance of event flags.

LED and Touch-Sense (LEDTS)

| 0 | [31:19], [15:4] | r | Reserved Read as 0; should be written with 0. |

TSVAL

The TSVAL register holds the current and shadow touch sense counter values.

TSVAL

Touch-sense TS-Counter Value (10_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| TSCTRVALR | [15:0] | rh | Shadow TS-Counter Value (Read) This is the latched value of the TS-counter (on every extended time frame event). It shows the latest valid oscillation count from the last completed time slice. |

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|-----------------|---------|------|--|
| TSCTRVAL | [31:16] | rwh | TS-Counter Value This is the actual TS-counter value. It can only be written when no pad turn is active. The counter may be enabled for automatic reset once per (extended) frame on the start of a new pad turn on the next TSIN[x] pin. |

LINE_x (x = 0-1)

The LINE_x registers hold the values that are output to the respective line pins during their active column period.

LINE0

Line Pattern Register 0 (14_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---|--|------|---|
| LINE_0, LINE_1, LINE_2, LINE_3 | [7:0], [15:8], [23:16], [31:24] | rw | Output on LINE[x] This value is output on LINE[x] to pin when LED COL[x] is active. |

LED and Touch-Sense (LEDTS)
LINE1
Line Pattern Register 1
(18_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---|------------------------------|------|---|
| LINE_4, LINE_5, LINE_6 | [7:0], [15:8], [23:16] | rw | Output on LINE[x] This value is output on LINE[x] to pin when LED COL[x] is active. |
| LINE_A | [31:24] | rw | Output on LINE[x] This value is output on LINE[x] to pin when LED COLA or touch-sense time slice is active. |

LDCMPx (x = 0-1)

The LDCMPx registers hold the COMPARE values for their respective LED columns. These values are used for LED brightness control.

LDCMP0
LED Compare Register 0
(1C_H)
Reset Value: 0000 0000_H

LED and Touch-Sense (LEDTS)

| Field | Bits | Type | Description |
|---|--|------|-------------------------------------|
| CMP_LD0, CMP_LD1, CMP_LD2, CMP_LD3 | [7:0], [15:8], [23:16], [31:24] | rw | Compare Value for LED COL[x] |

LDCMP1
LED Compare Register 1
(20_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--|------------------------------|------|---|
| CMP_LD4, CMP_LD5, CMP_LD6 | [7:0], [15:8], [23:16] | rw | Compare Value for LED COL[x] |
| CMP_LDA_TS COM | [31:24] | rw | Compare Value for LED COLA / Common Compare Value for Touch-sense Pad Turns LED function The compare value for LED COLA is only valid when touch-sense function is not enabled. Touch-sense function The common compare value for touch-sense pad turns is enabled by set TSCCMP bit. When enabled for common compare, settings in SFRs LEDTS_TSCMP0,1 are not referenced. |

TSCMPx (x = 0-1)

The TSCMPx registers hold the COMPARE values for their respective touch pad input lines. These values determine the size of the pad oscillation window for each pad input lines during their pad turn.

LED and Touch-Sense (LEDTS)

TSCMP0

Touch-sense Compare Register 0 (24_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---|--|------|--|
| CMP_TS0, CMP_TS1, CMP_TS2, CMP_TS3 | [7:0], [15:8], [23:16], [31:24] | rw | Compare Value for Touch-Sense TSIN[x] |

TSCMP1

Touch-sense Compare Register 1 (28_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---|--|------|--|
| CMP_TS4, CMP_TS5, CMP_TS6, CMP_TS7 | [7:0], [15:8], [23:16], [31:24] | rw | Compare Value for Touch-Sense TSIN[x] |

LED and Touch-Sense (LEDTS)
12.11 Interconnects

The LEDTS has interconnection to other peripherals enabling higher level of automation without requiring software. [Table 12-9](#) provides a list of the pin connections.

LEDTSx.FN is an output signal denoting LEDTS active function. This signal can be used as a source for VADC request gating and background gating. LEDTSx.SR0 is an output signal denoting LEDTS kernel service request. This signal can be used as an interrupt trigger .

Table 12-9 Pin Connection

| Input/Output | I/O | Connected To | Description |
|-----------------------------|-----|---------------------|---------------------------|

13 SD/MMC Interface (SDMMC)

This chapter describes the SD/MMC module. The XMC4[78]00 uses the following SD and MMC card standard specification. For more detailed information on how to operate the SDMMC interface, please refer to the SD and MMC specification referenced below.

13.1 Overview

The **Secure Digital/ MultiMediaCard** interface (SDMMC) of the XMC4[78]00 provides an interface between SD/SDIO/MMC cards and the AHB bus. The CPU is programmed to support SD, SDIO, SDHC and MMC cards, and can operate up to 48 MHz. The SDMMC module is able to transfer a maximum of 24 MB/sec for SD cards and 48 MB/sec for MMC cards.

13.1.1 Features

The SDMMC Host Controller handles SDIO/SD protocol at transmission level, packing data, adding cyclic redundancy check (CRC), start/end bit, and checking for transaction format correctness. Some useful applications of the SDMMC includes memory extension, data logging, and firmware update.

The SDMMC is compliant with the following specifications:

- SD Card Host Controller Version 2.0
- SD Physical Layer Specification Version 2.0
- SDIO Card Specification Version 2.0
- SD Memory Card Security Specification Version 1.01
- MMC Specification version 3.31, 4.2 and 4.4
- Fully compatible with earlier versions of MMC

The following functionalities are supported by the SDMMC module:

SD/MMC Interface (SDMMC)

- **System Interface**
 - Data transfer using Programmed IO mode on AHB Slave interface
- **SD/SDIO/MMC Card Interface**
 - Transfers data in 1 bit and 4 bit SD modes
 - Cyclic Redundancy Check CRC7 for command and CRC16 for data integrity
 - Variable-length data transfers for SD/SDIO cards
 - Designed to work with SD I/O cards, Read-only cards and Read/Write cards
 - Supports Read wait Control, and Suspend/Resume operation for SD/SDIO cards
 - Supports MMC Plus and MMC Mobile
 - MMC Card detection for insertion/removal
 - Error Correction Codes (ECC) for eMMC 4.4 cards
 - Password protection for MMC cards
 - Two 512 byte buffer for data transfers between core and cards
 - Handles FIFO overrun and underrun conditions

Table 13-1 SDMMC Applications

| Use Case SDMMC | Application |
|------------------------------------|--------------------|
| Memory Extension | All |
| Data Logging | All |
| Firmware Update | All |
| Data Transfer (PC and Application) | All |

13.1.2 Block Diagram

The SDMMC block diagram is shown in [Figure 13-1](#).

SD/MMC Interface (SDMMC)

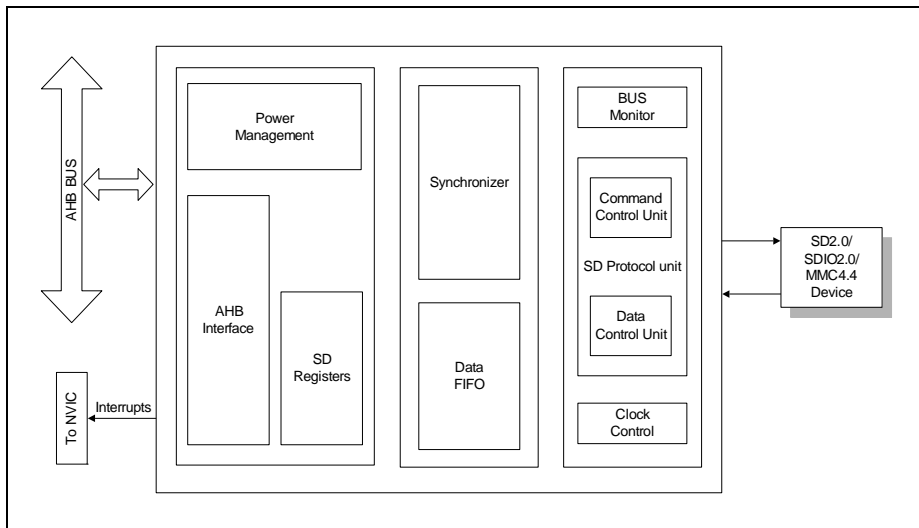

Figure 13-1 SDMMC Block Diagram

13.2 Functional Description

This section describes the functional blocks of the SDMMC.

AHB Interface

Host AHB interface acts as a bridge between AHB and the host controller. The SDMMC host controller provides Programmed IO method in which the ARM Host Driver transfers data using the Buffer Data Port Register **SDMMC_DATA_BUFFER**. The AHB target is having the Host control register **SDMMC_HOST_CTRL** and these registers are programmed by the CPU through the AHB target interface. The data transaction is performed through the AHB target interface in case of Programmed IO method of data transfer.

Interrupt controller

The SDMMC host controller generates interrupt to the Nested Vectored Interrupt Controller (NVIC) if any of the interrupt bits are set in the interrupt status register **SDMMC_INT_STATUS_NORM**.

DATA FIFO

The SDMMC host controller uses two 512 bytes dual port fifo for performing both read and write transactions. During a write transaction (data transferred from CPU to SD/SDIO/MMC card), the data will be filled in to the first and second fifo alternatively. When data from first fifo is transferring to the SD/SDIO/MMC card, the second fifo will be filled and vice versa. The two fifo's are alternatively used to store data which will give maximum throughput. During a read transaction (data transferred from SD/SDIO/MMC card to CPU), the data from SD/SDIO/MMC card will be written in to the two fifo's alternatively. When data from one fifo is transferring to the CPU, the second fifo will be filled and vice versa and thereby the throughput will be maximum. If the host controller cannot accept any data from SD/SDIO/MMC card, it will issue read wait (if card supports read wait mechanism) to stop the data coming from card or through stopping clock.

DAT[0-7] Control Logic

The DAT[0-7] control logic block transmits data in the data lines during write transaction and receives data in the data lines during read transaction.

BUS Monitor

Bus monitor will check for any violations occurring in the SD bus and time-out conditions.

Command Control Logic

The Command control logic block sends the command in the cmd line and receives the response coming from the SD/SDIO/MMC card.

Power Control

The SDMMC host controller controls the SD Bus Power depending on the value programmed in the Power Control Register **SDMMC_POWER_CTRL** by the CPU. The system has the responsibility to supply SD Bus Voltage according to card OCR and supply voltage capabilities depending on the host controller. If SD Bus power **SDMMC_POWER_CTRL.SD_BUS_POWER** = 1, the system shall supply voltage to the Card. If an unsupported voltage is selected in the SD Bus Voltage Select **SDMMC_POWER_CTRL.SD_BUS_VOLTAGE_SEL** field, the system may ignore write to SD Bus Power and keep its value at 0.

Clock Control

The Clock generation block will generate the SD clock depending on the value programmed by the CPU in the Clock Control Register **SDMMC_CLOCK_CTRL**.

Stream write and read transaction

SDMMC host controller will switch to second fifo after writing/reading a block of data to the first fifo, but in stream transaction, block size will not be programmed by the driver.

For both stream write and read transaction, it is recommended to write the maximum fifo size value to Block Size Register **SDMMC_BLOCK_SIZE**. For example if fifo size is 512 bytes, host driver needs to write 512 bytes to the **SDMMC_BLOCK_SIZE**. Fifo switching will occur after writing/ reading 512 bytes of data (fifo size).

13.3 Card Detection

When card insertion or removal in the slot is detected, the status will be sent to the CPU via interrupt methodology. The active low card signal `SDCD_n` is set to 0 during card detection. The `SDMMC_PRESENT_STATE.CARD_INSERTED` bit indicates whether a card has been inserted. A change from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register `SDMMC_INT_STATUS_NORM.CARD_INS = 1`, and a change from 1 to 0 generates a Card Removal Interrupt in the Normal Interrupt Status register `SDMMC_INT_STATUS_NORM.CARD_REMOVAL = 1`.

Note: LED light indicates that card is being accessed. Do not remove card when LED light is ON.

13.4 Data Transfer Modes

SDMMC transfers are classified into following three modes, according to how the number of blocks is specified:

Single Block Transfer

Single block transfer mode can be selected by setting `SDMMC_TRANSFER_MODE.MULTI_BLOCK_SELECT = 0`. The number of blocks is specified to the host controller before the transfer via Block Count Register, and it is always set to 1. `SDMMC_BLOCK_COUNT.BLOCK_COUNT = 0001H`.

Multiple Block Transfer

Multiple block transfer mode can be selected by setting `SDMMC_TRANSFER_MODE.MULTI_BLOCK_SELECT = 1`. The number of blocks is specified to the host controller before the transfer via Block Count Register `SDMMC_BLOCK_COUNT.BLOCK_COUNT`, and it can be set to 1 or more.

Infinite Block Transfer

The number of blocks is not specified to the host controller before the transfer. This transfer is continued until an abort transaction is executed. Refer to [Section 13.5.3](#) for details on Abort Transaction.

13.5 Read/ Write Operation

The controller will be configured to work with buffer data port registers **SDMMC_DATA_BUFFER** without internal DMA. The CPU will act as a master and start writing / reading data via **SDMMC_DATA_BUFFER**.

13.5.1 Write Operation

On receiving the Buffer Write Ready interrupt the CPU will act as a master and start transferring the data via Buffer data port register **SDMMC_DATA_BUFFER** (fifo_1). Transmitter starts sending the data in SD bus when a block of data is ready in fifo_1. While transmitting the data in sd bus, the buffer write ready interrupt is sent to the interrupt controller for the second block of data. The CPU will act as a master and start sending the second block of data via **SDMMC_DATA_BUFFER** to fifo_2. Buffer write ready interrupt will be asserted only when a fifo is empty to receive a block of data.

During write transaction the host controller will transmit data to card only when a block of data is ready to transmit and also the card is not driving busy. So underrun condition will not occur in SD side. The controller will assert buffer write ready interrupt **SDMMC_INT_STATUS_NORM.BUFF_WRITE_READY** = 1 only if space is available to accept a block of data.

13.5.2 Read Operation

Buffer Read Ready interrupt is asserted whenever a block of data is ready in one of the fifo's. On receiving the Buffer Read Ready interrupt, the CPU will act as a master and start reading the data via Buffer data port register **SDMMC_DATA_BUFFER** (fifo_1). Receiver start reading the data from SD bus only when a fifo is empty to receive a block of data. When both the fifo's are full the host controller will stop the data coming from the card through read wait mechanism (if card supports read wait) or through clock stopping. During read transaction when fifo is full, that is, no space to accept one block of data from card, the host controller will stop the clock to card so overrun condition will not occur in SD side. The controller will assert buffer read ready interrupt **SDMMC_INT_STATUS_NORM.BUFF_READ_READY** = 1 only on reception of block of data from card.

13.5.3 Abort Transaction

There are two cases where the host driver needs to perform an Abort Transaction:

1. When the host driver stops infinite block transfers.
2. When host driver stops transfers while a multiple block transfer is exacting.

There are two ways to issue an Abort command; Asynchronous Abort and Synchronous Abort.

Asynchronous Abort

In an Asynchronous Abort sequence, the host driver can issue an Abort Command at anytime unless Command Inhibit (CMD) in the Present State Register is set to 1. **SDMMC_PRESENT_STATE.COMMAND_INHIBIT_CMD** = 1.

Synchronous Abort

In a Synchronous Abort, the host driver shall issue an Abort command after the data transfer stopped by using Stop At Block Gap Request in the Block Gap Control register. **SDMMC_BLOCK_GAP_CTRL.STOP_AT_BLOCK_GAP** = 1.

13.6 Special Command Types

There are three types of special commands. Suspend, Resume and Abort. These bits shall be set to 00_B for all other commands.

Suspend Command

Suspend command can be selected by setting **SDMMC_COMMAND.CMD_TYPE** = 01_B.

If the Suspend command succeeds, the host controller shall assume the SD Bus has been released and that it is possible to issue the next command which uses the DAT line. The controller shall de-assert Read Wait for read transactions and stop checking busy for write transactions. The Interrupt cycle shall start, in 4-bit mode. If the Suspend command fails, the controller shall maintain its current state, and the host driver shall restart the transfer by setting Continue Request in the Block Gap Control Register **SDMMC_BLOCK_GAP_CTRL.CONTINUE_REQ** = 1 to restart the transfer.

*Note: Suspend / Resume cannot be supported if Read Wait Control is disabled. Set **SDMMC_BLOCK_GAP_CTRL.READ_WAIT_CTRL** = 1 to enable Read Wait Control if the SD/SDIO card supports read wait function.*

Resume Command

Resume command can be selected by setting **SDMMC_COMMAND.CMD_TYPE** = 10_B.

The host driver re-starts the data transfer by restoring the registers in the range of 000_H - 00D_H. The host controller shall check for busy before starting write transfers.

*Note: Suspend / Resume cannot be supported if Read Wait Control is disabled. Set **SDMMC_BLOCK_GAP_CTRL.READ_WAIT_CTRL** = 1 to enable Read Wait Control if the SD/SDIO card supports the read wait function.*

Abort Command

Abort command can be selected by setting **SDMMC_COMMAND.CMD_TYPE** = 11_B.

If this command is set when executing a read transfer, the host controller shall stop reads to the buffer. If this command is set when executing a write transfer, the host controller shall stop driving the DAT line. After issuing the Abort command, the controller should issue a software reset

13.7 Error Detection

This section describes data errors or defects detection methods.

Cyclic Redundancy Check (CRC)

The CRC7 and CRC16 generators calculate the CRC for Command and Data respectively to send the CRC to the SD/SDIO/MMC card. The CRC7 and CRC16 checker checks for any CRC error in the Response and Data sent by the SD/SDIO/MMC card. When a CRC error is generated, an interrupt will be triggered if the Error Interrupt Signal Enable is enabled. [SDMMC_EN_INT_SIGNAL_ERR.DATA_CRC_ERR_EN](#) = 1 for data CRC error, and [SDMMC_EN_INT_STATUS_ERR.COMD_CRC_ERR_EN](#) = 1 for command CRC error.

Error Correction Code (ECC)

Error correction codes (ECC) may be included in the payload data to detect data defects on the cards. An ECC code is used to store data on the MMC card. This ECC code is used by the SDMMC or application to decode the user data.

13.8 Service Request Generation

The SDMMC module provides one service request output. The service request output MMCI.SR0 is connected to interrupt node in the Nested Vectored Interrupt Controller (NVIC). For details on the service request and interrupt node, please refer to “Service Request Processing” and “Nested Vectored Interrupt Controller” chapters in the reference manual.

13.9 Debug Behavior

The SDMMC module is not affected when the CPU enters HALT mode.

13.10 Power, Reset and Clocks

This section describes the behaviour of power, reset and clocks.

Power

The SD/MMC card power supply can be controlled by the signal bus_pow. The SD bus voltage supported by the SDMMC is 3.3V. If the SD Bus power is set to 1 in the Power Control Register [SDMMC_POWER_CTRL.SD_BUS_POWER](#) = 1, the system shall supply voltage to the card.

Reset

The SDMMC host controller is reset asynchronously when one of the following occurs:

SD/MMC Interface (SDMMC)

- A hardware reset to the card triggered by the `MMC.RST` pin.
- A software reset occurs. A reset pulse is generated when writing 1 to each bit of the Software Reset Register `SDMMC_SW_RESET`.

Clocks

The clocks connected to SDMMC include:

- `clk_xin`
 - Input clock to the SDMMC controller.
 - This is used to generate `clk_sdcard_out` and `clk_sleep_out`.
 - Frequency of clock is 48 MHz, generated from the System Control Unit (SCU) module.
- `clk_sdcard_out`
 - Clock supplied to the SD/MMC card.
- `clk_sdcard_in`
 - Feedback clock of `clk_sdcard_out` from the pad.
 - Feedback clock is used to reduce the pad delay in the clock line.

13.10.1 Tap delay control

Tap delay is used for conditions where the hold time requirements could not be met due to different routing delays between the SD clock and the SD CMD/data line.

The delay chain will have 16 delay elements with each delay being 200ps. This provides the option of a maximum delay of 3.2ns.

Tap delay can be enabled by setting `SDMMCDEL.TAPEN = 1`. The delay time can be controlled by selecting the number of delay elements and writing the value to `SDMMCDEL.TAPDEL`. For more details, please refer to GCU Registers in the System Control Unit (SCU) chapter.

13.11 Initialisation and System Dependencies

This section provides information on how to initialise and use the SDMMC.

13.11.1 Setup SDMMC Data Transfer

Figure 13-2 shows the flowchart of SDMMC read/ write data transfer.

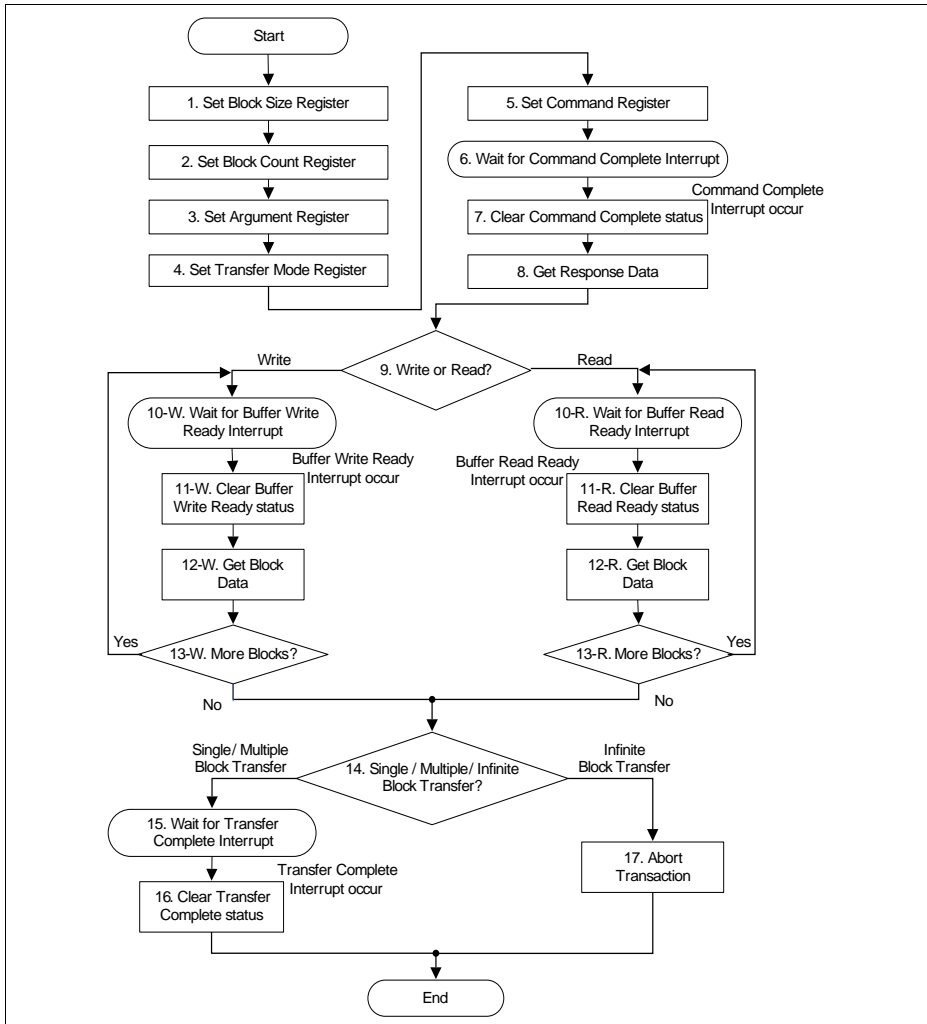

Figure 13-2 Data Transfer sequence

SD/MMC Interface (SDMMC)

The following describes how to setup read/ write data transfer:

1. Set Block Size Register. Set executed data byte length of one block.

`SDMMC_BLOCK_SIZE.TX_BLOCK_SIZE`

2. Set Block Count Register. Set executed data block count.

`SDMMC_BLOCK_COUNT.BLOCK_COUNT`

3. Set Argument Register. Set value corresponding to issued command.

`SDMMC_ARGUMENT1.ARGUMENT1`

4. Set Transfer Mode Register. Set Multi / single block, block count enable, data transfer direction, Auto CMD12 enable.

`SDMMC_TRANSFER_MODE.MULTI_BLOCK_SELECT.`

`SDMMC_TRANSFER_MODE.BLOCK_COUNT_EN`

`SDMMC_TRANSFER_MODE.TX_DIR_SELECT`

`SDMMC_TRANSFER_MODE.ACMD_EN`

5. Set Command Register. Set value corresponding to the issued command.

Note: When writing the upper byte of Command register, SD command is issued.

SDMMC_COMMAND

6. Wait for Command Complete Interrupt.

`SDMMC_INT_STATUS_NORM.CMD_COMPLETE`

7. Clear Command Complete status

Write `SDMMC_INT_STATUS_NORM.CMD_COMPLETE = 1` to clear bit

8. Read Response Register and get the necessary information in accordance with the issued command.

SDMMC_RESPONSE

9. For Read Operation (read from card), go to step (10-R). See **Section 13.11.2**.

For Write Operation (write to card), go to step (10-W). See **Section 13.11.3**.

13.11.2 Read Operation

The following shows the configurations for SDMMC read operation:

10-R. Wait for Buffer Read Ready Interrupt

`SDMMC_INT_STATUS_NORM.BUFF_READ_READY`

11-R. Clear Buffer Read Ready status

Write `SDMMC_INT_STATUS_NORM.BUFF_READ_READY = 1` to clear bit

12-R. Read Block Data (in accordance with the number of bytes specified in step (1))

`SDMMC_DATA_BUFFER`

13-R. Repeat until all blocks are received and then go to step (14)

14-R. For Single or Multiple Block Transfer, go to step (15). For Infinite Block Transfer, go to step (17)

15-R. Wait for Transfer Complete Interrupt

`SDMMC_INT_STATUS_NORM.TX_COMPLETE`

16-R. Get Transfer Complete status and end data transfer

Write `SDMMC_INT_STATUS_NORM.TX_COMPLETE = 1` to clear bit

17-R. Perform Abort Transaction. See [Section 13.11.4](#).

13.11.3 Write Operation

The following shows the configurations for SDMMC write operation:

10-W. Wait for Buffer Write Ready Interrupt

`SDMMC_INT_STATUS_NORM.BUFF_WRITE_READY`

11-W. Clear Buffer Write Ready status

Write `SDMMC_INT_STATUS_NORM.BUFF_WRITE_READY = 1` to clear bit

12-W. Write Block Data (in accordance with the number of bytes specified in step (1))

`SDMMC_DATA_BUFFER`

13-W. Repeat until all blocks are received and then go to step (14)

14-W. For Single or Multiple Block Transfer, go to step (15). For Infinite Block Transfer, go to step (17)

15-W. Wait for Transfer Complete Interrupt

`SDMMC_INT_STATUS_NORM.TX_COMPLETE`

16-W. Get Transfer Complete status and end data transfer

Write `SDMMC_INT_STATUS_NORM.TX_COMPLETE = 1` to clear bit

17-W. Perform Abort Transaction. See [Section 13.11.4](#).

13.11.4 Abort Transaction

This section describes the sequence for the abort transaction.

Asynchronous Abort

The following shows the asynchronous abort sequence:

1. Check **SDMMC_PRESENT_STATE**. **COMMAND_INHIBIT_CMD** is not set to 1.
2. Issue Abort Command. **SDMMC_COMMAND**. **CMD_TYPE** = 11_B.

Synchronous Abort

The following shows the synchronous abort sequence:

1. Set **SDMMC_BLOCK_GAP_CTRL**. **STOP_AT_BLOCK_GAP** = 1 to stop SD transactions.
2. Wait for Transfer Complete Interrupt. **SDMMC_INT_STATUS_NORM**. **TX_COMPLETE**.
3. Set **SDMMC_INT_STATUS_NORM**. **TX_COMPLETE** = 1 to clear this bit.
4. Issue Abort Command. **SDMMC_COMMAND**. **CMD_TYPE** = 11_B.
5. Set **SDMMC_SW_RESET**. **SW_RST_DAT_LINE** = 1 and **SDMMC_SW_RESET**. **SW_RST_CMD_LINE** = 1 to do software reset.
6. Check **SW_RST_DAT_LINE** and **SW_RST_CMD_LINE**. If both are 0, end data transfer. If either **SW_RST_DAT_LINE** or **SW_RST_CMD_LINE** is 1, repeat step (6).

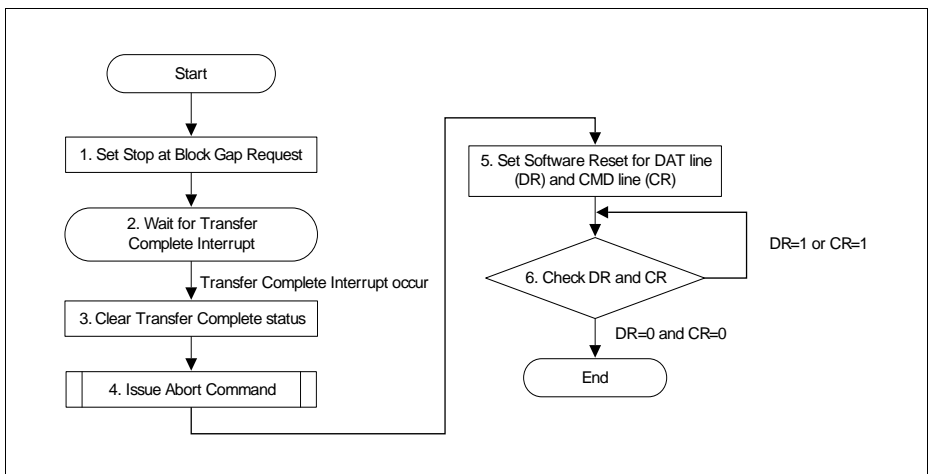

Figure 13-3 Synchronous Abort sequence

13.11.5 Write Protection and Card Detection Software Control

The SD card write protect and card detection pins can be used for other output functions in case the write protection and card detection features are not used.

Write Protection

By default, the input from the SD card write protect pin (P1.1) indicates whether the card is write protected or write enabled. The SDMMC write protection input can be switched to software control via the **SDMMC_CON** register in the System Control Unit (SCU).

The following shows the configurations for SDMMC write protection software control:

1. Set SDMMC write protection input multiplexer control to software bit WPSVAL. **SDMMC_CON.WPSEL** = 1.
2. Set **SDMMC_CON.WPSVAL** = 0 for no write protection, or **SDMMC_CON.WPSVAL** = 1 for write protection active.

Card Detection

By default, the input from the card detection pin (P1.10) indicates whether a card is present or not present. The SDMMC card detection input can be switched to software control via the **SDMMC_CON** register in the System Control Unit (SCU).

The following shows the configurations for SDMMC card detection software control:

1. Set SDMMC card detection control to software bit CDSVAL. **SDMMC_CON.CDSEL** = 1.
2. Set **SDMMC_CON.CDSVAL** = 0 for no card detected, or **SDMMC_CON.CDSVAL** = 1 for card detected.

13.12 Registers

Registers Overview

The absolute register address is calculated by adding:
Module Base Address + Offset Address

Table 13-2 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| SDMMC | 4801 C000 _H | 4801 FFFF _H | |

Table 13-3 Register Overview

| Short Name | Description | Offset Addr. | Access Mode | | Description See |

Access Restrictions

Note: The SDMMC registers are accessible only through word accesses. Half-word and byte accesses on SDMMC registers will not generate a bus error. Writes to unused address space will not cause an error but will be ignored.

13.12.1 Registers Description

SDMMC_BLOCK_SIZE

This register is used to configure the block size for data transfer.

SDMMC_BLOCK_SIZE

Block Size Register (0004_H) **Reset Value: 0000_H**

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------------------------|----------|----|----|----------------------|----|---|---|---|---|---|---|---|---|---|---|
| TX_BLOCK_SIZE_12 | 0 | | | TX_BLOCK_SIZE | | | | | | | | | | | |
| rw | rw | | | rw | | | | | | | | | | | |

| Field | Bits | Type | Description |
|-------------------------|---------|------|---|
| TX_BLOCK_SIZE | [11:0] | rw | Transfer Block Size This register specifies the block size for block data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. It can be accessed only if no transaction is executing (i.e after a transaction has stopped). Read operations during transfer return an invalid value and write operations shall be ignored. 0000 _H No Data Transfer 0001 _H 1 Byte 0002 _H 2 Bytes 0003 _H 3 Bytes 0004 _H 4 Bytes ... 01FF _H 511 Bytes 0200 _H 512 Bytes (Maximum Block Size) <i>Note: Other values are reserved</i> This bit can be set and cleared only by software. |
| 0 | [14:12] | rw | Reserved Read as 0; must be written with 0. |
| TX_BLOCK_SIZE_12 | 15 | rw | Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer. This bit can be set and cleared only by software. |

SDMMC_BLOCK_COUNT

This register is used to configure the block count for current transfer.

SDMMC_BLOCK_COUNT

| Field | Bits | Type | Description |
|--------------------|--------|------|--|
| BLOCK_COUNT | [15:0] | rw | <p>Blocks Count for Current Transfer</p> <p>This register is enabled when Block Count Enable in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. The host controller decrements the block count after each block transfer and stops when the count reaches zero. It can be accessed only if no transaction is executing (i.e after a transaction has stopped). Read operations during transfer return an invalid value and write operations shall be ignored.</p> <p>When saving transfer context as a result of Suspend command, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, the host driver shall restore the previously save block count.</p> <p>0000_H Stop Count 0001_H 1 block 0002_H 2 blocks ... FFFF_H 65535 blocks</p> <p>This bit can be set and cleared only by software.</p> |

SDMMC_ARGUMENT1

This register is used to configure the SD command argument.

SDMMC_ARGUMENT1

Argument1 Register

(0008_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| ARGUMENT1 | [31:0] | rw | Command Argument The SD Command Argument is specified as bit 39-8 of Command-Format. This bit can be set and cleared only by software. |

SDMMC_TRANSFER_MODE

This register is used to configure the data transfer mode.

SDMMC_TRANSFER_MODE

Transfer Mode Register

(000C_H)

Reset Value: 0000_H

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----|----|----|----|----|----|---|---|---|-------------------------|--|---------------------------|---------|---|--------------------------------|----|
| 0 | | | | | | | | | CMD CO MP_ ATA | MUL TI_B LOC K_S ELE CT | TX_ DIR_ SEL ECT | ACMD_EN | | BLO CK_ COU NT_ EN | 0 |
| r | | | | | | | | | rw | rw | rw | rw | | rw | rw |

| Field | Bits | Type | Description |
|-----------------------|------|------|---|
| 0 | 0 | rw | Reserved Read as 0; must be written with 0. |
| BLOCK_COUNT_EN | 1 | rw | Block Count Enable This bit is used to enable the Block count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. 0 _B Disable 1 _B Enable This bit can be set and cleared only by software. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|---------------------------|--------|------|--|
| ACMD_EN | [3:2] | rw | Auto CMD Enable This field determines use of auto command functions 00 _B Auto Command Disabled 01 _B Auto CMD12 Enable <i>Note: Other values are reserved</i> To stop Multiple-block read and write operation: <ul style="list-style-type: none"> Auto CMD12 Enable Multiple-block read and write commands for memory require CMD12 to stop the operation. When this field is set to 01_B, the host controller issues CMD12 automatically when last block transfer is completed. Auto CMD12 error is indicated to the Auto CMD Error Status register. The Host Driver shall not set this bit if the command does not require CMD12. This bit can be set and cleared only by software. |
| TX_DIR_SELECT | 4 | rw | Data Transfer Direction Select This bit defines the direction of DAT line data transfers. 0 _B Write (Host to Card) 1 _B Read (Card to Host) This bit can be set and cleared only by software. |
| MULTI_BLOCK_SELECT | 5 | rw | Multi / Single Block Select This bit enables multiple block DAT line data transfers. 0 _B Single Block 1 _B Multiple Block This bit can be set and cleared only by software. |
| CMD_COMP_AT A | 6 | rw | Command Completion Signal Enable for CE-ATA Device 1 _B Device will send command completion Signal 0 _B Device will not send command completion Signal This bit can be set and cleared only by software. |
| 0 | [15:7] | r | Reserved Read as 0; should be written with 0. |

Determination of transfer type

Table 13-4 Determination of transfer type

| Multi / Single Block Select | Block Count Enable | Block Count | Function |
|------------------------------------|---------------------------|--------------------|------------------------|
| 0 | Don't Care | Don't Care | Single Transfer |
| 1 | 0 | Don't Care | Infinite Transfer |
| 1 | 1 | Not Zero | Multiple Transfer |
| 1 | 1 | Zero | Stop Multiple Transfer |

SDMMC_COMMAND

This register is used to configure the SDMMC command.

SDMMC_COMMAND

Command Register

(000E_H)

Reset Value: 0000_H

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 0 | | CMD_IND | | | | | | CMD_TYP E | | DAT A_P RES ENT _SE LEC T | CMD _IND _CH ECK _EN | CMD _CR C_C HEC K_E N | 0 | RESP_TY PE_SELE CT | |
| r | | rw | | | | | | rw | | rw | rw | rw | r | rw | |

| Field | Bits | Type | Description |
|------------------|-------|------|---|
| RESP_TYPE_SELECT | [1:0] | rw | Response Type Select 00 _B No Response 01 _B Response length 136 10 _B Response length 48 11 _B Response length 48 check Busy after response This bit can be set and cleared only by software. |
| 0 | 2 | r | Reserved Read as 0; should be written with 0. |
| CMD_CRC_CHECK_EN | 3 | rw | Command CRC Check Enable If this bit is set to 1, the host controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. 0 _B Disable 1 _B Enable This bit can be set and cleared only by software. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|----------------------------|--------|------|---|
| CMD_IND_CHECK_EN | 4 | rw | Command Index Check Enable If this bit is set to 1, the host controller shall check the index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 0 _B Disable 1 _B Enable This bit can be set and cleared only by software. |
| DATA_PRESENT_SELECT | 5 | rw | Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. If is set to 0 for the following: 1. Commands using only CMD line (ex. CMD52) 2. Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) 3. Resume Command 0 _B No Data Present 1 _B Data Present This bit can be set and cleared only by software. |
| CMD_TYPE | [7:6] | rw | Command Type There are three types of special commands. Suspend, Resume and Abort. These bits shall be set to 00b for all other commands. 00 _B Normal 01 _B Suspend 10 _B Resume 11 _B Abort This bit can be set and cleared only by software. |
| CMD_IND | [13:8] | rw | Command Index This bit shall be set to the command number (CMD0-63, ACMD0-63). This bit can be set and cleared only by software. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|----------|---------|------|---|
| 0 | [15:14] | r | Reserved Read as 0; should be written with 0. |

SDMMC_RESPONSE

This register is used to configure the command response. [Table 13-5](#) shows the relation between parameters and the name of response type.

Table 13-5 Relation between parameters and the name of response type

| Response Type | Index Check Enable | CRC Check Enable | Name of Response Type |
|---------------|--------------------|------------------|-----------------------|
| 00 | 0 | 0 | No Response |
| 01 | 0 | 1 | R2 |
| 10 | 0 | 0 | R3, R4 |
| 10 | 1 | 1 | R1, R6, R5, R7 |
| 11 | 1 | 1 | R1b, R5b |

[Table 13-6](#) describes the mapping of command responses from the SD Bus to this register for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus, RESPONSE[] refers to a bit range within the Response register.

Table 13-6 Response bit definition for each response type

| Kind of Response | Meaning of Response | Response Field | Response Register |
|----------------------------------|----------------------------|----------------|--|
| R1, R1b (normal response) | Card Status | R[39:8] | RESPONSE 0[31:0] |
| R1b (Auto CMD12 response) | Card Status for Auto CMD12 | R[39:8] | RESPONSE 6[31:0] |
| R2 (CID, CSD Register) | CID or CSD reg. incl. | R[127:8] | RESPONSE 6[23:0], RESPONSE 4[31:0] RESPONSE 2[31:0], RESPONSE 0[31:0] |
| R3 (OCR Register) | OCR Register for memory | R[39:8] | RESPONSE 0[31:0] |
| R4 (OCR Register) | OCR Register for I/O etc. | R[39:8] | RESPONSE 0[31:0] |

SD/MMC Interface (SDMMC)

Table 13-6 Response bit definition for each response type (cont'd)

| Kind of Response | Meaning of Response | Response Field | Response Register |
|-----------------------------|-------------------------------|----------------|-------------------|
| R5, R5b | SDIO Response | R[39:8] | RESPONSE 0[31:0] |
| R6 (Published RCA response) | New published RCA[31:16] etc. | R[39:8] | RESPONSE 0[31:0] |

SDMMC_RESPONSE0

Response 0 Register

(0010_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------------|---------|------|--|
| RESPONSE0 | [15:0] | r | Response0 This bit is initialized to 0 at reset. |
| RESPONSE1 | [31:16] | r | Response1 This bit is initialized to 0 at reset. |

SDMMC_RESPONSE2

Response 2 Register

(0014_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------------|---------|------|--|
| RESPONSE2 | [15:0] | r | Response2 This bit is initialized to 0 at reset. |
| RESPONSE3 | [31:16] | r | Response3 This bit is initialized to 0 at reset. |

SDMMC_RESPONSE4

Response 4 Register

(0018_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------------|---------|------|--|
| RESPONSE4 | [15:0] | r | Response4 This bit is initialized to 0 at reset. |
| RESPONSE5 | [31:16] | r | Response5 This bit is initialized to 0 at reset. |

SDMMC_RESPONSE6

Response 6 Register

(001C_H)

Reset Value: 00000000_H

| Field | Bits | Type | Description |
|------------------|---------|------|--|
| RESPONSE6 | [15:0] | r | Response6 This bit is initialized to 0 at reset. |
| RESPONSE7 | [31:16] | r | Response7 This bit is initialized to 0 at reset. |

SDMMC_DATA_BUFFER

This register is used to configure the SDMMC host controller data buffer.

SDMMC_DATA_BUFFER

Data Buffer Register (0020_H) **Reset Value: 00000000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| DATA_BUFFER | [31:0] | rw | Data Buffer The host controller buffer can be accessed through this 32-bit Data Port Register. Reset: X This bit can be set and cleared only by software. |

SD/MMC Interface (SDMMC)

SDMMC_PRESENT_STATE

This register is used to check the present state of the SDMMC host controller.

SDMMC_PRESENT_STATE

Present State Register

(0024_H)

Reset Value: 00000000_H

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
|----|----|----|-------------------|--------------------|---------------------|--------------------------|---------------------------|----|-------------------|----|----|-------------------------|-----------------------|----------------------|---------------------|
| 0 | | | DAT_7_4_PIN_LEVEL | | | | CMD_LIN_E_LEVEL | | DAT_3_0_PIN_LEVEL | | | WRITE_PROTECT_PIN_LEVEL | CARD_DETECT_PIN_LEVEL | CARD_STATUS_TABLE | CARD_INSERTED |
| r | | | r | | | | r | | r | | | r | r | r | r |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | BUFFER_READ_ENABLE | BUFFER_WRITE_ENABLE | READ_TRANSMISSION_ACTIVE | WRITE_TRANSMISSION_ACTIVE | | 0 | | | | DAT_LINE_ACTIVE | COMMAND_INHIBIT_DATA | COMMAND_INHIBIT_CMD |
| r | | | | r | r | r | r | | r | | | | r | r | r |

| Field | Bits | Type | Description |
|----------------------------|------|------|---|
| COMMAND_INHIBIT_CMD | 0 | r | <p>Command Inhibit (CMD)</p> <p>If this bit is 0, it indicates the CMD line is not in use and the host controller can issue a SD command using the CMD line. This bit is set immediately after the Command register (00Fh) is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command complete interrupt in the Normal Interrupt Status register. If the host controller cannot issue the command because of a command conflict error or because of Command Not Issued By Auto CMD12 Error, this bit shall remain 1 and the Command Complete is not set. Status issuing Auto CMD12 is not read from this bit.</p> <p>Auto CMD12 consists of two responses. In this case, this bit is not cleared by the response of CMD12 but cleared by the response of a read/write command. Status issuing Auto CMD12 is not read from this bit. So if a command is issued during Auto CMD12 operation, host controller shall manage to issue two commands: CMD12 and a command set by Command register.</p> <p>This bit is initialized to 0 at reset.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|----------------------------|-------|------|---|
| COMMAND_INHIBIT_DAT | 1 | r | Command Inhibit (DAT) This status bit is generated if either the DAT Line Active or the Read transfer Active is set to 1. If this bit is 0, it indicates the host controller can issue the next SD command. Commands with busy signal belong to Command Inhibit (DAT) (ex. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Normal interrupt status register. <i>Note: The SD Host Driver can save registers in the range of 000_H - 00D_H for a suspend transaction after this bit has changed from 1 to 0.</i> 0 _B Can issue command which uses the DAT line 1 _B Cannot issue command which uses the DAT line This bit is initialized to 0 at reset. |
| DAT_LINE_ACTIVE | 2 | r | DAT Line Active This bit indicates whether one of the DAT line on SD bus is in use ¹⁾ . 0 _B DAT line inactive 1 _B DAT line active This bit is initialized to 0 at reset. |
| 0 | [7:3] | r | Reserved Read as 0; should be written with 0. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|------------------------------|------|------|--|
| WRITE_TRANSFER_ACTIVE | 8 | r | <p>Write Transfer Active</p> <p>This status indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the host controller. This bit is set in either of the following cases:</p> <ul style="list-style-type: none"> After the end bit of the write command. When writing a 1 to Continue Request in the Block Gap Control register to restart a write transfer. <p>This bit is cleared in either of the following cases:</p> <ul style="list-style-type: none"> After getting the CRC status of the last data block as specified by the transfer count (Single or Multiple) After getting a CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. <p>During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as a result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during write busy.</p> <p>0_B No valid data 1_B Transferring data</p> <p>This bit is initialized to 0 at reset.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-----------------------------|------|------|---|
| READ_TRANSFER_ACTIVE | 9 | r | <p>Read Transfer Active</p> <p>This status is used for detecting completion of a read transfer.</p> <p>This bit is set to 1 for either of the following conditions:</p> <p>After the end bit of the read command</p> <p>When writing a 1 to continue Request in the Block Gap Control register to restart a read transfer</p> <p>This bit is cleared to 0 for either of the following conditions:</p> <p>When the last data block as specified by block length is transferred to the system.</p> <p>When all valid data blocks have been transferred to the system and no current block transfers are being sent as a result of the Stop At Block Gap Request set to 1. A transfer complete interrupt is generated when this bit changes to 0.</p> <p>0_B No valid data</p> <p>1_B Transferring data</p> <p>This bit is initialized to 0 at reset.</p> |
| BUFFER_WRITE_ENABLE | 10 | r | <p>Buffer Write Enable</p> <p>This status is used for non-DMA write transfers. This read only flag indicates if space is available for write data. If this bit is 1, data can be written to the buffer. A change of this bit from 1 to 0 occurs when all the block data is written to the buffer. A change of this bit from 0 to 1 occurs when top of block data can be written to the buffer and generates the Buffer Write Ready Interrupt.</p> <p>0_B Write Disable</p> <p>1_B Write Enable.</p> <p>This bit is initialized to 0 at reset.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|---------------------------|---------|------|--|
| BUFFER_READ_ENABLE | 11 | r | Buffer Read Enable This status is used for non-DMA read transfers. This read only flag indicates that valid data exists in the host side buffer status. If this bit is 1, readable data exists in the buffer. A change of this bit from 1 to 0 occurs when all the block data is read from the buffer. A change of this bit from 0 to 1 occurs when all the block data is ready in the buffer and generates the Buffer Read Ready Interrupt. 0 _B Read Disable 1 _B Read Enable. This bit is initialized to 0 at reset. |
| 0 | [15:12] | r | Reserved Read as 0; should be written with 0. |
| CARD_INSERTED | 16 | r | Card Inserted This bit indicates whether a card has been inserted. Changing from 0 to 1 generates a Card Insertion interrupt in the Normal Interrupt Status register and changing from 1 to 0 generates a Card Removal Interrupt in the Normal Interrupt Status register. The Software Reset For All in the Software Reset register shall not affect this bit. If a Card is removed while its power is on and its clock is oscillating, the host controller shall clear SD Bus Power in the Power Control register and SD Clock Enable in the Clock control register. In addition the host driver should clear the host controller by the Software Reset For All in Software register. The card detect is active regardless of the SD Bus Power. 0 _B Reset or Debouncing or No Card 1 _B Card Inserted |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|--------------------------------|---------|------|--|
| CARD_STATE_STABLE | 17 | r | Card State Stable This bit is used for testing. If it is 0, the Card Detect Pin Level is not stable. If this bit is set to 1, it means the Card Detect Pin Level is stable. The Software Reset For All in the Software Reset Register shall not affect this bit. 0 _B Reset of Debouncing 1 _B No Card or Inserted Reset: 1 _B |
| CARD_DETECT_PIN_LEVEL | 18 | r | Card Detect Pin Level This bit reflects the inverse value of the SDCC module input from SCU. 0 _B No Card present (SDCC = 1) 1 _B Card present (SDCC = 0) <i>Note: Card detect settings via SDMMC_CON bit may be considered If card detection is switched to software control.</i> |
| WRITE_PROTECT_PIN_LEVEL | 19 | r | Write Protect Switch Pin Level The Write Protect Switch is supported for memory and combo cards. This bit reflects the SDWP module input from SCU. 0 _B Write protected (SDWP = 1) 1 _B Write enabled (SDWP = 0) <i>Note: Write protect settings via SDMMC_CON bit may be considered If write protection is switched to software control.</i> |
| DAT_3_0_PIN_LEVEL | [23:20] | r | Line Signal Level This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. D23 - DAT[3] D22 - DAT[2] D21 - DAT[1] D20 - DAT[0] Reset: F _H |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|--------------------------|---------|------|---|
| CMD_LINE_LEVEL | 24 | r | CMD Line Signal Level This status is used to check CMD line level to recover from errors, and for debugging. Reset: 1 _B |
| DAT_7_4_PIN_LEVEL | [28:25] | r | Line Signal Level This status is used to check DAT line level to recover from errors, and for debugging. D28 - DAT[7] D27 - DAT[6] D26 - DAT[5] D25 - DAT[4] Reset: F _H |
| 0 | [31:29] | r | Reserved Read as 0; should be written with 0. |

1) DAT line active indicates whether one of the DAT line is on SD bus is in use.

(a) In the case of read transactions

This status indicates whether a read transfer is executing on the SD Bus. Changing this value from 1 to 0 generates a Block Gap Event interrupt in the Normal Interrupt Status register, as the result of the Stop At Block Gap Request being set.

This bit shall be set in either of the following cases:

1. After the end bit of the read command.
2. When writing a 1 to Continue Request in the Block Gap Control register to restart a read transfer.

This bit shall be cleared in either of the following cases:

1. When the end bit of the last data block is sent from the SD Bus to the host controller.
2. When a read transfer is stopped at the block gap initiated by a Stop At BlockGap Request.

The host controller shall stop read operation at the start of the interrupt cycle of the next block gap by driving Read Wait or stopping SD clock. If the Read Wait signal is already driven (due to data buffer cannot receive data), the host controller can continue to stop read operation by driving the Read Wait signal. It is necessary to support Read Wait in order to use suspend / resume function.

(b) In the case of write transactions

This status indicates that a write transfer is executing on the SD Bus. Changing this value from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register.

This bit shall be set in either of the following cases:

1. After the end bit of the write command.
2. When writing to 1 to Continue Request in the Block Gap Control register to continue a write transfer.

This bit shall be cleared in either of the following cases:

1. When the SD card releases write busy of the last data block. If SD card does not drive busy signal for 8 SD Clocks, the host controller shall consider the card drive "Not Busy".
2. When the SD card releases write busy prior to waiting for write transfer as a result of a Stop At Block Gap Request.

(c) Command with busy

This status indicates whether a command indicates busy (ex. erase command for memory) is executing on the SD Bus. This bit is set after the end bit of the command with busy and cleared when busy is de-asserted. Changing this bit from 1 to 0 generate a Transfer Complete interrupt in the Normal Interrupt Status register.

Note: The host driver can issue cmd0, cmd12, cmd13 (for memory) and cmd52 (for SDIO) when the DAT lines are busy during data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DAT) is set to zero.

SD/MMC Interface (SDMMC)

SDMMC_HOST_CTRL

This register is used to configure the modes of the SDMMC host controller.

SDMMC_HOST_CTRL

Host Control Register

(0028_H)

Reset Value: 00_H

| | | | | | | | |
|---|---|--------------------------|----------|---|---------------------------|---------------------------|----------------------|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

SDMMC_BLOCK_GAP_CTRL

This register is used to configure the block gap request.

SDMMC_BLOCK_GAP_CTRL

Block Gap Control Register

(002A_H)

Reset Value: 00_H

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|---|---|----|---|------------------|----------------|--------------|-------------------|
| 0 | | 0 | | INT_AT_BLOCK_GAP | READ_WAIT_CTRL | CONTINUE_REQ | STOP_AT_BLOCK_GAP |
| r | | rw | | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------------------|------|------|--|
| STOP_AT_BLOCK_GAP | 0 | rw | <p>Stop At Block Gap Request</p> <p>This bit is used to stop executing a transaction at the next block gap for non- DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion the host driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request shall not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The host controller shall honour Stop At Block Gap Request for write transfers, but for read transfers it requires that the SD card support Read Wait. Therefore the host driver shall not set this bit during read transfers unless the SD card supports Read Wait and has set Read Wait Control to 1. In case of write transfers in which the host driver writes data to the Buffer Data Port register, the host driver shall set this bit after all block data is written. If this bit is set to 1, the host driver shall not write data to Buffer data port register. This bit affects Read Transfer Active, Write Transfer Active, DAT line active and Command Inhibit (DAT) in the Present State register.</p> <p>0_B Transfer 1_B Stop</p> <p>This bit can be set and cleared only by software.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-----------------------|------|------|--|
| CONTINUE_REQ | 1 | rw | <p>Continue Request</p> <p>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. To cancel stop at the block gap, set Stop At block Gap Request to 0 and set this bit to restart the transfer.</p> <p>The host controller automatically clears this bit in either of the following cases:</p> <ol style="list-style-type: none"> 1. In the case of a read transaction, the DAT Line Active changes from 0 to 1 as a read transaction restarts. 2. In the case of a write transaction, the Write transfer active changes from 0 to 1 as the write transaction restarts. <p>Therefore it is not necessary for Host driver to set this bit to 0. If Stop At Block Gap Request is set to 1, any write to this bit is ignored.</p> <p>0_B Ignored 1_B Restart</p> |
| READ_WAIT_CTRL | 2 | rw | <p>Read Wait Control</p> <p>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using DAT[2] line. Otherwise the host controller has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. If the card does not support read wait, this bit shall never be set to 1 otherwise DAT line conflict may occur. If this bit is set to 0, Suspend / Resume cannot be supported</p> <p>0_B Disable Read Wait Control 1_B Enable Read Wait Control</p> <p>This bit can be set and cleared only by software.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-------------------------|-------|------|---|
| INT_AT_BLOCK_GAP | 3 | rw | Interrupt At Block Gap This bit is valid only in 4-bit mode of the SDIO card and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. If the SD card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0. When the host driver detects an SD card insertion, it shall set this bit according to the CCCR of the SDIO card. This bit can be set and cleared only by software. |
| 0 | [6:4] | rw | Reserved Read as 0; must be written with 0. |
| 0 | 7 | r | Reserved Read as 0; should be written with 0. |

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the host controller issues a Suspend command or the SD card accepts the Suspend command.

1. If the host driver does not issue Suspend command, the Continue Request shall be used to restart the transfer.
2. If the host driver issues a Suspend command and the SD card accepts it, a Resume Command shall be used to restart the transfer.
3. If the host driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the host driver shall wait for Transfer Complete (in the Normal Interrupt Status register) before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver shall clear Stop At Block Gap Request before or simultaneously.

SDMMC_WAKEUP_CTRL

Wakeup functionality depends on the host controller system hardware and software. The host driver shall maintain voltage on the SD Bus, by setting SD Bus power to 1 in the Power Control register, when wakeup event via card interrupt is desired.

SDMMC_WAKEUP_CTRL

Wake-up Control Register

| rw | | | | | | | | rw | | r | | rw | r | rw | |

| Field | Bits | Type | Description |
|-----------------------|------|------|--|
| INTERNAL_CLOCK_EN | 0 | rw | Internal Clock Enable This bit is set to 0 when the host driver is not using the host controller or the host controller awaits a wakeup event. The host controller should stop its internal clock to go very low power state. Still, registers shall be able to be read and written. Clock starts to oscillate when this bit is set to 1. When clock oscillation is stable, the host controller shall set Internal Clock Stable in this register to 1. This bit shall not affect card detection. 0 _B Stop 1 _B Oscillate This bit can be set and cleared only by software. |
| INTERNAL_CLOCK_STABLE | 1 | r | Internal Clock Stable This bit is set to 1 when SD clock is stable after writing to Internal Clock Enable in this register to 1. The SD Host Driver shall wait to set SD Clock Enable until this bit is set to 1. <i>Note: This is useful when using PLL for a clock oscillator that requires setup time.</i> 0 _B Not Ready 1 _B Ready This bit is initialized to 0 at reset. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-------------------|-------|------|---|
| SDCLOCK_EN | 2 | rw | SD Clock Enable The host controller shall stop SDCLK when writing this bit to 0. SDCLK frequency Select can be changed when this bit is 0. Then, the host controller shall maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK = 0). If the host controller detects the No Card state, this bit shall be cleared. 0 _B Disable 1 _B Enable This bit can be set and cleared only by software. |
| 0 | [5:3] | r | Reserved Read as 0; should be written with 0. |
| 0 | [7:6] | rw | Reserved Read as 0; must be written with 0. |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| SDCLK_FREQ_SEL | [15:8] | rw | <p>SDCLK Frequency Select</p> <p>This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly; this register holds the divisor of the Base Clock Frequency for SD clock. Only the following settings are allowed.</p> <p>8-bit Divided Clock Mode</p> <p>00_H base clock(10MHz-63MHz) 01_H base clock divided by 2 10_H base clock divided by 32 02_H base clock divided by 4 04_H base clock divided by 8 08_H base clock divided by 16 20_H base clock divided by 64 40_H base clock divided by 128 80_H base clock divided by 256</p> <p>Setting 00_H specifies the highest frequency of the SD Clock. When setting multiple bits, the most significant bit is used as the divisor. But multiple bits should not be set. The two default divider values can be calculated by the Base Clock Frequency for SD Clock (48MHz).</p> <ol style="list-style-type: none"> 25 MHz divider value 400 kHz divider value <p>The frequency of the SDCLK is set by the following formula: Clock Frequency = (Base clock) / divisor. Thus choose the smallest possible divisor which results in a clock frequency that is less than or equal to the target frequency.</p> <p>Maximum Frequency for SD = 48 MHz (base clock) Maximum Frequency for MMC = 48 MHz (base clock) Minimum Frequency = 187.5 kHz (48 MHz / 256), same calculation for MMC</p> <p>This bit can be set and cleared only by software.</p> |

SDMMC_TIMEOUT_CTRL

This register is used to configure the interval for data timeout.

SDMMC_TIMEOUT_CTRL

Timeout Control Register

(002E_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|---------------------|-------|------|---|
| DAT_TIMEOUT_CNT_VAL | [3:0] | rw | Data Timeout Counter Value This value determines the interval by which DAT line time-outs are detected. Refer to the Data Time-out Error in the Error Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the sdclk TMCLK by this value. When setting this register, prevent inadvertent time-out events by clearing the Data Time-out Error Status Enable (in the Error Interrupt Status Enable register) 0000 _B TMCLK * 2 ¹³ 0001 _B TMCLK * 2 ¹⁴ ... 1110 _B TMCLK * 2 ²⁷ 1111 _B Reserved This bit can be set and cleared only by software. |
| 0 | [7:4] | r | Reserved Read as 0; should be written with 0. |

SD/MMC Interface (SDMMC)

SDMMC_SW_RESET

A reset pulse is generated when writing 1 to each bit of this register. After completing the reset, the host controller shall clear each bit. Because it takes some time to complete software reset, the SD Host Driver shall confirm that these bits are 0.

SDMMC_SW_RESET

Software Reset Register

| 0 | [7:3] | r | Reserved Read as 0; should be written with 0. |

SDMMC_INT_STATUS_NORM

The Normal Interrupt Status Enable affects read of this register, but Normal Interrupt Signal does not affect these reads. An Interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits except Card Interrupt and Error Interrupt, writing 1 to a bit clears it. The Card Interrupt is cleared when the card stops asserting the interrupt: that is when the Card Driver services the Interrupt condition.

SDMMC_INT_STATUS_NORM

Normal Interrupt Status Register

(0030_H)

Reset Value: 0000_H

A software write of 0 to the bit has no effect.</p> |

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| CARD_INT | 8 | r | Card Interrupt Writing this bit to 1 does not clear this bit. It is cleared by resetting the SD card interrupt factor. In 1-bit mode, the host controller shall detect the Card Interrupt without SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so there are some sample delays between the interrupt signal from the card and the interrupt to the Host system. When this status has been set and the host driver needs to start this interrupt service, Card Interrupt Status Enable in the Normal Interrupt Status register shall be set to 0 in order to clear the card interrupt statuses latched in the host controller and stop driving the Host System. After completion of the card interrupt service (the reset factor in the SD card and the interrupt signal may not be asserted), set Card Interrupt Status Enable to 1 and start sampling the interrupt signal again. Interrupt detected by DAT[1] is supported when there is a card in slot. 0 _B No Card Interrupt 1 _B Generate Card Interrupt |
| 0 | [12:9] | r | Reserved Read as 0; should be written with 0. |
| 0 | [14:13] | rw | Reserved Read as 0; must be written with 0. |
| ERR_INT | 15 | r | Error Interrupt If any of the bits in the Error Interrupt Status Register are set, then this bit is set. Therefore the host driver can test for an error by checking this bit first. 0 _B No Error. 1 _B Error. This bit is initialized to 0 at reset. |

Table 13-7 Relation between transfer complete and data timeout error

| Transfer Complete | Data Timeout Error | Meaning of the Status |
|--------------------------|---------------------------|--------------------------------|
| 0 | 0 | Interrupted by Another Factor. |
| 0 | 1 | Timeout occur during transfer. |
| 1 | Don't Care | Data Transfer Complete |

Table 13-8 Relation between command complete and command timeout error

| Command Complete | Command Timeout Error | Meaning of the Status |
|-------------------------|------------------------------|---|
| 0 | 0 | Interrupted by Another Factor. |
| Don't Care | 1 | Response not received within 64 SDCLK cycles. |
| 1 | 0 | Response Received |

SD/MMC Interface (SDMMC)

SDMMC_INT_STATUS_ERR

Status defined in this register can be enabled by the Error Interrupt Status Enable Register, but not by the Error Interrupt Signal Enable Register. The Interrupt is generated when the Error Interrupt Signal Enable is enabled and at least one of the statuses is set to 1. Writing to 1 clears the bit and writing to 0 keeps the bit unchanged. More than one status can be cleared at a single register write.

SDMMC_INT_STATUS_ERR

SD/MMC Interface (SDMMC)

| Field | Bits | Type | Description |
|-------------------------------------|--------|------|--|
| ACMD_CRC_ERR | 2 | r | Auto CMD CRC Error Occurs when detecting a CRC error in the command response. 0 _B No Error 1 _B CRC Error Generated This bit is initialized to 0 at reset. |
| ACMD_END_BIT_ERR | 3 | r | Auto CMD End Bit Error Occurs when detecting that the end bit of command response is 0. 0 _B No Error 1 _B End Bit Error Generated This bit is initialized to 0 at reset. |
| ACMD_IND_ERR | 4 | r | Auto CMD Index Error Occurs if the Command Index error occurs in response to a command. 0 _B No Error 1 _B Error This bit is initialized to 0 at reset. |
| 0 | [6:5] | r | Reserved Read as 0; should be written with 0. |
| CMD_NOT_ISSUED_BY_ACMD12_ERR | 7 | r | Command Not Issued By Auto CMD12 Error Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04 - D01) in this register. 0 _B No Error 1 _B Not Issued This bit is initialized to 0 at reset. |
| 0 | [15:8] | r | Reserved Read as 0; should be written with 0. |

Table 13-10 Relation between Auto CMD12 CRC error and Auto CMD12 timeout error

| Auto Cmd12 CRC Error | Auto CMD12 Timeout Error | Kinds of Error |
|----------------------|--------------------------|------------------------|
| 0 | 0 | No Error |
| 0 | 1 | Response Timeout Error |
| 1 | 0 | Response CRC Error |
| 1 | 1 | CMD Line Conflict |

The timing of changing Auto CMD12 Error Status can be classified in three scenarios:

1. When the host controller is going to issue Auto CMD12.
 - a) Set D00 to 1 if Auto CMD12 cannot be issued due to an error in the previous command.
 - b) Set D00 to 0 if Auto CMD12 is issued.
2. At the end bit of Auto CMD12 response.
 - a) Check received responses by checking the error bits D01, D02, D03, D04.
 - b) Set to 1 if Error is Detected.
 - c) Set to 0 if Error is Not Detected.
3. Before reading the Auto CMD12 Error Status bit D07
 - a) Set D07 to 1 if there is a command cannot be issued.
 - b) Set D07 to 0 if there is no command to issue.

Timing of generating the Auto CMD12 Error and writing to the Command register are Asynchronous. Then D07 shall be sampled when driver never writing to the Command register. So just before reading the Auto CMD12 Error Status register is good timing to set the D07 status bit.

SD/MMC Interface (SDMMC)

| SDMMC.DATA3_IN | I | P4.1 | SD4/MMC8 mode: Data3 Input |
| SDMMC.DATA2_IN | I | P1.7 | SD4/MMC8 : Data2 input |
| SDMMC.DATA1_IN | I | P1.6 | SD1 mode: Interrupt SD4 mode: Data1 Input or Interrupt (optional) MMC8 mode: Data1 Input |
| SDMMC.DATA0_IN | I | P4.0 | SD1/SD4/MMC8 : Data0 Input |
| SDMMC.SDCD | I | SCU | Active low. Card Detection |
| SDMMC.SDWC | I | SCU | Active High. SD Card Write Protect |
| SDMMC.CMD_IN | I | P3.5 | SD1/SD4/MMC8 : Command Input |
| SDMMC.CLK_OUT | O | P3.6 | Clock supplied to SD/MMC card |
| SDMMC.DATA7_OUT | O | P1.13 | MMC8 mode: Data7 Output |
| SDMMC.DATA6_OUT | O | P1.12 | MMC8 mode: Data6 Output |
| SDMMC.DATA5_OUT | O | P1.9 | MMC8 mode: Data5 Output |
| SDMMC.DATA4_OUT | O | P1.8 | MMC8 mode: Data4 Output |
| SDMMC.DATA3_OUT | O | P4.1 | SD4/MMC8 mode: Data3 Output |
| SDMMC.DATA2_OUT | O | P1.7 | SD1 mode: Read Wait(optional) SD4 mode: Data2 Output or Read Wait (optional) MMC8 mode: Data2 Output |
| SDMMC.DATA1_OUT | O | P1.6 | SD4/MMC8 : Data1 Output |
| SDMMC.DATA0_OUT | O | P4.0 | SD1/SD4/MMC8 : Data0 Output |

Table 13-12 SDMMC Pin Connections (cont'd)

| Input/ Output | I/O | Connected to | Description |
|-----------------|-----|--------------|-------------------------------|
| SDMMC.CMD_OUT | O | P3.5 | SD1/SD4/MMC8 : Command Output |
| SDMMC.BUS_POWER | O | P3.4 | Control Card Power Supply |
| SDMMC.LED | O | P3.3 | LED indication |
| SDMMC.RST | O | P0.11 | Hardware reset to card |
| SDMMC.SR0 | O | NVIC | Service request line |

SD/MMC Interface (SDMMC)

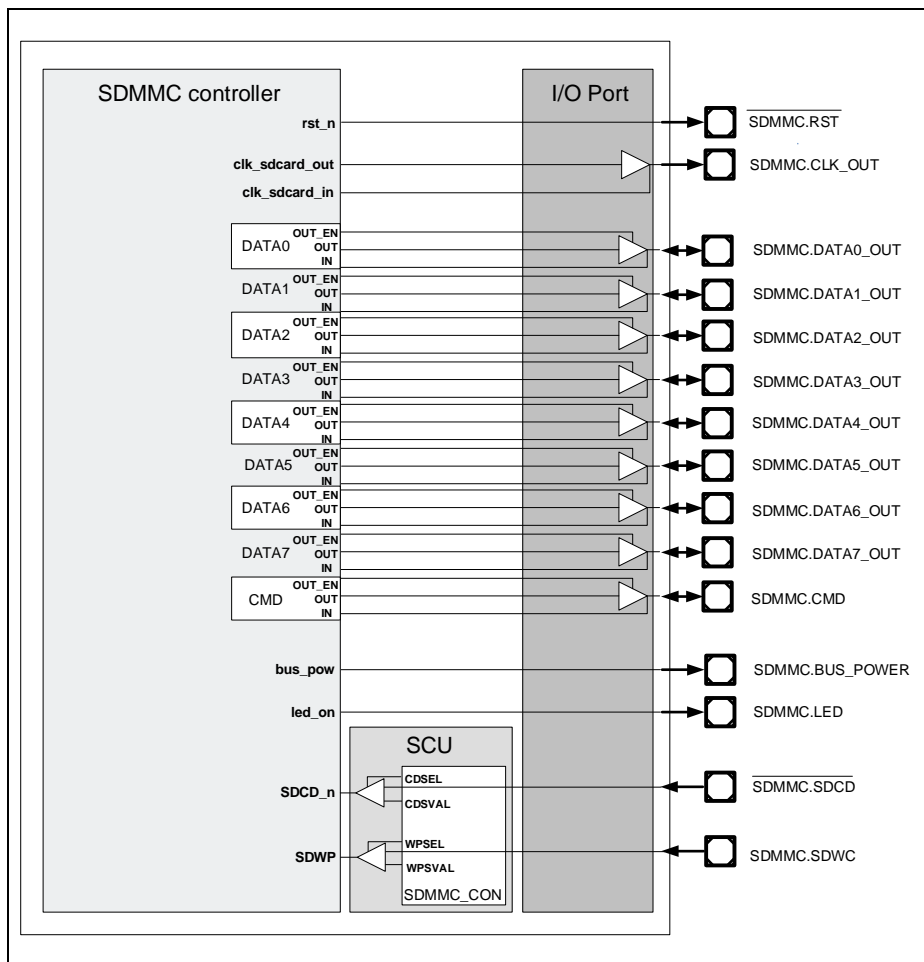

Figure 13-4 External Pin Connections of SDMMC

14 External Bus Unit (EBU)

The EBU controls the transactions between external memories or peripheral units, and the internal memories and peripheral units. Several external device configurations are supported with little or no additional circuitry, making the EBU a very powerful peripheral for expansion and support of several applications.

Table 14-1 Abbreviations

| SDRAM | Synchronous Dynamic Random Access Memory |
| Cellular RAM | Pseudo-static Dynamic Random Access Memory |
| NAND Flash | NAND type Flash Memory |
| NOR Flash | NOR type Flash Memory |
| Burst Flash | Flash Memory with Burst support |
| PCB | Printed Circuit Board |
| XIP | Execute in Place |

14.1 Overview

The Memory Controller module connects the CPU and GPDMA Controller to external resources such as memories and peripherals for code execution and data storage.

Several type of external memories are supported, such as: Burst FLASH, Cellular RAM, SDRAM or NAND.

Figure 14-1 Typical External Memory System

14.1.1 Features

The EBU provides the following features.

- Code execution and data storage supported.
- External bus frequency: Module frequency: flash clock = 1:1, 1:2, 1:3 or 1:4.

External Bus Unit (EBU)

- External bus frequency: Module frequency: SDRAM clock = 1:1, 1:2, or 1:4.
- Highly programmable access parameters.
- Intel-style peripheral/device support.
- Burst FLASH support (see [Section 14.11](#) for specific device types).
- Cellular RAM support (see [Section 14.11](#) for specific device types).
- SDRAM support (see [Section 14.12](#) for specific device types).
- NAND flash
- Asynchronous static memory device e.g. ROM, RAM, NOR Flash
- Multiplexed access (address & data on the same bus)
- Data Buffering: Two read buffers. One write buffer.
- Multiple (four) programmable address regions.
- Little-endian support.

14.1.2 Block Diagram

Figure 14-2 shows the block diagram of the EBU. The AHBIF bridge translates the transactions into requests that can be handled by the arbiter block. The arbiter after receiving the transaction requests, it forwards them to the appropriate state machine.

The dedicated state machines are used to sequence the control signals and to coordinate accesses, to each of the different external memory/device types.

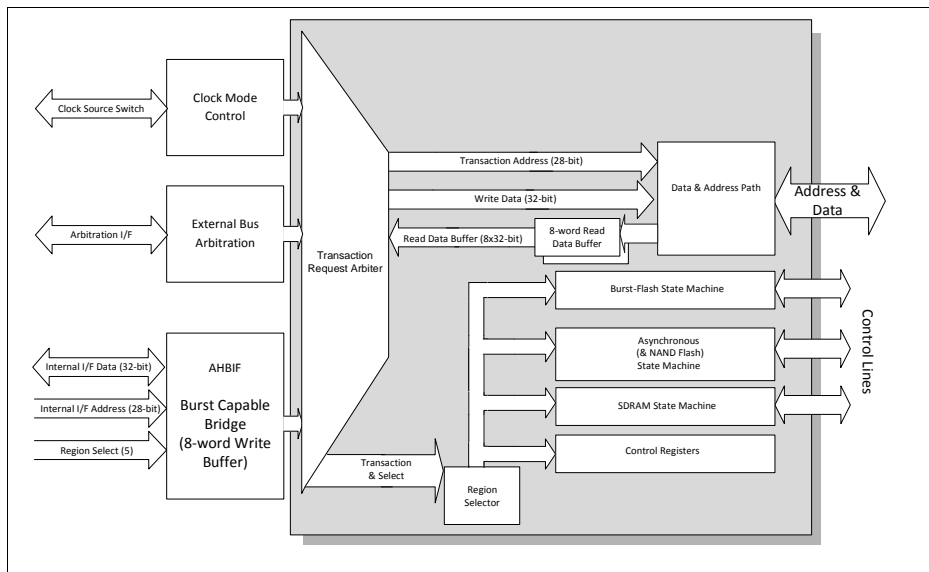

Figure 14-2 EBU Block Diagram

14.2 Interface Signals

The external EBU interface signals are listed in [Table 14-2](#) below.

Table 14-2 EBU Interface Signals

| Signal/Pin | Type | Function |
|---|------|---|
| AD[31:0] | I/O | Multiplexed Address/Data bus lines 0-31 |
| A[23:16] | O | Address bus lines 16-23 |
| $\overline{\text{CS}}[3:0]$ | O | Chip select 0-3 |
| $\overline{\text{RD}}$ | O | Read control line |
| $\overline{\text{RD}}/\overline{\text{WR}}$ | O | Write control line |
| $\overline{\text{ADV}}$ | O | Address valid output |
| $\overline{\text{BC}}[3:0]$ | O | Byte control lines 0-3 |
| BFCLKO | O | Clock Output for Synchronous Accesses |
| BFCLKI | I | Feedback clock input for Synchronous Accesses |
| SDCLKO | O | Clock Output for SDRAM Accesses |
| SDCLKI | I | Feedback Clock for SDRAM Clock Output |
| CKE | O | Clock Enable Output for SDRAM |
| $\overline{\text{RAS}}$ | O | Row Address Strobe for SDRAM |
| $\overline{\text{CAS}}$ | O | Column Address Strobe for SDRAM |
| $\overline{\text{WAIT}}$ | I | Wait input |
| $\overline{\text{HOLD}}$ | I | Hold request input |
| $\overline{\text{HLDA}}$ | I/O | Hold acknowledge |
| BREQ | O | Bus request output |

Address/Data Bus, AD[31:0]

This bus transfers address and data information. The width of this bus is 32 bits. External devices with 8, 16 or 32 bits of data width can be connected to the data bus. Burst Mode instruction fetches can be performed with only 32 or 16 bit data bus width. 8-bit devices have to be treated as 16-bit devices and data alignment accomplished using software.

- External devices with 8, 16 or 32 bits of data width can be connected to the data bus.
- Burst Mode instruction fetches can be performed with only 32 or 16 bit data bus width.
- 8-bit devices have to be treated as 16-bit devices and data alignment accomplished using software.

External Bus Unit (EBU)

The EBU adjusts the data on the data bus to the width of the external device, according to the programmed parameters in its control registers. The byte control signals $\overline{BC}[3:0]$ specify which parts of the data bus carry valid data.

Address Bus, $A[23:16]$

The total address bus of the EBU consists of 24 address output lines, giving a directly addressable range of up to 64 Mbyte ($2^{24} * 32\text{-bit}$). $A[15:0]$ will be output on $AD[31:16]$ restricting support for devices using separate address and data buses to those with a 16-bit data bus. An external device can be selected via one of the chip select lines. Since there are four chip select lines, four such devices with up to 256 Mbyte of address range can be used in the external system.

Chip Selects, $\overline{CS}[3:0]$

The EBU provides up to four chip select outputs, $\overline{CS0}$, $\overline{CS1}$, $\overline{CS2}$ and $\overline{CS3}$. The address range for each chip select is fixed. More details are described on [Section 14.6.2](#).

Read/Write Control Lines, \overline{RD} , $\overline{RD/\overline{WR}}$

Two lines are provided to trigger the read (\overline{RD}) and write ($\overline{RD/\overline{WR}}$) operations of external devices. While some read/write devices require both signals, there are devices with only one control input. The $\overline{RD/\overline{WR}}$ line is then used for these devices. This line will go to an active-low level on a write, and will stay inactive high on a read. The external device should only evaluate this signal in conjunction with an active chip select. Thus, an active chip select in combination with a high level on the $\overline{RD/\overline{WR}}$ line indicates a read access to this device.

Address Valid, \overline{ADV}

The address valid signal, \overline{ADV} , validates the address lines $A[23:0]$ (and also the address placed on the data bus $AD[31:0]$ when attaching multiplexed address/data devices). It can be used to latch these addresses externally.

Byte Controls, $\overline{BC}[3:0]$

The byte control signals $\overline{BC}[3:0]$ select the appropriate byte lanes of the data bus for both read and write accesses. [Table 14-3](#) shows the activation on access to a 16-bit or 8-bit external device. Please note that this scheme supports little-endian devices.

Table 14-3 Byte Control Pin Usage

| Width of External Device | $\overline{\text{BC3}}$ | $\overline{\text{BC2}}$ | $\overline{\text{BC1}}$ | $\overline{\text{BC0}}$ |
|--|-------------------------|-------------------------|-------------------------|-------------------------|
| 32-bit device with byte write capability | D[31:24] | D[23:16] | D[15:8] | D[7:0] |
| 16-bit device with byte write capability | inactive (high) | inactive (high) | D[15:8] | D[7:0] |
| 8-bit device | inactive (high) | inactive (high) | inactive (high) | D[7:0] |

Signals $\overline{\text{BCx}}$ can be programmed for different timing. The available modes cover a wide range of external devices, such as RAM with separate byte write-enable signals, and RAM with separate byte chip select signals. This allows external devices to connect without any external “glue” logic.

Table 14-4 Byte Control Signal Timing Options

| Mode | BUSCONx.BCGEN | Description |
|-------------------|-----------------|---|
| Chip Select Mode | 00 _B | $\overline{\text{BCx}}$ signals have the same timing as the generated chip select $\overline{\text{CS}}$. |
| Control Mode | 01 _B | $\overline{\text{BCx}}$ signals have the same timing as the generated control signals $\overline{\text{RD}}$ or $\overline{\text{RD/WR}}$. |
| Write Enable Mode | 10 _B | $\overline{\text{BCx}}$ signals have the same timing as the generated control signal $\overline{\text{RD/WR}}$. |

Burst Flash Clock Output/Input, BFCLKO/BFCLKI

The flash clock output signal of the EBU is provided at pin BFCLKO. It is used for timing purposes (timing reference) during Burst Mode accesses. BFCLKO is, by default, only generated during synchronous accesses.

The clock input BFCLKI of the EBU is used to latch read data into the EBU. Normally BFCLKI is directly fed back and connected to BFCLKO. This feedback path can be configured externally to maximize the operating frequency for a given Flash device or to compensate the BFCLKO clock pad delay. More details are given on [Section 14.11.4](#).

Wait Input, $\overline{\text{WAIT}}$

This is an input signal to the EBU that is used to dynamically insert wait states into read or write data cycles controlled by the device on the external bus.

SDRAM Clock Output/Input SDCLKO/SDCLKI

The EBU provides a clock output for SDRAM devices on the SDCLKO pin. SDCLKO is, by default, a continuously running signal but can also be configured to switch off between accesses to conserve power.

The feedback clock input, SDCLKI, is used as a timing reference for the capture of read data on SDRAM accesses. It should be connected via a PCB trace to the clock pin of the SDRAM device.

SDRAM Control Signals, CKE, $\overline{\text{CAS}}$ and $\overline{\text{RAS}}$

These signals implement, along with the RD/ $\overline{\text{WR}}$ signal, the command interface for an attached SDRAM memory device.

Bus Arbitration Signals, $\overline{\text{HOLD}}$, $\overline{\text{HLDA}}$, and $\overline{\text{BREQ}}$

The $\overline{\text{HOLD}}$ input signal is the external bus arbitration signal that indicates to the EBU when an external bus master requests to obtain ownership of the external bus.

The $\overline{\text{HLDA}}$ is used as input or output depending on the arbitration mode. With this signal the bus master informs the participant that ownership of the external bus has been obtained.

The $\overline{\text{BREQ}}$ output signal is the external bus arbitration signal that is asserted by the EBU when it requests to obtain back the ownership of the external bus.

14.2.1 Allocation of Unused Signals as GPIO

The EBU will allow pins not required for its programmed configuration to be allocated for use as GPIO. The signals required are as defined below:

Table 14-5 EBU Interface Signals Required by Operating Mode

| Signal/Pin | When Needed by EBU |
|-----------------------------|--|
| AD[15:0] | Always needed when the EBU is enabled. MODCON.ARBMODE != 00 _B ¹⁾ |
| $\overline{\text{RD}}$ | |
| RD/ $\overline{\text{WR}}$ | |
| $\overline{\text{BC}}[1:0]$ | |
| WAIT | This signal is required by the EBU when any enable region is configured to use WAIT by setting the BUSCONx.WAIT field to a value other than 00 _B (MODCON.ARBMODE != 00 _B) AND (ADDRSELx.REGENAB=1 _B OR ADDRSELx.ALTENAB=1 _B) AND (BUSRCONx.WAIT != 00 _B) |

External Bus Unit (EBU)
Table 14-5 EBU Interface Signals Required by Operating Mode (cont'd)

| Signal/Pin | When Needed by EBU |
|---------------------------------------|--|
| A[23:16] | These address bits can be individually enabled for use as GPIO by setting the relevant enable bit in the USERCON register. Setting MODCON.ARBMODE = 00 _B will also enable for GPIO. |
| ADV | The ADV output can be made available for GPIO by setting the relevant bit in the USERCON register. Setting MODCON.ARBMODE = 00 _B will also enable for GPIO. |
| BFCLKO BFCLKI | These signals are required by the EBU when the EBU is enabled and an enabled region is configured for burst device support BFCLKI can be driven from BFCLKO when configuring the chip internal feedback in the PORTS (MODCON.ARBMODE != 00 _B) AND (ADDRSELx.REGENAB=1 _B OR ADDRSELx.ALTENAB=1 _B) AND (BUSRCONx.AGEN = 1 _H OR 3 _H OR 5 _H OR 7 _H) |
| RAS CAS CKE SDCLKO SDCLKI | These signals are required by the EBU when the EBU is enabled and an enabled region is configured for SDRAM support (MODCON.ARBMODE != 00 _B) AND ((ADDRSELx.REGENAB=1 _B OR ADDRSELx.ALTENAB=1 _B) AND (BUSRCONx.AGEN = 1000 _B)) |
| HOLD BREQ HLDA | These signals are required by the EBU when the EBU is configured to arbitrate for the external bus. e.g. MODCON.ARBMODE = 01 _B or 10 _B |

External Bus Unit (EBU)
Table 14-5 EBU Interface Signals Required by Operating Mode (cont'd)

| Signal/Pin | When Needed by EBU |
|----------------------|--|
| AD[31:16] BC[3:2] | These signals are required by the EBU when the EBU is enabled and an enabled region is configured for accessing 32-bit memory or a non-muxed memory type (MODCON.ARBMODE != 00 _B) AND (((ADDRSELx.REGENAB=1 _B OR ADDRSELx.ALTENAB=1 _B) AND (BUSRCONx.PORTW = 10 _B or 11 _B) OR (BUSCONx.AGEN = non muxed device type)) Availability of pins AD[31:30] as GPIO is controlled directly by the PORTS module. These pins can be used as GPIO. |
| CS[3:0] | The Chip select lines are individually controlled and will be required for EBU operation when the associated memory region is enabled. (MODCON.ARBMODE != 00 _B) AND (ADDRSELx.REGENAB=1 _B OR ADDRSELx.ALTENAB=1 _B) |

1) If the EBU is disabled by writing 00 to the EBUCON.ARBMODE field, there will be a delay before the signals become available for GPIO usage as the EBU will wait for all pending external memory accesses to be completed and the arbitration logic to return to the "nobus" state before releasing the signals.

14.2.2 Signal States when EBU is inactive

The state of the various bus signals is controlled by the EBU during inactive states as listed below. Note that in the XMC4000 the PORTS unit disables the EBU port control lines during reset. The lines must be explicitly enabled by the user software.

