The information given in this document shall in no event be regarded as a guarantee of conditions or characteristics. With respect to any examples or hints given herein, any typical values stated herein and/or any information regarding the application of the device, Infineon Technologies hereby disclaims any and all warranties and liabilities of any kind, including without limitation, warranties of non-infringement of intellectual property rights of any third party.

Information

For further information on technology, delivery terms and conditions and prices, please contact the nearest Infineon Technologies Office (www.infineon.com).

Warnings

Due to technical requirements, components may contain dangerous substances. For information on the types in question, please contact the nearest Infineon Technologies Office. Infineon Technologies components may be used in life-support devices or systems only with the express written approval of Infineon Technologies, if a failure of such components can reasonably be expected to cause the failure of that life-support device or system or to affect the safety or effectiveness of that device or system. Life support devices or systems are intended to be implanted in the human body or to support and/or maintain and sustain and/or protect human life. If they fail, it is reasonable to assume that the health of the user or other persons may be endangered.

Preface
TriCore™ is a unified, 32-bit microcontroller-DSP, single-core architecture optimized for real-time embedded systems.

This document has been written for system developers and programmers, and hardware and software engineers.

• Volume 1 provides a detailed description of the Core Architecture and system interaction.
• Volume 2 (this volume) gives a complete description of the TriCore Instruction Set including optional extensions for the Memory Management Unit (MMU) and Floating Point Unit (FPU).

It is important to note that this document describes the TriCore architecture, not an implementation. An implementation may have features and resources which are not part of the Core Architecture. The documentation for that implementation will describe all implementation specific features.

When working with a specific TriCore based product always refer to the appropriate supporting documentation.

TriCore Versions
There have been several versions of the TriCore Architecture implemented in production devices. This manual documents the following architectures:

• TriCore 1.6

Please note that:
• Unless stated otherwise in the text, all descriptions are common to all TriCore versions listed in this preface.

Additional Information
For information and links to documentation for Infineon products that use TriCore, visit:
http://www.infineon.com/32-bit-microcontrollers
Text Conventions

This document uses the following text conventions:

- The default radix is decimal.
  - Hexadecimal constants are suffixed with a subscript letter ‘H’, as in: FFC\textsubscript{H}.
  - Binary constants are suffixed with a subscript letter ‘B’, as in: 111\textsubscript{B}.
- Register reset values are not generally architecturally defined, but require setting on startup in a given implementation of the architecture. Only those reset values that are architecturally defined are shown in this document. Where no value is shown, the reset value is not defined. Refer to the documentation for a specific TriCore implementation.
- Bit field and bits in registers are in general referenced as ‘Register name.Bit field’, for example PSW.IS. The Interrupt Stack Control bit of the PSW register.
- Units are abbreviated as follows:
  - MHz = Megahertz.
  - kBaud, kBit = 1000 characters/bits per second.
  - MBaud, MBit = 1,000,000 characters per second.
  - KByte = 1024 bytes.
  - MByte = 1048576 bytes of memory.
  - GByte = 1,024 megabytes.
- Data format quantities referenced are as follows:
  - Byte = 8-bit quantity.
  - Half-word = 16-bit quantity.
  - Word = 32-bit quantity.
  - Double-word = 64-bit quantity.
- Pins using negative logic are indicated by an overbar: BRKOUT.

In tables where register bit fields are defined, the conventions shown in the following table are used in this document.

<table>
<thead>
<tr>
<th>Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Read-only. The bit or bit field can only be read.</td>
</tr>
<tr>
<td>w</td>
<td>Write-Only. The bit or bit field can only be written.</td>
</tr>
<tr>
<td>rw</td>
<td>The bit or bit field can be read and written.</td>
</tr>
<tr>
<td>h</td>
<td>The bit or bit field can be modified by hardware (such as a status bit). ‘h’ can be combined with ‘rw’ or ‘r’ bits, to form ‘rwh’ or ‘rh’ bits.</td>
</tr>
<tr>
<td>-</td>
<td>Reserved. Read value is undefined, but must be written with 0.</td>
</tr>
</tbody>
</table>
1 Instruction Set Information

This chapter contains descriptions of all TriCore™ instructions. The instruction mnemonics are grouped into families of similar or related instructions, then listed in alphabetical order within those groups.

**Notes**
1. All instructions and operators are signed unless stated ‘unsigned’.
2. Information specific to 16-bit instructions is shown in a box with a grey background.

1.1 Instruction Syntax

The syntax definition specifies the operation to be performed and the operands used. Instruction operands are separated by commas.

1.1.1 Operand Definitions

The Operand definitions are detailed in the following table.

<table>
<thead>
<tr>
<th>Operand</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>D[n]</td>
<td>Data register n</td>
</tr>
<tr>
<td>A[n]</td>
<td>Address register n</td>
</tr>
<tr>
<td>E[n]</td>
<td>Extended data register n containing a 64-bit value made from an even/odd pair of registers (D[n], D[n+1]). The format is little endian. E[n][63:32] = D[n+1][31:0]; E[n][31:0] = D[n][31:0]</td>
</tr>
<tr>
<td>dispn</td>
<td>Displacement value of ‘n’ bits, used to form the effective address in branch instructions</td>
</tr>
<tr>
<td>constn</td>
<td>Constant value of ‘n’ bits, used as instruction operand</td>
</tr>
<tr>
<td>offn</td>
<td>Offset value of ‘n’ bits, used to form the effective address in Load and Store instructions</td>
</tr>
<tr>
<td>pos1, pos2</td>
<td>Used to specify the position in a bit field instruction</td>
</tr>
<tr>
<td>pos</td>
<td>Pos (position) is used with width to define a field</td>
</tr>
<tr>
<td>width</td>
<td>Specifies the width of the bit field in bit field instructions</td>
</tr>
</tbody>
</table>

1.1.2 Instruction Mnemonic

An instruction mnemonic is composed of up to three basic parts.

- A base operation
  - Specifies the instructions basic operation. For example: ADD for addition, J for jump and LD for memory load. Some instructions such as OR.EQ, have more than one base operation, separated by a period (.)
- An operation modifier
  - Specifies the operation more precisely. For example: ADDI for addition using an immediate value, or JL for a jump that includes a link. More than one operation modifier may be used for some instructions (ADDIH for example).
- An operand (data type) modifier.
  - Gives the data type of the source operands. For example: ADD.B for byte addition, JZ.A for a jump using an address register and LD.H for a half-word load. The data type modifier is separated by a period (.)

Using the ADDS.U instruction as an example:

- ‘ADD’ is the base operation.
- ‘S’ is an operation modifier specifying that the result is saturated.
- ‘U’ is a data type modifier specifying that the operands are unsigned.
Some instructions, typically 16-bit instructions, use a General Purpose Register (GPR) as an implicit source or destination.

### Table 1-2 Implicit Operand Definitions

<table>
<thead>
<tr>
<th>Operand</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>D[15]</td>
<td>Implicit Data register for many 16-bit instructions</td>
</tr>
<tr>
<td>A[10]</td>
<td>Stack Pointer (SP)</td>
</tr>
<tr>
<td>A[15]</td>
<td>Implicit Address Register for many 16-bit Load/Store instructions</td>
</tr>
</tbody>
</table>

Note: In the syntax section of the instruction descriptions, the implicit registers are included as explicit operands. However they are not explicitly encoded in the instructions.

### 1.1.3 Operation Modifiers

The operation modifiers are shown in the following table. The order of the modifiers in this table is the same as the order in which they appear as modifiers in an instruction mnemonic.

### Table 1-3 Operation Modifiers

<table>
<thead>
<tr>
<th>Operation Modifier</th>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Carry</td>
<td>Use and update PSW carry bit</td>
<td>ADDC</td>
</tr>
<tr>
<td>I</td>
<td>Immediate</td>
<td>Large immediate</td>
<td>ADDI</td>
</tr>
<tr>
<td>H</td>
<td>High Word</td>
<td>Immediate value put in most-significant bits</td>
<td>ADDIH</td>
</tr>
<tr>
<td>S</td>
<td>Saturation</td>
<td>Saturate result</td>
<td>ADDS</td>
</tr>
<tr>
<td>X</td>
<td>Carry out</td>
<td>Update PSW carry bit</td>
<td>ADDX</td>
</tr>
<tr>
<td>EQ</td>
<td>Equal</td>
<td>Comparison equal</td>
<td>JEQ</td>
</tr>
<tr>
<td>GE</td>
<td>Greater than</td>
<td>Comparison greater than or equal</td>
<td>JGE</td>
</tr>
<tr>
<td>L</td>
<td>Link</td>
<td>Record link (jump subroutine)</td>
<td>JL</td>
</tr>
<tr>
<td>A</td>
<td>Absolute</td>
<td>Absolute (jump)</td>
<td>JLA</td>
</tr>
<tr>
<td>I</td>

<td>Register indirect (jump)</td>
<td>JLI</td>
</tr>
<tr>
<td>LT</td>
<td>Less than</td>
<td>Comparison less than</td>
<td>JLT</td>
</tr>
<tr>
<td>NE</td>
<td>Not equal</td>
<td>Comparison not equal</td>
<td>JNE</td>
</tr>
<tr>
<td>D</td>
<td>Decrement</td>
<td>Decrement counter</td>
<td>JNED</td>
</tr>
<tr>
<td>I</td>
<td>Increment</td>
<td>Increment counter</td>
<td>JNEI</td>
</tr>
<tr>
<td>Z</td>
<td>Zero</td>
<td>Use zero immediate</td>
<td>JNZ</td>
</tr>
<tr>
<td>M</td>
<td>Multi-precision</td>
<td>Multi-precision result (&gt;32-bit) in Q format</td>
<td>MULM</td>
</tr>
<tr>
<td>R</td>
<td>Round</td>
<td>Round result</td>
<td>MULR</td>
</tr>
<tr>
<td>N</td>
<td>Not</td>
<td>Logical NOT</td>
<td>SELN</td>
</tr>
</tbody>
</table>
1.1.4 Data Type Modifiers

The data type modifiers used in the instruction mnemonics are listed here. When multiple suffixes occur in an instruction, the order of occurrence in the mnemonic is the same as the order in this table:

Table 1-4 Data Type Modifiers

<table>
<thead>
<tr>
<th>Data Type Modifier</th>
<th>Name</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Data</td>
<td>32-bit data</td>
<td>MOV.D</td>
</tr>
<tr>
<td>D</td>
<td>Double-word</td>
<td>64-bit data/address</td>
<td>LD.D</td>
</tr>
<tr>
<td>W</td>
<td>Word</td>
<td>32-bit (word) data</td>
<td>EQ.W</td>
</tr>
<tr>
<td>A</td>
<td>Address</td>
<td>32-bit address</td>
<td>ADD.A</td>
</tr>
<tr>
<td>Q</td>
<td>Q Format</td>
<td>16-bit signed fraction (Q format)</td>
<td>MADD.Q</td>
</tr>
<tr>
<td>H</td>
<td>Half-word</td>
<td>16-bit data or two packed half-words</td>
<td>ADD.H</td>
</tr>
<tr>
<td>B</td>
<td>Byte</td>
<td>8-bit data or four packed bytes</td>
<td>ADD.B</td>
</tr>
<tr>
<td>T</td>
<td>Bit</td>
<td>1-bit data</td>
<td>AND.T</td>
</tr>
<tr>
<td>U</td>
<td>Unsigned</td>
<td>Unsigned data type</td>
<td>ADDS.U</td>
</tr>
</tbody>
</table>

Note: Q format can be used as signed half-word multipliers.

1.2 Opcode Formats

1.2.1 16-bit Opcode Formats

Note: Bit[0] of the op1 field is always 0 for 16-bit instructions.

Table 1-5 16-bit Opcode Formats

1.3 Instruction Operation Syntax

The operation of each instruction is described using a ‘C-like’ Register Transfer Level (RTL) notation.

Notes
1. The numbering of bits begins with bit zero, which is the least-significant bit of the word.
2. All intermediate ‘result’ values are assumed to have infinite precision unless otherwise indicated.

