IR21571: Dual Lamp Ballast: Parallel Configuration

By T. Ribarich, E. Thompson, A. Mathur, International Rectifier

Table of Contents

Driving two lamps in parallel results in lower voltage stress on the ballast output stage components, the wiring, and the fixture sockets. Additionally, the resonant L and C associated with the lamps will be less sensitive to component tolerances due to the lower running lamp voltages compared to the series configuration. For these reasons, the parallel configuration is becoming more popular. The IR21571 can be used in a ballast to control parallel lamp configurations. Through externally programmable components, the IR21571 affords flexibility of various features such as preheat time and frequency, ignition ramp characteristics, and running mode operating frequency. Comprehensive protection features protect the circuit against conditions such as lamp strike failures, filament failures, low DC bus, thermal overload, and ramp failure during normal operation. **Two variations of this circuit are included in this application note. The first one switches off both lamps when one is taken out, and automatically restarts when both lamps are in place. The second variation allows one lamp to remain running when the other is removed. When the lamp is reinserted, the ballast restarts in the pre-heat mode.**

IR21571: Dual Lamp Ballast: Parallel Configuration

By T. Ribarich, E. Thompson, A. Mathur, International Rectifier

TOPICS COVERED

INTRODUCTION

Driving two lamps in parallel results in lower voltage stress on the ballast output stage components, the wiring, and the fixture sockets. Additionally, the resonant L and C associated with the lamps will be less sensitive to component tolerances due to the lower running lamp voltages compared to the series configuration. For these reasons, the parallel configuration is becoming more popular. The IR21571 can be used in a ballast to control parallel lamp configurations. Through externally programmable components, the IR21571 affords flexibility of various features such as preheat time and frequency, ignition ramp characteristics, and running mode operating frequency. Comprehensive protection features protect the circuit against conditions such as lamp strike failures, filament failures, low DC bus, thermal overload, and ramp failure during normal operation. ***Two variations of this circuit are included in this application note. The first one switches off both lamps when one is taken out, and automatically restarts when both lamps are in place. The second variation allows one lamp to remain running when the other is removed. When the lamp is reinserted, the ballast restarts in the pre-heat mode.***

FUNCTIONAL DESCRIPTION (Variation I: Both lamps turn off when one is removed)

The output stage circuitry for a dual lamp configuration is shown in Figure 1. This is the portion of the ballast that is controlled by the IR21571. The design is similar to that for a single lamp; with the addition of a second lamp resonant circuit connected in parallel. The second lamp in parallel is connected in a manner that mirrors the immediate circuitry surrounding the first bulb. This provides the exact same resonant L and C, and basic protective circuitry for both bulbs due to their parallel setting. Protective features include DC Bus Voltage Detection and Half Bridge Current Sensing and Protection. (For additional information on these protective features please see Page 2 of the IR21571 datasheet.) Lamp detection and automatic restart work similarly to a single lamp configuration. Both lower filament sensing networks are OR-ed into the SD pin through resistors R17A and R17B. If either lamp is removed, the SD pin is pulled above the internal turn-off threshold of 2V, and the half-bridge is disabled. When both lamps are in place, the shutdown pin falls below the internal 1.7V threshold and the IC re-initiates the preheat sequence

Note: Thick traces represent high-frequency, high-current paths. Lead lengths should be minimized to avoid high-frequency noise problems

MEASUREMENTS (VARIATION I: Both lamps turn off when one is removed)

The waveforms shown in Figures 2 and 3 were captured during the ignition mode. They are similar for either lamp in the parallel configuration. Dummy filament resistors have been inserted to simulate a lamp non-strike fault condition. This forces the over-current threshold of the IR21571 to be exceeded during igntion mode and the half bridge is disabled. It is at this time that maximum inductor current and lamp voltage are measured. Figures 4 and 5 show the filament current and lamp voltage during preheat and igntion modes. Figures 6 and 7 show the filament current and lamp voltage during preheat, ignition and run modes. Figure 8 shows a typical lamp filament voltage during preheat mode.

FUNCTIONAL DESCRIPTION (VARIATION II: One lamp remains running when the other is removed)

Figure 10 shows the output stage for the parallel lamp configuration with the additional control circuitry for lamp presence detection and automatic restart. When one of the lamps is removed, the base of Q1 is pulled high. This turns Q1 on but does not affect SD. The other lamp will therefore remain running. When the lamp is re-inserted, Q1 is turned off and a momentary voltage pulse appears at the SD pin due to C18, R20 and R21. This pulse momentarily pulls SD above the 2V threshold and resets the IR21571. As SD falls below 1.8V, the IR21571 is restarted in the preheat mode. This assures proper heating of the filaments before the lamp is re-ignited. If both lamps are removed, hard-switching will occur at the half-bridge and the resulting currents will cause the voltage across the current sensing resistor, RCS, to exceed the over-current threshold programmed by resistor ROC. This will disable the half-bridge driver outputs HO and LO.