Table 14-6 Memory Controller External Bus pin states during reset

| Pin Name | State during Reset and "No Bus" mode ¹⁾ | State during Idle ²⁾ |
|----------|--|--|
| AD[31:0] | GPIO | High Impedance - pull ups enabled to pull to '1'. |
| A[23:16] | GPIO | Driven to '0' after reset, otherwise last used address |
| CS[3:0] | GPIO | Driven to '1' (High). |
| RD | GPIO | Driven to '1' (High). |
| WR | GPIO | Driven to '1' (High). |
| CAS | GPIO | Driven to '1' (High). |
| RAS | GPIO | Driven to '1' (High). |
| CKE | GPIO | Dependant on SDRAM clocking/power save mode |

Table 14-6 Memory Controller External Bus pin states during reset (cont'd)

| Pin Name | State during Reset and “No Bus” mode ¹⁾ | State during Idle ²⁾ |
|----------|--|--|
| ADV | GPIO | Driven to ‘1’ (High). |
| SDCLKO | GPIO | Dependant on SDRAM clocking/power save mode |
| SDCLKI | GPIO | High Impedance |
| BFCLKI | GPIO | High Impedance |
| BFCLKO | GPIO | Driven to ‘0’ (Low). |
| BC[3:0] | GPIO | Driven to ‘1’ (High). |
| WAIT | GPIO | Always an input (must have a pull-resistor to inactive state). |

1) GPIO controlled pins should be high impedance with pull up during reset, except for CKE which should be high impedance with pull down.

2) Assuming that the pins have not been made available as GPIO.

Applicable reset is `cgu_con_clk_rst_n_i`.

14.3 Memory Controller Structure

The AHBIF bridges translate AHB transactions into appropriate transaction requests which can be transferred to the arbiter (see [Section 14.4](#)).

The arbiter looks at the transaction requests and schedules corresponding requests to the relevant state machine. Only one state machine can be active at any time. The dedicated state machines are used to sequence control signals and to co-ordinate accesses to each of the different external memory/device types and also the internal registers.

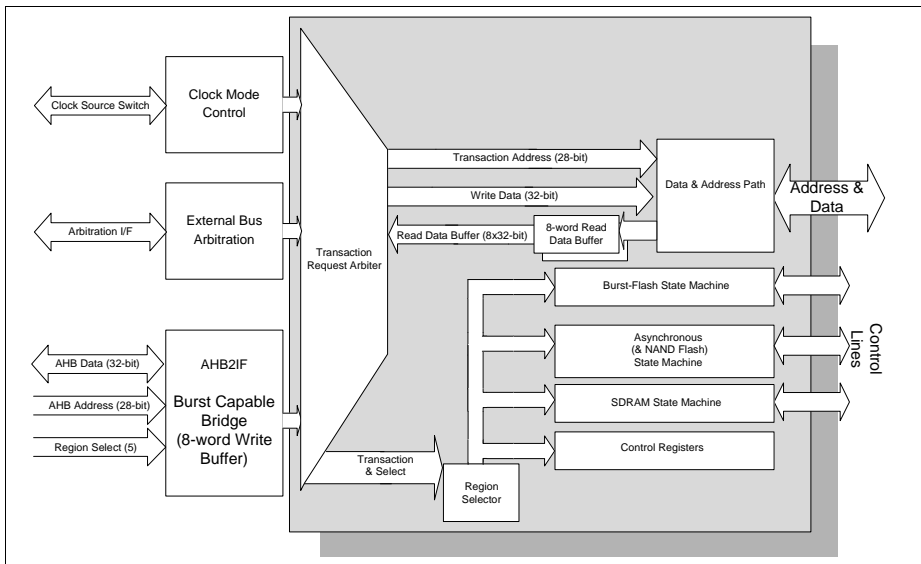

Figure 14-3 Memory Controller Block Diagram

14.4 Memory Controller AHBIF Bridge

As shown in the Memory Controller Block Diagram ([Figure 14-3](#)) Memory Controller contains an EBU specific AHBIF bridge. This bridge supports the AHB-lite protocol which means (among other things) that masters are not allowed to perform early burst termination (except after an error response) and that retries are not generated by slaves.

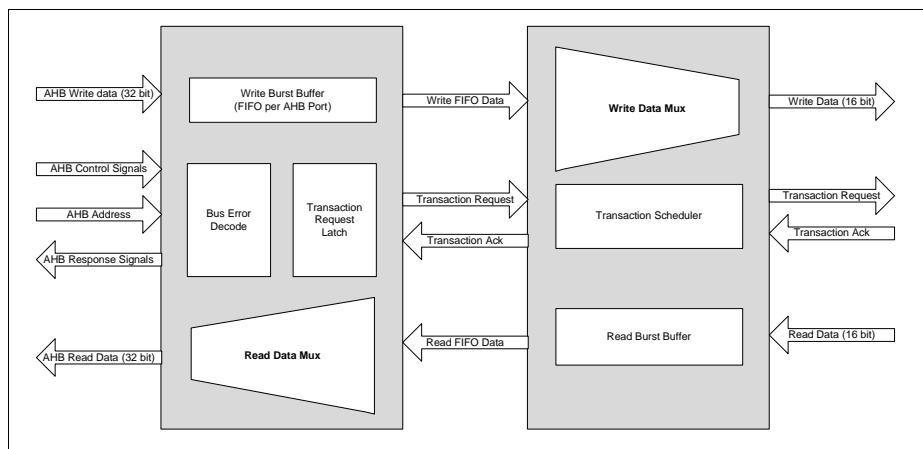

Figure 14-4 AHB Bridge Block Diagram

The bridges map the AHB accesses into appropriate external memory/device transaction requests. Only a limited subset of AHB transactions are supported optimally in order to simplify and reduce the area of the design. All other AHB transactions are split into single data phases and passed to the core logic as multiple accesses.

Table 14-7 Supported AHB Transactions

| AHB Transfer Type | | | Support ¹⁾ |
|---------------------|----------------------------------|--------|-----------------------|
| Transfer Size | Comment | Type | |
| Byte (8 bits) | Aligned to any byte address | single | Yes |
| | | others | No (split) |
| Half-Word (16-bits) | Aligned to any half-word address | single | Yes |
| | | others | No (split) |

Table 14-7 Supported AHB Transactions (cont'd)

| AHB Transfer Type | | | Support ¹⁾ |
|-------------------|-----------------------------|--------|--|
| Transfer Size | Comment | Type | |
| Word (32-bits) | Aligned to any word address | single | Yes |
| | | incr4 | Yes (if address aligned, otherwise split)) |
| | | incr8 | Yes (if address aligned, otherwise split)) |
| | | wrap8 | Yes |
| | | others | No (split) |

1) Unsupported transactions are split into multiple, 32-bit data transfers

The bridge contains a "Write Burst Buffer" which allows the bridge to accept a complete AHB Write Access prior to generation of the matching Write Transaction Request.

The bridge can be operated either Synchronously or Asynchronously. Support is provided for dynamic switching of clocking modes (see [Section 14.5.1](#)).

The AHB port is configured with a 8 x 32-bit word write buffer and supports all AHB transactions.

Byte and half-word transfers are supported for all transactions from external memory shown in the [Table 14-7](#). Byte accesses may be aligned to any byte boundary. Half-word accesses may be aligned to any half-word boundary.

The Memory Controller will ensure that the limitations of external memories are transparent to the AHB interfaces. If an AHB request cannot be directly mapped to an access supported by the external memory, the Memory Controller will split and realign the access into transfers supportable by the external memory. The most noticeable effects of this are:

1. All burst accesses to an external memory are realigned so that the lowest address is fetched first (unless specifically disabled using BUSRCON[3:0].dba)
This prevents unexpected interaction between AHB access wrapping and any wrapping built into external memories such as SDRAM or burst flash.
2. An AHB, burst access to an asynchronous memory such as SRAM will result in multiple accesses on the external bus as the Memory Controller fetches enough single words from the memory to complete the burst

14.4.1 AHB Error Generation

The bridge generates AHB Error Events as appropriate. There are several types of AHB Error Events which can be generated by Memory Controller. These errors are:-

External Bus Unit (EBU)

1. **Access to disabled region:** If an access is attempted to a memory region which is disabled then an AHB Error Response is returned (i.e. the AHB access is terminated with an error). Note that the region can be disabled for reads and/or writes separately.
2. **Illegal Register Access:** Register accesses must ONLY be 32-bit accesses. Write accesses must be performed with HPROT in privilege mode. Any write accesses attempted in user mode, or any type of access attempted as either an 8-bit or 16-bit transfer, or a burst will be terminated with an AHB Error Response.

Once a phase of a transaction has been errored, the initiating master is allowed to terminate the burst without completing the remaining phases. This is the only case in which the memory controller supports early burst termination.

14.4.2 Read Data Buffering

The memory controller contains two, identical read buffers with a capacity of eight 32-bit words. A read access will be allowed to proceed if one of the buffers is flagged as available. The data read from the external memory will be stored in the read buffer and the outputs from the read buffer will be multiplexed to the AHB port. Once the AHB port signals that all data has been returned to the requesting AHB master, the read buffer will again be flagged as available.

This architecture allows reads to be in progress simultaneously, as a second read can be running while the first read is still waiting for data to be returned to the AHB master.

14.4.3 Write Data Buffering

The data for all AHB writes are “posted” into a buffer in the AHB interface before the access is passed to the state machine blocks for execution.

14.5 Clocking Strategy and Local Clock Generation

The Memory Controller can be configured to operate from several possible clock sources. The clock generation logic is used to select between these clock sources and generate the internal clock used for the memory controller, EBU_CLK.

14.5.1 Clocking Modes

The bridges can be operated in one of three modes:-

- Asynchronous: The AHB clock and Memory Controller internal clock (EBU_CLK) are assumed to be asynchronous. EBU_CLK is derived from a dedicated clock source
- Synchronous: The EBU_CLK is derived from the AHB bus clock. The CLK and AHB interface clocks have aligned edges (although pulse swallowing can be used on the AHB interface clock, so that the AHB interfaces run at the same speed as the rest of the bus matrix).

External Bus Unit (EBU)

- Divide by 2: The EBU clock is running at half the frequency of the AHB bus clock. The EBU clock is edge aligned with the processor and AHB interface clock.

The clock for the AHB interface of the memory controller must always be derived from the same synchronous source (the AHB bus clock).

Operation of the bridge in Asynchronous mode provides maximum flexibility in clocking different domains at different frequencies. This is, however, at the cost of additional latency (for signal resynchronisation) through the bridge.

Operation of the bridge in synchronous mode minimizes the latency through the bridge at the cost of forcing the AHB and EBU_CLK domains to run from the same source clock (the AHB bus clock).

The mode of operation of the bridge is controlled by the **EBUCLC.SYNC** register field. The **EBUCLC.SYNACK** field will be updated to report the current operating mode.

The **CLC.SYNC** register field can be used (dynamically) to switch between these two modes. The Memory Controller contains internal control logic to sequence the switching between modes to ensure that external bus accesses are not corrupted as a result of switching clocking modes. The Memory Controller updates the **CLC.SYNACK** to signal the status of the bridge ('1' = operating in Synchronous Mode, '0' = operating in Asynchronous Mode).

If **CLC.DIV2** is set to 0_B, then EBU.CLC.SYNC also controls the clock input and switches it between the AHB bus clock and the dedicated EBU clock source from the Clock Generation Unit.

However, if **EBUCLC.DIV2** is set to 1_B, then EBU clock source is forced to be half the frequency of the AHB bus clock and **EBUCLC.SYNC** only enables and disables the resynchronisation stages necessary for asynchronous operation. Setting **EBUCLC.SYNC** to 0_B will only activate the resynchronisation stages, the EBU clock will remain fixed at half the AHB bus clock frequency. The value of **DIV2** in use by the memory controller is stored in the **EBUCLC.DIV2ACK** field.

Local Clock Divider

A local divider can be used to reduce the frequency of EBU_CLK. The divider can be programmed to for divide ratios of 1:1, 2:1, 3:1 or 4:1 using the **EBUCLC.DIV** register field. The ratio currently in use is provided in the **EBUCLC.DIVACK** register field.

The purposes of the divider is to allow the memory controller core to operate synchronously at an integer divide ratio of the AHB bus clock.

If a divide ratio other than 1:1 is selected using the local clock divider and a memory device is being used at a 1:1 external clock ratio, then the device clock outputs BFCLKO and SDCLKO will not have a 50% duty cycle. This is because the local divider operates by pulse swallowing the module input clock to generate EBU_CLK.

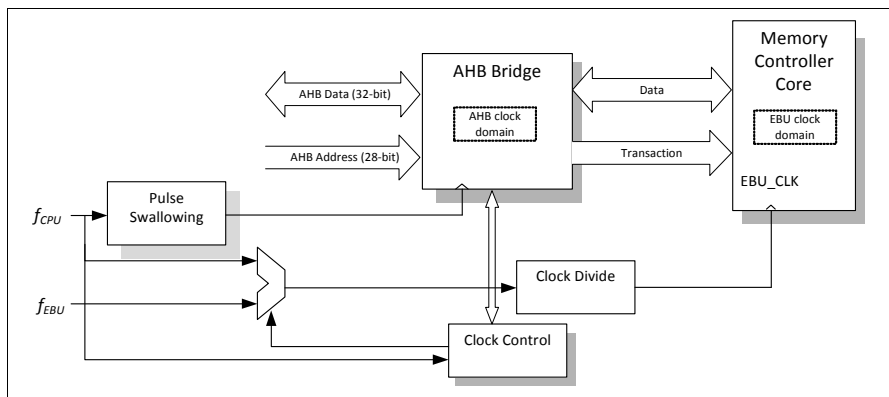

Figure 14-5 AHB/Memory Controller Clocking Domains (Simplified Block Diagram)

14.5.1.1 Clock Requirements

The Memory Controller has the ability to clock SDRAM and other synchronous memory devices at the same frequency as the Memory Controller core logic. In this case, using pulse swallowing on the clock inputs can cause the asymmetric clock waveform generated by pulse swallowing to violate clock pulse width parameters of the connected devices.

This is particularly important when using SDRAM at the maximum supported frequency of the device.

14.5.2 Standby Mode

The Memory Controller can be configured to disable its internal clock and enter standby mode by writing a logic '1' to the EBUCLC.DISR register field.

Once the register field is written, the Memory Controller will wait for any running accesses to finish and will then disable the clock to the core logic of the Memory Controller (EBU_CLK). As this will also disable the refresh counters, it is necessary to set the SDRMREF.AUTOSELFR register field if this mode is to be used with SDRAM. This will instruct the EBU to place any attached SDRAM into self refresh mode before allowing clock mode switching or standby.

Note: For the purposes of standby mode, AHB accesses which are split by the AHB interfaces into multiple accesses to the memory controller count as multiple accesses. This means that the memory controller will attempt to enter standby mode at the end of the current data transfer, not at the end of the final data transfer of the AHB access.

External Bus Unit (EBU)

An access arriving on any of the Memory Controller, AHB interfaces will trigger an automatic exit from standby mode to service the access request. This condition may also prevent standby mode being entered at all depending upon when the new access arrives at the AHB interface.

Note: Once a pending AHB access has triggered an exit from standby mode, if all pending AHB accesses have been serviced and the ARM is still in “standby wait for interrupt” mode, the EBU will not return to standby mode.

An automatic exit from standby mode will not clear the EBUCLC.DISR field. This has to be explicitly written with ‘0’ by software before writing another ‘1’ will trigger a further entry to standby mode.

14.6 External Bus Operation

The EBU supports interconnection to a wide variety of memory/peripheral devices with flexible programming of the access parameters. In the following sections, the basic features for these access modes are described. The types of external access cycles provided by the EBU are:

- Asynchronous and synchronous devices with demultiplexed access
 - ROMs, EPROMs
 - NOR flash devices
 - Static RAMs and PSRAMs
- Asynchronous and synchronous devices with multiplexed access
 - NOR flash devices
 - PSRAMs
- SDRAM Memories

Note: Not all memory types supported by the memory controller are known to be available in all quality grades.

Each internal AHB master can access external devices via the EBU. The EBU provides four user-programmable external memory regions. Each of these regions is provided with a set of registers that determine the parameters of the external bus transaction and one chip select signal. An AHB transaction that matches one of these external memory regions is translated by the EBU to the appropriate external access(es).

The address space of each of the four regions and the registers is defined at the system level by the address decoder in the AHB bus matrix.

14.6.1 External Memory Regions

The memory controller of the XMC4[78]00 supports four memory regions, which have its own associated chip select outputs CS[3:0]. Each of these regions has a set of control registers to specify the type of memory/peripheral device and the access parameters.

External Bus Unit (EBU)

Each of the four user-programmable regions can be configured to respond to a particular address space through registers ADDRSELx. The default region is enable by bit ADDRSELx.**REGENAB**, the alternate region by ADDRSELx.**ALTENAB**. Code and data access properties are defined by the memory model described in the CPU chapter.

Table 14-8 Address Regions

| Region | Associated Chip Select | Default Region (code and data) | Alternate Region (data storage only) |
|----------|------------------------|---|---|
| Region 0 | CS0 | 6000 0000 _H - 63FF FFFF _H | A000 0000 _H - A3FF FFFF _H |
| Region 1 | CS1 | 6400 0000 _H - 67FF FFFF _H | A400 0000 _H - A7FF FFFF _H |
| Region 2 | CS2 | 6800 0000 _H - 6BFF FFFF _H | A800 0000 _H - ABFF FFFF _H |
| Region 3 | CS3 | 6C00 0000 _H - 6FFF FFFF _H | AC00 0000 _H - AFFF FFFF _H |

The access parameters for each of the regions can be programmed individually to accommodate different types of external devices. Separate control registers are available to control read and write accesses. This allows optimal access types, speeds and parameters to be chosen. Access type is configured via BUSRCONx and BUSWCONx. Access parameters are configured via BUSRAPx and BUWAPx.

Throughout this document the generic term BUSCONx is used when either of BUSRCONx or BUSWCONx is applicable and BUSAPx is used when either of BUSRAPx or BUSWAPx is applicable.

Table 14-9 Region Control Registers

| Region | Associated Chip Select | Address Select Registers | Bus Configuration Registers | Bus Access Parameters Registers |
|----------|------------------------|--------------------------|-----------------------------|---------------------------------|
| Region 0 | CS0 | ADDRSEL0 | BUSRCON0 BUSWCON0 | BUSRAP0 BUSWAP0 |
| Region 1 | CS1 | ADDRSEL1 | BUSRCON1 BUSWCON1 | BUSRAP1 BUSWAP1 |
| Region 2 | CS2 | ADDRSEL2 | BUSRCON2 BUSWCON2 | BUSRAP2 BUSWAP2 |
| Region 3 | CS3 | ADDRSEL3 | BUSRCON3 BUSWCON3 | BUSRAP3 BUSWAP3 |

14.6.2 Chip Select Control

The EBU generates four chip select signals, \overline{CS}_x , which are all available at dedicated chip select outputs.

14.6.3 Programmable Device Types

Each CS region (0 to 3) can be individually configured using the BUSCONx.AGEN register field, to be connected to one of the following external memory/device types:

Table 14-10 AGEN description

| AGEN value | External Device Type |
|------------|---|
| 0 | Muxed Asynchronous Type (default after reset) |
| 1 | Muxed Burst Type |
| 2 | NAND flash (page optimized) |
| 3 | Muxed Cellular RAM |
| 4 | Demuxed Asynchronous Type |
| 5 | Demuxed Burst Type |
| 6 | Demuxed Page Mode |
| 7 | Demuxed Cellular RAM |
| 8 | SDRAM |
| 9 | Reserved |
| 10 | Reserved |
| 11 | Reserved |
| 12 | Reserved |
| 13 | Reserved |
| 14 | Reserved |

14.6.4 Support for Multiplexed Device Configurations

Memory Controller supports a number of configurations of Multiplexed memory/peripheral devices using different values of the BUSRCONx.PORTW bit-field. The BUSWCONx registers also contain the PORTW field but in this case the field is read only and reflects the value set in the related one of the BUSRCONx registers. The values set in the BUSRCONx registers are used for both read and write accesses.

Note: When using multiplexed devices a non-zero recovery phase is mandatory for all devices to prevent read data from one access conflicting with the address for the multiplexed memory.

Table 14-11 Pins used to connect Multiplexed Devices to Memory Controller

| Memory Device Configuration | Memory Controller Pins | | | Section |
|-----------------------------|------------------------|-------------------------|---------------------|---|
| | A[23:16] ¹⁾ | AD[31:16] ²⁾ | AD[15:0] | |
| 16-bit MUX | A[23:16] | - | A[15:0]/ D[15:0] | 16-bit Multiplexed Memory/Peripheral Configuration |
| Twin 16-bit MUX | A[23:16] | A[15:0]/ D[31:16] | A[15:0]/ D[15:0] | Twin 16-bit Multiplexed Device Configuration |
| 32-bit MUX | - | A[31:16]/ D[31:16] | A[15:0]/ D[15:0] | 32-bit Multiplexed Memory/Peripheral Configuration |

1) These pins are always outputs which are connected to address pins on the Multiplexed device(s)

2) These pins are dual function and act as AD[31:16] when required for 32-bit, multiplexed devices

Table 14-12 Selection of Multiplexed Device Configuration

| PORTW value | |
|-----------------|--|
| 00 _B | Reserved |
| 01 _B | 16-bit multiplexed ¹⁾ |
| 10 _B | Twin, 16-bit Multiplexed ²⁾ |
| 11 _B | 32-bit multiplexed ³⁾ |

1) Address will only be driven onto AD[15:0] during the address and address hold phases. A[15:0] will be driven with address for duration of access

2) Lower 16 bits of address will be driven onto both A[15:0] and AD[15:0] during the address and address hold phases

3) Full address will be driven onto A[15:0] and AD[15:0] during the address and address hold phases

16-bit Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address¹⁾ is driven onto EBU A[23:16]. During the address phase the low 16 bits of the address are driven to EBU AD[15:0]. Data (16-bit) is driven to/read back from the AD[15:0] pins during the data phase. The

1) This address is pre-aligned according to the bus width as detailed in [Section 14.6.7](#).

External Bus Unit (EBU)

interconnect between Memory Controller and a 16-bit Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

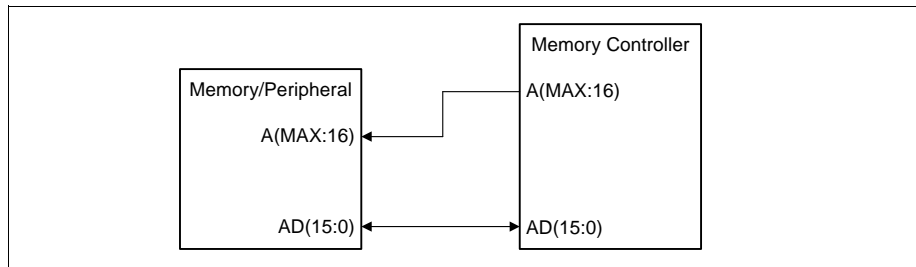

Figure 14-6 Connection of a 16-bit Multiplexed Device to Memory Controller

Twin 16-bit Multiplexed Device Configuration

This mode allows the use of two 16-bit multiplexed devices to create a 32-bit wide bus. Throughout the complete external bus cycle the address¹⁾ is driven onto EBU A[23:0]. During the address phase the low 16 bits of the address are driven (in parallel) to EBU AD[15:0] and AD[31:16]. This ensures that both multiplexed devices are issued with the same address during the address phase. Data (32-bit) is written to/read from the AD[31:16] pins for MSW and the AD[15:0] pins for LSW during the data phase. The interconnect between Memory Controller and two 16-bit Multiplexed devices in this mode is shown below (note: for clarity only the address/data signals are shown):-

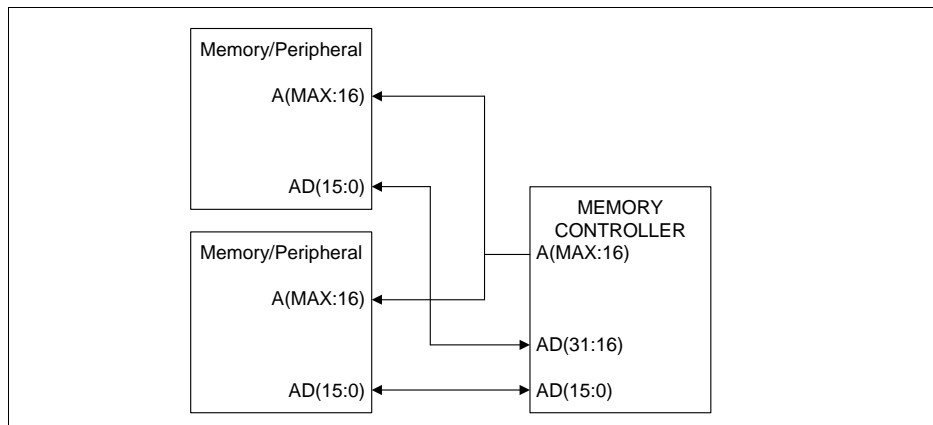

Figure 14-7 Connection of twin 16-bit Multiplexed Device's to Memory Controller

1) This address is pre-aligned according to the bus width as detailed in [Section 14.6.7](#).

32-bit Multiplexed Memory/Peripheral Configuration

During the address phase the lower 16 bits of the 25 bit address are driven to EBU AD[15:0], the most significant 9 bits of the address are driven to pins AD(24:16) and pins AD(31:17) are driven with 0 (zero). Data (32-bit) is driven to/read from the AD[31:0] pins during the data phase. The interconnect between Memory Controller and a 32-bit Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

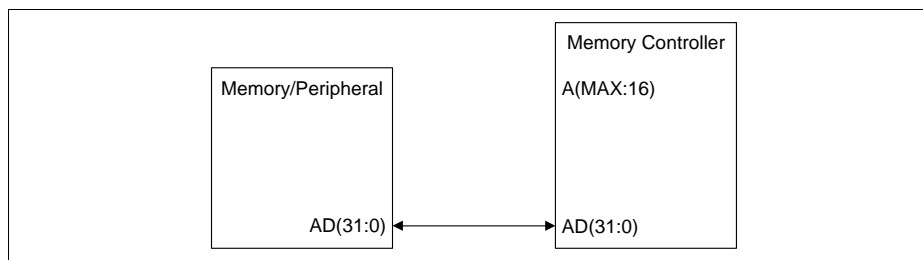

Figure 14-8 Connection of a 32-bit Multiplexed Device to Memory Controller

14.6.5 Support for Non-Multiplexed Device Configurations

The Memory Controller supports 16-bit non-multiplexed memory devices.

Table 14-13 Pins used to connect non-multiplexed Devices to Memory Controller

| Memory Device Configuration | Memory Controller Pins | | | Section |
|-----------------------------|------------------------|-----------|----------|---|
| | A[23:16] ¹⁾ | AD[31:16] | AD[15:0] | |
| 16-bit non-MUX | A[23:16] | A[15:0] | D[15:0] | 16-bit non-Multiplexed Memory/Peripheral Configuration |

1) These pins are always outputs which are connected to address pins on the device(s)

Table 14-14 Selection of non-Multiplexed Device Configuration

| PORTW value | |
|-----------------|------------------------|

| 01 _B | 16-bit ¹⁾ |
| 10 _B | Reserved |
| 11 _B | 32-bit - not supported |

- 1) Address will only be driven onto AD[15:0] during the address and address hold phases. AD[31:16] will be driven with address for duration of access

16-bit non-Multiplexed Memory/Peripheral Configuration

Throughout the complete external bus cycle the address¹⁾ is driven onto EBU A[23:16] and AD[15:0]. Data (16-bit) is driven to/read back from the AD[15:0] pins during the data phase. The interconnect between Memory Controller and a 16-bit non-Multiplexed device in this mode is shown below (note: for clarity only the address/data signals are shown):-

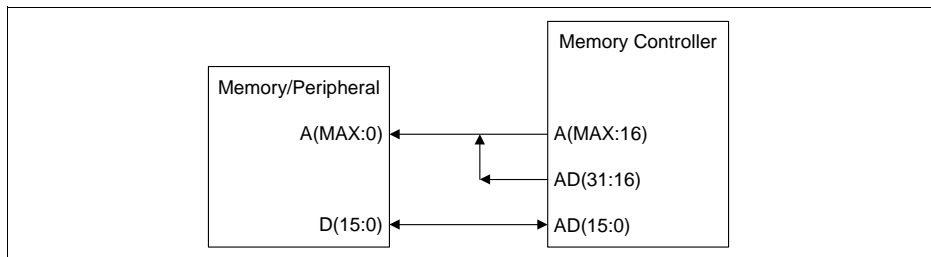

Figure 14-9 Connection of a 16-bit non-Multiplexed Device to Memory Controller

14.6.6 AHB Bus Width Translation

If the internal access width is wider than the external bus width specified for the selected external region, the internal access is split in the EBU into several external accesses. For example, if the AHB requests to read a 64-bit word and the external device is only 16-bit wide, the EBU will automatically perform four external 16-bit accesses. When multiple accesses are generated in this way, external bus arbitration is blocked until the multiple access is complete. This means that the EBU remains the owner of the external bus for the duration of the access sequence. The external accesses are performed in ascending AHB address order.

To allow proper bus width translation, the EBU has the capability to re-align data between the external bus and the AHB as shown in [Figure 14-10](#).

1) This address is pre-aligned according to the bus width as detailed in [Section 14.6.7](#).

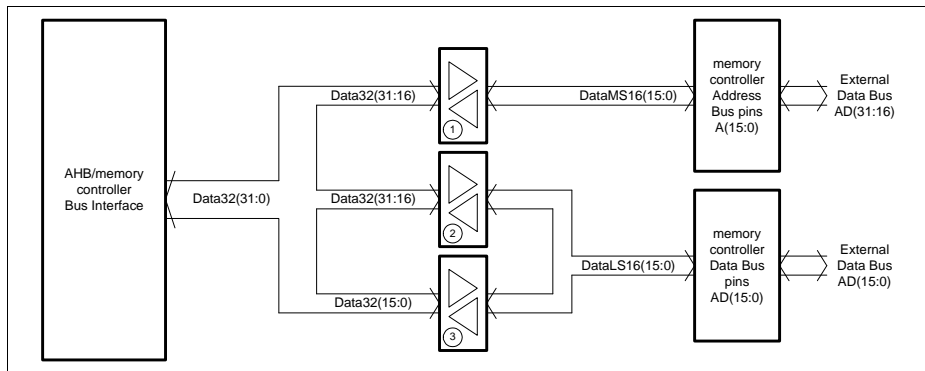

Figure 14-10 AHB to External Bus Data Re-Alignment

- During an access to a 32-bit wide external region, Buffer 1 and Buffer 2 are enabled.
- During an access to a 16-bit wide external region, either Buffer 1 or Buffer 3 is enabled (according to bit 1 of the AHB address being accessed). This allows either AHB channel byte pair (i.e. any properly aligned 16-bit data) to be re-aligned to the lower 16 bits of the external data bus D[15:0].

14.6.7 Address Alignment During Bus Accesses

During an external bus access, the EBU will align the internal byte address to generate the appropriate external word or half-word address aligned to the external address pins. The address alignment will be done as shown in the following table.

Table 14-15 Address Alignment in dependency from Bus Mode

| Bus Mode | Internal Bus | External Bus |
|-------------------------|---|----------------------------|
| 16-bit multiplexed | $A_{AHB}[24:17]$ | $A[23:16]$ |
| | $A_{AHB}[16:1]$ | $AD[15:0]$ |
| 16-bit non-multiplexed | $A_{AHB}[24:17]$ | $A[23:16]$ |
| | $A_{AHB}[16:1]$ | $AD[31:16]$ |
| 32-bit multiplexed | "00" + $A_{AHB}[31:2]$ (right-justified and zero-padded) | $AD[31:0]$ |
| Twin 16-bit multiplexed | $A_{AHB}[25:18]$ | $A[23:16]$ |
| | $A_{AHB}[17:2]$ | $AD[15:0]$ and $AD[31:16]$ |

14.7 External Bus Arbitration

External bus arbitration is provided to allow the EBU to share its external bus with other master devices. This capability allows other external master devices to obtain ownership of the external bus, and to use the bus to access external devices connected to this bus. The scheme provided by the EBU is compatible with other Infineon microcontroller devices and therefore allows the use of such devices as (external bus) masters together with the XMC4[78]00.

*Note: In this section, the term “external master” is used to denote a device which is located on the **external** bus and is capable of generating accesses across the external bus (i.e. is capable of driving the external bus). An external master is not able to access units that are located inside the XMC4[78]00.*

14.7.1 External Bus Modes

The EBU can operate in two bus modes on the external bus:

- Owner Mode
- Hold Mode

When in Owner Mode, the EBU operates as the master of the external bus. In other words, the EBU drives the external bus as required in order to access devices located on the external bus. While the EBU is in Owner Mode it is not possible for any other master to perform any accesses on the external bus.

During Hold Mode, the EBU tri-states the appropriate signal on the external bus in order to allow another external bus master to perform accesses on the external bus (i.e. to allow another master to drive the various external bus signals without contention with EBU).

14.7.2 Arbitration Signals and Parameters

The arbitration scheme consists of an external bus master that is responsible for controlling the allocation of the external bus. This master is referred to as the “Arbiter” within this document. The other external bus master (termed Participant within this document) requests ownership of the bus, and when necessary, from the Arbiter. The EBU can be programmed to operate either as an Arbiter or as a Participant (see [Section 14.7.3](#)). The following three lines are used by the EBU to arbitrate the external bus.

Table 14-16 EBU External Bus Arbitration Signals

| Signal | Direction | Function |
|--------------------------|----------------------|---|
| $\overline{\text{HOLD}}$ | In | $\overline{\text{HOLD}}$ is asserted (low) by an external bus master when the external bus master requests to obtain ownership of the external bus from the EBU. |
| $\overline{\text{HLDA}}$ | In/Out ¹⁾ | $\overline{\text{HLDA}}$ is asserted (low) by the Arbiter to signal that the external bus is available for use by the Participant (i.e. the bus is not being used by the Arbiter). $\overline{\text{HLDA}}$ is sampled by the Participant to detect when it may use the external bus. |
| $\overline{\text{BREQ}}$ | Out | $\overline{\text{BREQ}}$ is asserted (low) by the EBU when the EBU requests to obtain ownership of the external bus. |

1) The direction of this signal depends upon the mode in which the EBU is operating (see [Section 14.7.3](#)).

Two components that are equipped with the EBU arbitration protocol can be directly connected together (without additional external logic) as shown below:

Figure 14-11 Connection of Bus Arbitration Signals

Note: In the example of [Figure 14-11](#), it is possible for the EBU to perform the function of either Arbiter or Participant (or indeed both the Arbiter and Participant may be the EBU).

[Table 14-17](#) lists the programmable parameters for the external bus arbitration.

Table 14-17 External Bus Arbitration Programmable Parameters

| Parameter | Function | Description see |
|-----------------|---|--------------------------------|
| MODCON.ARBMODE | Arbitration mode selection | Section 14.7.3 |
| MODCON.ARBSYNC | Arbitration input signal sampling control | |
| MODCON.EXTLOCK | External bus ownership locking control | |
| MODCON.TIMEOUTC | External bus time-out control | |

14.7.3 Arbitration Modes

The arbitration mode of the EBU can be selected through configuration pins during reset or by programming the MODCON.ARBMODE bit field (see [Section 14.7.3](#)) after reset. Four different modes are available:

- “No Bus” Mode
- “Sole Master” Mode
- “Arbiter” Mode
- “Participant” Mode

14.7.3.1 No Bus Mode

All accesses of the EBU to devices on the external bus are prohibited and will generate an AHB bus error. The EBU operates in Hold Mode all the time.

No Bus Mode is selected by MODCON.ARBMODE = 00_B.

14.7.3.2 Sole Master Mode

In this mode, the EBU must be the only master on the external bus. Therefore no arbitration is necessary and the EBU has access to the external bus at any time. The EBU operates in Owner Mode all the time.

Sole Master Mode is selected by MODCON.ARBMODE = 11_B.

14.7.3.3 Arbiter Mode

The EBU is the default owner of the external bus (e.g. applicable when operating from external memory). Arbitration is performed if an external master (e.g. second CPU) needs to access the external bus.

The EBU is cooperative in relinquishing ownership of the external bus while operating in Arbiter Mode. When the HOLD input is active, the EBU will generate a “retry” in response to any attempt to access the external bus from the internal AHB. However, the EBU is aggressive in regaining ownership of the external bus while operating in Arbiter Mode. The EBU, having yielded ownership of the bus, will always request return of ownership even if there is no EBU external bus access pending.

Arbiter Mode is selected by MODCON.ARBMODE = 01_B.

[Table 14-18](#) and [Figure 14-12](#) show the functionality of the arbitration signals in Arbiter Mode.

Table 14-18 Function of Arbitration Pins in Arbiter Mode

| Pin | Type | Pin Function in Arbiter Mode |
|--------------------------|------|--|
| $\overline{\text{HOLD}}$ | In | In Owner Mode (EBU is the owner of the external bus), a low level at $\overline{\text{HOLD}}$ indicates a request for bus ownership from the external master. In Hold Mode (EBU is not the owner of the external bus), a high level at $\overline{\text{HOLD}}$ indicates that the external master has relinquished bus ownership, which causes the EBU to exit Hold Mode. |
| $\overline{\text{HLDA}}$ | Out | While $\overline{\text{HLDA}}$ is high, the EBU is operating in Owner Mode. A high-to-low transition indicates that the EBU has entered Hold Mode and that the external bus is available to the external master. While $\overline{\text{HLDA}}$ is low, the EBU is operating in Hold Mode. A low-to-high transition indicates that the EBU has exited Hold Mode, and has retaken ownership of the external bus. |
| $\overline{\text{BREQ}}$ | Out | $\overline{\text{BREQ}}$ is high during normal operation. The EBU drives $\overline{\text{BREQ}}$ low for two EBU clock cycles after entering Hold Mode (after asserting $\overline{\text{HLDA}}$ low). $\overline{\text{BREQ}}$ returns high one clock cycle after the EBU has exited Hold Mode (after driving $\overline{\text{HLDA}}$ high). |

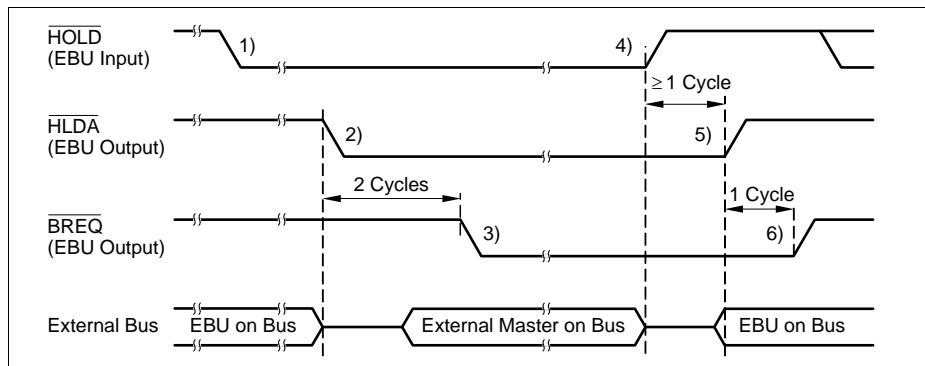

Figure 14-12 Arbitration Sequence with the EBU in Arbiter Mode

In Arbiter Mode, the arbitration sequence starts with the EBU as owner of the external bus.

1. The external master wants to perform an external bus access by asserting a low signal on the $\overline{\text{HOLD}}$ input.

External Bus Unit (EBU)

2. When the EBU is able to release bus ownership, it enters Hold Mode by tri-stating its bus interface lines and drives $\overline{HLDA} = 0$ to indicate that it has released the bus. At this point, the external master is allowed to drive the bus.
3. Two clock (EBU_CLK) cycles minimum after issuing \overline{HLDA} low, the EBU drives \overline{BREQ} low in order to regain bus ownership. This bus request is issued whether or not the EBU has a pending external bus access. However, the external master will ignore this signal until it has finished its bus access. This scheme assures that the external master can perform at least one complete external bus access.
4. When the external master has completed its access, it tri-states its bus interface and sets \overline{HOLD} to inactive (high) level to signal that it has released the bus back to the EBU.
5. When the EBU detects that the bus has been released, it returns \overline{HLDA} to high level and returns to Owner Mode by actively driving the bus interface lines. There is always at least one clock (EBU_CLK) cycle delay from the release of the \overline{HOLD} input to the EBU driving the bus.
6. Finally, the EBU deactivates the \overline{BREQ} signal a minimum of one clock (EBU_CLK) cycle after deactivation of \overline{HLDA} . Now (and not earlier) the external master can generate a new hold request to the EBU.

This sequence assures that the EBU can perform at least one complete bus cycle before it re-enters Hold Mode as a result of a request from the external master.

The conditions that cause change of bus ownership when the EBU is operating in Arbiter Mode are shown in **Figure 14-13**.

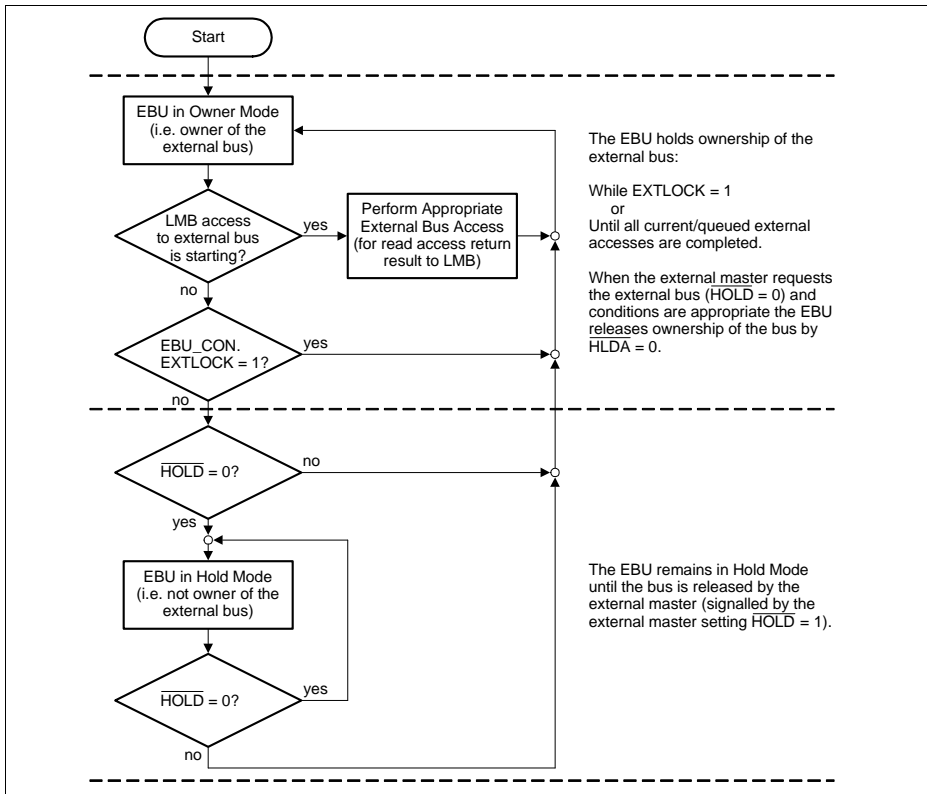

Figure 14-13 Bus Ownership Control in Arbitrator Mode

14.7.3.4 Participant Mode

The EBU tries to gain bus ownership only in case of pending transfers (e.g. when operating from internal memory and performing stores to external memory). While the EBU is not the owner of the external bus (default state), any AHB access to the external bus will be issued with a retry by the EBU. Any such access will, however, cause the EBU to arbitrate for ownership of the external bus.

Once the EBU has gained ownership of the external bus, it will wait until either the occurrence of an external bus access (e.g. the repeat of the request that originally caused the arbitration to occur) or for a programmable time-out (see [Section 14.7.7](#)). Once the first access has been completed, the EBU will continue to accept requests from the AHB bus until the external master asserts $\overline{\text{HOLD}} = 0$. After the external master has asserted $\overline{\text{HOLD}} = 0$, the EBU will respond to subsequent AHB accesses to external memory with a retry, and will return ownership of the bus to the external master once any ongoing transaction is complete.

Note: Regardless of the state of the $\overline{\text{HOLD}}$ input, the EBU will always perform at least one external bus access (assumed that there is not a time-out) before returning ownership of the bus to the external master.

The use of the arbitration signals in Participant Mode is:

Table 14-19 Function of Arbitration Pins in Participant Mode

| Pin | Type | Pin Function in Participant Mode |
|--------------------------|------|--|
| $\overline{\text{HOLD}}$ | In | When the EBU is not in Hold Mode ($\overline{\text{HLDA}} = 0$) and <u>has</u> completely taken over control of the external bus, a low level at $\overline{\text{HOLD}}$ requests the EBU to return to Hold Mode. |
| $\overline{\text{HLDA}}$ | In | When the $\overline{\text{HLDA}}$ signal is high, the EBU is in Hold Mode. When the EBU <u>has</u> requested ownership of the bus by a high-to-low transition at $\overline{\text{HLDA}}$, the EBU is released from Hold Mode. |
| $\overline{\text{BREQ}}$ | Out | $\overline{\text{BREQ}}$ remains high as long as the EBU does not need to access the external bus. When the EBU detects that an external access is required, it sets $\overline{\text{BREQ}} = 0$ and waits for signal $\overline{\text{HLDA}}$ to become low. When the EBU has completed the external bus access (and has re-entered Hold Mode), it will set $\overline{\text{BREQ}} = 1$ to signal that it has relinquished ownership of the external bus. |

Participant Mode arbitration mode is selected by $\text{CON.ARBMODE} = 10_{\text{B}}$.

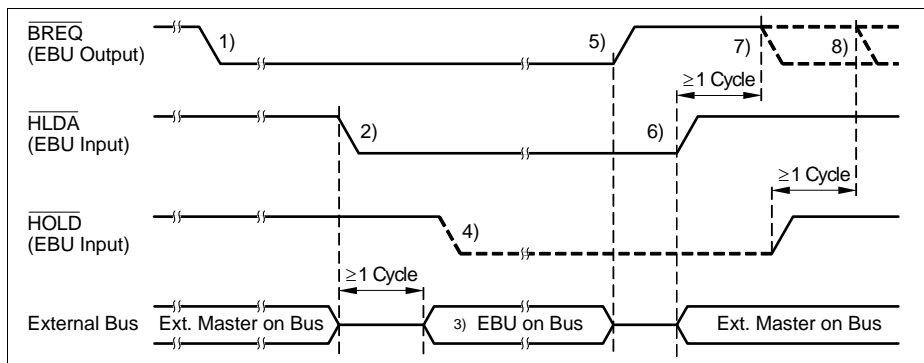

Figure 14-14 Arbitration Sequence with the EBU in Participant Mode

In Participant Mode, the arbitration sequence starts with the EBU in Hold Mode.

1. The EBU detects that it has to perform an external bus access by asserting a low signal on the $\overline{\text{BREQ}}$ output.
2. When the external master is able to release bus ownership, the external master releases the external bus by tri-stating its bus interface lines and drives the $\overline{\text{HLDA}} = 0$.
3. At least one clock (EBU_CLK) cycle after detecting $\overline{\text{HLDA}} = 0$, the EBU will start to drive the external bus.
4. When the EBU is in Owner Mode, the external master may optionally drive $\overline{\text{HOLD}} = 0$ to signal that it wants to regain ownership of the external bus.
5. When the criteria are met for the EBU to release the bus ownership, the EBU enters Hold Mode and drives $\overline{\text{BREQ}} = 1$ output high to signal that it has released the bus.
6. When the external master detects that the EBU has released the bus ($\overline{\text{BREQ}} = 1$), it returns $\overline{\text{HLDA}}$ to high level and takes ownership of the external bus.
7. The EBU will not request ownership of the external bus again ($\overline{\text{BREQ}} = 0$) at least one clock (EBU_CLK) cycle after $\overline{\text{HLDA}}$ has been driven high).
8. In Owner Mode, the EBU will not request ownership of the external bus ($\overline{\text{BREQ}} = 0$) for at least one clock (EBU_CLK) cycle after its $\overline{\text{HOLD}}$ input has been driven high.

The conditions that cause change of bus ownership when the EBU is operating in Participant Mode is shown in [Figure 14-13](#).

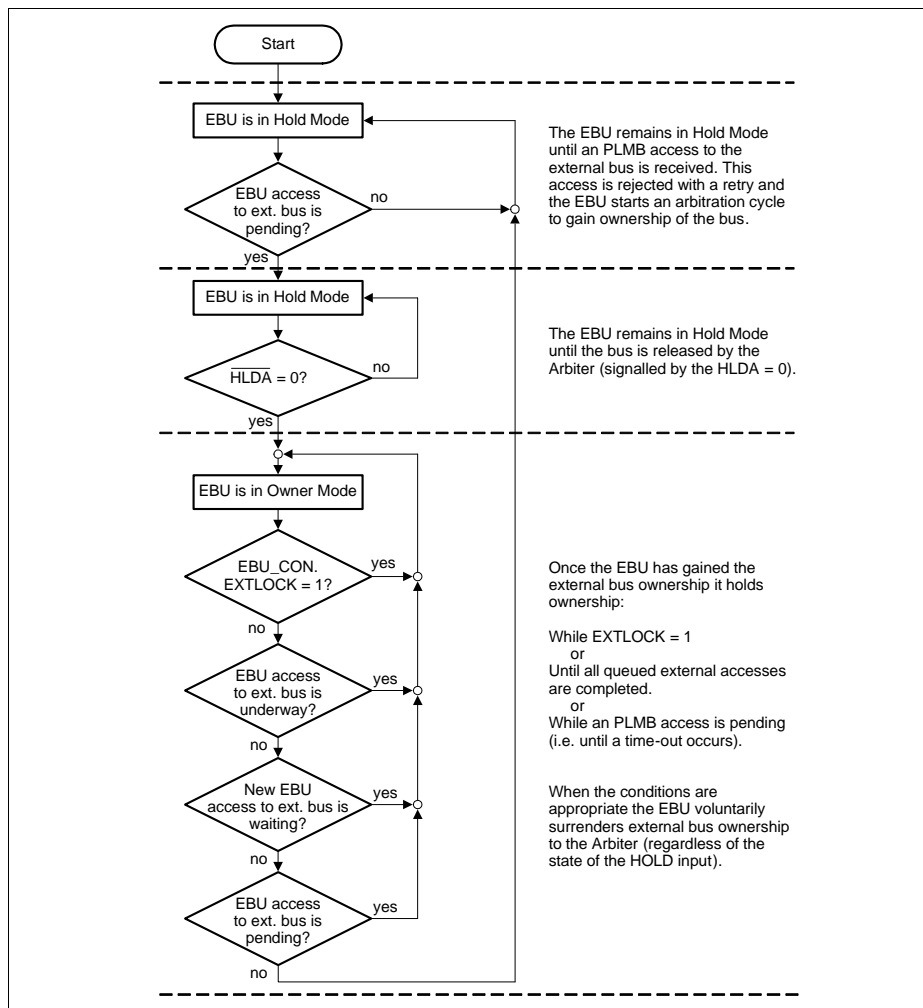

Figure 14-15 Bus Ownership Control with the EBU in Participant Mode

14.7.4 Arbitration Input Signal Sampling

The sampling of the arbitration inputs can be programmed for two modes:

- Synchronous Arbitration
- Asynchronous Arbitration

External Bus Unit (EBU)

When synchronous arbitration signal sampling is selected (ARBSYNC = 0), the arbitration input signals are sampled and evaluated in the same clock cycle. This mode provides the least overhead during arbitration (i.e. when changing bus ownership). The disadvantage is that the input signals must adhere to setup and hold times with respect to EBU_CLK to prevent the propagation of meta-stable signals in the EBU.

When asynchronous arbitration signal sampling is selected (ARBSYNC = 1), the arbitration signals are sampled and then fed to an additional latch to be evaluated in the cycle following that in which they were sampled. This provides the EBU with good immunity to signals changing state at or around the time at which they are sampled. The disadvantage is the introduction of additional latency during arbitration (i.e. when changing bus ownership).

14.7.5 Locking the External Bus

The external bus can be locked to allow the EBU to perform uninterrupted sequences of external bus accesses. The EBU allows two methods of locking the external bus:

- Locked AHB accesses
- Lock bit EXTLOCK

When the EBU has ownership of the external bus and is performing external bus accesses in response to a locked AHB access sequence, the ownership of the external bus will not be relinquished until the locked AHB access sequence has been completed.

When lock bit EXTLOCK = 1, the EBU will hold the ownership of the external bus until EXTLOCK is subsequently cleared. If EXTLOCK is written to 1 while the EBU is the owner of the external bus, the EBU is immediately prevented from responding to requests for the external bus until EXTLOCK is cleared¹⁾. If EXTLOCK is written to 1 while the EBU is not the owner of the external bus, the EBU will immediately attempt to gain ownership. When the EBU gains the ownership of the external bus the next time, the external master is prevented from regaining ownership of the external bus until EXTLOCK is again cleared.

Note: There is no time-out mechanism available for the EXTLOCK bit. When the EBU is owner of the external bus with EXTLOCK bit set, the external master will remain locked off the bus until the EXTLOCK bit is cleared by software.

1) Requests for the external bus already pending when EXTLOCK is set will not be cancelled so the EBU can give up control of the external bus after EXTLOCK is set provided that the request occurs before the EXTLOCK bit is set.

14.7.6 Reaction to an AHB Access to the External Bus

The reaction of the memory controller to an external bus request from an AHB master is controlled as shown in **Figure 14-16**.

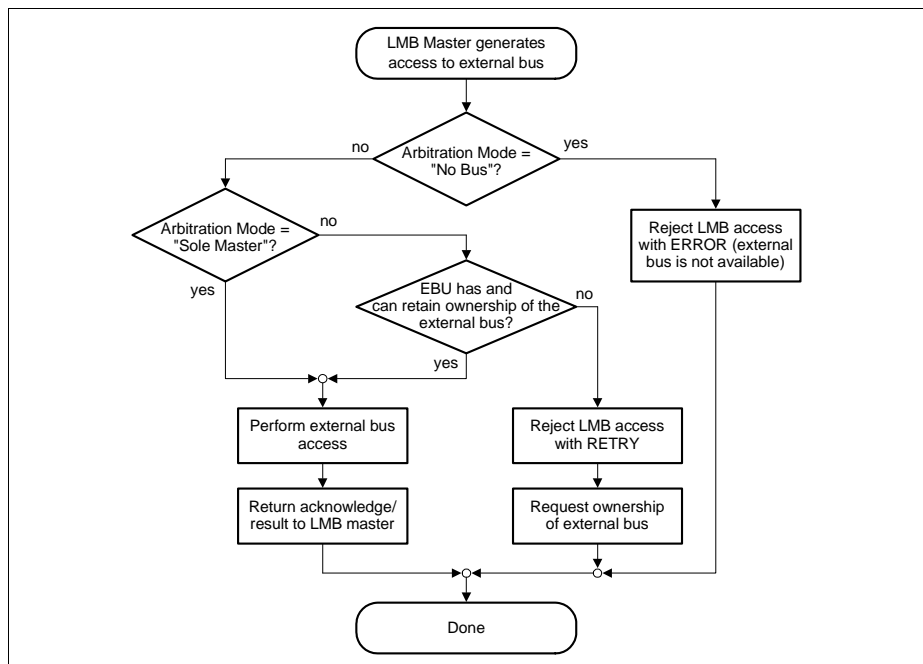

Figure 14-16 EBU Reaction to AHB to External Bus Access

If the EBU is operating in No Bus Mode, it is not possible for an AHB master to access the external bus. For this reason, the EBU generates an AHB error whenever an attempt is made to access the external bus while in No Bus Mode.

If the EBU is operating in Sole Master Mode, it has access to the external bus at all times and as a result it is possible for the EBU to immediately perform the required external bus access.

If the EBU is operating in Arbiter or Participant Modes and receives a request for an external access from an AHB when it is not the owner of the external bus (or is not able to retain ownership of the bus), the request is stalled by taking HRDY low. As shown in **Figure 14-16**, this event also triggers the EBU to arbitrate with the external master in order to attempt to gain ownership of the external bus so that the request can be serviced.

14.7.7 Pending Access Time-Out

The strategy of stalling an AHB access (when the EBU is not the owner of the external bus) as described in the previous section may result in the occurrence of a time-out condition.

To avoid a bus-locking condition, the EBU contains a time-out mechanism. When the EBU has gained ownership of the external bus, it will retain ownership only until a AHB-to-external bus access occurs or a programmable number of EBU_CLK clock cycles has elapsed. If one of these conditions has occurred, the pending access is cancelled and the EBU will continue to arbitrate the external bus in the normal fashion. The desired time-out time (number of EBU_CLK cycles) is programmed using bit field TIMEOUTC. The time-out value can be in the range 1×8 up to 255×8 EBU_CLK clock cycles.

14.7.8 Arbitrating SDRAM control signals

Normally, the memory controller will not surrender control of a connected SDRAM device when arbitrating the external bus. This is because the memory controller needs to keep track of which pages are open in the SDRAM and also because of restrictions on the SDRAM clock.

However, the memory controller can be programmed to tri-state the SDRAM control signals SDCLKO, CKE, $\overline{\text{RAS}}$ and CAS by setting the MODCON.SDTRI bit to 1_B. When this bit is set, SDRAM can be shared with another controller provided certain conditions are met by both memory controllers.

- The SDRAM must be in self refresh mode with the clock safely stopped before ownership of the external bus is transferred. This ensures that all pages in the SDRAM are closed and that the CKE signal is at logic zero. This can be achieved for the memory controller by setting the SDRMREF.AUTOSELR to 1_B.
- The SDRAM CKE input must have a pull down sufficient to ensure that there is a guaranteed logic zero on the input while bus ownership is being transferred.

14.8 Start-Up/Boot Process

The EBU pins will be held in a tri-state condition while the memory controller is in reset. After reset is removed, the EBU will configure itself for “No Bus” mode and wait for configuration by software. The PORTS logic also needs to be configured by software to allow the EBU to control its related pins.

14.9 Standard Access Phases

Accesses to asynchronous devices are composed of a number of standard access phases (according to the type of device and the type of access).

There are six access phases defined:

- Address Phase AP (mandatory for read and write cycles of both device types)

- Command Delay Phase CD (optional)
- Command Phase CP (mandatory for read and write cycles of asynchronous device types)
- Data Hold Phase DH (optional, only applies to write cycles)
- Recovery Phase RP (optional)

Throughout the remainder of this document, a short-hand notation is adopted to represent any clock cycle in any phase. This notation consists of two or three letters followed by a number. The letters identify the access phase within which the clock cycle is located (e.g. AP for Address Phase). The number denotes the number of EBU_CLK clock cycles within the phase (i.e. 1 = first, etc.). In the case of delays that can be extended by external control inputs the lower case letters “e” and “i” are inserted following the two letter phase identifier to differentiate between internally (“i”) and externally (“e”) generated delays. For example, AP2 identifies the second clock in the Address Phase. CPe3 identifies the third clock in the Command Phase which is being extended by external wait-states.

14.9.1 Address Phase (AP)

The Address Phase is mandatory. It always consists of at least one or more EBU_CLK cycles. The phase can be optionally extended to accommodate slower devices.

At the start of the Address Phase, the EBU:

- Selects the device to be accessed by asserting the appropriate \overline{CSx} signal,
- Issues the address which is to be accessed on the address bus,
- Asserts the \overline{ADV} signal low,¹⁾
- Asserts the appropriate \overline{BCx} signals if these are programmed to be asserted with the \overline{CSx} signal,
- At the end of the Address Phase the EBU returns the \overline{ADV} signal to high.

The length (number of EBU_CLK cycles) of the Address Phase is programmed via the BUSAPx.ADDRC bit field parameter.

14.9.2 Address Hold Phase (AH)

The Address Hold Phase is optional. It consists of zero or more EBU_CLK cycles. It is intended to provide hold time for the multiplexed address bits after the \overline{ADV} signal has returned to the inactive state.

At the end of the address hold phase, the multiplexed address can be removed from the bus:

- During a read access, the multiplexed address/data bus can return to the high impedance condition to allow the read data to be driven by the external memory

1) If an active high, ALE, signal is required, the polarity of the \overline{ADV} output can be inverted by setting the ALE field of the MODCON register.

- During a write access, the write data can be driven onto the multiplexed address/data bus

14.9.3 Command Delay Phase (CD)

The Command Delay phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. The CD phase allows for the insertion of a delay between Address Phase (or optional Address Hold phase) and Command Phase(s). This phase accommodates devices that are not fast enough to receive commands immediately after getting the address or multiplexed devices which require a bus turnaround delay on reads.

The length (number of EBU_CLK cycles) of the Command Delay phase is programmed via the BUSAPx.CMDDELAY bit field. This parameter makes it possible to select between zero to seven Command Delay phases.

14.9.4 Command Phase (CP)

The Command Phase is mandatory for asynchronous devices. It always consists of at least one or more EBU_CLK cycles. The phase can optionally be extended to accommodate slower devices.

The length (number of EBU_CLK cycles) of the Command Phase is separately programmable for read and write accesses. Bit field BUSAPx.WAITRDC determines the basic length of Command Phases during read cycles and bit field BUSAPx.WAITWRC determines the basic length of Command Phases during write cycles.

Additionally, when accessing asynchronous devices, a Command Phase can also be extended externally using the WAIT signal when the region being accessed is programmed for external command delay control via bit BUSCONx.WAIT or EMUBC.WAIT.

The Command Phase is further subdivided into:

- CPi (= internally-programmed Command Phase)
- CPe (= externally-prolonged Command Phase, i.e. prolonged by the assertion of the WAIT signal).

At the start of the Command Phase, the EBU:

- Asserts the appropriate control signal RD or RD/WR low according to the access type (read or write),
- Issues the data to be written on the data bus AD[15:0] (in the case of a write cycle),
- Asserts the appropriate BCx low (in the case where BCx is programmed to be asserted with the RD or RD/WR signals).

At the end of the Command Phase during an asynchronous access, the EBU:

- Returns the appropriate control signal RD or RD/WR high according to the type of access type (read or write),

External Bus Unit (EBU)

- Latches the data from the data bus AD[15:0] (in the case of a read cycle),
- Returns the appropriate \overline{BCx} high (in the case where \overline{BCx} is programmed to be asserted with the RD or RD/WR signals).

14.9.5 Data Hold Phase (DH)

The Data Hold phase is optional. This means that it can also be programmed for a length of zero EBU_CLK clock cycles. Furthermore, it is only available for asynchronous write accesses. The Data Hold phase extends the amount of time for which data is still held on the bus after the rising edge of the RD/WR signal occurred. The Data Hold phase is used to accommodate external devices that require a data hold time after the rising edge of the RD/WR signal. The length (number of EBU_CLK cycles) of the Data Hold phase is programmed via the BUSAPx.DATAC bit field.

14.9.6 Burst Phase (BP)

The Burst Phase is mandatory during burst accesses. At the end of the Burst Phase the EBU reads data from the data bus or updates the write data. During a burst access, Burst Phases are repeated as many times as required in order to read or write the required amount of data from or to the external memory device.

The first burst phase of an access will always start on arising edge of BFCLKO. If necessary, the length of the previous phase will be extended to ensure that this happens.

At the end of the last Burst Phase during a burst read access, the EBU:

- Returns the \overline{CSx} signal high,
- Returns the \overline{RD} signal high.

During accesses to Burst Flash devices the length of the Burst Phase must be programmed such that the end of the Burst Phase always coincides with a positive edge of the appropriate BFCLKO (Burst Flash Clock) signal.

A Burst Phase is always at least one clock cycle in length. When BUSRCONx.AGEN is not equal to 1101_B, Demuxed Burst Type External Memory (DDR flash protocol), then the length of each Burst Phase (i.e. the number of EBU_CLK cycles) is derived from the value of the EXTCLK and EXTDATA fields in the BUSAPx register. The length of the burst phase will be either be:

- one period of BFCLKO if EXTDATA is 00_B,
- two periods of BFCLKO if EXTDATA is 01_B.
- four periods of BFCLKO if EXTDATA is 10_B.
- eight periods of BFCLKO if EXTDATA is 11_B.

If BUSCON.AGEN is equal to 1101_B, then the length of the burst phase will be controlled by the EXTDATA field only and the burst phase length will be equal to EXTDATA+1. This allows the external clock period to be an integer multiple of the burst phase length. This will allow support for devices which return data on both edges of the device clock. (e.g. setting EXTDATA to 00_B and EXTCLK to 01_B will support a DDR style flash device)

14.9.7 Recovery Phase (RP)

The Recovery Phase is optional (although for access types which would cause a bus contention a single cycle of recovery is normally forced by the memory controller logic). This means that it can also be programmed for a length of zero EBU_CLK clock cycles. This phase allows the insertion of a delay following an external bus access that delays the start of the Address Phase for the next external bus access. This permits flexible adjustment of the delay between accesses to the various external devices. The following individually programmable delays are provided on a region by region basis for the following conditions:

- Bit fields BUSAPx.RDRECOVC determine the basic length of the Recovery Phase after a read access.
- Bit fields BUSAPx.WRRECOVC determine the basic length of the Recovery Phase after a write access.
- Bit fields BUSAPx.DTACS determine the length (basic number of EBU_CLK clock cycles) of the Recovery Phase after a read/write access of one region that is followed by a read/write access of another region or a read to one region is followed by a write to the same region (BUSRAPx.DTACS) or a write to one region is followed by a read to the same region (BUSWAPx.DTACS).

The EBU implements a “highest wins” algorithm to ensure that the longest applicable recovery delay is always used between consecutive accesses to the external bus. **Table 14-20** shows the scheme for determining this delay for all possible circumstances. For example, if a read access to a region associated with $\overline{CS1}$ is followed by a write to a region associated with $\overline{CS2}$, the delay will be the highest of BUSRAP1.DTACS and BUSRAP1.RDRECOVC. In this case, if BUSRAP1.DTACS is greater than BUSRAP1.RDRECOVC, then the number of recovery cycles between the two accesses is BUSRAP1.DTACS clock cycles (minimum).

Table 14-20 Parameters for Recovery Phase

| Region | Case | | Parameter(s) used to calculate “Highest Wins” Recovery Phase |
|---------------|----------------|-------------|---|
| | Current Access | Next Access | |
| Same CSn | Read | Read | RDRECOVC |
| | Write | Write | WRRECOVC |
| | Read | Write | BUSRAPx.DTACS |
| | Write | Read | BUSWAPx.DTACS |
| Different CSn | Read | Read | BUSRAPx.DTACS, RDRECOVC |
| | Write | Write | BUSWAPx.DTACS, WRRECOVC |
| | Read | Write | BUSRAPx.DTACS, RDRECOVC |
| | Write | Read | BUSWAPx.DTACS, WRRECOVC |

14.10 Asynchronous Read/Write Accesses

Asynchronous read/write access of the EBU support the following features:

- EBU_CLK clock-synchronous signal generation
- Support for 16-bit and 32-bit bus width
 Performing an AHB access with a data width greater than that of the external device automatically triggers a sequence of the appropriate number of external accesses to match the AHB access width.
- Demultiplexed address/data lines
- Programmable access parameters
 - Internal control of command delay cycles
 - External and/or internal control of wait states
 - Variable data hold cycles for write operation (to allow flexible hold time adjustment)
 - Variable inactive/recovery cycles when:
 - Switching between different memory regions (CS),
 - Switching between read and write operations,
 - After each read cycle,
 - After each write cycle.

Software driver routines are required in order to support Nand Flash devices using asynchronous device accesses. A single Nand Flash access sequence is performed by generating the appropriate sequence of discrete asynchronous device accesses in software.

The EBU does not provide support 8-bit bus width. When 8-bit SRAM devices are used, they must be used in pairs to implement a 16-bit wide memory region.

14.10.1 Signal List

The following signals of the EBU are used for asynchronous accesses:

Table 14-21 Asynchronous Mode Signal List

| Signal/Pin | Type | Function |
|---|------|-----------------------------|
| AD[31:0] | I/O | Address/Data bus lines 0-31 |
| A[23:16] | O | Address bus lines 16-23 |
| $\overline{\text{CS}}[3:0]$ | O | Chip select 0-3 |
| $\overline{\text{RD}}$ | O | Read control line |
| $\overline{\text{RD}}/\overline{\text{WR}}$ | O | Write control line |
| $\overline{\text{BC}}[3:0]$ | O | Byte control lines 0-3 |
| $\overline{\text{WAIT}}$ | I | Wait input |

14.10.2 Standard Asynchronous Access Phases

Accesses to asynchronous devices are composed of a subset of the standard access phases which are detailed in [Section 14.9](#). The standard access phases for asynchronous devices are:

- AP: Address Phase (compulsory - see [Section 14.9.1](#))
- CD: Command Delay Phase (optional - see [Section 14.9.3](#))
- CP: Command Phase (compulsory - see [Section 14.9.4](#))
- DH: Data Hold Phase (optional - see [Section 14.9.5](#))
- RP: Recovery Phase (optional - see [Section 14.9.7](#))

14.10.3 Control of $\overline{\text{ADV}}$ & $\overline{\text{CS}}$ Delays During Asynchronous Accesses

For asynchronous accesses, the Memory Controller output signals: $\overline{\text{ADV}}$, $\overline{\text{CS}}$, $\overline{\text{RD}}$, $\overline{\text{RD/WR}}$, $\overline{\text{BC}}$ and AD signals can be delayed with respect to the start of the access phases they are asserted in. The amount by which the signal is delayed depends on the setting of the EXTLOCK field of BUSAPx:-

- When EXTLOCK is set to 00_B, signals are asserted on the negative edge of EBU_CLK (i.e. it is in effect delayed by 1/2 an Memory Controller clock cycle with respect to the other signals).
- When EXTLOCK is not set to 00_B, control signals are asserted on the next positive edge of EBU_CLK (i.e. it is in effect delayed by an EBU_CLK cycle with respect to the other signals).

Memory Controller allows these delays to be removed independently via user programmable bits. The default setting after reset has the delay enabled

Table 14-22 $\overline{\text{ADV}}$ and Chip Select Signal Timing

| EXTLOCK is set to | Delay Disabled ¹⁾ | Delay Enabled |
|---|------------------------------|---------------|
| 00 _B | Start of AP1 | Middle of AP1 |
| 01 _B , 10 _B , 11 _B | Start of AP1 | End of AP1 |

1) See [Figure 14-24](#) for details of this signal positioning.

This function is controlled by the register bits BUSCONx.EBSE for $\overline{\text{ADV}}$ and BUSCONx.ECSE for the other control signals.

Note: If $\overline{\text{CS}}$ is delayed a recovery phase must be used to prevent conflicts between chip selects as the rising edge of chip select will be delayed past the end of the burst phases. Also, for muxed devices, the write data will be delayed into the address phase of the next access, resulting in the valid address being driven one clock after $\overline{\text{ADV}}$ is asserted.

14.10.4 Programmable Parameters

Table 14-23 lists the programmable parameters for asynchronous accesses. These parameters only apply to asynchronous devices when $BUSCONx.AGEN = 000_B$. Note that emulation registers “EMU...” include parameters that control the emulator chip select region (CSEMU output), while “BUS...x” registers include parameters that control the four CS[3:0] chip select regions x. The equivalent registers contain identical bits and bit fields.

Table 14-23 Asynchronous Access Programmable Parameters

| Register | Parameter (Bit/Bit field) | Function |
|----------|------------------------------|--|
| BUSAPx | ADDRC | Number of cycles in address phase |
| | CMDDELAY | Number of programmed command delay cycles. |
| | WAITRDC | Number of programmed wait states for read accesses. |
| | WAITWRC | Number of programmed wait states for write accesses. |
| | DATAAC | Number of Data Hold cycles. |
| BUSAPx | RDRECOVC | Number of minimum recovery cycles after a read access. |
| | WRRECOVC | Number of minimum recovery cycles after a write access. |
| | DTARDWR | Number of minimum recovery cycles between a read access and a write access. |
| | DTACS | Number of minimum recovery cycles when the next access going to a different memory region. |
| BUSCONx | WAIT | External Wait State control (OFF, asynchronous, synchronous) |
| | WAITINV | Reversed polarity at \overline{WAIT} : active low or active high |

14.10.5 Accesses to Multiplexed Devices

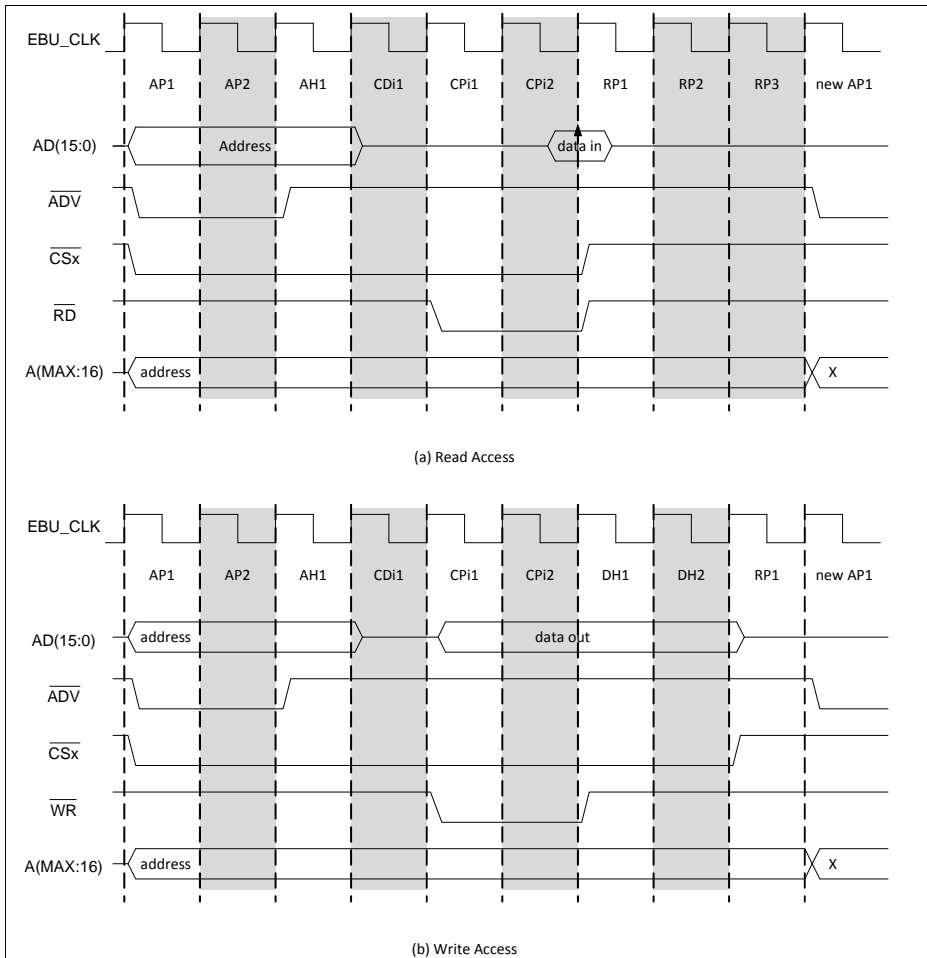

Figure 14-17 Multiplexed External Bus Access Cycles

Figure 14-17 shows an example of a read access to a multiplexed device. This type of access cycle consists of two to six phases as follows:

- Address Phase (compulsory)
- Address Hold Phase (optional)
- Command Delay Phase (optional)

- Command Phase (compulsory)
- Data Hold Phase (optional)
- Recovery Phase (optional)

14.10.6 Dynamic Command Delay and Wait State Insertion

In general, there are two critical phases during asynchronous device accesses. These phases are:

- **Command Delay Phase** (see [Section 14.9.3](#)).
- **Command Phase** (see [Section 14.9.4](#)).

In the EBU, internal length programming for the Command Delay Phase is available via bit fields BUSAPx.CMDDELAY.

The equivalent control capability for the Command Phase is available for bit fields BUSRAPx.WAITRDC and BUSWAPx.WAITWRC.

14.10.6.1 External Extension of the Command Phase by WAIT

The $\overline{\text{WAIT}}$ input can be used to cause the EBU to extend the Command Phase by inserting additional cycles prior to deactivation of the $\overline{\text{RD}}$ and $\text{RD}/\overline{\text{WR}}$ lines. This signal can be programmed separately for each region to be ignored or sampled either synchronously or asynchronously (selected via the BUSCONx.WAIT bit field). Additionally, the polarity of WAIT can be programmed for active low (default after reset) or active high function via bit BUSCONx.WAITINV. The signal will only take effect after the programmed number of Command Phase cycles has passed. This means that the signal can only be used to extend the phase, not to shorten it.

When programmed for synchronous operation, $\overline{\text{WAIT}}$ is sampled on every rising edge of EBU_CLK during the Command Phase. The sampled value is then used on the next rising edge of EBU_CLK to decide whether to prolong the Command Phase or to start the next phase. [Figure 14-18](#) shows an example of $\overline{\text{WAIT}}$ used in Synchronous Mode.

Note: Due to the one-cycle delay in Synchronous Mode between the sampling of the $\overline{\text{WAIT}}$ input and its evaluation by the EBU, the Command Phase must always be programmed to be at least one EBU_CLK cycle (via BUSAPx.WAITRDC or BUSAPx.WAITWRC) in this mode.

When programmed for asynchronous operation, $\overline{\text{WAIT}}$ is also sampled at each rising edge of EBU_CLK during the Command Phase. However, an extra synchronization cycle is inserted prior to the use of the sampled value. This means that the sampled value is not used until the second following rising edge of EBU_CLK. [Figure 14-19](#) shows an example of $\overline{\text{WAIT}}$ used in Asynchronous Mode.

Note: Due to the two-cycle delay in Asynchronous Mode between the sampling of the $\overline{\text{WAIT}}$ input and its evaluation by the EBU, the Command Phase must always be

programmed to be at least two EBU_CLK cycles (via `BUSAPx.WAITRDC` or `BUSAPx.WAITWRC`) in this mode.

Figure 14-18 shows an example of the extension of the Command Phase through the `WAIT` input in synchronous mode:

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the `WAIT` input as low and starts the first cycle of the Command Phase (CPI1 - internally programmed).
- At EBU_CLK edge 2, the EBU samples the `WAIT` input as low and starts an additional Command Phase cycle (CPe2 - externally generated) as a result of the `WAIT` input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 3, the EBU samples the `WAIT` input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the `WAIT` input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 4, as a result of the `WAIT` input sampled as high at point 3, the EBU terminates the Command Phase, reads the input data from D[31:0] and starts the Recovery Phase.

Note: Synchronous operation means that even though access to the device may be asynchronous, the control logic generating the control signals must meet setup and hold time requirements with respect to EBU_CLK.

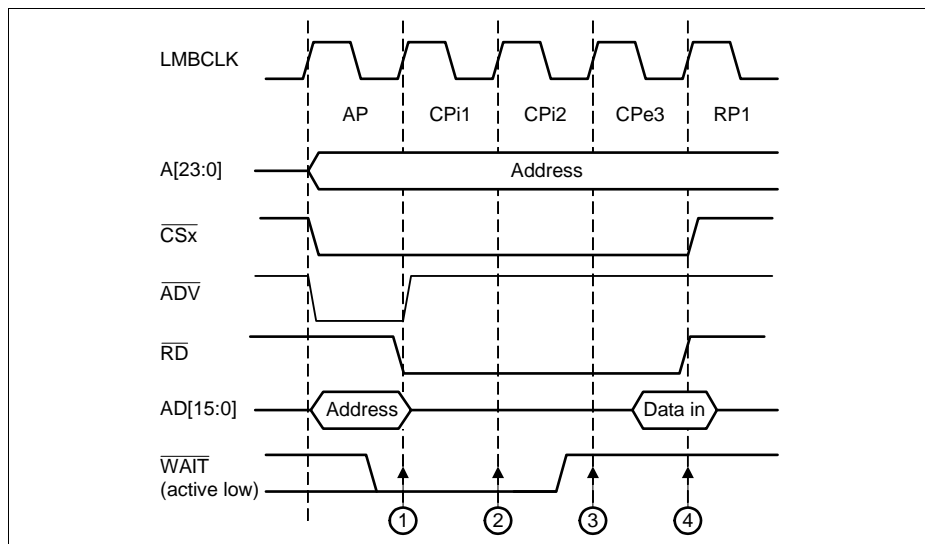

Figure 14-18 External Wait Insertion (Synchronous Mode)

Figure 14-19 shows an example of the extension of the Command Phase through the `WAIT` input in asynchronous mode:

External Bus Unit (EBU)

- At EBU_CLK edge 1 (at the end of the Address Phase), the EBU samples the $\overline{\text{WAIT}}$ input as low and starts the first cycle of the Command Phase (CPI1 - internally programmed).
- At EBU_CLK edge 2, the EBU samples the $\overline{\text{WAIT}}$ input as low and starts the second cycle of the Command Phase (CPI2 - internally programmed).
- At EBU_CLK edge 3, the EBU samples the $\overline{\text{WAIT}}$ input as high and starts an additional Command Phase cycle (CPe3 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 1.
- At EBU_CLK edge 4, the EBU starts an additional Command Phase cycle (CPe4 - externally generated) as a result of the $\overline{\text{WAIT}}$ input sampled as low at EBU_CLK edge 2.
- Finally at EBU_CLK edge 5, as a result of the $\overline{\text{WAIT}}$ input sampled as high at EBU_CLK edge 3, the EBU terminates the Command Phase, reads the input data from AD[15:0], and starts the Recovery Phase.

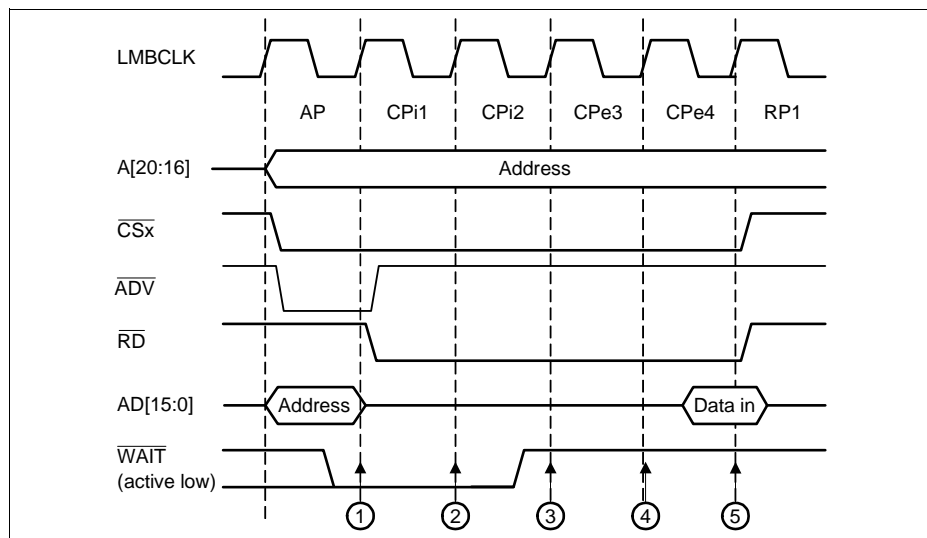

Figure 14-19 External Wait Insertion (Asynchronous Mode)

14.10.7 Interfacing to Nand Flash Devices

The memory controller provides limited support for specific Nand Flash devices. The required access sequences (read or write) are generated by connecting the Nand Flash device as an Asynchronous Device and using appropriate processor generated access sequences to emulate the NAND flash commands. **Figure 14-20** Shows an example of Memory Controller connected to a Nand Flash device:-

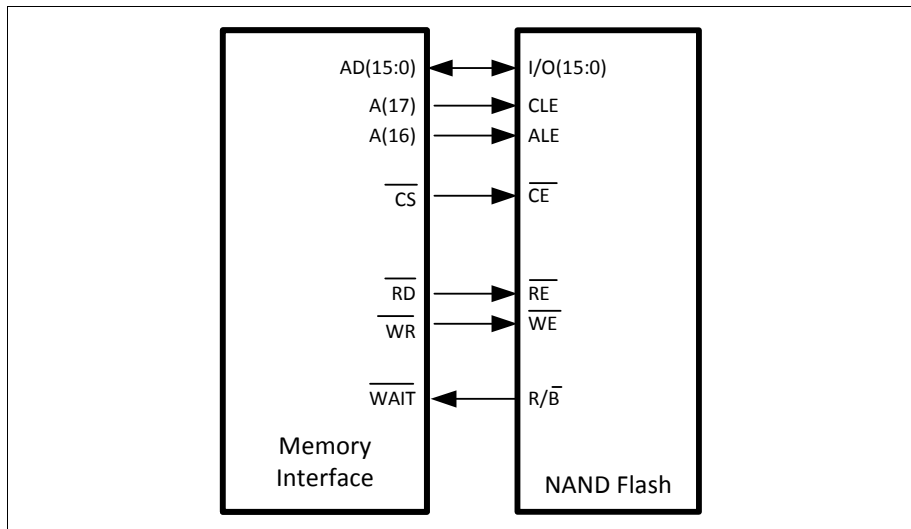

Figure 14-20 Example of interfacing a Nand Flash device to the Memory Controller

The $\overline{R/B}$ input from the NAND flash is connected to the memory controller \overline{WAIT} input and is available as the MODCON.STS. This enables a NAND flash to be driven by software from the processor.

As shown above only two address lines are connected to the Nand Flash, and rather than being connected to address inputs, they are connected to control inputs. This allows access to three “registers” in the Nand Flash as follows:-

Table 14-24 Nand Flash “Registers”

| AHB Address | “Register” | Comment |
|---------------------------|------------------|--|
| Base + 00000 _H | Data Register | Read/Write: Used to read data from and write data to the device. |
| Base + 20000 _H | Address Register | Write only: Used to write the required access address to the device. |
| Base + 40000 _H | Command Register | Write only: Used to write the required command to the device. |

Note: AHB addresses are byte addresses and addresses on the external bus are 16-bit word addresses. Therefore [AHB address(18)]->[external address(17)] and [AHB address(17)]->[external address(16)].

Note that the Memory Controller does not directly support byte wide devices. Writes to 8-bit, NAND Flash devices must therefore be done as 16-bit word writes with the valid byte in the lower part and the upper-byte padded.