Table 1-8 RTL Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>bpos3</td>
<td>Bit position</td>
</tr>
<tr>
<td>const’n’</td>
<td>Constant value of ‘n’ bits, used as instruction operand</td>
</tr>
<tr>
<td>disp’n’</td>
<td>Displacement value of ‘n’ bits, used to form the effective address in branch instructions</td>
</tr>
<tr>
<td>(expression)[p]</td>
<td>A single bit, with ordinal index ‘p’ in the bit field ‘expression’</td>
</tr>
<tr>
<td>n’bx</td>
<td>Constant bit string, where ‘n’ is the number of bits in the constant and ‘x’ is the constant in binary. For example; 2'b11</td>
</tr>
<tr>
<td>n’hx</td>
<td>Constant bit string, where ‘n’ is the number of bits in the constant and ‘x’ is the constant in hexadecimal. For example, 16'hFFFF</td>
</tr>
<tr>
<td>off’n’</td>
<td>Offset value of ‘n’ bits, used to form the effective address in Load and Store instructions</td>
</tr>
<tr>
<td>pos</td>
<td>Single bit position</td>
</tr>
<tr>
<td>signed</td>
<td>A value that can be positive, negative or zero</td>
</tr>
<tr>
<td>sssov</td>
<td>Saturation on signed overflow</td>
</tr>
<tr>
<td>suov</td>
<td>Saturation on unsigned overflow</td>
</tr>
<tr>
<td>unsigned</td>
<td>A value that can be positive or zero</td>
</tr>
<tr>
<td>{x,y}</td>
<td>A bit string where ‘x’ and ‘y’ are expressions representing a bit or bit field. Any number of expressions can be concatenated. For example, {x,y,z}</td>
</tr>

### 1.3.1 RTL Functions

Register Transfer Level functions are defined in the table which follows.

<table>
<thead>
<tr>
<th>Function</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>abs(x)</td>
<td>abs(x) returns ((x &lt; 0) ? (0 - x) : x);</td>
</tr>
<tr>
<td>cache_address_ivld(EA)</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_address_wb(EA)</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_address_wi(EA)</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_index_ivld</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_index_wb</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_index_wi</td>
<td>Defined in ‘Cache RTL Functions’, which follows</td>
</tr>
<tr>
<td>cache_index_wbi(EA)</td>
<td>Defined in the ‘Cache RTL Functions’ section, which follows. (TriCore1.6)</td>
</tr>
<tr>
<td>cache_index_wbi(EA)</td>
<td>Defined in the ‘Cache RTL Functions’ section, which follows. (TriCore1.6)</td>
</tr>
<tr>
<td>carry(a,b,c)</td>
<td>carry(a,b,c) { result = a + b + c; // unsigned additions return result[32];</td>
</tr>
<tr>
<td>cdc_decrement()</td>
<td>If PSW.CDC == 7'b1111111 returns FALSE, otherwise decrements</td>
</tr>
<tr>
<td>cdc_increment()</td>
<td>If PSW.CDC == 7'b1111111 returns FALSE, otherwise increments</td>
</tr>
<tr>
<td>cdc_zero()</td>
<td>Returns TRUE if PCW.CDC.COUNT == 0 or if PSW.CDC == 7'b1111111, otherwise returns FALSE</td>
</tr>
<tr>
<td>leading_ones(x)</td>
<td>Returns the number of leading ones of ‘x’</td>
</tr>
<tr>
<td>leading_signs(x)</td>
<td>Returns the number of leading sign bits of ‘x’</td>
</tr>
<tr>
<td>leading_zeros(x)</td>
<td>Returns the number of leading zeros of ‘x’</td>
</tr>
<tr>
<td>reverse16(n)</td>
<td>reverse16(n) {n[0], n[1], n[2], n[3], n[4], n[5], n[6], n[7], n[8], n[9], n[10], n[11], n[12], n[13], n[14], n[15]}</td>
</tr>
<tr>
<td>round16(n)</td>
<td>round16(n) = {(x + 32'h00000800)[31:16],16'h0000};</td>
</tr>
<tr>
<td>sssov(x,y)</td>
<td>max_pos = (1 &lt;&lt; (y - 1)) - 1; max_neg = -(1 &lt;&lt; (y - 1)); return ((x &gt; max_pos) ? max_pos : ((x &lt; max_neg) ? max_neg : x ));</td>
</tr>
<tr>
<td>suov(x,y)</td>
<td>max_pos = (1 &lt;&lt; y) - 1; return ((x &gt; max_pos) ? max_pos : ((x &lt; 0) ? 0 : x));</td>
</tr>
<tr>
<td>sign_ext(x)</td>
<td>Sign extension; high-order bit of x is left extended</td>
</tr>
<tr>
<td>trap(x)</td>
<td>Instruction will take trap ‘x’</td>
</tr>
<tr>
<td>zero_ext(x)</td>
<td>Zero extensions; high-order bits are set to 0</td>
</tr>
</tbody>
</table>
1.3.2  Cache RTL Functions

CACHE[] is a syntactic structure which hides the implementation characteristics of the cache implemented. CACHE can be associatively accessed either by:

- A single argument which is an address.
- Two arguments consisting of implementation defined ranges for set_index and set_element.

In either case the CACHE[] access returns a structure with:

- Boolean validity information (CACHE[].valid).
- Boolean data modification information (CACHE[].modified).
- Physical address of the copied location (CACHE[].physical_address).
- Stored data associated with the address (CACHE[].data).

The cache function descriptions are given in the following table.

Notes
1. ‘cacheline’, which appears in the cache function descriptions, is the size of the cache line in bytes and is implementation dependent.
2. ‘index’ and ‘elem’, which appear in the cache function descriptions, are the set_index and set_element values. These values are implementation dependent.

Table 1-10 Cache Functions

</tr>
<tr>
<td>is_neg_inf(x)</td>
<td>Takes the IEEE754 32-bit single precision floating point format value ‘x’ and returns the boolean result of the expression: ((x[31:0] == \text{NEG}_\text{INFINITY});)</td>
</tr>
<tr>
<td>is_inf(x)</td>
<td>Takes the IEEE754 32-bit single precision floating point format value ‘x’ and returns the boolean result of the expression: ((\text{is}<em>\neg_\text{inf}(x) \text{ OR } \text{is}</em>\text{pos}_\text{inf}(x));)</td>
</tr>
<tr>
<td>is_zero(x)</td>
<td>Takes the IEEE754 32-bit single precision floating point format value ‘x’ and returns the boolean result of the expression: ((x[30:0] == 0);)</td>
</tr>
<tr>
<td>is_denorm(x)</td>
<td>Takes the IEEE754 32-bit single precision floating point format value ‘x’ and returns the boolean result of the expression: ((x[30:23] == 0) AND (x[22:0] != 0);)</td>
</tr>
<tr>
<td>denorm_to_zero(x)</td>
<td>If the IEEE754 32-bit single precision floating point format value ‘x’ is a denormal value return the appropriately signed infinitely accurate real value 0. Otherwise return ‘x’ as an infinitely accurate real value; i.e. if((x &lt; 0) \text{ AND } (x &gt; -2-126)) \text{ then return } -0.0;) else if((x &gt; 0) \text{ AND } (x &lt; 2126)) \text{ then return } +0.0;) else return f_real(x);</td>
</tr>
<tr>
<td>round_to_integer(x,y)</td>
<td>Returns a signed integer result of infinite width by rounding the IEEE754 32-bit single precision floating point format value ‘x’ to an integer value using the IEEE754 mode specified by ‘y’.</td>
</tr>
<tr>
<td>round_to_unsigned(x,y)</td>
<td>Returns an unsigned integer result of infinite width by rounding the IEEE754 32-bit single precision floating point format value ‘x’ to an integer value using the IEEE754 mode specified by ‘y’.</td>
</tr>
<tr>
<td>round_to_q31(x,y)</td>
<td>Returns a Q format result of infinite width by rounding the real value ‘x’ to a Q format value using the IEEE754 mode specified by ‘y’.</td>
</tr>
</tbody>
</table>
### Floating Point Operation Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>i_real(x)</td>
<td>Returns a infinitely accurate real number of equal value to the 32-bit signed integer value ‘x’.</td>
</tr>
<tr>
<td>u_real(x)</td>
<td>Returns a infinitely accurate real number of equal value to the 32-bit unsigned integer value ‘x’.</td>
</tr>
<tr>
<td>f_real(x)</td>
<td>Returns the IEEE754 32-bit single precision floating point format value ‘x’ as an infinitely accurate real value.</td>
</tr>
<tr>
<td>q_real(x)</td>
<td>Returns the Q31 format value ‘x’ as an infinitely accurate real value.</td>
</tr>
<tr>
<td>add(x,y)</td>
<td>Adds the real value ‘x’ to the real value ‘y’ and returns an infinitely accurate real result.</td>
</tr>
<tr>
<td>mul(x,y)</td>
<td>Multiply the real value ‘x’ by the real value ‘y’ and return an infinitely accurate real result.</td>
</tr>
<tr>
<td>divide(x,y)</td>
<td>Divides the real value ‘x’ by the real value ‘y’ and returns an infinitely accurate real result.</td>
</tr>
<tr>
<td>ieee754_round(x,y)</td>
<td>Rounds the real value ‘x’ using the type of rounding specified by ‘y’ compliant with IEEE754.</td>
</tr>
<tr>
<td>ieee754_32bit_format(x)</td>
<td>Returns the real value ‘x’ in the standard 32-bit single precision IEEE754 floating point format. ‘x’ is converted to the correct IEEE754 result on overflow or underflow.</td>
</tr>
<tr>
<td>ieee754_lt(x,y)</td>
<td>Returns TRUE if ‘x’ is less than ‘y’ according to the IEEE754 rules for 32-bit single precision floating point numbers otherwise returns FALSE.</td>
</tr>
<tr>
<td>ieee754_gt(x,y)</td>
<td>Returns TRUE if ‘x’ is greater than ‘y’ according to the IEEE754 rules for 32-bit single precision floating point numbers otherwise returns FALSE.</td>
</tr>
<tr>
<td>ieee754_eq(x,y)</td>
<td>Returns TRUE if ‘x’ is equal to ‘y’ according to the IEEE754 rules for 32-bit single precision floating point numbers otherwise returns FALSE.</td>
</tr>
<tr>
<td>fp_abs(x)</td>
<td>Returns the infinitely accurate absolute value of the real value ‘x’; i.e. (x &lt; 0.0) ? (0.0 - x) : x;</td>
</tr>
<tr>
<td>approx_inv_sqrt(x)</td>
<td>Takes the real argument x and returns the approximate inverse square root (x^{0.5}) to at least 6.75 bits of precision.</td>
</tr>
</tbody>
</table>
1.4 Coprocessor Instructions

The TriCore® instruction set architecture may be extended with implementation defined, application specific coprocessor instructions. These instructions are executed on dedicated coprocessor hardware attached to the coprocessor interface.

The coprocessors operate in a similar manner to the integer instructions, receiving operands from the general purpose data registers, returning a result to the same registers.

The architecture supports the operation of up to four concurrent coprocessors \( n = 0, 1, 2, 3 \).

Two of these \( n = 0, 1 \) are reserved for use by the TriCore CPU, allowing two \( n = 2, 3 \) for use by the application hardware.

\end{array}
\]