14.10.7.1 NAND flash page mode

NAND flash memories are page oriented devices capable of extended read operations with a single setup phase for command signals at the beginning of the access. The asynchronous controller of the Memory Controller will split a large transfer into multiple accesses to external memory but each of these accesses will have the overhead of the initial setup phase. Enabling page mode, using the AGEN field in BUSCONx will cause the standard flow of the controller to be modified as follows:

- For a read, if data remains to be fetched at the end of a command phase, the controller will start a new command delay phase, instead of a new address phase or recovery phase and the address will not be incremented. If BUSRAPx.cmddelay is set to zero, the command delay phase will have a duration of one clock cycle but in this case the command delay phase is mandatory to ensure that the \overline{RD} and RD/\overline{WR} signals return to the high state.
- For a write, if data remains to be written at the end of a data hold phase (or command phase if the length of data hold is zero), the controller will start a new command phase, instead of a new address phase or recovery phase and the address will not be incremented. If BUSWAPx.dataac is set to zero, the data hold phase will have a duration of one clock cycle as in this case the data hold phase is mandatory to ensure that the \overline{RD} and RD/\overline{WR} signals return to the high state. The command phase will be forced to have a minimum length of two clocks.

See [Figure 14-21](#) for example waveforms.

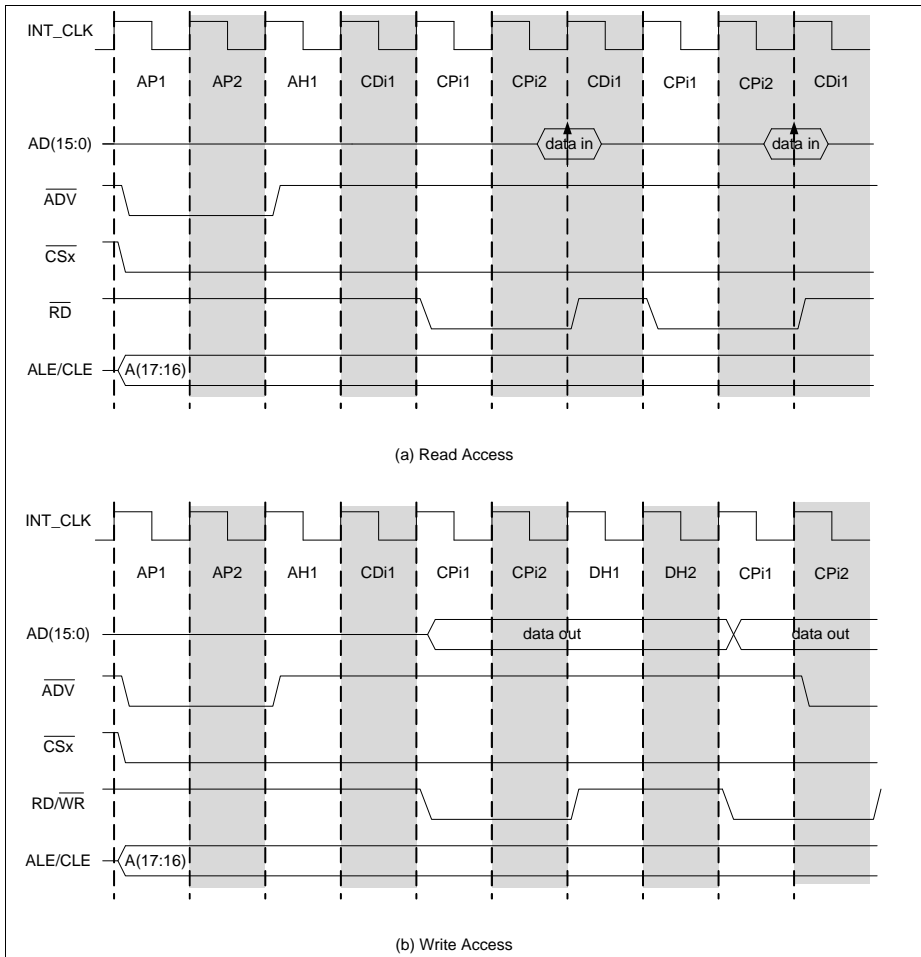

Figure 14-21 NAND Flash Page Mode Accesses

Example Nand Flash Read Sequence

Figure 14-22 shows an example of how the processor can generate a Nand Flash read access sequence given this configuration:-

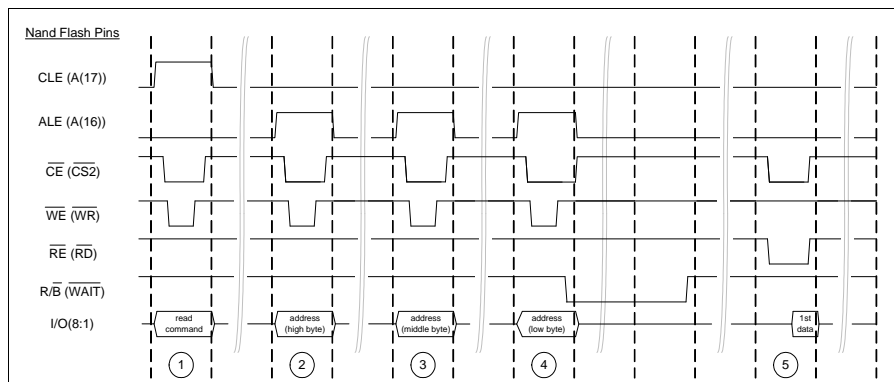

Figure 14-22 Example of an Memory Controller Nand Flash access sequence (read)

1. In the cycle marked '1' in **Figure 14-22** the processor initiates a read sequence by writing the "Read Command" value to address "NAND_FLASH_BASE + 0x40000". This generates a write sequence with CLE (A[17]) driven high and ALE (A[16]) driven low.
2. In the cycle marked '2' the processor loads the most significant byte of the read address by writing to address "NAND_FLASH_BASE + 0x20000". This generates a write sequence with CLE (A[17]) driven low and ALE (A[16]) driven high.
3. In the cycle marked '3' the processor loads the middle significant byte of the read address by repeating the access specified in '2' above.
4. In the cycle marked '4' the processor loads the least significant byte of the read address by repeating the access specified in '2' above. The Nand Flash responds to this final address byte by driving its R/B output low. The processor monitors this pin (using the MODCON.sts bit) until the Nand Flash has completed its internal data fetch.
5. In the cycle marked '5' the processor reads the first byte of data by reading address "NAND_FLASH_BASE + 0x00000". The processor can subsequently read any additionally required (sequential) data bytes by repeating cycle '5'.

Note: A similar scheme can be used to generate write access sequences.

14.11 Synchronous Read/Write Accesses

The Memory Controller is designed to generate waveforms compatible with the burst modes of:

1. INTEL and compatible burst flash devices
2. SPANSION and compatible burst flash devices
3. INFINEON and MICRON cellular RAM

4. Fujitsu and Compatible FCRAM/uTRAM/CosmoRAM
5. Samsung OneNAND burst capable NAND flash and compatible devices
6. M-Systems DiskOnchipG3 and compatible devices
7. GSI SSRAM

Features

The Synchronous Access Controller is primarily designed to perform burst mode read cycles for an external instruction memory and read and write cycles for an external Cellular RAM or FCRAM data memory. In general, the features are:-

- Fully synchronous timing with flexible programmable timing parameters (address cycles, read wait cycles, data cycles).
- Programmable WAIT function.
- Programmable burst (mode and length)
- 16-bit device width.
- 32-bit device width
- Page mode read accesses.
- Resynchronisation of read data to a feedback clock to maximize the frequency of operation (optional).

14.11.1 Signals

The following signals are used for the Burst FLASH interface:-

Table 14-25 Burst Flash Signal List

| Signal | Type | Function |
|-----------------|------|---|
| AD[31:0] | I/O | Multiplexed Address/Data bus |
| <u>RD</u> | O | Read control |
| <u>WR</u> | O | Write control |
| A[23:16] | O | Most Significant Part of Address bus |
| <u>ADV</u> | O | Address valid strobe |
| <u>WAIT</u> | I | Wait/terminate burst control |
| <u>CS</u> [3:0] | O | Chip select |
| BFCLKO | O | Burst FLASH Clock, running equal to, 1/2, 1/3 or 1/4 of the frequency of EBU_CLK. |
| BFCLKI | I | Burst FLASH Clock Feedback. |
| STS | I | Burst FLASH Status Input (Optional, value of <u>WAIT</u> pin available through status register) |

14.11.2 Support for four Burst FLASH device types

Support is provided for a maximum of four different Burst FLASH configurations on the external bus - i.e. one on each external chip select.

Bit-fields BUSCONx.EBSE, BUSCONx.ECSE, BUSCONx.wait, BUSCONx.FBBMSEL, BUSCONx.BFCMSEL and BUSCONx.FETBLEN are used to configure specific characteristics for burst access cycles.

14.11.3 Typical Burst Flash Connection

The figure below shows a typical burst flash connection.

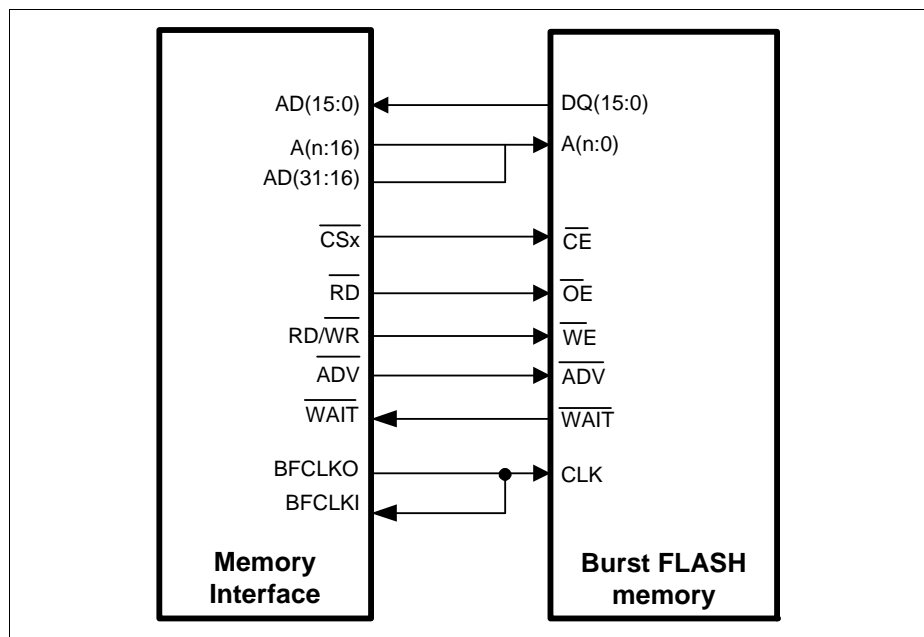

Figure 14-23 Typical Burst Flash Connection

14.11.4 Burst Flash Clock

Since the EBU_CLK can run too fast for clocking Burst FLASH devices, the Memory Controller provides an additional clock source (BFCLKO). This signal is generated by a programmable clock divider driven by EBU_CLK and allows EBU_CLK to BFCLKO ratios of 1:1, 2:1, 3:1 and 4:1 to be selected. The frequency of the signal is determined by bit-field BUSRP.EXTCLOCK. Note that it is possible to set a different clock rate for

synchronous writes to the same device by programming BUSWP.EXTCLOCK to a different value.

If a continuously running BFCLKO is required, then the BUSRCONx.BFCMSEL field can be used to enable an ungated flash clock. This bit is normally set to 1_B in all the BUSRCONx registers after reset. If cleared, the related BUSRAPx.EXTCLOCK field will be used to generate a stable BFCLKO. If multiple BUSRCONx.BFCMSEL fields are set to 0_B, then the highest priority (lowest index) BUSRAPx.EXTCLOCK field will be used.

During a burst access to a synchronous device, BFCLKO will generate correctly aligned clock edges as shown in **Figure 14-24**. The BFCLKO signal is gated to ensure that it is low (zero) at all other times (including asynchronous read/writes of/to synchronous devices). This provides power savings and ensures correct asynchronous accesses to Burst FLASH device(s).

The start of the address and burst phases are synchronized, by hardware, to the rising edge of BFCLKO. Exiting from a phase extended by the WAIT input will also be synchronized to the rising edge of BFCLKO.

Note: The length of the standard accesses phases during Burst FLASH accesses are programmed as a multiple of EBU_CLK independent of the BFCLKO frequency. It is the users responsibility to program the access phases to ensure that the sampling of data by Memory Controller guarantees valid sampling of the data from the Burst FLASH device.

The EBU uses the EBU_CLK clock to generate all external bus access sequences.

Table 14-26 EXTCLOCK to clock ratio mapping

| EXTCLOCK value | BFCLKO divide ratio |
|----------------|---------------------|
| 00 | 1:1 |
| 01 | 1:2 |
| 10 | 1:3 |
| 11 | 1:4 |

Unless documented elsewhere, all outputs to the external bus are generated of the rising edge of EBU_CLK.

The BFCLKO phase is controlled so that control signal changes will normally occur at the rising edge of BFCLKO unless configured otherwise by register settings.

14.11.5 Standard Access Phases

Accesses to burst FLASH devices are composed of a number of “Standard Access Phases” (which are detailed in **Section 14.9**). The Standard Access Phases for Burst FLASH devices are:-

- AP: Address Phase (compulsory - see [Section 14.9.1](#)).
- AH: Address Hold Phase (optional see [Section 14.9.2](#)).
- CD: Command Delay Phase (optional - see [Section 14.9.3](#)).
- CP: Command Phase (compulsory - see [Section 14.9.4](#)).
- BP: Burst Phase (compulsory - see [Section 14.9.6](#)).
- RP: Recovery Phase (optional - see [Section 14.9.7](#)).

Note: During a burst access the Burst Phase (BP) is repeated the required number of times to complete the burst length.

14.11.6 Burst Length Control

The maximum number of valid data samples that can be generated by a flash device in a single read access is set by the BUSCONx.FBBMSEL bit and the BUSCONx.FETBLEN bit field.

The BUSCONx.FBBMSEL bit is used to select Continuous Burst Mode where there is no limit to the number of data samples in a burst read access.

The BUSCONx.FBBMSEL and BUSCONx.FETBLEN bit-fields are used to select the maximum number of data samples in a single access. Where an AHB request exceeds the amount of data that can be fetched or stored by the programmed number of data samples, the EBU will automatically generate the appropriate number of burst accesses to transfer the required amount of data.

Note: Selection of Continuous Burst Mode (by use of the 'FBBMSEL' bit) overrides the maximum burst setting (specified by the FETBLEN bit-field).

14.11.7 Control of \overline{ADV} & \overline{CS} Delays During Burst FLASH Access

By default the Memory Controller output signals: \overline{ADV} , \overline{CS} , \overline{RD} , $\overline{RD}/\overline{WR}$, \overline{BC} and AD signals are delayed with respect to the other clock. The amount by which the signal is delayed depends on the ratio of EBU_CLK to the Burst FLASH clock as follows:-

- When the ratio of EBU_CLK to BFCLKO is 1:1, signals are asserted on the negative edge of EBU_CLK (i.e. it is in effect delayed by 1/2 an Memory Controller clock cycle with respect to the other signals).
- When the ratio of EBU_CLK to BFCLKO is 1:2 or 1:3, control signals are asserted on the next positive edge of EBU_CLK (i.e. it is in effect delayed by an EBU_CLK cycle with respect to the other signals).
- When the ratio of EBU_CLK to BFCLKO is 1:4, control signals are asserted on the negative edge of BFCLK (i.e. it is in effect delayed by two EBU_CLK cycles with respect to the other signals).

The default setting after reset has the delay enabled

If the delay is disabled, then the signals will not be delayed in 1:1 mode (except for \overline{ADV} which will be guaranteed to be after the edge of BFCLKO). In 2:1, 3:1 and 4:1 mode, the

signals will be delayed by half of an EBU_CLK cycle from the start of the cycle in which they are asserted.

Table 14-27 $\overline{\text{ADV}}$ and Chip Select Signal Timing

| EBU_CLK:BFCLKO Ratio | Delay Disabled ¹⁾ | Delay Enabled |
|----------------------|-------------------------------------|---------------|
| 1:1 | Start of AP1 | Middle of AP1 |
| 2:1, 3:1 | half clock cycle after start of AP1 | End of AP1 |
| 4:1 | half clock cycle after start of AP1 | End of AP2 |

1) See [Figure 14-24](#) for details of this signal positioning.

This function is controlled by the register bits BUSCONx.EBSE for the $\overline{\text{ADV}}$ signal and by BUSCON.ECSE for the $\overline{\text{CS}}$, RD/WR and write data signals

Note: If CS is delayed a recovery phase must be used to prevent conflicts between chip selects as the rising edge of chip select will be delayed past the end of the burst phases. Also, for muxed devices, the write data will be delayed into the address phase of the next access, resulting in the valid address being driven one clock after ADV is asserted.

14.11.8 Burst Flash Clock Feedback

The Memory Controller can be configured to use clock feedback to optimize the operating frequency for a given flash device. This is enabled by setting the BUSCONx.FDBKEN bit to one. With this bit enabled the first sampling stage for read data has its own clock (BFCLKFEEDBK). This will be derived from the BFCLKO output by using a second pad (BFCLKI) to monitor the BFCLKO signal after the output pad delay.

Clock feedback should be used whenever possible as it allows the best possible performance

In addition the number of synchronization stages (one or two) used to transfer the read-data into the EBU_CLK domain can also be selected via the EBUCON_BUSAPx.BFSSS bit.

When using two synchronization stages (default) the data is initially resynchronized to BFCLKFEEDBK and then is additionally internally resynchronized to BFCLKO before being passed to the normal logic. In this mode BFCLKFEEDBK can therefore be skewed by almost an entire BFCLK cycle relative to the EBU_CLK clock without losing data integrity. A side effect of using this mode is an increase in data latency of two cycles of BFCLK (compared to not using clock feedback).

When using a single synchronization stage the data is resynchronized to BFCLKFEEDBK before being passed to the normal logic. This provides a compromise

setting for operating frequency and latency for 1:1 clocking mode where the second resynchronisation stage offers no advantage.

Note: If $EBU_CLK:BFCLKO = 1:1$, then the second and third resynchronisation stages have identical clock signals. There is therefore no advantage to having the second resynchronisation stage and it can be bypassed without loss of performance.

As above, a side effect of using this mode is an increase in data latency. In this case addition of one BFCLK cycle (compared to not using clock feedback).

Note: Clock feedback will be automatically disabled for burst writes as the additional latency on the WAIT input cannot be tolerated

14.11.9 Asynchronous Address Phase

As operating frequency increases, it becomes increasingly hard to avoid violating some timing parameters. The asynchronous address phase allows the address to be latched into the flash memory using the ADV signal before the clock is enabled. This is only possible if explicitly allowed by the flash data sheet

If the **BUSCONx.AAP** is set, then the clock will not start until the end of the address hold phase of the access. The rising edge of the clock will always be co-incident with the transition from the address hold phase. If the address hold phase has zero length then the first rising edge of the clock will coincide with the transition from the address phase. If this mode is enabled a recovery phase of one BFCLK period will be enforced at the end of the previous transaction to ensure that the clock has time to turn off before the start of the next access.

Setting this mode for any region will force the clocks on all synchronous accesses to be disabled in the recovery phase. Only one clock pulse will occur during the recovery phase.

AAP mode is incompatible with the continuous clock mode and will be disabled automatically if continuous clocking is enabled by setting any **BUSRCONx.BFCMSEL** bit to 0_B.

14.11.10 Page Mode Support

If page mode support is enabled using the correct setting of the **AGEN** field in **BUSRCONx** or **BUSWCONx** then the address on the dedicated address bus pins, A[23:0], will be incremented at the end of every burst phase and the clock will not run for the duration of the access.

The page size of the attached device should be programmed using the **FETBLEN** and **FBBMSEL** fields of the **BUSCONx** register to ensure that the address is not incremented past the page end of the memory device. 16-bit devices with a page size of 16 words should be configured for continuous burst.

Note: The cache line fill will use an AHB, INCR8 (or WRAP8) transfer. This translates to a 16 word burst for a 16-bit device and is the largest AHB transfer supported by the memory controller as a single transfer on the external bus. The memory controller supports a 16 word burst using the continuous burst setting for FBBMSEL.

Page mode devices do not support WAIT and the relevant **BUSRCONx.WAIT** and **BUSWCONx.WAIT** should be set to b00.

Note: This mode can only be used with devices that have a separate address and data bus. Use with devices with muxed address/data connections will not return correct data

14.11.11 Critical Word First Read Accesses

In the default case, the memory controller will always start a burst at the lowest address possible and wrapping of the burst data is handled internally to the memory controller. However, some burst devices implement a wrapping feature which is compatible with the wrapped bursts used by the processor cache fill requests. If this is the case, there is an advantage to using the wrapping mode in the device as the instruction required by the processor (the critical word) can be fetched first from the external memory.

The mode is enabled by setting the BUSCONx.dba bit for the appropriate region. Once enabled, the memory controller will not align the start address for the burst and the device will be relied on to return data in the correct order. The memory controller must fetch all the data in a single burst. If the transaction is split into multiple accesses on the external bus by use of the FETBLEN field, the issued addresses will be incorrect.

Note: The cache line fill will use an AHB, INCR8 (or WRAP8) transfer. This translates to a 16 word burst for a 16-bit device. The device must therefore support a 16 word wrap setting. A 32-bit memory must support a 8 word wrap setting. The memory controller supports a 16 word burst using the continuous burst setting for FBBMSEL. Other BTR opcodes must not be generated for accesses to the external memory by the system if this mode is enabled, otherwise data corruption will occur.

14.11.12 Example Burst Flash Access Cycle

The figure below shows an example burst flash access.

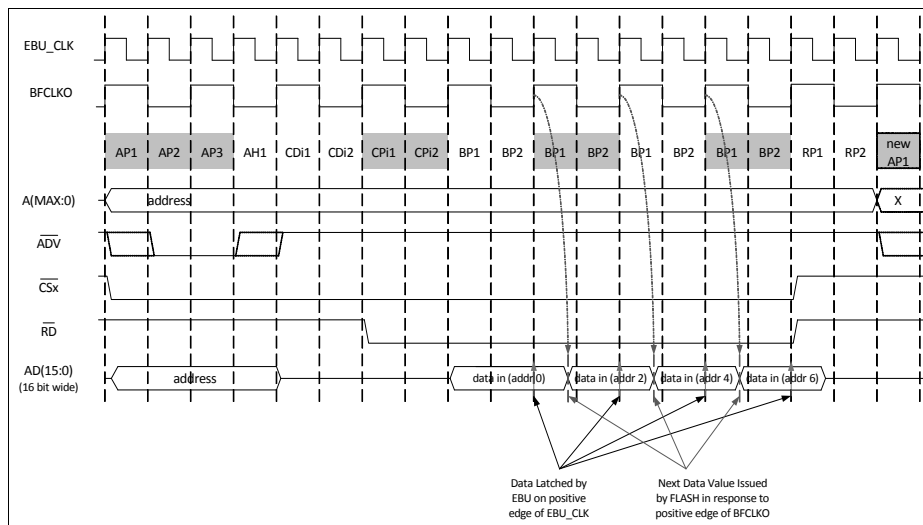

Figure 14-24 Burst FLASH Read without Clock Feedback (burst length of 4)

Notes

1. The start of the cycle is synchronised to a positive edge of the BFCLKO signal
2. The BFCLKO signal is used to clock the Burst FLASH devices
3. BFCLKO to Internal Clock frequency ratio can be programmed to 1:1, 1:2, 1:3 or 1:4. Each BFCLKO positive edge is generated from a positive edge of internal clock
4. Addresses show are "byte addresses"
5. ADV signal positioning is programmable via the EBSE bitfield in the BUSCON registers

Figure 14-24 shows an example of a burst read access (burst length of four) to a Burst FLASH device with WAIT and clock feedback functions disabled.

Programmability of the length of the Address, Command Delay and Command phases allows flexible configuration to meet the initial read access time of a Burst FLASH device.

Data is sampled at the end of each Burst Phase cycle. The Burst Phase is repeated the appropriate number of times for the programmed burst length (programmable for lengths of 1, 2, 4 or 8 via the BUSCONx.FETBLEN bit-field).

Figure 14-24 shows an access cycle with the following settings:-

- Clock Feedback disabled.
- Address Phase length = 3 EBU_CLK cycles (see ADDRRC and [Section 14.9.1](#)).
- Command Delay Phase length = 3 EBU_CLK cycles (see CMDDELAY and [Section 14.9.3](#)).

- Command Phase length = 2 EBU_CLK cycles (see WAITRDC and [Section 14.9.4](#)).
- Burst Phase length = 2 EBU_CLK cycles (see EXTCLK, EXTDATA and [Section 14.9.6](#)).
- Recovery Phase length = 2 EBU_CLK cycles (see [Section 14.9.7](#)).
- Burst Length = 4 (see FETBLEN).
- BFCLKO frequency = 1/2 of EBU_CLK frequency (see EXTCLK).

14.11.13 External Cycle Control via the $\overline{\text{WAIT}}$ Input

Memory Controller provides control of the Burst FLASH device via the $\overline{\text{WAIT}}$ input. This allows Memory Controller to support operation of Burst FLASH while crossing Burst FLASH page boundaries. During a Burst FLASH access the $\overline{\text{WAIT}}$ input operates in one of four modes:-

- Disabled
- Early Wait for Page Load.
- Wait for Page Load.
- Abort and Retry Access.

Selection of the mode in which the $\overline{\text{WAIT}}$ input operates during Burst FLASH reads is selected via the BUSCONx.wait bits.

Note: Selection of "Disabled" via the wait bit-field prevents the $\overline{\text{WAIT}}$ input having any effect on a Burst FLASH access cycle

Wait for Page Load Mode

This mode supports devices which assert a $\overline{\text{WAIT}}$ output for the duration of clock cycles in which the data output by the device is invalid or, alternatively, one clock cycle earlier than the data output is invalid. This includes Intel and AMD Burst FLASH devices (and compatibles) configured for Early Wait Generation Mode (BUSCONX.wait=01_B) and standard wait generation (BUSCONX.wait=10_B).

In operation, the burst flash controller loads a counter with the required number of samples at the start of each burst. At the end of each burst phase, the burst flash controller samples the $\overline{\text{WAIT}}$ input and the data bus at the end of each Burst phase. If $\overline{\text{WAIT}}$ is inactive, the sample is valid, the sample counter is decremented and the sampled data is passed to the datapath of the Memory Controller. This synchronous sampling means that the validity of the sample can not be determined until the clock cycle after the end of the burst phase. The Burst Flash controller will therefore overrun and generate extra burst phases until the sample counter is decremented to zero. Extra data samples returned after the sample counter is zero will be discarded.

The only difference if early wait is used is that the validity of data in burst phase "n" is determined by the value of $\overline{\text{WAIT}}$ in burst phase "n-1".

This mode of operation is compatible with the use of clock feedback as, with feedback enabled, $\overline{\text{WAIT}}$ is fed through the same resynchronisation signals as the data bus. The

only effect on operation is that the number of overrun cycles will increase as the decrementing of the sample counter will be lagged by the resynchronisation stages.

During the initial phases of an access, $\overline{\text{WAIT}}$ is sampled on every edge of EBU_CLK. This is so the first burst phase is working with an accurate value for the WAIT signal. To ensure this is the case, the command phase should be of sufficient length to allow the device to drive $\overline{\text{WAIT}}$ and for the signal to propagate to the controller.

14.11.14 Flash Non-Array Access Support

Several types of flash memories will assert $\overline{\text{WAIT}}$ permanently during an access which is not directed to the memory array. An example of this would be polling the status register to check if a programming operation has completed. If the BUSRCON[3:0].NAA field is set, then an access to the region with AHB A[26] set will proceed as if the appropriate wait field in BUSRCON[3:0] or BUSWCON[3:0] was set to 00_B and $\overline{\text{WAIT}}$ was disabled. When set, this field affects both read and write accesses.

14.11.15 Termination of a Burst Access

A burst read operation is terminated by de-asserting $\overline{\text{CSx}}$ signal followed by the appropriate length Recovery Phase. [Figure 14-25](#) shows an example of termination of a burst access following the read of two locations (i.e. two Burst Phases) from a 16-bit non-multiplexed Burst FLASH device.

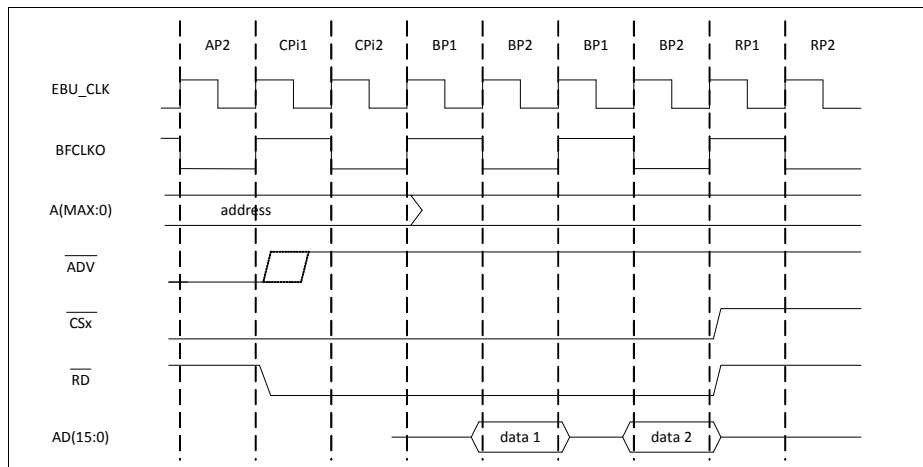

Figure 14-25 Terminating a Burst by de-asserting CS

14.11.16 Burst Flash Device Programming Sequences

Command sequences for some Burst Flash devices must not be interrupted by other read/write operations to the same device. If this applies to an attached device, the AHB bus master initiating the command sequence must ensure that no accesses are allowed from another AHB bus master until the command sequence has completed.

14.11.17 Cellular RAM

Cellular RAM devices have been designed to meet the growing memory and bandwidth demands of modern cellular phone designs. The devices have been designed with a “multi-protocol” interface to allow use of the devices with existing memory interfaces (i.e. by re-use of existing memory protocols). The supported interface protocols supported by Cellular RAM devices are:-

1. SRAM (Asynchronous Read and Write).
2. NOR Flash (Synchronous Burst Read, Asynchronous Write).
3. Synchronous (Synchronous Burst Read and Write).

In principle, when using previous versions of Memory Controller, the first two of the above modes (1 and 2 above) provided Cellular RAM support. For maximum performance, the Memory Controller now supports Synchronous Mode (3 above) for Cellular RAM (Synchronous Burst Read and Write).

As Cellular RAM Synchronous Mode consists of a Burst FLASH compatible Burst Read access, Cellular RAM support has been provided by enhancing the Burst FLASH interface by the inclusion of a Burst Write capability. For this reason Cellular RAM is treated as a special type of Burst FLASH device.

Cellular RAM support is selected by programming the desired region as cellular RAM via the BUSCONx.AGEN bit-field.

Synchronous Read Access

A Synchronous Cellular RAM Burst Read Access is compatible with a Burst FLASH Burst Read Access. As a result preceding sections applying to Burst FLASH devices apply and should be consulted for details of Cellular RAM Burst Read Accesses.

Synchronous Write Access

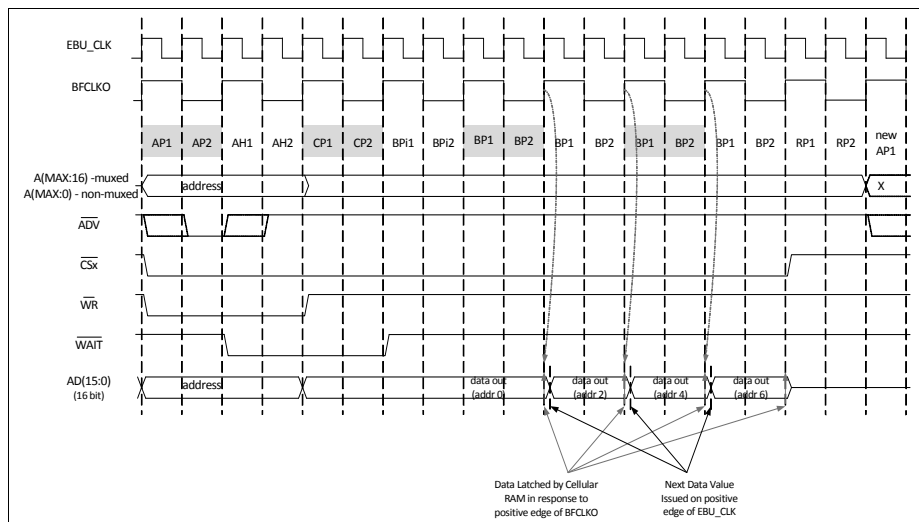

Figure 14-26 Burst Cellular RAM Burst Write Access (burst length of 4)

Notes

1. The start of the cycle is synchronised to a positive edge of the BFCLKO signal
2. The BFCLKO signal is used to clock the Cellular RAM devices
3. BFCLKO to Internal Clock frequency ratio can be programmed to 1:1, 1:2, 1:3 or 1:4. Each BFCLKO positive edge is generated from a positive edge of internal clock
4. Addresses show are "byte addresses"
5. ADV signal positioning is programmable via the EBSE bitfield in the BUSCON registers

Figure 14-26 shows an example of a Cellular RAM burst write access.

Note: **Figure 14-26** shows operation with a BFCLKO to EBU_CLK ratio of 1:2.

The Start of the access cycle is the same as for a Synchronous Read access (see **Figure 14-24**) except that the WR signal is treated as an address phase signal (i.e. it is asserted active during the Address Phase and Address Hold Phase and is then deasserted). See **"Fujitsu FCRAM Support (burst write with WR active during data phase)"** on **Page 14-65** for alternative WR timing during burst write.

The remaining sequence is as follows (with reference to the figure above):-

1. At the positive edge of EBU_CLK labelled as '1' above the first Burst Phase starts. As the state machine is currently in the command phase, the interface samples the WAIT input. This is sampled as "active". By coincidence, in this example, the Cellular

External Bus Unit (EBU)

RAM also deasserts its $\overline{\text{WAIT}}$ output as a response to this clock edge to signal that it will start to take the data from the data bus on the BFCLKO rising clock edge after the next (i.e. the rising edge of BFCLKO labelled as '5' above) - this need not be the case.

2. At the positive edge of EBU_CLK labelled as '2' above the second programmed EBU_CLK period of the Burst Phase begins.
3. At the positive edge of EBU_CLK labelled as '3' above the Burst FLASH evaluates the $\overline{\text{WAIT}}$ sample from '1' above. As this sample was "active" the write data is not updated. As this clock edge is coincident with the end of a burst phase the $\overline{\text{WAIT}}$ input is resampled. The value of this new $\overline{\text{WAIT}}$ sample is "inactive".
4. At the positive edge of EBU_CLK labelled as '5' above the Burst FLASH again evaluates the $\overline{\text{WAIT}}$ sample from '3' above. As this sample was "in-active", and the edge is coincident with the end of a burst phase, the next data value is issued to the AD[15:0] pins and the next Burst Phase is started.

This process continues until all the data is written.

Fujitsu FCRAM Support (burst write with $\overline{\text{WR}}$ active during data phase)

The FCRAM device type can be supported in two ways. Later FCRAMs have a compatibility bit in the device configuration register which programmes the device to expect the $\overline{\text{WR}}$ signal to be active with the address and to be latched with the $\overline{\text{ADV}}$ signal. In this mode, FCRAM can be treated as an Infineon/Micron cellular RAM.

Alternatively, if a write is attempted to a region configured as a burst flash, the memory controller will generate a burst write with the $\overline{\text{WR}}$ signal asserted with the write data. This should be directly compatible with an FCRAM operating in its native mode.

14.11.18 Programmable Parameters

The following table lists the programmable parameters for burst flash accesses. These parameters only apply when the BUSCONx.AGEN parameter for a particular memory region is set for access to synchronous burst devices (page mode or otherwise).

Table 14-28 Burst Flash Access Programmable Parameters

| Parameter | Function | Register |
|-----------|--|----------|
| ADDRC | Number of cycles in Address Phase. | BUSAPx |
| AHOLDC | Number of cycles in Address Hold. | BUSAPx |
| CMDDELAY | Number of programmed Command Delay cycles. | BUSAPx |
| WAITRDC | Number of programmed wait states for read accesses. | BUSAPx |
| WAITWRC | Number of programmed wait states for write accesses. | BUSWAPx |
| EXTDATA | Extended data | BUSAPx |

External Bus Unit (EBU)
Table 14-28 Burst Flash Access Programmable Parameters (cont'd)

| Parameter | Function | Register |
|-----------|---|----------|
| RDRECOVC | Number of minimum recovery cycles after a read access when the next access is to the same region. | BUSRAPx |
| WRRECOVC | Number of minimum recovery cycles after a write access when the next access is to the same region. | BUSWAPx |
| RDDTACS | Number of minimum recovery cycles after a read access when the next access is to a different region. | BUSRAPx |
| WRDTACS | Number of minimum recovery cycles after a write access when the next access is to a different region. | BUSWAPx |
| WAIT | Sampling of $\overline{\text{WAIT}}$ input: OFF, SYNCHRONOUS, ASYNCHRONOUS or WAIT_CELLULAR_RAM | BUSCONx |
| FBMSEL | Flash synchronous burst mode: CONTINUOUS or DEFINED (as in FETBLEN) | BUSCONx |
| FETBLEN | Synchronous burst length: SINGLE, BURST2, BURST4 or BURST8 | BUSCONx |
| BFCMSEL | Flash Clock Mode, continuous or gated | BUSRCONx |
| EXTCLOCK | Frequency of external clock at pin BFCLKO: equal, 1/2, 1/3 or 1/4 of EBU_CLK | BUSCONx |
| EBSE | delay $\overline{\text{ADV}}$ output to improve hold margin | BUSCONx |
| ECSE | delay $\overline{\text{CS}}$, $\overline{\text{WR}}$ and write data outputs to improve hold margin | BUSCONx |
| LOCKCS | enable locked write sequences for this region | BUSWCONx |
| FDBKEN | enable clock feedback to improve read data margins | BUSRCONx |
| BFSSS | disable second pipeline stage for clock feedback | BUSRCONx |
| DBA | disable alignment of read bursts on external bus | BUSRCONx |
| AAP | enable the "asynchronous address phase" mode. | BUSCONx |
| PORTW | memory port width | BUSRCONx |

Note: datac is not used for burst write accesses

14.12 SDRAM Interface

The SDRAM interface supports:-

- 64 MBit (organized as 4 banks x 1M x 16)
- 128 MBit (as 4 banks x 2M x16)
- 256 MBit (as 4 banks x 4M x16) SDRAMs.
- 512 MBit (as 4 banks x 16M x16) SDRAMs.

The Memory Controller can support a single SDRAM region. To enable SDRAM support the **AGEN** fields of a single register pair of BUSRCON and BUSWCON must be set to 1000_b.

*Note: Programming the **AGEN** fields of multiple regions for SDRAM and connecting multiple SDRAMs will result in data corruption as the “page open” tags in the SDRAM controller will be applied indiscriminately to all connected devices.*

14.12.1 Features

- Compatible with mobile PC133/PC100 memories at 100 MHz (if maximum bus load is not exceeded).
- Mobile SDRAM support.
- Multibank support.
- Interleaved access support.
- Support for 64, 128, 256 and 512 MBit SDRAM devices.
- Auto-refresh mode support for power-down mode.
- Data types (16-bit bus): byte and half-word for single reads/writes and half-word for burst reads/writes.
- Power-on/mode-set sequence triggered by AHB write to SDRAM configuration register.
- Programmable refresh rate.
- Programmable timing parameters (row-to-column delay, row-precharge time, mode-register setup time, initialization refresh cycles, refresh periods).

14.12.2 Signal List

The following signals are used for the SDRAM interface:-

Table 14-29 SDRAM Signal List (16-bit support)

| Signal | Type | Function |
|-----------|------|------------------------|
| AD[15:0] | I/O | Data bus |
| AD[31:16] | O | Address bus |
| RD/WR | O | Read and write control |

Table 14-29 SDRAM Signal List (16-bit support) (cont'd)

| Signal | Type | Function |
|----------|------|---|
| CKE | O | Clock enable |
| CS[3:0] | O | Chip select |
| SDCLK0 | O/I | External SDRAM Clock. |
| SDCLKI | I | External SDRAM Clock Feedback |
| RAS | O | Row Address Strobe for SDRAM accesses. |
| CAS | O | Column Address Strobe for SDRAM accesses. |
| DQM[1:0] | O | Data Qualifiers (output on $\overline{BC}[1:0]$) |

14.12.3 External Interface

The external interface can be directly connected to DRAM chips without any glue-logic. Special board layout and timing constraints may apply when additional memory/peripherals (in addition to SDRAM devices) are directly connected to the bus.

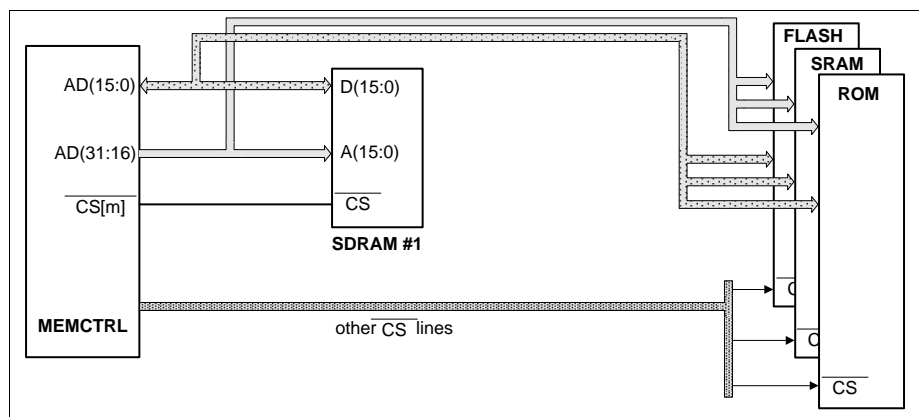

Figure 14-27 Connectivity for 16-bit SDRAM

14.12.4 External Bus Clock Generation

The Memory Controller uses the EBU_CLK clock to generate all external bus access sequences.

SDCLK0 is required by SDRAM memories and the frequency of this output is controlled by the BUSRAP.EXTCLOCK field of the highest priority (lowest region number) region which has BUSRCON.AGEN set to 0b1000 which is the value used to select SDRAM. BUWAP.EXTCLOCK has no effect for SDRAM.

Unless documented elsewhere, all outputs to the external bus are generated of the rising edge of EBU_CLK. The SDCLKO signal (in 1:1 mode) is antiphase to EBU_CLK. This means that the SDRAM memory device sees control signal changes occur on the negative clock edge. The clock generation logic is constructed so that this relationship is maintained for the other clock ratios.

Table 14-30 EXTCLOCK to clock ratio mapping

| EXTCLOCK value | SDCLKO divide ratio |
|----------------|---------------------|
| 00 | 1:1 |
| 01 | 1:2 |
| 10 | 1:4 |
| 11 | 1:4 |

14.12.5 SDRAM Characteristics

SDRAMs are synchronous DRAMs with burst read/write capability which are controlled by a set of commands at the pins CS, RAS, CAS, WE, DQM and A10. As for standard DRAMs, a periodic refresh must be performed.

SDRAM devices are subdivided into “banks”. Each bank is subdivided into a number of “rows¹⁾”. Each row is, in turn, subdivided into a number of “columns”. The number of banks and the size of a row varies from one SDRAM device to another. A specific location (half-word) within a device is specified by supplying a bank, row and column address. Devices supported by Memory Controller must conform to the following criteria:-

- **Number of Banks:** 2 or 4 only.
- **Row Size:** 256, 512 or 1024 only.

SDRAM devices produce high speed data transfer rates by use of the bank and row architecture. When an initial access is made to a specific row within a specific bank then Memory Controller must issue a “row” address to specify which row in which bank is to be accessed. In response to this the SDRAM device loads the entire row to a local (high speed) buffer area. At this point (i.e. when the local buffer associated with a bank contains data from the main SDRAM array) the bank is said to be “open”. Memory Controller then issues a “column” address to specify which location(s) within the row are to be accessed. Subsequent accesses to locations within the same row can then be performed at high speed (with Memory Controller supplying only a column address) since the appropriate data is already contained within the local buffer and there is no requirement for the SDRAM to fetch data from the main SDRAM array. Prior to

1) Previous Memory Controller documentation uses the term “page” to refer to a “row”. Where possible this has been changed to reflect the more commonly used term “row”.

External Bus Unit (EBU)

accessing a location in a different row Memory Controller must issue a “precharge” command so that the local buffer is written back to the main SDRAM array.

An SDRAM device provides a local buffer for each bank within the device, thus it is simultaneously possible for each of the banks to be “open”, this is termed “Multibanking”. Multibanking is supported in order to allow interleaved bank accesses. Comparison of banks is done prior to initiating external memory accesses (see [Section 14.12.13](#)).

14.12.6 Supported SDRAM commands

Table 14-31 lists the supported SDRAM commands, how they are triggered and which signals are activated:-

Table 14-31 Supported SDRAM commands

| Command | Event | CKE (n-1) | CKE (n) | CS | RAS | CAS | RDWR | See Table 14-43 for Memory Controller pins | | | |
|--------------------------|---|-----------|---------|----|-----|-----|------|--|-----|---------------|----------|
| | | | | | | | | A12 ¹⁾ A11 | A10 | A [9:0] | BA [1:0] |
| Device deselect | region not selected | H | - | H | - | - | - | - | - | - | - |
| Nop | idle | H | - | L | H | H | H | - | - | - | - |
| Bank activate | open a closed bank | H | - | L | L | H | H | valid address | | | |
| Read | read access | H | - | L | H | L | H | valid addr | L | valid address | |
| Write | write access | H | - | L | H | L | L | valid addr | L | valid address | |
| Read with autoprecharge | read access | H | - | L | H | L | H | valid addr | H | valid address | |
| Write with autoprecharge | write access | H | - | L | H | L | L | valid addr | H | valid address | |
| Precharge selective | bank or row miss | H | - | L | L | H | L | - | L | - | bank |
| Precharge all | refresh is due or going into power down | H | - | L | L | H | L | - | H | - | - |
| Autorefresh | refresh is due, after precharge all is done | H | H | L | L | L | H | - | - | - | - |

Table 14-31 Supported SDRAM commands (cont'd)

| Command | Event | CKE (n-1) | CKE (n) | CS | RAS | CAS | RD/WR | See Table 14-43 for Memory Controller pins | | | |
|----------------------------|---|-----------|---------|----|-----|-----|-------|--|-----|---------|-------------------------------|
| | | | | | | | | A12 ¹⁾ A11 | A10 | A [9:0] | BA [1:0] |
| Self refresh entry | going into power down after precharge all is done | H | L | L | L | L | H | - | - | - | - |
| Self refresh exit | coming out of power down | L | H | H | - | - | - | - | - | - | - |
| Mode register set | during initialization | H | - | L | L | L | L | valid mode (see register SDRMOD) | | | 00 _B |
| Extended Mode register set | during initialization | H | - | L | L | L | L | valid mode (see register SDRMOD) | | | 10 _B ²⁾ |

1) A12 is required by larger memories

2) 10_B is default value for SDRAM. This can be changed using the SDRMCON.XBA field

14.12.7 SDRAM device size

Memory Controller supports SDRAM's with the following sizes:-

- **Size¹⁾**: 64MBit, 128MBit, 256MBit and 512MBit.

14.12.8 Power Up Sequence

During power-up the SDRAM should be initialized with the proper sequence. This includes the requirement of bringing up the VDD, VDDQ and the stable clock (minimum 200 ms before any accesses to SDRAM) and CS remains inactive.

14.12.9 Initialization sequence

SDRAMs must be initialized before being used. Application of power must be followed by 200 ms pause (timed by software) with a stable clock. Then a Precharge All Banks command must be issued. Following this, the device must go through Auto Refresh Cycles (the number of refresh commands is programmable through **Crfs** in SDRMCON registers and the number of NOP cycles in between is programmable through **Crc**). At the end of it, the Mode Register must be programmed through the address lines. Following that some number of NOP cycles programmable through **Crsc** in SDRMCON.

1) In addition verified support is limited to specific SDRAM device geometries (number of banks and row size). Support for other sizes/geometries may be possible but this has not been verified.

External Bus Unit (EBU)

Note: This sequence will be referred to as a “cold start”, and is necessary when both the memory and the memory controller have just had power applied. Conversely a “warm start” will be required when the memory controller has just been powered up but data has been retained in the external memory by the use of self refresh mode.

The SDRAM controller will power up with the SDRAM clock set to gated mode and CKE high. However until an EBU region is configured for SDRAM by setting BUSRCON.AGEN the SDRAM clock and CKE pins will be allocated for GPIO.

Care must be taken during software configuration of Memory Controller to ensure the correct SDRAM initialization sequence is generated for both cold start and warm start.

The recommended sequence for Memory Controller register initialization after a cold start when using SDRAM devices is as follows:-

1. Write to SDRMREF to set CKE high. (**SELFREF** = ‘1’) but leave all refresh fields at 0 to disable auto refresh. This will maintain CKE high when BUSRCON is written in the next step
2. Write to BUSRCON to define which region has SDRAM connected and the required divide ratio for the SDRAM clock.
3. Write to SDRMCON to configure the controller for the attached SDRAM device(s) and to enable the SDRAM clock. (**SDCMSEL**=0.)
4. All other Memory Controller registers except SDRAM specific registers (i.e. other than those listed below).
5. Wait for 200ms (or the appropriate initialization delay required by the attached device)
6. Write to SDRMOD with the **COLDSTART** bit set to write the mode register values to the SDRAM mode register.
7. Write to SDRMREF to configure refresh rate.

The recommended sequence for Memory Controller register initialization after a warm start when using SDRAM devices is as follows:-

1. Write to BUSCON to define which region has SDRAM connected and the required divide ratio for the SDRAM clock.
2. Write to SDRMCON to configure the controller for the attached SDRAM device(s) and to enable the SDRAM clock. (**SDCMSEL**=0.)
3. Write to SDRMREF to set CKE high. (**SELFREF**=‘1’) but leave all refresh fields at 0 to disable
4. All other Memory Controller registers except SDRAM specific registers (i.e. other than those listed below).
5. Write to SDRMOD with the **COLDSTART** bit cleared to update the mode register values.
6. Write to SDRMREF to configure refresh rate.

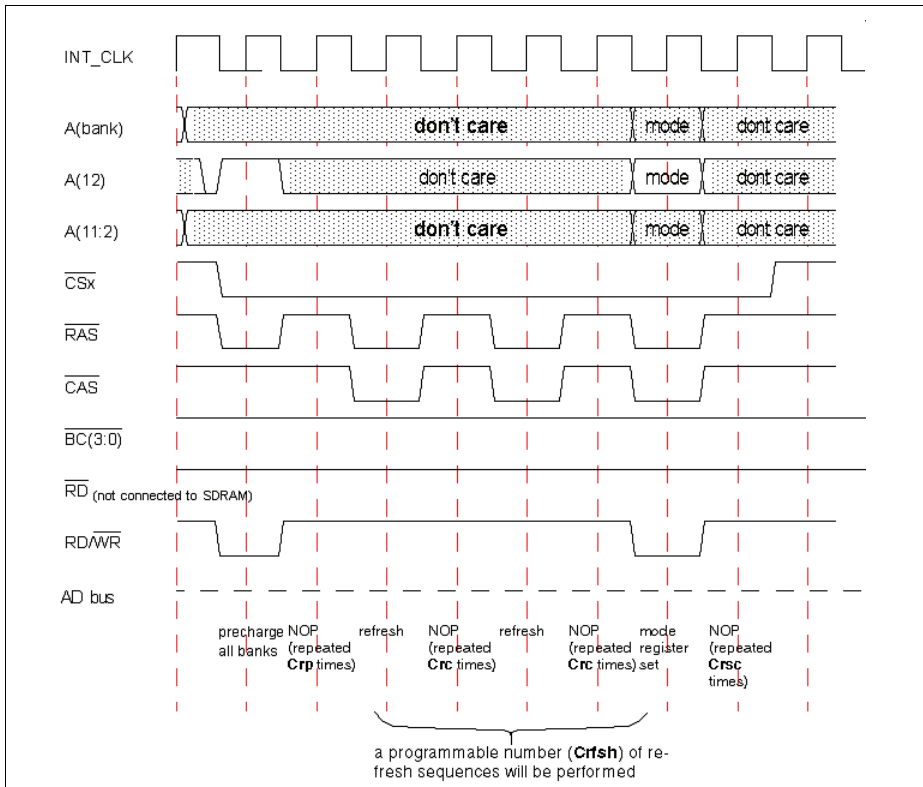

Figure 14-28 SDRAM Initialization

The sequence is triggered by a write to the SDRAM mode register SDRMOD. A region having **AGEN** in BUSCONx set to 1000_B will be configured with the mode from SDRMOD. While this sequence is being executed, **sdrambusy** flag in the SDRMSTAT status register will be set accordingly.

Note: As no other accesses are permitted in the current implementation while the SDRAM initialization sequence is running, it will not be possible to poll the sdrambusy bit at '1' unless there has been a failure in the controller logic.

The user has to make sure that the SDRAM is programmed in the following way:

Table 14-32 SDRAM Mode Register Setting

| Field | Value | Meaning | SDRMODE Position | Corresponding Address Pins |
|----------------|--|---|----------------------|----------------------------|
| Burst length | 100 _B 011 _B 010 _B 001 _B 000 _B | Bursts of length 16 Bursts of length 8 Bursts of length 4 Bursts of length 2 Bursts of length 1 | burstl [2:0] | A[2:0] |
| Burst type | '0' | sequential bursts | btyp [3] | A[3] |
| CAS latency | 001 _B 010 _B 011 _B 1XX _B | Reserved Latency 2 Latency 3 Reserved | caslat [6:4] | A[6:4] |
| Operation Mode | all '0' | Burst read and burst write | opmode [13:7] | A[12:7] |

The Memory Controller uses the **CAS** latency value and burst length to adjust the burst read timing. All other fields have no influence on the Memory Controller, which means only single value is accepted for those fields.

The complete initialization sequence described will only be issued on the first write (since reset) to the SDRMODE register with the **COLDSTART** field set to logic '1'. On subsequent writes with the **COLDSTART** field set to logic '1', the SDRAM device does not need to be initialized, so a simple mode register set command can be issued to refresh the contents of the registers in the SDRAM. A precharge-all command needs to be issued to the SDRAM before this can happen.

An initialization sequence will write to both the mode register and the extended mode register (if the extended mode register has been enabled).

A write to the SDRMODE register with the **COLDSTART** cleared will update the EBU register and will also write to the configuration registers of the SDRAM but will not execute the refresh cycles which are part of the full initialization required at cold start.

14.12.10 Mobile SDRAM Support

Mobile SDRAMs include an "Extended Mode Register". This is accessed using a similar mechanism to the existing PC-133 Mode Register but with an additional select code on the SDRAM device BA pins.

The SDRMODE.**XBA** bits are used to select "Mobile" SDRAM support for each of the SDRAM devices. If this field is non-zero, then the Extended Mode Register will be automatically written during the Initialization phase (immediately after the "standard"

Mode Register write). In addition writes to the Extended Mode Register(s) will be triggered by writes to the SDRMOD register (i.e. whenever the “standard” Mode Register is written). The SDRMOD.**XOPM** bit-field is used to program the value that is to be written to the Extended Mode Register. The SDRMOD.**XBA** bit-field is used to program the logic levels asserted on the device BA[1:0] pins (i.e. to program the specific command used to access the extended mode register).

The **XBA** field contains four bits even though there are only two bank address connections to SDRAM devices. This is because, for normal accesses, the Memory Controller assumes that the SDRAM bank address lines are connected to the least-significant, available address lines (see [Table 14-43](#) for details). This means that the bank address inputs to the SDRAM can be connected to either A[13:12], A[14:13] or A[15:14] depending on the number of rows in the connected SDRAM. The **XBA** field value will be output on A[15:12] and the **XOPM** field will be output on A[11:0] allowing all possible SDRAM connections to be handled correctly.

Note: In order to cater for possible future device variations the Memory Controller allows the user to select the logic levels issued on the BA[1:0] pins during an Extended Mode Register. Care should be taken in programming this bit field since it is possible to generate an unwanted “standard” Mode Register write by use of this bit field.

14.12.11 Burst Accesses

The Memory Controller supports burst lengths of 1, 2, 4, 8 and 16. Bursts of other lengths are supported but are implemented using data-masking. Burst length 16 is currently not supported by available SDRAM memories.

14.12.12 Short Burst Accesses

The Memory Controller can be configured to generate SDRAM bursts lengths of either one, four or eight via the SDRMOD.**BURSTL** bit fields. When configured for burst lengths of four or eight the interface will use data masking to support shorter write accesses. However, when configured for a burst length of one data masking is not used. [Figure 14-29](#) shows how short burst write accesses are handled. During the write access data masking is activated (with zero clock latency) to prevent unwanted write operation. Data masking is activated through the $\overline{\text{BC}}_x$ outputs (connected to $\overline{\text{DQM}}$) during a write cycle.

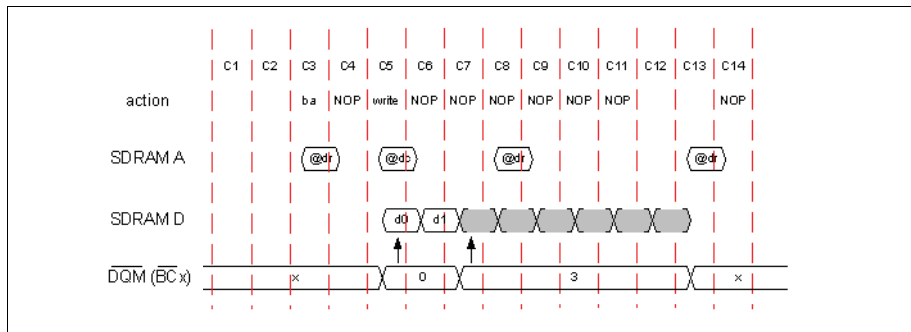

Figure 14-29 Short Burst Write Access through Data Masking

The figure shows how a two beat burst write is translated to an eight beat burst write with data masking. During the first two data cycles (C5 and C6) the $\overline{BC0}$ and $\overline{BC1}$ outputs are driven low to cause the SDRAM device to write the required data. In cycle C7 the $\overline{BC0}$ and $\overline{BC1}$ outputs are driven high to mask subsequent data writes.

14.12.13 Multibanking Operation

The design supports up to 4 banks being simultaneously open for an SDRAM region. This means that for each bank Memory Controller must track the status of the bank ("open" or "closed") and the last row address issued to that bank. This allows the Memory Controller to determine whether each access is a "row hit" or a "row miss".

- A "row hit" means that the access can be serviced by data which is already in the SDRAM local data buffer of the specified bank (i.e. the bank is open and the last row address that was issued to the bank matches the row address for the current access - see [Section 14.12.5](#)). In this case Memory Controller can then proceed with one of the access commands without having to close the specified bank.
- A "row miss" means that the access cannot be serviced from the SDRAM local data buffer (i.e. the specified bank is closed, or the last row address that was issued to the bank does not match the row address of the current access). In this case Memory Controller must close the specified bank and then re-open it with the new row address.

The Memory Controller must be configured so that it can detect "row hits" and "row misses" for different SDRAM configurations (number of banks/row size). This allows the Memory Controller to properly issue the appropriate SDRAM commands to allow up to four SDRAM rows to be kept open simultaneously (i.e. one row open in each bank assuming a four bank device). To perform this Memory Controller maintains two items of data for each bank:-

1. Bank status (1 bit): "open" or "closed" (upon reset all of these bits are preloaded with "closed").

2. Last row address (up to 18 bits).

These two items are referred to as a “bank tag”. In order to maintain these bank tags The Memory Controller must be made aware of:-

- The AHB address range that defines which bank is being accessed.
- The AHB address range that defines which row is being accessed.

These AHB address ranges change according to the geometry of an SDRAM device. **Table 14-43** shows some examples of how banks and rows are determined from the address bits. This configuration is performed by means of the “Bank Mask” and “Row Mask”. For example, if the SDRAM is configured as:-

- 16-bit wide
- 4 banks in the device
- 8192 rows
- row size of 512

The bank to be accessed is determined by bits 24 and 23 of the address (Address[24:23]). Each open bank has an associated open row, and for our example the row tag is Address[22:10].

Each time there is a new AHB request, the address is compared against the appropriate bank tag. After one clock cycle there will be two decisions to make. If the current access is targeted to an SDRAM region(s) then Memory Controller must determine whether the requested address is a row hit or row miss.

14.12.14 Bank Mask

The SDRAMCON.**BANKM** (bank mask) bit-field must be set to the appropriate value to set the AHB address bit range used to detect which bank is being accessed. The value to be written to this bit-field is determined by the device size setting (see “**SDRAM device size**” on Page 14-71) and the number of banks in the device.

- When the device has 2 banks then the **BANKM** value must be set to include the most significant address bit of the AHB address range occupied by the SDRAM device (i.e. region) - see **Table 14-43**.
- When the device has 4 banks then the **BANKM** value must be set to include the most significant two address bits of the AHB address range occupied by the SDRAM device (i.e. region) - see **Table 14-43**.

The following settings should be used:-

Table 14-33 BANKM selection

| BANKM setting | AHB Address Bits used to determine bank hit/miss | Comment |
|----------------------|---|--|
| 0 | none | Reserved - do not use (default after reset). |
| 1 | A _{AHB} [21 to 20] | Bank Size = 8MBit |
| 2 | A _{AHB} [22 to 21] | Bank Size = 16MBit |
| 3 | A _{AHB} [23 to 22] | Bank Size = 32MBit |
| 4 | A _{AHB} [24 to 23] | Bank Size = 64MBit |
| 5 | A _{AHB} [25 to 24] | Bank Size = 128MBit |
| 6 | A _{AHB} [26 to 25] | Bank Size = 256MBit. |
| 7 | A _{AHB} [27 to 26] | not supported for SDRAM/DDRAM |

14.12.15 Row Mask

The SDRMCON.**ROWM** bit-field must be set to the appropriate value to set the AHB address range used to detect row hit/miss. The value to be written to this bit-field is determined by the device size setting (see above), the number of banks in the device and the number of rows in the device.

The following **ROWM** settings should be used:-

Table 14-34 ROWM selection

| ROWM setting | AHB Address Bits used to determine row hit/miss | Comment |
|---------------------|--|---|
| 0 | none | Reserved - do not use (default after reset) (Always generate row miss, may cause invalid SDRAM command sequences). |
| 1 | A _{AHB} [n to 9] | Row size = 256 x 16 bit. |
| 2 | A _{AHB} [n to 10] | Row size = 512 x 16 bit, 256 x 32 bit. |
| 3 | A _{AHB} [n to 11] | Row size = 1024 x 16 bit, 512 x 32 bit. |
| 4 | A _{AHB} [n to 12] | Row size = 1024 x 32 bit. |
| 5 | A _{AHB} [n to 13] | Not appropriate. |
| 6 | Reserved | |
| 7 | Reserved | |

External Bus Unit (EBU)

It can be seen that the **ROWM** bit-field only has an effect on the low-end of the address range used to determine the row address (i.e. for use in comparison of the AHB address with the address stored in the bank tag). The upper end of the comparison is determined by the **BANKM** setting. “n” is therefore (**BANKM**+18)

Decisions over “row hit”

When a row hit occurs, Memory Controller can continue the access operation without updating the stored bank tag.

A row miss unfortunately can result in several other activities.

- If the row miss is due to the bank being closed then Memory Controller does not have to issue a precharge operation but can activate the bank, update the appropriate bank tag to reflect the new bank status (i.e. to “open” with the specified row address) and continue the access operation.
- If the row miss occurs on an open bank then Memory Controller has to close the current bank, (i.e. do a precharge). This is then followed by (re-)activating the bank, updating the appropriate bank tag to reflect the new bank status (i.e. remaining “open” with the new row address) and continuing the access operation.

Table 14-35 lists the activities on a cycle by cycle basis.

Table 14-35 Cycle by cycle activities of multibanking operation

| Cycle n | Cycle n+1 | Cycle n+2 | Cycle n+3 |
|--|--|---|---|
| Comparing the AHB address with the stored bank tags. | row_hit: | | |
| | Continue with read or write command. | not relevant | not relevant |
| | row_miss and bank_open: | | |
| | Issue Precharge to the specific bank and change the bank tag to reflect the new row address. | Insert idle cycles (repeatable) to satisfy t_{RP} . | Continue with bank activate command, etc. |
| | row_miss and bank_closed: | | |
| | Issue Bank Activate to the specific bank and change the bank tag to reflect the new status (“open”) and row address. | not relevant | not relevant |

14.12.16 Banks Precharge

The system is required to precharge a bank under one of the following conditions:

1. When the next access to a bank is to a different row to the previous access within the bank.
2. When an AHB request cannot be completed before the row active time $t_{\text{RAS max}}$ is due, then the bank must explicitly be closed and opened again for the current request. Since $t_{\text{RAS max}}$ (of the order of 100 ms) is usually much greater compared to the refresh period (distributed refresh is in order of 15 ms for 4096 rows) this is generally fulfilled by systematically carrying out refresh to the SDRAMs (see 'd' below).
3. Accompanying a row miss is also naturally a selective bank precharge operation, as mentioned previously.
4. All banks must also be pre-charged, when a refresh cycle is due as explained next. See [Section 14.12.17](#).
5. All banks must also be pre-charged, prior to issuing Self Refresh Entry command. See [Section 14.12.18](#).

Activities in (1) and (3) are carried out as a result of the address comparison explained in [Section 14.12.13](#). Activity (2) and (4) are covered by refresh timer.

14.12.17 Refresh Cycles

It is required within certain time limit that the devices must be refreshed. Prior to being refreshed the devices must be pre-charged as mentioned above.

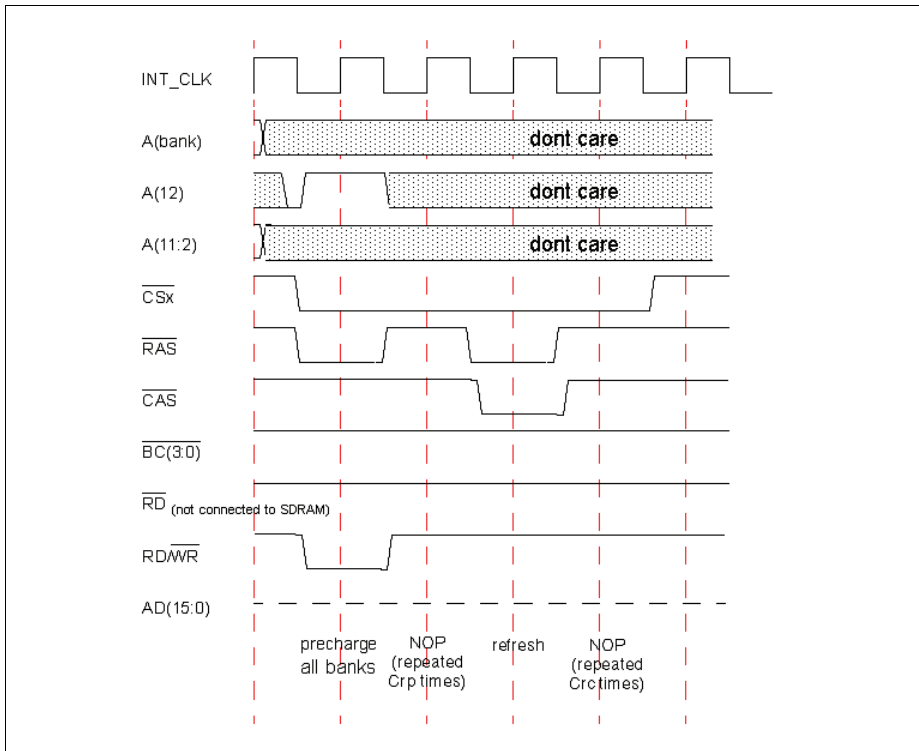

Figure 14-30 SDRAM Refresh

This sequence is periodically triggered by an internal refresh counter with programmable rate set using the **ERFSHC** and **refreshc** fields in the SDRMREF register. These fields are combined to create an eight bit value (**ERFSHC** as MSBs). This value is then multiplied by 64 and used as the number of EBU_CLK cycles between refresh operations being requested.

All SDRAM banks will be pre-charged before the refresh sequence can be started. The specific refresh command being issued is Auto Refresh (CBR) command, in which the device keeps track of the row addresses to be refreshed. The number of this command being issued for each refresh operation is programmable through **refreshr** in SDRMREF.

A refresh request has precedence over a AHB access to SDRAM, i.e. if both occur at the same time the refresh sequence is entered and the AHB access is delayed. A refresh error occurs when a previous refresh request has not been satisfied yet and another refresh request occurs and an error flag (**referr**) in the SDRSTAT status register will be

set accordingly. This error flag can be cleared by writing to SDRMCON respective to the appropriate address region.

14.12.18 Self-Refresh Mode

SDRAM devices provide a Self-Refresh Mode. In this mode the SDRAM automatically performs internal refresh sequences in response to an on-chip timer. Self Refresh Mode is entry command is asserted with RAS, CAS, and CKE low and \overline{WE} high. In Self-Refresh Mode all external control signals except CKE (but including the clock) are disabled). Returning CKE to high enables the clock and initiates the Self-Refresh Mode exit operation. After the exit command, at least one tRC delay is required prior to any access command.

Low Power SDRAMs provide additional power saving features such as:-

Programmable refresh period of the on-chip timer such that the refresh period can be optimized (maximized) by taking the device operating temperature in to account.

Partial array self-refresh mode such that only selected banks will be refreshed. Data written to the non-selected banks will be lost (due to lack of refresh to the bank) after a period defined by t_{REF} .

These additional features are programmed by issuing an Extended Mode Register write (see [Section 14.12.10](#)).

To activate Self-Refresh Mode, software must write '1' to bit **selfren** in SDRMREF register. Memory Controller will then:

1. precharge all the banks, and
2. issue a self refresh command (see [Table 14-31](#)) to all SDRAM devices (regardless whether the device belongs to access type0 or type1).

In completion of this command all SDRAM devices will ignore all inputs but CKE signal. The read-only bit **selfrenst** reflects the status of issuing this command. When the command is completed, power-down can be safely entered. The devices would perform low-current self refresh during the power down. When exiting from power-down and before doing any accesses to SDRAM, software must write '1' to bit **selfrex** in SDRMREF registers. Memory Controller will then assert the CKE signal for all the SDRAM devices to get out of the self-refresh mode. The read-only bit **selfrexst** reflects the completion of this command, upon which an access to SDRAMs can be performed. As the SDRAM controller has CKE set low after reset a '1' must be written to **SELFREX** as part of the initialization sequence to enable CKE. See [Section 14.12.9](#).

Two additional fields affect the method the memory controller uses to exit self refresh.

1. After CKE is taken high (self refresh exit command), a single NOP cycle is generated. The SDRMREF.**ARFSH** field is checked. If set to one a single auto refresh command is output to the memory.
2. After step 1, the SDRMREF.**SELFREX_DLY** field is checked. If the field is non-zero, the value in the field is used to generate a sequence of NOP instructions to the

memory. This allows between 1 and 255 NOPs to be inserted before the device sees a non-null command.

For predictable operation of the device during warm start, both the SDRMREF.**ARFSH** and SDRMREF.**SELFREX_DLY** fields should be set to 0.

14.12.19 SDRAM Addressing Scheme

SDRAM devices use a multiplexed address issued as “bank”, “row” and “column” addresses. The column address determines which location is being accessed within a row. The row address determines which row is being accessed within a bank. Since row sizes can differ from one SDRAM device to another it is necessary to provide a programmable address multiplexing scheme. Selection of the multiplexing scheme is via the SDRMCON.**AWIDTH** bit-field.

The SDRMCON.**AWIDTH** bit-field must be set to the appropriate value to set the address multiplexing (i.e. row/column) to be used to issue the address (and command) to the SDRAM. The value to be written to this bit-field is determined by the device row size.

Table 14-36 Selection of address multiplexing

| AWIDTH | Row size | 16-bit DRAM |
|-----------------|----------------------|-------------------------|
| 00 _B | Reserved; do not use | - |
| 01 _B | 256 words | A _{AHB} [8:0] |
| 10 _B | 512 words | A _{AHB} [9:0] |
| 11 _B | 1024 words | A _{AHB} [10:0] |

When performing byte writes, byte selection is handled via the $\overline{BC}[3:0]$ signals which used to generate DQM signals during an SDRAM access.

Row Address Multiplexing

When a row address is issued (with the above specified settings):-

- The most significant Memory Controller address outputs not required by the SDRAM (A[23:16]) are driven with '0' (zero).
- The least significant sixteen address outputs (AD[31:16]) are driven with the (correctly aligned) row address. This address alignment is performed according to the device row size specified by the **AWIDTH** bit-field (see [Table 14-37](#)).

During the issue of a row address the following address multiplexing is used:-

Table 14-37 Row address generation for 16-bit SDRAM

| AWIDTH | 16-bit, $PORTW=01_B$ Address Generation (at Memory Controller pins) | Comment |
|---------------|---|-------------------------|
| 01_B | $A[23:16] = '0'$ $AD[31:16] = A_{AHB}[24:9]$ | Row size is 256 words. |
| 10_B | $A[23:16] = '0'$ $AD[31:16] = A_{AHB}[25:10]$ | Row size is 512 words. |
| 11_B | $A[23:16] = '0'$ $AD[31:16] = A_{AHB}[26:11]$ | Row size is 1024 words. |

Column Address Multiplexing

When a column address is issued (with the above specified settings):-

- The most significant Memory Controller address outputs ($A[23:16]$) are driven with '0' (zero).
- The least significant ten address outputs ($A[9:0]$) are driven with the (correctly aligned) column address. This address alignment is a one bit right shift of the AHB address if the SDRAM is 16 bit or a two bit shift if the SDRAM is 32 bit.
- Address output ten ($A[10]$) is driven with a "command" value (used by the SDRAM in conjunction with the other control signals to determine which command is to be executed).
- The remaining address outputs ($A[15:11]$) are driven with the appropriate AHB addresses (matching the multiplexing scheme for these pins during a row address shown in [Table 14-37](#) above) to ensure that consistent row selection is achieved (i.e. the row information must be the same regardless of whether a row or column address is being issued).

During the issue of a column address the following address multiplexing is used:-

Table 14-38 Column Address Generation for 16-bit SDRAM

| AWIDTH | 16-bit, $\text{PORTW}=01_B$ Address Generation (at Memory Controller pins) |
|---------------|---|
| 01_B | $A[23:16] = '0'$ $A[15:11] = A_{\text{AHB}}[24:20]$ $A[10] = \text{Command}$ $A[9:0] = A_{\text{AHB}}[10:1]$ |
| 10_B | $A[23:16] = '0'$ $A[15:11] = A_{\text{AHB}}[25:21]$ $A[10] = \text{Command}$ $A[9:0] = A_{\text{AHB}}[10:1]$ |
| 11_B | $A[23:16] = '0'$ $A[15:11] = A_{\text{AHB}}[26:22]$ $A[10] = \text{Command}$ $A[9:0] = A_{\text{AHB}}[10:1]$ |

Bank Address Multiplexing

A bank address is always issued whenever either a row or column address is issued. As a result the Bank Address multiplexing must be the same regardless of whether a row or column address is being issued. From [Table 14-37](#) and [Table 14-38](#) it can be seen that, with the same “awidth” value, the address multiplexing for the address output pins $A[15:11]$ is the same regardless of the type of address being issued.

Note: Memory Controller uses its address output pins to select the bank being accessed (rather than having dedicated Bank Select outputs).

The SDRAM Bank Select pin(s) (BA0 and BA1) must be connected to the appropriate Memory Controller $A[15:11]$ address pins to ensure that they are driven by the appropriate AHB Address (according to the SDRAM geometry). In practice this means that BA0 and BA1 (if present) must be wired to the sequential Memory Controller address outputs above those which are connected to the highest SDRAM address input. As a result, since Memory Controller only supports devices with more rows than columns, this can be determined directly from the number of rows in the device as follows:-

Table 14-39 Bank Address to Memory Controller Address Pin Connection

| Number of Rows | BA0 | BA1 ¹⁾ |
|----------------|-------|-------------------|
| 2048 | A[11] | A[12] |
| 4096 | A[12] | A[13] |
| 8192 | A[13] | A[14] |
| 16384 | A[14] | A[15] |

1) For devices with four banks only.

The following table shows all the multiplexing schemes discussed in the previous sections:

Table 14-40 SDRAM Address Multiplexing Scheme

| Port Width | Address Type | Pin Usage | Mode |
|--|----------------|---|--------------------------|
| 16-bit (PORTW = 01 _B) | column address | EBU A[9:0] = A _{AHB} [10:1] EBU A[10] = CMD | all modes |
| | | EBU A[15:11] = A _{AHB} [26:22] | awidth = 11 _B |
| | | EBU A[15:11] = A _{AHB} [25:21] | awidth = 10 _B |
| | | EBU A[15:11][9:0] = A _{AHB} (24:20) | awidth = 01 _B |
| | row address | EBU A[15:0] = A _{AHB} [26:11] | awidth = 11 _B |
| | | EBU A[15:0] = A _{AHB} [25:10] | awidth = 10 _B |
| | | EBU A[15:0] = A _{AHB} [24:9] | awidth = 01 _B |

The Memory Controller requires the SDRAM to be configured to read / write bursts of length 1, 4 or 8. A burst shorter than the programmed burst (e.g. a single access) can be generated by masking the excess data phases with DQM. Due to the wrap around feature of the SDRAMs a burst has to start at certain addresses to prevent the wrap around (a burst must not cross an address modulo 8*4). This guarantees also that the internal row boundaries of the SDRAMs will not be crossed by any burst access. For bursts that are 16-bit transfers, AHB address A[0] of any burst address must be 0. For bursts that are 32-bit transfers, AHB address A[1:0] of any burst address must be 0. This restriction is currently enforced by the AHB interface logic which will split any unsupported bursts into 32-bit transfers

Table 14-41 16-bit Burst Address Restrictions, A[0] = 0_B

| Burst Length | AHB Address A[4:1] | SDRAM Burst Address Generation |
|---------------------|---------------------------|--|
| 1 | any | single access |
| 2 | XXX0 _B | 0 -> 1 |
| 4 | XX00 _B | 0 -> 1 -> 2 -> 3 |
| 8 | X000 _B | 0 -> 1 -> 2 -> 3 -> 4 -> 5 -> 6 -> 7 |
| 16 | 0000 _B | 0 -> 1 -> 2 -> 3 -> 4 -> 5 -> 6 -> 7 -> 8 -> 9 -> 10 -> 11 -> 12 - 13 -> 14 -> 15 |

Table 14-42 32-bit Burst Address Restrictions, A[1:0] = 00_B

| Burst Length | AHB Address A[4:2] | SDRAM Burst Address Generation |
|---------------------|---------------------------|---------------------------------------|
| 1 | any | single access |
| 2 | XX0 _B | 0 -> 1 |
| 4 | X00 _B | 0 -> 1 -> 2 -> 3 |
| 8 | 000 _B | 0 -> 1 -> 2 -> 3 -> 4 -> 5 -> 6 -> 7 |

The following SDRAM types can be connected to Memory Controller:

Notes to following table

1. *RA: row address*
2. *BA: bank select (MSB of row address)*
3. *CA: column address*
4. *CMD: auto pre-charge command is currently not supported*

Table 14-43 Supported Configurations for 16-bit wide data bus (Part 1)

| SDRAM portw = 01 _B (16-bit) | | | Memory Controller Pins | | | | | | |
|---|------------|-----|------------------------|--------|--------|--------|--------|--------|---------|

14.12.20 Power Down Mode

In order to reduce standby power consumption SDRAM devices provide a Power Down Mode. All banks can optionally be pre-charged before the device enters Power Down mode. Once Power Down mode is initiated by holding CKE low, all receiver circuits except for CLK and CKE are gated off. Power Down mode does not perform any refresh operations, therefore to prevent loss of data, the device must not remain in Power Down mode longer than the Refresh period (tREF) of the device. Exit from this mode is performed by taking CKE “high”. One clock delay is required for power down mode entry and exit.

The Memory Controller provides automatic support for Power Down Mode via the SDRMCON.SDCMSEL (SDRAM clock mode select) bit. When this bit is ‘0’ Power Down mode will not be used and the SDRAM clock will always be present at the SDCLKO pin. When the bit is ‘1’ the device will automatically be placed into Power Down Mode when there are no SDRAM accesses pending. In this case the SDRAM clock will only be present during an Memory Controller-generated SDRAM access (data, refresh, bank/row open etc.) and will be gated off at all other times.

When a refresh is required (at the programmed rate) Memory Controller will automatically take the device out of Power Down Mode, issue the required refresh and will then return the device to Power Down Mode (providing no other SDRAM accesses are pending following the refresh).

By default, the Memory Controller automatically issues the “Pre-Charge All” command sequence and closes all pages prior to entry into Power Down Mode (SDRMCON.PWR_MODE set to 00_B).

The memory controller can also be configured to use the auto-precharge option when running a command (SDRMCON.PWR_MODE set to 01_B) or not to precharge banks at all (active power down mode) with SDRMCON.PWR_MODE set to 10_B.

As a final option, “clock stop” power down mode is also supported. In this case, the clock is disabled between accesses with no preparatory command cycles (SDRMCON.PWR_MODE set to 11_B).

The default reset state of Memory Controller is Power Down Mode enabled (SDRMCON.SDCMSEL = ‘1’).

Note: The programmer should be very careful about the use of this feature as external devices may require this clock to be running in some modes. There are restrictions within the PC-133 specification about when the clock can be disabled, especially if the SDRAMs are operated in self-refresh mode.

A separate field SDRMCON.RES_DLY is provided to allow a delay to be programmed after exiting the power down mode. This field is the delay, in external clock cycles (NOPs), after CKE is taken high on exiting power down mode before another command is permitted.

An additional bit **SDRMCON.CLKDIS** is provided to allow the clock output to be completely disabled. The projected use for this bit is for DDR cold start where **CKE** should be high before the clock is enabled. Setting this bit will allow a self refresh exit to be performed to enable **CKE** without starting the clock.

14.12.21 SDRAM Recovery Phases

A recovery phase can be programmed to increase the minimum gap between an SDRAM access and an access to another connected memory.

For write cycles, the minimum value for this gap is two periods of the internal clock between last command/data driven and the next access starting (for DDR the gap for data is one cycle). This can be increased by setting the **BUSWAP.WRDTACS** field to the required number of internal clock cycles.

For read accesses, the gap can also be increased using the **BUSRAP.RDDTACS** field in the same way. However, the counter is started when the last read command is issued by the controller and the controller does not permit another device to be accessed until two clock cycles after the last data has been read into the read buffers. As the read data is significantly delayed by the latency through the read synchronization logic (minimum latency is 2 clock cycles CAS latency plus 2 clock cycles internal latency), setting this for read accesses is unlikely to make a significant difference unless very large values are used.

14.12.22 Programmable Parameters

The following table lists programmable parameters for SDRAM accesses. These parameters only matter when parameter **AGEN** (in **BUSCONx** registers) for a particular memory region is set to 1000_B.

Table 14-45 SDRAM Access Programmable Parameters

| Parameter | Function | Register |
|--------------------------|--|----------|
| refreshr | Number of refresh commands issued during each refresh operation. | SDRMREF |
| ERFSHC & refreshc | Number of cycles (multiplied by 64) between refresh operations: 0: no refresh needed 1 - 255: refresh period defined | SDRMREF |
| ARFSH | execute auto refresh on exit from self refresh when set to one | SDRMREF |
| SELFREX_DLY | delay after exiting self refresh before permitting any command other than NOP | SDRMREF |
| bankm | To select one pattern for bank mask. | SDRMCON |

Table 14-45 SDRAM Access Programmable Parameters (cont'd)

| Parameter | Function | Register |
|----------------|--|----------|
| rowm | To select one pattern for row mask | SDRMCON |
| Crc | Number of NOP cycles between refresh commands. | SDRMCON |
| Crcd | Number of NOP cycles between a row and column address | SDRMCON |
| awidth | Number of address bits to be used for column address | SDRMCON |
| Crp | Number of NOP cycles after a precharge command | SDRMCON |
| Crsc | Number of NOP cycles after a mode register set command | SDRMCON |
| Crfsh | Number of refresh commands during initialization | SDRMCON |
| Cras | Number of cycles between row activate and a precharge command | SDRMCON |
| opmode | To specify write operation mode: only BURST_WRITE is recognized | SDRMODE |
| caslat | To specify $\overline{\text{CAS}}$ latency: 2 or 3 clocks | SDRMODE |
| btyp | To specify burst operation mode: SEQUENTIAL | SDRMODE |
| burstl | To specify burst length: 1,2,4, 8 or 16 | SDRMODE |
| XOPM | Value to be written to the extended mode register | SDRMODE |
| XBA | Bank Address value to be used for extended mode register write | SDRMODE |
| sdrmbusy | Indicate the busy status of SDRAM | SDRSTAT |
| referr | Indicate a refresh error | SDRSTAT |
| SDERR | Indicates an error has occurred on and SDRAM read | SDRSTAT |
| selfren | To kick-off a self refresh entry command | SDRMREF |
| selfrenst | Status of self refresh entry command | SDRMREF |
| selfrex | To kick-off a self refresh exit command | SDRMREF |
| selfrexst | Status of self refresh exit command | SDRMREF |
| autoselfr | To activate automatic self refresh entry/exit | SDRMREF |
| RDDTACS | recovery time after read command before accessing another region | BUSRAP |

Table 14-45 SDRAM Access Programmable Parameters (cont'd)

| Parameter | Function | Register |
|-----------------|---|----------|
| WRDTACS | recovery time after write command before accessing another region | BUSWAP |
| EXTCLOCK | ratio between internal clock and external memory clock for SDRAM accesses (no effect for DDR. External clock always runs at internal clock frequency) | BUSRAP |

14.13 Debug Behavior

The EBU will lock the external bus arbitration with the EBU owning the external bus to allow the debug system unrestricted access to external memories if the debug suspend input becomes active.

The entry into debug mode is controlled via the halted signal triggered by the CPU.

14.14 Power, Reset and Clock

This section summarizes EBU properties and interaction with the SoC with respect to Power, Reset and Clock.

14.14.1 Clocks

The EBU receives two clocks from the system:

- AHB bus clock: f_{CPU}
- dedicated EBU clock: f_{EBU}

The dedicated EBU clock is allowed to be asynchronous to AHB clock. Therefore it is also possible to run the EBU at a higher clock rate than the AHB. This mode is suitable for higher performance applications.

If higher EBU performance is not required it is recommended to operate the EBU on the AHB bus clock because this will save resynchronisation cycles.

The dedicated EBU clock is described on the SCU (System Control Unit) chapter as f_{EBU} . The AHB bus clock for the EBU block is described on the SCU chapter as f_{CPU} .

It is possible to program the frequency of f_{EBU} via SCU register EBUCLKCR. It can also be enabled or disabled via CLKSET.EBUCEN and CLKR.EBUCDI bit-fields, respectively (see the SCU chapter for a complete description).

14.14.2 Module Reset

The EBU is configured so that its port control lines are going to be in the “No Bus” mode (see [Section 14.7.3.1](#)) during and after reset. In this state the EBU will still take control over the ports but it is not wanted that this state control is applied to the external pins

External Bus Unit (EBU)

until the EBU is explicitly programmed by the user. Therefore the default state of the PORTS logic is so that EBU hardware control is ignored.

The assertion or deassertion of the EBU reset is controlled via the PRSET3.EBU and PRCLR3.EBU bit-fields, respectively (these fields are described on the SCU chapter).

14.14.3 Power

The EBU is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For an explanation about the different power domains, please address the SCU (System Control Unit) chapter.

An internal power down mode for the EBU, can be achieved by disabling the clock provided to it. For this one should disable the clock via the specific SCU bitfield (CLKCLR.EBU CDI).

14.15 System Dependencies

Following features are made available in the different packages.

Table 14-46 Supported operating modes per package

| Mode | 100 pins | 144 pins |
|------------------------------|-----------------|-----------------|
| 16-bit MUX | Yes | Yes |
| Twin 16-bit MUX | No | Yes |
| 32-bit MUX | No | Yes |
| 16-bit DEMUX, Burst Flash | No | Yes |
| 16-bit SDRAM | No | Yes |

14.16 Registers

This section describes the registers and programmable parameters of the EBU. All these registers can be read in User Mode, but can only be written in Supervisor Mode.

All registers are reset by the module reset.

Table 14-47 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| EBU | 5800 8000 _H | 5800 BFFF _H | - |

Access Restrictions

Note: The EBU registers are accessible only through word accesses. Half-word and byte accesses on EBU registers will generate a bus error. Writes to unused address space will not cause an error but be ignored.

14.16.1 General Control Registers

EBU basic enabling and setup is supported by the registers in this section.

CLC

Use this register to enable/disable EBU and to configure various clock settings.

CLC

Clock Control Register (000_H) **Reset Value: 0011 0000_H**

| | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|---------------|-------------|-----------------|--------|------|----------|------|------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

| 0 | | | | | | | | | | | | | | DISS | DISR |
| r | | | | | | | | | | | | | | r | rw |

| Field | Bits | Type | Description |
|-------------|------|------|--|
| DISR | 0 | rw | EBU Disable Request Bit This bit is used for enable/disable control of the EBU. 0 _B EBU disable is not requested 1 _B EBU disable is requested |
| DISS | 1 | r | EBU Disable Status Bit DISS is always read as 0, as accessing the register in the EBU will cause the EBU to be automatically enabled. 0 _B EBU is enabled (default after reset) 1 _B EBU is disabled |
| SYNC | 16 | rw | EBU Clocking Mode 0 _B request EBU to run asynchronously to AHB bus clock and use separate clock source 1 _B request EBU to run synchronously to ARM processor (default after reset) |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|------------------|--------------------|------|--|
| DIV2 | 17 | rw | DIV2 Clocking Mode 0_B standard clocking mode. clock input selected by SYNC bitfield (default after reset). 1_B request EBU to run off AHB bus clock divided by 2. |
| EBUDIV | [19:18] | rw | EBU Clock Divide Ratio 00_B request EBU to run off input clock (default after reset) 01_B request EBU to run off input clock divided by 2 10_B request EBU to run off input clock divided by 3 11_B request EBU to run off input clock divided by 4 |
| SYNCACK | 20 | r | EBU Clocking Mode Status 0_B the EBU is asynchronous to the AHB bus clock and is using a separate clock source 1_B EBU is synchronous to the AHB bus clock (default after reset) |
| DIV2ACK | 21 | r | DIV2 Clocking Mode Status 0_B EBU is using standard clocking mode. clock input selected by SYNC bitfield (default after reset). 1_B EBU is running off AHB bus clock divided by 2. |
| EBUDIVACK | [23:22] | r | EBU Clock Divide Ratio Status 00_B EBU is running off input clock (default after reset) 01_B EBU is running off input clock divided by 2 10_B EBU is running off input clock divided by 3 11_B EBU is running off input clock divided by 4 |
| 0 | [15:2], [31:24] | r | Reserved Read as 0; should be written with 0. |

Note: While the DISR bit is implemented in the EBU, it connects to the standby logic which will disable the clock tree. Standby mode will be exited automatically when an attempt is made to access the EBU. This register can be Endinit-protected after initialization. Writing to this register in this state will cause the EBU to generate an AHB Error.

MODCON

This register is used to configure special bus and timing behaviors. To configure the general EBU operation mode (per region) please use the BUSCONx registers.

MODCON

Modes Configuration Register (004_H)

| Field | Bits | Type | Description |
|--------------|-----------------|------|---|
| ADDIO | [24:16] | rw | Address Pins to GPIO Mode Individual Control Bits for Address Bus Bits 24 down to 16 respectively. 0 _B Address Bit is required for addressing memory 1 _B Address Bit is available for GPIO function |
| ADVIO | 25 | rw | ADV Pin to GPIO Mode Control Bit for the ADV/ALE output 0 _B ADV pin is required for controlling memory 1 _B ADV pin is available for GPIO function |
| 0 | [15:1], [31:26] | r | Reserved Read as 0; should be written with 0. |

14.16.2 Region Control Registers

Each address region is controlled by it's dedicated set of registers listed in this section.

ADDRSEL

Controls the enable and protection settings of a region.

ADDRSELx (x = 0-3)

EBU Address Select Register x (018_H+x*4_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------------|------|------|--|
| REGENAB | 0 | rw | Memory Region Enable 0 _B Memory region is disabled (default after reset). 1 _B Memory region is enabled. |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|----------------|--------|------|---|
| ALTENAB | 1 | rw | Alternate Region Enable 0 _B Memory region is disabled (default after reset). 1 _B Memory region is enabled. |
| WPROT | 2 | rw | Memory Region Write Protect 0 _B Region is enabled for write accesses 1 _B Region is write protected. |
| 0 | [31:3] | r | Reserved Read as 0; should be written with 0. |

BUSRCONx

Configures various READ related settings for a region.

BUSRCONx (x = 0-3)
Bus Read Configuration Register (028_H+x*10_H)

Reset Value: 00D3 0040_H

| | | | | | | | | | | | | | | | |
|-------------|----|----|----|----------|------------|-------------|--------------|--------------|----------------|------------|------------|------------|----------------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| AGEN | | | | 0 | AAP | WAIT | PORTW | BCGEN | WAITINV | DBA | EBS | ECS | | | |
| rw | | | | r | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 0 | | | | | | | | NAA | BFC | FDB | BFS | FBB | FETBLEN | | |
| r | | | | | | | | rw | rw | rw | rw | rw | rw | | |

| Field | Bits | Type | Description |
|----------------|-------|------|---|
| FETBLEN | [2:0] | rw | Burst Length for Synchronous Burst Defines maximum number of burst data cycles which are executed by Memory Controller during a burst access to a Synchronous Burst device. 000 _B 1 data access (default after reset). 001 _B 2 data accesses. 010 _B 4 data accesses. 011 _B 8 data accesses. Others: Reserved |

| Field | Bits | Type | Description |
|----------------|------|------|--|
| FBBMSEL | 3 | rw | Synchronous burst buffer mode select 0_B Burst buffer length defined by value in FETBLEN (default after reset). 1_B Continuous mode. All data required for transaction is transferred in a single burst. |
| BFSSS | 4 | rw | Read Single Stage Synchronization: The second read-data synchronization stage in the pad-logic can be bypassed. Reduces access latency at the expense of the maximum achievable operating frequency. 0_B Two stages of synchronization used. (maximum margin) 1_B One stage of synchronization used. (minimum latency) |
| FDBKEN | 5 | rw | Burst FLASH Clock Feedback Enable 0_B BFCLK feedback not used. 1_B Incoming data and control signals (from the Burst FLASH device) are re-synchronized to the BFCLKI input. |
| BFCMSEL | 6 | rw | Burst Flash Clock Mode Select 0_B Burst Flash Clock runs continuously with values selected by this register 1_B Burst Flash Clock is disabled between accesses |
| NAA | 7 | rw | Enable flash non-array access workaround set to logic one to enable workaround when region is accessed with address bit 28 set. See Section 14.11.14 |
| ECSE | 16 | rw | Early Chip Select for Synchronous Burst 0_B CS is delayed. 1_B CS is not delayed. <i>Note: (see Section 14.10.3 and Section 14.11.7)</i> |
| EBSE | 17 | rw | Early Burst Signal Enable for Synchronous Burst 0_B ADV is delayed. 1_B ADV is not delayed. <i>Note: (see Section 14.10.3 and Section 14.11.7)</i> |

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| DBA | 18 | rw | Disable Burst Address Wrapping 0 _B Memory Controller automatically re-aligns any non-aligned synchronous burst access so that data can be fetched from the device in a single burst transaction. 1 _B Memory Controller always starts any burst access to a synchronous burst device at the address specified by the AHB request. Any required address wrapping must be automatically provided by the Burst FLASH device. <i>Note: Care must be taken with the use of this feature. The Burst capable device must be programmed to wrap at the appropriate address boundary prior to selection of this mode. Section 14.11.11</i> |
| WAITINV | 19 | rw | Reversed polarity at WAIT 0 _B OFF , input at WAIT pin is active low (default after reset). 1 _B Polarity reversed , input at WAIT pin is active high. <i>Note: This bit has no effect when using Burst FLASH Data Handshake Mode</i> |
| BCGEN | [21:20] | rw | Byte Control Signal Control This bit field selects the timing mode of the byte control signals. 00 _B Byte control signals follow chip select timing. 01 _B Byte control signals follow control signal timing (RD, RD/WR) (default after reset). 10 _B Byte control signals follow write enable signal timing (RD/WR only). 11 _B Reserved. |
| PORTW | [23:22] | rw | Device Addressing Mode See Table 14-12 and Table 14-14 |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|-------------|---------------|------|---|
| WAIT | [25:24] | rw | External Wait Control Function of the WAIT input. This is specific to the device type (i.e. the AGEN field). Details for Asynchronous (ASYNC) Devices see Section 14.10.6.1 Details for Synchronous Burst (SYNC) Devices see Section 14.11.13 0 _D OFF (default after reset). 1 _D ASYNC: Asynchronous input at WAIT. SYNC: Wait for page load (Early WAIT). 2 _D ASYNC: Synchronous input at WAIT. SYNC: Wait for page load (WAIT with data). 3 _D ASYNC: Reserved. SYNC: Abort and retry access. |
| AAP | 26 | rw | Asynchronous Address phase: Enables an access mode for synchronous memories where the clock is not started until after the address hold phase. 0 _B Clock is enabled at beginning of access. 1 _B Clock is enabled at after address phase. |
| AGEN | [31:28] | rw | Device Type for Region See Section 14.6.3 |
| 0 | [15:8], 27 | r | Reserved Read as 0; should be written with 0. |

BUSWCONx

Configures various WRITE related settings for a region.

BUSWCONx (x = 0-3)

EBU Bus Write Configuration Register(030_H+x*10_H)

Reset Value: 00D3 0000_H

| | | | | | | | | | | | | | | | |

| r | | | | | | | | r | r | | | rw | rw | | |

| Field | Bits | Type | Description |
|---------|-------|------|---|
| FETBLEN | [2:0] | rw | Burst Length for Synchronous Burst Defines maximum number of burst data cycles which are executed by Memory Controller during a burst access to a Synchronous Burst device. 000 _B 1 data access (default after reset). 001 _B 2 data accesses. 010 _B 4 data accesses. 011 _B 8 data accesses. Others: Reserved |
| FBBMSEL | 3 | rw | Synchronous burst buffer mode select 0 _B Burst buffer length defined by value in FETBLEN (default after reset). 1 _B Continuous mode. All data required for transaction transferred in single burst |
| NAA | 7 | r | Enable flash non-array access workaround When set to logic one workaround for non-array is access when region is accessed with address bit 28 set is enabled. See Section 14.11.14 . Mirror of equivalent field in BUSRCON register. To set write to equivalent field in BUSRCON register |

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| ECSE | 16 | rw | Early Chip Select for Synchronous Burst 0_B CS is delayed. 1_B CS is not delayed. <i>Note: (see Section 14.10.3 and Section 14.11.7)</i> |
| EBSE | 17 | rw | Early Burst Signal Enable for Synchronous Burst 0_B ADV is delayed. 1_B ADV is not delayed. <i>Note: (see Section 14.10.3 and Section 14.11.7)</i> |
| WAITINV | 19 | rw | Reversed polarity at WAIT 0_B OFF , input at WAIT pin is active low (default after reset). 1_B Polarity reversed , input at WAIT pin is active high. <i>Note: This bit has no effect when using Burst FLASH Data Handshake Mode</i> |
| BCGEN | [21:20] | rw | Byte Control Signal Control This bit field selects the timing mode of the byte control signals. 00_B Byte control signals follow chip select timing. 01_B Byte control signals follow control signal timing (\overline{RD} , $\overline{RD}/\overline{WR}$) (default after reset). 10_B Byte control signals follow write enable signal timing ($\overline{RD}/\overline{WR}$ only). 11_B Reserved. |
| PORTW | [23:22] | r | Device Addressing Mode See Table 14-12 and Table 14-13 |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|---------------|-------------------------|------|---|
| WAIT | [25:24] | rw | External Wait Control Function of the WAIT input. This is specific to the device type (i.e. the AGEN field). Details for Asynchronous (ASYNC) Devices see Section 14.10.6.1 Details for Synchronous Burst (SYNC) Devices see Section 14.11.13 0 _D OFF (default after reset). 1 _D ASYNC: Asynchronous input at WAIT. SYNC: Wait for page load (Early WAIT). 2 _D ASYNC: Synchronous input at WAIT. SYNC: Wait for page load (WAIT with data). 3 _D ASYNC: Reserved. SYNC: Abort and retry access. |
| AAP | 26 | rw | Asynchronous Address phase: Enables an access mode for synchronous memories where the clock is not started until after the address hold phase. 0 _B Clock is enabled at beginning of access. 1 _B Clock is enabled at after address phase. |
| LOCKCS | 27 | rw | Lock Chip Select Enable Chip Select for Automatic Locking in the event of a write access 0 _B Chip Select cannot be locked (default after reset). 1 _B Chip Select will be automatically locked when written to from the processor data port. |
| AGEN | [31:28] | rw | Device Type for Region See Section 14.6.3 |
| 0 | [6:4], [15:8], 18 | r | Reserved Read as 0; should be written with 0. |

BUSRAPx

Configures the READ timing for a region.

BUSRAP_x (x = 0-3)

Bus Read Access Parameter Register

(02C_H+x*10_H)

Reset Value: FFFF FFFF_H

| | | | | | | | | | | | | | | | |

14.16.3 SDRAM Control Registers

Registers in this section are used to control the SDRAM settings.

SDRMCON

Basic SDRAM configuration done with this register.

SDRMCON

SDRAM Control Register

(068_H)

Reset Value: 8000 0000_H

| | | | | | | | | | | | | | | | |
|---------------------|-----------------|---------------|--------------------|-------------|-------------|----|--------------|----|----|-------------|-------------|----|------------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| SDC MSEL | PWR_MODE | | CLK DIS | CRCE | | | BANKM | | | ROWM | | | CRC | | |
| rw | rw | | rw | rw | | | rw | | | rw | | | rw | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CRCD | | AWIDTH | | CRP | CRSC | | CRFSH | | | | CRAS | | | | |
| rw | | rw | | rw | rw | | rw | | | | rw | | | | |

| Field | Bits | Type | Description |
|-----------------|---------|------|---|
| SDCMSEL | 31 | rw | SDRAM clock mode select 1 _B clock disabled between accesses 0 _B clock continuously runs <i>Note: (see Section 14.12.20)</i> |
| PWR_MODE | [30:29] | rw | Power Save Mode used for gated clock mode 0 _H precharge before clock stop (default after reset) 1 _H auto-precharge before clock stop 2 _H active power down (stop clock without precharge) 3 _H clock stop power down <i>Note: (see Section 14.12.20)</i> |
| CLKDIS | 28 | rw | Disable SDRAM clock output 0 _B clock enabled 1 _B clock disabled <i>Note: (see Section 14.12.20)</i> |
| CRCE | [27:25] | rw | Row cycle time counter extension Extends the range of the Crc bit field (see below). |

| Field | Bits | Type | Description |
|--------------|---------|------|---|
| BANKM | [24:22] | rw | Mask for bank tag AHB address bits to be used for determining bank number. 0 _H Reserved; (default after reset) 1 _H Address bit 21 to 20 2 _H Address bit 22 to 21 3 _H Address bit 23 to 22 4 _H Address bit 24 to 23 5 _H Address bit 25 to 24 6 _H Address bit 26 to 25 7 _H Address bit 26 <i>Note: See Section 14.12.14.</i> |
| ROWM | [21:19] | rw | Mask for row tag Number of address bits from bit 26 to be used for comparing row tags. 0 _H Reserved; (default after reset) 1 _H Address bit 26 to 9 2 _H Address bit 26 to 10 3 _H Address bit 26 to 11 4 _H Address bit 26 to 12 5 _H Address bit 26 to 13 6 _H Reserved 7 _H Reserved <i>Note: See Section 14.12.15</i> |
| CRC | [18:16] | rw | Row cycle time counter Number of NOP cycles following a refresh command before another command (other than a NOP) can be issued to the SDRAM. Combined with the CRCE bit as follows: Insert (CRCE * 8) + CRC + 1 NOP cycles. |
| CRCD | [15:14] | rw | Row to column delay counter Number of NOP cycles between a row address and a column address: Insert CRCD + 1 NOP cycles (default after reset CRCD is 0). |

| Field | Bits | Type | Description |
|---------------|---------|------|--|
| AWIDTH | [13:12] | rw | Width of column address Number of address bits from bit 0 to be used for column address. See also Section 14.12.19 . e.g. for 16-bit DRAMs 0 _H Reserved , do not use 1 _H Address[8:0] 2 _H Address[9:0] 3 _H Address[10:0] |
| CRP | [11:10] | rw | Row precharge time counter Number of NOP cycles inserted after a precharge command. The actual number performed can be greater due to CAS latency and burst length. Insert CRP + 1 NOP cycles (default after reset CRP is 0) |
| CRSC | [9:8] | rw | Mode register set-up time Number of NOP cycles after a mode register set command. Insert CRSC + 1 NOP cycles (default after reset CRSC is 0) |
| CRFSH | [7:4] | rw | Initialization refresh commands counter Number of refresh commands issued during power-up initialization sequence. Perform CRFSH + 1 refresh cycles (default after reset CRFSH is 0) |
| CRAS | [3:0] | rw | Row to precharge delay counter Number of clock cycles between row activate command and a precharge command. Minimum CRAS + 1 clock cycles (default after reset CRAS is 0) |

SDRMOD

Use this register to configure the SDRAM operation modes.

SDRMOD

SDRAM Mode Register

(6C_H)

Reset Value: 0000 0020_H

| | | | | | | | | | | | | | | | |
|----------------------------|----------|---------------|----|-------------|----|----|----|---------------|----|----|-------------|----------|---------------|----|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |
| XBA | | | | XOPM | | | | | | | | | | | |
| rw | | | | rw | | | | | | | | | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| COL DST ART | 0 | OPMODE | | | | | | CASLAT | | | BTYP | P | BURSTL | | |
| w | r | rw | | | | | | rw | | | rw | | rw | | |

| Field | Bits | Type | Description |
|------------|---------|------|--|
| XBA | [31:28] | rw | <p>Extended Operation Bank Select</p> <p>Value to be written to the bank select pins of a “Mobile” SDRAM device during an extended mode register write operation. Control of these bits is provided to allow support of future enhanced “Mobile” SDRAM devices. See Section 14.12.10</p> <p>Notes</p> <ol style="list-style-type: none"> <i>Care must be taken when programming these bits to ensure that a valid extended mode register access occurs (e.g. it is possible to generate an extra unwanted standard mode register write by incorrect programming of these bits).</i> <i>Consult the appropriate SDRAM documentation for the function of these bits.</i> |

| Field | Bits | Type | Description |
|------------------|---------|------|---|
| XOPM | [27:16] | rw | Extended Operation Mode Value to be written to the extended mode register of a “Mobile” SDRAM device. This value is issued to the SDRAM via it’s address inputs during an extended mode register write. This field is wider than current extended mode registers to allow support of future enhanced “Mobile” SDRAM devices. Notes <ol style="list-style-type: none"> 1. Consult the appropriate SDRAM documentation for the function of these bits. 2. The Memory Controller provides a 13-bit wide bit-field for the extended mode register to cater for devices that could theoretically use an additional control bit (in comparison to currently available devices). |
| COLDSTART | 15 | w | SDRAM cold start This bit will always read 0. If a write to the SDRMOD register takes place with this bit set, the SDRAM device mode register will be updated to match the data written to the register. See Section 14.12.9 |
| OPMODE | [13:7] | rw | Operation Mode Memory Controller only supports burst write standard operation. 000000 _B Only this value must be written (default after reset) Others: Reserved |
| CASLAT | [6:4] | rw | CAS latency Number of clocks between a READ command and the availability of data. 2 _D Two clocks (default after reset) 3 _D Three clocks Others: Reserved |
| BTYP | 3 | rw | Burst type Memory Controller only supports sequential burst. 0 _B Only this value should be written (default after reset) 1 _B Reserved |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|---------------|-------|------|--|
| BURSTL | [2:0] | rw | Burst length Number of locations can be accessed with a single command. 0 _D 1 (default after reset) 1 _D 2 2 _D 4 3 _D 8 4 _D 16 Others: Reserved |
| 0 | 14 | r | Reserved Read as 0; should be written with 0. |

SDRMREF

Used to set up the right SDRAM refresh parameters.

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| RES_DLY | [27:25] | rw | Delay on Power Down Exit Number of NOPs after the SDRAM controller exits power down before an active command is permitted. <i>Note: See Section 14.12.20</i> |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| ARFSH | 24 | rw | Auto Refresh on Self refresh Exit If set to one, an auto refresh cycle will be performed on exiting self refresh before the self refresh exit delay. If set to zero, no refresh will be performed. <i>Note: See Section 14.12.18</i> |
| SELFREX_DLY | [23:16] | rw | Self Refresh Exit Delay Number of NOP cycles inserted after a self refresh exit before a command is permitted to the SDRAM/DDRAM. <i>Note: See Section 14.12.18</i> |
| ERFSHC | [15:14] | rw | Extended Refresh Counter Period This field is used to increase the range of the refreshc field from 6 bits to 8 bits with ERFSHC being used as bits 7 and 6 of the extended field and refreshc as bit 5 to 0. |
| AUTOSELFR | 13 | rw | Automatic Self Refresh When this bit is set to '1', Memory Controller will automatically issue the Self Refresh Entry command to all SDRAM devices when it gives up control of the external bus, and will automatically issue Self Refresh Exit when it regains control of the bus. |
| SELFREN | 12 | rw | Self Refresh Entry When this bit is written with '1' the Self Refresh Entry command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1. |
| SELFRENST | 11 | r | Self Refresh Entry Status. If this bit is set to '1', it means the Self Refresh Entry command has been successfully issued. This bit is reset when bit SELFREX is set to '1' or a reset takes place. |
| SELFREX | 10 | rw | Self Refresh Exit (Power Up). When this bit is written with '1' the Self Refresh Exit command is issued to all SDRAM devices, regardless whether they are attached to type 0 or type 1. |

External Bus Unit (EBU)

| Field | Bits | Type | Description |
|------------------|---------|------|--|
| SELFREXST | 9 | r | Self Refresh Exit Status. If this bit is set to '1', it means the Self Refresh Exit command has been successfully issued. This bit is reset when bit SELFREN is set to '1' or a reset takes place. |
| REFRESHR | [8:6] | rw | Number of refresh commands The number of additional refresh commands issued to SDRAM each time a refresh is due. Number of refresh commands to use is REFRESHR + 1 |
| REFRESHC | [5:0] | rw | Refresh counter period Number of clock cycles between refresh operations. Refresh period is REFRESHC x 64 clock cycles. |
| 0 | [31:28] | r | Reserved Read as 0; should be written with 0. |

SDRSTAT

Reflects SDRAM Error or Busy states.

15 Ethernet MAC (ETH)

The Ethernet MAC (ETH) is a major communication peripheral that supports 10/100 MBit/s data transfer rates in compliance with the IEEE 802.3-2002 standard. The ETH may be used to implement Internet connected applications using IPv4 and IPv6. The ETH also includes support for IEEE1588 time synchronisation to allow implementation of Real Time Ethernet protocols.

Table 15-1 Abbreviations

| | |
|------|-------------------------------------|
| ETH | Ethernet MAC Peripheral |
| MTL | MAC Transaction Layer |
| PHY | Physical Layer Interface |
| MMC | MAC Management Counters |
| SMI | Station Management Interface |
| COE | Checksum Offload Engine |
| PMT | Power Management |
| MII | Media Independent Interface |
| RMII | Reduced media Independent interface |

15.1 Overview

The ETH peripheral is comprised of five major functional units. The ETH-Core takes user provided data frames and formats them for transmission to an external PHY via an MII or RMII interface. The ETH MAC Transaction Layer (MTL) acts as a bridge between the application and the ETH Core. The MTL provides two 2K byte FIFO's to buffer the transmit and receive frames. The application may write data frames directly to the MTL (cut through mode) or more normally will use the dedicated ETH DMA unit. The ETH DMA allows the application to define a region of RAM to be used as transmit and receive buffers. DMA transfers are initiated by DMA descriptors which are also held in RAM. The ETH also includes a system time module which allows timestamping of transmit and receive frames. The ETH also includes an extensive set of MAC Management counters which provide detailed bus statistics.

The ETH includes the following features, listed by category.

15.1.1 ETH Core Features

- Supports 10/100-Mbit/s data transfer rates with the following PHY interfaces
 - IEEE 802.3-compliant RMII/MII (default) interface to communicate with an external Fast Ethernet PHY
- Supports both full-duplex and half-duplex operation
 - Supports CSMA/CD Protocol for half-duplex operation
 - Supports IEEE 802.3x flow control for full-duplex operation
 - Optional forwarding of received pause control frames to the user application in full-duplex operation
 - Back-pressure support for half-duplex operation
 - Automatic transmission of zero-quantum pause frame on deassertion of flow control input in full-duplex operation
- Preamble and start-of-frame data (SFD) insertion in Transmit, and deletion in Receive paths
- Automatic CRC and pad generation controllable on a per-frame basis
- Options for Automatic Pad/CRC Stripping on receive frames
- Programmable frame length to support Standard or Jumbo Ethernet frames with sizes up to 16 KB
- Programmable InterFrameGap (40-96 bit times in steps of 8)
- Supports a variety of flexible address filtering modes:
 - Up to 3 additional 48-bit perfect (DA) address filters with masks for each byte
 - Up to 3 48-bit SA address comparison check with masks for each byte
 - 64-bit Hash filter for multicast and uni-cast (DA) addresses
 - Option to pass all multicast addressed frames
 - Promiscuous mode support to pass all frames without any filtering for network monitoring
 - Passes all incoming packets (as per filter) with a status report
- Separate 32-bit status returned for transmission and reception packets
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Separate transmission, reception, and control interfaces to the Application
- Supports 32-bit data transfer interface on the system-side
- Complete network statistics with RMON/MIB Counters (RFC1757/RFC2819 / RFC2665). It is completely under control of higher protocol level (SW) to make use of these counters.
- MDIO Master interface for PHY device configuration and management, e.g. for switching the PHY in external loopback mode.
- Detection of LAN wake-up frames and AMD Magic Packet frames
- Enhanced Receive module for checking IPv4 header checksum and TCP, UDP, or ICMP checksum encapsulated in IPv4 or IPv6 datagrams.
- Module to support Ethernet frame time stamping as described in IEEE 1588-2008. Sixty-four-bit time stamps are given in each frame's transmit or receive status.

15.1.2 DMA Block Features

The DMA block exchanges data between the MTL block and the XMC4[78]00 memory. A set of registers (DMA CSR) to control DMA operation is accessible by the XMC4[78]00.

DMA features include:

- 32-bit data transfers
- Single-channel Transmit and Receive engines
- Fully synchronous design operating on a single system clock (except for CSR module, when a separate CSR clock is configured)
- Optimization for packet-oriented DMA transfers with frame delimiters
- Byte-aligned addressing for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptor architecture, allowing large blocks of data transfer with minimum CPU intervention; each descriptor can transfer up to 8 KB of data
- Comprehensive status reporting for normal operation and transfers with errors
- Individual programmable burst size for Transmit and Receive DMA Engines for optimal bus utilization
- Programmable interrupt options for different operational conditions
- Per-frame Transmit/Receive complete interrupt control
- Round-robin or fixed-priority arbitration between Receive and Transmit engines
- Start/Stop modes
- Separate ports for CPU CSR access and data interface

15.1.3 Transaction Layer (MTL) Features

The MTL block consists of two sets of FIFOs: a Transmit FIFO with programmable threshold capability, and a Receive FIFO with a configurable threshold (default of 64 bytes).

MTL features include:

- 32-bit Transaction Layer block providing a bridge between the application and the -CORE
- Single-channel Transmit and Receive engines
- Data transfers executed using simple FIFO-protocol
- Synchronization for all clocks in the design (Transmit, Receive and system clocks)
- Optimization for packet-oriented transfers with frame delimiters
- Four Separate ports for system-side and -CORE-side transmission and reception
- Two RAM-based asynchronous FIFOs of 2K Bytes depth with synchronous/asynchronous Read and Write operation with respect to the Read and Write clocks (one for transmission and one for reception)
- Receive Status vectors inserted into the Receive FIFO after the EOF transfer enables multiple-frame storage in the Receive FIFO without requiring another FIFO to store those frames' Receive Status.

Ethernet MAC (ETH)

- Configurable Receive FIFO threshold (default fixed at 64 bytes) in Cut-Through mode
- Option to filter all error frames on reception and not forward them to the application in Store-and-Forward mode
- Option to forward under-sized good frames
- Supports statistics by generating pulses for frames dropped or corrupted (due to overflow) in the Receive FIFO
- Supports Store and Forward mechanism for transmission to the core
- Supports threshold control for transmit buffer management
- Supports configurable number of frames to be stored in FIFO at any time. The default is up to 8 frames in -MTL configuration.
- Automatic generation of PAUSE frame control or backpressure signal to the -core based on Receive FIFO-fill (threshold configurable) level.
- Handles automatic retransmission of Collision frames for transmission
- Discards frames on late collision, excessive collisions, excessive deferral and underrun conditions
- Software control to flush Tx FIFO
- Data FIFO RAM chip-select disabled when inactive, to reduce power consumption
- module to calculate and insert IPv4 header checksum and TCP, UDP, or ICMP checksum in frames transmitted in Store-and-Forward mode.

15.1.4 Monitoring, Test, and Debugging Support Features

- Supports internal loopback on the MII for debugging
- External loopback is supported via the integrated MDIO controlling the PHY
- DMA states (Tx and Rx) given as status bits
- Debug status register that gives status of FSMs in Transmit and Receive data-paths and FIFO fill-levels.
- Application Abort status bits
- MMC (RMON) module in the core
- Current Tx/Rx Buffer pointer as status registers
- Current Tx/Rx Descriptor pointer as status registers

15.1.5 Block Diagram

A block diagram of the ETH's major system configurations is provided in [Figure 15-1](#).

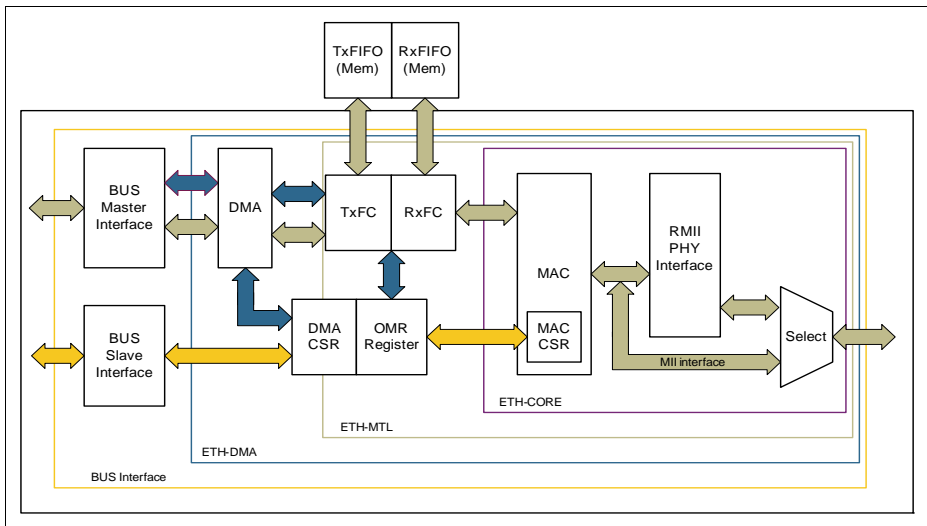

Figure 15-1 ETH Block Diagram

15.2 Functional Description

This chapter describes the structure and programming requirements of the features within the ETH subsystem. Each significant programming feature is discussed in a separate section.

15.2.1 ETH Core

The ETH core supports two interfaces towards the PHY chip, MII and RMII. The PHY interface can be selected only once after reset. The ETH core communicates with the application side with the MAC Transmit Interface (MTI), MAC Receive Interface (MRI) and the MAC Control Interface (MCI).

15.2.1.1 Transmission

Transmission is initiated when the MTL Application pushes in data with the SOF . When the SOF signal is detected, the ETH accepts the data and begins transmitting to the MII. The time required to transmit the frame data to the RMII/MII after the Application initiates transmission is variable, depending on delay factors like IFG delay, time to transmit preamble/SFD, and any back-off delays for Half-Duplex mode. Until then, the ETH does not accept the data received from MTL.

After the EOF is transferred to the ETH Core, the core complete normal transmission and then gives the Status of Transmission back to the MTL. If a normal collision (in Half-duplex mode) occurs during transmission, the ETH core makes valid the Transmit Status to the MTL. It then accepts and drops all further data until the next SOF is received. The MTL block should retransmit the same frame from SOF on observing a Retry request (in the Status) from the ETH.

The ETH issues an underflow status if the MTL is not able to provide the data continuously during the transmission. During the normal transfer of a frame from MTL, if the ETH receives a SOF without getting an EOF for the previous frame, then it (the SOF) is ignored and the new frame is considered as continuation of the previous frame.

The following six modules constitute the transmission function of the ETH:

- Transmit Bus Interface Module (TBU)
- Transmit Frame Controller Module (TFC)
- Transmit Protocol Engine Module (TPE)
- Transmit Scheduler Module (STX)
- Transmit CRC Generator Module (CTX)
- Transmit Flow Control Module (FTX)

Transmit Bus Interface Module

This module interfaces the transmit path of the ETH core with the external frame with a FIFO interface.

This module also outputs the (32-bit) Transmit Status to the application at the end of normal transmission or collision.

Additionally, this module outputs the Transmit Snapshot register value.

Transmit Frame Controller Module

The Transmit Frame Controller (TFC) consists of two registers to hold data, byte enables, and the last data control received from the TBU. The register provides a buffer between the Application and the TPE to regulate data flow as well as converts the input data into an 8-bit bus towards the TPE.

When the number of bytes received from the Application falls below 60 (DA+SA+LT+DATA), the state machine that interfaces with the TBU automatically appends zeros to the transmitting frame to make the data length exactly 46 bytes to meet the minimum data field requirement of IEEE 802.3. The ETH can be programmed not to append any padding.

The cyclic redundancy check (CRC) for the Frame Check Sequence (FCS) field is calculated before transmission to the TPE module. This value is computed by CTX module. The TFC module receives the computed CRC and appends it to the data being transmitted to the TPE module. When the ETH is programmed to not append the CRC value to the end of Ethernet frames, the TFC module ignores the computed CRC and transmits only the data received from the TBU module to the TPE module. An exception to this rule is that when the ETH is programmed to append pads for frames (DA+SA+LT+DATA) less than 60 bytes sent by the TBU module, the TFC module will append the CRC at the end of padded frame.

The TFC converts the data received from the TBU into 8-bit data for the TPE module.

Transmit Protocol Engine Module

The Transmit Protocol Engine (TPE) module consists of a transmit state machine that controls the operation of Ethernet frame transmission. The module's transmit state machine performs the following functions to meet the IEEE 802.3 specifications.

- Generates preamble and SFD
- Generates jam pattern in Half-Duplex mode
- Jabber timeout
- Flow control for Half-Duplex mode (back pressure)
- Generates transmit frame status
- Contains time stamp snapshot logic for IEEE 1588 support

When a new frame transmission from the TFC is requested, the transmit state machine sends out the preamble and SFD, followed by the data received. The preamble is defined as 7 bytes of 10101010_B pattern, and the SFD is defined as 1 byte of 10101011_B pattern.

The collision window is defined as 1 slot time (512 bit times for 10/100 Mbit/s Ethernet). The jam pattern generation is applicable only to Half-Duplex mode, not to Full-Duplex mode. In Full-Duplex mode, the transmit state machine ignores the collision signal from the PHY.

In MII mode, if a collision occurs any time from the beginning of the frame to the end of the CRC field, the transmit state machine sends a 32-bit jam pattern of 55555555_H on the MII to inform all other stations that a collision has occurred. If the collision is seen during the preamble transmission phase, the transmit state machine completes the transmission of preamble and SFD and then sends the jam pattern.

If the collision occurs after the collision window and before the end of the FCS field (or the end of Burst if the Frame Burst mode is enabled), the transmit state machine sends a 32-bit jam pattern and sets the late collision bit in the transmit frame status.

The TPE module maintains a jabber timer to cut off the transmission of Ethernet frames if the TFC module transfers more than 2048 (default) bytes. The time-out is changed to 10240 bytes when the Jumbo frame is enabled.

The Transmit state machine uses the deferral mechanism for the flow control (Back Pressure) in Half-Duplex mode. When the Application requests to stop receiving frames, the Transmit state machine sends a JAM pattern of 32 bytes whenever it senses a reception of a frame, provided the transmit flow control is enabled. This will result in a collision and the remote station will back off. The Application requests the flow control by setting **ETH0_FLOW_CONTROL.FCA_BPA** bit. If the application requests a frame to be transmitted, then it will be scheduled and transmitted even when the backpressure is activated. Note that if the backpressure is kept activated for a long time (and more than 16 consecutive collision events occur) then the remote stations will abort their transmissions due to excessive collisions.

If IEEE 1588 time stamping is enabled for the transmit frame, this block takes a snapshot of the system time when the SFD is put onto the transmit MII bus. The system time source is either an external input or internally generated, according to the configuration selected.

Transmit Scheduler Module

The Transmit Scheduler (STX) module is responsible for scheduling the frame transmission on the MII. The two major functions of this module are to maintain the inter-frame gap between two transmitted frames and to follow the Truncated Binary Exponential Back-off algorithm for Half-Duplex mode. This module provides an enable signal to the TPE module after satisfying the IFG and Back-off delays.

The STX module maintains an idle period of the configured inter-frame gap (**ETH0_MAC_CONFIGURATION.IFG** bits) between any two transmitted frames. If frames from the TFC arrive at the TPE module sooner than the configured IFG time, the TPE module waits for the enable signal from the STX module before starting the transmission on the MII. The STX module starts its IFG counter as soon as the carrier signal of the MII goes inactive. At the end of programmed IFG value, the module issues an enable signal to the TPE module in Full-Duplex mode. In Half-Duplex mode and when IFG is configured for 96 bit times, the STX module follows the rule of deference specified in Section 4.2.3.2.1 of the IEEE 802.3 specification. The module resets its IFG counter

if a carrier is detected during the first two-thirds (64-bit times for all IFG values) of the IFG interval. If the carrier is detected during the final one third of the IFG interval, the STX module continues the IFG count and enables the transmitter after the IFG interval.

The STX module implements the Truncated Binary Exponential Back-off algorithm when it operates in Half-Duplex mode.

Transmit CRC Generator Module

The Transmit CRC Generator (CTX) module interfaces with the TFC module to generate CRC for the FCS field of the Ethernet frame. The TFC module sends the frame data and any necessary padding to the CTX module through an 8-bit interface.

This module calculates the 32-bit CRC for the FCS field of the Ethernet frame. The encoding is defined by the following generating polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The module gets the Ethernet frame's byte data from the TFC module (DA + SA + LT + DATA + PAD) qualified with a Data Valid signal. The TFC also indicates to the CTX when to reset the previously calculated CRC and to start the new CRC calculation for the coming frame. The TFC module issues the start command before sending the new frame data for calculation. The calculated CRC is valid on the next clock after the data is received.

Transmit Flow Control Module

The Transmit Flow Control (FTX) module generates Pause frames and transmit them to the TFC module as necessary, in Full-Duplex mode. The TFC module receives the Pause frame from the FTX module, appends the calculated CRC, and sends the frame to the TPE module. Pause frame generation can be initiated in two ways. The Application can request the FTX module to send a Pause frame either by setting the **ETH0_FLOW_CONTROL.FCB** bit or in response to the receive FIFO full conditions (packet buffer).

If the Application has requested the flow control by setting the **FLOW_CONTROL.FCB** bit of, the FTX module will generate and transmit a single Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in the **FLOW_CONTROL** Register. To extend the pause or end the pause prior to the time specified in the previously transmitted Pause frame, the application must request another Pause frame transmission after programming the Pause Time register with appropriate value.

If the Application has requested the flow control by asserting the **mti_flowctrl_i** signal, the FTX module will generate and transmit a Pause frame to the TFC module. The value of the Pause Time in the generated frame contains the programmed Pause Time value in the **FLOW_CONTROL** Register. The FTX module monitors the **MTI Flow Control Signal**. If it remains asserted at a configurable number of slot-times (**FLOW_CONTROL.PLT**

bits) before this Pause-time runs-out, a second Pause frame will be transmitted to the TFC module. The process will be repeated as long as the MTI flow control signal remains asserted.

If the MTI flow control signal goes inactive prior to the sampling time, the FTX module will transmit a Pause frame with zero Pause Time to indicate to the remote end that the receive buffer is ready to receive new data frames.

15.2.1.2 MAC Transmit Interface Protocol

The MAC Transmit Interface (MTI) connects the application with the MTL in the ETH to provide the Ethernet data for transmission.

The application initiates the Ethernet frame transmission by writing the first data of the frame to the ETH, provided the ETH is ready to accept data . The Application can push-in data as long as the ETH core is ready to accept it.

If the frame transmission is not successful (due to underflow, collision, jabber timeout, excessive deferral events), the ETH core will assert the transmit status even before the EOF is received. The Application will have to take the appropriate action as per the status. The ETH will drop all further data input to it until the next SOF.

15.2.1.3 Reception

A receive operation is initiated when the ETH detects an SFD on the MII. The core strips the preamble and SFD before proceeding to process the frame. The header fields are checked for the filtering and the FCS field used to verify the CRC for the frame. The received frame is stored in a shallow buffer until the address filtering is performed. The frame is dropped in the core if it fails the address filter.

The following are the functional blocks in the Receive path of the ETH core.

- Receive Protocol Engine Module (RPE)
- Receive CRC Module (CRX)
- Receive Frame Controller Module (RFC)
- Receive Flow Control Module (FRX)
- Receive IP Checksum checker (IPC)
- Receive Bus Interface Unit Module (RBU)
- Address Filtering Module (AFM)

Receive Protocol Engine Module

The RPE consists of the receive state machine which strips the preamble SFD. Once the external PHY detects ethernet traffic, the RPE's receive state machine begins hunting for the SFD field from the receive modifier logic. Until then, the state machine drops the receiving preambles. Once the SFD is detected, the state machine begins sending the data of the Ethernet frame to the RFC module, beginning with the first byte following the SFD (destination address).

Ethernet MAC (ETH)

If IEEE 1588 time stamping is enabled, the RPE takes a snapshot of the system time when any frame's SFD is detected on the MII. Unless the MAC filters out and drops the frame, this time stamp is passed on to the application.

In MII mode, the RPE converts the received nibble data into bytes, then forwards the valid frame data to the RFC module

The receive state machine of the RPE module decodes the Length/Type field of the receiving Ethernet frame. If the Length/Type field is less than 600 (hex) and if the MAC is programmed for the auto crc/pad stripping option, the state machine sends the data of the frame up to the count specified in the Length/Type field, then starts dropping bytes (including the FCS field). The state machine of the RPE module decodes the Length/Type field and checks for the Length interpretation.

If the Length/Type field is greater than or equal to 600 (hex), the RPE module will send all received Ethernet frame data to the RFC module, irrespective of the value on the programmed auto-CRC strip option.

As a default, the ETH is programmed for watchdog timer to be enabled, that is, frames above 2.048 (10.240 if Jumbo Frame is enabled) bytes (DA + SA + LT + DATA + PAD + FCS) are cut off at the RPE module. This feature can be disabled by programming the [ETH0_MAC_CONFIGURATION](#).WD bit. However even if the watchdog timer is disabled, frames greater than 16 KB in size are cut off and a watchdog time-out status is given.

The ETH supports loopback of transmitted frames onto its receiver. As a default, the ETH loopback function is disabled, but this feature can be enabled by programming the ETH Configuration register, Loopback bit. The transmit and receive clocks can have an asynchronous timing relationship, so an asynchronous FIFO is used to make the loopback path of the PHY transmit path connected onto the receive path. The asynchronous FIFO is 6 bits wide to accommodate the PHY transmit, receive and enable signals. The FIFO is nine words deep and free-running to write on the write clock and read on every read clock.

The write and read pointers gets re-initialized to have an offset of 4 at the start of each frame read out of the FIFO. This helps to avoid overflow/underflow during the transfer of a frame, and ensures that the overflow/underflow occurs only during the IFG period between the frames. Please note that the FIFO depth of nine is sufficient to prevent data corruption for frame sizes up to 9.022 bytes with a difference of 200 ppm between the MII Transmit and Receive clock frequencies. Hence, bigger frames should not be looped back, as they may get corrupted in this loopback FIFO.

At the end of every received frame, the RPE module generates received frame status and sends it to the RFC module. Control, missed frame, and filter fail status are added to the receive status in the RFC module.

Receive CRC Module

The Receive CRC (CRX) interfaces to the RPE module to check for any CRC error in the receiving frame.

This module calculates the 32-bit CRC for the received frame that includes the Destination address field through the FCS field. The encoding is defined by the following generating polynomial.

$$G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

The module gets the data from the RPE module (DA+SA+LT+DATA+PAD+FCS). The RPE module also sends a control signal that indicates the validity of the data. Irrespective of the auto pad/CRC strip, the CRX module receives the entire frame to compute the CRC check for received frame. As a note on the auto pad/CRC strip settings, the entire frame is not transferred between the RPE and RFC 8-bit interface.

Receive Checksum Offload Engine

The Receive Checksum Offload engine can detect both IPv4 and IPv6 frames in the received ethernet packets. Once an IP frame is detected it is processed for data integrity.

The Receive Checksum Offload engine is enabled by setting the **ETH0_MAC_CONFIGURATION**.IPC bit. The ETH receiver identifies IPv4 or IPv6 frames by checking for value 0800_H or 86DD_H, respectively, in the received Ethernet frames' Type field. This identification applies to VLAN-tagged frames as well.

The Receive Checksum Offload engine calculates IPv4 header checksums and checks that they match the received IPv4 header checksums. The result of this operation (pass or fail) is given to the RFC module for insertion into the receive status word. The IP Header Error bit is set for any mismatch between the indicated payload type (Ethernet Type field) and the IP header version, or when the received frame does not have enough bytes, as indicated by the IPv4 header's Length field (or when fewer than 20 bytes are available in an IPv4 or IPv6 header).

This engine also identifies a TCP, UDP or ICMP payload in the received IP datagrams (IPv4 or IPv6) and calculates the checksum of such payloads properly, as defined in the TCP, UDP, or ICMP specifications. This engine includes the TCP/UDP/ICMPv6 pseudo-header bytes for checksum calculation and checks whether the received checksum field matches the calculated value. The result of this operation is given as a Payload Checksum Error bit in the receive status word. This status bit is also set if the length of the TCP, UDP, or ICMP payload does not tally to the expected payload length given in the IP header.

As mentioned in **TCP/UDP/ICMP Checksum Engine**, this engine bypasses the payload of fragmented IP datagrams, IP datagrams with security features, IPv6 routing headers, and payloads other than TCP, UDP or ICMP.

In this configuration, the core does not append any payload checksum bytes to the received Ethernet frames.

Receive Frame Controller Module

The Receive Frame Controller (RFC) receives the Ethernet frame data and status from the RPE module. The RFC module consists of a FIFO of parameterized depth (default set to 4 deep and 37 bits wide) and two state machines for writing and reading the FIFO. The FIFO holds the received Ethernet frame data and byte enables, along with a control bit to indicate the last data. The state machines manage the FIFO and provide a frame buffering for the receiving Ethernet frame from the RPE module. The main functions of the RFC module are:

- Data path conversion, which converts the 8-bit data to 32-bit data to the RBU module.
- Frame filtering
- Attaching the calculated IP Checksum input from IPC.
- Update the Receive Status and forward to RBU.

If the **ETH0_MAC_FRAME_FILTER.RA** bit is set, the RFC module initiates the data transfer to the RBU module as soon as 4 bytes of Ethernet data are received from the RPE module. At the end of the data transfer, the RFC module sends out the received frame status that includes the frame filter bits (RDES0.SAF SA Filterfail and RDES0.AFM DA Filterfail) and status from the RFC module. These bits are generated based on the filter-fail signals from the AFM module. This status bit indicates to the Application whether the received frame has passed the filter controls (both address filter and Frame Filter controls from CSR). The RFC module will not drop any frame on its own in this mode.

If the **MAC_FRAME_FILTER.RA** bit is reset, the RFC module performs frame filtering based on the destination/source address (the Application still needs to perform another level of filtering if it decides not to receive any bad frames like runt, CRC error frames, etc. The RFC module waits to receive the first 14 bytes of received data (type field) from the RPE module. Until then, the module will not initiate any transfers to the RBU module. After receiving the destination/source address bytes, the RFC checks the filter-fail signal from the AFM module for an address match. On detecting a filter-fail from AFB, the frame is dropped at the RFC module and not transferred to the Application.

On a delayed filter response from the AFM (this can only occur if you change the AFM logic), the RFC module waits until the FIFO is full, and then proceeds with the frame transfer to the RBU module. However, it will still take the delayed response from the AFM module and if it is a (DA/SA) filter failure, then it will drop the rest of the frame and send the Rx Status Word (with zero frame-length, CRC Error and Runt Error bits set) immediately indicating the filter-fail. If there is no response from the AFM until the end of frame is transmitted, the filter fail status in the Rx Status Word is updated accordingly.

When the PMT module is configured for power-down mode, all received frames are dropped by this block, and are not forwarded to the application.

Receive Flow Control Module

The Receive Flow Controller (FRX) detects the receiving Pause frame and pauses the frame transmission for the delay specified within the received Pause frame. The FRX module is enabled only in Full-Duplex mode. The Pause frame detection function can be enabled or disabled with the **ETH0_FLOW_CONTROL.RFE** bit.

Once the receive flow control is enabled, the FRX module begins monitoring the received frame destination address for any match with the multicast address of the control frame (0180C2000001_H). If a match is detected, the FRX module indicates to the RFC module, that the destination address of the received frame matches the reserved control frame destination address. The RFC module then decides whether or not to transfer the received control frame to the Application, based on the **ETH0_MAC_FRAME_FILTER.PCF** bit.

The FRX module also decodes the Type, Op-code, and Pause Timer field of the receiving control frame. At the end of received frame, the FRX module gets the received frame status from RPE. If the byte count of the status indicates 64 bytes, and if there is no CRC error, the FRX module requests the MAC transmitter to pause the transmission of any data frame for the duration of the decoded Pause Time value, multiplied by the slot time (64 byte times). Meanwhile, if another Pause frame is detected with a zero Pause Time value, the FRX module resets the Pause Time and gives another pause request to the Transmitter. If the received control frame matches neither the Type field (8808_H), Opcode (00001_H), nor byte length (64 bytes), or if there is a CRC error, the FRX module does not generate a Pause request to Transmitter.

In the case of a pause frame with a multicast destination address, the RFC filters the frame based on the address match from the FRX module. For a pause frame with a unicast destination address, the filtering in the FRX module depends on whether the DA matched the contents of the MAC Address Register 0 and the **ETH0_FLOW_CONTROL.UP** bit is set (detecting a pause frame even with a unicast destination address). The **MAC_FRAME_FILTER.PCF** register bits control the filtering for control frames in addition to the Address filter module.

Receive Bus Interface Unit Module

The Receive Bus Interface Unit (RBU) converts the 32-bit data received from the RFC module into a 32-bit FIFO protocol on the Application side. The RBU module interfaces with the Application through the MAC receive interface (MRI).

If IEEE 1588 time stamping is enabled, the RBU also outputs the time stamp captured from the received frame.

Address Filtering Module

The Address Filtering (AFM) module performs the destination and source address checking function on all received frames and reports the address filtering status to the

RFC module. The address checking is based on different parameters (Frame Filter register) chosen by the Application. These parameters are inputs to the AFM module as control signals, and the AFM module reports the status of the address filtering based on the combination of these inputs. The AFM module does not filter the receive frames by itself, but reports the status of the address filtering (whether to drop the frame or not) to the RFC module. The AFM module also reports whether the receiving frame is a multicast frame or a broadcast frame, as well as the address filter status.

The AFM module probes the 8-bit receive data path between the RPE module and the RFC module and checks the destination and source address field of each incoming packet. In MII mode the module takes 14/26 clocks (from the start of frame) to compare the destination/ source address of the receiving frame. The AFM module gets the station's physical (MAC) address and the Multicast Hash table from CSR module for address checking. The CSR module provides the Frame Filter register parameters to AFM.

Unicast Destination Address Filter

The AFM supports up to 4 MAC addresses for unicast perfect filtering. If perfect filtering is selected (HUC bit of Frame Filter register is reset), the AFM compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr3 are selected with an individual enable bit. Each byte of these other addresses (MacAddr1–MacAddr3) can be masked during comparison with the corresponding received DA byte by setting the corresponding Mask Byte Control bit in the register. This helps group address filtering for the DA.

In Hash filtering mode (When HUC bit is set), the AFM performs imperfect filtering for unicast addresses using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received destination address to index the content of the Hash table. A value of 000000 selects Bit 0 of the selected register, and a value of 111111 selects Bit 63 of the Hash Table register. If the corresponding bit (indicated by the 6-bit CRC) is set to 1, the unicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Multicast Destination Address Filter

The ETH can be programmed to pass all multicast frames by setting the **ETH0_MAC_FRAME_FILTER.PM** bit. If the **MAC_FRAME_FILTER.PM** bit is reset, the AFM performs the filtering for multicast addresses based on the **MAC_FRAME_FILTER.HMC** bit. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported.

In Hash filtering mode, the AFM performs imperfect filtering using a 64-bit Hash table. For hash filtering, the AFM uses the upper 6 bits CRC of the received multicast address

to index the content of the Hash table. A value of 000000_B selects Bit 0 of the selected register and a value of 111111_B selects Bit 63 of the Hash Table register.

If the corresponding bit is set to 1, then the multicast frame is said to have passed the Hash filter; otherwise, the frame has failed the Hash filter.

Hash or Perfect Address Filter

The DA filter can be configured to pass a frame when its DA matches either the Hash filter or the Perfect filter by setting the MAC_FRAME_FILTER.HPF bit and setting the corresponding **ETH0_MAC_FRAME_FILTER.HUC** or **MAC_FRAME_FILTER.HMC** bits. This configuration applies to both unicast and multicast frames. If the HPF bit is reset, only one of the filters (Hash or Perfect) is applied to the received frame.

Broadcast Address Filter

The AFM doesn't filter any broadcast frames in the default mode. However, if the ETH is programmed to reject all broadcast frames by setting the MAC_FRAME_FILTER.DBF bit, the DAF module asserts the Filter fail signal to RFC, whenever a broadcast frame is received. This will tell the RFC module to drop the frame.

Unicast Source Address Filter

The ETH can also perform a perfect filtering based on the source address field of the received frames. By default, the AFM compares the SA field with the values programmed in the SA registers. The MAC Address registers [1:3] can be configured to contain SA instead of DA for comparison, by setting Bit 30 of the corresponding Register. Group filtering with SA is also supported. The frames that fail the SA Filter are dropped by the ETH if the MAC_FRAME_FILTER.SAF bit of Frame Filter register is set.

When MAC_FRAME_FILTER.SAF bit is set, the result of SA Filter and DA filter is AND'ed to decide whether the frame needs to be forwarded. This means that either of the filter fail result will drop the frame and both filters have to pass in-order to forward the frame to the application.

Inverse Filtering Operation

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. These are controlled by the DAIF and SAIF bits of the Frame Filter register respectively. The MAC_FRAME_FILTER.DAIF bit is applicable for both Unicast and Multicast DA frames. The result of the unicast/multicast destination address filter is inverted in this mode. Similarly, when the MAC_FRAME_FILTER.SAIF bit is set, the result of unicast SA filter is reversed.

Table 15-2 and **Table 15-3** summarize the Destination and Source Address filtering based on the type of frames received.

Table 15-2 Destination Address Filtering Table

| Frame Type | PR | HPF | HUC | DAIF | HMC | PM | DB | DA Filter Operation |
|------------|----|-----|-----|------|-----|----|----|---|
| Broadcast | 1 | X | X | X | X | X | X | Pass |
| | 0 | X | X | X | X | X | 0 | Pass |
| | 0 | X | X | X | X | X | 1 | Fail |
| Unicast | 1 | X | X | X | X | X | X | Pass all frames. |
| | 0 | X | 0 | 0 | X | X | X | Pass on Perfect/Group filter match. |
| | 0 | X | 0 | 1 | X | X | X | Fail on Perfect/Group filter match. |
| | 0 | 0 | 1 | 0 | X | X | X | Pass on Hash filter match. |
| | 0 | 0 | 1 | 1 | X | X | X | Fail on Hash filter match. |
| | 0 | 1 | 1 | 0 | X | X | X | Pass on Hash or Perfect/Group filter match. |
| | 0 | 1 | 1 | 1 | X | X | X | Fail on Hash or Perfect/Group filter match. |
| | 0 | 1 | 1 | 1 | X | X | X | Fail on Hash or Perfect/Group filter match. |
| Multicast | 1 | X | X | X | X | X | X | Pass all frames. |
| | X | X | X | X | X | 1 | X | Pass all frames. |
| | 0 | X | X | 0 | 0 | 0 | X | Pass on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |
| | 0 | 0 | X | 0 | 1 | 0 | X | Pass on Hash filter match and drop PAUSE control frames if PCF = 0x. |
| | 0 | 1 | X | 0 | 1 | 0 | X | Pass on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |
| | 0 | X | X | 1 | 0 | 0 | X | Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |
| | 0 | X | X | 1 | 0 | 0 | X | Fail on Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |

Table 15-2 Destination Address Filtering Table (cont'd)

| Frame Type | PR | HPF | HUC | DAIF | HMC | PM | DB | DA Filter Operation |
|------------|----|-----|-----|------|-----|----|----|---|
| | 0 | 0 | X | 1 | 1 | 0 | X | Fail on Hash filter match and drop PAUSE control frames if PCF = 0x. |
| | 0 | 1 | X | 1 | 1 | 0 | X | Fail on Hash or Perfect/Group filter match and drop PAUSE control frames if PCF = 0x. |

Table 15-3 Source Address Filtering Table

| Frame Type | PR | SAIF | SAF | SA Filter Operation |
|------------|----|------|-----|---|
| Unicast | 1 | X | X | Pass all frames. |
| | 0 | 0 | 0 | Pass status on Perfect/Group filter match but do not drop frames that fail. |
| | 0 | 1 | 0 | Fail status on Perfect/Group filter match but do not drop frame. |
| | 0 | 0 | 1 | Pass on Perfect/Group filter match and drop frames that fail. |
| | 0 | 1 | 1 | Fail on Perfect/Group filter match and drop frames that fail. |

15.2.2 MAC Transaction Layer (MTL)

The MAC Transaction Layer provides FIFO memory to buffer and regulate the frames between the application system memory and the ETH core. It also enables the data to be transferred between the application clock domain and the ETH clock domains. The MTL layer has 2 data paths, namely the Transmit path and the Receive Path. The data path for both directions is 32-bit wide and operates with a simple FIFO protocol.

The ETH-MTL communicates with the application side with the Application Transmit Interface (ATI), Application Receive Interface (ARI), and the MAC Control Interface (MCI).

15.2.2.1 Transmit Path

DMA controls all transactions for the transmit path through the ATI. Ethernet frames read from the system memory is pushed into the FIFO by the DMA. The frame is then popped

out and transferred to the ETH core when triggered. When the end-of-frame is transferred, the status of the transmission is taken from the ETH core and transferred back to the DMA.

The Transmit FIFO has a depth of 2K bytes. A 2 FIFO-fill level is indicated to the DMA so that it can initiate a data fetch in required bursts from the system memory, using the Bus interface. The data from the Bus Master interface is pushed into the FIFO with the appropriate byte lanes qualified by the DMA. The DMA also indicates the start-of-frame (SOF) and end-of-frame (EOF) transfers along with a few signals controlling the pad-insertion/CRC generation for that frame in the ETH core.

Per-frame control bits, such as Automatic Pad/CRC Stripping disable, time stamp capture, and so forth are taken as control inputs on the ATI, stored in a separate register FIFO, and passed on to the core transmitter when the corresponding frame data is read from the Transmit FIFO.

There are two modes of operation for popping data towards the ETH core. In Threshold mode, as soon as the number of bytes in the FIFO crosses the configured threshold level (or when the end-of-frame is written before the threshold is crossed), the data is ready to be popped out and forwarded to the ETH core. The threshold level is configured using the TTC bits of DMA **ETH0_BUS_MODE** Register. In store-and-forward mode, the MTL pops the frame towards the ETH core only when one or more of the following conditions are true:

- When a complete frame is stored in the FIFO
- When the TX FIFO becomes almost full
- When the ATI watermark becomes low. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst-length on the ATI.

Therefore, the MTL never stops in the store-and-forward mode even if the Ethernet frame length is bigger than the Tx FIFO depth.

The application can flush the Transmit FIFO of all contents by setting the **ETH0_OPERATION_MODE**.FTF bit. This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer from the MTL to the ETH core, then the MTL stops further transfer as the FIFO is considered to be empty. Hence an underflow event occurs at the ETH transmitter and the corresponding Status word is forwarded to the DMA.

Initialization through **Transmit Status Word** detail initialization and transmit operations for the MTL Layer.

Initialization

Upon reset, the MTL is ready to manage the flow of data to and from the DMA and the ETH .

There are no requirements for enabling the MTL. However, the ETH block and the DMA controller must be enabled individually through their respective CSRs.

Single-Packet Transmit Operation

During a transmit operation, the MTL block is slaved to the DMA controller. The general sequence of events for a transmit operation is as follows.

1. If the system has data to be transferred, the DMA controller, if enabled, fetches data from the XMC4[78]00 RAM through the Bus Master interface and starts forwarding it to the MTL. The MTL pushes the data received from the DMA into the FIFO. It continues to receive the data until the end-of frame of the frame is transferred.
2. The data is taken out of the FIFO and sent to the MAC by the FIFO controller engine. When the threshold level is crossed or a full packet of data is received into the FIFO, the MTL pops out the frame data and drives them to the ETH core. The engine continues to transfer data from the FIFO until a complete packet has been transferred to the MAC. Upon completion of the frame, the MTL receives the Status from the ETH and then notifies the DMA controller

Transmit Operation—Two Packets in the Buffer

1. Because the DMA must update the descriptor status before releasing it to the CPU, there can be at the most two frames inside a transmit FIFO. The second frame will be fetched by the DMA and put into the FIFO only if the OSF (Operate on Second Frame bit is set). If this bit is not set, the next frame will be fetched from the memory only after the MAC has completely processed the frame and the DMA has released the descriptors.
2. If the OSF bit is set, the DMA starts fetching the second frame immediately after completing the transfer of the first frame to the FIFO. It does not wait for the status to be updated. The MTL, in the meantime, receives the second frame into the FIFO while transmitting the first frame. As soon as the first frame has been transferred and the status is received from the MAC, the MTL pushes it to the DMA. If the DMA has already completed sending the second packet to the MTL, it must wait for the status of the first packet before proceeding to the next frame.

Transmit Operation—Multiple Packets in Buffer

In ETH -MTL configuration, the transmit FIFO can be configured to accept more than 2 packets at a time. This option limits the number of status words that can be stored in the MTL before it is transferred to the DMA/CPU. By default, this number is limited to 2 but can be configured for 4 or 8 as well. Once the MTL FIFO accepts the number of frames equal to the status FIFO depth, it will stop accepting further frames unless the transmit Status that is given out and accepted by the CPU/DMA thus freeing up the space in this small FIFO.

Retransmission During Collision

While a frame is being transferred from the MTL to the ETH, a collision event occurs on the ETH line interface in Half-Duplex mode. The ETH then indicates a retry attempt to the MTL by giving the status even before the end-of-frame is transferred from MTL. Then the MTL will enable the retransmission by popping out the frame again from the FIFO.

After more than 96 bytes are popped towards the ETH core, the FIFO controller frees up that space and makes it available to the DMA to push in more data. This means that the retransmission is not possible after this threshold is crossed or when the ETH core indicates a late-collision event.

Transmit FIFO Flush Operation

The ETH provides a control signal to the software to flush the Transmit FIFO in the MTL layer through the use of the **ETH0_OPERATION_MODE.FTF** bit. The Flush operation is immediate and the MTL clears the Tx FIFO and the corresponding pointers to the initial state even if it is in the middle of transferring a frame to the ETH Core. The data which is already accepted by the MAC transmitter will not be flushed. It will be scheduled for transmission and will result in underflow as Tx FIFO does not complete the transfer of rest of the frame. As in all underflow conditions, a runt frame will be transmitted and observed on the line. The status of such a frame will be marked with both Underflow and Frame Flush events (TDES0_{RAM} bits 13 and 1).

The MTL layer also stops accepting any data from the application (DMA) during the Flush operation. It will generate and transfer Transmit Status Words to the application for the number of frames that is flushed inside the MTL (including partial frames). Frames that are completely flushed in the MTL will have the Frame Flush Status bit (TDES0 13_{RAM}) set. The MTL completes the Flush operation when the application (DMA) accepts all of the Status Words for the frames that were flushed, and then clears the Transmit FIFO Flush control register bit. At this point, the MTL starts accepting new frames from the application (DMA).

Transmit Status Word

At the end of transfer of the Ethernet frame to the ETH core and after the core completes the transmission of the frame, the MTL outputs the transmit status to the application. The detailed description of the Transmit Status is the same as for bits [23:0] of TDES0_{RAM} given in [Table 15-9](#).

If IEEE 1588 time stamping is enabled, the MTL returns specific frame's 64-bit time stamp, along with the ATI's transmit status.

Transmit Checksum Offload Engine

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread

Ethernet MAC (ETH)

use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the ETH has an Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. This section explains the operation of the Checksum Offload Engine for transmitted frames.

*Note: The checksum for TCP, UDP, or ICMP is calculated over a complete frame, then inserted into its corresponding header field. Due to this requirement, this function is enabled only when the Transmit FIFO is configured for Store-and-Forward mode (that is, when the **ETH0_OPERATION_MODE.TSF** bit is set .). If the core is configured for Threshold (cut-through) mode, the Transmit COE is bypassed.*

Note: You must make sure that the Transmit FIFO is deep enough to store a complete frame before that frame is transferred to the ETH Core transmitter. The reason being that when space is not available to accept the programmed burst length of the data, then the MTL TxFIFO starts reading to avoid dead-lock. Once reading starts, then checksum insertion engine fails and consequently all succeeding frames may get corrupted due to improper recovery. Therefore, you must enable the checksum insertion only in the frames that are less than the following number of bytes in size (even in the store-and-forward mode):

FIFO Depth – PBL – 3 FIFO Locations

*The **ETH0_BUS_MODE.PBL** is the programmed burst-length.*

This checksum engine can be controlled for each frame by setting the CIC bits (Bits 28:27 of TDES1_{RAM}, described in **Transmit Descriptor 1**).

Note: See IETF specifications RFC 791, RFC 793, RFC 768, RFC 792, RFC 2460, and RFC 4443 for IPv4, TCP, UDP, ICMP, IPv6, and ICMPv6 packet header specifications, respectively.

IP Header Checksum Engine

In IPv4 datagrams, the integrity of the header fields is indicated by the 16-bit Header Checksum field (the eleventh and twelfth bytes of the IPv4 datagram). The COE detects an IPv4 datagram when the Ethernet frame's Type field has the value 0800_H and the IP datagram's Version field has the value 4_H. The input frame's checksum field is ignored during calculation and replaced with the calculated value.

IPv6 headers do not have a checksum field; thus, the COE does not modify IPv6 header fields.

The result of this IP header checksum calculation is indicated by the IP Header Error status bit in the Transmit status (Bit 16 in **Table 15-9**). This status bit is set whenever the values of the Ethernet Type field and the IP header's Version field are not consistent, or when the Ethernet frame does not have enough data, as indicated by the IP header Length field.

In other words, this bit is set when an IP header error is asserted under the following circumstances:

For IPv4 datagrams

- The received Ethernet type is 0800_H, but the IP header's Version field does not equal 4_H
- The IPv4 Header Length field indicates a value less than 5_H (20 bytes)
- The total frame length is less than the value given in the IPv4 Header Length field

For IPv6 datagrams

- The Ethernet type is 86DD_H but the IP header Version field does not equal 6_H
- The frame ends before the IPv6 header (40 bytes) or extension header (as given in the corresponding Header Length field in an extension header) is completely received.

Even when the COE detects such an IP header error, it inserts an IPv4 header checksum if the Ethernet Type field indicates an IPv4 payload.

TCP/UDP/ICMP Checksum Engine

The TCP/UDP/ICMP Checksum Engine processes the IPv4 or IPv6 header (including extension headers) and determines whether the encapsulated payload is TCP, UDP, or ICMP.

Note: For non-TCP, -UDP, or -ICMP/ICMPv6 payloads, this checksum engine is bypassed and nothing further is modified in the frame.

Note: Fragmented IP frames (IPv4 or IPv6), IP frames with security features (such as an authentication header or encapsulated security payload), and IPv6 frames with routing headers are not processed by this engine, and therefore must be bypassed. In other words, payload checksum insertion must not be enabled for such frames.

The checksum is calculated for the TCP, UDP, or ICMP payload and inserted into its corresponding field in the header. This engine can work in the following two modes:

- In the first mode, the TCP, UDP, or ICMPv6 pseudo-header is not included in the checksum calculation and is assumed to be present in the input frame's Checksum field. This engine includes the Checksum field in the checksum calculation, then replaces the Checksum field with the final calculated checksum.
- In the second mode, the engine ignores the Checksum field, includes the TCP, UDP, or ICMPv6 pseudo-header data into the checksum calculation, and overwrites the checksum field with the final calculated value.

Note: For ICMP-over-IPv4 packets, the Checksum field in the ICMP packet must always be 16'h0000 in both modes, because pseudo-headers are not defined for such packets. If it does not equal 16'h0000, an incorrect checksum may be inserted into the packet.

The result of this operation is indicated by the Payload Checksum Error status bit in the Transmit Status vector (Bit 12 in [Table 15-9](#)). This engine sets the Payload Checksum

Error status bit when it detects that the frame has been forwarded to the MAC Transmitter engine in Store-and-Forward mode without the end-of-frame being written to the FIFO, or when the packet ends before the number of bytes indicated by the Payload Length field in the IP Header is received. When the packet is longer than the indicated payload length, the COE ignores them as stuff bytes, and no error is reported. When this engine detects the first type of error, it does not modify the TCP, UDP, or ICMP header. For the second error type, it still inserts the calculated checksum into the corresponding header field.

15.2.2.2 Receive Path

This module receives the frames given out by the ETH core and pushes them into the Rx FIFO. The status (fill level) of this FIFO is indicated to the DMA once it crosses the configured Receive threshold (**ETH0_OPERATION_MODE.RTC** bits). The MTL also indicates the FIFO fill level so that the DMA can initiate pre-configured burst transfers towards the Bus interface.

Receive Operation through **Receive Status Word** detail receive operations for the MTL Layer.

Receive Operation

During an Rx operation, the MTL is slaved to the ETH. The general sequence of Receive operation events is as follows:

1. When the ETH receives a frame, it pushes in data along with byte enables. The ETH also indicates the SOF and EOF. The MTL accepts the data and pushes it into the Rx FIFO. After the EOF is transferred, the ETH drives the status word, which is also pushed into the same Rx FIFO by the MTL.
2. When IEEE 1588 time stamping is enabled and the 64-bit time stamp is available along with the receive status, it is appended to the frame received from the ETH and is pushed into the Rx FIFO before the corresponding receive status word is written. Thus, two additional locations per frame are taken for storing the time stamp in the Rx FIFO.
3. The MTL_RX engine takes the data out of the FIFO and sends it to the DMA. In the default Cut-Through mode, when 64 bytes (configured with the **ETH0_OPERATION_MODE.RTC** bits or a full packet of data are received into the FIFO, the MTL_RX engine pops out the data and indicates its availability to the DMA. Once the DMA initiates the transfer to the Bus interface, the MTL_RX engine continues to transfer data from the FIFO until a complete packet has been transferred. Upon completion of the EOF frame transfer, the MTL pops out the status word and sends it to the DMA controller.
4. In Rx FIFO Store-and-Forward mode (configured by the Operation Mode.RSF bit), a frame is read out only after being written completely into the Receive FIFO. In this mode, all error frames are dropped (if the core is configured to do so) such that only

valid frames are read out and forwarded to the application. In Cut-Through mode, some error frames are not dropped, because the error status is received at the end-of-frame, by which time the start of that frame has already been read out of the FIFO.

Note: The time-stamp transfer takes two clock cycles and the lower 32-bit of the time-stamp is given out first. The status also may be extended to two cycles when Advanced Time-stamp feature is enabled.

Receive Operation Multiframe Handling

Since the status is available immediately following the data, the MTL is capable of storing any number of frames into the FIFO, as long as it is not full.

Error Handling

If the MTL Rx FIFO is full before it receives the EOF data from the ETH, an overflow is declared, the whole frame (including the status word) is dropped, and the overflow counter in the DMA (**ETH0_MISSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER** Register) is incremented. This is true even if the Forward Error Frame (**ETH0_OPERATION_MODE.FEF** bit) is set. If the start address of such a frame has already been transferred to the Read Controller, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status will indicate a partial frame due to overflow. In such frames, the Frame Length field is invalid.

The MTL Rx Control logic can filter error and undersized frames, if enabled (using the Operation Mode.FEF and Operation Mode.FUF bits). If the start address of such a frame has already been transferred to the Rx FIFO Read Controller, that frame is not filtered. The start address of the frame is transferred to the Read Controller after the frame crosses the receive threshold (set by the Operation Mode.RTC bits).

If the MTL Receive FIFO is configured to operate in Store-and-Forward mode, all error frames can be filtered and dropped.

Receive Status Word

At the end of the transfer of the Ethernet frame to the XMC4[78]00 RAM, the MTL outputs the receive status to the Application. The detailed description of the receive status is the same as for Bits[31:0] of RDES_{0RAM}, given in [Table 15-4](#), except that Bits 31, 14, 9, and 8 are reserved and have a reset of 0 by default. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

Note: When Advanced Time Stamp feature is enabled, the status is composed of two parts - normal (default [31:0]), and extended. The extended status[63:32] gives the information about the received ethernet payload when it is carrying PTP packets or TCP/UDP/ICMP over IP packets. These are transferred over two clock cycles. The detailed description of the receive status is the same as described in RDES0

and RDES4 in **Receive Descriptor**, except that bits 31, 14, 9, and 8 of normal status is reserved and have a reset value of 0_B. When the status of a partial frame due to overflow is given out, the Frame Length field in the status word is not valid.

15.2.3 DMA Controller

The DMA has independent Transmit and Receive engines, and a CSR space. The Transmit Engine transfers data from system memory to the device port (MTL), while the Receive Engine transfers data from the device port to system memory. The controller utilizes descriptors to efficiently move data from source to destination with minimal CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the CPU for situations such as Frame Transmit and Receive transfer completion, and other normal/error conditions.

The DMA and the CPU driver communicate through two data structures:

- Control and Status registers (CSR)
- Descriptor lists and data buffers

Control and Status registers are described in detail in **Chapter 15.6**. Descriptors are described in detail in **DMA Descriptors**.

The DMA descriptors are held in ram. To avoid confusion with the ETH registers the DMA descriptors use the subscript RAM for example RDES0[0]_{RAM}.

The DMA transfers data frames received by the core to the Receive Buffer in the XMC4[78]00 memory, and Transmit data frames from the Transmit Buffer in the XMC4[78]00 memory. Descriptors that reside in the XMC4[78]00 memory act as pointers to these buffers.

There are two descriptor lists; one for reception, and one for transmission. The base address of each list is written into DMA RECEIVE_DESCRIPTOR_LIST_ADDRESS Register and TRANSMIT_DESCRIPTOR_LIST_ADDRESS Register, respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both Receive and Transmit descriptors (RDES1[24]_{RAM} and TDES1[24]_{RAM}). The descriptor lists resides in the XMC4[78]00 physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.

A data buffer resides in the XMC4[78]00 physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA will skip to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.

The descriptor ring and chain structure is shown in **Figure 15-2**.

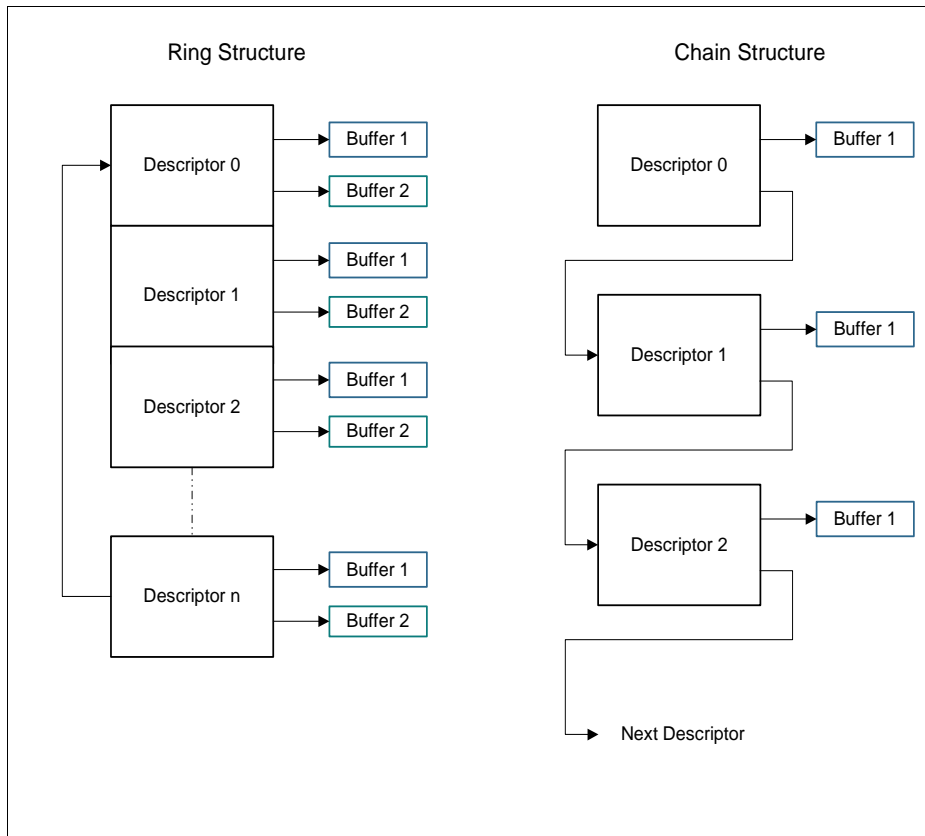

Figure 15-2 Descriptor Ring and Chain Structure

15.2.3.1 Initialization

Initialization for the ETH is as follows.

1. Write to **ETH0_BUS_MODE** Register to set XMC4[78]00 bus access parameters.
2. Write to **ETH0_INTERRUPT_ENABLE** Register to mask unnecessary interrupt causes.
3. The software driver creates the Transmit and Receive descriptor lists. Then it writes to both DMA **ETH0_RECEIVE_DESCRIPTOR_LIST_ADDRESS** Register and DMA **ETH0_TRANSMIT_DESCRIPTOR_LIST_ADDRESS** Register, providing the DMA with the starting address of each list.

Ethernet MAC (ETH)

4. Write to ETH Registers **ETH0_TRANSMIT_POLL_DEMAND**, **ETH0_RECEIVE_POLL_DEMAND**, and Receive Descriptor List Address for desired filtering options.
5. Write to **ETH0_MAC_CONFIGURATION** Register to configure and enable the Transmit and Receive operating modes. The **ETH0_MAC_CONFIGURATION.DM** bit is set based on the auto-negotiation result (read from the PHY).
6. Write to **ETH0_OPERATION_MODE.ST** and **ETH0_OPERATION_MODE.SR** bits start transmission and reception.
7. The Transmit and Receive engines enter the Running state and attempt to acquire descriptors from the respective descriptor lists. The Receive and Transmit engines then begin processing Receive and Transmit operations. The Transmit and Receive processes are independent of each other and can be started or stopped separately.

XMC4[78]00 Bus Burst Access

The DMA will attempt to execute fixed-length Burst transfers on the Bus Master interface if configured to do so (**ETH0_BUS_MODE.FB** Register). The maximum Burst length is indicated and limited by the PBL field (Bus Mode.PBL Register). The Receive and Transmit descriptors are always accessed in the maximum possible (limited by PBL or $(16 * 8)/32$) burst-size for the 16-bytes to be read.

The Transmit DMA will initiate a data transfer only when sufficient space to accommodate the configured burst is available in MTL Transmit FIFO or the number of bytes till the end of frame (when it is less than the configured burst-length). The DMA will indicate the start address and the number of transfers required to the Bus Master Interface. When the Bus Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions.

The Receive DMA will initiate a data transfer only when sufficient data to accommodate the configured burst is available in MTL Receive FIFO or when the end of frame (when it is less than the configured burst-length) is detected in the Receive FIFO. The DMA will indicate the start address and the number of transfers required to the Bus Master Interface. When the Bus Interface is configured for fixed-length burst, then it will transfer data using the best combination of INCR4/8 and SINGLE transactions. If the end-of frame is reached before the fixed-burst ends on the Bus interface, then dummy transfers are performed in-order to complete the fixed-burst.

When the Bus interface is configured for address-aligned beats, both DMA engines ensure that the first burst transfer the Bus initiates is less than or equal to the size of the configured PBL. Thus, all subsequent beats start at an address that is aligned to the configured PBL. The DMA can only align the address for beats up to size (for $PBL >$), because the Bus interface does not support more than INCR8/16.

XMC4[78]00 Data Buffer Alignment

The Transmit and Receive data buffers do not have any restrictions on start address alignment. For example, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame.

Example - Buffer Read

If the Transmit buffer address is 00000FF2_H, and 15 bytes need to be transferred, then the DMA will read five full words from address 00000FF0_H, but when transferring data to the MTL Transmit FIFO, the extra bytes (the first two bytes) will be dropped or ignored. Similarly, the last 3 bytes of the last transfer will also be ignored. The DMA always ensures it transfers a full 32-bit data to the MTL Transmit FIFO, unless it is the end-of-frame.

Buffer Size Calculations

The DMA does not update the size fields in the Transmit and Receive descriptors. The DMA updates only the status fields (RDES_{RAM} and TDES_{RAM}) of the descriptors. The driver has to perform the size calculations.

The transmit DMA transfers to the ETH the exact number of bytes (indicated by buffer size field of TDES1_{RAM}) towards the ETH core. If a descriptor is marked as first (FS bit of TDES1_{RAM} is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as last (LS bit of TDES1_{RAM}), then the DMA marks the last transfer from that data buffer as the end-of frame to the MTL.

The Receive DMA transfers data to a buffer until the buffer is full or the end-of frame is received from the MTL. If a descriptor is not marked as last (LS bit of RDES0_{RAM}), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as last, then the buffer may not be full (as indicated by the buffer size in RDES1_{RAM}). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]_{JRAM}) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The Receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to a word boundary, the system should allocate a receive buffer aligned to a word boundary. For example, if the system allocates a 1024-byte (1 KB) receive buffer starting from address 1000_H, the software can program the buffer start address in the Receive descriptor to have a 1002_H offset. The Receive DMA writes the frame to this buffer with dummy data in the first two locations (1000_H and 1001_H). The actual frame is written from location 1002_H. Thus, the actual useful space in this buffer is 1022

bytes, even though the buffer size is programmed as 1024 bytes, due to the start address offset.

DMA Arbiter

The arbiter inside the DMA module performs the arbitration between the Transmit and Receive channel accesses to the Bus Master interface. Two types of arbitrations are possible: round-robin, and fixed-priority.

When round-robin arbitration is selected (**ETH0_BUS_MODE**.DA bit is reset), the arbiter allocates the data bus in the ratio set by the Bus Mode.PR Bits, when both Transmit and Receive DMAs are requesting for access simultaneously. When the DA bit is set, the Receive DMA always gets priority over the Transmit DMA for data access.