D[c] = op2[n] (D[d], D[a], D[b]);
```
1.5 PSW Status Flags (User Status Bits)

The Status section of a given instruction description lists the five status flags that may be affected by the operation. The PSW logically groups the five user bits together as shown below.

**Notes**

1. *In the following table, ‘result’ for 32-bit instructions is D[c]. For 16-bit instructions it is D[a] or D[15](when implicit).*
2. *The PSW register is defined in Volume 1, Core Registers.*

### Table 1-13 PSW Status Flags

<table>
<thead>
<tr>
<th>Field</th>
<th>PSW Bit</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>31</td>
<td>rw</td>
<td>Carry</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>The result has generated a carry_out.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>if (carry_out) then PSW.C = 1 else PSW.C = 0;</td>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>if (overflow) then PSW.SV = 1 else PSW.SV = PSW.SV;</td>
</tr>
<tr>
<td>AV</td>
<td>28</td>
<td>rw</td>
<td>Advance Overflow *</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>if (advanced_overflow) then PSW.AV = 1 else PSW.AV = 0;</td>
</tr>
<tr>
<td>SAV</td>
<td>27</td>
<td>rw</td>
<td>Sticky Advance Overflow</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>A memorized advanced overflow. Advanced_overflow is defined by AV, above.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>if (advanced_overflow) then PSW.SAV = 1 else PSW.SAV = PSW.SAV;</td>
</tr>
</tbody>
</table>

*Programming Note: V (Overflow) and AV (Advanced Overflow) Status Bits*

Because the TriCore Instruction Set contains many compound instructions (MULR, MAC, ABSDIF), it is necessary to understand when the overflow flags are computed.

The AV and V flags are computed on the final operation, except in the case of instructions with saturation, when it is always before saturation. Saturation is not part of the operation as such, but is the resulting effect (chosen by the user) of an overflow situation.

1.6 List of OS and I/O Privileged Instructions

The following is a list of operating system Input/Output privileged instructions:

</tbody>
</table>
2 Instruction Set Overview

This chapter provides an overview of the TriCore™ Instruction Set Architecture (ISA). The basic properties and use of each instruction type are described, together with a description of the selection and use of the 16-bit (short) instructions.

2.1 Integer Arithmetic

This section covers the following topics:

- Move, page 2-1
- Addition and Subtraction, page 2-1
- Multiply and Multiply-Add, page 2-2
- Division, page 2-2
- Absolute Value, Absolute Difference, page 2-2
- Min, Max, Saturate, page 2-2
- Conditional Arithmetic Instructions, page 2-2
- Logical, page 2-3
- Count Leading Zeros, Ones and Signs, page 2-3
- Shift, page 2-4
- Bit-Field Extract and Insert, page 2-4

2.1.1 Move

The move instructions move a value in a data register or a constant value in the instruction to a destination data register, and can be used to quickly load a large constant into a data register.

A 16-bit constant is created using MOV (which sign-extends the value to 32-bits) or MOV.U (which zero-extends to 32-bits).

The MOVH (Move High-word) instruction loads a 16-bit constant into the most-significant 16 bits of the register and zero fills the least-significant 16-bits. This is useful for loading a left-justified constant fraction.

Loading a 32-bit constant is achieved by using a MOVH instruction followed by an ADDI (Add Immediate), or a MOV.U followed by ADDIH (Add Immediate High-word).

2.1.2 Addition and Subtraction

The addition instructions have three versions:

- ADD (No saturation)
- ADDS (Signed saturation)
- ADDS.U (Unsigned saturation)

For extended precision addition, the ADDX (Add Extended) instruction sets the PSW carry bit to the value of the ALU carry out. The ADDC (Add with Carry) instruction uses the PSW carry bit as the carry in, and updates the PSW carry bit with the ALU carry out. For extended precision addition, the least-significant word of the operands is added using the ADDX instruction, and the remaining words are added using the ADDC instruction. The ADDC and ADDX instructions do not support saturation.

It is often necessary to add 16-bit or 32-bit constants to integers. The ADDI (Add Immediate) and ADDIH (Add Immediate High) instructions add a 16-bit, sign-extended constant or a 16-bit constant, left-shifted by 16. Addition of any 32-bit constant is carried out using ADDI followed by an ADDIH.

All add instructions except those with constants, have similar corresponding subtract instructions. Because the immediate of ADDI is sign-extended, it may be used for both addition and subtraction.

The RSUB (Reverse Subtract) instruction subtracts a register from a constant. Using zero as the constant yields negation as a special case.
2.1.3 Multiply and Multiply-Add
For the multiplication of 32-bit integers, the available mnemonics are:
- MUL (Multiply Signed)
- MULS (Multiply Signed with Saturation)
- MULS.U (Multiply Unsigned with Saturation)
These translate to machine instructions producing either 32-bit or 64-bit results, depending on whether the destination operand encoded in the assembly instruction is a single data register D[n] (where n = 0, 1, …15), or an extended data register E[n] (where n = 0, 2, …14).
In those cases where the number of bits in the destination is 32-bit, the result is taken from the lower bits of the product. This corresponds to the standard ‘C’ multiplication of two integers.
The MAC instructions (Multiplication with Accumulation) follow the instruction forms for multiplication; MADD, MADDU, MADD.U, and MSUB, MSUBU, MSUBU.U.
In all cases a third source operand register is specified, which provides the accumulator to which the multiplier results are added.

2.1.4 Division
Division of 32-bit by 32-bit integers is supported for both signed and unsigned integers. Because an atomic divide instruction would require an excessive number of cycles to execute, a divide-step sequence is used, which keeps interrupt latency down. The divide step sequence allows the divide time to be proportional to the number of significant quotient bits expected.
The sequence begins with a Divide-Initialize instruction: DVINIT(.U), DVINIT.H(U) or DVINIT.B(U), depending on the size of the quotient and on whether the operands are to be treated as signed or unsigned. The divide initialization instruction extends the 32-bit dividend to 64-bits, then shifts it left by 0, 16 or 24-bits. It simultaneously shifts in that many copies of the quotient sign bit to the low-order bit positions. 4, 2 or 1 Divide-Step instructions (DVSTEP or DVSTEP.U) then follow. Each Divide-Step instruction develops eight bits of quotient.
At the end of the divide step sequence, the 32-bit quotient occupies the low-order word of the 64-bit dividend register pair, and the remainder is held in the high-order word. If the divide operation was signed, the Divide-Adjust instruction (DVADJ) is required to perform a final adjustment of negative values. If the dividend and the divisor are both known to be positive, the DVADJ instruction can be omitted.

2.1.5 Absolute Value, Absolute Difference
A common operation on data is the computation of the absolute value of a signed number or the absolute value of the difference between two signed numbers. These operations are provided directly by the ABS and ABSDIF instructions. There is a version of each instruction which saturates when the result is too large to be represented as a signed number.

2.1.6 Min, Max, Saturate
Instructions are provided that directly calculate the minimum or maximum of two operands. The MIN and MAX instructions are used for signed integers, and MIN.U and MAX.U are used for unsigned integers.
The SAT instructions can be used to saturate the result of a 32-bit calculation before storing it in a byte or half-word, in memory or a register.

2.1.7 Conditional Arithmetic Instructions
Conditional arithmetic instructions are:
- CADD (Conditional Add) and CADDN (Conditional Add-Not)
- CSUB (Conditional Subtract) and CSUBN (Conditional Subtract-Not)
- SEL (Select) and SELN (Select-Not)
The conditional instructions provide efficient alternatives to conditional jumps around very short sequences of
code. All of the conditional instructions use a condition operand that controls the execution of the instruction.
The condition operand is a data register, with any non-zero value interpreted as TRUE, and a zero value
interpreted as FALSE. For the CADD and CSUB instructions, the addition/subtraction is performed if the condition
is TRUE. For the CADDN and CSUBN instructions it is performed if the condition is FALSE.
The SEL instruction copies one of its two source operands to its destination operand, with the selection of source
operands determined by the value of the condition operand (This operation is the same as the C language ?
operation). A typical use might be to record the index value yielding the larger of two array elements:

\[
\text{index}\_\text{max} = (a[i] > a[j]) \ ? i : j;
\]

If one of the two source operands in a SEL instruction is the same as the destination operand, then the SEL
instruction implements a simple conditional move. This occurs often in source statements of the general form:

\[
\text{if} <\text{condition}> \text{ then } <\text{variable}> = <\text{expression}>;
\]

Provided that <expression> is simple, it is more efficient to evaluate it unconditionally into a source register, using
a SEL instruction to perform the conditional assignment, rather than conditionally jumping around the assignment
statement.

### 2.1.8 Logical

The TriCore architecture provides a complete set of two-operand, bit-wise logic operations. In addition to the AND,
OR, and XOR functions, there are the negations of the output; NAND, NOR, and XNOR, and negations of one of
the inputs; ANDN and ORN (the negation of an input for XOR is the same as XNOR).

### 2.1.9 Count Leading Zeros, Ones and Signs

To provide efficient support for normalization of numerical results, prioritization, and certain graphics operations,
three Count Leading instructions are provided:

- CLZ (Count Leading Zeros)
- CLO (Count Leading Ones)
- CLS (Count Leading Signs)

These instructions are used to determine the amount of left shifting necessary to remove redundant zeros, ones,
or signs.

*Note: The CLS instruction returns the number of leading redundant signs, which is the number of leading signs
minus one.*

The following special cases are defined:

- CLZ(0) = 32, CLO(-1) = 32
- CLS(0) = CLS(-1) = 31

For example, CLZ returns the number of consecutive zeros starting from the most significant bit of the value in the
source data register. In the example shown in Figure 2-1, there are seven zeros in the most significant portion of
the input register. If the most significant bit of the input is a 1, CLZ returns 0:
2.1.10 Shift
The shift instructions support multi-bit shifts.

The shift amount is specified by a signed integer (n), which may be the contents of a register or a sign-extended constant in the instruction.

If n >= 0, the data is shifted left by n[4:0]; otherwise, the data is shifted right by (-n)[4:0].

The (logical) shift instruction SH, shifts in zeros for both right and left shifts.

The arithmetic shift instruction SHA, shifts in sign bits for right shifts and zeros for left shifts.

The arithmetic shift with saturation instruction SHAS, will saturate (on a left shift) if the sign bits that are shifted out are not identical to the sign bit of the result.

2.1.11 Bit-Field Extract and Insert
The TriCore architecture supports three, bit-field extract instructions:

- EXTR (Extract bit field)
- EXTR.U (Extract bit field unsigned)
- DEXTR (Extract from Double Register)

The INSERT instruction is described on Page 2-6.

EXTR and EXTR.U
The EXTR and EXTR.U instructions extract width consecutive bits from the source, beginning with the bit number specified by the pos (position) operand. The width and pos can be specified by two immediate values, by an immediate value and a data register, or by a data register pair.

The EXTR instruction fills the most-significant bits of the result by sign-extending the bit field extracted (duplicating the most-significant bit of the bit field). See Figure 2-2.

EXTR.U zero-fills the most significant (32-w) bits of the result. See Figure 2-3.
DEXTR

The DEXTR instruction concatenates two data register sources to form a 64-bit value from which 32 consecutive bits are extracted. The operation can be thought of as a left shift by pos bits, followed by the truncation of the least-significant 32-bits of the result. The value of pos is contained in a data register, or is an immediate value in the instruction.

The DEXTR instruction can be used to normalize the result of a DSP filter accumulation in which a 64-bit accumulator is used with several guard bits. The value of pos can be determined by using the CLS (Count Leading Signs) instruction. The DEXTR instruction can also be used to perform a multi-bit rotation by using the same source register for both of the sources (that are concatenated).
INSERT
The INSERT instruction takes the width least-significant bits of a source data register, shifted left by pos bits and substitutes them into the value of another source register. All other (32-w) bits of the value of the second register are passed through. The width and pos can be specified by two immediate values, by an immediate value and a data register, or by a data register pair.

There is also an alternative form of INSERT that allows a zero-extended 4-bit constant to be the value which is inserted.

Figure 2-5  INSERT Operation

2.2    Packed Arithmetic
The packed arithmetic instructions partition a 32-bit word into several identical objects which can then be fetched, stored, and operated on in parallel. These instructions in particular allow the full exploitation of the 32-bit word of the TriCore architecture in signal and data processing applications.

The TriCore architecture supports two packed formats:
• Packed Half-word Data format
• Packed Byte Data format

The Packed Half-word Data format divides the 32-bit word into two, 16-bit (half-word) values. Instructions which operate on data in this way are denoted in the instruction mnemonic by the .H and .HU modifiers.

Figure 2-6  Packed Half-word Data Format
The Packed Byte Data format divides the 32-bit word into four, 8-bit values. Instructions which operate on the data in this way are denoted by the .B and .BU data type modifiers.
The loading and storing of packed values into data registers is supported by the normal Load Word and Store Word instructions (LD.W and ST.W). The packed objects can then be manipulated in parallel by a set of special packed arithmetic instructions that perform such arithmetic operations as addition, subtraction, multiplication, and so on.

Addition is performed on individual packed bytes or half-words using the ADD.B and ADD.H instructions. The saturating variation (ADDS.H) only exists for half-words.