15.2.3.2 Transmission

The Transmit DMA engine has two operating modes, default and Operate Second Frame (OSF). Both these modes are described below.

TxDMA Operation: Default (Non-OSF) Mode

The Transmit DMA engine in default mode proceeds as follows:

1. The CPU sets up the transmit descriptor (TDES0_{RAM} - TDES3_{RAM}) and sets the Own bit (TDES0[31]_{RAM}) after setting up the corresponding data buffer(s) with Ethernet Frame data.
2. Once the **ETH0_OPERATION_MODE**.ST bit is set, the DMA enters the Run state.
3. While in the Run state, the DMA polls the Transmit Descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the CPU, or if an error condition occurs, transmission is suspended and both the Transmit Buffer Unavailable (**ETH0_STATUS**.TU) and Normal Interrupt Summary (STATUS.NIS Register) bits are set. The Transmit Engine proceeds to Step 8.
4. If the acquired descriptor is flagged as owned by DMA (TDES0[31]_{RAM} = 1_B), the DMA decodes the Transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the Transmit data from the XMC4[78]00 memory and transfers the data to the MTL for transmission.
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Steps Step 2, Step 3 and Step 4 are repeated until the end-of-Ethernet-frame data is transferred to the MTL.
7. When frame transmission is complete, if IEEE 1588 time stamping was enabled for the frame (as indicated in the transmit status) the time-stamp value obtained from MTL is written to the transmit descriptor (TDES2_{RAM} and TDES3_{RAM}) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0_{RAM}). Because the Own bit is cleared during this step, the CPU now owns this

Ethernet MAC (ETH)

descriptor. If time stamping was not enabled for this frame, the DMA does not alter the contents of TDES2_{RAM} and TDES3_{RAM}.

8. Transmit Interrupt (**ETH0_STATUS.TI**) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]_{RAM}) set in its Last Descriptor. The DMA engine then returns to Step 2.
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to Step 2) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared.

The TxDMA transmission flow in default mode is shown in **Figure 15-3**.

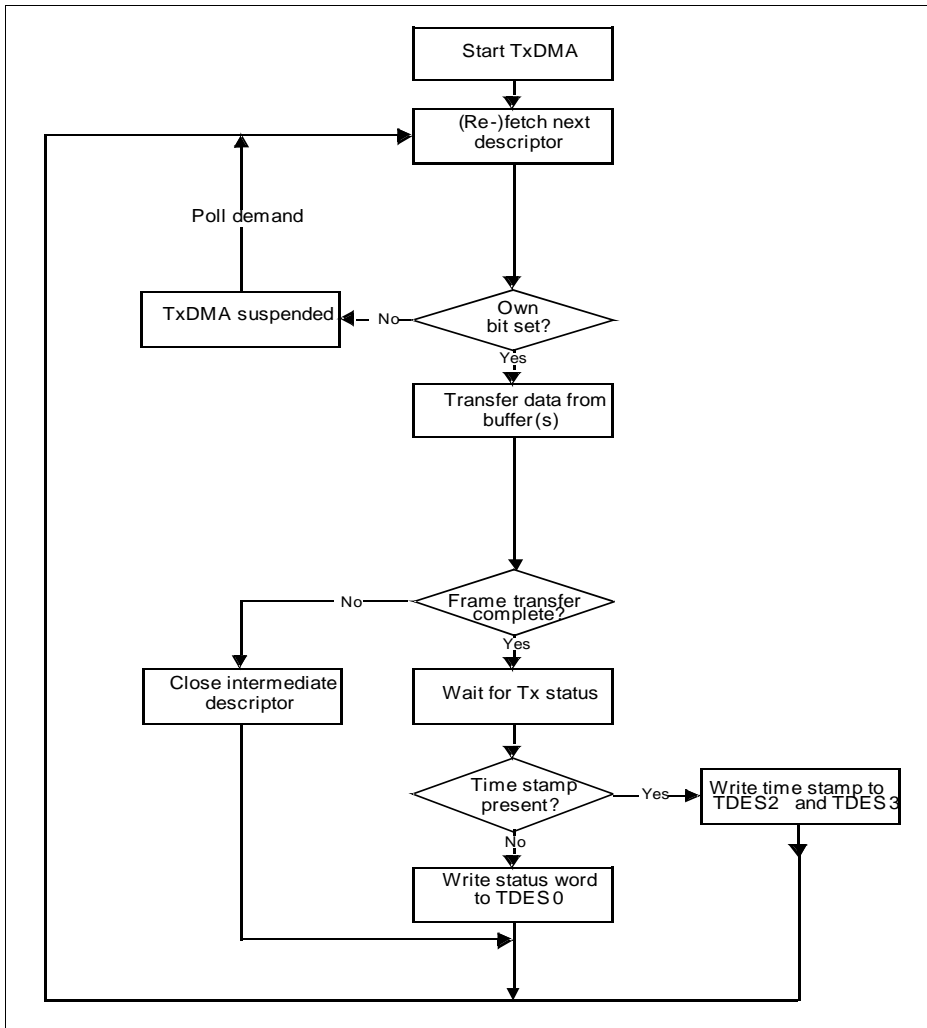

Figure 15-3 TxDMA Operation in Default Mode

TxDMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first if **ETH0_OPERATION_MODE.OSF** is set. As the transmit process finishes transferring the first frame, it immediately polls the

Transmit Descriptor list for the second frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information.

In OSF mode, the Run state Transmit DMA operates in the following sequence:

1. The DMA operates as described in Step 1–Step 5 of the TxDMA (default mode).
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor.
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to Step 6.
4. The DMA fetches the Transmit frame from the XMC4[78]00 memory and transfers the frame to the MTL until the End-of-Frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors.
5. The DMA waits for the previous frame's frame transmission status and time stamp. Once the status is available, the DMA writes the time stamp to TDES2_{RAM} and TDES3_{RAM}, if such time stamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0_{RAM}, thus closing the descriptor. If time stamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2_{RAM} and TDES3_{RAM}.
6. If enabled, the Transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to Step 2 (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (Step 6).
7. In Suspend mode, if a pending status and time stamp are received from the MTL, the DMA writes the time stamp (if enabled for the current frame) to TDES2_{RAM} and TDES3_{RAM}, then writes the status to the corresponding TDES0_{RAM}. It then sets relevant interrupts and returns to Suspend mode.
8. The DMA can exit Suspend mode and enter the Run state (go to Step 1 or Step 2 depending on pending status) only after receiving a Transmit Poll demand (**ETH0_TRANSMIT_POLL_DEMAND** Register).

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than 2 different descriptors for correct and proper operation.

The basic flow is charted in **Figure 15-4**.

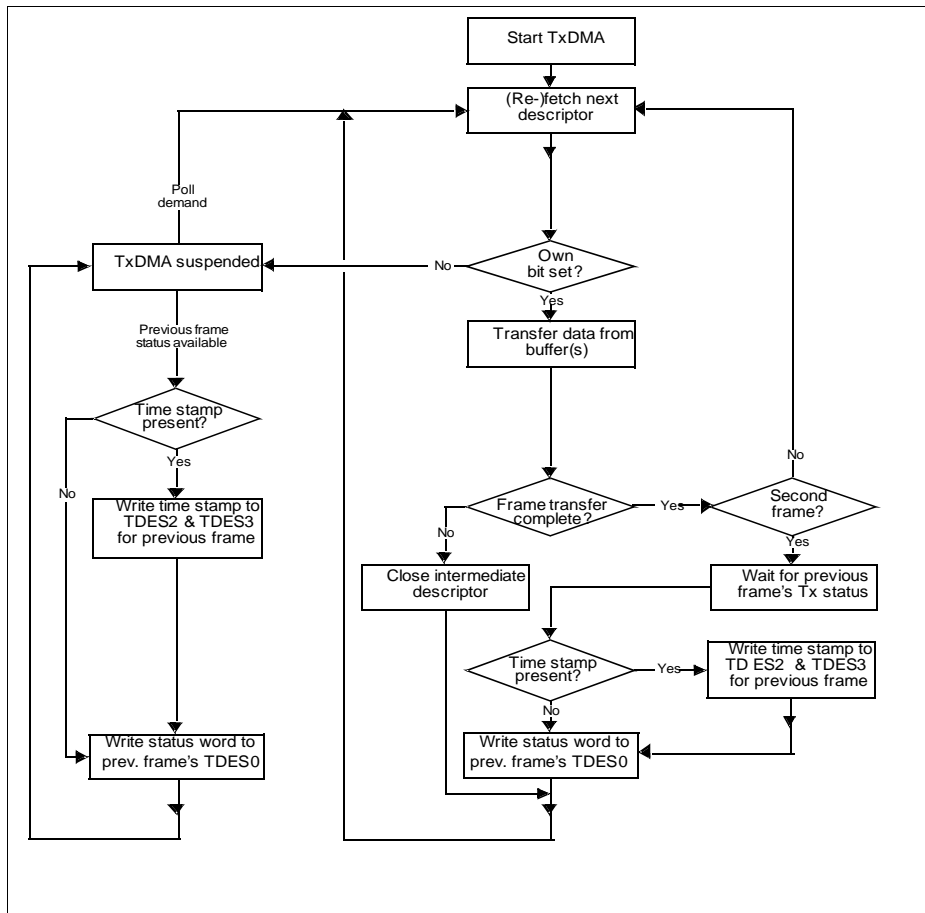

Figure 15-4 TxDMA Operation in OSF Mode

Transmit Frame Processing

The Transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields. The DA, SA, and Type/Len fields must contain valid data. If the Transmit Descriptor indicates that the MAC core must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes.

Frames can be data-chained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]_{RAM}) and the Last Descriptor (TDES1[30]_{RAM}), respectively.

As transmission starts, the First Descriptor must have (TDES1[29]_{RAM}) set. When this occurs, frame data transfers from the XMC4[78]00 RAM buffer to the MTL Transmit FIFO. Concurrently, if the current frame has the Last Descriptor (TDES1[30]_{RAM}) clear, the Transmit Process attempts to acquire the Next Descriptor. The Transmit Process expects this descriptor to have TDES1[29]_{RAM} clear. If TDES1[30]_{RAM} is clear, it indicates an intermediary buffer. If TDES1[30]_{RAM} is set, it indicates the last buffer of the frame.

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0_{RAM}) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]_{RAM}). At this time, if Interrupt on Completion (TDES1[31]_{RAM}) was set, Transmit Interrupt (ETH0_STATUS.TI) is set, the Next Descriptor is fetched, and the process repeats.

Actual frame transmission begins after the MTL Transmit FIFO has reached either a programmable transmit threshold (ETH0_OPERATION_MODE.TTC), or a full frame is contained in the FIFO. There is also an option for Store and Forward Mode (Operation Mode.TSF). Descriptors are released (Own bit TDES0[31]_{RAM} clears) when the DMA finishes transferring the frame.

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions:

- The DMA detects a descriptor owned by the CPU (TDES0[31]_{RAM}=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command.
- A frame transmission is aborted when a transmit error due to underflow is detected. The appropriate Transmit Descriptor 0 (TDES0_{RAM}) bit is set.

If the second condition occurs, both Abnormal Interrupt Summary (STATUS.AIS) and Transmit Underflow bits (STATUS.TU) are set, and the information is written to Transmit Descriptor 0, causing the suspension. If the DMA goes into SUSPEND state due to the first condition, then both Normal Interrupt Summary (STATUS.NIS) and Transmit Buffer Unavailable (STATUS.TU) are set.

In both cases, the position in the Transmit List is retained. The retained position is that of the descriptor following the Last Descriptor closed by the DMA.

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause.

15.2.3.3 Reception

The Receive DMA engine's reception sequence is depicted in **Figure 15-5** and proceeds as follows:

Ethernet MAC (ETH)

1. The CPU sets up Receive descriptors (RDES0_{RAM} -RDES3_{RAM}) and sets the Own bit (RDES0[31]_{RAM}).
2. Once the **ETH0_OPERATION_MODE**.SR bit is set, the DMA enters the Run state. While in the Run state, the DMA polls the Receive Descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the CPU), the DMA enters the Suspend state and jumps to Step 8.
3. The DMA decodes the receive data buffer address from the acquired descriptors.
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.
5. When the buffer is full or the frame transfer is complete, the Receive engine fetches the next descriptor.
6. If the current frame transfer is complete, the DMA proceeds to Step 6. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to Step 7. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to Step 3.
7. If IEEE 1588 time stamping is enabled, the DMA writes the time stamp (if available) to the current descriptor's RDES2_{RAM} and RDES3_{RAM}. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0_{RAM}, with the Own bit cleared and the Last Segment bit set.
8. The Receive engine checks the latest descriptor's Own bit. If the CPU owns the descriptor (Own bit is 1'b0) the Receive Buffer Unavailable bit (**ETH0_STATUS**.RU) is set and the DMA Receive engine enters the Suspended state (Step 8). If the DMA owns the descriptor, the engine returns to Step 3 and awaits the next frame.
9. Before the Receive engine enters the Suspend state, partial frames are flushed from the Receive FIFO (You can control flushing using Operation Mode.DFF).
10. The Receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's Receive FIFO. The engine proceeds to Step 1 and refetches the next descriptor.

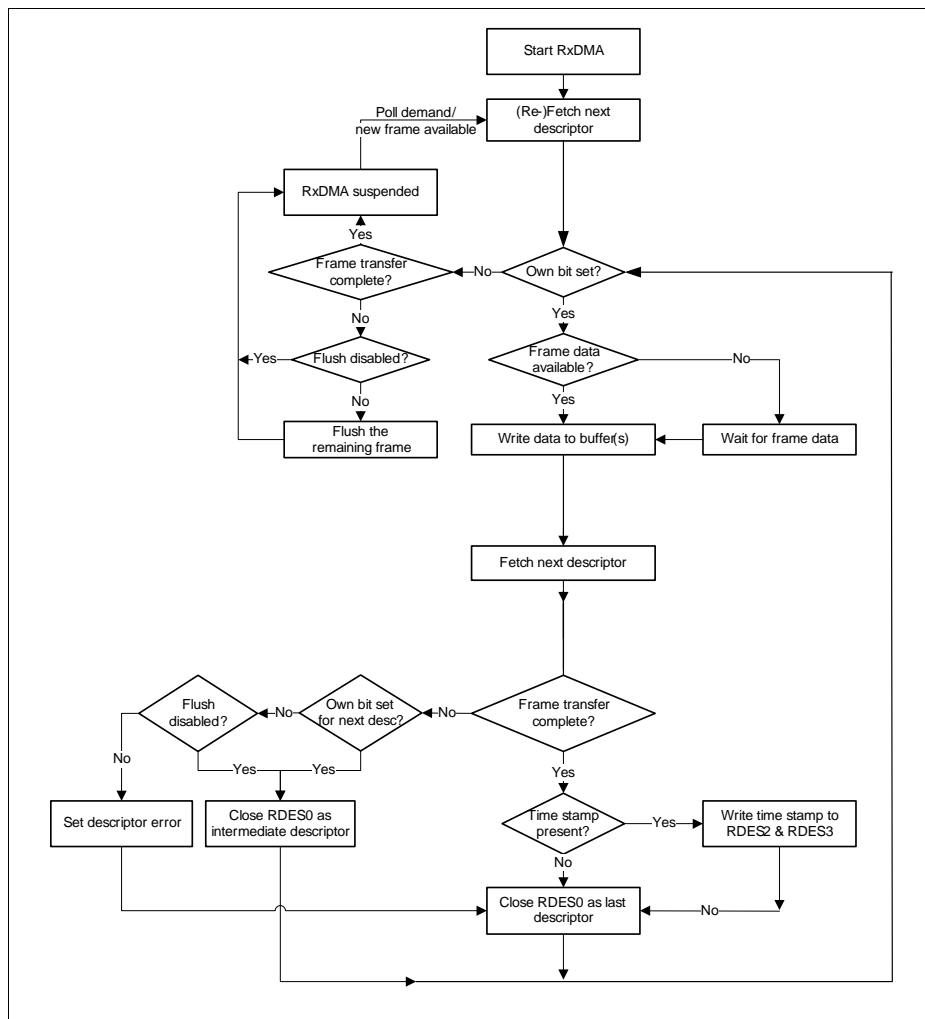

Figure 15-5 Receive DMA Operation

The DMA does not acknowledge accepting the status from the MTL until it has completed the time stamp write-back and is ready to perform status write-back to the descriptor.

If software has enabled time stamping through CSR, when a valid time stamp value is not available for the frame (for example, because the receive FIFO was full before the time stamp could be written to it), the DMA writes all-ones to RDES2_{RAM} and RDES3_{RAM}.

Otherwise (that is, if time stamping is not enabled), the RDES2_{RAM} and RDES3_{RAM} remain unchanged.

Receive Descriptor Acquisition

The Receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied:

- The receive Start/Stop bit (**ETH0_OPERATION_MODE**.SR) has been set immediately after being placed in the Run state.
- The data buffer of current descriptor is full before the frame ends for the current transfer.
- The controller has completed frame reception, but the current Receive Descriptor is not yet closed.
- The receive process has been suspended because of a CPU-owned buffer (RDES0[31]_{RAM} = 0) and a new frame is received.
- A Receive poll demand has been issued.

Receive Frame Processing

The ETH transfers the received frames to the XMC4[78]00 memory only when the frame passes the address filter and frame size is greater than or equal to configurable threshold bytes set for the Receive FIFO of the MTL, or when the complete frame is written to the FIFO in Store-and-Forward mode.

If the frame fails the address filtering, it is dropped in the ETH block itself (unless Receive All **ETH0_MAC_FRAME_FILTER**.RA is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be purged from the MTL Receive FIFO.

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the Receive Buffer pointed to by the current descriptor. The DMA sets the First Descriptor bit (RDES0[9]_{RAM}) after the DMA CPU Interface becomes ready to receive a data transfer (if DMA is not fetching transmit data from the XMC4[78]00 RAM), to delimit the frame. The descriptors are released when the Own (RDES[31]_{RAM}) bit is reset to 1'b0, either as the Data buffer fills up or as the last segment of the frame is transferred to the Receive buffer. If the frame is contained in a single descriptor, both Last Descriptor bit (RDES[8]_{RAM}) and First Descriptor bit (RDES[9]_{RAM}) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]_{RAM}) bit, and releases the RDES0_{RAM} status bits in the previous frame descriptor. Then the DMA sets Receive Interrupt flag (**ETH0_STATUS**.RI). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the CPU. If this occurs, the Receive Process sets Receive Buffer Unavailable (STATUS.RU) and then enters the Suspend state. The position in the receive list is retained.

Receive Process Suspended

If a new Receive frame arrives while the Receive Process is in Suspend state, the DMA refetches the current descriptor in the XMC4[78]00 memory. If the descriptor is now owned by the DMA, the Receive Process re-enters the Run state and starts frame reception. If the descriptor is still owned by the CPU, by default, the DMA discards the current frame at the top of the MTL Rx FIFO and increments the missed frame counter. If more than one frame is stored in the MTL Rx FIFO, the process repeats.

The discarding or flushing of the frame at the top of the MTL Rx FIFO can be avoided by setting **ETH0_OPERATION_MODE.DFF** bit. In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state.

15.2.3.4 Interrupts

Interrupts can be generated as a result of various events. The **ETH0_STATUS** Register contains all the bits that might cause an interrupt. The **ETH0_INTERRUPT_ENABLE** Register contains an enable bit for each of the events that can cause an interrupt.

There are two groups of interrupts, Normal and Abnormal, as described in the STATUS Register. Interrupts are cleared by writing 1_B to the corresponding bit position. When all the enabled interrupts within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the interrupt signal to the NVIC is deasserted. If the ETH core is the cause for assertion of the interrupt, then any of the ELI, EMI, or EPI bits of DMA STATUS Register will be set high.

Note: The interrupt signal to the NVIC will be asserted due to any event in the DMA STATUS register only if the corresponding interrupt enable bit is set in DMA Interrupt Enable Register.

Interrupts are not queued and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Receive Interrupt (STATUS.RI) indicates that one or more frames was transferred to the XMC4[78]00 RAM buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the STATUS Register for the cause of the interrupt. The interrupt is not generated again unless a new interrupting event occurs, after the driver has cleared the appropriate bit in the STATUS Register. For example, the controller generates a Receive interrupt (DMA STATUS.RI) and the driver begins reading the STATUS Register. Next, Receive Buffer Unavailable (STATUS Register) occurs. The driver clears the Receive interrupt. Even then, the DMA interrupt signal to the NVIC is not deasserted, due to the active or pending Receive Buffer Unavailable interrupt.

An interrupt timer (**ETH0_RECEIVE_INTERRUPT_WATCHDOG_TIMER**) is given for flexible control of Receive Interrupt (STATUS.RI). When this Interrupt timer is programmed with a non-zero value, it will get activated as soon as the RxDMA

Ethernet MAC (ETH)

completes a transfer of a received frame to system memory without asserting the Receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31]_{RAM} in Table 7-3). When this timer runs out as per the programmed value, RI bit is set and the interrupt is asserted if the corresponding **ETH0_INTERRUPT_ENABLE**.RI bit is enabled. This timer gets disabled before it runs out, when a frame is transferred to memory and the **ETH0_STATUS**.RI is set because it is enabled for that descriptor.

15.2.4 DMA Descriptors

This chapter describes the descriptor format used by the ETH DMA. The ETH DMA descriptors are held in RAM. To avoid confusion with the ETH registers the DMA descriptors use the subscript $]_{RAM}$ for example $RDES0[0]_{RAM}$.

15.2.4.1 Descriptor Formats

The DMA in the Ethernet subsystem transfers data based on a linked list of descriptors, as explained in **DMA Controller**. The default descriptor formats (common for both Receive and Transmit Descriptors) are shown in **Figure 15-6**, and field descriptions are provided in “**Receive Descriptor**” on Page 15-41 to “**Transmit Descriptor**” on Page 15-47.

Note:

3. *Changes to the default descriptor format when IEEE1588 time stamping is enabled are described in **Chapter “Descriptor Format With IEEE 1588 Time Stamping Enabled”** on Page 15-53“.*

Each descriptor contains two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory management schemes.

The descriptor addresses must be aligned to 32 bit word boundaries .

Figure 15-6 show the descriptor format .

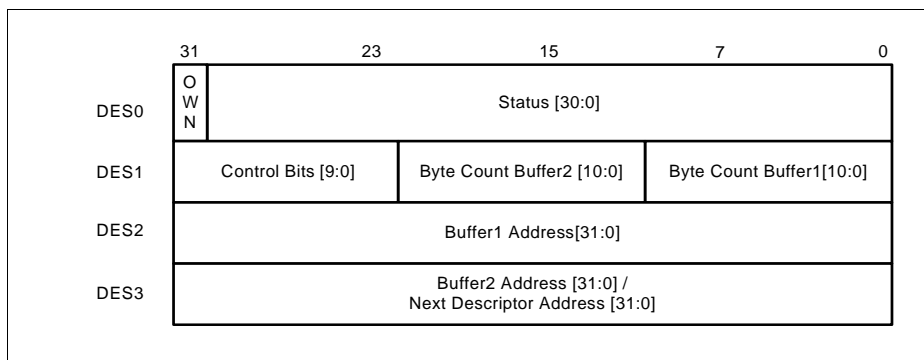

Figure 15-6 Rx/Tx Descriptors

Receive Descriptor

The ETH Subsystem requires at least two descriptors when receiving a frame. The Receive state machine of the DMA (in the ETH Subsystem) always attempts to acquire an extra descriptor in anticipation of an incoming frame. (The size of the incoming frame

is unknown). Before the RxDMA closes a descriptor, it will attempt to acquire the next descriptor even if no frames are received.

In a single descriptor (receive) system, the subsystem will generate a descriptor error if the receive buffer is unable to accommodate the incoming frame and the next descriptor is not owned by the DMA. Thus, the CPU is forced to increase either its descriptor pool or the buffer size. Otherwise, the subsystem starts dropping all incoming frames.

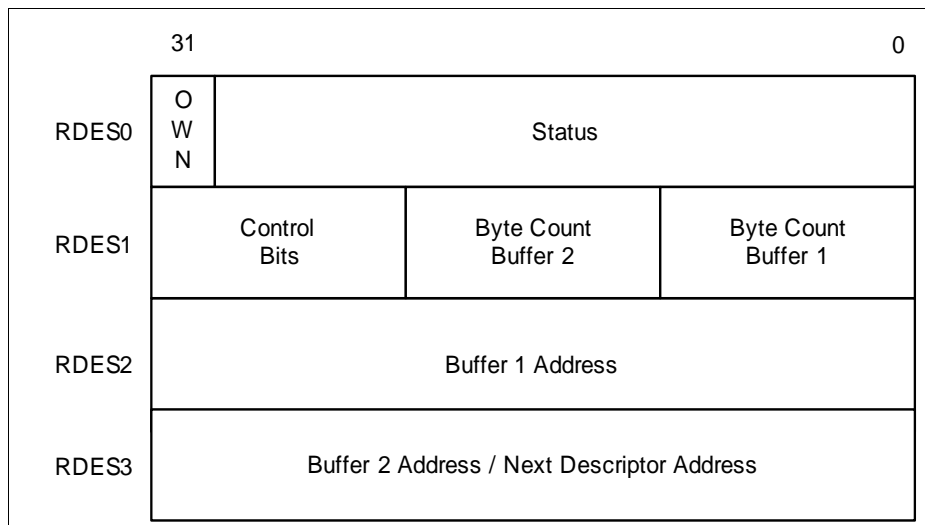

Figure 15-7 Receive Descriptor Format

Receive Descriptor 0 (RDES0_{RAM})

RDES0_{RAM} contains the received frame status, the frame length, and the descriptor ownership information. The format of the descriptor is given in tables [Table 15-4](#) through [Table 15-12](#).

Table 15-4 Receive Descriptor 0

| Bit | Description |
|-----|---|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA of the ETH Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the CPU. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full. |
| 30 | AFM: Destination Address Filter Fail When set, this bit indicates a frame that failed in the DA Filter in the ETH Core. |

Table 15-4 Receive Descriptor 0 (cont'd)

| Bit | Description |
|-----------|--|
| 29:1 6 | <p>FL: Frame Length</p> <p>These bits indicate the byte length of the received frame that was transferred to XMC4[78]00 memory (including CRC). This field is valid when Last Descriptor (RDES0[8]_{RAM}) is set and either the Descriptor Error (RDES0[14]_{RAM}) or Overflow Error bits are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame.</p> <p>This field is valid when Last Descriptor (RDES0[8]_{RAM}) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame.</p> |
| 15 | <p>ES: Error Summary</p> <p>Indicates the logical OR of the following bits:</p> <ul style="list-style-type: none"> • RDES0[0]_{RAM}: Payload Checksum Error • RDES0[1]_{RAM}: CRC Error • RDES0[3]_{RAM}: Receive Error • RDES0[4]_{RAM}: Watchdog Timeout • RDES0[6]_{RAM}: Late Collision • RDES0[7]_{RAM}: IPC Checksum (Type 2) / Giant Frame • RDES0[11]_{RAM}: Overflow Error • RDES0[14]_{RAM}: Descriptor Error <p>This field is valid only when the Last Descriptor (RDES0[8]_{RAM}) is set.</p> |
| 14 | <p>DE: Descriptor Error</p> <p>When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]_{RAM}) is set.</p> |
| 13 | <p>SAF: Source Address Filter Fail</p> <p>When set, this bit indicates that the SA field of frame failed the SA Filter in the ETH Core.</p> |
| 12 | <p>LE: Length Error</p> <p>When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]_{RAM}) bit is reset. Length error status is not valid when CRC error is present.</p> |
| 11 | <p>OE: Overflow Error</p> <p>When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL.</p> |

Table 15-4 Receive Descriptor 0 (cont'd)

| Bit | Description |
|-----|---|
| 10 | VLAN: VLAN Tag When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the ETH Core. |
| 9 | FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame. |
| 8 | LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame |
| 7 | IPC Checksum Error/Giant Frame This bit indicates an error in the IPv4 or IPv6 header. This error can be due to inconsistent Ethernet Type field and IP header Version field values, a header checksum mismatch in IPv4, or an Ethernet frame lacking the expected number of IP header bytes. Refer to Table 15-5 for more details. |
| 6 | LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode. |
| 5 | FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 0600 _H). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. Refer to Table 15-5 for more details. |
| 4 | RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. |
| 3 | RE: Receive Error When set, this bit indicates that the MII Receive Error signal is asserted while Carrier Sense signal is asserted during frame reception. This error also includes carrier extension error in MII and Half-duplex mode. Error can be of less/no extension, or error (rxd ≠ 0f) during extension. |
| 2 | DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode. |

Table 15-4 Receive Descriptor 0 (cont'd)

| Bit | Description |
|-----|--|
| 1 | CE: CRC Error When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8] _{RAM}) is set. |
| 0 | Payload Checksum Error When set, indicates the TCP, UDP, or ICMP checksum the core calculated does not match the received encapsulated TCP, UDP, or ICMP segment's Checksum field. This bit is also set when the received number of payload bytes does not match the value indicated in the Length field of the encapsulated IPv4 or IPv6 datagram in the received Ethernet frame. Refer to Table 15-5 for more details. |

The permutations of bits 5, 7, and 0 reflect the conditions discussed in [Table 15-5](#).

Table 15-5 Receive Descriptor 0 When COE (Type 2) Is Enabled

| Bit 5: Frame Type | Bit 7: IPC Checks um Error | Bit 0: Payload Checks um Error | Frame Status |
|-------------------------|--|--|---|
| 0 | 0 | 0 | IEEE 802.3 Type frame (Length field value is less than 0600 _H) |
| 1 | 0 | 0 | IPv4/IPv6 Type frame, no checksum error detected |
| 1 | 0 | 1 | IPv4/IPv6 Type frame with a payload checksum error (as described for PCE) detected |
| 1 | 1 | 0 | IPv4/IPv6 Type frame with an IP header checksum error (as described for IPC CE) detected |
| 1 | 1 | 1 | IPv4/IPv6 Type frame with both IP header and payload checksum errors detected |
| 0 | 0 | 1 | IPv4/IPv6 Type frame with no IP header checksum error and the payload check bypassed, due to an unsupported payload |
| 0 | 1 | 1 | A Type frame that is neither IPv4 or IPv6 (the Checksum Offload engine bypasses checksum completely.) |
| 0 | 1 | 0 | Reserved |

Receive Descriptor 1 (RDES1_{RAM})

RDES1_{RAM} contains the buffer sizes and other bits that control the descriptor chain/ring.

Note: See [Buffer Size Calculations](#) for further detail on calculating buffer sizes.

Table 15-6 Receive Descriptor 1

| Bit | Description |
|-------|--|
| 31 | Disable Interrupt on Completion When set, this bit will prevent the setting of the ETH0_STATUS.RI bit of the Status Register for the received frame that ends in the buffer pointed to by this descriptor. This, in turn, will disable the assertion of the interrupt to the CPU due to RI for that frame. |
| 30:26 | Reserved |
| 25 | RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a Descriptor Ring. |
| 24 | RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When RDES1[24] _{RAM} is set, RBS2 _{RAM} (RDES1[21-11] _{RAM}) is a “don't care” value. RDES1[25] _{RAM} takes precedence over RDES1[24] _{RAM} . |
| 23:22 | Reserved |
| 21:11 | RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size in bytes. The buffer size must be a multiple of 4, even if the value of RDES3 _{RAM} (buffer2 address pointer) is not aligned to bus width. In the case where the buffer size is not a multiple of 4, the resulting behavior is undefined. This field is not valid if RDES1[24] _{RAM} is set. |
| 10:0 | RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, even if the value of RDES2 _{RAM} (buffer1 address pointer) is not aligned. In the case where the buffer size is not a multiple of 4/8/16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 24). |

Receive Descriptor 2 (RDES2_{RAM})

RDES2_{RAM} contains the address pointer to the first data buffer in the descriptor.

Note: See [XMC4\[78\]00 Data Buffer Alignment](#) for further detail on buffer address alignment.

Table 15-7 Receive Descriptor 2 (Default Operation)

| Bit | Description |
|------|--|
| 31:0 | Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] _{RAM} bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] _{RAM} if the address pointer is to a buffer where the middle or last part of the frame is stored. |

Receive Descriptor 3 (RDES3_{RAM})

RDES3_{RAM} contains the address pointer either to the second data buffer in the descriptor or to the next descriptor.

Table 15-8 Receive Descriptor 3

| Bit | Description |
|------|---|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address) These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24] _{RAM}) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. If RDES1[24] _{RAM} is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] _{RAM} = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] _{RAM} is reset, there are no limitations on the RDES3 _{RAM} value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] _{RAM} if the address pointer is to a buffer where the middle or last part of the frame is stored. |

Transmit Descriptor

The descriptor addresses must be aligned to the 32 bit word boundary . **Figure 15-8** shows the transmit descriptor format.

Each descriptor is provided with two buffers, two byte-count buffers, and two address pointers, which enable the adapter port to be compatible with various types of memory-management schemes.

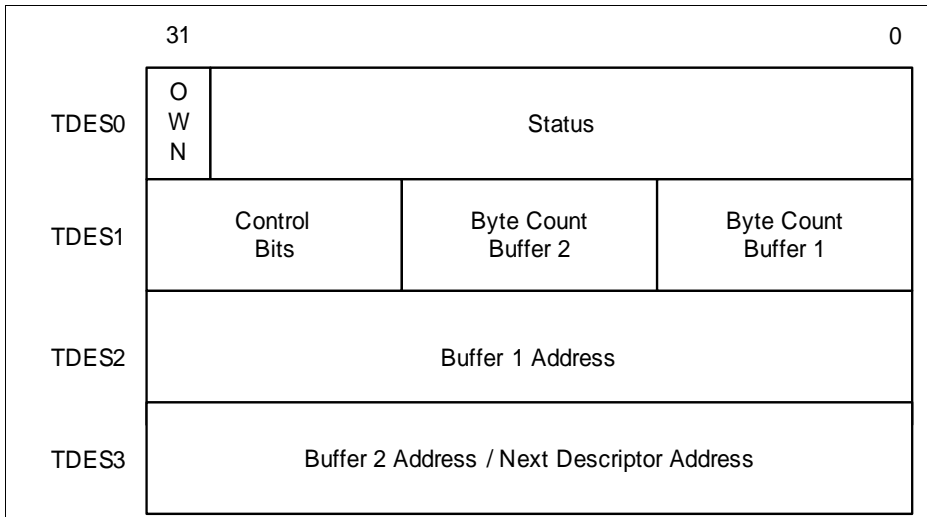

Figure 15-8 Transmit Descriptor Format

Transmit Descriptor 0 (TDES0_{RAM})

TDES0_{RAM} contains the transmitted frame status and the descriptor ownership information.

Table 15-9 Transmit Descriptor 0

| Bit | Description |
|-------|---|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, this bit indicates that the descriptor is owned by the CPU. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are empty. The ownership bit of the First Descriptor of the frame should be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30:18 | Reserved |

Table 15-9 Transmit Descriptor 0 (cont'd)

| Bit | Description |
|-----|--|
| 17 | TTSS: Tx Time Stamp Status This status bit indicates that a time stamp has been captured for the corresponding transmit frame. When this bit is set, TDES2 _{RAM} and TDES3 _{RAM} have time stamp values that were captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30] _{RAM}) in a descriptor is set. This bit is valid only when IEEE1588 time stamping feature is enabled; otherwise, it is reserved. |
| 16 | IHE: IP Header Error When set, this bit indicates that the Checksum Offload engine detected an IP header error and consequently did not modify the transmitted frame for any checksum insertion. |
| 15 | ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none"> • TDES0[14]_{RAM}: Jabber Timeout • TDES0[13]_{RAM}: Frame Flush • TDES0[11]_{RAM}: Loss of Carrier • TDES0[10]_{RAM}: No Carrier • TDES0[9]_{RAM}: Late Collision • TDES0[8]_{RAM}: Excessive Collision • TDES0[2]_{RAM}: Excessive Deferral • TDES0[1]_{RAM}: Underflow Error |
| 14 | JT: Jabber Timeout When set, this bit indicates the ETH transmitter has experienced a jabber timeout. This bit is only set when the ETH configuration register's JD bit is not set. |
| 13 | FF: Frame Flushed When set, this bit indicates that the DMA/MTL flushed the frame due to a SW flush command given by the CPU. |
| 12 | PCE: Payload Checksum Error This bit, when set, indicates that the Checksum Offload engine had a failure and did not insert any checksum into the encapsulated TCP, UDP, or ICMP payload. This failure can be either due to insufficient bytes, as indicated by the IP Header's Payload Length field, or the MTL starting to forward the frame to the MAC transmitter in Store-and-Forward mode without the checksum having been calculated yet. This second error condition only occurs when the Transmit FIFO depth is less than the length of the Ethernet frame being transmitted: to avoid deadlock, the MTL starts forwarding the frame when the FIFO is full, even in Store-and-Forward mode. |

Table 15-9 Transmit Descriptor 0 (cont'd)

| Bit | Description |
|-----|--|
| 11 | LC: Loss of Carrier When set, this bit indicates that Loss of Carrier occurred during frame transmission . This is valid only for the frames transmitted without collision and when the ETH operates in Half-Duplex Mode. |
| 10 | NC: No Carrier When set, this bit indicates that the carrier sense signal form the PHY was not asserted during transmission. |
| 9 | LC: Late Collision When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte times including Preamble in MII Mode). Not valid if Underflow Error is set. |
| 8 | EC: Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the ETH Configuration Register is set, this bit is set after the first collision and the transmission of the frame is aborted. |
| 7 | VF: VLAN Frame When set, this bit indicates that the transmitted frame was a VLAN-type frame. |
| 6:3 | CC: Collision Count This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8] _{RAM}) is set. |
| 2 | ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1000 Mbit/s mode, or in Jumbo Frame enabled mode) if the Deferral Check (DC) bit is set high in the ETH Control Register. |
| 1 | UF: Underflow Error When set, this bit indicates that the ETH aborted the frame because data arrived late from the XMC4[78]00 memory. Underflow Error indicates that the DMA encountered an empty Transmit Buffer while transmitting the frame. The transmission process enters the suspended state and sets both STATUS.TU and STATUS.TI. |
| 0 | DB: Deferred Bit When set, this bit indicates that the ETH defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode. |

Transmit Descriptor 1 (TDES1_{RAM})

TDES1_{RAM} contains the buffer sizes and other bits which control the descriptor chain/ring and the frame being transferred.

Note: See [Buffer Size Calculations](#) for further detail on calculating buffer sizes.

Table 15-10 Transmit Descriptor 1

| Bit | Description |
|-------|--|
| 31 | IC: Interrupt on Completion When set, this bit sets Transmit Interrupt, STATUS.TI bit after the present frame has been transmitted. |
| 30 | LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. |
| 29 | FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame. |
| 28:27 | CIC: Checksum Insertion Control These bits control the insertion of checksums in Ethernet frames that encapsulate TCP, UDP, or ICMP over IPv4 or IPv6 as described below. <ul style="list-style-type: none"> • 00: Do nothing. Checksum Engine is bypassed • 01: Insert IPv4 header checksum. Use this value to insert IPv4 header checksum when the frame encapsulates an IPv4 datagram. • 10: Insert TCP/UDP/ICMP checksum. The checksum is calculated over the TCP, UDP, or ICMP segment only and the TCP, UDP, or ICMP pseudo-header checksum is assumed to be present in the corresponding input frame's Checksum field. An IPv4 header checksum is also inserted if the encapsulated datagram conforms to IPv4. • 11: Insert a TCP/UDP/ICMP checksum that is fully calculated in this engine. In other words, the TCP, UDP, or ICMP pseudo-header is included in the checksum calculation, and the input frame's corresponding Checksum field has an all-zero value. An IPv4 Header checksum is also inserted if the encapsulated datagram conforms to IPv4. The Checksum engine detects whether the TCP, UDP, or ICMP segment is encapsulated in IPv4 or IPv6 and processes its data accordingly. |
| 26 | DC: Disable CRC When set, the ETH does not append the Cyclic Redundancy Check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES1[29] _{RAM}) bit is set. |
| 25 | TER: Transmit End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The returns to the base address of the list, creating a descriptor ring. |

Table 15-10 Transmit Descriptor 1 (cont'd)

| Bit | Description |
|-------|--|
| 24 | TCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When $TDES1[24]_{RAM}$ is set, $TBS2$ ($TDES1[21-11]_{RAM}$) are "don't care" values. $TDES1[25]_{RAM}$ takes precedence over $TDES1[24]_{RAM}$. |
| 23 | DP: Disable Padding When set, the ETH does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes and the CRC field is added despite the state of the DC ($TDES1[26]_{RAM}$) bit. This is valid only when the first segment ($TDES1[29]_{RAM}$) is set. |
| 22 | TTSE: Transmit Time Stamp Enable When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit ($TDES1[29]_{RAM}$) is set. |
| 21:11 | TBS2: Transmit Buffer 2 Size These bits indicate the Second Data Buffer in bytes. This field is not valid if $TDES1[24]_{RAM}$ is set. |
| 10:0 | TBS1: Transmit Buffer 1 Size These bits indicate the First Data Buffer byte size. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of TCH (Bit 24). |

Transmit Descriptor 2 ($TDES2$)

$TDES2$ contains the address pointer to the first buffer of the descriptor.

Table 15-11 Transmit Descriptor 2

| Bit | Description |
|------|---|
| 31:0 | Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See XMC4[78]00 Data Buffer Alignment for further detail on buffer address alignment. |

Transmit Descriptor 3 ($TDES3_{RAM}$)

$TDES3_{RAM}$ contains the address pointer either to the second buffer of the descriptor or the next descriptor.

Table 15-12 Transmit Descriptor 3

| Bit | Description |
|------|--|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24] _{RAM}) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] _{RAM} is set. (LSBs are ignored internally.) |

Descriptor Format With IEEE 1588 Time Stamping Enabled

The default descriptor format (as described in [“Receive Descriptor” on Page 15-55](#) and [“Transmit Descriptor” on Page 15-47](#)), and field descriptions remain unchanged when created by software (Own bit is set in DES0_{RAM}). However, if the software has enabled IEEE 1588 functionality, the DES2_{RAM} and DES3_{RAM} descriptor fields (see [Figure 15-9](#)) take on a different meaning when the DMA closes the descriptor (own bit in DES0_{RAM} is cleared).

The DMA updates the DES2_{RAM} and DES3_{RAM} with the time stamp value before clearing the Own bit in DES0_{RAM}.

DES2_{RAM} is updated with the lower 32 time stamp bits (the Sub-Second field, called TSL in subsequent sections) and DES3_{RAM} is updated with the upper 32 time stamp bits (the Seconds field, called TSH in subsequent sections).

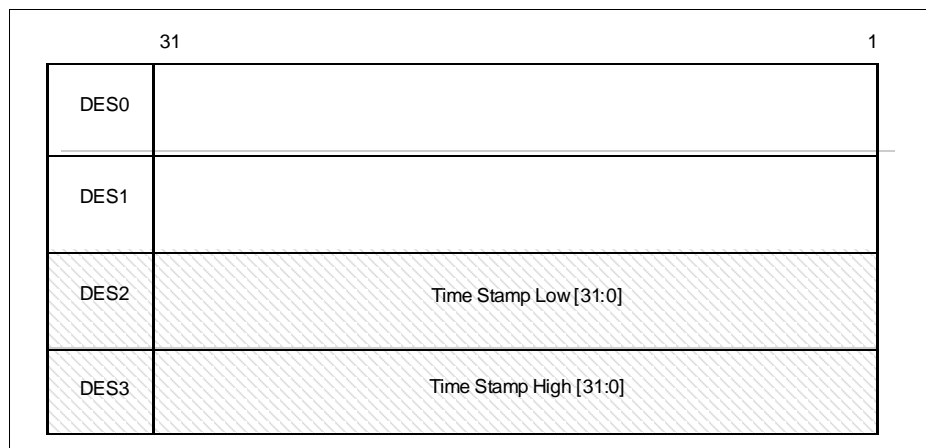

Figure 15-9 Receive Descriptor Fields When DMA Clears the Own Bit

The following sections describe the details specific to receive and transmit descriptors in this mode.

Receive Descriptor

Receive Time Stamp

The tables below describe the fields that have different meaning for RDES2_{RAM} and RDES3_{RAM} when the receive descriptor is closed and time stamping is enabled.

*Note: When software disables the time stamping feature (the **ETH0_TIMESTAMP_CONTROL.TSENA** bit is low), the DMA does not update the descriptor's RDES2_{RAM}/RDES3_{RAM} fields before closing the RDES0_{RAM}.*

Table 15-13 Receive Descriptor Fields (RDES2)

| Bit | Description |
|------|---|
| 31:0 | RTSL: Receive Frame Time Stamp Low The DMA updates this field with the least significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8] _{RAM}). When this field and the RTSH field in RDES3 _{RAM} show an all-ones value, the time stamp must be treated as corrupt. |

Table 15-14 Receive Descriptor Fields (RDES3)

| Bit | Description |
|------|--|
| 31:0 | RTSH: Receive Frame Time Stamp High The DMA updates this field with the most significant 32 bits of the time stamp captured for the corresponding receive frame. The DMA updates this field only for the last descriptor of the receive frame indicated by Last Descriptor status bit (RDES0[8] _{RAM}). When this field and RDES2 _{RAM} 's RTSL field show all-ones values, the time stamp must be treated as corrupt. |

Transmit Descriptor

In addition to the changes described in “**Descriptor Format With IEEE 1588 Time Stamping Enabled**” on Page 15-53, the Transmit descriptor has additional control and status bits (TTSE and TTSS, respectively) for time stamping, as shown in **Figure 15-10**. Software sets the TTSE bit (when the Own bit is set), instructing the core to generate a time stamp for the corresponding Ethernet frame being transmitted. The DMA sets the TTSS bit if the time stamp has been updated in the TDES2_{RAM} and TDES3_{RAM} fields when the descriptor is closed (Own bit is cleared).

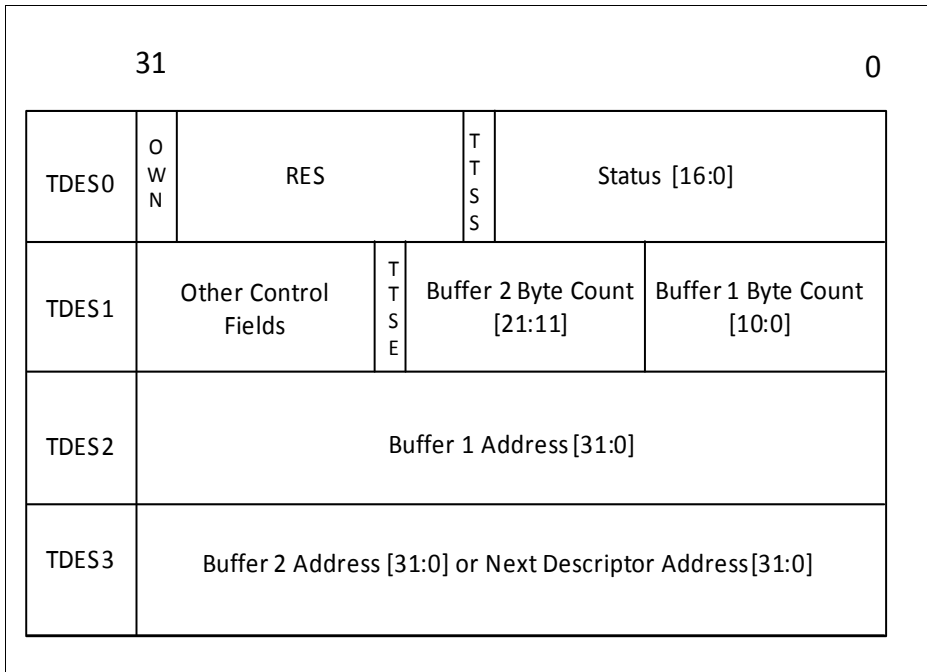

Figure 15-10 Transmit Descriptor Fields

Transmit Time Stamp Control and Status Fields

The value of this field shall be preserved by the DMA at the time of closing the descriptor.

Updates to [Table 15-8](#) and [Table 15-9](#) are described below.

Table 15-15 Transmit Time Stamp Status – Normal Descriptor Format Case (TDES0RAM)

| Bit | Description |
|-----|--|
| 17 | TTSS: Transmit Time Stamp Status This field is a status bit indicating that a time stamp was captured for the corresponding transmit frame. When this bit is set, both TDES2RAM and TDES3RAM have a time stamp value that was captured for the transmit frame. This field is valid only when the Last Segment control bit (TDES1[30]RAM in the descriptor) is set. |

Table 15-16 Transmit Time Stamp Control – Normal Descriptor Format Case (TDES1_{RAM})

| Bit | Description |
|-----|---|
| 22 | TTSE: Transmit Time Stamp Enable When set, this field enables IEEE1588 hardware time stamping for the transmit frame described by the descriptor. This field is valid only when the First Segment control bit (TDES1[29] _{RAM} in the descriptor) is set. |

Transmit Time Stamp Field

The transmit descriptor format and field descriptions remain unchanged when they are created by software (when the Own bit is set). However, when the DMA closes the last descriptor and IEEE 1588 functionality is enabled (the Own bit is cleared), the TDES2_{RAM} and TDES3 descriptor fields are updated with the time stamp, if taken, for that frame.

Table 15-17 and **Table 15-18** describe the fields that have a different meaning when the descriptor is closed.

Table 15-17 Transmit Descriptor Fields (TDES2_{RAM})

| Bit | Description |
|------|--|
| 31:0 | TTSL: Transmit Frame Time Stamp Low This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set. |

Table 15-18 Transmit Descriptor Fields (TDES3)

| Bit | Description |
|------|--|
| 31:0 | TTSH: Transmit Frame Time Stamp High This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment control bit (LS) in the descriptor is set. |

Alternate or Enhanced Descriptors

The alternate (or enhanced) descriptor structure can have 8 DWORDS (32-bytes) instead of the 4 DWORDS as in the case of normal descriptor format. The features of the alternate descriptor structure are

- The normal descriptor structure allows data buffers of up to 2.048 bytes. The alternative descriptor structure has been implemented to support buffers of up to 8 KB (useful for Jumbo frames).
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (Advanced time stamp or IPC full offload configuration), RDES1.
- The transmit descriptor stores the time stamp in TDES6 and TDES7 when advanced time stamp feature is selected.
- This receive descriptor structure is also used for storing the extended status (RDES4) and time stamp (RDES6 and RDES7) when advanced time stamp feature or IPC full offload is selected.
- When alternate descriptor mode is selected, and Time-stamping feature is enabled, the software needs to allocate 32-bytes (8 DWORDS) of memory for every descriptor. When Time-stamping or Receive IPC FullOffload engine are not enabled, the extended descriptors are not required and the SW can use alternate descriptors with the default size of 16 bytes. The core also needs to be configured for this change using the DMA Bus Mode Register[7].
- When alternate descriptor is chosen without Time Stamp or Full IPC Offload feature, the descriptor size is always 4 DWORDs (DES0-DES3).

The description or bit-mapping alternate descriptor structure (in Little Endian mode) is given below.

Note: When alternate descriptor with only Full IPC Offload (Type 2) is selected, it is not backward compatible to the previous release 3.4x with respect to status bits[7,5,0] in RDES0. In this mode, you should enable the extended descriptor mode (8 DWORDS) to get the IPC checksum engine status in RDES4.

Transmit Descriptor

The transmit descriptor structure is shown in **Figure 15-11**. The application software must program the control bits TDES0[31:20] during descriptor initialization. When the DMA updates the descriptor, it write backs all the control bits except the OWN bit (which it clears) and updates the status bits[19:0]. The contents of the transmitter descriptor word 0 (TDES0) through word 3 (TDES3) are given in **Table 15-19** through **Table 15-22**, respectively.

With the advance time stamp support, the snapshot of the time stamp to be taken can be enabled for a given frame by setting the “TTSE: Transmit Time Stamp Enable” (bit-25 of TDES0). When the descriptor is closed (i.e. when the OWN bit is cleared), the time-stamp is written into TDES6 and TDES7. This is indicated by the status bit “TTSS: Transmit Time Stamp Status” (bit-17 of TDES0). This is shown in **Figure 15-11**. The contents of TDES6 and TDES7 are mentioned in **Table 15-23** and **Table 15-24**.

Note: When either of Advanced Time Stamp or IPC Offload (Type 2) features is enabled, the SW should set the DMA Bus Mode register[7], so that the DMA operates with extended descriptor size. When this control bit is reset, the TDES4-TDES7 descriptor space are not valid.

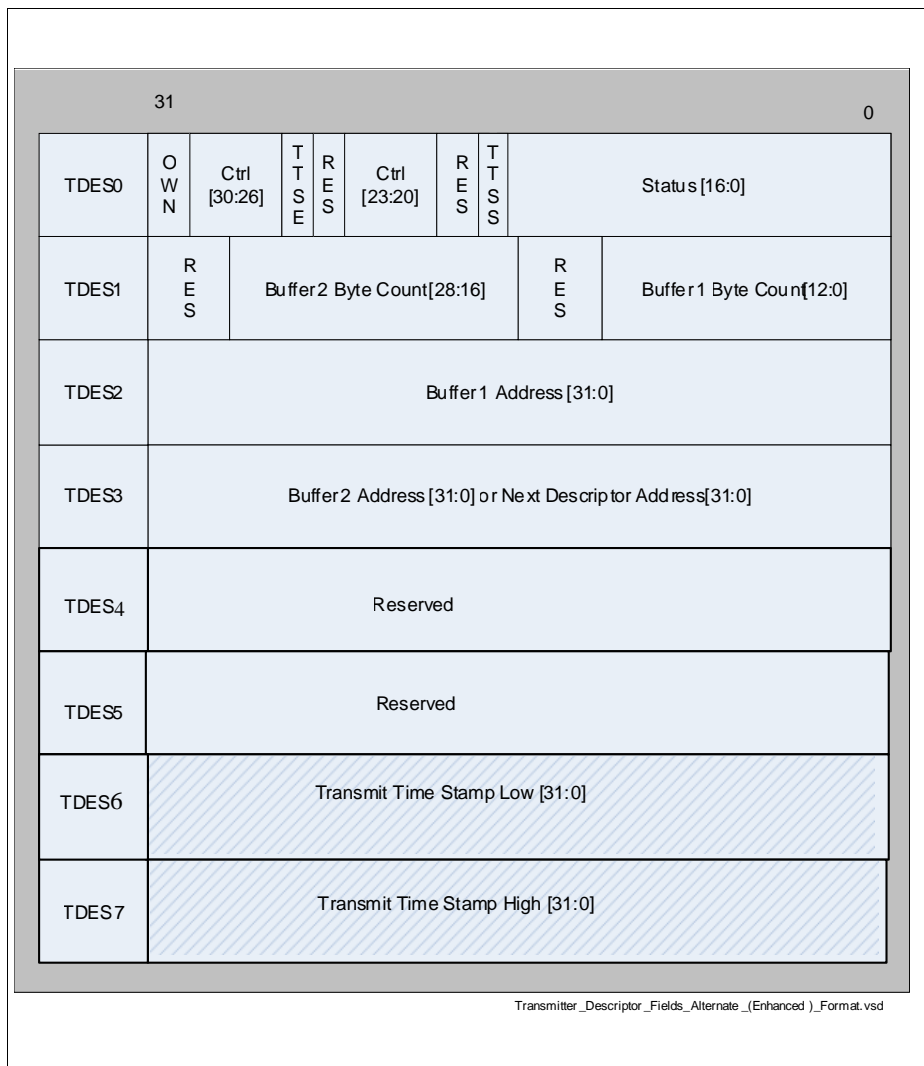

Figure 15-11 Transmitter Descriptor Fields - Alternate (Enhanced) Format

Table 15-19 Transmit Descriptor Word 0 (TDES0)

| Bit | Description |
|-----|---|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is reset, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set. This avoids a possible race condition between fetching a descriptor and the driver setting an ownership bit. |
| 30 | IC: Interrupt on Completion When set, this bit sets the Transmit Interrupt (Register 5[0]) after the present frame has been transmitted. |
| 29 | LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. |
| 28 | FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame. |
| 27 | DC: Disable CRC When this bit is set, the GMAC does not append a cyclic redundancy check (CRC) to the end of the transmitted frame. This is valid only when the first segment (TDES0[28]) is set. |
| 26 | DP: Disable Pad When set, the GMAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is reset, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This is valid only when the first segment (TDES0[28]) is set. |
| 25 | TTSE: Transmit Time Stamp Enable When set, this bit enables IEEE1588 hardware time stamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set. |
| 24 | Reserved |

Table 15-19 Transmit Descriptor Word 0 (TDES0) (cont'd)

| Bit | Description |
|-------|---|
| 23:22 | <p>CIC: Checksum Insertion Control</p> <p>These bits control the checksum calculation and insertion. Bit encodings are as shown below.</p> <ul style="list-style-type: none"> • 2'b00: Checksum Insertion Disabled. • 2'b01: Only IP header checksum calculation and insertion are enabled. • 2'b10: IP header checksum and payload checksum calculation and insertion are enabled, but pseudo-header checksum is not calculated in hardware. • 2'b11: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudo-header checksum is calculated in hardware. <p>This field is reserved when the IPC_FULL_OFFLOAD configuration parameter is not selected.</p> |
| 21 | <p>TER: Transmit End of Ring</p> <p>When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring.</p> |
| 20 | <p>TCH: Second Address Chained</p> <p>When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a "don't care" value. TDES0[21] takes precedence over TDES0[20].</p> |
| 19:18 | Reserved |
| 17 | <p>TTSS: Transmit Time Stamp Status</p> <p>This field is used as a status bit to indicate that a time stamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a time stamp value captured for the transmit frame. This field is only valid when the descriptor's Last Segment control bit (TDES0[29]) is set.</p> |
| 16 | <p>IHE: IP Header Error</p> <p>When set, this bit indicates that the GMAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IP header version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5.</p> |

Table 15-19 Transmit Descriptor Word 0 (TDES0) (cont'd)

| Bit | Description |
|-----|---|
| 15 | ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none"> • TDES0[14]: Jabber Timeout • TDES0[13]: Frame Flush • TDES0[11]: Loss of Carrier • TDES0[10]: No Carrier • TDES0[9]: Late Collision • TDES0[8]: Excessive Collision • TDES0[2]: Excessive Deferral • TDES0[1]: Underflow Error • TDES0[16]: IP Header Error • TDES0[12]: IP Payload Error |
| 14 | JT: Jabber Timeout When set, this bit indicates the GMAC transmitter has experienced a jabber time-out. This bit is only set when the GMAC configuration register's JD bit is not set. |
| 13 | FF: Frame Flushed When set, this bit indicates that the DMA/MTL flushed the frame due to a software Flush command given by the CPU. |
| 12 | IPE: IP Payload Error When set, this bit indicates that GMAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch. |
| 11 | LC: Loss of Carrier When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This is valid only for the frames transmitted without collision when the GMAC operates in Half-Duplex mode. |
| 10 | NC: No Carrier When set, this bit indicates that the Carrier Sense signal from the PHY was not asserted during transmission. |
| 9 | LC: Late Collision When set, this bit indicates that frame transmission was aborted due to a collision occurring after the collision window (64 byte-times, including preamble, in MII mode and 512 byte-times, including preamble and carrier extension, in GMII mode). This bit is not valid if the Underflow Error bit is set. |

Table 15-19 Transmit Descriptor Word 0 (TDES0) (cont'd)

| Bit | Description |
|-----|---|
| 8 | EC: Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If the DR (Disable Retry) bit in the GMAC Configuration register is set, this bit is set after the first collision, and the transmission of the frame is aborted. |
| 7 | VF: VLAN Frame When set, this bit indicates that the transmitted frame was a VLAN-type frame. |
| 6:3 | CC: Collision Count This 4-bit counter value indicates the number of collisions occurring before the frame was transmitted. The count is not valid when the Excessive Collisions bit (TDES0[8]) is set. |
| 2 | ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbit/s mode or if Jumbo Frame is enabled) if the Deferral Check (DC) bit in the GMAC Control register is set high. |
| 1 | UF: Underflow Error When set, this bit indicates that the GMAC aborted the frame because data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). |
| 0 | DB: Deferred Bit When set, this bit indicates that the GMAC defers before transmission because of the presence of carrier. This bit is valid only in Half-Duplex mode. |

Table 15-20 Transmit Descriptor Word 1 (TDES1)

| Bit | Description |
|-------|--|
| 31:29 | Reserved |
| 28:16 | TBS2: Transmit Buffer 2 Size These bits indicate the second data buffer size in bytes. This field is not valid if TDES0[20] is set. See Buffer Size Calculations for further detail on calculating buffer sizes. |

Table 15-20 Transmit Descriptor Word 1 (TDES1) (cont'd)

| Bit | Description |
|-------|--|
| 15:13 | Reserved |
| 12:0 | TBS1: Transmit Buffer 1 Size These bits indicate the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). |

Table 15-21 Transmit Descriptor 2 (TDES2)

| Bit | Description |
|------|---|
| 31:0 | Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. See XMC4[78]00 Data Buffer Alignment for further detail on buffer address alignment. |

Table 15-22 Transmit Descriptor 3 (TDES3)

| Bit | Description |
|------|---|
| 31:0 | Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.) |

Table 15-23 Transmit Descriptor 6 (TDES6)

| Bit | Description |
|------|--|
| 31:0 | TTSL: Transmit Frame Time Stamp Low This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding transmit frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set. |

Table 15-24 Transmit Descriptor 7 (TDES7)

| Bit | Description |
|------|---|
| 31:0 | TTSH: Transmit Frame Time Stamp High This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field has the time stamp only if the Last Segment bit (LS) in the descriptor is set and Time stamp status (TTSS) bit is set. |

Receive Descriptor

The structure of the received descriptor is shown in [Figure 15-12](#). This can have 32 bytes of descriptor data (8 DWORDs) when Advanced Time Stamping or IPC Full Offload feature is selected.

Note: When either of these features is enabled, the SW should set the DMA Bus Mode register[7] so that the DMA operates with extended descriptor size. When this control bit is reset, RDES0[7] and RDES0[0] will be always cleared and the RDES4-RDES7 descriptor space are not valid

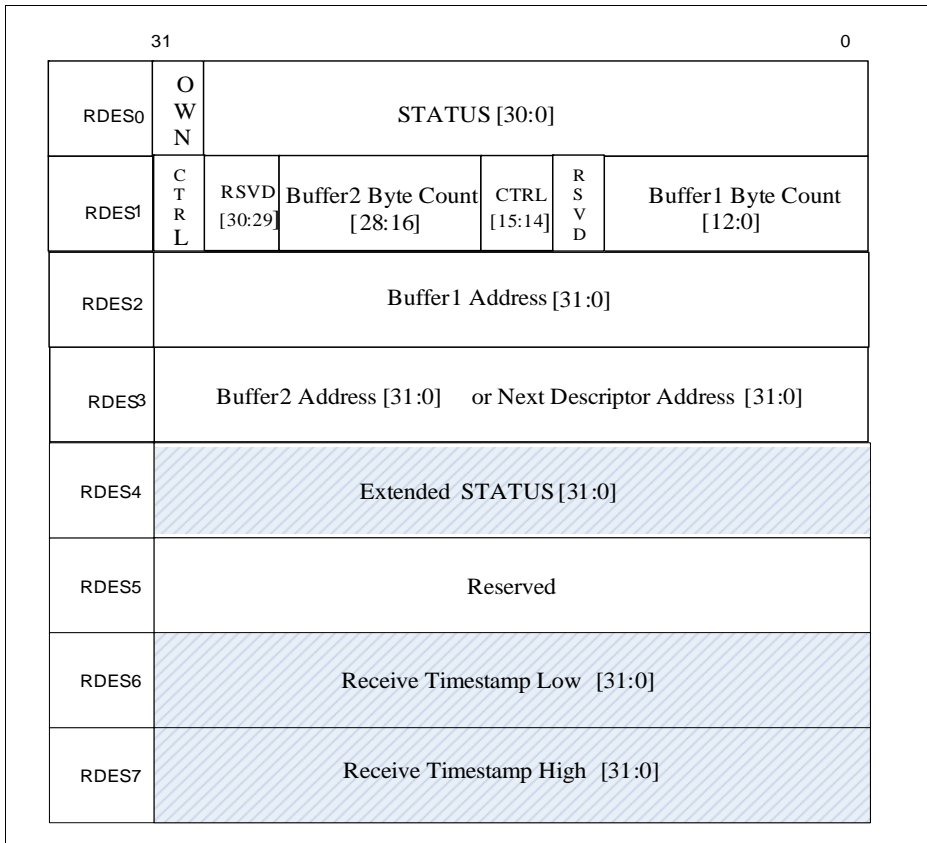

Figure 15-12 Receive Descriptor Fields - Alternate (Enhanced) Format

The contents of RDES0 are identified in [Table 15-25](#). The contents of RDES1 through RDES3 are identified in [Table 15-26](#) through [Table 15-28](#), respectively.

Note: Some of the bit functions of RDES0 are not backward compatible to Release 3.41a and previous versions. These bits are Bit[7], Bit[0] and Bit[5]. The function of Bit[5] is backward compatible to Release 3.30a and previous versions.

Table 15-25 Receive Descriptor Fields (RDES0)

| Bit | Description |
|-------|---|
| 31 | OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA of the GMAC Subsystem. When this bit is reset, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full. |
| 30 | AFM: Destination Address Filter Fail When set, this bit indicates a frame that failed in the DA Filter in the GMAC Core. |
| 29:16 | FL: Frame Length These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are reset. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. |
| 15 | ES: Error Summary Indicates the logical OR of the following bits: <ul style="list-style-type: none"> • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header/Payload Error • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set. |
| 14 | DE: Descriptor Error When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next Descriptor. The frame is truncated. This field is valid only when the Last Descriptor (RDES0[8]) is set. |
| 13 | SAF: Source Address Filter Fail When set, this bit indicates that the SA field of frame failed the SA Filter in the GMAC Core. |

Table 15-25 Receive Descriptor Fields (RDES0) (cont'd)

| Bit | Description |
|-----|---|
| 12 | LE: Length Error When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is reset. |
| 11 | OE: Overflow Error When set, this bit indicates that the received frame was damaged due to buffer overflow in MTL. |
| 10 | VLAN: VLAN Tag When set, this bit indicates that the frame pointed to by this descriptor is a VLAN frame tagged by the GMAC Core. |
| 9 | FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next Descriptor contains the beginning of the frame. |
| 8 | LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame |
| 7 | Time Stamp Available/IP Checksum Error (Type1) /Giant Frame When Advanced Time Stamp feature is present, this bit, when set, indicates that a snapshot of the timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When IP Checksum Engine (Type 1) is selected, this bit, when set, indicates that the 16-bit IPv4 Header checksum calculated by the core did not match the received checksum bytes. Otherwise, this bit, when set, indicates the Giant Frame Status. Giant frames are larger-than-1,518-byte (or 1,522-byte for VLAN) normal frames and larger-than-9,018-byte (9,022-byte for VLAN) frame when Jumbo Frame processing is enabled. |
| 6 | LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in Half-Duplex mode. |
| 5 | FT: Frame Type When set, this bit indicates that the Receive Frame is an Ethernet-type frame (the LT field is greater than or equal to 16'h0600). When this bit is reset, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes. |

Table 15-25 Receive Descriptor Fields (RDES0) (cont'd)

| Bit | Description |
|-----|--|
| 4 | RWT: Receive Watchdog Timeout When set, this bit indicates that the Receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. |
| 3 | RE: Receive Error When set, this bit indicates that the gmii_rxr_i signal is asserted while gmii_rxdv_i is asserted during frame reception. This error also includes carrier extension error in GMII and Half-duplex mode. Error can be of less/no extension, or error (rxd \neq 0f) during extension. |
| 2 | DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in MII Mode. |
| 1 | CE: CRC Error When set, this bit indicates that a Cyclic Redundancy Check (CRC) Error occurred on the received frame. This field is valid only when the Last Descriptor (RDES0[8]) is set. |
| 0 | Extended Status Available/Rx MAC Address When either Advanced Time Stamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This is valid only when the Last Descriptor bit (RDES0[8]) is set. When Advance Time Stamp Feature or IPC Full Offload is not selected, this bit indicates Rx MAC Address status. When set, this bit indicates that the Rx MAC Address registers value (1 to 31) matched the frame's DA field. When reset, this bit indicates that the Rx MAC Address Register 0 value matched the DA field. |

Table 15-26 Receive Descriptor Fields 1 (RDES1)

| Bit | Description |
|-------|--|
| 31 | DIC: Disable Interrupt on Completion When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. This, in turn, disables the assertion of the interrupt to Host due to RI for that frame. |
| 30:29 | Reserved |

Table 15-26 Receive Descriptor Fields 1 (RDES1) (cont'd)

| Bit | Description |
|-------|---|
| 28:16 | RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, 8, or 16, depending on the bus widths (32, 64, or 128, respectively), even if the value of RDES3 (buffer2 address pointer) is not aligned to bus width. If the buffer size is not an appropriate multiple of 4, 8, or 16, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. See Buffer Size Calculations for further details on calculating buffer sizes. |
| 15 | RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. |
| 14 | RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next Descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a “don't care” value. RDES1[15] takes precedence over RDES1[14]. |
| 13 | Reserved |
| 12:0 | RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, 8, or 16, depending upon the bus widths (32, 64, or 128), even if the value of RDES2 (buffer1 address pointer) is not aligned. When the buffer size is not a multiple of 4, 8, or 16, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or next descriptor depending on the value of RCH (Bit 14). See Buffer Size Calculations for further details on calculating buffer sizes. |

Table 15-27 Receive Descriptor Fields 2 (RDES2)

| Bit | Description |
|------|---|
| 31:0 | <p>Buffer 1 Address Pointer</p> <p>These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the configured value for its address generation when the RDES2 value is used to store the start of frame. Note that the DMA performs a write operation with the RDES2[3/2/1:0] bits as 0 during the transfer of the start of frame but the frame data is shifted as per the actual Buffer address pointer. The DMA ignores RDES2[3/2/1:0] (corresponding to bus width of 128/64/32) if the address pointer is to a buffer where the middle or last part of the frame is stored. See XMC4[78]00 Data Buffer Alignment for further details on buffer address alignment.</p> |

Table 15-28 Receive Descriptor Fields 3 (RDES3)

| Bit | Description |
|------|--|
| 31:0 | <p>Buffer 2 Address Pointer (Next Descriptor Address)</p> <p>These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next Descriptor is present.</p> <p>If RDES1[24] is set, the buffer (Next Descriptor) address pointer must be bus width-aligned (RDES3[3, 2, or 1:0] = 0, corresponding to a bus width of 128, 64, or 32. LSBs are ignored internally.) However, when RDES1[24] is reset, there are no limitations on the RDES3 value, except for the following condition: The DMA uses the configured value for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3[3, 2, or 1:0] (corresponding to a bus width of 128, 64, or 32) if the address pointer is to a buffer where the middle or last part of the frame is stored.</p> |

The extended status written is as shown in [Table 15-29](#). The extended status is written only when there is status related to IPC or Time Stamp available. The availability of extended status is indicated by bit-0 of RDES0. This status is available only when Advance Time Stamp or IPC Full Offload feature is selected.

Table 15-29 Receive Descriptor Fields 4 (RDES4)

| Bit | Description |
|-------|---|
| 31:14 | Reserved |
| 13 | PTP Version When set, indicates that the received PTP message is having the IEEE 1588 version 2 format. When reset, it has the version 1 format. This is valid only if the message type is non-zero. This bit is available only if Advance Time Stamp feature is selected else it is reserved |
| 12 | PTP Frame Type When set, this bit that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information on IPv4 or IPv6 can be obtained from bits 6 and 7. This bit is available only if Advanced Time Stamp feature is selected |
| 11:8 | Message Type These bits are encoded to give the type of the message received. <ul style="list-style-type: none"> • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1111: Reserved These bits are valid only when you select the Advance Time Stamp feature. |
| 7 | IPv6 Packet Received When set, this bit indicates that the received packet is an IPv6 packet. |
| 6 | IPv4 Packet Received When set, this bit indicates that the received packet is an IPv4 packet. |
| 5 | IP Checksum Bypassed When set, this bit indicates that the checksum offload engine is bypassed. |

Table 15-29 Receive Descriptor Fields 4 (RDES4) (cont'd)

| Bit | Description |
|-----|--|
| 4 | IP Payload Error When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the core calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. |
| 3 | IP Header Error When set, this bit indicates either that the 16-bit IPv4 header checksum calculated by the core does not match the received checksum bytes, or that the IP datagram version is not consistent with the Ethernet Type value. |
| 2:0 | IP Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the Receive Checksum Offload Engine (COE). The COE also sets these bits to 2'b00 if it does not process the IP datagram's payload due to an IP header error or fragmented IP. <ul style="list-style-type: none"> • 3'b000: Unknown or did not process IP payload • 3'b001: UDP • 3'b010: TCP • 3'b011: ICMP • 3'b1xx: Reserved |

RDES6 and RDES7 contain the snapshot of the time-stamp. The availability of the snapshot of the time-stamp in RDES6 and RDES7 is indicated by bit-7 in the RDES0 descriptor. The contents of RDES6 and RDES7 are identified in [Table 15-30](#) and [Table 15-31](#), respectively.

Table 15-30 Receive Descriptor Fields 6 (RDES6)

| Bit | Description |
|------|--|
| 31:0 | RTSL: Receive Frame Time Stamp Low This field is updated by DMA with the least significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]). |

Table 15-31 Receive Descriptor Fields 7 (RDES7)

| Bit | Description |
|------|--|
| 31:0 | RTSH: Receive Frame Time Stamp High This field is updated by DMA with the most significant 32 bits of the time stamp captured for the corresponding receive frame. This field is updated by DMA only for the last descriptor of the receive frame which is indicated by Last Descriptor status bit (RDES0[8]). |

15.2.5 MAC Management Counters

The MMC module maintains a set of registers for gathering statistics on the received and transmitted frames. These include a control register for controlling the behavior of the registers, two 32-bit registers containing interrupts generated (receive and transmit), and two 32-bit registers containing masks for the Interrupt register (receive and transmit). These registers are accessible from the Application through the MAC Control Interface (MCI). Each register is 32 bits wide. Non-32-bit accesses are allowed as long as the address is word-aligned.

The organization of these registers is shown in [Table 15-40](#). The MMCs are accessed using transactions, in the same way the CSR address space is accessed. The following sections in the chapter describe the various counters and list the address for each of the statistics counters. This address will be used for Read/Write accesses to the desired transmit/receive counter.

The Receive MMC counters are updated for frames that are passed by the Address Filter (AFM) block. Statistics of frames that are dropped by the AFM module are not updated unless they are runt frames of less than 6 bytes (DA bytes are not received fully).

The MMC module gathers statistics on encapsulated IPv4, IPv6, TCP, UDP, or ICMP payloads in received Ethernet frames. The address map of the corresponding registers, 0200_H–02FC_H, is given in [Table 15-40](#).

15.2.6 Power Management Block

This section describes the power management (PMT) mechanisms supported by the ETH. PMT supports the reception of network (remote) wake-up frames and Magic Packet frames. PMT does not perform the clock gate function, but generates interrupts for wake-up frames and Magic Packets received by the ETH. The PMT block sits on the receiver path of the ETH and is enabled with remote wake-up frame enable and Magic Packet enable. These enables are in the PMT_CONTROL_STATUS register and are programmed by the Application.

PMT registers are accessed in the same manner as with ETH-CSR registers. Refer to [Figure 15-40](#) for mapping information.

When the power down mode is enabled in the PMT, then all received frames are dropped by the core and they are not forwarded to the application. The core comes out of the power down mode only when either a Magic Packet or a Remote Wake-up frame is received and the corresponding detection is enabled.

15.2.6.1 PMT Block Description

PMT Control and Status Register

The PMT CSR program the request wake-up events and monitor the wake-up events. See [ETH0_PMT_CONTROL_STATUS](#) register for a full description

Remote Wake-Up Frame Filter Register

The Remote Wake up Frame Filter consists of eight words which are programmed via the [ETH0_REMOTE_WAKE_UP_FRAME_FILTER](#) Register. The eight words of the Remote Wake Up Frame Filter must be written sequentially to the REMOTE_WAKE_UP_FRAME_FILTER Register. The structure of the Remote Wake Up Frame Filter is described below. The Remote Wake Up Frame Filter values must be loaded sequentially starting with `wkupfmfilter0` through to `wkupfmfilter7`. The REMOTE_WAKE_UP_FRAME_FILTER Register is read in the same way.

Note: The internal counter to access the appropriate `wkupfmfilter_reg` is incremented when `lane3` is accessed by the CPU. This should be kept in mind if you are accessing these registers in byte or half-word mode.

| | | | | | | | | |
|--------------------------|--------------------|------------------|-----------------|------------------|-------------------|------------------|-----------------|------------------|
| Wakeup fame filter reg0 | Filter 0 Byte Mask | | | | | | | |
| Wakeup frame filter reg1 | Filter 1 Byte Mask | | | | | | | |
| Wakeup frame filter reg2 | Filter 2 Byte Mask | | | | | | | |
| Wakeup frame filter reg3 | Filter 3 Byte Mask | | | | | | | |
| Wakeup frame filter reg4 | RSVD | Filter 3 Command | RSVD | Filter 2 Command | RSVD | Filter 1 Command | RSVD | Filter 0 Command |
| Wakeup frame filter reg5 | Filter 3 Offset | | Filter 2 Offset | | Filter 1 Offset | | Filter 0 Offset | |
| Wakeup frame filter reg6 | Filter 1 CRC - 16 | | | | Filter 0 CRC - 16 | | | |
| Wakeup frame filter reg7 | Filter 3 CRC - 16 | | | | Filter 2 CRC - 16 | | | |

Figure 15-13 Wake-Up Frame Filter Register

Filter i Byte Mask

This register defines which bytes of the frame are examined by filter i (0, 1, 2, and 3) in order to determine whether or not the frame is a wake-up frame. The Most Significant Bit (thirty-first bit) must be zero. Bit j [30:0] is the Byte Mask. If bit j (byte number) of the Byte Mask is set, then Filter i Offset + j of the incoming frame is processed by the CRC block; otherwise Filter i Offset + j is ignored.

Filter i Command

This 4-bit command controls the filter i operation. Bit 3 specifies the address type, defining the pattern's destination address type. When the bit is set, the pattern applies to only multicast frames; when the bit is reset, the pattern applies only to unicast frame. Bit 2 and Bit 1 are reserved. Bit 0 is the enable for filter i; if Bit 0 is not set, filter i is disabled.

Filter i Offset

This register defines the offset (within the frame) from which the frames are examined by filter i. This 8-bit pattern-offset is the offset for the filter i first byte to be examined. The minimum allowed is 12, which refers to the 13th byte of the frame (offset value 0 refers to the first byte of the frame).

Filter i CRC-16

This register contains the CRC_16 value calculated from the pattern, as well as the byte mask programmed to the wake-up filter register block.

15.2.6.2 Remote Wake-Up Frame Detection

When the ETH is in sleep mode and the remote wake-up bit is enabled in PMT Control and Status register, normal operation is resumed after receiving a remote wake-up frame. The Application writes all eight wake-up filter registers, by performing a sequential Write to **ETH0_REMOTE_WAKE_UP_FRAME_FILTER** Register. The Application enables remote wake-up by setting **ETH0_PMT_CONTROL_STATUS.PWRDWN**.

PMT supports four programmable filters that allow support of different receive frame patterns. If the incoming frame passes the address filtering of Filter Command, and if Filter CRC-16 matches the incoming examined pattern, then the wake-up frame is received.

Filter_offset (minimum value 12, which refers to the 13th byte of the frame) determines the offset from which the frame is to be examined. Filter Byte Mask determines which bytes of the frame must be examined. The thirty-first bit of Byte Mask must be set to zero.

The remote wake-up CRC block determines the CRC value that is compared with Filter CRC-16. The wake-up frame is checked only for length error, FCS error, dribble bit error, MII error, collision, and to ensure that it is not a runt frame. Even if the wake-up frame is more than 512 bytes long, if the frame has a valid CRC value, it is considered valid. Wake-up frame detection is updated in the PMT_Control_Status register for every remote Wake-up frame received. A PMT interrupt to the Application triggers a Read to the PMT_CONTROL_STATUS register to determine reception of a wake-up frame.

15.2.6.3 Magic Packet Detection

The Magic Packet frame is based on a method that uses Advanced Micro Device's Magic Packet technology to power up the sleeping device on the network. The ETH receives a specific packet of information, called a Magic Packet, addressed to the node on the network.

Only Magic Packets that are addressed to the device or a broadcast address will be checked to determine whether they meet the wake-up requirements. Magic Packets that pass the address filtering (unicast or broadcast) will be checked to determine whether they meet the remote Wake-on-LAN data format of 6 bytes of all ones followed by a ETH Address appearing 16 times.

The application enables Magic Packet wake-up by writing a 1 to Bit 1 of the **ETH0_PMT_CONTROL_STATUS** register. The PMT block constantly monitors each frame addressed to the node for a specific Magic Packet pattern. Each frame received is checked for a FFFF FFFF FFFF_H pattern following the destination and source address field. The PMT block then checks the frame for 16 repetitions of the ETH address without

any breaks or interruptions. In case of a break in the 16 repetitions of the address, the FFFF FFFF FFFF_H pattern is scanned for again in the incoming frame. The 16 repetitions can be anywhere in the frame, but must be preceded by the synchronization stream (FFFF FFFF FFFF_H). The device will also accept a multicast frame, as long as the 16 duplications of the ETH address are detected.

If the MAC address of a node is 0011 2233 4455_H, then the ETH scans for the data sequence:

```
Destination Address Source Address ..... FF FF FF FF FF FF
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33 44 55 00 11 22 33
44 55
...CRC
```

Magic Packet detection is updated in the PMT_CONTROL_STATUS register for Magic Packet received. A PMT interrupt to the Application triggers a read to the PMT CSR to determine whether a Magic Packet frame has been received.

15.2.6.4 System Considerations During Power-Down

The ETH neither gates nor stops clocks when Power-Down mode is enabled. Power saving by clock gating must be done outside the core by the application. The receive data path must be clocked during Power-Down mode, because it is involved in magic packet/wake-on-LAN frame detection. However, the transmit path and the application path clocks can be gated off during Power-Down mode.

The power management interrupt signal is asserted when a valid wake-up frame is received. This signal is generated in the receive clock domain.

The recommended power-down and wake-up sequence is as follows.

1. Disable the Transmit DMA (if applicable) and wait for any previous frame transmissions to complete. These transmissions can be detected when Transmit Interrupt, **ETH0_STATUS.TI** is received.
2. Disable the MAC transmitter and MAC receiver by clearing the appropriate bits in the **ETH0_MAC_CONFIGURATION** register.
3. Wait until the Receive DMA empties all the frames from the Rx FIFO (a software timer may be required).
4. Enable Power-Down mode by appropriately configuring the PMT registers.
5. Enable the MAC Receiver and enter Power-Down mode.

6. Gate the application and transmit clock inputs to the core (and other relevant clocks in the system) to reduce power and enter Sleep mode.
7. On receiving a valid wake-up frame, the ETH asserts the power management interrupt signal and exits Power-Down mode.
8. On receiving the interrupt, the system must enable the application and transmit clock inputs to the core.
9. Read the **ETH0_PMT_CONTROL_STATUS** register to clear the interrupt, then enable the other modules in the system and resume normal operation.

15.2.7 PHY Interconnect

The ETH supports two external interconnects to external PHY devices. The ETH peripheral may be connected to the external PHY by either a Media Independent Interface (MII) or by a Reduced Media Independent Interface (RMII). Additionally a Station Management Interface (SMI) provides a two wire serial interface between the external PHY and the ETH. The SMI allows the ETH to program the internal PHY configuration registers. The SMI supports connection of up to 32 external PHY devices.

15.2.7.1 PHY Interconnect selection

Selection of the external interconnect configuration between MII or RMII is made by the ETH0_CON.INFSEL register. This must be done while the ETH peripheral is held in reset. Once the PHY interconnect has been configured it may not be changed without placing the ETH back into reset.

15.2.8 Station Management Interface

The Station Management Agent (SMA) module allows the Application to access any PHY registers through a 2-wire Station Management interface (SMI). The PHY interconnect supports accessing up to 32 PHYs.

The application can select one of the 32 PHYs and one of the 32 registers within any PHY and send control data or receive status information. Only one register in one PHY can be addressed at any given time. For more details on the communication from the Application to the PHYs, refer to the Reconciliation Sublayer and Media Independent Interface Specifications section of the IEEE 802.3z specification, 1000BASE Ethernet. The application sends the control data to the PHY and receives status information from the PHY through the SMA module, as shown in **Figure 15-14**.

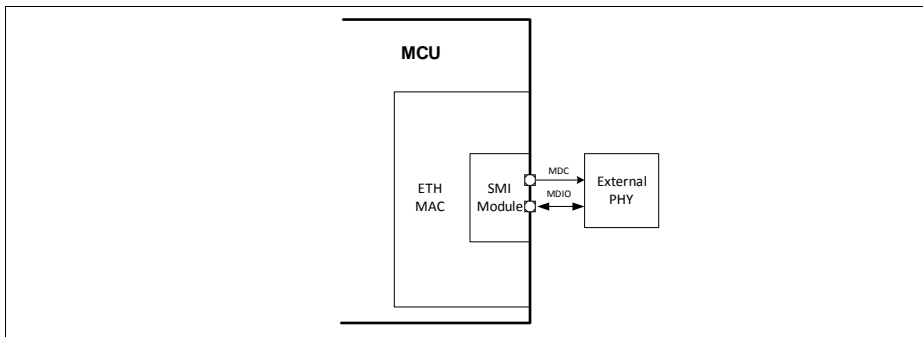

Figure 15-14 SMA Interface Block

15.2.8.1 Station Management Functions

The ETH initiates the Management Write/Read operation. The MDC clock is a divided clock from the ETH MAC clock. The divide factor depends on the clock range setting in the MII Address register. Clock range is set as follows:

| Selection | ETH MAC Clock | MDC Clock |
|------------|---------------|---------------|
| 0000 | 60-100 MHz | ETH Clock/42 |
| 0001 | 100-150 MHz | ETH Clock/62 |
| 0010 | 20-35 MHz | ETH Clock/16 |
| 0011 | 35-60 MHz | ETH Clock/26 |
| 0100 | 150-250 MHz | ETH Clock/102 |
| 0101 | 250-300 MHz | ETH Clock/124 |
| 0110, 0111 | Reserved | |

The frame structure on the MDIO line is shown below.