The ADD.H instruction ignores overflow or underflow within individual half-words. ADDS.H will saturate individual half-words to the most positive 16-bit signed integer ($2^{15}-1$) on individual overflow, or to the most negative 16-bit signed integer ($-2^{15}$) on individual underflow. Saturation for unsigned integers is also supported by the ADDS.HU instruction. Similarly, all packed addition operations have an equivalent subtraction.

Besides addition and subtraction, arithmetic on packed data includes absolute value, absolute difference, shift, and count leading operations.

Packed multiplication is described in the section **Packed Multiply and Packed MAC, page 2-10**.

Compare instructions are described in **Compare Instructions, page 2-11**.
2.3 PSW (Program Status Word) Status Flags and Arithmetic Instructions

Arithmetic instructions operate on data and addresses in registers. Status information about the result of the arithmetic operations is recorded in the five status flags in the Program Status Word (PSW) register.

2.3.1 Usage

The status flags can be read by software using the Move From Core Register (MFCR) instruction, and can be written using the Move to Core Register (MTCR) instruction.

*Note: MTCR is only available in Supervisor mode.*

The Trap on Overflow (TRAPV) and Trap on Sticky Overflow (TRAPSV) instructions can be used to cause a trap if the respective V (overflow) and SV (sticky overflow) bits are set. The overflow bits can be cleared using the Reset Overflow Bits instruction (RSTV).

Individual arithmetic operations can be checked for overflow by reading and testing V. If it is only necessary to determine if an overflow occurred somewhere in an entire block of computation, then the SV bit is reset before the block (using the RSTV instruction) and tested after completion of the block (using MFCR).

Jumping based on the overflow result is achieved by using a MFCR instruction followed by a JZ.T or JNZ.T (conditional jump on the value of a bit) instruction.

2.3.2 Saturation

Because most signal-processing applications can handle overflow by simply saturating the result, most of the arithmetic instructions have a saturating version for signed and unsigned overflow.

*Note: Saturating versions of all instructions can be synthesized using short code sequences.*

When saturation is used for 32-bit signed arithmetic overflow, if the true result of the computation is greater than $2^{31} - 1$ or less than $-2^{31}$, the result is set to $2^{31} - 1$ or $-2^{31}$, respectively.

The bounds for 16-bit signed arithmetic are $2^{15} - 1$ and $-2^{15}$, and the bounds for 8-bit signed arithmetic are $2^7 - 1$ and $-2^7$.

When saturation is used for unsigned arithmetic, the lower bound is always zero and the upper bounds are $2^{32} - 1$, $2^{16} - 1$, and $2^8 - 1$.

Saturation is indicated in the instruction mnemonic by an S and unsigned is indicated by a U following the period (.) For example, the instruction mnemonic for a signed saturating addition is ADDS, and the mnemonic for an unsigned saturating addition is ADDS.U.

2.4 DSP Arithmetic

DSP arithmetic instructions operate on 16-bit signed fractional data in the 1.15 format (also known as Q15), and 32-bit signed fractional data in 1.31 format (Q31).

Data values in this format have a single, high-order sign bit, with a value of 0 or -1, followed by an implied binary point and fraction. Their values are in the range [-1, 1).

2.4.1 Scaling

The multiplier result can be treated in one of two ways:

- Left shifted by 1
  - One sign bit is suppressed and the result is left-aligned, so conserving the input format.
- Not shifted
  - The result retains its two sign bits (2.30 format). This format can be used with IIR (Infinite Impulse Response) filters for example, in which some of the coefficients are between 1 and 2, and to have one guard bit for accumulation.
2.4.2 Special Case: \(-1 \times -1\)

When multiplying two maximum-negative 1.15 format values \((-1\), the result is the positive number \((+1)\). For example:

\[
8000H \times 8000H = 4000 0000H
\]

This is correctly interpreted in Q format as:

\[-1(1.15 \text{ format}) \times -1(1.15 \text{ format}) = +1 (2.30 \text{ format})\]

However, when the result is shifted left by 1 (left-justified), the result is 8000 0000H. This is incorrectly interpreted as:

\[-1(1.15 \text{ format}) \times -1(1.15 \text{ format}) = -1 (1.31 \text{ format})\]

To avoid this problem, the result of a Q format operation \((-1 \times -1\) that has been left-shifted by 1, is saturated to the maximum positive value. Therefore:

\[
8000H \times 8000H = 7FFF FFFFH
\]

This is correctly interpreted in Q format as:

\[-1(1.15 \text{ format}) \times -1(1.15 \text{ format}) = (\text{nearest representation of}) +1 (1.31 \text{ format})\]

This operation is completely transparent to the user and does not set the overflow flags. It applies only to 16-bit by 16-bit multiplies and does not apply to 16 by 32-bit or 32 by 32-bit multiplies.

2.4.3 Guard Bits

When accumulating sums (in filter calculations for example), guard bits are often required to prevent overflow. The instruction set directly supports the use of one guard bit when using a 32-bit accumulator (2.30 format, where left shift by 1-bit of result is not requested).

When more guard bits are required a register pair (64-bits) can be used. In that instance the intermediate result (also in 2.30 format, where left shift by 1-bit is not performed) is left shifted by 16-bits giving effectively a 18.46 format.

2.4.4 Rounding

Rounding is used to retain the 16 most-significant bits of a 32-bit result. Rounding is implemented by adding 1 to bit 15 of a 32-bit intermediate result.

If the operation writes a full 32-bit register (i.e. is not a component of a packed half-word operation), it then clears the lower 16-bits.

2.4.5 Overflow and Saturation

Saturation on overflow is available on all DSP instructions.

2.4.6 Sticky Advance Overflow and Block Scaling if FFT

The Sticky Advance Overflow (SAV) bit, which is set whenever an overflow ‘almost’ occurred, can be used in block scaling of intermediate results during an FFT calculation.

Before each pass of applying a butterfly operation, the SAV bit is cleared.

After the pass the SAV bit is tested. If it is set then all of the data is scaled (using an arithmetic right shift) before starting the next pass.

This procedure gives the greatest dynamic range for intermediate results without the risk of overflow.
2.4.7 Multiply and MAC

The available instructions for multiplication include:
- MUL.Q (Multiply Q format)
- MULR.Q (Multiply Q format with Rounding)

The operand encodings for the MUL.Q instruction distinguish between 16-bit source operands in either the upper D[n]U or lower half D[n]L of a data register, 32-bit source operands (D[n]), and 32-bit or 64-bit destination operands (D[n] or E[n]). This gives a total of eight different cases:
- 16U * 16U → 32
- 16L * 16L → 32
- 16U * 32 → 32
- 16L * 32 → 32
- 32 * 32 → 32
- 16U * 32 → 64
- 16L * 32 → 64
- 32 * 32 → 64

In those cases where the number of bits in the destination is less than the sum of the bits in the two source operands, the result is taken from the upper bits of the product.

The MAC instructions consist of all the MUL combinations described above, followed by addition (MADD.Q, MADDS.Q,) and the rounding versions (MADDR.Q, MADDRS.Q). For the subtract versions of these instructions, ADD is replaced by SUB.

2.4.8 Packed Multiply and Packed MAC

There are three instructions for various forms of multiplication on packed 16-bit fractional values:
- MUL.H (Packed Multiply Q format)
- MULR.H (Packed Multiply Q format with Rounding)
- MULM.H (Packed Multiply Q format, Multi-Precision)

These instructions perform two 16 x 16 bit multiplications in parallel, using 16-bit source operands in the upper or lower halves of their source operand registers.

MUL.H produces two 32-bit products, stored into the upper and lower registers of an extended register pair. Its results are exact, with no need for rounding.

MULR.H produces two 16-bit Q-format products, stored into the upper and lower halves of a single 32-bit register. Its 32-bit intermediate products are rounded before discarding the low order bits, to produce the 16-bit Q-format results.

MULM.H sums the two intermediate products, producing a single result that is stored into an extended register.

For all three instruction groups there are four supported source operand combinations for the two multiplications. They are:
- 16U * 16U, 16L * 16L
- 16U * 16L, 16L * 16U
- 16U * 16L, 16L * 16L
- 16L * 16U, 16U * 16L

There is also a large group of Packed MAC instructions. These consist of all the MUL combinations described above, followed by addition, subtraction or a combination of both. Typical examples are MADD.H, MADDR.H, and MADDM.H.

All combinations are found as either MADxxx.H or MSUxxx.H instructions.
2.5 Compare Instructions

The compare instructions perform a comparison of the contents of two registers.
The Boolean result (1 = true and 0 = false) is stored in the least-significant bit of a data register. The remaining
bits in the register are cleared to zero.

2.5.1 Simple Compare

Figure 2-8 illustrates the operation of the LT (Less Than) compare instruction:

![Figure 2-8 LT (Less Than) Comparison](TC1051B)

The comparison instructions are:
- EQ (Equal)
- NE (Not Equal)
- LT (Less Than)
- GE (Greater than or Equal to)

Versions for both signed and unsigned integers are available.

Comparison conditions not explicitly provided in the instruction set can be obtained by either swapping the
operands when comparing two registers, or by incrementing the constant by one when comparing a register and
a constant (See Table 2-1).

Table 2-1 Equivalent Comparison Operations

<td>GE D[c], D[a], (const+1)</td>
</tr>
</tbody>
</table>

2.5.2 Accumulating Compare

To accelerate the computation of complex conditional expressions, accumulating versions of the comparison
instructions are supported.

These instructions, indicated in the instruction mnemonic by ‘op’ preceding the ‘.’ (for example, op.LT), combine
the result of the comparison with a previous comparison result.

The combination is a logic AND, OR, or XOR; for example, AND.LT, OR.LT, and XOR.LT.

Figure 2-9 illustrates the combination of the LT instruction with a Boolean operation.
The evaluation of the following C expression can be optimized using the combined compare-Boolean operation:
\[ d5 = (d1 < d2) || (d3 == d4); \]
Assuming all variables are in registers, the following two instructions compute the value in d5:
\[
\text{lt} \quad d5, d1, d2; \quad // \text{compute } (d1 < d2) \\
\text{or.eq} \quad d5, d3, d4; \quad // \text{or with } (d3 == d4)
\]

## 2.5.3 Compare with Shift

Certain control applications require that several Booleans be packed into a single register. These packed bits can be used as an index into a table of constants or a jump table, which permits complex Boolean functions and/or state machines to be evaluated efficiently.

To facilitate the packing of Boolean results into a register, compound Compare with Shift instructions (for example SH.EQ) are supported.

The result of the comparison is placed in the least-significant bit of the result after the contents of the destination register have been shifted left by one position.

**Figure 2-10** illustrates the operation of the SH.LT (Shift Less Than) instruction.

## 2.5.4 Packed Compare

For packed bytes, there are special compare instructions that perform four individual byte comparisons and produce a 32-bit mask consisting of four 'extended' Booleans.

For example, EQ.B yields a result where individual bytes are FFH for a match, or 00H for no match. Similarly for packed half-words there are special compare instructions that perform two individual half-word comparisons and
produce two extended Booleans. The EQ.H instruction results in two extended Booleans: FFFFH for a match and 0000H for no match. There are also abnormal packed-word compare instructions that compare two words in the normal way, but produce a single extended Boolean. The EQ.W instruction results in the extended Boolean FFFFFFH for match and 00000000H for no match.

Extended Booleans are useful as masks, which can be used by subsequent bit-wise logic operations. CLZ (Count Leading Zeros) or CLO (Count Leading Ones) can also be used on the result to quickly find the position of the left-most match. Figure 2-11 shows an example of the EQ.B instruction.

Figure 2-11 EQ.B Instruction Operation

2.6 Bit Operations

Instructions are provided that operate on single bits, denoted in the instruction mnemonic by the .T data type modifier (for example, AND.T).

There are eight instructions for combinatorial logic functions with two inputs, eight instructions with three inputs, and eight with two inputs and a shift.

2.6.1 Simple Bit Operations

The one-bit result of a two-input function (for example, AND.T) is stored in the least significant bit of the destination data register, and the most significant 31-bits are set to zero. The source bits can be any bit of any data register. This is illustrated in Figure 2-12. The available Boolean operations are:

- AND
- NAND
- OR
- NOR
- XOR
- XNOR
- ANDN
- ORN
2.6.2 Accumulating Bit Operations

Evaluation of complex Boolean equations can use the 3-input Boolean operations, in which the output of a two-input instruction, together with the least-significant bit of a third data register, forms the input to a further operation. The result is written to bit 0 of the third data register, with the remaining bits unchanged (Figure 2-13).

![Figure 2-13 Three-Input Boolean Operation](image)

Of the many possible 3-input operations, eight have been singled out for the efficient evaluation of logical expressions. The instructions provided are:

- AND.AND.T
- AND.ANDN.T
- AND.NOR.T
- AND.OR.T
- OR.AND.T
- OR.ANDN.T
- OR.NOR.T
- OR.OR.T

2.6.3 Shifting Bit Operations

As with the comparison instructions, the results of bit operations often need to be packed into a single register for controller applications. For this reason the basic two-input instructions can be combined with a shift prefix (for example, SH.AND.T).

These operations first perform a single-bit left shift on the destination register and then store the result of the two-input logic function into its least-significant bit (Figure 2-14, Page 2-15).
2.7 Address Arithmetic

The TriCore architecture provides selected arithmetic operations on the address registers. These operations supplement the address calculations inherent in the addressing modes used by the load and store instructions. Initialization of base pointers requires a constant to be loaded into an address register. When the base pointer is in the first 16-KBytes of each segment this can be achieved using the Load Effective Address (LEA) instruction, using the absolute addressing mode.

Loading a 32-bit constant into an address register is accomplished using MOVH.A followed by an LEA that uses the base plus 16-bit offset addressing mode. For example:

```plaintext
movh.a a5, ((ADDRESS+8000H)>>16) & FFFFH
lea   a5, [a5](ADDRESS & FFFFH)
```

The MOVH.A instruction loads a 16-bit immediate into the most-significant 16-bits of an address register and zero-fills the least-significant 16-bits.

A 16-bit constant can be added to an address register by using the LEA instruction with the base plus offset addressing mode. A 32-bit constant can be added to an address register in two instructions: an Add Immediate High-word (ADDIH.A), which adds a 16-bit immediate to the most-significant 16-bits of an address register, followed by an LEA using the base plus offset addressing mode. For example:

```plaintext
addih.a a8, ((OFFSET+8000H)>>16) & FFFFH
lea   a8, [a8](OFFSET & FFFFH)
```

The Add Scaled (ADDS.C.A) instruction directly supports the use of a data variable as an index into an array of bytes, half-words, words or double-words.

2.8 Address Comparison

As with the comparison instructions that use the data registers (see Compare Instructions, page 2-11), the comparison instructions using the address registers put the result of the comparison in the least-significant bit of the destination data register and clear the remaining register bits to zeros.

An example using the Less Than (LT.A) instruction is shown in Figure 2-15:

![Figure 2-14 Shift Plus Boolean Operation](image)
There are comparison instructions for equal (EQ.A), not equal (NE.A), less than (LT.A), and greater than or equal to (GE.A).

As with the comparison instructions using the data registers, comparison conditions not explicitly provided in the instruction set can be obtained by swapping the two operand registers (Table 2-2).

### Table 2-2 Operation Equivalents

<table>
<thead>
<tr>
<th>Implicit Comparison Operation</th>
<th>TriCore Equivalent Comparison Operation</th>

<tr>
<td>GE.a</td>
<td>D[c], A[b], A[a]</td>
</tr>
<tr>
<td>GT.A</td>
<td>D[c], A[b], A[a]</td>
</tr>
</tbody>
</table>

In addition to these instructions, instructions that test whether an address register is equal to zero (EQZ.A), or not equal to zero (NEZ.A), are supported. These instructions are useful to test for null pointers, a frequent operation when dealing with linked lists and complex data structures.

### 2.9 Branch Instructions

Branch instructions change the flow of program control by modifying the value in the PC register.

There are two types of branch instructions: conditional and unconditional. Whether a conditional branch is taken depends on the result of a Boolean compare operation.

#### 2.9.1 Unconditional Branch

There are three groups of unconditional branch instructions:

- Jump instructions
- Jump and Link instructions
- Call and Return instructions

A Jump instruction simply loads the Program Counter with the address specified in the instruction. A Jump and Link instruction does the same, and also stores the address of the next instruction in the Return Address (RA) register A[11]. A jump and Link instruction can be used to implement a subroutine call when the called routine does not modify any of the caller’s non-volatile registers.

The Call instructions differ from a Jump and Link in that the call instructions save the caller’s registers upper context in a dynamically-allocated save area.

The Return instruction, in addition to performing the return jump, restores the upper context.

Each group of unconditional jump instructions contains separate instructions that differ in how the target address is specified. There are instructions using a relative 24-bit signed displacement (J, JL, and CALL), instructions using a 24-bit field as an absolute address (JA, JLA, and CALLA), and instructions using the address contained in an address register (JL, JLI, CALLL, RET, and RFE).

There are additional 16-bit instructions for a relative jump using an 8-bit displacement (J), an instruction for an indirect jump (JI), and an instruction for a return (RET).
Both the 24-bit and 8-bit relative displacements are scaled by two before they are used, because all instructions must be aligned on an even address. The use of a 24-bit field as an absolute address is shown in Figure 2-16.

### Figure 2-16 Calculation of Absolute Address

#### 2.9.2 Conditional Branch

The conditional branch instructions use the relative addressing mode, with a displacement value encoded in 4, 8 or 15-bits. The displacement is scaled by 2 before it is used, because all instructions must be aligned on an even address. The scaled displacement is sign-extended to 32-bits before it is added to the program counter, unless otherwise noted.

**Conditional Jumps on Data Registers**

Six of the conditional jump instructions use a 15-bit signed displacement field:

- JEQ (Comparison for Equality)
- JNE (Non-Equality)
- JLT (Less Than)
- JLT.U (Less Than Unsigned)
- JGE (Greater Than or Equal)
- JGE.U (Greater Than or Equal Unsigned)

The second operand to be compared may be an 8-bit sign or zero-extended constant. There are two 16-bit instructions that test whether the implicit D[15] register is equal to zero (JZ) or not equal to zero (JNZ). The displacement is 8-bit in this case.

The 16-bit instructions JEQ and JNE compare the implicit D[15] register with a 4-bit, sign-extended constant. The jump displacement field is limited to a constant for these two instructions.

There is a full set of 16-bit instructions that compare a data register to zero; JZ, JNZ, JLTZ, JLEZ, JGTZ, and JGEZ.

Because any data register may be specified, the jump displacement is limited to a 4-bit zero-extended constant in this case.

**Conditional Jumps on Address Registers**

The conditional jump instructions that use address registers are a subset of the data register conditional jump instructions. Four conditional jump instructions use a 15-bit signed displacement field:

- JEQ.A (Comparison for Equality)
- JNE.A (Non-Equality)
- JZ.A (Equal to Zero)
- JNZ.A (Non-Equal to Zero)

Because testing pointers for equality to zero is so frequent, two 16-bit instructions, JZ.A and JNZ.A, are provided, with a displacement field limited to a 4-bit zero extended constant.
Conditional Jumps on Bits
Conditional jumps can be performed based on the value of any bit in any data register. The JZ.T instruction jumps when the bit is clear, and the JNZ.T instruction jumps when the bit is set. For these instructions the jump displacement field is 15-bits.

There are two 16-bit instructions that test any of the lower 16-bits in the implicit register D[15] and have a displacement field of 4-bit zero extended constant.

2.9.3 Loop Instructions
Four special versions of conditional jump instructions are intended for efficient implementation of loops:
- JNEI
- JNED
- LOOP
- LOOPU

Loop Instructions with Auto Incrementing/Decrementing Counter
The JNEI (Jump if Not Equal and Increment) and JNED (Jump if Not Equal and Decrement) instructions are similar to a normal JNE instruction, but with an additional increment or decrement operation of the first register operand. The increment or decrement operation is performed unconditionally after the comparison. The jump displacement field is 15 bits.

For example, a loop that should be executed for D[3] = 3, 4, 5 ... 10, can be implemented as follows:

```
lea d3, 3
loop1:
...
jnei d3, 10, loop1
```

Loop Instructions with Reduced Execution Overhead
The LOOP instruction is a special kind of jump which utilizes the TriCore hardware that implements ‘zero overhead’ loops.

The LOOP instruction only requires execution time in the pipeline the first and last time it is executed (for a given loop). For all other iterations of the loop, the LOOP instruction has zero execution time.

A loop that should be executed 100 times for example, may be implemented as:

```
mova a2, 99
loop2:
...
loop a2, loop2
```

This LOOP instruction (in the example above) requires execution cycles the first time it is executed, but the other 99 executions require no cycles.

Note that the LOOP instruction differs from the other conditional jump instructions in that it uses an address register, rather than a data register, for the iteration count. This allows it to be used in filter calculations in which a large number of data register reads and writes occur each cycle. Using an address register for the LOOP instruction reduces the need for an extra data register read port.

The LOOP instruction has a 32-bit version using a 15-bit displacement field (left-shifted by one bit and sign-extended), and a 16-bit version that uses a 4-bit displacement field. Unlike other 16-bit relative jumps, the 4-bit value is one-extended rather than zero-extended, because this instruction is specifically intended for loops.

An unconditional variant of the LOOP instruction, LOOPU, is also provided. This instruction utilizes the zero overhead LOOP hardware. Such an instruction is used at the end of a while LOOP body to optimize the jump back to the start of the while construct.
2.10 Load and Store Instructions

The load (LD.x) and store (ST.x) instructions move data between registers and memory using seven addressing modes (Table 2-3).

The addressing mode determines the effective byte address for the load or store instruction and any update of the base pointer address register.

<table>
<thead>
<tr>
<th>Addressing Mode</th>
<th>Syntax</th>
<th>Effective Address</th>
<th>Instruction Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Absolute</td>
<td>Constant</td>
<td>{offset 18[17:14], 14'b00000000000000, offset 18[13:0]}</td>
<td>ABS</td>
</tr>
</tbody>
</table>

2.10.1 Load/Store Basic Data Types

The TriCore architecture defines loads and stores for the basic data types (corresponding to bytes, half-words, words, and double-words), as well as for signed fractions and addresses.

Note that when the data loaded from memory is smaller than the destination register (i.e. 8-bit and 16-bit quantities), the data is loaded into the least-significant bits of the register (except for fractions which are loaded into the most-significant bits of a register), and the remaining register bits are sign or zero-extended to 32-bits, depending on the particular instruction.
2.10.2 Load Bit

The approaches for loading individual bits depend on whether the bit within the word (or byte) is given statically or dynamically.

Loading a single bit with a fixed bit offset from a byte pointer is accomplished with an ordinary load instruction. It is then possible to extract, logically operate on, or jump to any bit in a register.

Loading a single bit with a variable bit offset from a word-aligned byte pointer, is performed with a special scaled offset instruction. This offset instruction shifts the bit offset to the right by three positions (producing a byte offset), adds this result to the byte pointer above, and finally zeros out the two lower bits, so aligning the access on a word boundary.

A word load can then access the word that contains the bit, which can be extracted with an extract instruction that only uses the lower five bits of the bit pointer; i.e. the bits that were either shifted out or masked out above. For example:

```
ADDSC.AT A8, A9, D8; // A9 = byte pointer. D8 = bit offset
LD.W D9, [A8]
EXTR.U D10, D9, D8, 1; // D10[0] = loaded bit
```
The Insert Mask (IMASK) instruction can be used in conjunction with the Load Modify Store (LDMST) instruction, to store a single bit or a bit field to a location in memory, using any of the addressing modes. This operation is especially useful for reading and writing memory-mapped peripherals.

The IMASK instruction is very similar to the INSERT instruction, but IMASK generates a data register pair that contains a mask and a value. The LDMST instruction uses the mask to indicate which portion of the word to modify. An example of a typical instruction sequence is:

```
imask E8, 3, 4, 2; // insert value = 3, position = 4, width = 2
ldmst _IOREG, E8; // at absolute address "_IOREG"
```

To clarify the operation of the IMASK instruction, consider the following example. The binary value 1011B is to be inserted starting at bit position 7 (the width is four). The IMASK instruction would result in the following two values:

```
0000 0000 0000 0000 0000 0111 1000 0000B  // MASK
0000 0000 0000 0000 0000 0101 1000 0000B  // VALUE
```

To store a single bit with a variable bit offset from a word-aligned byte pointer, the word address is first determined in the same way as for the load above.

The special scaled offset instruction shifts the bit offset to the right by three positions, which produces a byte offset, then adds this offset to the byte pointer above.

Finally it zeros out the two lower bits, so aligning the access on a word boundary.

An IMASK and LDMST instruction can store the bit into the proper position in the word. An example is:

```
ADDSC.AT A8, A9, D8; // A9 = byte pointer. D8 = bit offset.
imask E10, D9, D8, 1; // D9[0] = data bit.
ldmst [A8], E10
```

### 2.11 Context Related Instructions

Besides the instructions that implicitly save and restore contexts (such as Calls and Returns), the TriCore instruction set includes instructions that allow a task’s contexts to be explicitly saved, restored, loaded, and stored. These instructions are detailed here.

#### 2.11.1 Lower Context Saving and Restoring

The upper context of a task is always automatically saved on a call, interrupt or trap, and is automatically restored on a return. However the lower context of a task must be explicitly saved or restored.

The SVLCX instruction (Save Lower Context) saves registers A[2] through A[7] and D[0] through D[7], together with the return address (RA) in register A[11] and the PCXI. This operation is performed when using the FCX and PCX pointers to manage the CSA lists.

The BISR instruction (Begin Interrupt Service Routine) enables the interrupt system (ICR.IE = 1), allows the modification of the CPU priority number (CCPN), and saves the lower context in the same manner as the SVLCX instruction.

#### 2.11.2 Context Loading and Storing

The effective address of the memory area where the context is stored to or loaded from, is part of the Load or Store instruction. The effective address must resolve to a memory location aligned on a 16-word boundary, otherwise a data address alignment trap (ALN) is generated.

The STUCX instruction (Store Upper Context) stores the same context information that is saved with an implicit upper context save operation: Registers A[10] to A[15] and D[8] to D[15], and the current PSW and PCXI.

2.12 System Instructions
The system instructions allow User mode and Supervisor mode programs to access and control various system services, including interrupts and the TriCore’s debugging facilities. There are also instructions that read and write the core registers, for both User and Supervisor-only mode programs. There are special instructions for the memory management system.

2.12.1 System Call
The SYSCALL instruction generates a system call trap, providing a secure mechanism for User mode application code to request Supervisor mode services.

The system call trap, like other traps, vectors to the trap handler table, using the three-bit hardware-furnished trap class ID as an index.

The trap class ID for system call traps is six.

The Trap Identification Number (TIN) is specified by an immediate constant in the SYSCALL instruction and serves to identify the specific Supervisor mode service that is being requested.

2.12.2 Synchronization Primitives (DYSNC and ISYNC)
The TriCore architecture provides two synchronization primitives, DYSNC and ISYNC. These primitives provide a mechanism to software through which it can guarantee the ordering of various events within the machine.

DYSNC
The DSYNC primitive provides a mechanism through which a data memory barrier can be implemented.

The DSYNC instruction guarantees that all data accesses associated with instructions semantically prior to the DSYNC instruction are completed before any data memory accesses associated with an instruction semantically after DSYNC are initiated. This includes all accesses to the system bus and local data memory.

ISYNC
The ISYNC primitive provides a mechanism through which the following can be guaranteed:

- If an instruction semantically prior to ISYNC makes a software visible change to a piece of architectural state, then the effects of this change are seen by all instructions semantically after ISYNC.
  - For example, if an instruction changes a code range in the protection table, the use of an ISYNC guarantees that all instructions after the ISYNC are fetched and matched against the new protection table entry.
- All cached states in the pipeline, such as loop cache buffers, are invalidated.

The operation of the ISYNC instruction is as follows:

1. Wait until all instructions semantically prior to the ISYNC have completed.
2. Flush the CPU pipeline and cancel all instructions semantically after the ISYNC.
3. Invalidate all cached state in the pipeline.
4. Re-Fetch the next instruction after the ISYNC.
2.12.3 Access to the Core Special Function Registers (CSFRs)

The core accesses the CSFRs through two instructions:

- **MFCR**
  - The Move From Core Register instruction moves the contents of the addressed CSFR into a data register. MFCR can be executed in any mode (i.e. User-1, User-0 or Supervisor mode).

- **MTCR**
  - The Move To Core Register instruction moves the contents of a data register to the addressed CSFR. To prevent unauthorized writes to the CSFRs the MTCR instruction can only be executed in Supervisor mode. An MTCR instruction should be followed by an ISYNC instruction. This ensures that all instructions following the MTCR see the effects of the CSFR update.

There are no instructions allowing bit, bit-field or load-modify-store accesses to the CSFRs. The RSTV instruction (Reset Overflow Flags) only resets the overflow flags in the PSW without modifying any of the other PSW bits. This instruction can be executed in any mode (i.e. User-1, User-0 or Supervisor mode).

The CSFRs are also mapped into the memory address space. This mapping makes the complete architectural state of the core visible in the address map, which allows efficient debug and emulator support. Note that it is not permitted for the core to access the CSFRs through this mechanism. The core must use MFCR and MTCR. **Figure 2-18** summarizes TriCore core behaviour when accessing CSFRs.

![Figure 2-18 TriCore, Core Behaviour Accessing CSFRs](image)

2.12.4 Enabling and Disabling the Interrupt System

For non-interruptible operations, the ENABLE and DISABLE instructions allow the explicit enabling and disabling of interrupts in both User and Supervisor mode. While disabled, an interrupt will not be taken by the CPU regardless of the relative priorities of the CPU and the highest interrupt pending. The only ‘interrupt’ that is serviced while interrupts are disabled is the NMI (Non-Maskable Interrupt), because it bypasses the normal interrupt structure.

If a user process accidentally disables interrupts for longer than a specified time, watchdog timers can be used to recover.
Programs executing in Supervisor mode can use the 16-bit BISR instruction (Begin Interrupt Service Routine) to save the lower context of the current task, set the current CPU priority number and re-enable interrupts (which are disabled by the processor when an interrupt is taken).

2.12.5 Return (RET) and Return From Exception (RFE) Instructions
The RET (Return) instruction is used to return from a function that was invoked via a CALL instruction. The RFE (Return From Exception) instruction is used to return from an interrupt or trap handler.

These two instructions perform very similar operations; they restore the upper context of the calling function or interrupted task and branch to the return address contained in register A[11] (prior to the context restore operation).

The two instructions differ in the error checking they perform for call depth management. Issuing an RFE instruction when the current call depth (as tracked in the PSW) is non-zero, generates a context nesting error trap. Conversely, a context call depth underflow trap is generated when an RET instruction is issued when the current call depth is zero.

2.12.6 Trap Instructions
The Trap on Overflow (TRAPV) and Trap on Sticky Overflow (TRAPSV) instructions can be used to cause a trap if the PSWs V and SV bits respectively, are set. See PSW (Program Status Word) Status Flags and Arithmetic Instructions, page 2-8.

2.12.7 No-Operation (NOP)
Although there are many ways to represent a no-operation (for example, adding zero to a register), an explicit NOP instruction is included so that it can be easily recognized.

2.13 Coprocessor (COP) Instructions
The TriCore instruction set architecture may be extended with implementation defined, application specific instructions. These instructions are executed on dedicated coprocessor hardware attached to the coprocessor interface.

The coprocessors operate in a similar manner to the integer instructions, receiving operands from the general purpose data registers and able to return a result to the same registers.

The architecture supports the operation of up to four concurrent coprocessors (n = 0, 1, 2, 3). Two of these (n = 0, 1) are reserved for use by the TriCore CPU allowing two (n = 2, 3) for use by the application hardware.

2.14 16-bit Instructions
The 16-bit instructions are a subset of the 32-bit instruction set, chosen because of their frequency of static use. The 16-bit instructions significantly reduce static code size and therefore provide a reduction in the cost of code memory and a higher effective instruction bandwidth. Because the 16-bit and 32-bit instructions all differ in the primary opcode, the two instruction sizes can be freely intermixed.

The 16-bit instructions are formed by imposing one or more of the following format constraints:

- Smaller constants
- Smaller displacements
- Smaller offsets
- Implicit source, destination, or base address registers
- Combined source and destination registers (the 2-operand format)

In addition, the 16-bit load and store instructions support only a limited set of addressing modes.
The registers D[15] and A[15] are used as implicit registers in many 16-bit instructions. For example, there is a 16-bit compare instruction (EQ) that puts a Boolean result in D[15], and a 16-bit conditional move instruction (CMOV) which is controlled by the Boolean in D[15].

The 16-bit load and store instructions are limited to the register indirect (base plus zero offset), base plus offset (with implicit base or source/destination register), and post-increment (with default offset) addressing modes. The offset is a scaled offset. It is scaled up to 10-bit by the type of instruction (byte, half-word, word).
### 3 Instruction Set

The instruction mnemonics which follow are grouped into families of similar or related instructions, then listed in alphabetical order within those groups.

For explanations of the syntax used, please refer to the previous chapter.

#### 3.1 CPU Instructions

Each page for this group of instructions is laid out as follows:

<table>
<thead>
<tr>
<th>Instruction Mnemonic</th>
<th>Instruction Longname</th>
<th>Description</th>
<th>Syntax</th>
<th>Opcodes (32-bit)</th>
<th>Operation in RTL format (32-bit)</th>
<th>Status Flags</th>

ABS

Absolute Value

Description
Put the absolute value of data register D[b] in data register D[c]: If the contents of D[b] are greater than or equal to zero then copy it to D[c], otherwise change the sign of D[b] and copy it to D[c].

The operands are treated as signed 32-bit signed integers.

ABS.B
Absolute Value Packed Byte

ABS.H
Absolute Value Packed Half-word

Description
Put the absolute value of each byte (ABS.B) or half-word (ABS.H) in data register D[b] into the corresponding byte or half-word of data register D[c]. The operands are treated as signed, 8-bit or 16-bit integers.

The overflow condition is calculated for each byte or half-word of the packed quantity.

Absolute Value of Difference Packed Byte

ABSDIF.H
Absolute Value of Difference Packed Half-word

Description
Compute the absolute value of the difference between the corresponding bytes (ABSDIF.B) or half-words (ABSDIF.H) of D[a] and D[b], and put each result in the corresponding byte or half-word of D[c]. The operands are treated as signed, 8-bit or 16-bit integers.

The overflow condition is calculated for each byte (ABSDIF.B) or half-word (ABSDIF.H) of the packed register.

ABSDIFS
Absolute Value of Difference with Saturation

Description
Put the absolute value of the difference between D[a] and either D[b] (instruction format RR) or const9 (instruction format RC) in D[c]; i.e. if the contents of data register D[a] are greater than either D[b] (format RR) or const9 (format RC), then subtract D[b] (format RR) or const9 (format RC) from D[a] and put the result in data register D[c]; otherwise, subtract D[a] from either D[b] (format RR) or const9 (format RC) and put the result in D[c]. The operands are treated as signed, 32-bit integers, with saturation on signed overflow (ssov). The const9 value is sign-extended.

**ABSDIFS D[c], D[a], const9 (RC)**

\[
\begin{array}{cccccc}
31 & 28 & 27 & 21 & 20 & 12 & 11 & 8 & 7 & 0 \\
& c & 0F_H & const9 & a & 8B_H \\
\end{array}
\]

result = (D[a] > sign_ext(const9)) ? D[a] - sign_ext(const9) : sign_ext(const9) - D[a];
D[c] = sssov(result, 32);

ADDC
Add with Carry

Description
Add the contents of data register D[a] to the contents of either data register D[b] (instruction format RR) or const9 (instruction format RC) plus the carry bit, and put the result in data register D[c]. The operands are treated as 32-bit integers. The value const9 is sign-extended before the addition is performed. The PSW carry bit is set to the value of the ALU carry out.

\[
\text{ADDCD}[c], D[a], \text{const9 (RC)}
\]

ADDSC.A  
Add Scaled Index to Address  

ADDSC.AT  
Add Bit-Scaled Index to Address  

Description  
For ADDSC.A, left-shift the contents of data register D[a] by the amount specified by n, where n can be 0, 1, 2, or 3. Add that value to the contents of address register A[b] and put the result in address register A[c].  

For ADDSC.AT, right-shift the contents of D[a] by three (with sign fill). Add that value to the contents of address register A[b] and clear the bottom two bits to zero. Put the result in A[c]. The ADDSC.AT instruction generates the address of the word containing the bit indexed by D[a], starting from the base address in A[b].  

ADDSC.A A[c], A[b], D[a], n (RR)  

\[ A[c] = A[b] + (D[a] \ll n); \]  

ADDSC.AT A[a], A[b], D[a] (RR)  

\[ A[a] = (A[b] + (D[a] \gg 3)) \land 32'hFFFFFFFC; \]

AND.EQ
Equal Accumulating

Description
Compute the logical AND of D[c][0] and the boolean result of the equality comparison operation on the contents of data register D[a] and either data register D[b] (instruction format RR) or const9 (instruction RC). Put the result in D[c][0]. All other bits in D[c] are unchanged. The const9 value is sign-extended.

AND.EQD[c], D[a], const9 (RC)

\[
\begin{array}{cccccc}
31 & 28 & 27 & 26 & 25 & 24 \\
\text{c} & 20 & \text{const9} & a & 8B_H \\
\end{array}
\]

\(D[c] = \{D[c][31:1], D[c][0] \text{ AND } (D[a] == \text{sign\_ext(const9))};\)

BISR
Begin Interrupt Service Routine

Description

*Note: BISR can only be executed in Supervisor mode.*

Save the lower context by storing the contents of A[2]-A[7], D[0]-D[7], and the current A[11] (return address) to the current memory location pointed to by the FCX.

Set the current CPU priority number (ICR.CCPN) to the value of either const9[7:0] (instruction format RC) or const8 (instruction format SC), and enable interrupts (set ICR.IE to one).

This instruction is intended to be one of the first executed instructions in an interrupt routine. If the interrupt routine has not altered the lower context, the saved lower context is from the interrupted task. If a BISR instruction is issued at the beginning of an interrupt, then an RSLCX instruction should be performed before returning with the RFE instruction.

**BISRconst9 (RC)**

```
if (FCX == 0) trap(FCU);
tmp_FCX = FCX;
EA = {FCX.FCXS, 6'b0, FCX.FCXO, 6'b0};
new_FCX = M(EA, word);
M(EA,16 * word) = {PCXI, A[11], A[2], A[3], D[0], D[1], D[2], D[3], A[4], A[5], A[6], A[7], D[4], D[5], D[6], D[7]};
PCXI.PCPN = ICR.CCPN;
PCXI.PIE = ICR.IE;
PCXI.UL = 0;
PCXI[19:0] = FCX[19:0];
FCX[19:0] = new_FCX[19:0];
ICR.IE = 1;
ICR.CCPN = const9[7:0];
if (tmp_FCX == LCX) trap(FCD);
```

**BISRconst8 (SC)**

```
tmp_FCX = FCX;
```
if (FCX == 0) trap(FCU);
EA = {FCX.FCXS, 6'b0, FCX.FCXO, 6'b0};
new_FCX = M(EA, word);
M(EA,16 * word) = {PCXI, A[11], A[2], A[3], D[0], D[1], D[2], D[3], A[4], A[5], A[6], A[7], D[4], D[5], D[6], D[7]};
PCXI.PCPN = ICR.CCPN;
PCXI.PIE = ICR.IE;
PCXI.UL = 0;
FCX[19:0] = FCX[19:0];
PCXI[19:0] = new_FCX[19:0];

BMERGE
Bit Merge

Description
Take the lower 16-bits of data register D[a] and move them to the odd bit positions of data register D[c]. The lower 16-bits of data register D[b] are moved to the even bit positions of data register D[c]. The upper 16-bits of D[a] and D[b] are not used.
This instruction is typically used to merge two bit streams such as commonly found in a convolutional coder.

BMERGE
Description

Note: This instruction can only be executed in Supervisor mode.

If the cache line containing the byte memory location specified by the addressing mode is present in the L1 data cache, invalidate the line. Note that there is no writeback of any dirty data in the cache line prior to the invalidation.

If the cache line containing the byte memory location specified by the addressing mode is not present in the L1 data cache, then no operation should be performed in the L1 data cache. Specifically a refill of the line containing the byte pointed to by the effective address should not be performed. Any address register updates associated with the addressing mode are always performed regardless of the cache operation. The effective address is a virtual address when operating in virtual mode.

**CACHEA.I**

Cache Address, Invalidate

**Description**

If the cache line containing the byte memory location specified by the addressing mode is present in the L1 data cache, invalidate the line. Note that there is no writeback of any dirty data in the cache line prior to the invalidation.

If the cache line containing the byte memory location specified by the addressing mode is not present in the L1 data cache, then no operation should be performed in the L1 data cache. Specifically a refill of the line containing the byte pointed to by the effective address should not be performed. Any address register updates associated with the addressing mode are always performed regardless of the cache operation. The effective address is a virtual address when operating in virtual mode.

CACHEA.WI
Cache Address, Writeback and Invalidate

Description
If the cache line containing the byte memory location specified by the addressing mode is present in the L1 data cache, write back any modified data and then invalidate the line in the L1 data cache.
If the cache line containing the byte memory location specified by the addressing mode is not present in the L1 data cache then no operation should be performed in the L1 data cache. Specifically a refill of the line containing the byte pointed to by the effective address should not be performed. Any address register updates associated with the addressing mode are always performed regardless of the cache operation. The effective address is a virtual address when operating in virtual mode.

CACHEI.W
Cache Index, Writeback

Description
If any modified cache line at the memory index/way specified by address register A[b] is present in the L1 data cache, writeback the modified data. The line will still be present within the L1 data cache but will be marked as unmodified.

The address specified by the address register A[b] undergoes standard protection checks. Address register updates associated with the addressing mode are performed regardless of the cache operation.

The location of way/index within A[b] is implementation dependent.

CALLI
Call Indirect

Description
Jump to the address specified by the contents of address register A[a]. In parallel with the jump save the caller’s Upper Context to an available Context Save Area (CSA). Set register A[11] (return address) to the address of the next instruction beyond the call.

Note: When the PSW is saved, the CDE bit is forced to ‘1’.

DEXTR
Extract from Double Register

Description
Extract 32-bits from registers (D[a], D[b]), where D[a] contains the most-significant 32-bits of the value, starting at the bit number specified by either 32 - D[d][4:0] (instruction format RRRR) or 32 - pos (instruction format RRPW). Put the result in D[c].

Note: D[a] and D[b] can be any two data registers or the same register. For this instruction they are treated as a 64-bit entity where D[a] contributes the high order bits and D[b] the low order bits.

DEXTRD[c], D[a], D[b], pos (RRPW)

\[D[c] = ([D[a], D[b]] \ll pos)[63:32];\]

DEXTRD[c], D[a], D[b], D[d] (RRRR)

\[D[c] = ([D[a], D[b]] \ll D[d][4:0])[63:32];\]
If D[d] > 31 the result is undefined.

ISYNC
DVADJ
Divide-Adjust

Description
Divide-adjust the contents of the formatted data register E[d] using the divisor in D[b] and store the result in E[c]. E[d][63:32] contains the sign-extended final remainder from a previous DVSTEP instruction and E[d][31:0] contains the sign-extended final quotient in ones complement format. The DVADJ instruction converts the final quotient to twos complement format by adding one if the final quotient is negative, and corrects for a corner case that occurs when dividing a negative dividend that is an integer multiple of the divisor. The corner case is resolved by setting the remainder E[d][63:32] to zero and increasing the magnitude of the quotient E[d][31:0] by one. Note that the increment for converting a negative ones complement quotient to twos complement, and the decrement of a negative quotient in the corner case (described above), cancel out.

*Note: This operation must not be performed at the end of an unsigned divide sequence.*

**DVADJE[c], E[d], D[b] (RRR)**

```
31  28  27  24  23  20  19  18  17  16  15  12  11  8  7  0

DIV
Divide
DIV.U
Divide Unsigned

Description
Divide the contents of register D[a] by the contents of register D[b]. Put the resulting quotient in E[c][31:0] and the remainder in E[c][63:32].

The operands and results are treated as signed 32-bit integers for the DIV instruction and as unsigned 32-bit integers for the DIV.U instruction.

Overflow occurs if the divisor (D[b]) is zero. For DIV, Overflow also occurs if the dividend (D[a]) is the maximum negative number and the divisor is minus 1.

DIVE[c], D[a], D[b] (RR)

\[
\begin{array}{cccccc}

DVINIT.BU
Divide-Initialization Byte Unsigned
DVINIT.H
Divide-Initialization Half-word
DVINIT.HU
Divide-Initialization Half-word Unsigned

Description
The DVINIT group of instructions prepare the operands for a subsequent DVSTEP instruction (see DVSTEP) from the dividend D[a] and divisor D[b], and also check for conditions that will cause overflow of the final quotient result. After a DVINIT instruction E[c] contains the partially calculated remainder (equal to the sign-extended dividend) and partially calculated quotient (equal to + or - zero in ones complement format, depending on the signs of the dividend and divisor).

For signed operands DVINIT, DVINIT.H or DVINIT.B must be used. For unsigned operands DVINIT.U, DVINIT.HU and DVINIT.BU are used.

The size of the remainder and quotient bit fields in E[c] depend upon the variant of DVINIT used, which in turn depends upon the number of subsequent DVSTEP instructions required to calculate the final remainder and quotient results.

If the final quotient result is guaranteed to fit into 8 bits then a DVINIT.B(U) can be used, but must be followed by only one DVSTEP instruction.

If the quotient result is guaranteed to fit into 16 bits then a DVINIT.H(U) can be used but must be followed by two DVSTEP instructions.

For a quotient result of 32 bits a DVINIT(.U) must be used, followed by four DVSTEP instructions.

The resultant bit fields in E[c] are as follows:
- DVINIT(.U) E[c][63:0] = partially calculated remainder.

The .B(U) and .H(U) suffixes of the DVINIT group of instructions indicate an 8-bit and 16-bit quotient result, not 8-bit and 16-bit operands as in other instructions. The operands supplied to a DVINIT, DVINIT.H or DVINIT.B instruction are required to be 32-bit sign-extended values. The operands supplied to the DVINIT.U, DVINIT.HU and DVINIT.BU instructions are 32-bit zero-extended values.

Overflow occurs if the divisor is zero, or if the dividend is the maximum negative value for the instruction variant and the divisor is minus one. No check is performed to ensure that the expected quotient can be represented in 32, 16, 8 bits, depending on the DVINIT variant used.

DVADJ, DVSTEP, DVSTEP.U
DVSTEP
Divide-Step
DVSTEP.U
Divide-Step Unsigned

Description
The DVSTEP(.U) instruction divides the contents of the formatted data register E[d] by the divisor in D[b], producing 8-bits of quotient at a time. E[d] contains a partially calculated remainder and partially calculated quotient (in ones complement format) in bit fields that depend on the number of DVSTEP instructions required to produce a final result (see DVSTEP).
DVSTEP uses a modified restoring division algorithm to calculate 8-bits of the final remainder and quotient results. The size of the bit fields of the output register E[c] depend on the size of the bit fields in the input register E[d].

Resultant bit field sizes of E[c]:
- If E[d][63:0] = partially calculated remainder then E[c][63:8] = partially calculated remainder and E[c][7:0] = partially calculated quotient.
- If E[d][63:8] = partially calculated remainder then E[c][63:16] = partially calculated remainder and E[c][15:0] = partially calculated quotient.

The DVSTEP and DVSTEP.U operate on signed and unsigned operands respectively. A DVSTEP instruction that yields the final remainder and final quotient should be followed by a DVADJ instruction (see DVADJ).

EXTR
Extract Bit Field

EXTR.U
Extract Bit Field Unsigned

Description
Extract the number of consecutive bits specified by either E[d][36:32] (instruction format RRRR) or width (instruction formats RRRW and RRPW) from D[a], starting at the bit number specified by either E[d][4:0] (instruction format RRRR), D[d][4:0] (instruction format RRRW) or pos (instruction format RRPW). Put the result in D[c], sign-extended (EXTR) or zero-extended (EXTR.U).

EXTRD[c], D[a], pos, width (RRPW)

width = E[d][36:32];
D[c] = sign_ext((D[a] >> pos)[width-1:0]);
If pos + width > 32 or if width = 0, then the results are undefined.

EXTRD[c], D[a], E[d] (RRRR)

width = E[d][36:32];
D[c] = sign_ext((D[a] >> E[d][4:0])[width-1:0]);
If E[d][4:0] + width > 32 or if width = 0, then the results are undefined.

EXTRD[c], D[a], D[d], width (RRRW)

D[c] = sign_ext((D[a] >> D[d][4:0])[width-1:0]);
If D[d][4:0] + width > 32 or if width = 0, then the results are undefined.

EXTR.UD[c], D[a], pos, width (RRPW)

D[c] = zero_ext((D[a] >> pos)[width-1:0]);
If pos + width > 32 or if width = 0, then the results are undefined.

EXTR.UD[c], D[a], E[d] (RRRR)

width = E[d][36:32];
D[c] = zero_ext((D[a] >> E[d][4:0])[width-1:0]);
If E[d][4:0] + width > 32 or if width = 0, then the results are undefined.
D[c] = zero_ext((D[a] >> E[d][4:0])[width-1:0]);
If E[d][4:0] + width > 32 or if width = 0, then the results are undefined.

EXTR.UD[c], D[a], D[d], width (RRRW)

D[c] = zero_ext((D[a] >> D[d][4:0])[width-1:0]);
If D[d][4:0] + width > 32 or if width = 0, then the results are undefined.

GE
Greater Than or Equal

GE.U
Greater Than or Equal Unsigned

Description
If the contents of data register D[a] are greater than or equal to the contents of either data register D[b] (instruction format RR) or const9 (instruction format RC), set the least-significant bit of D[c] to one and clear the remaining bits to zero; otherwise clear all bits in D[c]. D[a] and D[b] are treated as 32-bit signed (GE) or unsigned (GE.U) integers. The const9 value is sign-extended (GE) or zero-extended (GE.U).

GED[c], D[a], const9 (RC)

result = (D[a] >= sign_ext(const9));
D[c] = zero_ext(result);

GED[c], D[a], D[b] (RR)

result = (D[a] >= D[b]);
D[c] = zero_ext(result);

GE.U D[c], D[a], const9 (RC)

result = (D[a] >= zero_ext(const9)); // unsigned
D[c] = zero_ext(result);

GE.U D[c], D[a], D[b] (RR)

result = (D[a] >= D[b]); // unsigned
D[c] = zero_ext(result);

**IMASK**

**Insert Mask**

**Description**

Create a mask containing the number of bits specified by `width`, starting at the bit number specified by either `D[d][4:0]` (instruction formats `RRRW` and `RRCW`) or `pos` (instruction formats `RRPW` and `RCPW`), and put the mask in data register `E[c][63:32]`.

Left-shift the value in either `D[b]` (formats `RRRW` and `RRPW`) or `const4` (formats `RRCW` and `RCPW`) by the amount specified by either `D[d][4:0]` (formats `RRRW` and `RRCW`) or `pos` (formats `RRPW` and `RCPW`) and put the result value in data register `E[c][31:0]`.

The value `const4` is zero-extended. This mask and value can be used by the Load-Modify-Store (LDMST) instruction to write a specified bit field to a location in memory.

**IMASKE[c], const4, pos, width (RCPW)**

INSERT
Insert Bit Field

Description
Starting at bit zero, extract from either D[b] (instruction formats RRRR, RRRW, RRPW) or const4 (instruction formats RCRR, RCRW, RCPW) the number of consecutive bits specified by either E[d][36:32] (formats RRRR, RCRR) or width (formats RRRW, RRPW, RCRW, RCPW).
Shift the result left by the number of bits specified by either E[d][4:0] (formats RRRR, RCRR), D[d] (formats RRRW, RCRW) or pos (formats RRPW, RCPW); extract a copy of D[a], clearing the bits starting at the bit position specified by either E[d][4:0] (formats RRRR, RCRR), D[d] (formats RRRW, RCRW) or pos (formats RRPW, RCPW), and extending for the number of bits specified by either E[d][36:32] (formats RRRR, RCRR) or width (formats RRRW, RRPW, RCRW, RCPW). Put the bitwise OR of the two extracted words into D[c].