IDLE The mdio line is Tri-state; there is no clock on mdc
 PREAMBLE 32 continuous bits of value 1
 START Start-of-frame is 01_B
 OPCODE 10_B for Read and b01_B for Write
 PHY ADDR 5-bit address select for one of 32 PHYs

REG_ADDR Register address in the selected PHY
 TA Turnaround is 20_B for Read and 10_B for Write
 DATA Any 16-bit value. In a Write operation, the ETH drives mdio; in a Read operation, PHY drives it.

15.2.8.2 Station Management Write Operation

When the user sets the MII Write and Busy bits ([ETH0_GMII_ADDRESS.MW](#) and [GMII_ADDRESS.MB](#)) the ETH CSR module transfers the PHY address, the register address in PHY, and the write data to the SMA to initiate a Write operation into the PHY registers. At this point, the SMA module starts a Write operation on the MII Management Interface using the Management Frame Format specified in the MII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the [GMII_ADDRESS](#) register contents or the [GMII_DATA](#) register while the transaction is ongoing. Write operations to the [GMII_ADDRESS](#) register or the [ETH0_GMII_DATA](#) Register during this period are ignored (the Busy bit is high), and the transaction is completed without any error on the MCI interface.

After the Write operation has completed, the SMA indicates this to the CSR which then resets the Busy bit. The SMA module divides the CSR (Application) clock with the clock divider programmed (CR bits of MII Address Register) to generate the MDC clock for this interface. The ETH drives the MDIO line for the complete duration of the frame. The frame format for the Write operation is as follows:

| IDLE | PREAMBLE | START | OPCODE | PHY ADDR | REG ADDR | TA | DATA | IDLE |
|------|-----------|-------|--------|----------|----------|----|----------------|------|
| Z | 1111...11 | 01 | 01 | AAAAA | RRRRR | 10 | DDD... .DDD | Z |

Figure 15-15 Management Write Operation

Figure 15-15 is a reference for the Write operation.

15.2.8.3 Station Management Read Operation

When the user sets the MII Busy bit ([ETH0_GMII_ADDRESS.MB](#)) with the MII Write bit ([GMII_ADDRESS.WB](#)) as 0, the ETH CSR module transfers the PHY address and the

register address in PHY to the SMA to initiate a Read operation in the PHY registers. At this point, the SMA module starts a Read operation on the MII Management Interface using the Management Frame Format specified in the MII specifications (Section 22.2.4.5 of IEEE Standard). The application should not change the GMII_ADDRESS register contents or the GMII_DATA register while the transaction is ongoing. Write operations to the GMII_ADDRESS register or **ETH0_GMII_DATA** Register during this period are ignored (the Busy bit is high) and the transaction completed without any error on the MCI interface.

After the Read operation has completed, the SMA indicates this to the CSR, which then resets the Busy bit and updates the GMII_DATA register with the data read from the PHY. The SMA module divides the CSR (Application) clock with the clock divider programmed (GMII_ADDRESS.CR bits) to generate the MDC clock for this interface. The ETH drives the MDIO line for the complete duration of the frame except during the Data fields when the PHY is driving the MDIO line. The frame format for the Read operation is as follows:

| IDLE | PREAMBLE | START | OPCODE | PHY ADDR | REG ADDR | TA | DATA | IDLE |
|------|-----------|-------|--------|----------|----------|----|-----------------|------|
| Z | 1111...11 | 01 | 10 | AAAAA | RRRRR | Z0 | DDDDDD | Z |

Figure 15-16 is a reference for the read operation.

Figure 15-16 Management Read Operation

15.2.9 Media Independent interface

The Media Independent Interface (MII) provides an interconnect to external PHY devices standardised by IEEE 802.3u. The MII interconnect consists of 16 pins for data and control. The MII interconnect provides two separate nibble wide busses for transmit and receive each with a dedicated clock running at 2.5Mhz for 10Mbit/s and 25Mhz for 100Mbit/s speeds. Transmit and receive control signals consist of a TX Enable (TX_EN) that allows the ETH to present data to the PHY and a Receive Data Valid (RX_DV) that allows the PHY to present data to the ETH. A Receive Error (RX_ER) signal is also provided that allows the PHY signal the ETH when an error was detected somewhere in

the current received packet. The two remaining control signals are MII collision detect (MII_COL) which is asserted by the PHY when an arbitration collision occurs and MII carrier sense (MII_CRS) which is asserted by the PHY when either Transmit or Receive are not idle.

Figure 15-17 Media Independent Interface

15.2.10 Reduced Media Independent Interface

The Reduced Media Independent Interface (RMII) specification reduces the pin count between Ethernet PHYs and Switch ASICs. According to the IEEE 802.3u standard, an MII contains 16 pins for data and control. In devices incorporating multiple MAC or PHY interfaces (such as switches), the number of pins adds significant cost with increase in port count. The RMII specification addresses this problem by reducing the pin count to 7 for each port — a 62.5% decrease in pin count.

- The RMII module is instantiated between the ETH and the PHY. This helps translation of the MAC's MII into the RMII. The RMII block has the following characteristics:
- Supports 10 Mbit/s and 100 Mbit/s operating rates.
- Two clock references are sourced externally, providing independent, 2-bit wide transmit and receive paths.

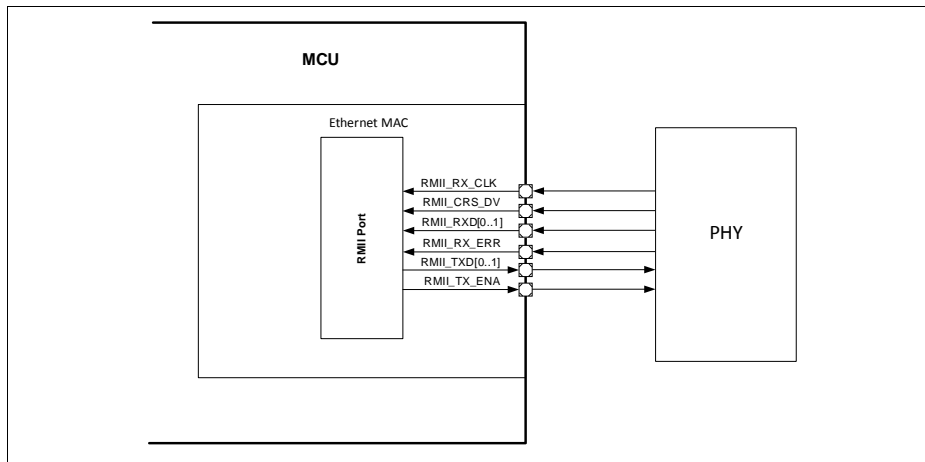

Figure 15-18 Reduced Media Independent Interface

Note: The MAC Configuration.FES bit configures the RMII to operate at 10 Mbit/s or 100 Mbit/s.

15.2.10.1 RMII Block Diagram

Figure 15-19 shows the position of the RMII block relative to the ETH and RMII PHY. The RMII block is placed in front of the ETH to translate the MII signals to RMII signals.

Figure 15-19 RMII Block Diagram

15.2.10.2 RMII Block Overview

The following list describes the RMII's hardware components, which are shown in **Figure 15-19**. Each of these blocks is briefly described in the following sections.

MII-RMII Transmit (MRT) Block: This block translates all MII transmit signals to RMII transmit signals.

MII-RMII Receive (MRR) Block: This block translates all RMII receive signals to MII receive signals.

15.2.10.3 Transmit Bit Ordering

Each nibble from the MII must be transmitted on the RMI a di-bit at a time with the order of di-bit transmission shown in [Figure 15-20](#). The lower order bits (D1 and D0) are transmitted first followed by higher order bits (D2 and D3).

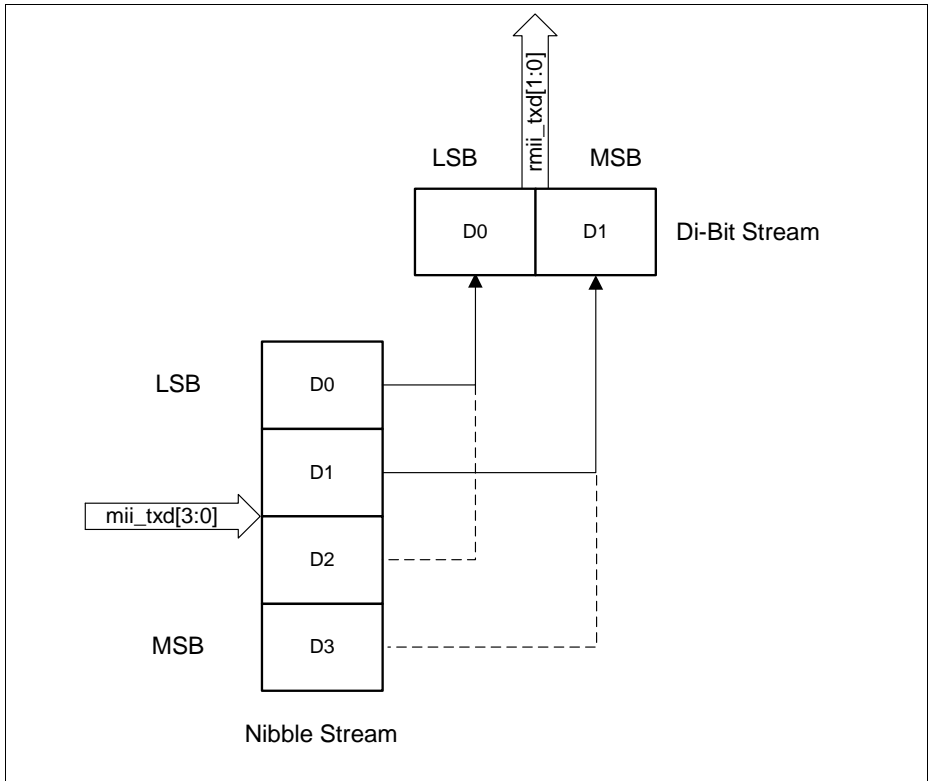

Figure 15-20 Transmission Bit Ordering

15.2.10.4 RMII Transmit Timing Diagrams

[Figure 15-21](#) through [Figure 15-24](#) show MII-to-RMII transaction timing.

[Figure 15-21](#) shows the start of MII transmission and the following RMII transmission in 100 Mbit/s mode.

Figure 15-21 Start of MII and RMII Transmission in 100 Mbit/s Mode

Figure 15-22 shows the end of frame transmission for MII and RMII in 100 Mbit/s mode.

Figure 15-22 End of MII and RMII Transmission in 100 Mbit/s Mode

Figure 15-23 shows the start of MII transmission and the following RMII transmission in 10 Mbit/s mode.

Figure 15-23 Start of MII and RMII Transmission in 10 Mbit/s Mode

Figure 15-24 shows the end of MII transmission and RMII transmission in 10 Mbit/s mode.

Figure 15-24 End of MII and RMII Transmission in 10 Mbit/s Mode

Receive Bit Ordering

Each nibble is transmitted to the MII from the di-bit received from the RMII in the nibble transmission order shown in **Figure 15-25**. The lower order bits (D0 and D1) are received first, followed by the higher order bits (D2 and D3).

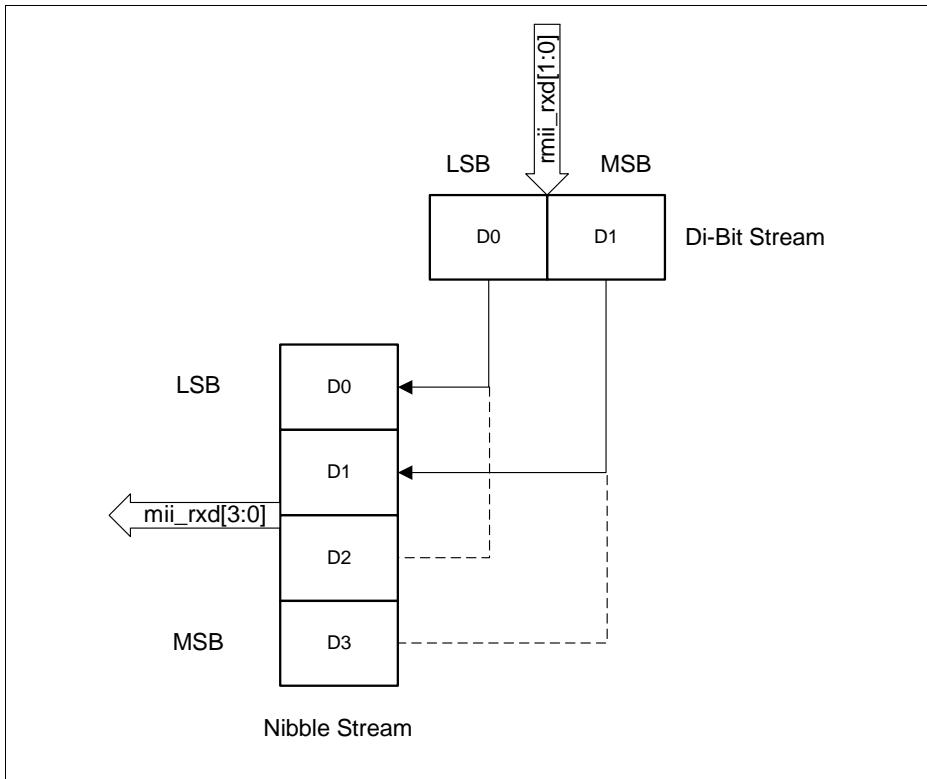

Figure 15-25 Receive Bit Ordering

15.2.11 IEEE 1588-2002 Overview

The IEEE 1588 standard defines a protocol enabling precise synchronization of clocks in measurement and control systems implemented with technologies such as network communication, local computing, and distributed objects. The protocol applies to systems communicating by local area networks supporting multicast messaging, including (but not limited to) Ethernet. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. The protocol supports system-wide synchronization accuracy in the sub-microsecond range with minimal network and local clock computing resources.

The message-based protocol, named Precision Time Protocol (PTP), is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing/clock information. The protocol's technique for synchronizing a slave node to a master node by exchanging PTP messages is depicted in [Figure 15-26](#).

Figure 15-26 Networked Time Synchronization

1. The master broadcasts PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t_1 and must, for Ethernet ports, be captured at the MII.
2. A slave receives the Sync message and also captures the exact time, t_2 , using its timing reference.
3. The master then sends the slave a Follow_up message, which contains t_1 information for later use.
4. The slave sends the master a Delay_Req message, noting the exact time, t_3 , at which this frame leaves the MII.
5. The master receives this message, capturing the exact time, t_4 , at which it enters its system.
6. The master sends the t_4 information to the slave in the Delay_Resp message.
7. The slave uses the four values of t_1 , t_2 , t_3 , and t_4 to synchronize its local timing reference to the master's timing reference.

Most of the protocol implementation occurs in the software, above the UDP layer. As described above, however, hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at the MII. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.

15.2.11.1 Reference Timing Source

To get a snapshot of the time, the core requires a reference time in 64-bit format (split into two 32-bit channels, with the upper 32-bits providing time in seconds, and the lower 32-bits indicating time in nanoseconds) as defined in the IEEE 1588 specification.

Internal Reference Time

This takes only the reference clock input and uses it to generate the Reference time (also called the System Time) internally and use it to capture time stamps. The generation, update, and modification of the System Time are described in [System Time Register Module](#).

15.2.11.2 Transmit Path Functions

When a frame's SFD is output on the MII, a time stamp is captured. Frames for which capturing a time stamp is required are controllable on a per-frame basis. In other words, each transmit frame can be marked to indicate whether or not a time stamp must be captured for that frame.

No snooping or processing of the transmitted frames is performed to identify PTP frames. Framewise control is exercised through control bits in the transmit descriptor (as described in [Descriptor Format With IEEE 1588 Time Stamping Enabled](#)).

Captured time stamps are returned to the application in a manner similar to that in which status is provided for frames. time stamp is returned to software inside the corresponding transmit descriptor, thus connecting the time stamp automatically to the specific PTP frame. The 64-bit time stamp information is written back to the TDES2_{RAM} and TDES3_{RAM} fields, with TDES2 holding the time stamp's 32 least significant bits, except as described in [Transmit Time Stamp Field](#).

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in TDES6_{RAM} and TDES7_{RAM}, respectively

15.2.11.3 Receive Path Functions

When the IEEE 1588 time-stamping feature is selected and enabled, the Ethernet MAC captures the time stamp of all frames received on the MII. No snooping or processing of the received frames is performed to identify PTP frames in the default mode (Advanced Time Stamp feature is not selected).

The core returns the time-stamp to the software in the corresponding receive descriptor. The 64-bit time stamp information is written back to the RDES2 and RDES3 fields, with RDES2 holding the time stamp's 32 least significant bits, except as mentioned in [Receive Time Stamp](#). The time stamp is only written to the receive descriptor for which the Last Descriptor status field has been set to 1 (the EOF marker). When the time stamp is not available (for example, due to an RxFIFO overflow) an all-ones pattern is written

to the descriptors (RDES2 and RDES3), indicating that time stamp is not correct. If the software uses a control register bit to disable time stamping, the DMA does not alter RDES2 or RDES3.

Note: When the alternate (enhanced) descriptor is selected, the 64-bit time-stamp is written in RDES6 and RDES7, respectively. RDES0[7] will indicate whether the time-stamp is updated in RDES6/7 or not.

15.2.11.4 Time Stamp Error Margin

According to the IEEE 1588 specifications, the time stamp must be captured at the SFD of transmitted and received frames at the MII interface. Since the reference timing source is different from the MII clocks, a small error margin is introduced, due to the transfer of information across asynchronous clock domains.

In the transmit path, the captured and reported time stamp has a maximum error margin of 2 PTP clocks. In other words, the captured time stamp has the value of the reference time source given within 2 clocks after the SFD has been transmitted on the MII.

Similarly, on the receive path, the error margin is 3 MII clocks, plus up to 2 PTP clocks. You can ignore the error margin due to the 3 MII clocks by assuming that this constant delay is present in the system (or link) before the SFD data reaches the ETH's MII interface.

15.2.11.5 Frequency Range of Reference Timing Clock

Because asynchronous logic is in place for time stamp information transfers across clock domain, a minimum delay is required between two consecutive time stamp captures. This delay is 3 clock cycles of both the MII and PTP clocks. If the gap is shorter, the ETH does not take a time stamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time and the timing constraints achievable for logic operating on the PTP clock. Another factor to consider is that the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Hence, a higher PTP clock frequency gives better system performance. The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the MII clock frequency is fixed by IEEE specification, the minimum PTP clock frequency required for proper operation depends on the core's operating mode and operating speed.

For example, in 100 Mbit/s full-duplex operation, the minimum gap between two SFDs is 160 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 8 clocks of preamble).

In the example, $(3 \times \text{PTP}) + (3 \times \text{MII}) \leq 160 \times \text{MII}$; thus, the minimum PTP clock frequency is about 0.5 MHz $((160 - 3) \times 40 \text{ ns} \div 3 = 2.093 \text{ ns period})$

15.2.11.6 Advanced Time Stamp Feature Support

In addition to the basic features for time stamp mentioned in [Receive Time Stamp](#), the advanced time stamp option has the following features.

- Support for the IEEE 1588-2008 (Version 2) timestamp format.
- Option to take snapshot for all frames or for PTP type frames.
- Option for taking snapshot for event messages only.
- Option to take the snapshot based on the clock type (ordinary, boundary, end-to-end and peer-to-peer)
- Option to select the node to be a Master or Slave for ordinary and boundary clock.
- Identification of PTP message type, version, and PTP payload sent directly over Ethernet given as status.
- Option to measure time in digital or binary format.

15.2.11.7 Peer-to-Peer PTP (Pdelay) Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Pdelay message in addition to SYNC, Delay Request, Follow-up and Delay Response messages. [Figure 15-27](#) shows the method to calculate the propagation delay in clocks supporting peer-to-peer path correction.

Figure 15-27 Propagation Delay Calculation in Clocks Supporting Peer-to-Peer Path Correction

The link delay measurement starts with port-1 issuing a “Pdelay_Req” message and generating a timestamp, for the Pdelay_Req message. Port-2 receives the “Pdelay_Req” message and generates a timestamp, t_2 , for this message. Port-2 returns a Pdelay_Resp message and generates a timestamp, t_3 , for this message. To minimize errors due to any frequency offset between the two ports, Port-2 returns the Pdelay_Resp message as quickly as possible after the receipt of the Pdelay_Req message.

Port-2 either:

- Returns the difference between the timestamps t_2 and t_3 in the Pdelay_Resp message,
- Returns the difference between the timestamps t_2 and t_3 in a Pdelay_Resp_Follow_Up message, or
- Returns the timestamps t_2 and t_3 in the Pdelay_Resp and Pdelay_Resp_Follow_Up messages respectively.

Port-1 generates a timestamp, t_4 , upon receiving the Pdelay_Resp message. Port-1 then uses these four timestamps to compute the mean link delay.

15.2.11.8 Clock Types

The type of clock nodes supported in IEEE 1588-2008 is described in this section. The corresponding support provided by the advanced time stamp feature for each of the clock type is also mentioned.

1. Ordinary clock support: In this type the clock can be a grandmaster or a slave clock. This clock has a single PTP state.

Table 15-32 shows the messages for which time-stamp snapshot is taken on the receive side for Master and Slave nodes.

The ordinary clock in the domain supports a single copy of the protocol and has a single PTP state and will typically be a single physical port. In typical industrial automation applications, an ordinary clock is associated with an application device such as sensors and actuators. In telecom applications, the ordinary clock may be associated with a timing demarcation device.

Typically for ordinary clock, you will need to take snapshot for only one type of PTP messages. For e.g. you will require supporting either version 1 or 2 PTP messages, not both.

The following features are supported.

- a) Sends and receives PTP messages. The time stamp snapshot can be controlled as described by the **ETH0_TIMESTAMP_CONTROL** Register.
- b) Maintains the data sets (e.g., time stamp values).
2. Boundary clock support: This type of clock is similar to the ordinary clock except for the following.

Hence the features of ordinary clock holds good for the boundary clock also.

The boundary clock typically has several physical ports communicating with the network. The messages related to synchronization, master-slave hierarchy and signaling terminate in the protocol engine of the boundary clock and are not forwarded. The PTP message type status given by the core (refer to **Receive Path Functions**) will help you to quickly identify the type of message and take appropriate action.

- a) The clock data sets are common to all ports of the boundary clock
- b) The local clock is common to all ports of the boundary clock.
3. End to end transparent clock support: The end-to-end transparent clock forwards all messages like normal bridge, router or repeater. The resident time needs to be computed to update the correctionField. Hence snapshot needs to be taken for the messages mentioned in **Table 15-33**.

In the end-to-end transparent clock, the residence times are accumulated in a special field (correctionField) of the PTP event (SYNC) message or the associated Follow-up (FOLLOW_UP) Message. Hence it is important to take a snapshot for these messages alone. This can be quickly done by setting the control bit (TSEVNTENA), which enables snapshot to be taken for event messages and also selecting the type of clock in the **ETH0_TIMESTAMP_CONTROL** Register.

The residence time is also corrected for Delay_Req messages (but snapshot of the

timestamp is not required). The message type statuses provided helps you to quickly identify the message and update the correctionField.

The message type status provided will also help in taking appropriate action depending on the type of PTP message received.

4. Peer to peer transparent clock support: In this type of clock the computation of the link delay is based on an exchange of Pdelay_Req, Pdelay_Resp and Pdelay_Resp_Follow_Up messages with the link peer. Hence support for taking snapshot for the event messages related to Pdelay is added. **Table 15-34**.

The transparent clock corrects only the SYNC and Follow-up message. As discussed earlier this can be achieved using the message status provided.

The type of clock to be implemented will be configurable through **ETH0_TIMESTAMP_CONTROL** register. To ensure that the snapshot is taken only for the messages indicated in the table for the corresponding clock type, the **ETH0_TIMESTAMP_CONTROL.TSEVNTENA** bit has to be set.

Table 15-32 PTP Messages for which Snapshot is Taken on Receive Side for Ordinary Clock

| Master | Slave |
|-----------|-------|
| Delay_Req | SYNC |

15.2.11.9 PTP Processing and Control

The common message header for PTP messages is shown below. This format is taken from IEEE standard 1588-2008 (Revision of IEEE Std. 1588-2002).

Table 15-35 Message Format Defined in IEEE 1588-2008

| BITS | | OCTETS | OFFSET |
|----------------------------|-------------|--------|--------|
| transportSpecific | messageType | 1 | 0 |
| Reserved | versionPTP | 1 | 1 |
| messageLength | | 2 | 2 |
| domainNumber | | 1 | 4 |
| Reserved | | 1 | 5 |
| flagField | | 2 | 6 |
| correctionField | | 8 | 8 |
| Reserved | | 4 | 16 |
| sourcePortIdentity | | 10 | 20 |
| sequenceId | | 2 | 30 |
| controlField ¹⁾ | | 1 | 32 |
| logMessageInterva | | 1 | 33 |

1) controlField is used in version 1. For version 2, messageType field will be used for detecting different message types.

There are some fields in the PTP frame that are used to detect the type and control the snapshot to be taken. This is different for PTP frames sent directly over Ethernet, PTP frames sent over UDP / IPv4 and PTP frames that are sent over UDP / IPv6. The following sections provide information on the fields that are used to control taking the snapshot.

PTP Frame Over IPv4

Table 15-36 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv4 for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-D of the IEEE 1588-2008 standard and the message format defined in **Table 15-35**.

Table 15-36 IPv4-UDP PTP Frame Fields Required for Control and Status

| Field Matched | Octet Position | Matched Value | Description |
|------------------------------|----------------|-------------------|--------------------|
| MAC Frame type | 12, 13 | 0800 _H | IPv4 datagram |
| IP Version and Header Length | 14 | 45 _H | IP version is IPv4 |
| Layer-4 protocol | 23 | 11 _H | UDP |

Table 15-36 IPv4-UDP PTP Frame Fields Required for Control and Status (cont'd)

| Field Matched | Octet Position | Matched Value | Description |
|--|----------------|--|---|
| IP Multicast address (IEEE 1588 version 1) | 30, 31, 32, 33 | E0 _H , 00 _H , 01 _H , 81 _H (or 82 _H or 83 _H or 84 _H) | Multicast IPv4 addresses allowed. 224.0.1.129 224.0.1.130 224.0.1.131 224.0.1.132 |
| IP Multicast address (IEEE 1588 version 2) | 30, 31, 32, 33 | E0 _H , 00 _H , 01 _H , 81 _H E0 _H , 00 _H , 00 _H , 6B _H | PTP-primary multicast address: 224.0.1.129 PTP-Pdelay multicast address: 224.0.0.107 |
| UDP destination port | 36, 37 | 013F _H , 0140 _H | 013F _H – PTP event message ¹⁾ 0140 _H – PTP general messages |
| PTP control field (IEEE version 1) | 74 | 00 _H /01 _H /02 _H /03 _H / 04 _H | 00 _H – SYNC, 01 _H – Delay_Req, 02 _H – Follow_Up 03 _H – Delay_Resp 04 _H – Management |
| PTP Message Type Field (IEEE version 2) | 42 (nibble) | 0 _H /1 _H /2 _H /3 _H /8 _H /9 _H / B _H /C _H /D _H | 0 _H – SYNC 1 _H – Delay_Req 2 _H – Pdelay_Req 3 _H – Pdelay_Resp 8 _H – Follow_Up 9 _H – Delay_Resp A _H – Pdelay_Resp_Follow_Up B _H – Announce C _H – Signaling D _H – Management |
| PTP version field | 43 (nibble) | 1 _H or 2 _H | 1 – Supports PTP version 1 2 – Supports PTP version 2 |

1) PTP event messages are SYNC, Delay_Req (IEEE 1588 version 1 and 2) or Pdelay_Req, Pdelay_Resp (IEEE 1588 version 2 only).

PTP Frame Over IPv6

Table 15-37 gives the details of the fields that will be matched to control snapshot for PTP packets over UDP over IPv6 for IEEE 1588 version 1 and 2. Note that the octet positions for tagged frames will be offset by 4. This is based on Appendix-E of the IEEE 1588-2008 standard and the message format defined in **Table 15-35**.

Table 15-37 IPv6-UDP PTP Frame Fields Required for Control and Status

| Field Matched | Octet Position | Matched Value | Description |
|---|------------------|--|---|
| MAC Frame type | 12, 13 | 86DD _H | IP datagram |
| IP version | 14 (bits [7:4]) | 6 _H | IP version is IPv6 |
| Layer-4 protocol | 20 ¹⁾ | 11 _H | UDP |
| PTP Multicast address | 38 – 53 | FF0:0:0:0:0:0:181 _H FF02:0:0:0:0:0:0:6B _H | PTP – primary multicast address: FF0:0:0:0:0:0:0:0:181 _H PTP – Pdelay multicast address: FF02:0:0:0:0:0:0:0:6B _H |
| UDP destination port | 56, 57 (*) | 013F _H , 140 _H | 013F _H – PTP event message 0140 _H – PTP general messages |

| MAC Destination multicast address ¹⁾ | 0-5 | 01-1B-19-00-00-00 _H 01-80-C2-00-00-0E _H | All except peer delay messages - 01-1B-19-00-00-00 _H Pdelay messages - 01-80-C2-00-00-0E _H |
| PTP version field | 15 (nibble) | 1 _H or 2 _H | 1 _H – Supports PTP version 1 2 _H – Supports PTP version 2 |

1) In addition, the address match of destination addresses (DA) programmed in MAC address 1 to 31 will be used, if the control bit 18 (TSENMACADDR: Enable MAC address for PTP frame filtering) of the Time Stamp Control register is set.

15.2.11.10Reference Timing Source (for Advance Timestamp Feature)

The updated functionality for advanced timestamp support is mentioned in the following points.

1. The IEEE 1588-2008 standard defines the seconds field of the time to be 48 bits wide. The fields to time-stamp will be the following.
 - a) UInteger48- seconds field

b) UInteger32-nanoseconds field

The “seconds” field is the integer portion of the timestamp in units of seconds. The “nanoseconds” field is the fractional portion of the timestamp in units of nanoseconds. E.g. 2.000000001 seconds is represented as secondsField = 0000 0000 0002_H and nanoSeconds = 0000 0001_H. Thus the maximum value in nanoseconds field in this format will be 3B9A C9FF_H value (i.e (10e9-1) nano-seconds). This is defined as digital rollover mode of operation. It will also support the older mode in which the nano-seconds field will roll-over and increment the seconds field after the value of 7FFF FFFF_H. (Accuracy is ~0.466 ns per bit). This is defined as the binary rollover mode. The modes can be controlled using the “**ETH0_TIMESTAMP_CONTROL.TSCTRLSSR**” bit.

- When the Advanced IEEE 1588 time-stamp feature is selected time maintained in the core will still be 64-bit wide, as the overflow to the upper 16-bits of seconds register happens once in 130 years. The value of the upper 16-bits of the seconds field can only be obtained from the CSR register.

15.2.11.11 Transmit Path Functions

There are no changes in the transmit path functions for ETH-CORE and ETH-MTL configuration for the Advanced time stamp option.

structure of the descriptor changes when Advanced IEEE 1588 version support is enabled. The IEEE 1588 timestamp feature is supported using Alternate (Enhanced) descriptors format only. The descriptor is 32-bytes long (8 DWORDS) and the snapshot of the timestamp is written in descriptor 6 and 7.

15.2.11.12 Receive Path Functions

When the advanced time stamp feature is selected, processing of the received frames to identify valid PTP frames is done. The snapshot of the time to be sent to the application can be controlled.

The following options are provided in the **TIMESTAMP_CONTROL** register to control the snapshot.

- Option to enable snapshot for all frames.
- Enable snapshot for IEEE 1588 version 2 or version 1 time stamp.
- Enable snapshot for PTP frames transmitted directly over Ethernet or UDP-IP-Ethernet.
- Enable time stamp snapshot for the received frame for IPv4 or IPv6.
- Enable time stamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ or PDELAY_RESP) only.
- Enable the node to be a Master or Slave. This will control the type of messages for which snap-shot will be taken (this depends on the type of clock that is selected and is valid for ordinary or boundary clock only).

Note that PTP messages over VLAN frames are also supported.

15.2.12 System Time Register Module

A system time clock is maintained in this module. A 64 bit timer is incremented using the PTP clock (f_{CPU}) as reference. This time is the source for taking snapshots (time stamps) of Ethernet frames being transmitted or received at the MII.

The System Time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Time Stamp Update register. For initialization, the System Time counter(**ETH0_SYSTEM_TIME_SECONDS** and **ETH0_SYSTEM_TIME_NANOSECONDS**) is written with the value in the Time Stamp Update registers (**ETH0_SYSTEM_TIME_SECONDS_UPDATE** and **ETH0_SYSTEM_TIME_NANOSECONDS_UPDATE**), while for system time correction, the offset value is added to or subtracted from the system time.

In the fine correction method, a slave clock's (f_{CPU}) frequency drift with respect to the master clock (as defined in IEEE 1588) is corrected over a period of time instead of in one clock, as in coarse correction. This helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP Sync message intervals. In this method, an accumulator sums up the contents of the Addend register, as shown in **Figure 15-28**. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

This algorithm is depicted in **Figure 15-28**:

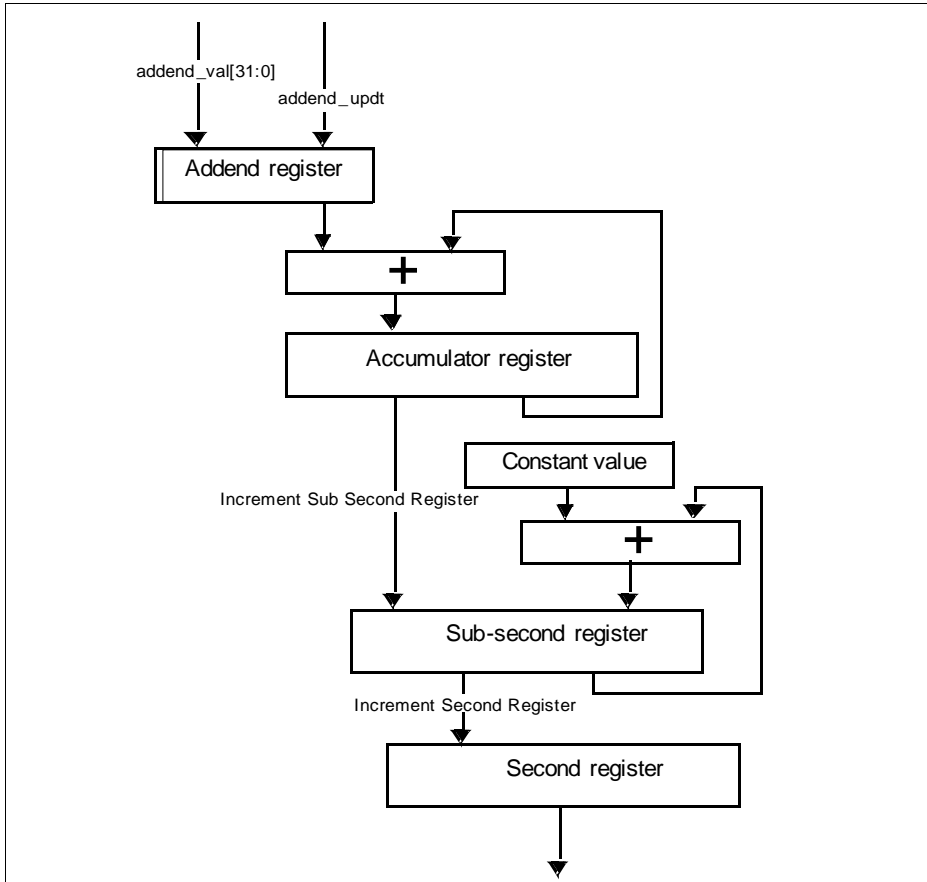

Figure 15-28 System Time Update Using Fine Method

The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (f_{CPU}) is, for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to be set in the register is $2^{32} / 1.32$, 0C1F07C1F_H.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is $2^{32} / 1.30$, or 0C4EC4EC4_H. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0BF0B7672_H. When the clock drift is nil, the default addend value of 0C1F07C1F_H ($2^{32} / 1.32$) must be programmed.

In **Figure 15-28**, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps). Two different methods are used to update the System Time register, depending on which configuration you choose (See **Block Diagram**).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:

$$\text{FreqCompensationValue}_0 = 2^{32} / \text{FreqDivisionRatio}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive Sync messages, the algorithm described below must be applied. After a few Sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.

The algorithm is as follows:

- At time MasterSyncTime_n the master sends the slave clock a Sync message. The slave receives this message when its local clock is SlaveClockTime_n and computes MasterClockTime_n as:

$$\text{MasterClockTime}_n = \text{MasterSyncTime}_n + \text{MasterToSlaveDelay}_n$$
- The master clock count for current Sync cycle, MasterClockCount_n is given by:

$$\text{MasterClockCount}_n = \text{MasterClockTime}_n - \text{MasterClockTime}_{n-1}$$
 (assuming that MasterToSlaveDelay is the same for Sync cycles n and n – 1)
- The slave clock count for current Sync cycle, SlaveClockCount_n is given by:

$$\text{SlaveClockCount}_n = \text{SlaveClockTime}_n - \text{SlaveClockTime}_{n-1}$$
- The difference between master and slave clock counts for current Sync cycle, ClockDiffCount_n is given by:

$$\text{ClockDiffCount}_n = \text{MasterClockCount}_n - \text{SlaveClockCount}_n$$
- The frequency-scaling factor for slave clock, FreqScaleFactor_n is given by:

$$\text{FreqScaleFactor}_n = (\text{MasterClockCount}_n + \text{ClockDiffCount}_n) / \text{SlaveClockCount}_n$$
- The frequency compensation value for Addend register, FreqCompensationValue_n is given by:

$$\text{FreqCompensationValue}_n = \text{FreqScaleFactor}_n * \text{FreqCompensationValue}_{n-1}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, due to changing network propagation delays and operating conditions.

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm will correct it at the cost of more Sync cycles.

15.2.13 Application BUS Interface

In the ETH core, the DMA Controller interfaces with the CPU through the Bus Interface. The Bus Master Interface controls data transfers while the Bus Slave interface accesses

CSR space. The DMA can be used in applications where DMA is required to optimize data transfer between the ETH and system memory.

The Bus Master interface converts the internal DMA request cycles into Bus cycles.

Characteristics of this interface include the following:

- You can choose fixed burst length of SINGLE, INCR4, INCR8 by programming the **ETH0_BUS_MODE**.MB bits
 - When transferring fixed burst length data, the Bus master always initiates a burst with SINGLE or INCR4/8 type. But when such a burst is responded with SPLIT/RETRY/early burst termination, the Bus master will re-initiate the pending transfers of the burst with INCR or SINGLE burst-length type. It will terminate such INCR bursts when the original requested fixed-burst is transferred. In Fixed Burst-Length mode, if the DMA requests a burst transfer that is not equal to INCR4/8, the Bus interface splits the transfer into multiple burst transactions. For example, if the DMA requests a 15-beat burst transfer, the Bus interface splits it into multiple transfers of INCR8 and INCR4 and 3 SINGLE transactions.
 - Takes care of Bus SPLIT, RETRY, and ERROR conditions. Any ERROR response will halt all further transactions for that DMA, and indicate the error as fatal through the CSR and interrupt. The application must give a hard or soft reset to the module to restart the operation.
 - Takes care of Bus 1K boundary breaking
 - Handles all data transfers, except for Descriptor Status Write accesses (which are always 32-bit). In any burst data transfer, the address bus value is always aligned to the data bus width and need not be aligned to the beat size.
- All Bus burst transfers can be aligned to an address value by enabling the **ETH0_BUS_MODE**.AAL bit. If both the FB and AAL bits are set to 1, the Bus interface and the DMA together ensure that all initiated beats are aligned to the address, completing the frame transfer in the minimum number of required beats. For example, if a data buffer transfer's start address is F000 0008_H and the DMA is configured for a maximum beat size of, the Bus transfers occur in the following sequence:
- 2 SINGLE transfers at addresses F000 0008_H and F000 000C_H
 - 1 INCR4 transfer at address F000 0010_H
- The DMA Controller requests an Bus Burst Read transfer only when it can accept the received burst data completely. Data read from the Bus is always pushed into the DMA without any delay or BUSY cycles.
 - The DMA requests an Bus Burst Write transfer only when it has the sufficient data to transfer the burst completely. The Bus interface always assumes that it has data available to push into the bus. However, the DMA can prematurely indicate end-of-valid data (due to the transfer of end-of-frame of an Ethernet frame) during the burst. The Bus Master interface continues the burst with dummy data until the specified length is completed.

The Bus 32-bit Slave interface provides access to the DMA and ETH CSR space. Characteristics of this interface include the following:

- Supports single and INCR4/8 transfers
- Supports busy and early terminations
- Supports 32-bit, 16-bit, and 8-bit write/read transfers to the CSR; 32-bit access to the CSR are recommended to avoid any SW synchronization problems.
- Generates OKAY only response; does not generate SPLIT, RETRY, or ERROR responses.

15.3 Service Request Generation

Service requests can be generated from the ETH core as a result of various events in the modules within the ETH peripheral. There are four sources of service request, the ETH DMA, The Power Management module, the System timer module and the MAC management counters. Each of the events raised by these modules are ORed together and connected to an ETH Service Request line which is connected to the NVIC. The events are not queued and the application software must check all the status bits to ensure all events are serviced. Before exiting the service request routine the application software must ensure all status bits are deasserted or spurious service requests will be generated.

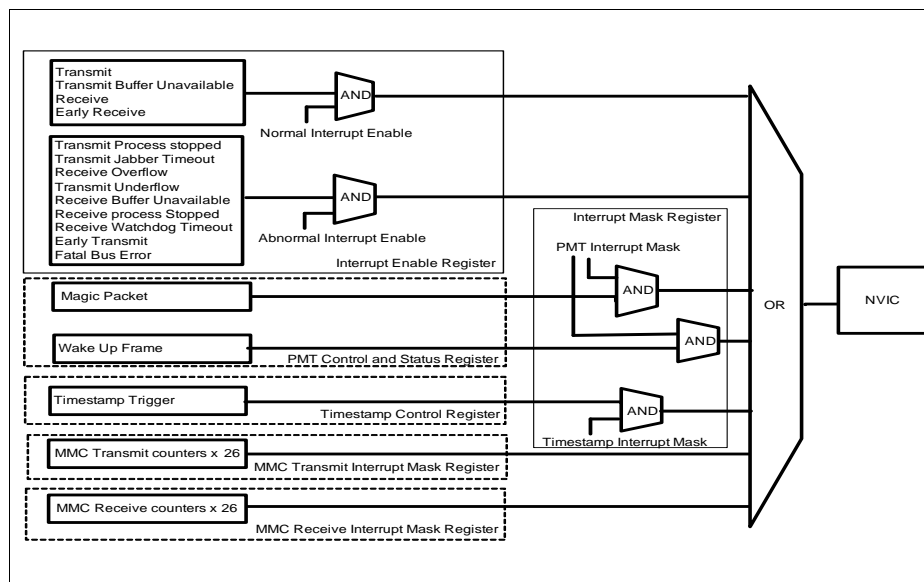

Figure 15-29 ETH Core Service Request Structure

15.3.1 DMA Service Requests

The ETH DMA has two groups of Service Request, Normal and Abnormal requests. Each Service Request source is enabled in the **ETH0_INTERRUPT_ENABLE** register. Each group of Service Requests must also be enabled by setting the Normal Interrupt enable and Abnormal Interrupt enable bits in the same register. When a service request is raised the matching Service request bits will be set in the **ETH0_STATUS** register. Global summary bits for the Power management MAC management counters and system time module are also provided in the status register.

15.3.2 Power Management Service Requests

The power management module provides two Service Requests, Wake up Frame and Magic packet. Both of these service requests may be enabled and monitored in the **PMT_CONTROL_STATUS** Register. To enable any power management service request it is also necessary to clear the **INTERRUPT_MASK.PMTIM** bit. The **INTERRUPT_STATUS.PMTIS** bit provides a global status bit for power management service requests.

15.3.3 System Time Module

The system time module provides a single Timestamp trigger service request which can be enabled in the timestamp control register. The **INTERRUPT_MASK.TSIM** bit must also be cleared to enable the timestamp trigger Service request. The **INTERRUPT_STATUS.TSIS** is set when a system time module service request occurs.

15.3.4 MAC Management Counter Service Requests

Each of the MAC Management Counters can generate a service request. The service requests are split into two groups of transmit and receive counters. Each counter may be individually enabled in either the **MMC_RECEIVE_INTERRUPT_MASK** register or the **MMC_TRANSMIT_INTERRUPT_MASK** register. When a MMC service request is generated status bits for each counter are set in the **MMC_RECEIVE_INTERRUPT** register or the **MMC_TRANSMIT_INTERRUPT** register. Two global status bits for the transmit and receive counters are provided in the **INTERRUPT_STATUS** register

15.4 Debug

Module specific debug behavior TBD

In addition the ETH has a number of intrinsic features to assist debugging, these are described below.

- The **DEBUG** register provides flags which indicate the operating status of the ETH MAC and MTL.
- The **STATUS** register provides information on the operating status of the DMA.
- The **MAC Management Counters** provide extensive information about the Received and transmitted Ethernet frames.
- The **MAC_CONFIGURATION**.LM bit places the ETH in internal loopback mode for self test and debug
- External loopback is supported via the integrated MDIO controlling the PHY
- The **CURRENT_HOST_TRANSMIT_DESCRIPTOR** and **CURRENT_HOST_RECEIVE_DESCRIPTOR** provide pointers to the current location of the transmit and receive frame buffers held in RAM

15.5 Power Reset and Clock

The module, including all registers, can be reset to its default state by a system reset or a software reset triggered through the setting of corresponding bits in the SCU PRSETx registers.

Important

After the XMC4[78]00 is released from reset the ETH module remains held in reset. While the ETH is held in reset the software driver must select the PHY interconnect see [Section 15.2.7.1](#) . Once the PHY interconnect has been selected ETH reset line must be deasserted by setting PRCLR2.ETH0RS in the system control unit.

For proper operation of the Ethernet Interface it is required that $f_{\text{SYS}} \geq 100 \text{ MHz}$.

15.6 ETH Registers

The application controls the ETH by reading from and writing to the Control and Status Registers (CSRs) through the BUS Slave interface. These registers are 32 bits wide and the addresses are 32-bit block aligned

1) The absolute register address is calculated as follows:
Module Base Address + Offset Address (shown in this column)

15.6.2.1 Registers Description

MAC_CONFIGURATION

The MAC Configuration register establishes receive and transmit operating modes.

ETH0_MAC_CONFIGURATION

MAC Configuration Register (0_H) **Reset Value: 0000 8000_H**

| | | | | | | | | | | | | | | | |

| Reserved | FES | DO | LM | DM | IPC | DR | Reserved_8 | ACS | BL | | DC | TE | RE | PRELEN | |
| r | rw | rw | rw | rw | rw | rw | r | rw | rw | | rw | rw | rw | rw | |

| Field | Bits | Type | Description |
|--------|-------|------|--|
| PRELEN | [1:0] | rw | Preamble Length for Transmit Frames These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating in the full-duplex mode. * 00 _B : 7 bytes of preamble * 01 _B : 5 byte of preamble * 10 _B : 3 bytes of preamble * 11 _B : reserved |
| RE | 2 | rw | Receiver Enable When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the MII. |

| Field | Bits | Type | Description |
|-----------|------|------|--|
| TE | 3 | rw | Transmitter Enable When this bit is set, the transmit state machine of the MAC is enabled for transmission on the MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames. |
| DC | 4 | rw | Deferral Check When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times . If the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on the MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. |

| Field | Bits | Type | Description |
|-------------------|-------|------|--|
| BL | [6:5] | rw | Back-Off Limit The Back-Off limit determines the random integer number (r) of slot time delays (512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode and is reserved (RO) in the full-duplex-only configuration. * 00 _B : $k = \min(n, 10)$ * 01 _B : $k = \min(n, 8)$ * 10 _B : $k = \min(n, 4)$ * 11 _B : $k = \min(n, 1)$ where $\langle i \rangle n \langle /i \rangle =$ retransmission attempt. The random integer $\langle i \rangle r \langle /i \rangle$ takes the value in the range $0 \leq r < k$ th power of 2 |
| ACS | 7 | rw | Automatic Pad or CRC Stripping When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the XMC4[78]00 Memory. |
| Reserved_8 | 8 | r | Reserved |
| DR | 9 | rw | Disable Retry When this bit is set, the MAC attempts only one transmission. When a collision occurs on the MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode and is reserved (RO with default value) in the full-duplex-only configuration. |

| Field | Bits | Type | Description |
|------------|------|------|---|
| IPC | 10 | rw | Checksum Offload When this bit is set, the MAC calculates the 16-bit ones complement of the ones complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. |
| DM | 11 | rw | Duplex Mode When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. |
| LM | 12 | rw | Loopback Mode When this bit is set, the MAC operates in the loopback mode using the MII. The MII Receive clock input is required for the loopback to work properly, because the Transmit clock is not looped-back internally. |
| DO | 13 | rw | Disable Receive Own When this bit is set, the MAC disables the reception of frames in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. |
| FES | 14 | rw | Speed This bit selects the speed in the MII or RMII: * 0 _B : 10 Mbps * 1 _B : 100 Mbps This bit generates link speed encoding when TC (Bit 24) is set in the RMII mode. |

| Field | Bits | Type | Description |
|-----------------|---------|------|--|
| Reserved | 15 | r | Reserved |
| DCRS | 16 | rw | Disable Carrier Sense During Transmission When set high, this bit makes the MAC transmitter ignore the MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. |
| IFG | [19:17] | rw | Inter-Frame Gap These bits control the minimum IFG between frames during transmission. * 000 _B : 96 bit times * 001 _B : 88 bit times * 010 _B : 80 bit times * ... * 111 _B : 40 bit times In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100 _B). Lower values are not considered. |
| JE | 20 | rw | Jumbo Frame Enable When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status. |
| BE | 21 | r | Frame Burst Enable When this bit is set, the MAC allows frame bursting during transmission in the MII half-duplex mode. This bit is reserved (and RO) in the 10/100 Mbps only or full-duplex-only configurations. |
| JD | 22 | rw | Jabber Disable When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission. |

| Field | Bits | Type | Description |
|--------------------|------|------|---|
| WD | 23 | rw | Watchdog Disable When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes. |
| TC | 24 | r | Transmit Configuration in RMII When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in RMII. When this bit is reset, no such information is driven to the PHY. |
| CST | 25 | rw | CRC Stripping of Type Frames When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0600 _H) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. |
| Reserved_26 | 26 | r | Reserved |
| TWOKPE | 27 | rw | IEEE 802.3as support for 2K packets Enable When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status. |

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| SARC | [30:28] | r | <p>Source Address Insertion or Replacement Control</p> <p>This field controls the source address insertion or replacement for all transmitted frames. Bit 30 specifies which MAC Address register (0 or 1) is used for source address insertion or replacement based on the values of Bits [29:28]:</p> <p>* 10_B:</p> <ul style="list-style-type: none"> - If Bit 30 is set to 0, the MAC inserts the content of the MAC Address 0 registers (ETH0_MAC_ADDRESS0_HIGH and ETH0_MAC_ADDRESS0_LOW) in the SA field of all transmitted frames. - If Bit 30 is set to 1 the MAC inserts the content of the MAC Address 1 registers (ETH0_MAC_ADDRESS1_HIGH and ETH0_MAC_ADDRESS1_LOW) in the SA field of all transmitted frames. <p>* 11_B:</p> <ul style="list-style-type: none"> - If Bit 30 is set to 0, the MAC replaces the content of the MAC Address 0 registers (ETH0_MAC_ADDRESS0_HIGH and ETH0_MAC_ADDRESS0_LOW) in the SA field of all transmitted frames. - If Bit 30 is set to 1 and the Enable MAC Address Register 1 option is selected during core configuration, the MAC replaces the content of the MAC Address 1 registers (ETH0_MAC_ADDRESS1_HIGH and ETH0_MAC_ADDRESS1_LOW) in the SA field of all transmitted frames. <p>Note:</p> <ul style="list-style-type: none"> - Changes to this field take effect only on the start of a frame. If you write this register field when a frame is being transmitted, only the subsequent frame can use the updated value, that is, the current frame does not use the updated value. |
| Reserved_31 | 31 | r | Reserved |

MAC_FRAME_FILTER

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

ETH0_MAC_FRAME_FILTER

MAC Frame Filter

(4_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|------|------|---|
| PR | 0 | rw | Promiscuous Mode When this bit is set, the Address Filter module passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set. |
| HUC | 1 | rw | Hash Unicast When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO). |

| Field | Bits | Type | Description |
|-------------|------|------|---|
| HMC | 2 | rw | Hash Multicast When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. If Hash Filter is not selected during core configuration, this bit is reserved (and RO). |
| DAIF | 3 | rw | DA Inverse Filtering When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed. |
| PM | 4 | rw | Pass All Multicast When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit. |
| DBF | 5 | rw | Disable Broadcast Frames When this bit is set, the AFM module filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM module passes all received broadcast frames. |

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| PCF | [7:6] | rw | <p>Pass Control Frames</p> <p>These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames).</p> <ul style="list-style-type: none"> * 00B: MAC filters all control frames from reaching the application. * 01B: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. * 10B: MAC forwards all control frames to application even if they fail the Address Filter. * 11B: MAC forwards control frames that pass the Address Filter. <p>The following conditions should be true for the PAUSE control frames processing:</p> <ul style="list-style-type: none"> * Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting FLOW_CONTROL.RFE. * Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when FLOW_CONTROL.UP is set. * Condition 3: The Type field of the received frame is 8808H and the OPCODE field is 0001H. <p>Note:</p> <p>This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application).</p> |
| SAIF | 8 | rw | <p>SA Inverse Filtering</p> <p>When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter.</p> <p>When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter.</p> |

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| SAF | 9 | rw | Source Address Filter Enable When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA Match bit of RxStatus Word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application and with the updated SA Match bit of the RxStatus depending on the SA address comparison. |
| HPF | 10 | rw | Hash or Perfect Filter When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. |
| Reserved_15_11 | [15:11] | r | Reserved |
| VTFE | 16 | rw | VLAN Tag Filter Enable When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag. |
| Reserved_19_17 | [19:17] | r | Reserved |
| IPFE | 20 | r | Layer 3 and Layer 4 Filter Enable When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 fields. If the Layer 3 and Layer 4 Filtering feature is not selected during core configuration, this bit is reserved (RO with default value). |

| Field | Bits | Type | Description |
|-----------------------|---------|------|---|
| DNTU | 21 | r | Drop non-TCP/UDP over IP Frames When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. |
| Reserved_30_22 | [30:22] | r | Reserved |
| RA | 31 | rw | Receive All When this bit is set, the MAC Receiver module passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver module passes only those frames to the Application that pass the SA or DA address filter. |

HASH_TABLE_HIGH

The 64-bit Hash table is used for group address filtering. For hash filtering, the contents of the destination address in the incoming frame is passed through the CRC logic, and the upper 6 bits of the CRC register are used to index the contents of the Hash table. The most significant bit determines the register to be used (Hash Table High or Hash Table Low), and the other 5 bits determine which bit within the register. A hash value of 00000B selects Bit 0 of the selected register, and a value of 11111B selects Bit 31 of the selected register. The hash value of the destination address is calculated in the following way:

1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32).
2. Perform bitwise reversal for the value obtained in Step 1.
3. Take the upper 6 bits from the value obtained in Step 2.

For example, if the DA of the incoming frame is received as 1F52 419C B6AFH (1FH is the first byte received on MII interface), then the internally calculated 6-bit Hash value is 2CH and Bit 12 of Hash Table High register is checked for filtering. If the DA of the incoming frame is received as A00A 9800 0045H, then the calculated 6-bit Hash value is 07H and Bit 7 of Hash Table Low register is checked for filtering. Note: To help you program the hash table, a sample C routine that generates a DA's 6-bit hash is included in the /sample_codes/ directory of your workspace. If the corresponding bit value of the register is 1, the frame is accepted. Otherwise, it is rejected. If the PM (Pass All Multicast) bit is set in the MAC Frame Filter Register, then all multicast frames are accepted regardless of the multicast hash values. If the Hash Table register is configured to be double-synchronized to the MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) of the Hash Table High or Low registers are written. Consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain when double-synchronization is enabled. The Hash Table High register contains the higher 32 bits of the Hash table.

ETH0_HASH_TABLE_HIGH

| Field | Bits | Type | Description |
|-------|--------|------|--|
| HTH | [31:0] | rw | Hash Table High This field contains the upper 32 bits of the Hash table. |

HASH_TABLE_LOW

The Hash Table Low register contains the lower 32 bits of the Hash table. Both Register 2 and Register 3 are reserved if the Hash Filter Function is disabled or the 128-bit or 256-bit Hash Table is selected during core configuration.

ETH0_HASH_TABLE_LOW

Hash Table Low Register

(C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| HTL | [31:0] | rw | Hash Table Low This field contains the lower 32 bits of the Hash table. |

GMII_ADDRESS

The MII Address register controls the management cycles to the external PHY through the management interface.

ETH0_GMII_ADDRESS

MIl Address Register (10_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|------|------|---|
| MB | 0 | rw | MIl Busy This bit should read logic 0 before writing to the MII Address and Data registers. During a PHY register access, the software sets this bit to 1 to indicate that a Read or Write access is in progress. The MII Data Register is invalid until this bit is cleared by the MAC. Therefore the MII Data Register should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of the MII Data Register are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present. |
| MW | 1 | rw | MIl Write When set, this bit indicates to the PHY that this is a Write operation using the MII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the MII Data register. |

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| CR | [5:2] | rw | <p>CSR Clock Range</p> <p>The CSR Clock Range selection determines the frequency of the MDC clock according to the ETH Clock frequency used in your design. The suggested range of ETH Clock frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz.</p> <ul style="list-style-type: none"> - 0000B: The frequency of the ETH Clock is 60-100 MHz and the MDC clock is ETH Clock /42. - 0001B: The frequency of the ETH Clock is 100-150 MHz and the MDC clock is ETH Clock /62. - 0010B: The frequency of the ETH Clock is 20-35 MHz and the MDC clock is ETH Clock /16. - 0011B: The frequency of the ETH Clock is 35-60 MHz and the MDC clock is ETH Clock /26. - 0100B: The frequency of the ETH Clock is 150-250 MHz and the MDC clock is ETH Clock /102. - 0100B: The frequency of the ETH Clock is 250-300 MHz and the MDC clock is ETH Clock /124. - 0110B and 0111B: Reserved <p>When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when the ETH Clock is of 100 MHz frequency and you program these bits as 1010B, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Program the following values only if the interfacing chips support faster MDC clocks:</p> <ul style="list-style-type: none"> - 1000: ETH Clock /4 - 1001: ETH Clock /6 - 1010: ETH Clock /8 - 1011: ETH Clock /10 - 1100: ETH Clock /12 - 1101: ETH Clock /14 - 1110: ETH Clock /16 - 1111:ETH Clock /18 |
| MR | [10:6] | rw | <p>MII Register</p> <p>These bits select the desired MII register in the selected PHY device.</p> |

| Reserved_31_16 | [31:16] | r | Reserved |

FLOW_CONTROL

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control module. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The CPU must make sure that the Busy bit is cleared before writing to the register.

ETH0_FLOW_CONTROL

Flow Control Register

| Field | Bits | Type | Description |
|----------------|------|------|---|
| FCA_BPA | 0 | rw | <p>Flow Control Busy or Backpressure Activate</p> <p>This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set.</p> <p>In the full-duplex mode, this bit should be read as 0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared.</p> <p>In the half-duplex mode, when this bit is set (and TFE is set), then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled.</p> |
| TFE | 1 | rw | <p>Transmit Flow Control Enable</p> <p>In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames.</p> <p>In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled.</p> |
| RFE | 2 | rw | <p>Receive Flow Control Enable</p> <p>When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled.</p> |

| Field | Bits | Type | Description |
|-------------------|-------|------|---|
| UP | 3 | rw | Unicast Pause Frame Detect When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard. |
| PLT | [5:4] | rw | Pause Low Threshold This field configures the threshold of the PAUSE timer at which the input flow control signal is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the flow control signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The following list provides the threshold values for different values: - 00B: The threshold is Pause time minus 4 slot times (PT - 4 slot times). - 01B: The threshold is Pause time minus 28 slot times (PT - 28 slot times). - 10B: The threshold is Pause time minus 144 slot times (PT - 144 slot times). - 11B: The threshold is Pause time minus 256 slot times (PT - 256 slot times). The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the MII interface. |
| Reserved_6 | 6 | r | Reserved |
| DZPQ | 7 | rw | Disable Zero-Quanta Pause When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer. When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. |

| Field | Bits | Type | Description |
|----------------------|---------|------|---|
| Reserved_15_8 | [15:8] | r | Reserved |
| PT | [31:16] | rw | Pause Time This field holds the value to be used in the Pause Time field in the transmit control frame. If the Pause Time bits is configured to be double-synchronized to the MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain. |

VLAN_TAG

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 8100H, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. If the VLAN Tag register is configured to be double-synchronized to the MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

ETH0_VLAN_TAG

VLAN Tag Register

(1C_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| VL | [15:0] | rw | VLAN Tag Identifier for Receive Frames This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: <ul style="list-style-type: none"> * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 8100H or 88A8H as VLAN frames. |

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| ETV | 16 | rw | Enable 12-Bit VLAN Tag Comparison When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits 11-0 of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. |
| VTIM | 17 | rw | VLAN Tag Inverse Match Enable When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched. |
| ESVL | 18 | rw | Enable S-VLAN When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 88A8H) frames as valid VLAN tagged frames. |
| VTHM | 19 | r | VLAN Tag Hash Table Match Enable When set, the most significant four bits of the VLAN tags CRC are used to index the content of Register 354 [VLAN Hash Table Register]. A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed. |
| Reserved_31_20 | [31:20] | r | Reserved |

VERSION

The VERSION registers identifies the version of the ETH. This register contains two bytes: one that Synopsys uses to identify the core release number, and the other that you set during core configuration.

ETH0_VERSION

Version Register

(20_H)

Reset Value: 0000 1037_H

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| SNPSVER | [7:0] | r | Synopsys-defined Version (3.7) |
| USERVER | [15:8] | r | User-defined Version (Configured with the coreConsultant) |
| Reserved_31_16 | [31:16] | r | Reserved |

DEBUG

The DEBUG register gives the status of all main modules of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

ETH0_DEBUG

Debug Register

(24_H)
Reset Value: 0000 0000_H

| Reserved_23 | 23 | r | Reserved |
| TXFSTS | 24 | r | MTL Tx FIFO Not Empty Status When high, this bit indicates that the MTL Tx FIFO is not empty and some data is left for transmission. |
| TXSTSFS TS | 25 | r | MTL TxStatus FIFO Full Status When high, this bit indicates that the MTL TxStatus FIFO is full. Therefore, the MTL cannot accept any more frames for transmission. This bit is reserved in the ETH-AHB and ETH-DMA configurations. |
| Reserved_31_26 | [31:26] | r | Reserved |

REMOTE_WAKE_UP_FRAME_FILTER

This is the address through which the application writes or reads the remote wake-up frame filter registers (wkupfmfilter_reg). The wkupfmfilter_reg register is a pointer to eight wkupfmfilter_reg registers. The wkupfmfilter_reg register is loaded by sequentially loading the eight register values. Eight sequential writes to this address (0028H) writes all wkupfmfilter_reg registers. Similarly, eight sequential reads from this address (0028H) read all wkupfmfilter_reg registers. This register contains the higher 16 bits of the seventh MAC address.

ETH0_REMOTE_WAKE_UP_FRAME_FILTER

Remote Wake Up Frame Filter Register (28_H)

Reset Value: 0000 0000_H

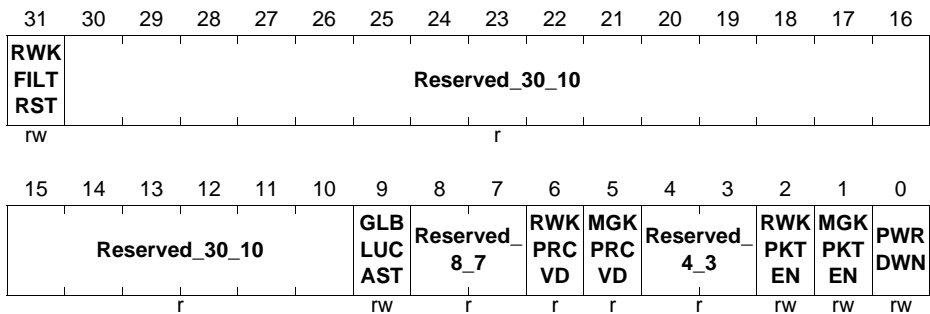

| Field | Bits | Type | Description |
|-------------------|--------|------|------------------------------------|
| WKUPFRMFTR | [31:0] | rw | Remote Wake-Up Frame Filter |

PMT_CONTROL_STATUS

ETH0_PMT_CONTROL_STATUS

PMT Control and Status Register (2C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|------|------|---|
| PWRDWN | 0 | rw | Power Down When set, the MAC receiver drops all received frames until it receives the expected magic packet or wake-up frame. This bit is then self-cleared and the power-down mode is disabled. The Software can also clear this bit before the expected magic packet or wake-up frame is received. The frames, received by the MAC after this bit is cleared, are forwarded to the application. This bit must only be set when the Magic Packet Enable, Global Unicast, or Wake-Up Frame Enable bit is set high. Note: You can gate-off the CSR clock during the power-down mode. However, when the CSR clock is gated-off, you cannot perform any read or write operations on this register. Therefore, the Software cannot clear this bit. |
| MGKPKTEN | 1 | rw | Magic Packet Enable When set, enables generation of a power management event because of magic packet reception. |
| RWKPKTEN | 2 | rw | Wake-Up Frame Enable When set, enables generation of a power management event because of wake-up frame reception. |

| Field | Bits | Type | Description |
|-----------------------|---------|------|---|
| Reserved_4_3 | [4:3] | r | Reserved |
| MGKPRC VD | 5 | r | Magic Packet Received When set, this bit indicates that the power management event is generated because of the reception of a magic packet. This bit is cleared by a Read into this register. |
| RWKPRC VD | 6 | r | Wake-Up Frame Received When set, this bit indicates the power management event is generated because of the reception of a wake-up frame. This bit is cleared by a Read into this register. |
| Reserved_8_7 | [8:7] | r | Reserved |
| GLBLUCA ST | 9 | rw | Global Unicast When set, enables any unicast packet filtered by the MAC (DAF) address recognition to be a wake-up frame. |
| Reserved_30_10 | [30:10] | r | Reserved |
| RWKFILTER RST | 31 | rw | Wake-Up Frame Filter Register Pointer Reset When set, resets the remote wake-up frame filter register pointer to 000B. It is automatically cleared after 1 clock cycle. |

INTERRUPT_STATUS

The Interrupt Status register identifies the events in the MAC that can generate interrupt.

ETH0_INTERRUPT_STATUS

Interrupt Register (38_H) **Reset Value: 0000 0000_H**

| r | | | | | r | r | r | r | r | r | r | r | r | | |

| Field | Bits | Type | Description |
|---------------------|-------|------|---|
| Reserved_2_0 | [2:0] | r | Reserved |
| PMTIS | 3 | r | PMT Interrupt Status This bit is set when a Magic packet or Wake-on-LAN frame is received in the power-down mode. This bit is cleared when both PMT_CONTROL_STATUS.MGKPRCVD and PMT_CONTROL_STATUS.RWKPRCVD are cleared because of a read operation to the PMT Control and Status register. |
| MMCIS | 4 | r | MMC Interrupt Status This bit is set high when any of the Bits MMCRXIS, MMCTXIS or MMCRXIPIS is set high and cleared only when all of these bits are low. |
| MMCRXIS | 5 | r | MMC Receive Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. |
| MMCTXIS | 6 | r | MMC Transmit Interrupt Status This bit is set high when an interrupt is generated in the MMC Transmit Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. |

| Field | Bits | Type | Description |
|-----------------------|---------|------|---|
| MMCRXIPIS | 7 | r | MMC Receive Checksum Offload Interrupt Status This bit is set high when an interrupt is generated in the MMC Receive Checksum Offload Interrupt Register. This bit is cleared when all the bits in this interrupt register are cleared. |
| Reserved_8 | 8 | r | Reserved |
| TSIS | 9 | r | Timestamp Interrupt Status When the Advanced Timestamp feature is enabled, this bit is set when any of the following conditions is true: * The system time value equals or exceeds the value specified in the Target Time High and Low registers. * There is an overflow in the seconds register. This bit is cleared on reading Timestamp STATUS.TSSOVF Register. If default Timestamping is enabled, when set, this bit indicates that the system time value is equal to or exceeds the value specified in the Target Time registers. In this mode, this bit is cleared after the completion of the read of this bit. In all other modes, this bit is reserved. |
| Reserved_10 | 10 | r | Reserved |
| Reserved_31_11 | [31:11] | r | Reserved |

INTERRUPT_MASK

The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register.

ETH0_INTERRUPT_MASK

Interrupt Mask Register (3C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------------|---------|------|---|
| Reserved_2_0 | [2:0] | r | Reserved |
| PMTIM | 3 | rw | PMT Interrupt Mask When set, this bit disables the assertion of the interrupt signal because of the setting of PMT Interrupt Status bit INTERRUPT_STATUS.PMTIS. |
| Reserved_8_4 | [8:4] | r | Reserved |
| TSIM | 9 | rw | Timestamp Interrupt Mask When set, this bit disables the assertion of the interrupt signal because of the setting of Timestamp Interrupt Status bit INTERRUPT_STATUS.TSIS. This bit is valid only when IEEE1588 timestamping is enabled. In all other modes, this bit is reserved. |
| Reserved_31_10 | [31:10] | r | Reserved |

MAC_ADDRESS0_HIGH

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 1122 3344 5566H is received (11H in lane 0 of the first column) on the MII as the destination address, then the MacAddress0 Register [47:0] is compared with 6655 4433 2211H. If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH0_MAC_ADDRESS0_HIGH
MAC Address0 High Register
(40_H)
Reset Value: 8000 FFFF_H

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| ADDRHI | [15:0] | rw | MAC Address0 [47:32] This field contains the upper 16 bits (47:32) of the first 6-byte MAC address. The MAC uses this field for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames. |
| Reserved_30_16 | [30:16] | r | Reserved |
| AE | 31 | r | Address Enable This bit is always set to 1. |

MAC_ADDRESS0_LOW

The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

ETH0_MAC_ADDRESS0_LOW

MAC Address0 Low Register

(44_H)

Reset Value: FFFF FFFF_H

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| ADDRLO | [31:0] | rw | MAC Address0 [31:0] This field contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames. |

32-bit Register - MAC_ADDRESS1_HIGH

The MAC Address1 High register holds the upper 16 bits of the second 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

ETH0_MAC_ADDRESS1_HIGH

MAC Address1 High Register

(48_H)
Reset Value: 0000 FFFF_H

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| ADDRHI | [15:0] | rw | MAC Address1 [47:32] This field contains the upper 16 bits (47:32) of the second 6-byte MAC address. |
| Reserved_23_16 | [23:16] | r | Reserved |

| Field | Bits | Type | Description |
|------------|---------|------|--|
| MBC | [29:24] | rw | Mask Byte Control These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address1 registers. Each bit controls the masking of the bytes as follows: * Bit 29: MAC_ADDRESS1_HIGH [15:8] * Bit 28: MAC_ADDRESS1_HIGH [7:0] * Bit 27: MAC_ADDRESS1_LOW [31:24] * ... * Bit 24: MAC_ADDRESS1_LOW [7:0] You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. |
| SA | 30 | rw | Source Address When this bit is set, the MAC Address1[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address1[47:0] is used to compare with the DA fields of the received frame. |
| AE | 31 | rw | Address Enable When this bit is set, the address filter module uses the second MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. |

MAC_ADDRESS1_LOW

The MAC Address1 Low register holds the lower 32 bits of the second 6-byte MAC address of the station.

ETH0_MAC_ADDRESS1_LOW

MAC Address1 Low Register

(4C_H)

Reset Value: FFFF FFFF_H

| Field | Bits | Type | Description |
|--------|--------|------|--|
| ADDRLO | [31:0] | rw | MAC Address1 [31:0] This field contains the lower 32 bits of the second 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process. |

MAC_ADDRESS2_HIGH

The MAC Address2 High register holds the upper 16 bits of the third 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address2 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH0_MAC_ADDRESS2_HIGH

MAC Address2 High Register (50_H) **Reset Value: 0000 FFFF_H**

| Field | Bits | Type | Description |
|-----------------------|---------|------|---|
| ADDRHI | [15:0] | rw | MAC Address2 [47:32] This field contains the upper 16 bits (47:32) of the third 6-byte MAC address. |
| Reserved_23_16 | [23:16] | r | Reserved |
| MBC | [29:24] | rw | Mask Byte Control These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address2 registers. Each bit controls the masking of the bytes as follows: * Bit 29: MAC_ADDRESS1_HIGH [15:8] * Bit 28: MAC_ADDRESS1_HIGH [7:0] * Bit 27: MAC_ADDRESS1_LOW [31:24] * ... * Bit 24: MAC_ADDRESS1_LOW [7:0] |

| Field | Bits | Type | Description |
|-----------|------|------|---|
| SA | 30 | rw | Source Address When this bit is set, the MAC Address2[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address2[47:0] is used to compare with the DA fields of the received frame. |
| AE | 31 | rw | Address Enable When this bit is set, the address filter module uses the third MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. |

MAC_ADDRESS2_LOW

The MAC Address2 Low register holds the lower 32 bits of the third 6-byte MAC address of the station.

ETH0_MAC_ADDRESS2_LOW

MAC Address2 Low Register

(54_H)

Reset Value: FFFF FFFF_H

| Field | Bits | Type | Description |
|--------|--------|------|---|
| ADDRLO | [31:0] | rw | MAC Address2 [31:0] This field contains the lower 32 bits of the third 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process. |

MAC_ADDRESS3_HIGH

The MAC Address3 High register holds the upper 16 bits of the fourth 6-byte MAC address of the station. If the MAC address registers are configured to be double-synchronized to the MII clock domains, then the synchronization is triggered only when Bits[31:24] of the MAC Address3 Low Register are written. For proper synchronization updates, consecutive writes to this MAC Address3 Low Register must be performed after at least four clock cycles in the destination clock domain.

ETH0_MAC_ADDRESS3_HIGH

MAC Address3 High Register

(58_H)
Reset Value: 0000 FFFF_H

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| ADDRHI | [15:0] | rw | MAC Address3 [47:32] This field contains the upper 16 bits (47:32) of the fourth 6-byte MAC address. |
| Reserved_23_16 | [23:16] | r | Reserved |
| MBC | [29:24] | rw | Mask Byte Control These bits are mask control bits for comparison of each of the MAC Address bytes. When set high, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address3 registers. Each bit controls the masking of the bytes as follows: <ul style="list-style-type: none"> * Bit 29: MAC_ADDRESS1_HIGH [15:8] * Bit 28: MAC_ADDRESS1_HIGH [7:0] * Bit 27: MAC_ADDRESS1_HIGH [31:24] * ... * Bit 24: MAC_ADDRESS1_HIGH [7:0] |

| Field | Bits | Type | Description |
|-----------|------|------|---|
| SA | 30 | rw | Source Address When this bit is set, the MAC Address3[47:0] is used to compare with the SA fields of the received frame. When this bit is reset, the MAC Address3[47:0] is used to compare with the DA fields of the received frame. |
| AE | 31 | rw | Address Enable When this bit is set, the address filter module uses the fourth MAC address for perfect filtering. When this bit is reset, the address filter module ignores the address for filtering. |

MAC_ADDRESS3_LOW

The MAC Address3 Low register holds the lower 32 bits of the fourth 6-byte MAC address of the station.

ETH0_MAC_ADDRESS3_LOW

MAC Address3 Low Register

(5C_H)

Reset Value: FFFF FFFF_H

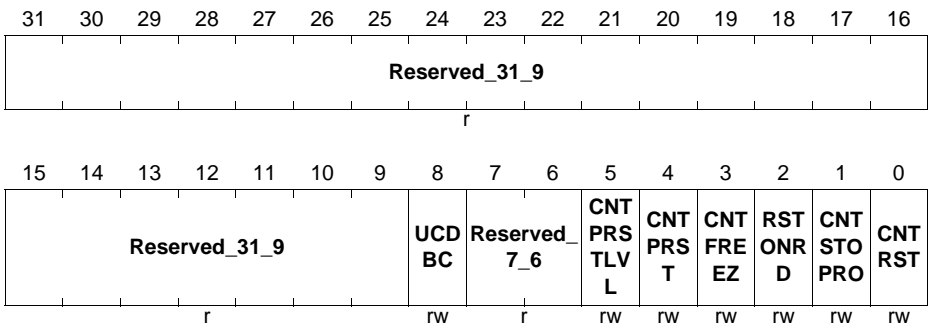

| Field | Bits | Type | Description |
|--------|--------|------|--|
| ADDRLO | [31:0] | rw | MAC Address3 [31:0] This field contains the lower 32 bits of the fourth 6-byte MAC address. The content of this field is undefined until loaded by the Application after the initialization process. |

MMC_CONTROL

The MMC Control register establishes the operating mode of the management counters.
 Note: The bit 0 (Counters Reset) has higher priority than bit 4 (Counter Preset). Therefore, when the Software tries to set both bits in the same write cycle, all counters are cleared and the bit 4 is not set.

ETH0_MMC_CONTROL

MMC Control Register (100_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------|------|------|---|
| CNTRST | 0 | rw | Counters Reset When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle. |
| CNTSTOPRO | 1 | rw | Counters Stop Rollover When this bit is set, after reaching maximum value, the counter does not roll over to zero. |
| RSTONRD | 2 | rw | Reset on Read When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read. |
| CNTFREEZ | 3 | rw | MMC Counter Freeze When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. |

| Field | Bits | Type | Description |
|----------------------|--------|------|---|
| CNTPRST | 4 | rw | Counters Preset When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. |
| CNTPRST LVL | 5 | rw | Full-Half Preset When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 7FFF F800H (half - 2KBytes) and all frame-counters gets preset to 7FFF FFF0H (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to FFFF F800H (full - 2KBytes) and all frame-counters gets preset to FFFF FFF0H (full - 16). For 16-bit counters, the almost-half preset values are 7800H and 7FF0H for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are F800H and FFF0H. |
| Reserved_7_6 | [7:6] | r | Reserved |
| UCDBC | 8 | rw | Update MMC Counters for Dropped Broadcast Frames When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of MAC_Filter.DBF bit. When reset, MMC Counters are not updated for dropped Broadcast frames. |
| Reserved_31_9 | [31:9] | r | Reserved |

MMC_RECEIVE_INTERRUPT

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (8000 0000H for 32-bit counter and 8000H for 16-bit counter). * Receive statistic counters cross their maximum values (FFFF FFFFH for 32-bit counter and FFFFH for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

ETH0_MMC_RECEIVE_INTERRUPT

MMC Receive Interrupt Register

MMC_TRANSMIT_INTERRUPT

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (8000 0000H for 32-bit counter and 8000H for 16-bit counter), and the maximum values (FFFF FFFFH for 32-bit counter and FFFFH for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

| Field | Bits | Type | Description |
|---------|--------|------|--|
| TXOCTGB | [31:0] | r | This field indicates the number of bytes transmitted in good and bad frames exclusive of preamble and retried bytes. |

TX_FRAME_COUNT_GOOD_BAD

This register maintains the number of good and bad frames transmitted, exclusive of retried frames.

ETH0_TX_FRAME_COUNT_GOOD_BAD

Transmit Frame Count for Good and Bad Frames Register (118_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------|--------|------|---|
| TXFRMGB | [31:0] | r | This field indicates the number of good and bad frames transmitted, exclusive of retried frames |

TX_BROADCAST_FRAMES_GOOD

This register maintains the number of transmitted good broadcast frames.

ETH0_TX_BROADCAST_FRAMES_GOOD

Transmit Frame Count for Good Broadcast Frames (11C_H)

Reset Value: 0000

0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| TXBCASTG | [31:0] | r | This field indicates the number of transmitted good broadcast frames. |

TX_MULTICAST_FRAMES_GOOD

This register maintains the number of transmitted good multicast frames.

ETH0_TX_MULTICAST_FRAMES_GOOD

Transmit Frame Count for Good Multicast Frames (120_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| TXMCASTG | [31:0] | r | This field indicates the number of transmitted good multicast frames. |

TX_64OCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames.

ETH0_TX_64OCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 64 Byte Frames (124_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| TX64OCTGB | [31:0] | r | This field indicates the number of transmitted good and bad frames with length of 64 bytes, exclusive of preamble and retried frames. |

TX_65TO127OCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames.

ETH0_TX_65TO127OCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 65 to 127 Bytes Frames (128_H)Reset

Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| TX65_127 OCTGB | [31:0] | r | This field indicates the number of transmitted good and bad frames with length between 65 and 127 (inclusive) bytes, exclusive of preamble and retried frames. |

TX_128TO255OCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames.

ETH0_TX_128TO255OCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 128 to 255 Bytes Frames (12C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------------|--------|------|---|
| TX128_255OCTGB | [31:0] | r | This field indicates the number of transmitted good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble and retried frames. |

TX_256TO511OCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames.

ETH0_TX_256TO511OCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 256 to 511 Bytes Frames(130_H) Reset
Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------|--------|------|---|
| TX256_511OCTGB | [31:0] | r | This field indicates the number of transmitted good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble and retried frames. |

TX_512TO1023OCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames.

ETH0_TX_512TO1023OCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 512 to 1023 Bytes Frames(134_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|---|
| TX512_1023OCTGB | [31:0] | r | This field indicates the number of transmitted good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble and retried frames. |

TX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames.

ETH0_TX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

Transmit Octet Count for Good and Bad 1024 to Maxsize Bytes Frames(138_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------------|--------|------|---|
| TX1024_M AXOCTGB | [31:0] | r | This field indicates the number of good and bad frames transmitted with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames. |

TX_UNICAST_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad unicast frames.

ETH0_TX_UNICAST_FRAMES_GOOD_BAD

Transmit Frame Count for Good and Bad Unicast Frames (13C_H) **Reset Value:**
0000 0000_H

| Field | Bits | Type | Description |
|-------------------|--------|------|--|
| TXUCASGTGB | [31:0] | r | This field indicates the number of transmitted good and bad unicast frames. |

TX_MULTICAST_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad multicast frames.

ETH0_TX_MULTICAST_FRAMES_GOOD_BAD

Transmit Frame Count for Good and Bad Multicast Frames(140_H) **Reset Value:**
0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|--|
| TXMCASTGB | [31:0] | r | This field indicates the number of transmitted good and bad multicast frames. |

TX_BROADCAST_FRAMES_GOOD_BAD

This register maintains the number of transmitted good and bad broadcast frames.

ETH0_TX_BROADCAST_FRAMES_GOOD_BAD

Transmit Frame Count for Good and Bad Broadcast Frames(144_H) **Reset Value:**
0000 0000_H

| Field | Bits | Type | Description |
|-------------------|--------|------|--|
| TXBCAST GB | [31:0] | r | This field indicates the number of transmitted good and bad broadcast frames. |

TX_UNDERFLOW_ERROR_FRAMES

This register maintains the number of frames aborted because of frame underflow error.

ETH0_TX_UNDERFLOW_ERROR_FRAMES

Transmit Frame Count for Underflow Error Frames (148_H) Reset Value: 0000

0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| TXUNDRFLW | [31:0] | r | This field indicates the number of frames aborted because of frame underflow error. |

TX_SINGLE_COLLISION_GOOD_FRAMES

This register maintains the number of successfully transmitted frames after a single collision in the half-duplex mode.

ETH0_TX_SINGLE_COLLISION_GOOD_FRAMES

Transmit Frame Count for Frames Transmitted after Single Collision(14C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------------|--------|------|---|
| TXSNGLCOLG | [31:0] | r | This field indicates the number of successfully transmitted frames after a single collision in the half-duplex mode. |

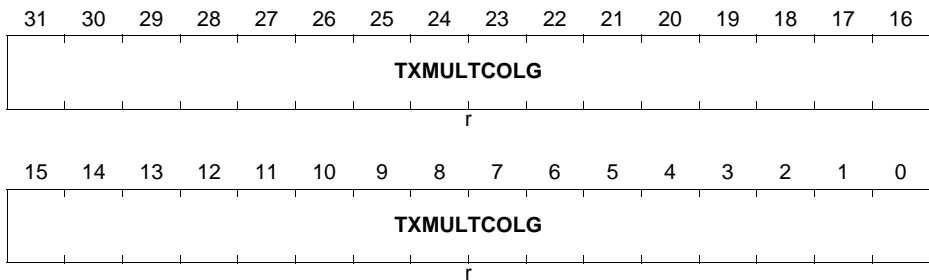

TX_MULTIPLE_COLLISION_GOOD_FRAMES

This register maintains the number of successfully transmitted frames after multiple collisions in the half-duplex mode.

ETH0_TX_MULTIPLE_COLLISION_GOOD_FRAMES

Transmit Frame Count for Frames Transmitted after Multiple Collision(150_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|---|
| TXMULTCOLG | [31:0] | r | This field indicates the number of successfully transmitted frames after multiple collisions in the half-duplex mode. |

TX_DEFERRED_FRAMES

This register maintains the number of successfully transmitted frames after a deferral in the half-duplex mode.

ETH0_TX_DEFERRED_FRAMES

Tx Deferred Frames Register (154_H) **Reset Value: 0000 0000_H**

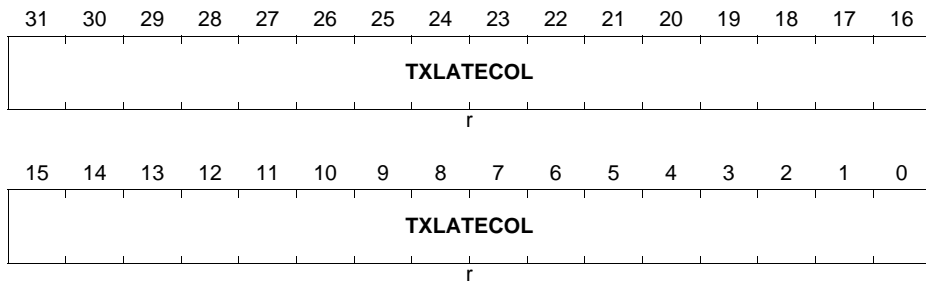

| Field | Bits | Type | Description |
|---------|--------|------|--|
| TXDEFRD | [31:0] | r | This field indicates the number of successfully transmitted frames after a deferral in the half-duplex mode. |

TX_LATE_COLLISION_FRAMES

This register maintains the number of frames aborted because of late collision error.

ETH0_TX_LATE_COLLISION_FRAMES

Transmit Frame Count for Late Collision Error Frames(158_H) Reset Value: 0000 0000_H

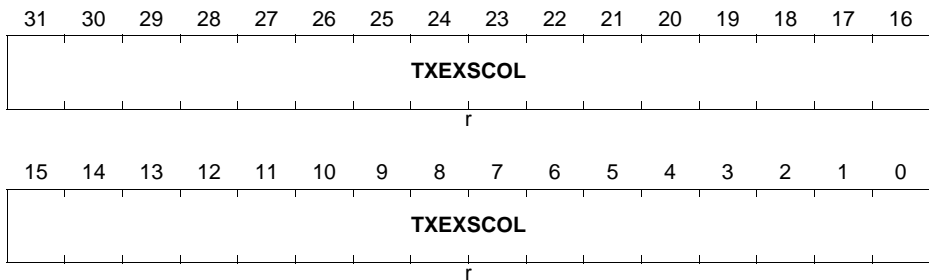

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| TXLATECOL | [31:0] | r | This field indicates the number of frames aborted because of late collision error. |

TX_EXCESSIVE_COLLISION_FRAMES

This register maintains the number of frames aborted because of excessive (16) collision error.

ETH0_TX_EXCESSIVE_COLLISION_FRAMES

Transmit Frame Count for Excessive Collision Error Frames(15C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| TXEXSCOL | [31:0] | r | This field indicates the number of frames aborted because of excessive (16) collision error. |

TX_CARRIER_ERROR_FRAMES

This register maintains the number of frames aborted because of carrier sense error (no carrier or loss of carrier).

ETH0_TX_CARRIER_ERROR_FRAMES

Transmit Frame Count for Carrier Sense Error Frames(160_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------|--------|------|---|
| TXCARR | [31:0] | r | This field indicates the number of frames aborted because of carrier sense error (no carrier or loss of carrier). |

TX_OCTET_COUNT_GOOD

This register maintains the number of bytes transmitted, exclusive of preamble, in good frames.

ETH0_TX_OCTET_COUNT_GOOD

Tx Octet Count Good Register (164_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------|--------|------|--|
| TXOCTG | [31:0] | r | This field indicates the number of bytes transmitted, exclusive of preamble, in good frames. |

TX_FRAME_COUNT_GOOD

This register maintains the number of transmitted good frames, exclusive of preamble.

ETH0_TX_FRAME_COUNT_GOOD

Tx Frame Count Good Register (168_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------|--------|------|--|
| TXFRMG | [31:0] | r | This field indicates the number of transmitted good frames, exclusive of preamble. |

TX_EXCESSIVE_DEFERRAL_ERROR

This register maintains the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times.

ETH0_TX_EXCESSIVE_DEFERRAL_ERROR

Transmit Frame Count for Excessive Deferral Error Frames(16C_H) **Reset Value:**
0000 0000_H

| Field | Bits | Type | Description |
|----------|--------|------|--|
| TXEXSDEF | [31:0] | r | This field indicates the number of frames aborted because of excessive deferral error, that is, frames deferred for more than two max-sized frame times. |

TX_PAUSE_FRAMES

This register maintains the number of transmitted good PAUSE frames.

ETH0_TX_PAUSE_FRAMES

Transmit Frame Count for Good PAUSE Frames(170_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------|--------|------|---|
| TXPAUSE | [31:0] | r | This field indicates the number of transmitted good PAUSE frames. |

TX_VLAN_FRAMES_GOOD

This register maintains the number of transmitted good VLAN frames, exclusive of retried frames.

ETH0_TX_VLAN_FRAMES_GOOD

Transmit Frame Count for Good VLAN Frames(174_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------------|--------|------|---|
| TXVLANG | [31:0] | r | This register maintains the number of transmitted good VLAN frames, exclusive of retried frames. |

TX_OSIZE_FRAMES_GOOD

This register maintains the number of transmitted good Oversize frames, exclusive of retried frames.

ETH0_TX_OSIZE_FRAMES_GOOD

Transmit Frame Count for Good Oversize Frames(178_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------|--------|------|--|
| TXOSIZG | [31:0] | r | This field indicates the number of frames transmitted without errors and with length greater than the maxsize (1,518 or 1,522 bytes for VLAN tagged frames; 2000 bytes if enabled by setting MAC Configuration.TWOKP). |

RX_FRAMES_COUNT_GOOD_BAD

This register maintains the number of received good and bad frames.

ETH0_RX_FRAMES_COUNT_GOOD_BAD

Receive Frame Count for Good and Bad Frames(180_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------|--------|------|--|
| RXFRMGB | [31:0] | r | This field indicates the number of received good and bad frames. |

RX_OCTET_COUNT_GOOD_BAD

This register maintains the number of bytes received, exclusive of preamble, in good and bad frames.

ETH0_RX_OCTET_COUNT_GOOD_BAD

Receive Octet Count for Good and Bad Frames(184_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------|--------|------|---|
| RXOCTGB | [31:0] | r | This field indicates the number of bytes received, exclusive of preamble, in good and bad frames. |

RX_OCTET_COUNT_GOOD

This register maintains the number of bytes received, exclusive of preamble, only in good frames.

ETH0_RX_OCTET_COUNT_GOOD

Rx Octet Count Good Register

(188_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| RXOCTG | [31:0] | r | This field indicates the number of bytes received, exclusive of preamble, only in good frames. |

RX_BROADCAST_FRAMES_GOOD

This register maintains the number of received good broadcast frames.

ETH0_RX_BROADCAST_FRAMES_GOOD

Receive Frame Count for Good Broadcast Frames(18C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|--|
| RXBCASTG | [31:0] | r | This field indicates the number of received good broadcast frames. |

RX_MULTICAST_FRAMES_GOOD

This register maintains the number of received good multicast frames.

ETH0_RX_MULTICAST_FRAMES_GOOD

Receive Frame Count for Good Multicast Frames(190_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------|--------|------|--|
| RXMCASTG | [31:0] | r | This field indicates the number of received good multicast frames. |

RX_CRC_ERROR_FRAMES

This register maintains the number of frames received with CRC error.

ETH0_RX_CRC_ERROR_FRAMES

Receive Frame Count for CRC Error Frames(194_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|--------|------|--|
| RXCRCERR | [31:0] | r | This field indicates the number of frames received with CRC error. |

RX_ALIGNMENT_ERROR_FRAMES

This register maintains the number of frames received with alignment (dribble) error.

ETH0_RX_ALIGNMENT_ERROR_FRAMES

Receive Frame Count for Alignment Error Frames(198_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| RXALGNERR | [31:0] | r | This field indicates the number of frames received with alignment (dribble) error. |

RX_RUNT_ERROR_FRAMES

This register maintains the number of frames received with runt error(<64 bytes and CRC error).

ETH0_RX_RUNT_ERROR_FRAMES

Receive Frame Count for Runt Error Frames(19C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RXRUNTE RR | [31:0] | r | This field indicates the number of frames received with runt error(<64 bytes and CRC error). |

RX_JABBER_ERROR_FRAMES

This register maintains the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames.

ETH0_RX_JABBER_ERROR_FRAMES

Receive Frame Count for Jabber Error Frames(1A0_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|--------|------|--|
| RXJABERR | [31:0] | r | This field indicates the number of giant frames received with length (including CRC) greater than 1,518 bytes (1,522 bytes for VLAN tagged) and with CRC error. If Jumbo Frame mode is enabled, then frames of length greater than 9,018 bytes (9,022 for VLAN tagged) are considered as giant frames. |

RX_UNDSIZE_FRAMES_GOOD

This register maintains the number of frames received with length less than 64 bytes and without errors.

ETH0_RX_UNDSIZE_FRAMES_GOOD

Receive Frame Count for Undersize Frames(1A4_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|---|
| RXUNDER SZG | [31:0] | r | This field indicates the number of frames received with length less than 64 bytes and without errors. |

RX_OVERSIZE_FRAMES_GOOD

This register maintains the number of frames received with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames) and without errors.

ETH0_RX_OVERSIZE_FRAMES_GOOD

Rx Oversize Frames Good Register (1A8_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| RXOVERSZG | [31:0] | r | This field indicates the number of frames received without errors, with length greater than the maxsize (1,518 or 1,522 for VLAN tagged frames; 2,000 bytes if enabled by setting MAC Configuration.TWOKPE). |

RX_64OCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames with length 64 bytes, exclusive of preamble.

ETH0_RX_64OCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 64 Byte Frames(1AC_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| RX64OCTGB | [31:0] | r | This field indicates the number of received good and bad frames with length 64 bytes, exclusive of preamble. |

RX_65TO127OCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble.

ETH0_RX_65TO127OCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 65 to 127 Bytes Frames(1B0_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RX65_127 OCTGB | [31:0] | r | This field indicates the number of received good and bad frames received with length between 65 and 127 (inclusive) bytes, exclusive of preamble. |

RX_128TO255OCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble.

ETH0_RX_128TO255OCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 128 to 255 Bytes Frames(1B4_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RX128_255OCTGB | [31:0] | r | This field indicates the number of received good and bad frames with length between 128 and 255 (inclusive) bytes, exclusive of preamble. |

RX_256TO511OCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble.

ETH0_RX_256TO511OCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 256 to 511 Bytes Frames(1B8_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RX256_511OCTGB | [31:0] | r | This field indicates the number of received good and bad frames with length between 256 and 511 (inclusive) bytes, exclusive of preamble. |

RX_512TO1023OCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble.

ETH0_RX_512TO1023OCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 512 to 1,023 Bytes Frames(1BC_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|---|
| RX512_1023OCTGB | [31:0] | r | This field indicates the number of received good and bad frames with length between 512 and 1,023 (inclusive) bytes, exclusive of preamble. |

RX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

This register maintains the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble.

ETH0_RX_1024TOMAXOCTETS_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad 1,024 to Maxsize Bytes Frames(1C0_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------------|--------|------|--|
| RX1024_M AXOCTGB | [31:0] | r | This field indicates the number of received good and bad frames with length between 1,024 and maxsize (inclusive) bytes, exclusive of preamble and retried frames. |

RX_UNICAST_FRAMES_GOOD

This register maintains the number of received good unicast frames.

ETH0_RX_UNICAST_FRAMES_GOOD

Receive Frame Count for Good Unicast Frames(1C4_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------|--------|------|--|
| RXUCASTG | [31:0] | r | This field indicates the number of received good unicast frames. |

RX_LENGTH_ERROR_FRAMES

This register maintains the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field.

ETH0_RX_LENGTH_ERROR_FRAMES

Receive Frame Count for Length Error Frames(1C8_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------------------|--------|------|--|
| RXLENER R | [31:0] | r | This field indicates the number of frames received with length error (Length type field not equal to frame size) for all frames with valid length field. |

RX_OUT_OF_RANGE_TYPE_FRAMES

This register maintains the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536).

ETH0_RX_OUT_OF_RANGE_TYPE_FRAMES

Receive Frame Count for Out of Range Frames(1CC_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|--|
| RXOUTOFRNG | [31:0] | r | This field indicates the number of received frames with length field not equal to the valid frame size (greater than 1,500 but less than 1,536). |

RX_PAUSE_FRAMES

This register maintains the number of received good and valid PAUSE frames.

ETH0_RX_PAUSE_FRAMES

Receive Frame Count for PAUSE Frames(1D0_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------------|--------|------|---|
| RXPAUSE FRM | [31:0] | r | This field indicates the number of received good and valid PAUSE frames. |

RX_FIFO_OVERFLOW_FRAMES

This register maintains the number of received frames missed because of FIFO overflow.

ETH0_RX_FIFO_OVERFLOW_FRAMES

Receive Frame Count for FIFO Overflow Frames(1D4_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|---|
| RXFIFOOVFL | [31:0] | r | This field indicates the number of received frames missed because of FIFO overflow. |

RX_VLAN_FRAMES_GOOD_BAD

This register maintains the number of received good and bad VLAN frames.

ETH0_RX_VLAN_FRAMES_GOOD_BAD

Receive Frame Count for Good and Bad VLAN Frames(1D8_H) **Reset Value: 0000**
0000_H

| Field | Bits | Type | Description |
|------------|--------|------|---|
| RXVLANFRGB | [31:0] | r | This field indicates the number of received good and bad VLAN frames. |

RX_WATCHDOG_ERROR_FRAMES

This register maintains the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load).

ETH0_RX_WATCHDOG_ERROR_FRAMES

Receive Frame Count for Watchdog Error Frames(1DC_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| RXWDGERR | [31:0] | r | This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load). |

RX_RECEIVE_ERROR_FRAMES

This register maintains the number of frames received with error because of the MII RXER error.

ETH0_RX_RECEIVE_ERROR_FRAMES

Receive Frame Count for Receive Error Frames(1E0_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------|--------|------|--|
| RXRCVERR | [31:0] | r | This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load). |

RX_CONTROL_FRAMES_GOOD

This register maintains the number of good control frames received.

ETH0_RX_CONTROL_FRAMES_GOOD

Receive Frame Count for Good Control Frames (1E4_H) Reset Value: 0000
0000_H

| Field | Bits | Type | Description |
|----------------|--------|------|--|
| RXCTRLG | [31:0] | r | This field indicates the number of frames received with error because of the watchdog timeout error (frames with more than 2,048 bytes data load). |

MMC_IPC_RECEIVE_INTERRUPT_MASK

This register maintains the mask for the interrupt generated from the receive IPC statistic counters. This register is 32-bits wide.

ETH0_MMC_IPC_RECEIVE_INTERRUPT_MASK

MMC Receive Checksum Offload Interrupt Mask Register(200_H) Reset Value: 0000 0000_H

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

RXIPV4_GOOD_FRAMES

This register maintains the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload.

ETH0_RXIPV4_GOOD_FRAMES

RxIPv4 Good Frames Register (210_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------|--------|------|---|
| RXIPV4GDFRM | [31:0] | r | This field indicates the number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload. |

RXIPV4_HEADER_ERROR_FRAMES

This register maintains the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch).

ETH0_RXIPV4_HEADER_ERROR_FRAMES

Receive IPV4 Header Error Frame Counter Register(214_H)Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|--|
| RXIPV4HDRERRFRM | [31:0] | r | This field indicates the number of IPv4 datagrams received with header errors (checksum, length, or version mismatch). |

RXIPV4_NO_PAYLOAD_FRAMES

This register maintains the number of received IPv4 datagram frames without a TCP, UDP, or ICMP payload processed by the Checksum engine.

ETH0_RXIPV4_NO_PAYLOAD_FRAMES

Receive IPV4 No Payload Frame Counter Register(218_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------------|--------|------|--|
| RXIPV4NO PAYFRM | [31:0] | r | This field indicates the number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine. |

RXIPV4_FRAGMENTED_FRAMES

This register maintains the number of good IPv4 datagrams received with fragmentation.

ETH0_RXIPV4_FRAGMENTED_FRAMES

Receive IPV4 Fragmented Frame Counter Register(21C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------|--------|------|---|
| RXIPV4FRAGFRM | [31:0] | r | This field indicates the number of good IPv4 datagrams received with fragmentation. |

RXIPV4_UDP_CHECKSUM_DISABLED_FRAMES

This register maintains the number of received good IPv4 datagrams which have the UDP payload with checksum disabled.

ETH0_RXIPV4_UDP_CHECKSUM_DISABLED_FRAMES

Receive IPV4 UDP Checksum Disabled Frame Counter Register(220_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RXIPV4UDSBLFRM | [31:0] | r | This field indicates the number of received good IPv4 datagrams which have the UDP payload with checksum disabled. |

RXIPV6_GOOD_FRAMES

This register maintains the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads.

ETH0_RXIPV6_GOOD_FRAMES

RxIPv6 Good Frames Register (224_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------|--------|------|--|
| RXIPV6GDFRM | [31:0] | r | This field indicates the number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads. |

RXIPV6_HEADER_ERROR_FRAMES

This register maintains the number of IPv6 datagrams received with header errors (length or version mismatch).

ETH0_RXIPV6_HEADER_ERROR_FRAMES

Receive IPV6 Header Error Frame Counter Register(228_H)Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|---|
| RXIPV6HDRERRFRM | [31:0] | r | This field indicates the number of IPv6 datagrams received with header errors (length or version mismatch). |

RXIPV6_NO_PAYLOAD_FRAMES

This register maintains the number of received IPv6 datagram frames without a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers.

ETH0_RXIPV6_NO_PAYLOAD_FRAMES

Receive IPV6 No Payload Frame Counter Register(22C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------------|--------|------|--|
| RXIPV6NO PAYFRM | [31:0] | r | This field indicates the number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers. |

RXUDP_GOOD_FRAMES

This register maintains the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented.

ETH0_RXUDP_GOOD_FRAMES

RxUDP Good Frames Register (230_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------------------|--------|------|--|
| RXUDPGDFRM | [31:0] | r | This field indicates the number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented. |

RXUDP_ERROR_FRAMES

This register maintains the number of good IP datagrams whose UDP payload has a checksum error.

ETH0_RXUDP_ERROR_FRAMES

RxUDP Error Frames Register (234_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------|--------|------|--|
| RXUDPER RFRM | [31:0] | r | This field indicates the number of good IP datagrams whose UDP payload has a checksum error. |

RXTCP_GOOD_FRAMES

This register maintains the number of good IP datagrams with a good TCP payload.

ETH0_RXTCP_GOOD_FRAMES

RxTCP Good Frames Register (238_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| RXTCPGD FRM | [31:0] | r | This field indicates the number of good IP datagrams with a good TCP payload. |

RXTCP_ERROR_FRAMES

This register maintains the number of good IP datagrams whose TCP payload has a checksum error.

ETH0_RXTCP_ERROR_FRAMES

RxTCP Error Frames Register (23C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| RXTCPERRFRM | [31:0] | r | This field indicates the number of good IP datagrams whose TCP payload has a checksum error. |

RXICMP_GOOD_FRAMES

This register maintains the number of good IP datagrams with a good ICMP payload.

ETH0_RXICMP_GOOD_FRAMES

RxICMP Good Frames Register (240_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------------------|--------|------|--|
| RXICMPG DFRM | [31:0] | r | This field indicates the number of good IP datagrams with a good ICMP payload. |

RXICMP_ERROR_FRAMES

This register maintains the number of good IP datagrams whose ICMP payload has a checksum error.

ETH0_RXICMP_ERROR_FRAMES

RxICMP Error Frames Register (244_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------------------|--------|------|---|
| RXICMPERRFRM | [31:0] | r | This field indicates the number of good IP datagrams whose ICMP payload has a checksum error. |

RXIPV4_GOOD_OCTETS

This register maintains the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data.

ETH0_RXIPV4_GOOD_OCTETS

RxIPv4 Good Octets Register (250_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------|--------|------|---|
| RXIPV4GDOCT | [31:0] | r | This field indicates the number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXIPV4_HEADER_ERROR_OCTETS

This register maintains the number of bytes received in IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of the IPv4 header is used to update this counter.

ETH0_RXIPV4_HEADER_ERROR_OCTETS

Receive IPV4 Header Error Octet Counter Register(254_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|--|
| RXIPV4HDRERROCT | [31:0] | r | <p>This field indicates the number of bytes received in the IPv4 datagrams with header errors (checksum, length, or version mismatch). The value in the Length field of IPv4 header is used to update this counter.</p> <p>The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.</p> |

RXIPV4_NO_PAYLOAD_OCTETS

This register maintains the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter.

ETH0_RXIPV4_NO_PAYLOAD_OCTETS

Receive IPV4 No Payload Octet Counter Register(258_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|----------------------------|--------|------|--|
| RXIPV4NO PAYOCT | [31:0] | r | This field indicates the number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXIPV4_FRAGMENTED_OCTETS

This register maintains the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter.

ETH0_RXIPV4_FRAGMENTED_OCTETS

Receive IPV4 Fragmented Octet Counter Register(25C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------|--------|------|--|
| RXIPV4FRAGOCT | [31:0] | r | This field indicates the number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS

This register maintains the number of bytes received in a UDP segment that had the UDP checksum disabled.

ETH0_RXIPV4_UDP_CHECKSUM_DISABLE_OCTETS

Receive IPV4 Fragmented Octet Counter Register(260_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------------|--------|------|--|
| RXIPV4UDSBLOCT | [31:0] | r | This field indicates the number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXIPV6_GOOD_OCTETS

This register maintains the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.

ETH0_RXIPV6_GOOD_OCTETS

RxIPv6 Good Octets Register (264_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------|--------|------|--|
| RXIPV6GDOCT | [31:0] | r | <p>This field indicates the number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data.</p> <p>This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.</p> |

RXIPV6_HEADER_ERROR_OCTETS

This register maintains the number of bytes received in IPv6 datagrams with header errors (length or version mismatch).

ETH0_RXIPV6_HEADER_ERROR_OCTETS

Receive IPV6 Header Error Octet Counter Register(268_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|--|
| RXIPV6HDRERROCT | [31:0] | r | <p>This field indicates the number of bytes received in IPv6 datagrams with header errors (length or version mismatch). The value in the IPv6 headers Length field is used to update this counter.</p> <p>This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.</p> |

RXIPV6_NO_PAYLOAD_OCTETS

This register maintains the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload.

ETH0_RXIPV6_NO_PAYLOAD_OCTETS

Receive IPV6 No Payload Octet Counter Register(26C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------------|--------|------|--|
| RXIPV6NO PAYOCT | [31:0] | r | <p>This field indicates the number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter.</p> <p>This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.</p> |

RXUDP_GOOD_OCTETS

This register maintains the number of bytes received in a good UDP segment.

ETH0_RXUDP_GOOD_OCTETS

Receive UDP Good Octets Register (270_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|--|
| RXUDPGDOCT | [31:0] | r | This field indicates the number of bytes received in a good UDP segment. This counter does not count IP header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXUDP_ERROR_OCTETS

This register maintains the number of bytes received in a UDP segment with checksum errors.

ETH0_RXUDP_ERROR_OCTETS

Receive UDP Error Octets Register (274_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| RXUDPERROCT | [31:0] | r | This field indicates the number of bytes received in a UDP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXTCP_GOOD_OCTETS

This register maintains the number of bytes received in a good TCP segment.

ETH0_RXTCP_GOOD_OCTETS

Receive TCP Good Octets Register (278_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| RXTCPGD OCT | [31:0] | r | This field indicates the number of bytes received in a good TCP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXTCP_ERROR_OCTETS

This register maintains the number of bytes received in a TCP segment with checksum errors.

ETH0_RXTCP_ERROR_OCTETS

Receive TCP Error Octets Register (27C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| RXTCPERROCT | [31:0] | r | This field indicates the number of bytes received in a TCP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXICMP_GOOD_OCTETS

This register maintains the number of bytes received in a good ICMP segment.

ETH0_RXICMP_GOOD_OCTETS

Receive ICMP Good Octets Register (280_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| RXICMPGDOCT | [31:0] | r | This field indicates the number of bytes received in a good ICMP segment. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter. |

RXICMP_ERROR_OCTETS

This register maintains the number of bytes received in a ICMP segment with checksum errors. This counter does not count the IP Header bytes. The Ethernet header, FCS, pad, or IP pad bytes are not included in this counter.

ETH0_RXICMP_ERROR_OCTETS

Receive ICMP Error Octets Register (284_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|--|
| RXICMPE RROCT | [31:0] | r | Number of bytes received in an ICMP segment with checksum errors |

TIMESTAMP_CONTROL

This register controls the operation of the System Time generator and the processing of PTP packets for timestamping in the Receiver.

ETH0_TIMESTAMP_CONTROL
Timestamp Control Register
(700_H)
Reset Value: 0000 2000_H

| | | | | | | | | | | | | | | | |

| rw | rw | rw | rw | rw | rw | rw | rw | r | | rw | rw | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-----------------|------|------|---|
| TSENA | 0 | rw | Timestamp Enable When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set. |
| TSCFUPDT | 1 | rw | Timestamp Fine or Coarse Update When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method. |
| TSINIT | 2 | rw | Timestamp Initialize When set, the system time is initialized (overwritten) with the value specified in the SYSTEM_TIME_SECONDS_UPDATE Register and SYSTEM_TIME_NANOSECONDS_UPDATE Register. This bit should be read zero before updating it. This bit is reset when the initialization is complete. |

| Field | Bits | Type | Description |
|---------------------|-------|------|--|
| TSUPDT | 3 | rw | Timestamp Update When set, the system time is updated (added or subtracted) with the value specified in System Time_Seconds_Update Register and SYSTEM_TIME_NANOSECONDS_UPDATE Register. This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. |
| TSTRIG | 4 | rw | Timestamp Interrupt Trigger Enable When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt. |
| TSADDRE G | 5 | rw | Addend Reg Update When set, the content of the TIMESTAMP_ADDEND register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it. |
| Reserved_7_6 | [7:6] | r | Reserved |
| TSENALL | 8 | rw | Enable Timestamp for All Frames When set, the timestamp snapshot is enabled for all frames received by the MAC. |
| TSCTRLS SR | 9 | rw | Timestamp Digital or Binary Rollover Control When set, the Timestamp Low register rolls over after 3B9A C9FFH value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 7FFF FFFFH. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit. |
| TSVER2E NA | 10 | rw | Enable PTP packet Processing for Version 2 Format When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format. |
| TSIPENA | 11 | rw | Enable Processing of PTP over Ethernet Frames When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets. |

| Field | Bits | Type | Description |
|--------------------------|---------|------|---|
| TSIPV6EN A | 12 | rw | Enable Processing of PTP Frames Sent Over IPv6-UDP When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets. |
| TSIPV4EN A | 13 | rw | Enable Processing of PTP Frames Sent over IPv4-UDP When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. |
| TSEVNTENA | 14 | rw | Enable Timestamp Snapshot for Event Messages When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling. |
| TSMSTRENA | 15 | rw | Enable Snapshot for Messages Relevant to Master When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. |
| SNAPTYPSEL | [17:16] | rw | Select PTP packets for Taking Snapshots These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken. |
| TSENMACH ADDR | 18 | rw | Enable MAC address for PTP Frame Filtering When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet. |
| Reserved_23_19 | [31:19] | r | Reserved |

SUB_SECOND_INCREMENT

In the Coarse Update mode (**TIMESTAMP_CONTROL.TSCFUPDT** bit), the value in this register is added to the system time every clock cycle of the PTP reference clock. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

ETH0_SUB_SECOND_INCREMENT

Sub-Second Increment Register (704_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| SSINC | [7:0] | rw | Sub-second Increment Value The value programmed in this field is accumulated every clock cycle of the PTP reference clock with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (14H) when the System Time-Nanoseconds register has an accuracy of 1 ns (TIMESTAMP_CONTROL.TSCTRLSSR bit is set). When Timestamp.Control.TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (2BH) that is derived by 20ns/0.465. |
| Reserved_31_8 | [31:8] | r | Reserved |

SYSTEM_TIME_SECONDS

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies .

ETH0_SYSTEM_TIME_SECONDS

System Time - Seconds Register (708_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TSS | [31:0] | r | Timestamp Second The value in this field indicates the current value in seconds of the System Time maintained by the MAC. |

SYSTEM_TIME_NANOSECONDS

The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When `TIMESTAMP_CONTROL.TSCTRLSSR` is set, each bit represents 1 ns and the maximum value is 3B9A C9FFH, after which it rolls-over to zero.

ETH0_SYSTEM_TIME_NANOSECONDS

System Time Nanoseconds Register (70C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| TSSS | [30:0] | r | Timestamp Sub Seconds The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When <code>TIMESTAMP_CONTROL.TSCTRLSSR</code> is set, each bit represents 1 ns and the maximum value is 3B9A C9FFH, after which it rolls-over to zero. |
| Reserved_31 | 31 | r | Reserved |

SYSTEM_TIME_SECONDS_UPDATE

The System Time - Seconds Update register, along with the System_Time_Nanoseconds_Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the TIMESTAMP_CONTROL.TSINIT or TIMESTAMP_CONTROL.TSUPDT bits.

ETH0_SYSTEM_TIME_SECONDS_UPDATE

System Time - Seconds Update Register(710_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TSS | [31:0] | rw | Timestamp Second The value in this field indicates the time in seconds to be initialized or added to the system time. |

SYSTEM_TIME_NANOSECONDS_UPDATE

The System Time - Seconds Update register, along with the System_Time_Nanoseconds_Update register, initializes or updates the system time maintained by the MAC. You must write both of these registers before setting the `TIMESTAMP_CONTROL.TSINIT` or `TIMESTAMP_CONTROL.TSUPDT` bits.

ETH0_SYSTEM_TIME_NANOSECONDS_UPDATE

System Time Nanoseconds Update Register(714_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| TSSS | [30:0] | rw | Timestamp Sub Second The value in this field has the sub second representation of time, with an accuracy of 0.46 ns. When <code>TIMESTAMP_CONTROL.TSCTRLSSR</code> is set, each bit represents 1 ns and the programmed value should not exceed 3B9A C9FFH. |
| ADDSUB | 31 | rw | Add or subtract time When this bit is set, the time value is subtracted with the contents of the update register. When this bit is reset, the time value is added with the contents of the update register. |

32-bit Register - TIMESTAMP_ADDEND

This register value is used only when the system time is configured for Fine Update mode using `TIMESTAMP_CONTROL.TSCFUPDT` bit. This register content is added to a 32-bit accumulator in every clock cycle of the PTP reference clock and the system time is updated whenever the accumulator overflows.

ETH0_TIMESTAMP_ADDEND

Timestamp Addend Register

(718_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TSAR | [31:0] | rw | Timestamp Addend Register This field indicates the 32-bit time value to be added to the Accumulator register to achieve time synchronization. |

TARGET_TIME_SECONDS

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event triggered by the TimestampStatus.TSTARGET bit when Advanced Timestamping is enabled; otherwise, the INTERRUPT_STATUS.TSIS will trigger the interrupt when the system time exceeds the value programmed in these registers.

ETH0_TARGET_TIME_SECONDS

Target Time Seconds Register (71C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TSTR | [31:0] | rw | Target Time Seconds Register This register stores the time in seconds. When the timestamp value matches or exceeds both Target Timestamp registers, then based on PPS_CONTROL.TRGTMODSEL0, the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). |

TARGET_TIME_NANOSECONDS

The Target Time Seconds register, along with Target Time Nanoseconds register, is used to schedule an interrupt event triggered by the TimestampStatus.TSTARGET bit when Advanced Timestamping is enabled; otherwise, the INTERRUPT_STATUS.TSIS will trigger the interrupt when the system time exceeds the value programmed in these registers.

ETH0_TARGET_TIME_NANOSECONDS

Target Time Nanoseconds Register (720_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TTSLO | [30:0] | rw | Target Timestamp Low Register This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the PPS_CONTROL.TPPSRGTMODSEL0 field , the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 3B9A C9FFH when TIMESTAMP_CONTROL.TSCTRLSSR is set . The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value. |

| Field | Bits | Type | Description |
|-----------------|------|------|--|
| TRGTBUSY | 31 | r | <p>Target Time Register Busy</p> <p>The MAC sets this bit when the PPS_CONTROL.PPSCMD field is programmed to 010B or 011B. Programming the PPSCMD field to 010B or 011B, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain. The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.</p> |

SYSTEM_TIME_HIGHER_WORD_SECONDS

This register contains the most significant 16-bits of the timestamp seconds value.

ETH0_SYSTEM_TIME_HIGHER_WORD_SECONDS

System Time - Higher Word Seconds Register (724_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------|---------|------|--|
| TSHWR | [15:0] | rw | Timestamp Higher Word Register This field contains the most significant 16-bits of the timestamp seconds value. The register is directly written to initialize the value. This register is incremented when there is an overflow from the 32-bits of the SYSTEM_TIME_SECONDS register. |
| Reserved_31_16 | [31:16] | r | Reserved |

TIMESTAMP_STATUS

This register contains the Timestamp status information. All bits except Bits[27:25] gets cleared when the CPU reads this register.

ETH0_TIMESTAMP_STATUS
Timestamp Status Register

| PR | | PBL | | | | ATD S | | DSL | | | | DA | | SWR | |
| rw | | rw | | | | rw | | rw | | | | rw | | rw | |

| Field | Bits | Type | Description |
|------------|------|------|--|
| SWR | 0 | rw | Software Reset When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the DWC_ETH clock domains. Before reprogramming any register of the DWC_ETH, you should read a zero (0) value in this bit . Note: * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion. |

| Field | Bits | Type | Description |
|-------------|-------|------|--|
| DA | 1 | rw | DMA Arbitration Scheme This bit specifies the arbitration scheme between the transmit and receive paths of Channel 0. * 0: Weighted round-robin with Rx:Tx or Tx:Rx. The priority between the paths is according to the priority specified in BUS_MODE.PR and priority weights specified in BUS_MODE.TXPR. * 1: Fixed priority. The transmit path has priority over receive path when BUS_MODE.TXPR is set. Otherwise, receive path has priority over the transmit path. |
| DSL | [6:2] | rw | Descriptor Skip Length This bit specifies the number of Words to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode. |
| ATDS | 7 | rw | Alternate Descriptor Size When set, the size of the alternate descriptor increases to 32 bytes. This is required when the Advanced Timestamp feature or Full IPC Offload Engine is enabled in the receiver. |

| Field | Bits | Type | Description |
|------------|---------|------|---|
| PBL | [13:8] | rw | <p>Programmable Burst Length</p> <p>These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When BUS_MODE.USP is set high, this BUS_MODE.PBL value is applicable only for Tx DMA transactions.</p> <p>If the number of beats to be transferred is more than 32, then perform the following steps:</p> <ol style="list-style-type: none"> 1. Set the PBLx8 mode. 2. Set the PBL. <p>For example, if the maximum number of beats to be transferred is 64, then first set PBLx8 to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.</p> <p>For different data bus widths and FIFO sizes, the valid PBL range (including x8 mode) is provided in the following list. If the PBL is common for both transmit and receive DMA, the minimum Rx FIFO and Tx FIFO depths must be considered.</p> <p>Note: In the half-duplex mode, the valid PBL range specified in the following list is applicable only for Tx FIFO.</p> |
| PR | [15:14] | rw | <p>Priority Ratio</p> <p>These bits control the priority ratio in the weighted round-robin arbitration between the Rx DMA and Tx DMA. These bits are valid only when Bit 1 (DA) is reset. The priority ratio is Rx:Tx or Tx:Rx depending on whether Bit 27 (TXPR) is reset or set.</p> <ul style="list-style-type: none"> * 00B: The Priority Ratio is 1:1. * 01B: The Priority Ratio is 2:1. * 10B: The Priority Ratio is 3:1. * 11B: The Priority Ratio is 4:1. |

| Field | Bits | Type | Description |
|--------------|---------|------|--|
| FB | 16 | rw | Fixed Burst This bit controls whether the Bus Master interface performs fixed burst transfers or not. When set, the AHB interface uses only SINGLE, INCR4, INCR8, or INCR16 during start of the normal burst transfers. When reset, the AHB interface uses SINGLE and INCR burst transfer operations. |
| RPBL | [22:17] | rw | Rx DMA PBL This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high. |
| USP | 23 | rw | Use Seperate PBL When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The BUS_MODE.PBL value is applicable only to the Tx DMA operations. When reset to low, the BUS_MODE.PBL value is applicable for both DMA engines. |
| PBLx8 | 24 | rw | PBLx8 Mode When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the BUS_MODE.PBL value. |
| AAL | 25 | rw | Address Aligned Beats When this bit is set high and the BUS_MODE.FB bit is equal to 1, the AHB interface generates all bursts aligned to the start address LS bits. If the BUS_MODE.FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. |

| Field | Bits | Type | Description |
|-----------------------|---------|------|---|
| MB | 26 | rw | Mixed Burst When this bit is set high and the BUS_MODE.FB bit is low, the Bus Master interface starts all bursts of length more than 16 with INCR (undefined burst) whereas it reverts to fixed burst transfers (INCRx and SINGLE) for burst length of 16 and less. |
| TXPR | 27 | rw | Transmit Priority When set, this bit indicates that the transmit DMA has higher priority than the receive DMA during arbitration for the system-side bus. |
| PRWG | [29:28] | r | Channel Priority Weights This field sets the priority weights for Channel 0 during the round-robin arbitration between the DMA channels for the system bus. * 00B: The priority weight is 1. * 01B: The priority weight is 2. * 10B: The priority weight is 3. * 11B: The priority weight is 4. |
| Reserved_31_30 | [31:30] | r | Reserved |

TRANSMIT_POLL_DEMAND

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from the XMC4[78]00 memory.

ETH0_TRANSMIT_POLL_DEMAND

Transmit Poll Demand Register (1004_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|---|
| TPD | [31:0] | rw | Transmit Poll Demand When these bits are written with any value, the DMA reads the current descriptor pointed to by the Current Host Transmit Descriptor Register. If that descriptor is not available (owned by the CPU), the transmission returns to the Suspend state and STATUS.TU is asserted. If the descriptor is available, the transmission resumes. |

RECEIVE_POLL_DEMAND

The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

ETH0_RECEIVE_POLL_DEMAND

Receive Poll Demand Register (1008_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-------|--------|------|--|
| RPD | [31:0] | rw | Receive Poll Demand When these bits are written with any value, the DMA reads the current descriptor pointed to by the Current Host Receive Descriptor Register. If that descriptor is not available (owned by the CPU), the reception returns to the Suspended state and STATUS.RU is not asserted. If the descriptor is available, the Rx DMA returns to the active state. |

RECEIVE_DESCRIPTOR_LIST_ADDRESS

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the XMC4[78]00's physical memory space and must be Word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in the Operation Mode Register. When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH0_RECEIVE_DESCRIPTOR_LIST_ADDRESS

Receive Descriptor Address Register (100C_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------------|--------|------|---|
| Reserved_1_0 | [1:0] | r | Reserved |
| RDESLA_32bit | [31:2] | rw | Start of Receive List This field contains the base address of the first descriptor in the Receive Descriptor list. The LSB bits (1:0) for 32-bit bus width are ignored and internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO). |

TRANSMIT_DESCRIPTOR_LIST_ADDRESS

The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the XMC4[78]00's physical memory space and must be Word-aligned. The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, OPERATION_MODE.ST is set to zero. When stopped, this register can be written with a new descriptor list address. When you set the OPERATION_MODE.ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

ETH0_TRANSMIT_DESCRIPTOR_LIST_ADDRESS
Transmit descriptor Address Register (1010_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| Reserved_1_0 | [1:0] | r | Reserved |
| TDESLA_32bit | [31:2] | rw | Start of Transmit List This field contains the base address of the first descriptor in the Transmit Descriptor list. The LSB bits (1:0) are ignored and are internally taken as all-zero by the DMA. Therefore, these LSB bits are read-only (RO). |

STATUS

The STATUS register contains all status bits that the DMA reports to the CPU. The Software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the CPU to be interrupted. The bits of this register are not cleared when read. Writing 1 to (unreserved) Bits[16:0] of this register clears these bits and writing 0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in the Interrupt Enable Register.

ETH0_STATUS

Status Register

(1014_H)

Reset Value: 0000 0000_H

| rw | rw | rw | r | | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw | rw |

| Field | Bits | Type | Description |
|-------|------|------|---|
| TI | 0 | rw | Transmit Interrupt This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor. |
| TPS | 1 | rw | Transmit Process Stopped This bit is set when the transmission is stopped. |
| TU | 2 | rw | Transmit Buffer Unavailable This bit indicates that the CPU owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. The TS bit field explains the Transmit Process state transitions. To resume processing Transmit descriptors, the CPU should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command. |

| Field | Bits | Type | Description |
|------------|------|------|--|
| TJT | 3 | rw | Transmit Jabber Timeout This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled). When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert. |
| OVF | 4 | rw | Receive Overflow This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11]. |
| UNF | 5 | rw | Transmit Underflow This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set. |
| RI | 6 | rw | Receive Interrupt This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state. |
| RU | 7 | rw | Receive Buffer Unavailable This bit indicates that the CPU owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the CPU should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA. |
| RPS | 8 | rw | Receive Process Stopped This bit is asserted when the Receive Process enters the Stopped state. |

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| RWT | 9 | rw | Receive Watchdog Timeout This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled). |
| ETI | 10 | rw | Early Transmit Interrupt This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO. |
| Reserved_12_11 | [12:11] | r | Reserved |
| FBI | 13 | rw | Fatal Bus Error Interrupt This bit indicates that a bus error occurred, as described in the EB bit field. When this bit is set, the corresponding DMA engine disables all of its bus accesses. |
| ERI | 14 | rw | Early Receive Interrupt This bit indicates that the DMA had filled the first data buffer of the packet. STATUS.RI automatically clears this bit. |
| AIS | 15 | rw | Abnormal Interrupt Summary Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Interrupt Enable Register: * STATUS.TPS: Transmit Process Stopped * STATUS.TJT: Transmit Jabber Timeout * STATUS.OVF : Receive FIFO Overflow * STATUS.UNF: Transmit Underflow * STATUS.RU: Receive Buffer Unavailable * STATUS.RPS: Receive Process Stopped * STATUS.RWT: Receive Watchdog Timeout * STATUS.ETI: Early Transmit Interrupt * STATUS.FBI: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared. |

| Field | Bits | Type | Description |
|------------|---------|------|--|
| NIS | 16 | rw | <p>Normal Interrupt Summary</p> <p>Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in the Interrupt Enable Register:</p> <ul style="list-style-type: none"> * STATUS.TI: Transmit Interrupt * STATUS.TU: Transmit Buffer Unavailable * STATUS.RI: Receive Interrupt * STATUS.ERI: Early Receive Interrupt <p>Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit.</p> <p>This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.</p> |
| RS | [19:17] | r | <p>Received Process State</p> <p>This field indicates the Receive DMA FSM state. This field does not generate an interrupt.</p> <ul style="list-style-type: none"> * 000B: Stopped: Reset or Stop Receive Command issued * 001B: Running: Fetching Receive Transfer Descriptor * 010B: Reserved for future use * 011B: Running: Waiting for receive packet * 100B: Suspended: Receive Descriptor Unavailable * 101B: Running: Closing Receive Descriptor * 110B: TIME_STAMP write state * 111B: Running: Transferring the receive packet data from receive buffer to the XMC4[78]00's memory |

| Field | Bits | Type | Description |
|--------------------|---------|------|---|
| TS | [22:20] | r | Transmit Process State This field indicates the Transmit DMA FSM state. This field does not generate an interrupt. * 000B: Stopped; Reset or Stop Transmit Command issued * 001B: Running; Fetching Transmit Transfer Descriptor * 010B: Running; Waiting for status * 011B: Running; Reading Data from the memory buffer and queuing it to transmit buffer (Tx FIFO) * 100B: TIME_STAMP write state * 101B: Reserved for future use * 110B: Suspended; Transmit Descriptor Unavailable or Transmit Buffer Underflow * 111B: Running; Closing Transmit Descriptor |
| EB | [25:23] | r | Error Bits This field indicates the type of error that caused a Bus Error, for example, error response on the AHB interface. This field is valid only when Bit 13 (FBI) is set. This field does not generate an interrupt. * Bit 23 - 1: Error during data transfer by the Tx DMA - 0: Error during data transfer by the Rx DMA * Bit 24 - 1: Error during read transfer - 0: Error during write transfer * Bit 25 - 1: Error during descriptor access - 0: Error during data buffer access |
| Reserved_26 | 26 | r | Reserved |
| EMI | 27 | r | ETH MMC Interrupt This bit reflects an interrupt event in the MMC module of the DWC_ETH. The software must read the corresponding registers in the DWC_ETH to get the exact cause of interrupt and clear the source of interrupt to make this bit as 0. The interrupt signal from the DWC_ETH subsystem is high when this bit is high. |

| Field | Bits | Type | Description |
|--------------------|------|------|---|
| EPI | 28 | r | ETH PMT Interrupt This bit indicates an interrupt event in the PMT module of the ETH. The software must read the PMT Control and STATUS Register in the MAC to get the exact cause of interrupt and clear its source to reset this bit to 0. The interrupt signal from the ETH subsystem is high when this bit is high. Note: This interrupt is different from the Power Management interrupt. |
| TTI | 29 | r | Timestamp Trigger Interrupt This bit indicates an interrupt event in the Timestamp Generator block of ETH. The software must read the corresponding registers in the ETH to get the exact cause of interrupt and clear its source to reset this bit to 0. When this bit is high, the interrupt signal from the ETH subsystem is high. |

| Field | Bits | Type | Description |
|-------|-------|------|--|
| SR | 1 | rw | <p>Start or Stop Receive</p> <p>When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Receive Descriptor List Address Register or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and STATUS.RU is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Receive Descriptor List Address Register, the DMA behavior is unpredictable.</p> <p>When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state.</p> |
| OSF | 2 | rw | <p>Operate on Second Frame</p> <p>When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained.</p> |
| RTC | [4:3] | rw | <p>Receive Threshold Control</p> <p>These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. The value of 11 is not applicable if the configured Receive FIFO size is 128 bytes. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1.</p> <ul style="list-style-type: none"> * 00B: 64 * 01B: 32 * 10B: 96 * 11B: 128 |

| Field | Bits | Type | Description |
|----------------------|--------|------|--|
| Reserved_5 | 5 | r | Reserved |
| FUF | 6 | rw | Forward Undersized Good Frames When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01B. |
| FEF | 7 | rw | Forward Error Frames When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, MII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. In the ETH-MTL configuration in which the Frame Length FIFO is also enabled during core configuration, the Rx FIFO drops the error frames if that frame's start byte is not transferred (output) on the ARI bus. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the RSF bit is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the RSF bit is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA. |
| Reserved_12_8 | [12:8] | r | Reserved |

| Field | Bits | Type | Description |
|-------|------|------|---|
| ST | 13 | rw | <p>Start or Stop Transmission Command</p> <p>When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 [Transmit Descriptor List Address Register], or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 [STATUS Register] is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 [Transmit Descriptor List Address Register], then the DMA behavior is unpredictable.</p> <p>When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 [Transmit Descriptor List Address Register] with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state.</p> |

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| TTC | [16:14] | rw | Transmit Threshold Control These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. * 000B: 64 * 001B: 128 * 010B: 192 * 011B: 256 * 100B: 40 * 101B: 32 * 110B: 24 * 111B: 16 |
| Reserved_19_17 | [19:17] | r | Reserved |
| FTF | 20 | rw | Flush Transmit FIFO When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the CPU. To complete this flush operation, the PHY transmit clock is required to be active. |
| TSF | 21 | rw | Transmit Store and Forward When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped. |
| Reserved_23_22 | [23:22] | r | Reserved |

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| DFF | 24 | rw | Disable Flushing of Received Frames When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. |
| RSF | 25 | rw | Receive Store and Forward When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits. |
| DT | 26 | rw | Disable Dropping of TCP/IP Checksum Error Frames When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. |
| Reserved_31_27 | [31:27] | r | Reserved |

INTERRUPT_ENABLE

The Interrupt Enable register enables the interrupts reported by **ETH0_STATUS** Register. Setting a bit to 1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

MISSSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the RAM buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

ETH0_MISSED_FRAME_AND_BUFFER_OVERFLOW_COUNTER

Missed Frame and Buffer Overflow Counter Register (1020_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|-----------------------|---------|------|--|
| MISFRMCNT | [15:0] | r | This field indicates the number of frames missed by the controller because of the RAM Receive Buffer being unavailable. This counter is incremented each time the DMA discards an incoming frame. The counter is cleared when this register is read. |
| MISCNTOVF | 16 | r | Overflow bit for Missed Frame Counter |
| OVFFRMCNT | [27:17] | r | This field indicates the number of frames missed by the application. The counter is cleared when this register is read. |
| OVFCNTOVF | 28 | r | Overflow bit for FIFO Overflow Counter |
| Reserved_31_29 | [31:29] | r | Reserved |

RECEIVE_INTERRUPT_WATCHDOG_TIMER

This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of STATUS Register]

ETH0_RECEIVE_INTERRUPT_WATCHDOG_TIMER
Receive Interrupt Watchdog Timer Register (1024_H)
Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| RIWT | [7:0] | rw | RI Watchdog Timer Count This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame. |
| Reserved_31_8 | [31:8] | r | Reserved |

AHB_Status

This register provides the active status of the AHB master interface. This register is useful for debugging purposes. In addition, this register is valid only in the Channel 0 DMA when multiple channels are present in the AV mode.

ETH0_AHB_Status

AHB Status Register (102C_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| AHBMS | 0 | r | AHB Master Status When high, it indicates that the AHB master interface FSMs are in the non-idle state. |
| Reserved_1 | 1 | r | Reserved |
| Reserved_31_2 | [31:2] | r | Reserved |

CURRENT_HOST_TRANSMIT_DESCRIPTOR

The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

ETH0_CURRENT_HOST_TRANSMIT_DESCRIPTOR

Current Host Transmit Descriptor Register (1048_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |

16 EtherCAT Slave Controller (ECAT)

The EtherCAT Slave Controller (ESC) takes care of the EtherCAT communication as an interface between the EtherCAT fieldbus and the slave application. This chapter describes the implementation of the ECAT module into the XMC4800 devices. More information about the EtherCAT working principle can be found under the referenced documents.

16.1 Overview

EtherCAT is an Ethernet-based fieldbus system, invented by Beckhoff Automation and is standardized in IEC 61158. Using standard Ethernet packets or frames (according to IEEE 802.3) the EtherCAT Slave Controller (ECAT) does not received, interpret, and copies the process data at every node. The the EtherCAT Slave Controller read the data addressed to them while the telegram passes through the device.

16.1.1 Features

The ECAT provides the following functionality:

- 2 MII Ports to connect Ethernet PHYs
- 8 FMMUs.
- 8 SyncManagers
- 8 Kbyte of Process Data Memory with Parity
- 64Bit Distributed Clocks

16.1.2 Block Diagram

The ECAT block diagram is shown in [Figure 16-1](#).

Figure 16-1 EtherCAT Slave Controller Block Diagram

16.1.3 EtherCAT Slave Controller Function Blocks

EtherCAT Processing Unit

The EtherCAT Processing Unit (EPU) receives, analyses and processes the EtherCAT data stream. It is logically located between port 0 and port 1. The main purpose of the EtherCAT Processing unit is to enable and coordinate access to the internal registers and the memory space of the ESC, which can be addressed both from the EtherCAT master and from the local application via the PDI. Data exchange between master and slave application is comparable to a dual-ported memory (process memory), enhanced by special functions e.g. for consistency checking (SyncManager) and data mapping (FMMU). The EtherCAT Processing Units contains the main function blocks of EtherCAT slaves besides Auto-Forwarding, Loop-back function, and PDI.

Memory

The EtherCAT Slave controller has an address space of up to 64 Kbyte. The first block of 4 Kbyte (0x0000 to 0x0FFF) is used for registers and user memory. The memory space from address 0x1000 onwards is used as the process memory. The XMC4800 supports 8 Kbyte of Process Data RAM. .

FMMU

Fieldbus Memory Management Units are used for bitwise mapping of logical addresses to physical addresses of the ESC.

SyncManager

SyncManagers are responsible for consistent data exchange and mailbox communication between EtherCAT master and slaves. The communication direction can be configured for each SyncManager. Read or write transactions may generate events for the EtherCAT master and an attached EtherCAT Slave respectively. The SyncManagers are responsible for the main difference between an ESC and a dual-ported memory, because they map addresses to different buffers and block accesses depending on the SyncManager state. This is also a fundamental reason for bandwidth restrictions of the PDI.

16.1.4 Further Reading on EtherCAT

For further information on EtherCAT, refer to the EtherCAT specification ETG.1000, available from the EtherCAT Technology Group (ETG, <http://www.ethercat.org>), and the IEC standard “Digital data communications for measurement and control – Fieldbus for use in industrial control systems”, IEC 61158 Type 12: EtherCAT, available from the IEC (<http://www.iec.ch>).

16.2 EtherCAT Protocol

EtherCAT uses standard IEEE 802.3 Ethernet frames, thus a standard network controller can be used and no special hardware is required on master side. EtherCAT has a reserved EtherType of 0x88A4 that distinguishes it from other Ethernet frames. Thus, EtherCAT can run in parallel to other Ethernet protocols. EtherCAT does not need the IP protocol, however it can be encapsulated in IP/UDP. The EtherCAT Slave Controller processes the frame in hardware. Thus, communication performance is independent from processor power. An EtherCAT frame is subdivided into the EtherCAT frame header followed by one or more EtherCAT datagrams. At least one EtherCAT datagram has to be in the frame. Only EtherCAT frames with Type 1 in the EtherCAT Header are currently processed by the ESCs. The ESCs also support IEEE802.1Q VLAN Tags, although the VLAN Tag contents are not evaluated by the ESC. If the minimum Ethernet frame size requirement is not fulfilled, padding bytes have to be added. Otherwise the EtherCAT frame is exactly as large as the sum of all EtherCAT datagrams plus EtherCAT frame header.

16.3 Ethernet Physical Layer

EtherCAT slave devices with Ethernet Physical Layer usually support MII interfaces, some do also support the RMII interface. Since RMII PHYs include TX FIFO's, they increase the packet forwarding delay of an EtherCAT slave device as well as the jitter.

EtherCAT Slave Controller (ECAT)

RMII as a Ethernet Physical Layer is not supported by the XMC4800 due to these reasons.

16.3.1 MII Interface

The following signals are used by the ECAT to connect a Ethernet PHY.

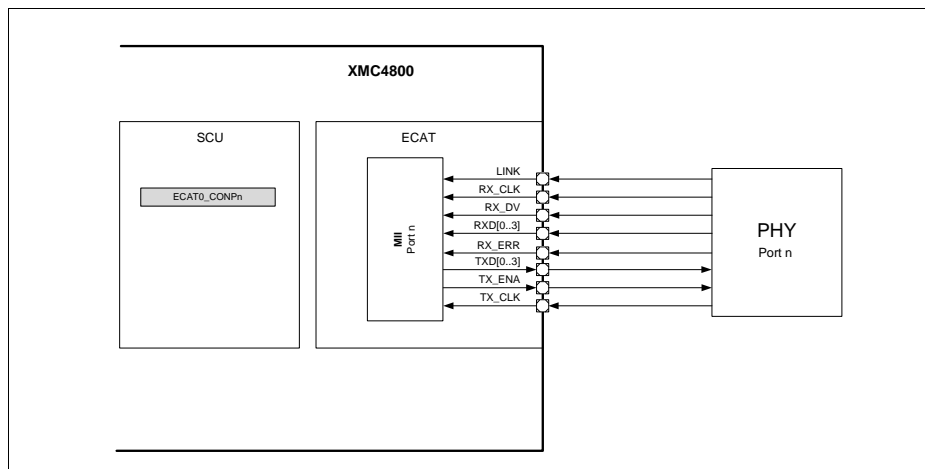

Figure 16-2 MII Interface Signals

The MII signals TX_ERR, COL and CRS are not used by the ESC. TX_CLK is used for automatic TX Shift compensation.

If an ESC MII interface is not used, input pins like LINK_MII has to be tied to the logic value high which indicates no link. RX_CLK, RXD, RX_ER, and especially RX_DV have to be tied to GND. For this purpose you can select a input position in register ECAT0_CONPx of these signals which are not connected to a pin on the XMC4800.

For more details about the MII interface, refer to IEEE Standard 802.3, available from the IEEE (<http://standards.ieee.org/getieee802>).

16.3.1.1 LINK_MII Signal

The LINK_MII signal used for link detection is typically an LED output signal of the Ethernet PHY. If available, LINK_MII should be connected to a combined signal indicating a 100 Mbit/s Full Duplex link. If such a signal is not available, a signal indicating a 100 Mbit/s link (speed LED) might be used. If only a Link signal is available (link LED), this might be used. Never use (combined) activity signals, e.g., Link/Act LED outputs, because the link state will toggle upon activity.

EtherCAT Slave Controller (ECAT)

The main advantage of using a dedicated link signal instead of reading out MII management interface registers is the fast reaction time in case of a link loss. This is crucial for redundancy operation, since only one lost frame is tolerated. The EtherCAT port of an ESC which loses a link has to be closed as fast as possible to maintain EtherCAT communication at the other ports and to reduce the number of lost frames.

The LINK_MII signal state is reflected in the register.

16.3.2 PHY Management Interface

Most EtherCAT slave controllers with MII/RMII/RGMII ports use the MII management interface for communication with the Ethernet PHYs. The MII management interface can be used as well by the EtherCAT master if supported by the ESC. Enhanced MII link detection uses the management interface for configuration and restarting auto negotiation after communication errors occurred (TX PHYs only). Some ESCs can make use of the MII management interface for link detection and PHY configuration. For fast link detection, the ESCs require to use a separate signal (LINK_MII).

16.3.2.1 PHY Management Interface Signals

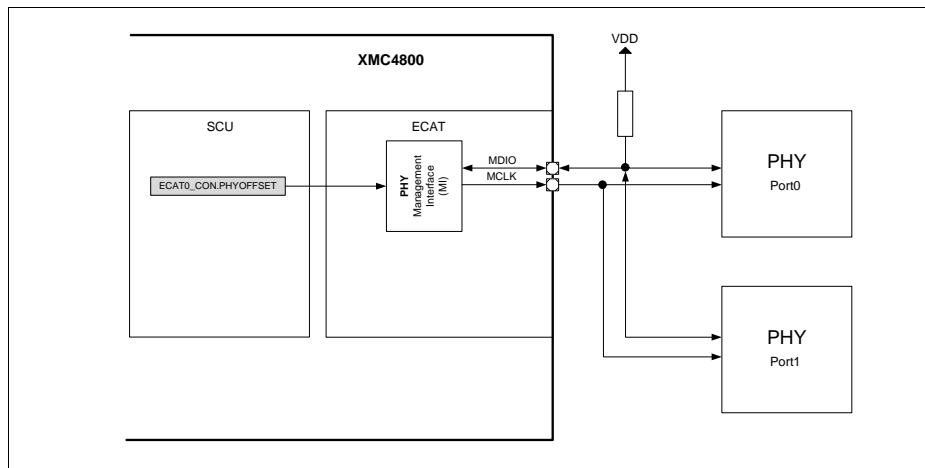

Figure 16-3 PHY management Interface Signals

MDIO must have a pull-up resistor (4.7 kOhm recommended) externally. MCLK is driven rail-to-rail, idle value is High.

16.3.2.2 PHY Address Configuration

The EtherCAT IP Core addresses Ethernet PHYs typically using logical port number plus PHY address offset. Ideally, the Ethernet PHY addresses should correspond with the logical port number, so PHY addresses 0 and 1 are used.

A PHY address offset of 0-31 can be applied which moves the PHY addresses to any consecutive address range. The ECAT module expects logical port 0 to have PHY address 0 plus PHY address offset. The PHY address offset can be selected in register ECAT0_CON.

16.3.2.3 PHY Reset Signal

The PHY reset signal is generated out of the ECAT module. It is required to release the both, PHY and ECAT module synchronous out of reset, this signal should be used. Since there are no pull devices active on the XMC4800 during and after reset, a pull down resistor must be added on this signal on board level.([Figure 16-10](#))

In some case PHYs may be released from reset after releasing the ECAT module. To generate a delay, the pin for nPHY_RESET can be used as an I/O and shall be switched later to the alternate output function.

16.3.2.4 PHY Clock

Both PHYs connected to the ECAT module and the ECAT itself must share the same clock source. This is achieved by providing the 25MHz clock signal which is used for the ECAT module on a output pin (PHY_CLK25) of the XMC4800.([Figure 16-10](#))

16.4 FMMU

Fieldbus Memory Management Units (FMMU) convert logical addresses into physical addresses by the means of internal address mapping. Thus, FMMUs allow to use logical addressing for data segments that span several slave devices: one datagram addresses data within several arbitrarily distributed ESCs. Each FMMU channel maps one continuous logical address space to one continuous physical address space of the slave. The FMMUs of Beckhoff ESCs support bit wise mapping, the number of supported FMMUs depends on the ESC. The access type supported by an FMMU is configured to be either read, write, or read/write.

16.5 SyncManager

The memory of an ESC can be used for exchanging data between the EtherCAT master and a local application (on a micro controller attached to the PDI) without any restrictions. Using the memory for communication like this has some draw-backs which are addressed by the SyncManagers inside the ESCs:

EtherCAT Slave Controller (ECAT)

Data consistency is not guaranteed. Semaphores have to be implemented in software for exchanging data in a coordinated way.

Data security is not guaranteed. Security mechanisms have to be implemented in software.

Both EtherCAT master and application have to poll the memory in order to get to know when the access of the other side has finished.

SyncManagers enable consistent and secure data exchange between the EtherCAT master and the local application, and they generate interrupts to inform both sides of changes.

SyncManagers are configured by the EtherCAT master. The communication direction is configure able, as well as the communication mode (Buffered Mode and Mailbox Mode). SyncManagers use a buffer located in the memory area for exchanging data. Access to this buffer is controlled by the hardware of the SyncManagers.

A buffer has to be accessed beginning with the start address, otherwise the access is denied. After accessing the start address, the whole buffer can be accessed, even the start address again, either as a whole or in several strokes. A buffer access finishes by accessing the end address, the buffer state changes afterwards and an interrupt or a watchdog trigger pulse is generated (if configured). The end address cannot be accessed twice inside a frame.

Two communication modes are supported by SyncManagers:

Buffered Mode

The buffered mode allows both sides, EtherCAT master and local application, to access the communication buffer at any time. The consumer gets always the latest consistent buffer which was written by the producer, and the producer can always update the content of the buffer. If the buffer is written faster than it is read out, old data will be dropped.

The buffered mode is typically used for cyclic process data.

Mailbox Mode

The mailbox mode implements a handshake mechanism for data exchange, so that no data will be lost. Each side, EtherCAT master or local application, will get access to the buffer only after the other side has finished its access. At first, the producer writes to the buffer. Then, the buffer is locked for writing until the consumer has read it out. Afterwards, the producer has write access again, while the buffer is locked for the consumer.

The mailbox mode is typically used for application layer protocols.

The SyncManagers accept buffer changes caused by the master only if the FCS of the frame is correct, thus, buffer changes take effect shortly after the end of the frame.

16.6 EtherCAT State Machine

The EtherCAT State machine (ESM) is responsible for the coordination of master and slave applications at start up and during operation. State changes are typically initiated by requests of the master. They are acknowledged by the local application after the associated operations have been executed. Unsolicited state changes of the local application are also possible.

There are four states an EtherCAT slave shall support, plus one optional state:

- Init (state after Reset)
- Pre-Operational
- Safe-Operational
- Operational
- Bootstrap (optional)

The states and the allowed state changes are shown in **Figure 16-4**.

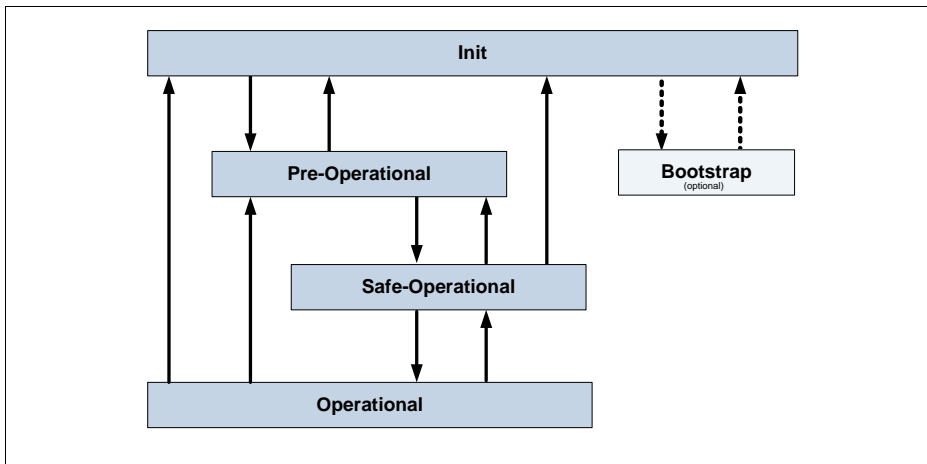

Figure 16-4 EtherCAT State Machine

Not all state changes are possible, e.g., the transition from Init to Operational requires the following sequence: Init -> Pre-Operational -> Safe-Operational -> Operational.

Each state defines required services. Before a state change is confirmed by the slave all services required for the requested state have to be provided or stopped respectively.

16.7 EtherCAT Slave Controller Address Space Overview

An EtherCAT Slave Controller has an maximum address space of 64KByte. The first block of 4KByte (0x0000 to 0x0FFF) is dedicated for registers. The Process Data RAM

EtherCAT Slave Controller (ECAT)

starts at address 0x1000. The size of the Process Data RAM is 8 Kbyte for the XMC4800.

Figure 16-5 EtherCAT Slave Controller Address Space Overview

16.8 ESI EEPROM

EtherCAT slave controllers use a mandatory NVRAM (typically a serial EEPROM with I²C interface) to store device configuration and device description.

The EtherCAT IP Core supports omitting the serial IIC EEPROM if a micro controller with a read/write access to an NVRAM (embedded Flash) can be used to emulate the EEPROM transactions. Since the logical interface is the same in this case, the EEPROM emulation is treated to be equivalent to the typical IIC EEPROM solution. XMC4800 uses EEPROM emulation.

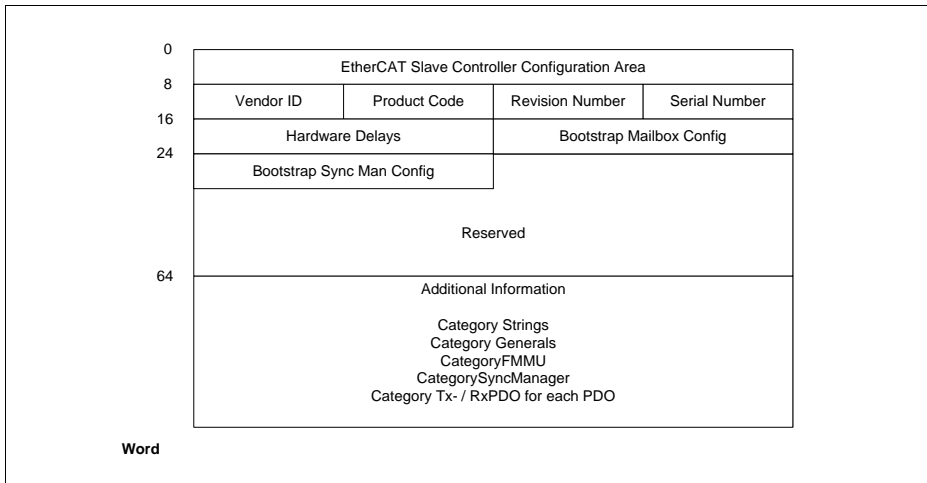

Figure 16-6 ESI EEPROM Layout

At least the information stored in the address range from word 0 to 63 (0x00 to 0x3F) is mandatory.

16.8.1 EEPROM Emulation

The EEPROM emulation mode is used in IP Core based ESCs with a non-volatile memory (NVRAM) attached or integrated to a micro controller. The ESC configuration and the device description can be stored in the Flash of the micro controller, e.g., together with the program or other configuration data. An additional external EEPROM chip for the system is not needed any more if EEPROM emulation is used.

The micro controller emulates the EEPROM interface actions of the ESC and executes all EEPROM reload, read, and write requests. EEPROM write data is stored in the Flash of the micro controller, and EEPROM read data is read from the Flash and presented to the EEPROM interface of the ESC.

From the EtherCAT master's point of view, EEPROM emulation mode is equivalent to an external connected IIC EEPROM. The master issues EEPROM commands and waits until the EEPROM interface is not busy anymore.

In EEPROM emulation mode, the EEPROM interface of the ESC issues an interrupt to the micro controller if an EEPROM command is pending and sets the busy bit. While the busy bit is set, the micro controller can read out the command and the EEPROM address. For a write access, write data is present in the data register. For a read command, read data has to be stored in the data register by the micro controller.

EtherCAT Slave Controller (ECAT)

A reload command requires the micro controller to place the Configured Station Alias and Enhanced Link detection settings in the data register.

Once the micro controller has finished reading/writing the EEPROM data register, it acknowledges the command by writing to the EEPROM command register bits. The micro controller has to write the command value it has executed into the EEPROM command register. Errors can be indicated using two of the error bits. After acknowledging the command, the EEPROM state machine is not busy anymore and the interrupt is released.

Table 16-2 EtherCAT EEPROM Configuration Area

| Word Address | Parameter | Description | Register |
|--------------|------------------------------|---|--|
| 0x0 | PDI Control | Initialization value for PDI Control register | PDI_CONTROL ¹⁾ , ESC_CONFIG |
| 0x1 | PDI Configuration | Initialization value for PDI Configuration register | PDI_CONFIG ²⁾ , SYNC_LATCH_CONFIG |
| 0x2 | Pulse Length of SYNC Signals | Initialization value for Pulse Length of SYNC Signals register | DC_PULSE_LEN |
| 0x3 | Extended PDI Configuration | Initialization value for extended PDI Configuration register, shall be set to all zero (0x0000) | PDI_EXT_CONFIG |
| 0x4 | Configured Station Alias | Initialization value for Configured Station Alias Address register | STATION_ALIAS |
| 0x5 | Reserved | Reserved, shall be zero | - |
| 0x6 | Reserved | Reserved, shall be zero | - |
| 0x7 | Checksum | Low byte contains remainder of division of word 0 to word 6 as unsigned number divided by the polynomial x^8+x^2+x+1 (initial value 0xFF). <i>Note: For debugging purposes it is possible to disable the checksum validation with a checksum value of 0x88A4. Never use this for production!</i> | - |

1) Register value for PDI_CONTROL must be set to 0x80. All other values are reserved and shall not be used.

2) Register value for PDI_CONFIG must be 0x81. All other values are reserved and shall not be used.

EtherCAT Slave Controller (ECAT)

Note: The EEPROM can be assigned to the PDI even if EEPROM Emulation is used. EEPROM_SIZE has to be 0 for EEPROM emulation (EEPROM emulation with EEPROM_SIZE=1 is for testing only: all commands are acknowledged automatically).

Note: Reserved words or reserved bits of the ESC Configuration Area should be filled with 0.

16.9 Sync/Latch Signals

ESCs with Distributed Clocks support generation of Sync-Signals and time stamping of Latch-Signals.

The SyncSignals can be used internally for:

- Interrupt generation (mapping to AL Event Request register 0x0220:0x0223 and PDI IRQ to the XMC4800 NVIC)
- PDI Digital Output Update events
- PDI Digital Input Latch events

The Latch Event unit supports time stamping of up to two Latch-Signals (LATCH edge separately), and time stamping of SyncManager events for debugging purposes.

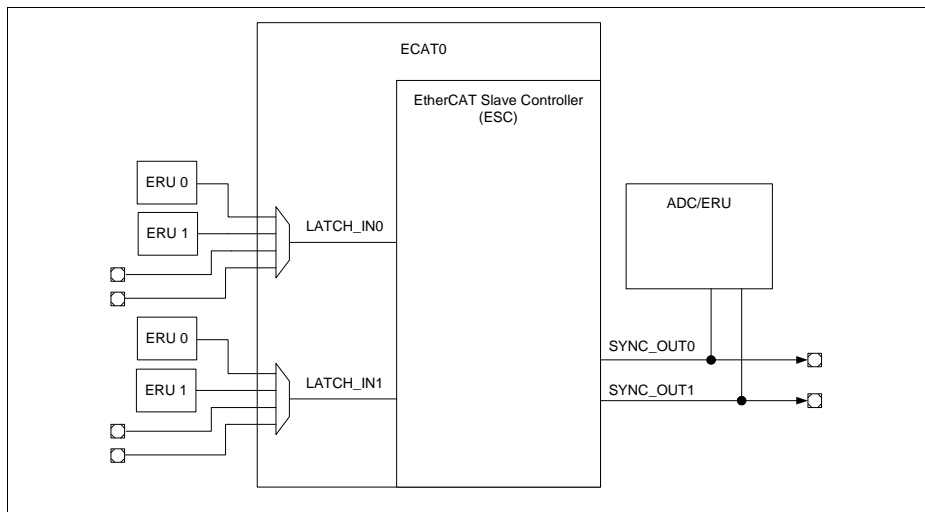

Figure 16-7 EtherCAT Slave Controller Sync/Latch Signals

Note: For LATCH signals derived from pins should not exceed $ECAT\ CLK100/2 = 50MHz$. Peripheral trigger signals derived from ERU1 need to be gated by the ERU to meet this requirements.

EtherCAT Slave Controller (ECAT)

Note: The length of SYNC pulses can be adjusted via EEPROM to meet the system requirements of a minimum plus length of $> f_{sys}/2$ (ERU) and $f_{ADC}/2$ (Peripherals 0 clock).

16.10 LED Signals (Indicators)

EtherCAT slave controllers support different LED's regarding link state and AL status. The XMC4800 support a LED_RUN, LED_ERR, LED_STAT_RUN and LED_LINK_ACT for each port.

16.10.1 RUN LED

The AL status is displayed with the RUN LED (green). The RUN output of an ESC is controlled by the AL status register [Page 16-47](#) and supports the following states, which are automatically translated into blink codes:

Table 16-3 RUN LED States

| ERR LED | Description |
|-------------------|--|
| OFF | The device is in state INIT |
| Blinking (slow) | The device is in state PRE-OPERATIONAL |
| Single Flash | The device is in state SAFE-OPERATIONAL |
| On | The device is in state OPERATIONAL |
| Flickering (fast) | The device is in state BOOTSTRAP or loading the EEPROM |

The XMC4800 support optional RUN LED outputs by overriding the state indication of the RUN LED. The output can be set by master or local application. This can be used e.g. for locating a specific slave by forcing the RUN LED to indicate a triple flash (Device Identification).

16.10.2 ERR LED

The ERR LED indicates local errors and application errors. Some errors are automatically indicated by the ECAT module, other error states are detected by the XMC4800, and indicated by writing to the ERR LED Override register [Page 16-50](#).

The following ERR LED states can be automatically generated by an ECAT, without interaction of the XMC4800.

Table 16-4 ERR LED States

| ERR LED | Description | Examples |
|-------------------|---|---|
| OFF | No Error | |
| Flickering (fast) | EEPROM loading error | not loaded (default after reset deassert of ECAT module) or CRC error |
| Single Flash | AL Status register Error Indication bit 4 is set while device emulation is disabled | XMC4800 sets Error Indication bit. |
| Double Flash | Process Data Watchdog time-out (edge detected) while device is OPERATIONAL | master is disconnected/not sending process data any more |
| On | PDI Watchdog time-out (edge detected) or Build-In self-test error | XMC4800 is not accessing the ECAT module (example: CPU is halted by the debugger) |

16.10.3 STATE RUN LED

The STATE LED is used to drive a bicolor-LED combining RUN and ERR LED. Since the RUN LED part of the STATE LED must be turned off while the ERR LED part is active, the RUN and ERR LED signals cannot be simply combined to drive the bicolor LED. XMC4800 support a STATE_RUN signal, which is turned off while ERR LED is on, so STATE_RUN and ERR signals can be used to drive the bicolor STATE LED.

16.10.4 LINK ACT LED

The Link/Activity state of each port is displayed with the LINK_ACT LED. It is recommended to use a green LED for that purpose. It is recommended to use the LINK_ACT LED signals of the ECAT module instead of the Link/Activity LED signals of the PHY, because the ECAT signals reflect the actual link/activity state of the device, not only the state of the PHYs.

Table 16-5 LINK_ACT LED States

| LINK_ACT LED | Description |
|---------------------|-----------------------|
| OFF | No Link |
| Blinking | Link and activity |
| ON | Link without activity |

16.11 Service Request Generation

ESCs support two types of interrupts. AL Event Requests dedicated for the XMC4800, and ECAT event requests dedicated for the EtherCAT master.

AL Event Requests can be signaled to the NVIC using the PDI Interrupt Request signal (SR0). For Interrupt generation, the AL Event Request register is combined with the AL Event Mask register using a logical AND operation, then all resulting bits are combined (logical OR) into one interrupt signal. The AL Event Mask register allows for selecting the interrupts which are relevant for the system and handled by the application.

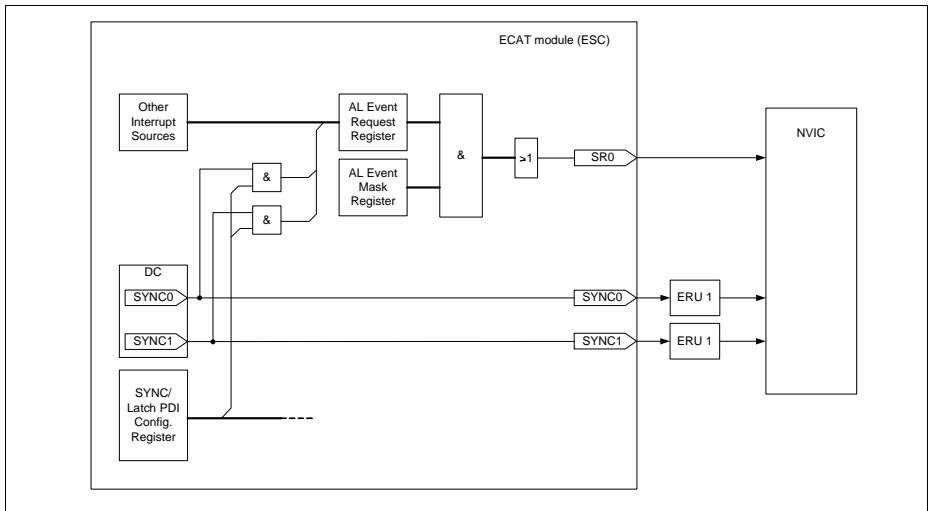

Figure 16-8 EtherCAT Interrupt Masking and Interrupt Signals

The DC SyncSignals can be used for interrupt generation in two ways.

The DC SYNC signals are mapped into the AL Event Request Register (configured with SYNC/LATCH PDI Configuration register 0x0151.3/7). In this case, all interrupts from the ESC to the NVIC are combined into one IRQ signal, and the Distributed Clocks LATCH0/1 inputs can still be used.

The DC SyncSignals are connected via ERU to NVIC interrupt inputs. The System can react on DC Sync-Signal interrupts faster (without reading AL Request register). To route the signal through ERU the customer software must setup the ERU module.

16.12 Debug Behavior

The ECAT module is not supporting any special mode when the CPU enters HALT mode.

16.13 Power, Reset and Clock

The following sections describe the operating conditions, characteristics and timing requirements for the ECAT. All the timing information is related to the module clock, f_{ECAT} .

16.13.1 Power

The ECAT module is inside the power core domain, therefore no special considerations about power up or power down sequences need to be taken. For a explanation about the different power domains, please address the SCU (System Control Unit) chapter.

16.13.2 Module Reset

The ECAT module has one reset source. This reset source is handled at system level and it can be generated independently via a system control register, PRSET2 (address SCU chapter for a full description). After setting the bit PRCLR2.ECAT0RS it's recommended to poll the bit PRSTAT2.ECAT0RS before accessing the ECAT module first time. The sequence to release the module out of reset is explained in [Chapter 16.14](#).

16.13.3 EtherCAT Reset

An EtherCAT master is capable to request a reset of an EtherCAT slave. Therefore a reset signal is connected to the XMC4[78]00 SCU. It can be selected in if a TRAP should be requested or a system reset generated. For more information about global parity handling please refer to the SCU chapter EtherCAT Reset.

16.13.4 Module Clock

The module clock of the ECAT module is described in the SCU chapter as f_{ECAT} . The clock for the PHY's is generated out of the ECAT module shown as f_{ECATPHY} and available on GPIO's as signal PHY_CLK25.

It's recommended to supervise the clock generation in the SCU. For this in case of clock fails or PLL loss of lock a TRAP should be generated to signalize the application software the clock fail. After Power-on reset the module clock is gated and need to be de-asserted. Once done and starting up/running the ECAT the clock should not be gated again without set the module reset before since this would breakdown the EtherCAT bus system.

The bus interface clock of the ECAT module is described in the SCU chapter as f_{PERIPH} .

16.14 Initialization and System Dependencies

After Power up the ECAT module is in reset state. The following sequence shown in **Figure 16-9** should be executed.

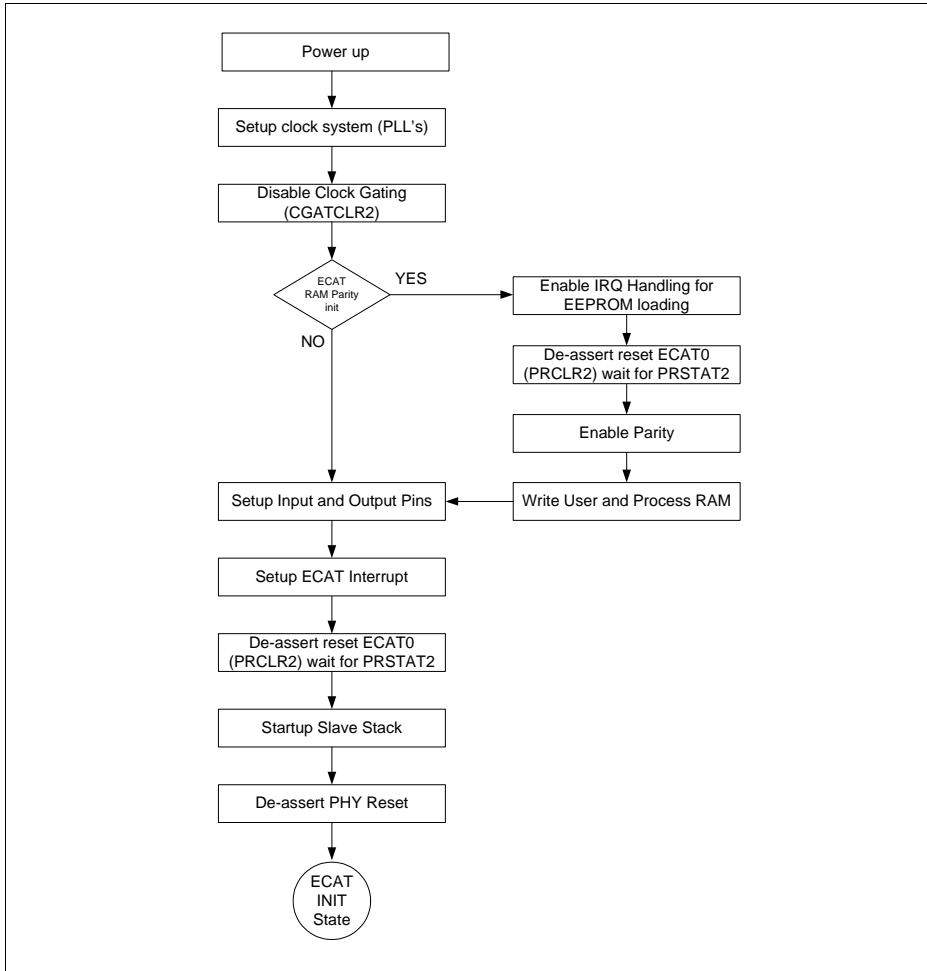

Figure 16-9 EtherCAT Module Initialization

16.14.1 Process and User RAM Parity handling

The process and user RAM provide protection of data integrity via parity checking. A read operation implies checking of the previous stored parity information.

An occurrence of a parity error is forwarded to the SCU and reflected in the ECAT register ECAT0_STATUS [Page 16-135](#). At the same time a PDI Error is activated. In this state the process data RAM returns 0_H for PDI accesses (EEP_CONT_STAT.L_STAT). By resetting the parity error in SCU the modules returns in normal operating mode, all flags in the ECAT module are cleared automatic.

For more information about global parity handling please refer to the SCU chapter Memory Parity Protection.

16.15 Registers

Registers Overview

the absolute register address is calculated by adding:

module base address + offset address

More information of the address space is shown in [Chapter 16.7](#).

An EtherCAT slave controller (ESC) has an address space of 64 kBytes. The first block of 4 kBytes (0000_H:0FFF_H) is dedicated for registers. The process data RAM starts at address 1000_H, its size depends on the ESC implementation. Availability of registers depends on the ESC as well.

Note: Address areas not listed in the [Table 16-7](#) are reserved. They are not writable. Read data from reserved addresses has to be ignored. Reserved addresses must not be written.

Table 16-6 Registers Address Space

| Module | Base Address | End Address | Note |
|--------|------------------------|------------------------|------|
| ECAT0 | 5401 0000 _H | 5401 FFFF _H | |

16.15.1 ECAT kernel registers

Type register of ethercat controller (TYPE)

The TYPE register shows the implementation type of the ECAT module. This number is defined by Beckhoff.

ECAT0_TYPE

Type of EtherCAT Controller (0000_H) Reset Value: 98_H

| Field | Bits | Type | Description |
|-------|-------|------|-----------------------------|
| Type | [7:0] | r | Type of EtherCAT controller |

Revision of EtherCAT controller (REVISION)

The revision register shows the revision of the ECAT module.

ECAT0_REVISION

Revision of EtherCAT Controller (0001_H) Reset Value: 01_H

| Field | Bits | Type | Description |
|----------|-------|------|--|
| Revision | [7:0] | r | Revision of EtherCAT controller major version X |

Build register (BUILD)

The build register shows the actual build version of the ECAT module.

ECAT0_BUILD

| Field | Bits | Type | Description |
|-------|--------|------|-------------------------------------|
| BUILD | [15:0] | r | Actual build of EtherCAT controller |

FMMUs supported (FMMU_NUM)

The register FMMU_NUM shows the number of supported FMMU channels.

ECAT0_FMMU_NUM

| Field | Bits | Type | Description |
|----------|-------|------|--|
| NUM_FMMU | [7:0] | r | Number of supported FMMU channels (or entities) of the EtherCAT Slave Controller |

EtherCAT Slave Controller (ECAT)

SyncManager supported (SYNC_MANAGER)

The register SYNC_MANAGER shows the number of supported SyncManager channels.

ECAT0_SYNC_MANAGER

SyncManagers Supported

(0005_H)

Reset Value: 08_H

| Field | Bits | Type | Description |
|--------|-------|------|---|
| NUM_SM | [7:0] | r | Number of supported SyncManager channels (or entities) of the EtherCAT Slave Controller |

RAM size of the ECAT module (RAM_SIZE)

The RAM_SIZE register shows implemented Process Data RAM size in KByte.

ECAT0_RAM_SIZE

RAM Size

(0006_H)

Reset Value: 08_H

| Field | Bits | Type | Description |
|----------|-------|------|---|
| RAM_Size | [7:0] | r | Process Data RAM size supported by the EtherCAT Slave Controller in KByte |

Port descriptor register (PORT_DESC)

The port descriptor register shows the feature and availability of the implemented communication port of the ECAT module.

ECAT0_PORT_DESC

Port Descriptor

(0007_H)

Reset Value: 0F_H

| Field | Bits | Type | Description |
|-------|-------|------|---|
| Port0 | [1:0] | r | Port Configuration 00 _B Not implemented 01 _B Not configured (SII EEPROM) 10 _B EBUS 11 _B MII / RMII / RGMII |
| Port1 | [3:2] | r | Port Configuration 00 _B Not implemented 01 _B Not configured (SII EEPROM) 10 _B EBUS 11 _B MII / RMII / RGMII |
| Port2 | [5:4] | r | Port Configuration 00 _B Not implemented 01 _B Not configured (SII EEPROM) 10 _B EBUS 11 _B MII / RMII / RGMII |
| Port3 | [7:6] | r | Port Configuration 00 _B Not implemented 01 _B Not configured (SII EEPROM) 10 _B EBUS 11 _B MII / RMII / RGMII |

EtherCAT Slave Controller (ECAT)

ECAT features supported (FEATURE)

The register features supported shows the activated functionality of the ECAT module.

ECAT0_FEATURE

ESC Features Supported

(0008_H)

Reset Value: 01CC_H

| Res | [15:12] | r | Reserved Read as 0; should be written with 0. |

16.15.2 Station Address

Configured Station Address (STATION_ADR)

The STATION_ADR register is used for node addressing.

ECAT0_STATION_ADR

Configured Station Address (0010_H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| NODE_ADDR | [15:0] | r | Address used for node addressing (FPxx commands) |

Configured Station Alias (STATION_ALIAS)

The STATION_ALIAS register is used for station addressing.

ECAT0_STATION_ALIAS

Configured Station Alias (0012_H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|------------|--------|------|--|
| ALIAS_ADDR | [15:0] | rw | Alias Address used for node addressing (FPxx commands) The use of this alias is activated by Register . / . (0x0103.0) <i>Note: NOTE: EEPROM value is only taken over at first EEPROM load after power-on or reset.</i> |

16.15.3 Write Protection

Write Register Enable (WR_REG_ENABLE)

The Write Register Enable register has to be written in the same Ethernet frame (value does not care) before other writes to this station are allowed.

ECAT0_WR_REG_ENABLE

Write Register Enable

(0020_H)

Reset Value: 00_H

| | | | | | | | |

16.15.4 Data Link Layer

ESC Reset ECAT - Write (ESC_RESET_ECAT)

The ESC_RESET_ECAT register is used from the EtherCAT Master to reset the ESC.

ECAT0_ESC_RESET_ECAT

ESC Reset ECAT [WRITE Mode] (0040_H) Reset Value: 00_H

| Field | Bits | Type | Description |
|-----------|-------|------|--|
| RESET_CMD | [7:0] | r | Reset commands issued by EtherCAT Master A reset is asserted after writing 0x52 ('R'), 0x45 ('E') and 0x53 ('S') in this register with 3 consecutive frames. |

Register ESC Reset ECAT - Read (ESC_RESET_ECAT)

ECAT0_ESC_RESET_ECAT

ESC Reset ECAT [READ Mode] (0040_H) Reset Value: 00_H

| Field | Bits | Type | Description |
|-----------------|-------|------|--|
| RESET_CMD_STATE | [1:0] | r | Progress of the reset procedure 01 _B after writing 0x52 10 _B after writing 0x45 (if 0x52 was written before) 00 _B default |
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

ESC Reset PDI - Write (ESC_RESET_PDI)

The ESC_RESET_PDI register is used from the XMC4800 to reset the ESC.

ECAT0_ESC_RESET_PDI

ESC Reset PDI [WRITE Mode]

(0041_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|-----------|-------|------|---|
| RESET_CMD | [7:0] | w | Reset commands issued by XMC4800 A reset is asserted after writing 0x52 ('R'), 0x45 ('E') and 0x53 ('S') in this register with 3 consecutive writes accesses. |

Register ESC Reset PDI - Read (ESC_RESET_PDI)

ECAT0_ESC_RESET_PDI

ESC Reset PDI [READ Mode]

(0041_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|-----------------|-------|------|--|
| RESET_CMD_STATE | [1:0] | r | Progress of the reset procedure 01 _B after writing 0x52 10 _B after writing 0x45 (if 0x52 was written before) 00 _B default |
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

ESC DL Control (ESC_DL_CONTROL)

The ESC_DL_CONTROL register is used to handle specific feature of the Data Link Layer.

ECAT0_ESC_DL_CONTROL

ESC DL Control

(0100_H)

Reset Value: 0007 C001_H

|-------|-------|------|---|
| FR | 0 | r | Forwarding rule 0 _B EtherCAT frames are processed, Non-EtherCAT frames are forwarded without processing 1 _B EtherCAT frames are processed, Non- EtherCAT frames are destroyed The source MAC address is changed for every frame (SOURCE_MAC[1] is set to 1 – locally administered address) regardless of the forwarding rule. |
| TEMP | 1 | r | Temporary use of settings in LP1-LP3 0 _B permanent use 1 _B use for about 1 second, then revert to previous settings |
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|------------|---------|------|--|
| LP0 | [9:8] | r | Loop Port 0 00 _B Auto 01 _B Auto Close 10 _B Open 11 _B Closed <i>Note: Loop open means sending/receiving over this port is enabled, loop closed means sending/receiving is disabled and frames are forwarded to the next open port internally.</i> <i>Auto: loop closed at link down, opened at link up</i> <i>Auto Close: loop closed at link down, opened with writing 01 again after link up (or receiving a valid Ethernet frame at the closed port)</i> <i>Open: loop open regardless of link state</i> <i>Closed: loop closed regardless of link state</i> |
| LP1 | [11:10] | r | Loop Port 1 00 _B Auto 01 _B Auto Close 10 _B Open 11 _B Closed |
| LP2 | [13:12] | r | Loop Port 2 00 _B Auto 01 _B Auto Close 10 _B Open 11 _B Closed |
| LP3 | [15:14] | r | Loop Port 3 00 _B Auto 01 _B Auto Close 10 _B Open 11 _B Closed |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|---------------------|---------|------|--|
| RX_FIFO_SIZE | [18:16] | r | RX FIFO Size ESC delays start of forwarding until FIFO is at least half full RX FIFO Size/RX delay reduction value: ¹⁾ MII 0 _D -40 ns (-80 ns ²⁾) 1 _D -40 ns (-80 ns ²⁾) 2 _D -40 ns 3 _D -40 ns 4 _D no change 5 _D no change 6 _D no change 7 _D default |
| LJ | 19 | r | EBUS Low Jitter 0 _B Normal jitter 1 _B Reduced jitter |
| Res | [21:20] | r | Reserved Read as 0; should be written with 0. |
| RLD_ST | 22 | r | EBUS remote link down signaling time 0 _B Default (~660 ms) 1 _B Reduced (~80 µs) |
| Res | 23 | r | Reserved Read as 0; should be written with 0. |
| S_ALIAS | 24 | r | Station alias 0 _B Ignore Station Alias 1 _B Alias can be used for all configured address command types (FPRD, FPWR, ...) |
| Res | [31:25] | r | Reserved Read as 0; should be written with 0. |

1) The possibility of RX FIFO Size reduction depends on the clock source accuracy of the ESC and of every connected EtherCAT/Ethernet devices (master, slave, etc.). RX FIFO Size of 7 is sufficient for 100ppm accuracy, FIFO Size 0 is possible with 25ppm accuracy (frame size of 1518/1522 Byte).

2) IP Core since V3.0.0/V3.00c only

Physical Read/Write Offset (PHYSICAL_RW_OFFSET)

The PHYSICAL_RW_OFFSET register is used by the EtherCAT Master to generate offset of R/W Commands (FPRW, APRW) between Read address and Write address.

ECAT0_PHYSICAL_RW_OFFSET

Physical Read/Write Offset

(0108_H)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|--------|--------|------|--|
| OFFSET | [15:0] | r | Offset of R/W Commands (FPRW, APRW) between Read address and Write address RD_ADR = ADR and WR_ADR = ADR + R/W-Offset |

ESC DL Status (ESC_DL_STATUS)

The ESC_DL_STATUS register shows the current state of the Data Link Layer.

ECAT0_ESC_DL_STATUS

ESC DL Status (0110_H) Reset Value: 5000_H

| | | | | | | | | | | | | | | | |

16.15.5 Application Layer

AL Control (AL_CONTROL)

The AL_CONTROL register reflect the current state of the ESC.

ECAT0_AL_CONTROL

AL Control (0120_H) **Reset Value: 0001_H**

| | | | | | | | | | | | | | | | |
|-----|----|----|----|----|----|---|---|---|---|-----|-----|-----|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | | | | | DID | EIA | IST | | | |
| r | | | | | | | | | | r | r | r | | | |

| Field | Bits | Type | Description |
|-------|--------|------|--|
| IST | [3:0] | r | Initiate State Transition of the Device State Machine 1 _H Request Init State 2 _H Request Pre-Operational State 3 _H Request Bootstrap State 4 _H Request Safe-Operational State 8 _H Request Operational State |
| EIA | 4 | r | Error Ind Ack 0 _B No Ack of Error Ind in AL status register 1 _B Ack of Error Ind in AL status register |
| DID | 5 | r | Device Identification 0 _B No request 1 _B Device Identification request |
| Res | [15:6] | r | Reserved Read as 0; should be written with 0. |

Note: AL Control register behaves like a mailbox if Device Emulation is off (0x0140.8=0): The PDI has to read/write the AL Control register after EtherCAT Master has written it. Otherwise the EtherCAT Master cannot write again to the AL Control register. After Reset, AL Control register can be written by EtherCAT Master. (Regarding mailbox functionality, both registers and are equivalent, e.g. reading is sufficient to make this register writeable again.)*

* PDI register function acknowledge by Write command is disabled: Reading AL Control from PDI clears AL Event Request .AL_CE. Writing to this register from PDI is not possible.

EtherCAT Slave Controller (ECAT)

PDI register function acknowledge by Write command is enabled: Writing AL Control from PDI clears AL Event Request .AL_CE. Writing to this register from PDI is possible; write value is ignored (write 0).

AL Status (AL_STATUS)

The AL_STATUS register is used to acknowledge the state change request from the EtherCAT Master.

ECAT0_AL_STATUS

AL Status (0130_H) **Reset Value: 0001_H**

| | | | | | | | | | | | | | | | |
|-----|----|----|----|----|----|---|---|---|---|-----|------|-------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | | | | | DID | ERRI | STATE | | | |
| rw | | | | | | | | | | rw | rw | rw | | | |

| Field | Bits | Type | Description |
|--------------|--------|------|---|
| STATE | [3:0] | rw | Actual State of the Device State Machine 1 _H Init State 2 _H Pre-Operational State 3 _H Bootstrap State 4 _H Safe-Operational State 8 _H Operational State |
| ERRI | 4 | rw | Error Ind 0 _B Device is in State as requested or Flag cleared by command 1 _B Device has not entered requested State or changed State as result of a local action |
| DID | 5 | rw | Device Identification 0 _B Device Identification not valid 1 _B Device Identification loaded |
| Res | [15:6] | rw | Reserved Read as 0; should be written with 0. |

Note: AL Status register is only writable from PDI if Device Emulation is off (.EMUL), otherwise AL Status register will reflect AL Control register values.

AL Status Code (AL_STATUS_CODE)

The AL_STATUS_CODE register is used to exchange Status Codes of the Application Layer.

ECAT0_AL_STATUS_CODE

AL Status Code

(0134_H)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|----------------|
| AL_S_CODE | [15:0] | rw | AL Status Code |

RUN LED Override (RUN_LED)

The RUN_LED register is used to overwrite the blinking sequences of the ECAT RUN LED.

ECAT0_RUN_LED

RUN LED Override

(0138_H)

Reset Value: 0E_H

| | | | | | | | |
|-----|---|---|----------|----------|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | EN_OVERR | LED_CODE | | | |
| rw | | | rw | rw | | | |

| Field | Bits | Type | Description |
|----------|-------|------|--|
| LED_CODE | [3:0] | rw | LED Code 0 _H OFF - Init State 1 _H Flash - SafeOp) D _H Blinking - PreOp E _H Flickering - Bootstrap F _H On - Operational Values 2-C are used for future LED flash sequences. |
| EN_OVERR | 4 | rw | Enable Override 0 _B Override disable 1 _B Override enable |
| Res | [7:5] | rw | Reserved Read as 0; should be written with 0. |

Note: The Reset value will change after reloading the EEPROM. This value will change to 0x00 to signalize the init State of the ECAT module.

Note: Changes to AL Status register with valid values will disable RUN LED Override. The value read in this register always reflects current LED output.

ERR LED Override (ERR_LED)

The ERR_LED register is used to overwrite the blinking sequences of the ECAT ERR LED.

ECAT0_ERR_LED

RUN ERR Override

(0139_H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|----------|----------|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | EN_OVERR | LED_CODE | | | |
| rw | | | rw | rw | | | |

| Field | Bits | Type | Description |
|----------|-------|------|---|
| LED_CODE | [3:0] | rw | LED Code 0 _H OFF D _H Blinking E _H Flickering F _H On Values 1-C are used for future LED flash sequences. |
| EN_OVERR | 4 | rw | Enable Override 0 _B Override disable 1 _B Override enable |
| Res | [7:5] | rw | Reserved Read as 0; should be written with 0. |

Note: New error conditions will disable the ERR LED Overwrite. The value read in this register always reflects the current LED output.

16.15.6 PDI / ESC Configuration

PDI CONTROL

The PDI_CONTROL register shows the used Interface for the process data interface.

ECAT0_PDI_CONTROL

PDI Control (0140_H) **Reset Value: 80_H**

| Field | Bits | Type | Description |
|-------|-------|------|---|
| PDI | [7:0] | r | On-chip bus clock 00 _H Interface deactivated (no PDI) 80 _H On-chip Bus |

EtherCAT Slave Controller (ECAT)

ESC Configuration (ESC_CONFIG)

The ESC_CONFIG register shows the used features depending on the EEPROM content.

ECAT0_ESC_CONFIG

ESC Configuration

(0141_H)

Reset Value: FE_H

| | | | | | | | |

| Field | Bits | Type | Description |
|-----------------|------|------|---|
| EMUL | 0 | r | Device emulation (control of AL status) 0 _B AL status register has to be set by PDI 1 _B AL status register will be set to value written to AL control register |
| EHL_D | 1 | r | Enhanced Link detection all ports 0 _B disabled (if bits [7:4]=0) 1 _B enabled at all ports (overrides bits [7:4]) |
| CLKS_OUT | 2 | r | Distributed Clocks SYNC Out Unit 0 _B disabled (power saving) 1 _B enabled |
| CLKS_IN | 3 | r | Distributed Clocks Latch In Unit 0 _B disabled (power saving) 1 _B enabled |
| EHL_D_P0 | 4 | r | Enhanced Link port 0 0 _B disabled (if bit 1 = 0) 1 _B enabled |
| EHL_D_P1 | 5 | r | Enhanced Link port 1 0 _B disabled (if bit 1 = 0) 1 _B enabled |
| EHL_D_P2 | 6 | r | Enhanced Link port 2 0 _B disabled (if bit 1 = 0) 1 _B enabled |
| EHL_D_P3 | 7 | r | Enhanced Link port 3 0 _B disabled (if bit 1 = 0) 1 _B enabled |

EtherCAT Slave Controller (ECAT)

Note: The Reset value will change after reloading the EEPROM.

PDI On-chip bus configuration (PDI_CONFIG)

The PDI_CONFIG register shows used on-chip bus used inside the XMC4800.

ECAT0_PDI_CONFIG

PDI Control (0150_H) Reset Value: 81_H

| | | | | | | | |
|---------------|---|---|----------------|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| OC_BUS | | | BUS_CLK | | | | |
| r | | | r | | | | |

| Field | Bits | Type | Description |
|----------------|-------|------|---|
| BUS_CLK | [4:0] | r | On-chip bus clock 00 _H asynchronous 01 _H values 1-31 is used for synchronous multiplication factor (N*25Mhz) |
| OC_BUS | [7:5] | r | On-chip bus 000 _H Altera Avalon 001 _H AXI 010 _H Xilinx PLB v4.6 100 _H Xilinx OPB |

Note: The On chip bus Xilinx OPB is bridged to AHB lite.

Sync/Latch[1:0] PDI Configuration (SYNC_LATCH_CONFIG)

The SYNC_LATCH_CONFIG register shows the setup of the SYNC pins.

ECAT0_SYNC_LATCH_CONFIG

Sync/Latch[1:0] PDI Configuration (0151_H) Reset Value: EE_H

| | | | | | | | |
|---------------|----------------|------------------|---------------|----------------|------------------|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| S1_MAP | SL1_CNF | SYNC1_POL | S0_MAP | SL0_CNF | SYNC0_POL | | |
| r | r | r | r | r | r | | |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|------------------|-------|------|---|
| SYNC0_POL | [1:0] | r | SYNC0 output driver/polarity¹⁾ 00 _B Push-Pull active low 01 _B Open Drain (active low) 10 _B Push-Pull active high 11 _B Open Source (active high) |
| SL0_CNF | 2 | r | SYNC0/LATCH0 configuration²⁾ 0 _B LATCH0 Input 1 _B SYNC0 Output |
| S0_MAP | 3 | r | SYNC0 mapped to register . 0 _B Disabled 1 _B Enabled |
| SYNC1_POL | [5:4] | r | SYNC1 output driver/polarity³⁾ 00 _B Push-Pull active low 01 _B Open Drain (active low) 10 _B Push-Pull active high 11 _B Open Source (active high) |
| SL1_CNF | 6 | r | SYNC1/LATCH1 configuration 0 _B LATCH1 Input 1 _B SYNC1 Output |
| S1_MAP | 7 | r | SYNC1 mapped to register . 0 _B Disabled 1 _B Enabled |

1) SYNC0 output driver modes are selected in the IOCR bitfile of the respective pin which is used.

2) The ECAT0 module uses independent SYNC[1:0] outputs and LATCH[1:0] inputs, independent of this configuration.

3) SYNC1 output driver modes are selected in the IOCR bitfile of the respective pin which is used.

Note: Register SYNC_LATCH_CONFIG is reloaded from EEPROM ADR 0x0001.

Register PDI On-chip bus extended Configuration (PDI_EXT_CONFIG)

ECAT0_PDI_EXT_CONFIG

PDI Synchronous Microcontroller extended Configuration

16.15.8 Error Counters

Register RX Error Counter Port p (RX_ERR_COUNT)

The RX_ERR_COUNT register shows the actual error count for each available and activated port (p).

ECAT0_RX_ERR_COUNTp (p = 0-1)

RX Error Counter Port p (0300_H+p*2H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|---------------|--------|------|---|
| INVALID_FRAME | [7:0] | r | Invalid frame counter of Port y Counting is stopped when FF _H is reached |
| RX_ERROR | [15:8] | r | RX Error counter of Port y (counting is stopped when 0xFF is reached). This is coupled directly to RX ERR of MII interface/EBUS interface. |

Note: Error Counters 0300H-030BH are cleared if one of the RX Error counters 0300H-030BH is written by the ECAT master. Write value is ignored (write 0).

EtherCAT Slave Controller (ECAT)

Register Forwarded RX Error Counter Port p (FWD_RX_ERR_COUNT)

The FWD_RX_ERR_COUNT shows the actual Forwarded RX Error Counter.

ECAT0_FWD_RX_ERR_COUNTp (p = 0-1)

Forwarded RX Error Counter Port p (0308_H+p)

Reset Value: 00_H

| Field | Bits | Type | Description |
|------------|-------|------|--|
| FORW_ERROR | [7:0] | r | Forwarded error counter of Port y counting is stopped when 0xFF is reached |

Note: Error Counters 0300H-030BH are cleared if one of the RX Error counters 0300H-030BH is written by the ECAT master. Write value is ignored (write 0).

Register ECAT Processing Unit Error Counter (PROC_ERR_COUNT)

The ECAT_PROC_ERR_COUNT shows the actual Processing Unit Error Counter.

ECAT0_PROC_ERR_COUNT

ECAT Processing Unit Error Counter (030C_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|------------|-------|------|---|
| UNIT_ERROR | [7:0] | r | ECAT Processing Unit error counter (counting is stopped when 0xFF is reached). Counts errors of frames passing the Processing Unit (e.g., FCS is wrong or datagram structure is wrong). |

Note: Error Counter 030CH is cleared if error counter 030CH is written by the ECAT master. Write value is ignored (write 0).

EtherCAT Slave Controller (ECAT)

Register PDI Error Counter (PDI_ERR_COUNT)

The PDI_ERR_COUNT shows the actual PDI Error Counter.

ECAT0_PDI_ERR_COUNT

PDI Error Counter (030D_H) **Reset Value: 00_H**

| Field | Bits | Type | Description |
|--------------------------|-------|------|---|
| PDI_ERROR_COUNTER | [7:0] | r | PDI Error counter (counting is stopped when 0xFF is reached). Counts if a PDI access has an interface error. |

Note: Error Counter 030DH and Error Code 030EH are cleared if error counter 030DH is written. Write value is ignored (write 0).

Register Lost Link Counter Port y

The LOST_LINK_COUNT shows the actual Lost Link Counter for each available/activated port.

ECAT0_LOST_LINK_COUNT_p (p = 0-1)

Lost Link Counter Port p (0310_{H+p}) **Reset Value: 00_H**

| Field | Bits | Type | Description |
|-------------------|-------|------|---|
| LL_COUNTER | [7:0] | r | Lost Link counter of Port p (counting is stopped when 0xff is reached). Counts only if port loop is Auto. |

Note: Only lost links at open ports are counted. Lost Link Counters 0310H-0313H are cleared if one of the Lost Link Counters 0310H-0313H is written by the ECAT master. Write value is ignored (write 0).

16.15.9 Watchdogs

Register Watchdog Divider (WD_DIVIDE)

The WD_DIVIDE register is used to configure the timebase of the Watchdogs.

ECAT0_WD_DIVIDE

| Field | Bits | Type | Description |
|--------|--------|------|---|
| WD_DIV | [15:0] | rw | Watchdog divider Number of 25 MHz tics (minus 2) that represents the basic watchdog increment. (Default value is 100is = 2498) |

Register Watchdog Time PDI (WD_TIME_PDI)

The WD_TPDI register is used to setup the time for the PDI Watchdog.

ECAT0_WD_TIME_PDI

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| WD_TIME_PDI | [15:0] | rw | Watchdog Time PDI Number or basic watchdog increments (Default value with Watchdog divider 100is means 100ms Watchdog) |

Note: Watchdog is disabled if Watchdog time is set to 0000H. Watchdog is restarted with every PDI access.

EtherCAT Slave Controller (ECAT)

Register Watchdog Time Process Data (WD_TIME_PDATA)

The WD_TIME_PDATA register is used to setup the time for the Process Data Watchdog.

ECAT0_WD_TIME_PDATA

Watchdog Time Process Data

(0420_H)

Reset Value: 03E8_H

| Field | Bits | Type | Description |
|------------|--------|------|--|
| WD_TIME_PD | [15:0] | rw | Watchdog Time Process Data Number of basic watchdog increments (Default value with Watchdog divider 100 is means 100 ms Watchdog) |

Note: There is one Watchdog for all SyncManagers. Watchdog is disabled if Watchdog time is set to 0000H. Watchdog is restarted with every write access to SyncManagers with Watchdog Trigger Enable Bit set.

Register Watchdog Status Process Data (WD_STAT_PDATA)

The WD_STAT_PDATA register shows the status of the Process Data WDT.

ECAT0_WD_STAT_PDATA

Watchdog Status Process Data

(0440_H)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|---|
| WD_STAT_PD | 0 | r | Watchdog Status of Process Data triggered by SyncManagers 0 _B Watchdog Process Data expired 1 _B Watchdog Process Data is active or disabled |
| Res | [15:1] | r | Reserved Read as 0; should be written with 0. |

Note: PDI register function acknowledge by Write command is enabled: Writing this register from PDI clears AL Event Request 0220H[6]. Writing to this register from PDI is possible; write value is ignored (write 0).

EtherCAT Slave Controller (ECAT)

Register Watchdog Counter Process Data (WD_COUNT_PDATA)

The WDC_PDI register shows the actual WDT counter for the Process Data.

ECAT0_WD_COUNT_PDATA

Watchdog Counter Process Data (0442_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|---------------|-------|------|---|
| WD_COUNTER_PD | [7:0] | r | Watchdog Counter Process Data (counting is stopped when 0xFF is reached). Counts if Process Data Watchdog expires. |

Note: Watchdog Counters or are cleared if one of the Watchdog Counters is written by the ECAT master. Write value is ignored (write 0).

Register Watchdog Counter PDI (WD_COUNT_PDI)

The WDC_PDI register shows the actual WDT counter for the PDI.

ECAT0_WD_COUNT_PDI

Watchdog Counter PDI (0443_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|----------------|-------|------|---|
| WD_COUNTER_PDI | [7:0] | r | Watchdog PDI counter (counting is stopped when 0xFF is reached). Counts if PDI Watchdog expires. |

Note: Watchdog Counters or are cleared if one of the Watchdog Counters is written by the ECAT master. Write value is ignored (write 0).

16.15.10 SII EEPROM Interface

SII EEPROM Interface (0500_H:050F_H)

Table 16-9 Table 63: SII EEPROM Interface Register overview

| Register Address | Length (Byte) | Description |
|------------------|---------------|-------------------------|
| 0500H | 1 | EEPROM Configuration |
| 0501H | 1 | EEPROM PDI Access State |
| 0502H:0503H | 2 | EEPROM Control/Status |
| 0504H:0507H | 4 | EEPROM Address |
| 0508H:050FH | 4/8 | EEPROM Data |

EtherCAT controls the SSI EEPROM interface if EEPROM configuration register .TO_PDI = 0 and EEPROM PDI Access register .ACCESS = 0, otherwise PDI controls the EEPROM interface.

In EEPROM emulation mode, the PDI executes outstanding EEPROM commands. The PDI has access to some registers while the EEPROM Interface is busy.

Register EEPROM Configuration (EEP_CONF)

The EEP_CONF register is typically used to decide if the EtherCAT slave controller CPU gets access to the EEPROM.

ECAT0_EEP_CONF

EEPROM Configuration

(0500_H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|---|-------|--------|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | FORCE | TO_PDI |
| r | | | | | | r | r |

| Field | Bits | Type | Description |
|--------|------|------|---|
| TO_PDI | 0 | r | EEPROM control is offered to PDI 0 _B No 1 _B Yes (PDI has EEPROM control) |
| FORCE | 1 | r | Force ECAT access 0 _B Do not change Bit 501.0 1 _B Reset Bit 501.0 to 0 |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|-------|-------|------|---|
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

Register EEPROM PDI Access State (EEP_STATE)

The EEP_STATE register is used by the PDI to take over EEPROM access.

ECAT0_EEP_STATE

EEPROM PDI Access State (0501_H) **Reset Value: 00_H**

| | | | | | | | |
|------------|---|---|---|---|---|---|---------------|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | | ACCESS |
| r | | | | | | | rw |

| Field | Bits | Type | Description |
|---------------|-------|------|---|
| ACCESS | 0 | rw | Access to EEPROM 0 _B PDI releases EEPROM access 1 _B PDI takes EEPROM access (PDI has EEPROM control) |
| Res | [7:1] | r | Reserved Read as 0; should be written with 0. |

Note: r/(w): write access is only possible if .TO_PDI =1 and .FORCE =0.

EtherCAT Slave Controller (ECAT)

Register EEPROM Control/Status (EEP_CONT_STAT)

The EEP_CONT_STAT register is used to handle the EEPROM operation triggered by the ECAT master, show status of the EEPROM process.

ECAT0_EEP_CONT_STAT

EEPROM Control/Status

(0502_H)

Reset Value: 9460_H

| | | | | | | | | | | | | | | | |
|----------|------------------|------------------|------------|-----------|---------|---|-----|-----------|----------|-----|---|---|---|------|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| BUS Y | ERR OR_ WE | ERR OR_ AC | L_ST AT | ERR OR | CMD_REG | | ALG | BYT ES | EMU L | Res | | | | W_EN | |
| r | r | rw | r | r | rw | | r | r | r | r | | | | r | |

| Field | Bits | Type | Description |
|---------|--------|------|---|
| W_EN | 0 | r | ECAT write enable¹⁾ 0 _B Write requests are disabled 1 _B Write requests are enabled This bit is always 1 if PDI has EEPROM control. |
| Res | [4:1] | r | Reserved Read as 0; should be written with 0. |
| EMUL | 5 | r | EEPROM emulation 0 _B Normal operation (I ² C interface used) 1 _B PDI emulates EEPROM (I ² C not used) |
| BYTES | 6 | r | Supported number of EEPROM read bytes 0 _B 4 Bytes 1 _B 8 Bytes |
| ALG | 7 | r | Selected EEPROM Algorithm 0 _B 1 address byte (1 KBit – 16 KBit EEPROMs) 1 _B 2 address bytes (32 KBit – 4 MBit EEPROMs) |
| CMD_REG | [10:8] | rw | Command register¹⁾ Write: Initiate command. Read: Currently executed command Commands: 000 _B No command/EEPROM idle (clear error bits) 001 _B Read 010 _B Write 100 _B Reload Others: Reserved/invalid commands (do not issue) EEPROM emulation only: after execution, PDI writes command value to indicate operation is ready. |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|-----------------|------|------|--|
| ERROR | 11 | r | Checksum Error at in ESC Configuration Area 0 _B Checksum OK 1 _B Checksum error |
| L_STAT | 12 | r | EEPROM loading status 0 _B EEPROM loaded, device information OK 1 _B EEPROM not loaded, device information not available (EEPROM loading in progress or finished with a failure) |
| ERROR_AC | 13 | rw | Error Acknowledge/Command²⁾ 0 _B No error 1 _B Missing EEPROM acknowledge or invalid command EEPROM emulation only: PDI writes 1 if a temporary failure has occurred. |
| ERROR_WE | 14 | r | Error Write Enable²⁾ 0 _B No error 1 _B Write Command without Write enable |
| BUSY | 15 | r | Busy 0 _B EEPROM Interface is idle 1 _B EEPROM Interface is busy |

1) Write Enable bit 0 is self-clearing at the SOF of the next frame, Command bits [10:8] are self-clearing after the command is executed (EEPROM Busy ends). Writing "000" to the command register will also clear the error bits [14:13]. Command bits [10:8] are ignored if Error Acknowledge/Command is pending (bit 13).

2) Error bits are cleared by writing "000" (or any valid command) to Command Register Bits [10:8].

Notes

1. *r(w): write access depends upon the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if EEPROM interface is busy (.BUSY = 1).*
2. *r/[w]: EEPROM emulation only: write access is possible if EEPROM interface is busy (.BUSY = 1). PDI acknowledges pending commands by writing a 1 into the corresponding command register bits (.CMD_REG). Errors can be indicated by writing a 1 into the error bit .ERROR_AC. Acknowledging clears AL Event Request [5].*

EtherCAT Slave Controller (ECAT)

Register EEPROM Address (EEP_ADR)

The EEP_ADR register defines the current used EEPROM address.

ECAT0_EEP_ADR

EEPROM Address

(0504_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| EEPROM_ADDR | [31:0] | rw | EEPROM Address 0 _B First word (= 16 bits) 1 _B Second word ... Actually used EEPROM Address bits: [9:0]: EEPROM size up to 16 kBit [17:0]: EEPROM size 32 kBit – 4 Mbit [32:0]: EEPROM Emulation |

Note: r/(w): write access depends upon the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if EEPROM interface is busy (.BUSY = 1).

Register EEPROM Data (EEP_DATA)

The EEP_DATA register is used to load and store data on the EEPROM.

ECAT0_EEP_DATAx (x = 0-1)

EEPROM Data x

(0508H + x * 4)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------------|--------|------|--|
| WRITE_READ_DATA | [31:0] | rw | EEPROM Read/Write data data to be written to EEPROM or data read from EEPROM |

Note: r/(w): write access to this register depends upon the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if EEPROM interface is busy (.BUSY = 1).

EEPROM emulation with IP Core:

Note: r/[w]: write access for EEPROM emulation if read or reload command is pending. See the following information for further details:

Write access to EEPROM Data register 0x0508:0x050F is possible if EEPROM interface is busy (0x0502.15=1). PDI places EEPROM read data in this register before the pending EEPROM Read command is acknowledged (writing to 0x0502[10:8]). For Reload command: place the following information in the EEPROM Data register before acknowledging the command. This data is automatically transferred to the designated registers when the Reload command is acknowledged.

16.15.11 MII Management Interface

MI Management Interface (0510H:0515H)

Table 16-10 MII Management Interface Register Overview

| Register Address | Length (Byte) | Description |
|------------------|---------------|---------------------------------|
| 0510H:0511H | 2 | MI Management Control/Status |
| 0512H | 1 | PHY Address |
| 0513H | 1 | PHY Register Address |
| 0514H:0515H | 2 | PHY Data |
| 0516H | 1 | MI Management ECAT Access State |
| 0517H | 1 | MI Management PDI Access State |
| 0518H:051BH | 4 | PHY Port Status |

PDI controls the MI management interface if MI Management PDI Access register 0x0517.0=1, otherwise EtherCAT controls the MI management interface. Exception for ET1100: PDI controls the MI management interface if Transparent Mode is enabled.

Register MI Management Control/Status (MI_CONT_STAT)

The MI_CONT_STAT register is used to control the MI PHY interface.

ECAT0_MI_CONT_STAT

MI Management Control/Status (0510_H) **Reset Value: XXXX_H**

| | | | | | | | | | | | | | | | |
|------------|------------|----|----|------------|----|---|----------------|---|---|---|-----------------|---|-------------|------------|------------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| BUS | ERR | | | | | | | | | | | | MI_L | MIC | W_E |
| Y | OR | | | Res | | | CMD_REG | | | | PHY_ADDR | | D | PDI | N |
| r | r | | | r | | | rw | | | | r | | r | r | r |

| Field | Bits | Type | Description |
|-------------|------|------|--|
| W_EN | 0 | r | Write enable¹⁾ 0 _B Write disabled 1 _B Write enabled This bit is always 1 if PDI has MI control. |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|-----------------|---------|------|--|
| MIC_PDI | 1 | r | Management Interface can be controlled by PDI Registers 0x0516-0 x0517 0 _B Only ECAT control 1 _B PDI control possible |
| MI_LD | 2 | r | MI link detection Registers 0x0516-0 x0517 0 _B Not available 1 _B MI link detection active |
| PHY_ADDR | [7:3] | r | PHY address of port 0 PHY address of port 0-3 depending on .7 |
| CMD_REG | [9:8] | rw | Command register Write: Initiate command. Read: Currently executed command Commands: 00 _B No command/MI idle (clear error bits) 01 _B Read 10 _B Write 11 _B Reserved/invalid commands (do not issue) |
| Res | [13:10] | r | Reserved Read as 0; should be written with 0. |
| ERROR | 14 | r | Command error 0 _B Last Command was successful 1 _B Invalid command or write command without Write Enable Cleared with a valid command or by writing "00" to Command register bits [9:8]. |
| BUSY | 15 | r | Busy 0 _B MI control state machine is idle 1 _B MI control state machine is active |

1) Write enable bit 0 is self-clearing at the SOF of the next frame (or at the end of the PDI access). Command bits [9:8] are self-clearing after the command is executed (Busy ends). Writing "00" to the command register will also clear the error bits [14:13]. The Command bits are cleared after the command is executed.

Note: r/ (w): write access depends on assignment of MI (ECAT/PDI). Write access is generally blocked if Management interface is busy (.BUSY = 1.

EtherCAT Slave Controller (ECAT)

Register MII PHY Address (MII_PHY_ADR)

The MII_PHY_ADR register selects the PHY which is intended to be read/write.

ECAT0_MII_PHY_ADR

PHY Address (0512_H) **Reset Value: 00_H**

| | | | | | | | |
|------------------|------------|---|-----------------|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PHY_CADDR | Res | | PHY_ADDR | | | | |
| rw | r | | rw | | | | |

| Field | Bits | Type | Description |
|------------------|-------|------|---|
| PHY_ADDR | [4:0] | rw | PHY Address |
| Res | [6:5] | r | Reserved Read as 0; should be written with 0. |
| PHY_CADDR | 7 | rw | Show configured PHY address of port 0-3 in register [7:3]. Select port x with bits [4:0] of this register (valid values are 0-3) 0 _B Show address of port 0 (offset) 1 _B Show individual address of port x |

Note: r/ (w): write access depends on assignment of MI (ECAT/PDI). Write access is generally blocked if Management interface is busy (.BUSY = 1).

Register MII PHY Register Address (MII_PHY_REG_ADR)

The MII_PHY_REG_ADR register is used to select the register of the PHY for read/write.

ECAT0_MII_PHY_REG_ADR

PHY Register Address (0513_H) **Reset Value: 00_H**

| | | | | | | | |
|------------|---|---|---------------------|---|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | PHY_REG_ADDR | | | | |
| r | | | rw | | | | |

| Field | Bits | Type | Description |
|---------------------|-------|------|---|
| PHY_REG_ADDR | [4:0] | rw | Address of PHY Register that shall be read/written |

EtherCAT Slave Controller (ECAT)

| Field | Bits | Type | Description |
|------------|-------|------|---|
| Res | [7:5] | r | Reserved Read as 0; should be written with 0. |

Note: rr/ (w): write access depends on assignment of MI (ECAT/PDI). Write access is generally blocked if Management interface is busy (.BUSY = 1).

Register MII PHY Data (MII_PHY_DATA)

The PHY_DATA register handles the read/write data.

ECAT0_MII_PHY_DATA

PHY Data (0514_H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|---------------------|
| PHY_RW_DATA | [15:0] | rw | PHY Read/Write Data |

Note: r/ (w): write access depends on assignment of MI (ECAT/PDI). Access is generally blocked if Management interface is busy (.BUSY = 1).

EtherCAT Slave Controller (ECAT)

Register MII Management ECAT Access State (MII_ECAC_ACS_STATE)

The MII_PDI_ACS_STATE register defines the access state to the MII management for the PDI interface.

ECAT0_MII_ECAC_ACS_STATE

MII ECAT ACS STATE

(0516_H)

Reset Value: 00_H

| Field | Bits | Type | Description |
|-------------------|-------|------|--|
| EN_ACS_MII_BY_PDI | 0 | r | Access to MII management 0 _B ECAT enables PDI takeover of MII management control 1 _B ECAT claims exclusive access to MII management |
| RES | [7:1] | r | Reserved, write 0 |

EtherCAT Slave Controller (ECAT)

Register MII Management PDI Access State (MII_PDI_ACS_STATE)

The MII_PDI_ACS_STATE register defines the access state to the MII management for the PDI interface.

ECAT0_MII_PDI_ACS_STATE

MII PDI ACS STATE

(0517_H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|---|---------------------|--------------------|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RES | | | | | | FORCE_P DI_ACS_S | ACS_MII_ BY_PDI |
| r | | | | | | r | rw |

| Field | Bits | Type | Description |
|-----------------|-------|------|--|
| ACS_MII_BY_PDI | 0 | rw | Access to MII management 0 _B ECAT has access to MII management 1 _B PDI has access to MII management |
| FORCE_PDI_ACS_S | 1 | r | Force PDI Access State by ECAT master 0 _B no change 1 _B Reset Bit ACS_MII_BY_PDI |
| RES | [7:2] | r | Reserved, write 0 |

Note: r/ (w): assigning access to PDI (bit 0 = 1) is only possible if 0x0516.0=0 and 0x0517.1=0, and if the SII EEPROM is loaded (0x0110[0]=1).

16.15.12 FMMU

FMMU (0600H:06FFH)

Each FMMU entry is described in 16 Bytes from 0600H:060FH to 06F0H:06FFH. y is the FMMU index (y=0 to 15).

Table 16-11 Table 78: FMMU Register overview

| Register Address Offset | Length (Byte) | Description |
|-------------------------|---------------|------------------------|
| +0x0:0x3 | 4 | Logical Start Address |
| +0x4:0x5 | 2 | Length |
| +0x6 | 1 | Logical Start bit |
| +0x7 | 1 | Logical Stop bit |
| +0x8:0x9 | 2 | Physical Start Address |

Table 16-11 Table 78: FMMU Register overview (cont'd)

| Register Address Offset | Length (Byte) | Description |
|-------------------------|---------------|--------------------|
| +0xA | 1 | Physical Start bit |
| +0xB | 1 | Type |
| +0xC | 1 | Activate |
| +0xD:0xF | 3 | Reserved |

EtherCAT Slave Controller (ECAT)

Register Logical Start address FMMU y

The FMMU_L_START_ADRy register is used to setup the logical start address of the FMMUy within the EtherCAT Address Space.

ECAT0_FMMU_L_START_ADRy (y = 0-7)

Logical Start address FMMU (0600_H+y*10H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|---|
| L_START_ADDR | [31:0] | r | Logical start address within the EtherCAT Address Space |

EtherCAT Slave Controller (ECAT)

Register Length FMMU y

The FMMU_LENy register is used to setup the Offset from the first logical FMMU Byte to the last FMMU Byte + 1.

ECAT0_FMMU_LENy (y = 0-7)

Length FMMU y (0604_H+y*10_H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|--------|--------|------|--|
| OFFSET | [15:0] | r | Offset from the first logical FMMU Byte to the last FMMU Byte + 1 e.g., if two bytes are used then this parameter shall contain 2 |

Register Start bit FMMU y in logical address space

The FMMU_L_START_BITy register is used to setup the Logical starting bit that shall be mapped.

ECAT0_FMMU_L_START_BITy (y = 0-7)

Start bit FMMU y in logical address space (0606_H+y*10_H) **Reset Value: 00_H**

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| L_START_BIT | [2:0] | r | Logical starting bit that shall be mapped bits are counted from least significant bit (=0) to most significant bit(=7) |
| Res | [7:3] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

Register Stop bit FMMU y in logical address space

The FMMU_L_STOP_BITy register is used to setup the last logical bit that shall be mapped.

ECAT0_FMMU_L_STOP_BITy (y = 0-7)

Stop bit FMMU y in logical address space ($0607_H + y * 10_H$)

Reset Value: 00_H

| Field | Bits | Type | Description |
|------------|-------|------|--|
| L_STOP_BIT | [2:0] | r | Last logical bit that shall be mapped bits are counted from least significant bit (=0) to most significant bit(=7) |
| Res | [7:3] | r | Reserved Read as 0; should be written with 0. |

Register Physical Start address FMMU y

The FMMU_P_START_ADDRy register is used to setup the physical start address.

ECAT0_FMMU_P_START_ADDRy (y = 0-7)

Physical Start address FMMU y ($0608_H + y * 10_H$)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| P_START_ADDR | [15:0] | r | Physical Start Address mapped to logical Start address |

Register Physical Start bit FMMU y

The FMMU_P_START_BITy register is used to setup the Physical starting bit as target of logical start bit mapping.

ECAT0_FMMU_P_START_BITy (y = 0-7)

Physical Start bit FMMU y (060A_H+y*10H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|-------------|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | P_START_BIT | | |
| r | | | | | r | | |

| Field | Bits | Type | Description |
|-------------|-------|------|---|
| P_START_BIT | [2:0] | r | Physical starting bit as target of logical start bit mapping bits are counted from least significant bit (=0) to most significant bit(=7) |
| Res | [7:3] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

Register Type FMMU y

The FMMU_TYPEy register is used to select if the mapping is used for read/write access.

ECAT0_FMMU_TYPEy (y = 0-7)

Type FMMU y

(060B_H+y*10H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|---|-------|-------|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | W_ACC | R_ACC |
| r | | | | | | r | r |

| Field | Bits | Type | Description |
|-------|-------|------|--|
| R_ACC | 0 | r | Read Access 0 _B Ignore mapping for read accesses 1 _B Use mapping for read accesses |
| W_ACC | 1 | r | Write Access 0 _B Ignore mapping for write accesses 1 _B Use mapping for write accesses |
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

EtherCAT Slave Controller (ECAT)

Register Activate FMMU y

The FMMU_ACTIVATEy register shows if the FMMU is enabled by the EtherCAT master.

ECAT0_FMMU_ACTy (y = 0-7)

Activate FMMU y (060C_H+y*10H) **Reset Value: 00_H**

| | | | | | | | |
|-----|---|---|---|---|---|---|-----|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | | | | ACT |
| r | | | | | | | r |

| Field | Bits | Type | Description |
|-------|-------|------|--|
| ACT | 0 | r | FMMU Activation 0 _B FMMU deactivated. 1 _B FMMU activated. FMMU checks logical addressed blocks to be mapped according to mapping configured |
| Res | [7:1] | r | Reserved Read as 0; should be written with 0. |

16.15.13 SyncManager

SyncManager (0x0800:0x087F)

SyncManager registers are mapped from 0x0800:0x0807 to 0x0818:0x087F.
 x specifies SyncManager (x=0 to 15).

Table 16-12 SyncManager Register overview

| Register Address Offset | Length (Byte) | Description |
|-------------------------|---------------|------------------------|
| +0x0:0x1 | 2 | Physical Start Address |
| +0x2:0x3 | 2 | Length |
| +0x4 | 1 | Control Register |
| +0x5 | 1 | Status Register |
| +0x6 | 1 | Activate |
| +0x7 | 1 | PDI Control |

Register physical Start Address SyncManager x

The SM_P_START_ADRx register is used to setup the first byte that will be handled by SyncManager.

ECAT0_SM_P_START_ADRx (x = 0-7)

Physical Start Address SyncManager x ($0800_H + x * 8_H$)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|------------|--------|------|--|
| FIRST_BYTE | [15:0] | r | Specifies first byte that will be handled by SyncManager |

EtherCAT Slave Controller (ECAT)

Register Length SyncManager x

The SM_LENx register is used to setup the number of bytes assigned to the SyncManager.

ECAT0_SM_LENx (x = 0-7)

Length SyncManager x

(0802_H+x*8_H)

Reset Value: 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| NO_BYTES | [15:0] | r | Number of bytes assigned to SyncManager shall be greater 1, otherwise SyncManager is not activated. If set to 1, only Watchdog Trigger is generated if configured |

EtherCAT Slave Controller (ECAT)
Register Control Register SyncManager x

The SM_CONTROLx register is used to configure the SyncManager.

ECAT0_SM_CONTROLx (x = 0-7)
Control Register SyncManager x (0804_H+x*8_H)
Reset Value: 00_H

| | | | | | | | |

PDI register function acknowledge by Write command is disabled: Reading this register from PDI in all SyncManagers which have changed activation clears AL Event Request 0x0220[4]. Writing to this register from PDI is not possible.

PDI register function acknowledge by Write command is enabled: Writing this register from PDI in all SyncManagers which have changed activation clears AL Event Request 0x0220[4]. Writing to this register from PDI is possible; write value is ignored (write 0).

EtherCAT Slave Controller (ECAT)
Register PDI Control SyncManager x

The SM_PDI_CTRx register is used for the PDI to control the SyncManager.

ECAT0_SM_PDI_CTRx (x = 0-7)
PDI Control SyncManager x (0807_H+x*8_H)

Reset Value: 00_H

| | | | | | | | |

| DEACT | 0 | rw | Deactivate SyncManager 0 _B Read 0 for Normal operation, SyncManager activated, write 0 for Activate SyncManager 1 _B Read 1 for SyncManager deactivated and reset SyncManager locks access to Memory area, write 1 for Request SyncManager deactivation <i>Note: Writing 1 is delayed until the end of a frame which is currently processed.</i> |
| REP_ACK | 1 | rw | Repeat Ack If this is set to the same value as set by Repeat Request, the PDI acknowledges the execution of a previous set Repeat request. |
| Res | [7:2] | r | Reserved Read as 0; should be written with 0. |

16.15.14 DC – Receive Times

Register Receive Time Port 0 (DC_RCV_TIME_PORT0)

The DC_RCV_TIME_PORT register is used to latch the local time of the beginning of the last receive frame.

ECAT0_DC_RCV_TIME_PORT0

Receive Time Port 0

(0900_H)

Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| LOCAL_TIME_P0 | [31:0] | r | Write by EtherCAT master A write access to register 0x0900 with BWR or FPWR latches the local time of the beginning of the receive frame (start first bit of preamble) at each port. Read Local time of the beginning of the last receive frame containing a write access to this register. |

Note: The time stamps cannot be read in the same frame in which this register was written.

EtherCAT Slave Controller (ECAT)

Register Receive Time Port 1 (DC_RCV_TIME_PORT1)

The DC_RCV_TIME_PORT register show the Local time of the beginning of a frame received at port 1.

ECAT0_DC_RCV_TIME_PORT1

Receive Time Port 1 (0904_H) Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|---------------|--------|------|--|
| LOCAL_TIME_P1 | [31:0] | r | Local time of the beginning of a frame (start first bit of preamble) received at port 1 containing a BWR or FPWR to Register 0x0900. |

16.15.15 Time Loop Control Unit

Time Loop Control unit is usually assigned to ECAT. Write access to Time Loop Control registers by PDI (and not ECAT) is only possible with explicit IP Core configuration.

Register Receive Time ECAT Processing Unit (RECEIVE_TIME_PU)

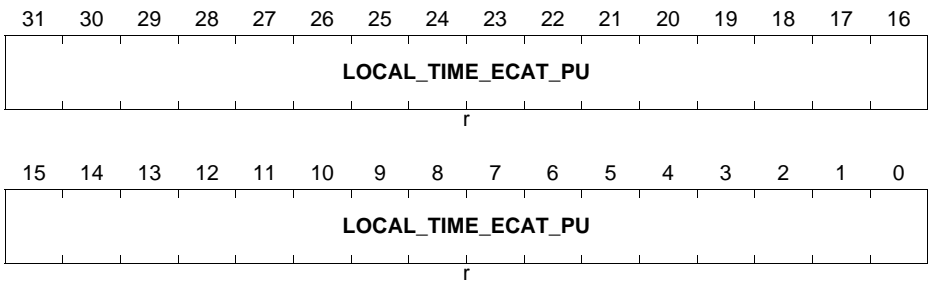

The xxx register is used show the Local time of the beginning of a frame received at the ECAT Processing Unit.

ECAT0_RECEIVE_TIME_PUx (x = 0-1)

Receive Time PU x

(918H + x *4)

Reset Value: XXXX XXXX_H

| Field | Bits | Type | Description |
|--------------------|--------|------|--|
| LOCAL_TIME_ECAT_PU | [31:0] | r | Local time of the beginning of a frame (start first bit of preamble) received at the ECAT Processing Unit containing a write access to Register 0x0900 |

Register System Time - Read

The DC_SYS_TIME register is used as a local copy of the actual system time latched by reading the first byte.

ECAT0_DC_SYS_TIME_x (x = 0-1)

System Time [READ Mode] x

(0910H + x *4)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|----------------------|--------|------|---|
| SYSTEM_TIME_L | [31:0] | r | System Time read access Local copy of the System Time. Time latched when reading first byte of this register. |

Note: E.g., if port 0 is open, this registers reflects the Receive Time Port 0 as a 64-bit value.

Register System Time - Write

The DC_SYS_TIME register is used to compared with Latch0 Time Positive Edge time.

ECAT0_DC_SYS_TIME

System Time [WRITE Mode] (0910_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|--------------|--------|------|--|
| WRITE_ACCESS | [31:0] | w | Write access Written value will be compared with Latch0 Time Positive Edge time. The result is an input to the time control loop. <i>Note: written value will be compared at the end of the access with Latch0 Time Positive Edge (0x09B0:0x09B3) if at least the last byte (0x0913) was written.</i> |

Notes

1. Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled).
2. Register 0x0918:0x091F is described in the previous chapter.

Register System Time Offset (DC_SYS_TIME_OFFSET)

The DC_SYS_TIME_OFFSET register is used to setup the difference between local time and System Time.

ECAT0_DC_SYS_TIME_OFFSETx (x = 0-1)

System Time Offset x

(920H + x * 4)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| TIME_DIFF | [31:0] | rw | Difference between local time and System Time Offset is added to the local time. |

Note: Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled). Reset internal system time difference filter and speed counter filter by writing Speed Counter Start (0x0930:0x0931) after changing this value.

EtherCAT Slave Controller (ECAT)

Register System Time Delay (DC_SYS_TIME_DELAY)

The DC_SYS_TIME_DELAY register is used to setup the delay between Reference Clock and the ESC.

ECAT0_DC_SYS_TIME_DELAY

System Time Delay (0928_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------|--------|------|---|
| CLK_DELAY | [31:0] | rw | Delay between Reference Clock and the ESC |

Note: Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled). Reset internal system time difference filter and speed counter filter by writing Speed Counter Start (0x0930:0x0931) after changing this value.

Register System Time Difference (DC_SYS_TIME_DIFF)

The DC_SYS_TIME_DIFF register show the difference between local copy of System Time and received System Time values.

ECAT0_DC_SYS_TIME_DIFF

System Time Difference (092C_H) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---|
| TIME_DIF | [30:0] | r | Mean difference between local copy of System Time and received System Time values |
| CPY | 31 | r | Local copy of System Time 0 _B Greater than or equal received System Time 1 _B Smaller than received System Time |

EtherCAT Slave Controller (ECAT)

Register Speed Counter Start (DC_SPEED_COUNT_START)

The DC_SPEED_COUNT_START register is used for Bandwidth for adjustment of local copy of System Time.

ECAT0_DC_SPEED_COUNT_START

Speed Counter Start (0930_H) **Reset Value: 1000_H**

| Field | Bits | Type | Description |
|-------------|--------|------|--|
| COUNT_START | [14:0] | rw | Bandwidth for adjustment of local copy of System Time (larger values → smaller bandwidth and smoother adjustment) A write access resets System Time Difference (0x092C:0x092F) and Speed Counter Diff (0x0932:0x0933). Minimum value: 0x0080 to 0x3FFF |
| Res | 15 | r | Reserved Read as 0; should be written with 0. |

Note: Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled).

Register Speed Counter Diff (DC_SPEED_COUNT_DIFF)

The DC_SPEED_COUNT_DIFF register is show the deviation between local clock period and Reference Clock's clock period.

ECAT0_DC_SPEED_COUNT_DIFF

Speed Counter Diff (0932_H) **Reset Value: 0000_H**

| Field | Bits | Type | Description |
|-----------|--------|------|--|
| DEVIATION | [15:0] | r | Representation of the deviation between local clock period and Reference Clock's clock period (representation: two' s complement) Range: ± (Speed Counter Start – 0x7F) |

Note: Calculate the clock deviation after System Time Difference has settled at a low value as follows:

$$\text{Deviation} = \text{Speed Counter Diff} / 5 * (\text{Speed Counter Start} + \text{Speed Counter Diff} + 2) * (\text{Speed Counter Start} - \text{Speed Counter Diff} + 2)$$

EtherCAT Slave Controller (ECAT)

Register System Time Difference Filter Depth (DC_SYS_TIME_FIL_DEPTH)

The DC_SYS_TIME_FIL_DEPTH register is used to setup the Filter depth for averaging the received System Time deviation.

ECAT0_DC_SYS_TIME_FIL_DEPTH

System Time Difference Filter Depth

(0934_H)

Reset Value: 04_H

| Field | Bits | Type | Description |
|--------------|-------|------|---|
| FILTER_DEPTH | [3:0] | rw | Filter depth for averaging the received System Time deviation |
| Res | [7:4] | r | Reserved Read as 0; should be written with 0. |

Notes

1. Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled).
2. Reset System Time Difference by writing Speed Counter Start (0x0930:0x0931) after changing this value.

EtherCAT Slave Controller (ECAT)

Register Speed Counter Filter Depth (DC_SPEED_COUNT_FIL_DEPTH)

The DC_SPEED_COUNT_FIL_DEPTH register is used to setup the Filter depth for averaging the clock period deviation.

ECAT0_DC_SPEED_COUNT_FIL_DEPTH

Speed Counter Filter Depth (0935_H)

Reset Value: 0C_H

| | | | | | | | |
|-----|---|---|---|--------------|---|---|---|
| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Res | | | | FILTER_DEPTH | | | |
| r | | | | rw | | | |

| Field | Bits | Type | Description |
|---------------------|-------|------|--|
| FILTER_DEPTH | [3:0] | rw | Filter depth for averaging the clock period deviation |
| Res | [7:4] | r | Reserved Read as 0; should be written with 0. |

Notes

1. Write access to this register depends upon ESC configuration (typically ECAT, PDI only with explicit ESC configuration: System Time PDI controlled) .
2. Reset internal speed counter filter by writing Speed Counter Start (0x0930:0x0931) after changing this value.

Register Cyclic Unit Control

The DC_CYC_CONT register show the control setup for the Sync and Latch Units.

ECAT0_DC_CYC_CONT
Cyclic Unit Control
(0980_H)
Reset Value: 00_H

| | | | | | | | |

|----------|-------|------|--|
| SYNC_OUT | 0 | rw | Sync Out Unit activation 0 _B Deactivated 1 _B Activated |
| SYNC_0 | 1 | rw | SYNC0 generation 0 _B Deactivated 1 _B SYNC0 pulse is generated |
| SYNC_1 | 2 | rw | SYNC1 generation 0 _B Deactivated 1 _B SYNC1 pulse is generated |
| Res | [7:3] | r | Reserved Read as 0; should be written with 0. |

Note: Write to this register depends upon setting of .SYNC

EtherCAT Slave Controller (ECAT)

Register Pulse Length of SyncSignals (DC_PULSE_LEN)

The DC_PULSE_LEN register is show the used Puls length of the SYNC signals. The value is configured by EEPROM

ECAT0_DC_PULSE_LEN

Pulse Length of SyncSignals

(0982_H)

Reset Value: XXXX_H

| Field | Bits | Type | Description |
|-------------|--------|------|---|
| PULS_LENGTH | [15:0] | r | Pulse length of SyncSignals (in Units of 10 ns) loaded by EEPROM ADR 0x0002 0 _B Acknowledge mode: SyncSignal will be cleared by reading SYNC[1:0] Status register |

EtherCAT Slave Controller (ECAT)

Register Activation Status (DC_ACT_STAT)

The DC_SYNC0_STAT register shows the activation status.

ECAT0_DC_ACT_STAT

Activation Status

(0984_H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|--------|--------------|--------------|

| Res | [7:1] | r | Reserved Read as 0; should be written with 0. |

Notes

1. PDI register function acknowledge by Write command is disabled: Reading this register from PDI clears AL Event Request 0x0220[3]. Writing to this register from PDI is not possible.
2. PDI register function acknowledge by Write command is enabled: Writing this register from PDI clears AL Event Request 0x0220[3]. Writing to this register from PDI is possible; write value is ignored (write 0).

Register Start Time Cyclic Operation (DC_CYC_START_TIME)

The DC_CYC_START_TIME register is used to setup cyclic operations in relation to the system time.

ECAT0_DC_CYC_START_TIME_x (x = 0-1)

Start Time Cyclic Operation x (0990H + x *4) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-------|--------|------|--|
| TIME | [31:0] | rw | Write Start time (System time) of cyclic operation in ns. Read System time of next SYNC0 pulse in ns. |

Note: Write to this register depends upon setting of 0x0980.0. Only writable if 0x0981.0=0. Auto-activation (0x0981.3=1): upper 32 bits are automatically extended if only lower 32 bits are written within one frame.

Register Next SYNC1 Pulse (DC_NEXT_SYNC1_PULSE)

The DC_NEXT_SYNC1_PULSE register show the system time for the next SYNC1 puls

ECAT0_DC_NEXT_SYNC1_PULSE_x (x = 0-1)

Next SYNC1 Pulse x (0998H + x *4) Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|-----------------|--------|------|---------------------------------------|
| TIME_NEXT_SYNC1 | [31:0] | r | System time of next SYNC1 pulse in ns |

Register SYNC0 Cycle Time (DC_SYNC0_CYC_TIME)

The DC_SYNC0_CYC_TIME register is to setup the Time between two consecutive SYNC0 pulses.

ECAT0_DC_SYNC0_CYC_TIME

SYNC0 Cycle Time (09A0_H) **Reset Value: 0000 0000_H**

| Field | Bits | Type | Description |
|--------------------|--------|------|---|
| TIME_BETWEEN_SYNC0 | [31:0] | rw | Time between two consecutive SYNC0 pulses in ns 0 _B Single shot mode, generate only one SYNC0 pulse |

Note: Write to this register depends upon setting of 0x0980.0.

EtherCAT Slave Controller (ECAT)

Register SYNC1 Cycle Time (DC_SYNC1_CYC_TIME)

The DC_SYNC1_CYC_TIME register is used to setup the Time between SYNC1 pulses and SYNC0 pulse.

ECAT0_DC_SYNC1_CYC_TIME

SYNC1 Cycle Time (09A4_H)

Reset Value: 0000 0000_H

| Field | Bits | Type | Description |
|------------------|--------|------|---|
| TIME_SYNC1_SYNC0 | [31:0] | rw | Time between SYNC1 pulses and SYNC0 pulse in ns |

Note: Write to this register depends upon setting of 0x0980.0.

EtherCAT Slave Controller (ECAT)

Register Latch0 Control (DC_LATCH0_CONT)

The DC_LATCH0_CONT register is used to setup LATCH0.

ECAT0_DC_LATCH0_CONT

Latch0 Control

(09A8_H)

Reset Value: 00_H

| | | | | | | | |
|-----|---|---|---|---|---|--------|--------|

17 Universal Serial Bus (USB)

The USB module is a Dual-Role Device (DRD) controller that supports both device and host functions and complies fully with the On-The-Go Supplement to the USB 2.0 Specification, Revision 1.3. It can also be configured as a host-only or device-only controller, fully compliant with the USB 2.0 Specification.

The USB core's USB 2.0 configurations support full-speed (12-Mbps) transfers.

The USB core is optimized for the following applications and systems:

- Portable electronic devices
- Point-to-point applications (direct connection to FS device)

References:

[18] USB 2.0 specification (April 27, 2000).

[19] On-The-Go Supplement to the USB 2.0 specification (Revision 1.3, December 5, 2006).

Table 17-1 Abbreviations

| | |
|-------|-------------------------|
| DWORD | 32-bit Data Word |
| DRD | Dual-Role Device |
| FS | Full Speed |
| MAC | Media Access Controller |
| OTG | On-The-Go |
| PHY | Physical Layer |
| SOF | Start of Frame |

17.1 Overview

This section describes the features and provides a block diagram of the USB module.

17.1.1 Features

The USB module includes the following features:

- Complies with the USB 2.0 Specification
- Complies with the On-The-Go Supplement to the USB 2.0 Specification (Revision 1.3)
- Configurable as Device only, Host only or as an OTG Dual Role Device
- Support for the Full-Speed (12-Mbps) mode
- Provides a USB OTG FS PHY interface
- Supports up to 7 bidirectional endpoints, including control endpoint 0

Universal Serial Bus (USB)

- Supports up to 14 Host channels
- Supports Session Request Protocol (SRP).
- Supports Host Negotiation Protocol (HNP).
- Supports SOFs in Full-Speed modes.
- Supports clock gating for power saving
- Supports USB suspend/resume
- Supports USB soft disconnect
- Supports DMA mode in:
 - Descriptor-Based Scatter/Gather DMA operation
 - Buffer DMA operation
- 2 Kbytes of RAM for data FIFO consisting of 512 DWORDs
- Dedicated transmit FIFO for each of the device IN endpoints in Slave and DMA modes. Each FIFO can hold multiple packets.
- Supports packet-based, Dynamic FIFO memory allocation for endpoints for small FIFOs and flexible, efficient use of RAM.
- Provides support to change an endpoint's FIFO memory size during transfers.
- Supports endpoint FIFO sizes that are not powers of 2, to allow the use of contiguous memory locations.

17.1.2 Block Diagram

Figure 17-1 shows the USB module block diagram.

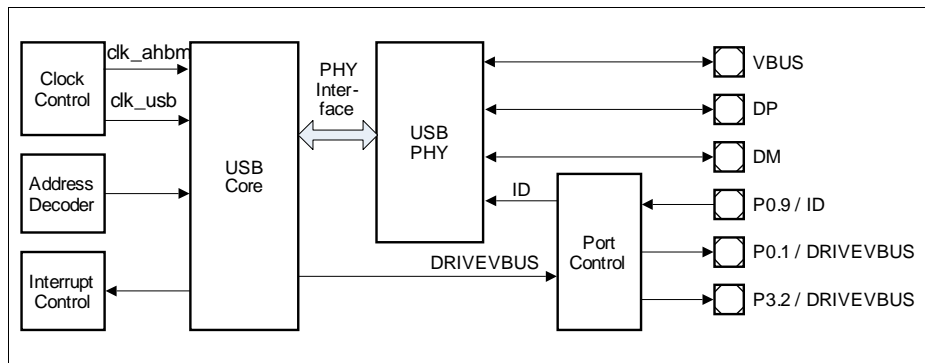

Figure 17-1 USB Module Block Diagram

17.2 Functional Description

This chapter describes the operation modes and the FIFO architecture of the USB module.

17.2.1 OTG Dual-Role Device (DRD)

The OTG DRD provides both Host and Device functions and supports the Host Negotiation Protocol (HNP) and Session Request Protocol (SRP). It is able to detect whether an A- or B-device is connected by sampling the ID input signal.

To drive the VBUS as an A-device, the OTG DRD requires an external charge pump, which is enabled through the output signal DRIVEBUS.

Figure 17-2 shows the connections of the DRD.

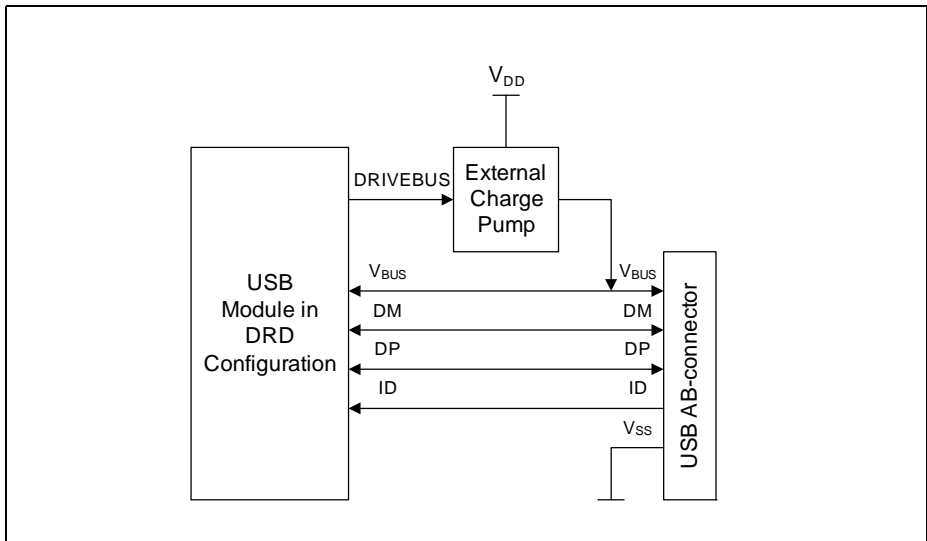

Figure 17-2 OTG DRD Connections

17.2.2 USB Host

The USB Host supports up to 14 Host channels, each configurable for the transfer type (Control, Bulk, Interrupt, or Isochronous) and direction (IN or OUT). To drive the VBUS, it requires an external charge pump, which is enabled through the output signal DRIVEBUS.

Figure 17-3 shows the connections of the USB Host.

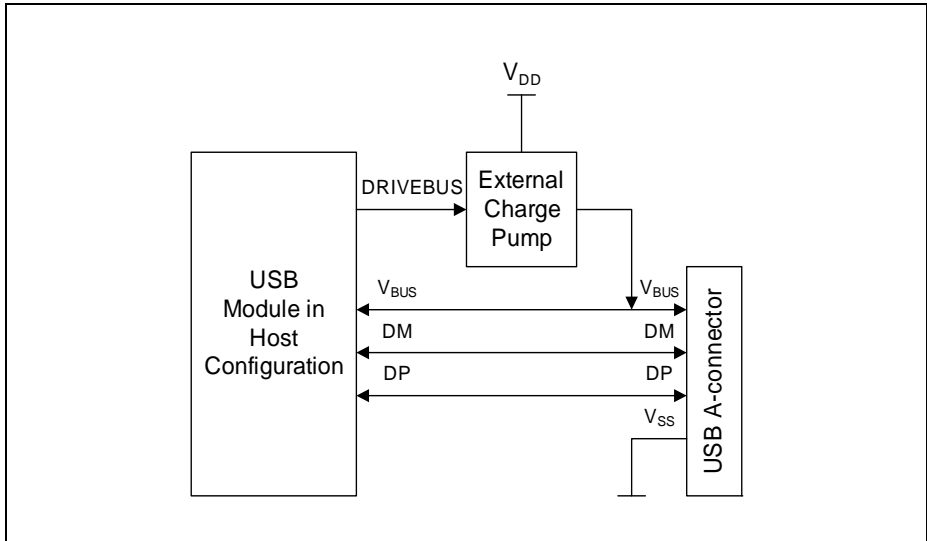

Figure 17-3 USB Host Connections

17.2.3 USB Device

The USB Device supports Control transfers through the bidirectional endpoint 0, and Bulk, Interrupt or Isochronous transfers configurable from within the other 6 bidirectional endpoints. Being a self-powered device, it does not require an additional external voltage regulator.

Software can disconnect the USB Device from the USB through the DCTL.SftDiscon bit.

Figure 17-4 shows the connections of the USB Device.

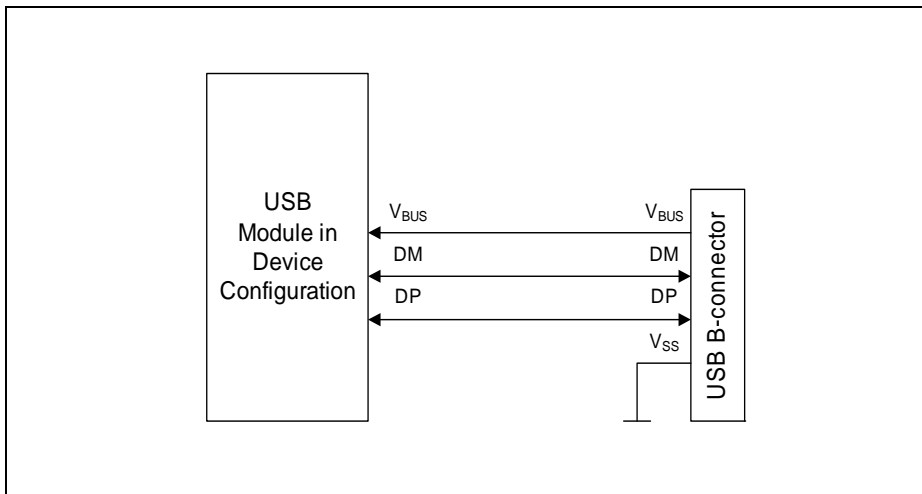

Figure 17-4 USB Device Connections

17.2.4 FIFO Architecture

This section describes the FIFO architecture in a USB Host and Device.

17.2.4.1 Host FIFO Architecture

The host uses one transmit FIFO for all non-periodic OUT transactions and one transmit FIFO for all periodic OUT transactions (periodic FIFOs 2 to n are only used in Device mode, where n is number of periodic IN endpoints in Device mode). These transmit FIFOs are used as transmit buffers to hold the data (payload of the transmit packet) to be transmitted over USB. The host pipes the USB transactions through Request queues (one for periodic and one for non-periodic). Each entry in the Request queue holds the IN or OUT channel number along with other information to perform a transaction on the USB. The order in which the requests are written into the queue determines the sequence of transactions on the USB. The host processes the periodic Request queue first, followed by the non-periodic Request queue, at the beginning of each frame.

The host uses one receive FIFO for all periodic and non-periodic transactions. The FIFO is used as a receive buffer to hold the received data (payload of the received packet) from the USB until it is transferred to the system memory. The status of each packet received also goes into the FIFO. The status entry holds the IN channel number along with other information, such as received byte count and validity status, to perform a transaction on the AHB.

17.2.4.2 Device FIFO Architecture

This section describes the USB device FIFO architecture.

Dedicated Transmit FIFO Operation

The core uses individual transmit FIFOs for each IN endpoint.

The core internally handles underrun condition during transmit and corrupts the packet (inverts the CRC) on the USB. If packet transmission results in an underrun condition (eventually resulting in packet corruption on the USB), the host can time out the endpoint after three consecutive errors.

Single Receive FIFO

The USB device uses a single receive FIFO to receive the data for all the OUT endpoints. The receive FIFO holds the status of the received data packet, such as byte count, data PID and the validity of the received data. The DMA or the application reads the data out of the receive FIFO as it is received.

17.3 Programming Overview

This section provides an overview of the programming options available in the USB core in different modes of operation.

17.3.1 Programming Options on DMA

The application can operate the core in either of two modes:

- In **DMA Mode** — the core fetches the data to be transmitted or updates the received data on the AHB.
- In **Slave Mode** — the application initiates the data transfers for data fetch and store.

The application cannot operate the core using a combination of DMA and Slave simultaneously. The application can operate the DMA in:

- Scatter/Gather mode (a Descriptor-Based mode).
- Buffer-pointer based mode.

17.3.1.1 DMA Mode

In this mode, the OTG host uses the AHB master Interface for transmit packet data fetch (AHB to USB) and receive data update (USB to AHB). The AHB master uses the programmed DMA address (HCDMAx register in host mode and DIEPDMAx/DOEPDMAx register in device mode) to access the data buffers.

Transfer-Level Operation

In DMA mode, the application is interrupted only after the programmed transfer size is transmitted or received (provided the USB core detects no NAK/NYET/Timeout/Error response in Host mode, or Timeout/CRC Error in Device mode). The application must handle all transaction errors. In Device mode with dedicated FIFOs, all the USB errors are handled by the core itself.

Transaction-Level Operation

This mode is similar to transfer-level operation with the programmed transfer size equal to one packet size (either maximum packet size, or a short packet size). When Scatter/Gather DMA is enabled, the transfer size is extracted from the descriptors.

17.3.1.2 Slave Mode

In Slave mode, the application can operate the USB core either in transaction-level (packet-level) operation or in pipelined transaction-level operation.

Transaction-Level Operation

The application handles one data packet at a time per channel/endpoint in transaction-level operations. Based on the handshake response received on the USB, the application determines whether to retry the transaction or proceed with the next, until the end of the transfer. The application is interrupted on completion of every packet. The application performs transaction-level operations for a channel/endpoint for a transmission (host: OUT/ device: IN) or reception (host: IN / device: OUT) as shown in [Figure 17-5](#) and [Figure 17-6](#).

Transaction-Level Operation: Host Mode

For an OUT transaction, the application enables the channel and writes the data packet into the corresponding (Periodic or Non-periodic) transmit FIFO. The USB core automatically writes the channel number into the corresponding (Periodic or Non-periodic) Request Queue, along with the last DWORD write of the packet.

For an IN transaction, the application enables the channel and the USB core automatically writes the channel number into the corresponding Request queue. The application must wait for the packet received interrupt, then empty the packet from the receive FIFO.

Transaction-Level Operation: Device Mode

For an IN transaction, the application enables the endpoint, writes the data packet into the corresponding transmit FIFO, and waits for the packet completion interrupt from the core.

For an OUT transaction, the application enables the endpoint, waits for the packet received interrupt from the core, then empties the packet from the receive FIFO.

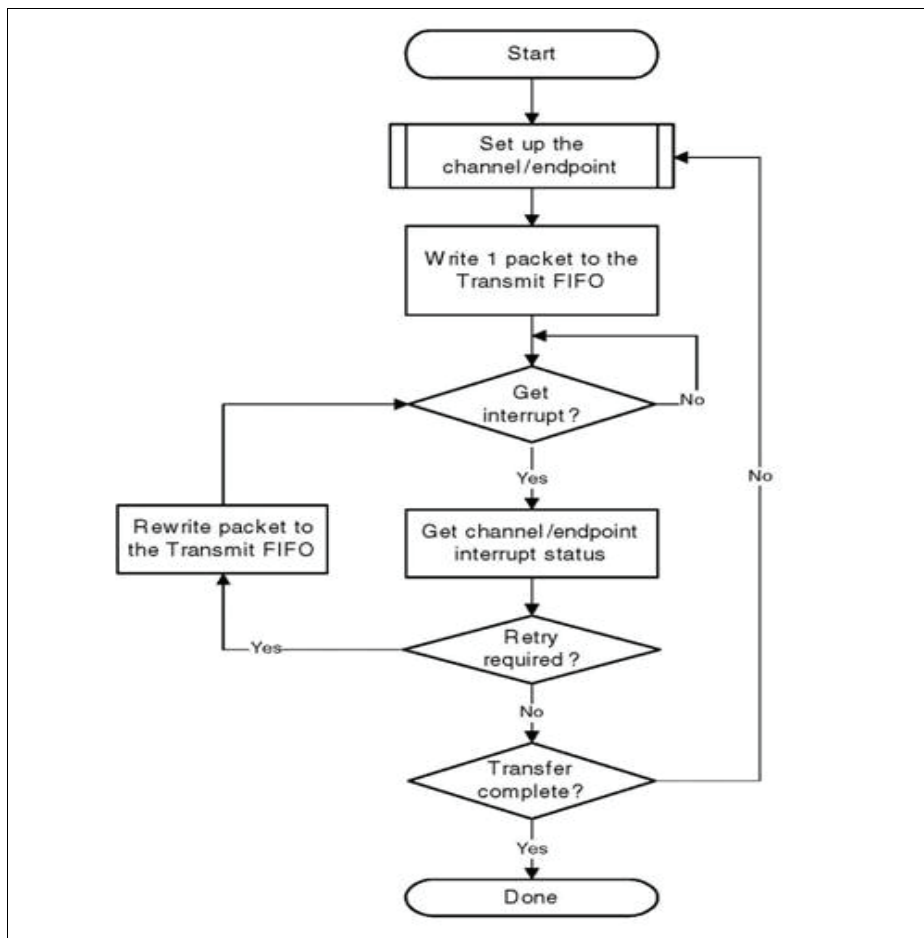

Figure 17-5 Transmit Transaction-Level Operation in Slave Mode

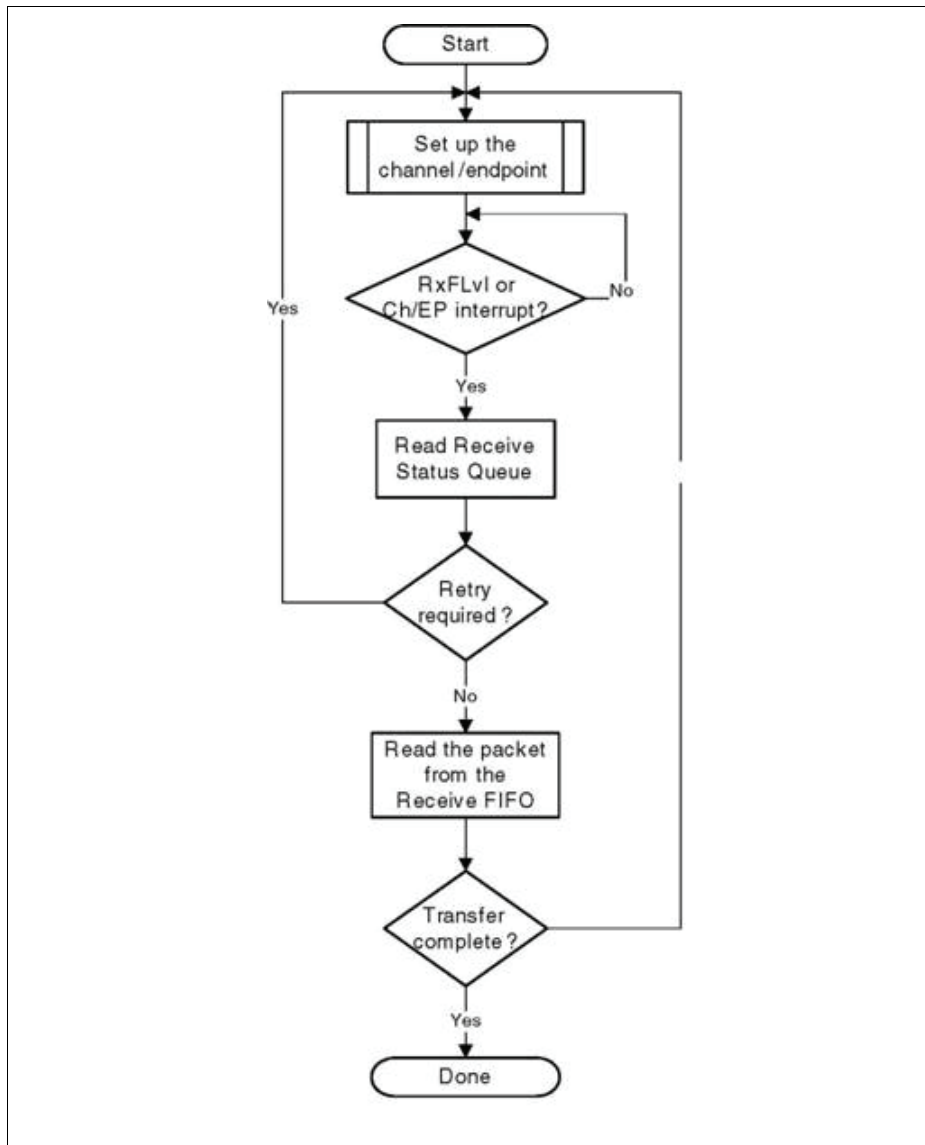

Figure 17-6 Receive Transaction-Level Operation in Slave Mode

Note: The application has to finish writing one complete packet before switching to a different channel/endpoint FIFO. Violating this rule results in an error.

Pipelined Transaction-Level Operation

The application can pipeline more than one transaction (IN or OUT) with pipelined transaction-level operation, which is analogous to Transfer mode in DMA mode. In pipelined transaction-level operation, the application can program the core to perform multiple transactions. The advantage of this mode compared to transaction-level operation is that the application is not interrupted on a packet basis.

Pipelined Transaction-Level Operation: Host Mode

For an OUT transaction, the application sets up a transfer and enables the channel. The application can write multiple packets back-to-back for the same channel into the transmit FIFO, based on the space availability. It can also pipeline OUT transactions for multiple channels by writing into the HCHARn register, followed by a packet write to that channel. The core writes the channel number, along with the last DWORD write for the packet, into the Request queue and schedules transactions on the USB in the same order.

For an IN transaction, the application sets up a transfer and enables the channel, and the USB core writes the channel number into the Request queue. The application can schedule IN transactions on multiple channels, provided space is available in the Request queue. The core initiates an IN token on the USB only when there is enough space to receive at least of one maximum-packet-size packet of the channel in the top of the Request queue.

Pipelined Transaction-Level Operation: Device Mode

For an IN transaction, the application sets up a transfer and enables the endpoint. The application can write multiple packets back-to-back for the same endpoint into the transmit FIFO, based on available space. It can also pipeline IN transactions for multiple channels by writing into the DIEPCTLx register followed by a packet write to that endpoint. The core writes the endpoint number, along with the last DWORD write for the packet into the Request queue. The core transmits the data in the transmit FIFO when an IN token is received on the USB.

For an OUT transaction, the application sets up a transfer and enables the endpoint. The core receives the OUT data into the receive FIFO, when it has available space. As the packets are received into the FIFO, the application must empty data from it.

From this point on in this chapter, the terms "Pipelined Transaction mode" and "Transfer mode" are used interchangeably.

17.3.2 Core Initialization

If the cable is connected during power-up, the Current Mode of Operation bit in the Core Interrupt register (GINTSTS.CurMod) reflects the mode. The USB core enters Host mode when an "A" plug is connected, or Device mode when a "B" plug is connected.

Universal Serial Bus (USB)

This section explains the initialization of the USB core after power-on. The application must follow the initialization sequence irrespective of Host or Device mode operation.

1. Program the following fields in the Global AHB Configuration (GAHB_CFG) register.
 - a) DMA Mode bit
 - b) AHB Burst Length field
 - c) Global Interrupt Mask bit = 1
 - d) RxFIFO Non-Empty (GINTSTS.RxFLVL) (applicable only when the core is operating in Slave mode)
 - e) Non-periodic TxFIFO Empty Level (can be enabled only when the core is operating in Slave mode as a host.)
 - f) Periodic TxFIFO Empty Level (can be enabled only when the core is operating in Slave mode)
2. Program the following fields in GUSBCFG register.
 - a) HNP Capable bit
 - b) SRP Capable bit