ISYNC
Synchronize Instructions

Description
The ISYNC instruction forces completion of all previous instructions, then flushes the CPU pipelines and invalidates any cached pipeline state before proceeding to the next instruction.

Note: I-cache is not invalidated by ISYNC.

Note: An ISYNC instruction should follow a MTCR instruction. This ensures that all instructions following the MTCR see the effects of the CSFR update.

Find Maximum Index (unsigned)

**Description**

Enables a search of maximum value and its related index in a vector of 16-bit signed (IXMAX) or unsigned (IXMAX.U) values.

The IXMAX and IXMAX.U instructions are not available in the TriCore 1.2 Architecture.

For all operations:

- $E[d][31:16]$ Current index of maximum.
- $E[d][63:48] 00_H$.
- $D[b][15:0]$ First compare value.
- $D[b][31:16]$ Second compare value.
- $E[c][15:0]$ Update working index.
- $E[c][31:16]$ Update index of maximum.
- $E[c][63:48] 00_H$.

**IXMAXE[c], E[d], D[b] (RRR)**

<td>0B_H</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For IXMAX.U, the comparison is on unsigned numbers.

$E[c][15:0] = E[d][15:0] + 2$;

$E[c][63:48] = 00_H$;
if (D[b][15:0] >= D[b][31:16]) AND (D[b][15:0] > E[d][47:32]) then {
  E[c][47:32] = D[b][15:0];
  E[c][31:16] = E[d][15:0];
} else if (D[b][31:16] > D[b][15:0]) AND (D[b][31:16] > E[d][47:32]) then {
  E[c][47:32] = D[b][31:16];
  E[c][31:16] = E[d][15:0]+1;
} else {
  E[c][47:32] = E[d][47:32];
  E[c][31:16] = E[d][31:16];
}

For all index additions, on overflow: wrapping, no trap.

If the 1st compare value and 2nd compare value and current maximum value are the same, the priority select is: current maximum is the highest priority then 1st compare value and 2nd compare value is in the lowest priority.

Find Minimum Index

**IXMIN.U**

Find Minimum Index (unsigned)

**Description**

Enables search of minimum value and its related index in a vector of 16-bit signed (IXMIN) or unsigned (IXMIN.U) values.

The IXMIN and IXMIN.U instructions are not available in the TriCore 1.2 Architecture.

For all operations:

- \( E[d][15:0] \) Working index.
- \( E[d][31:16] \) Current index of minimum.
- \( E[d][47:32] \) Current value of minimum.
- \( E[d][63:48] \) 00H.
- \( D[b][15:0] \) First compare value.
- \( D[b][31:16] \) Second compare value.
- \( E[c][15:0] \) Update working index.
- \( E[c][31:16] \) Update index of minimum.
- \( E[c][47:32] \) Update value of minimum.
- \( E[c][63:48] \) 00H.

Jump if Less Than

JLT.U
Jump if Less Than Unsigned

Description
If the contents of D[a] are less than the contents of either D[b] (instruction format BRR) or const4 (instruction format BRC), then add the value specified by disp15, sign-extended and multiplied by 2, to the contents of PC and jump to that address. The operands are treated as signed (JLT) or unsigned (JLT.U), 32-bit integers. The const4 value is sign-extended (JLT) or zero-extended (JLT.U).

JLTD[a], const4, disp15 (BRC)

if (D[a] < sign_ext(const4)) then PC = PC + sign_ext(disp15) * 2;

JLTD[a], D[b], disp15 (BRR)

if (D[a] < D[b]) then PC = PC + sign_ext(disp15) * 2;

JLT.UD[a], const4, disp15 (BRC)

if (D[a] < zero_ext(const4)) then { // unsigned comparison
PC = PC + sign_ext(disp15) * 2;
}

JLT.UD[a], D[b], disp15 (BRR)

if (D[a] < D[b]) then PC = PC + sign_ext(disp15) * 2; // unsigned comparison

LDLCX
Load Lower Context

Description
Load the contents of the memory block specified by the addressing mode into registers A[2]-A[7] and D[0]-D[7]. This operation is normally used to restore GPR values that were saved previously by an STLCX instruction.

Note: The effective address specified by the addressing mode must be aligned on a 16-word boundary. For this instruction the addressing mode is restricted to absolute (ABS) or base plus short offset (BO).

LDLCXoff18 (ABS) (Absolute Addressing Mode)

EA = \{off18[17:14],14b'0,off18[13:0]\};
{dummy, dummy, A[2:3], D[0:3], A[4:7], D[4:7]} = M(EA, 16-word);

LDLCXA[b], off10 (BO) (Base + Short Index Addressing Mode)

EA = A[b] + sign_ext(off10);
{dummy, dummy, A[2:3], D[0:3], A[4:7], D[4:7]} = M(EA, 16-word);

Load-Modify-Store

Description
The atomic Load-Modify-Store implements a store under a mask of a value to the memory word, whose address
is specified by the addressing mode. Only those bits of the value E[a][31:0] where the corresponding bits in the
mask E[a][63:32] are set, are stored into memory. The value and mask may be generated using the IMASK
instruction.

LDUCX
Load Upper Context

Description
Load the contents of the memory block specified by the addressing mode into registers A[10] to A[15] and D[8] to D[15]. This operation is used normally to restore GPR values that were saved previously by a STUCX instruction.

Note: The effective address (EA) specified by the addressing mode must be aligned on a 16-word boundary. For this instruction the addressing mode is restricted to absolute (ABS) or base plus short offset (BO).

LDUCXoff18 (ABS)(Absolute Addressing Mode)

\[
\begin{array}{cccccccc}
31 & 28 & 27 & 26 & 25 & 22 & 21 & 16 & 15 & 12 & 11 & 8 & 7 & 0 \\
\end{array}
\]

EA = \{\text{off18}[17:14], 14b'0, \text{off18}[13:0]\};
{\text{dummy}, \text{dummy}, A[10:11], D[8:11], A[12:15], D[12:15]} = M(EA, 16-word);

LDUCXA[b], off10 (BO)(Base + Short Index Addressing Mode)

\[
\begin{array}{cccccccc}
31 & 28 & 27 & 22 & 21 & 16 & 15 & 12 & 11 & 8 & 7 & 0 \\
\text{off10}[9:6] & 25_H & \text{off10}[5:0] & b & - & 49_H \\
\end{array}
\]

EA = A[b][31:0] + sign_ext(off10);
{\text{dummy}, \text{dummy}, A[10:11], D[8:11], A[12:15], D[12:15]} = M(EA, 16-word);

LT
Less Than

LT.U
Less Than Unsigned

Description
If the contents of data register D[a] are less than the contents of either data register D[b] (instruction format RR)
or const9 (instruction format RC), then set the least-significant bit of D[c] to one and clear the remaining bits to zero; otherwise clear all bits in D[c].
The operands are treated as signed (LT) or unsigned (LT.U) integers. The const9 value is sign-extended (LT) or zero-extended (LT.U).

If the contents of data register D[a] are less than the contents of either data register D[b] (instruction format SRR)or const4 (instruction format SRC), set the least-significant bit of D[15] to one and clear the remaining bits to zero; otherwise clear all bits in D[15]. The operands are treated as signed 32-bit integers, and the const4 value is sign-extended.

MADD.H
Packed Multiply-Add Q Format

MADDS.H
Packed Multiply-Add Q Format, Saturated

Description
Multiply two signed 16-bit (half-word) values, add the product (left justified if n == 1) to a signed 32-bit value and put the result into a 32-bit register. There are four cases of half-word multiplication.

Each MADDS.H result is independently saturated on overflow.

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

### MADD.Q
#### Multiply-Add Q Format

### MADDS.Q
#### Multiply-Add Q Format, Saturated

**Description**

Multiply two signed 16-bit or 32-bit values, add the product (left justified if \( n = 1 \)) to a signed 32-bit or 64-bit value and put the result into a 32-bit or 64-bit register. There are eight cases of 16*16 operations, eight cases of 16*32 operations and four cases of 32*32 operations. On overflow the MADDS.Q result is saturated.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( n = 1 \) then \( \text{8000}_H \times \text{8000}_H = \text{7FFFFFFFH} \) (for signed 16-bit * 16-bit multiplications only).

MADD.U
Multiply-Add Unsigned

MADDS.U
Multiply-Add Unsigned, Saturated

Description
Multiply two unsigned 32-bit integers, add the product to an unsigned 32-bit or 64-bit integer, and put the result into a 32-bit or 64-bit register. The value const9 is zero-extended before the multiplication is performed. The MADDS.U result is saturated on overflow.

MADD.UE[c], E[d], D[a], const9 (RCR)
64 + (32 * K9) --> 64 unsigned

```
31  28  27  24  23  21  20  12  11  8  7  0
   c   d   02H const9   a   13H
```

result = E[d] + (D[a] * zero_ext(const9)); // unsigned operators
E[c] = result[63:0];

MADD.UE[c], E[d], D[a], D[b] (RRR2)
32 + (32 * 32) --> 32 unsigned

```
31  28  27  24  23  21  20  12  11  8  7  0
   c   d   68H   b   a   03H
```

result = E[d] + (D[a] * D[b]); // unsigned operators
E[c] = result[63:0];

MADDS.UD[c], D[d], D[a], const9 (RCR)
32 + (32 * K9) --> 32 unsigned saturated

```
31  28  27  24  23  21  20  12  11  8  7  0
   c   d   04H const9   a   13H
```

result = D[d] + (D[a] * zero_ext(const9)); // unsigned operators
D[c] = suov(result, 32);

MADDS.UE[c], E[d], D[a], const9 (RCR)
64 + (32 * K9) --> 64 unsigned saturated

```
31  28  27  24  23  21  20  12  11  8  7  0
   c   d   06H const9   a   13H
```

result = E[d] + (D[a] * zero_ext(const9)); // unsigned operators
E[c] = suov(result, 64);

MADDS.UD[c], D[d], D[a], D[b] (RRR2)
32 + (32 * 32) --> unsigned saturated
result = D[d] + (D[a] * D[b]); // unsigned operators
D[c] = suov(result, 32);

**MADDS.UE[c], E[d], D[a], D[b] (RRR2)**

64 + (32 * 32) --> 64 unsigned saturated

result = E[d] + (D[a] * D[b]); // unsigned operators
E[c] = suov(result, 64);

### MADDM.H
Packed Multiply-Add Q Format Multi-precision

### MADDMS.H
Packed Multiply-Add Q Format Multi-precision, Saturated

**Description**
Perform two multiplications of two signed 16-bit (half-word) values. Add the two products (left justified if \( n = 1 \)) left-shifted by 16, to a signed 64-bit value and put the result in a 64-bit register. The MADDMS.H result is saturated on overflow. There are four cases of half-word multiplication.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( (n = 1) \) then \( 8000_{H} \times 8000_{H} = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

Packed Multiply-Add Q Format with Rounding

MADDRS.H
Packed Multiply-Add Q Format with Rounding, Saturated

Description
Multiply two signed 16-bit (half-word) values, add the product (left justified if \( n == 1 \)) to a signed 16-bit or 32-bit value and put the rounded result into half of a 32-bit register (Note that since there are two results the two register halves are used). There are four cases of half-word multiplication:

- \( 16U * 16U, 16L * 16L \)
- \( 16U * 16L, 16L * 16U \)
- \( 16U * 16L, 16L * 16L \)
- \( 16L * 16U, 16U * 16U \)

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( (n == 1) \) then \( 8000_{H} * 8000_{H} = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

MADDR.Q
Multiply-Add Q Format with Rounding
MADDRS.Q
Multiply-Add Q Format with Rounding, Saturated

Description
Multiply two signed 16-bit (half-word) values, add the product (left justified if n == 1) to a 32-bit signed value, and put the rounded result in a 32-bit register. The lower half-word is cleared. Overflow and advanced overflow are calculated on the final results.

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

MADDSUM.H
Packed Multiply-Add/Subtract Q Format Multi-precision

MADDSUMS.H
Packed Multiply-Add/Subtract Q Format Multi-precision Saturated

Description
Perform two multiplications of two signed 16-bit (half-word) values. Add one product and subtract the other product (left justified if n == 1) left-shifted by 16, to/from a signed 64-bit value and put the result in a 64-bit register. The MADDSUM.H result is saturated on overflow. There are four cases of half-word multiplication:

• 16U * 16U, 16L * 16L
• 16U * 16L, 16L * 16U
• 16U * 16L, 16L * 16L
• 16L * 16U, 16U * 16U

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

MADDSUR.H
Packed Multiply-Add/Subtract Q Format with Rounding

MADDSURS.H
Packed Multiply-Add/Subtract Q Format with Rounding Saturated

Description
Multiply two signed 16-bit (half-word) values. Add (subtract) the product (left justified if n == 1) to (from) a signed 16-bit value and put the rounded result into half of a 32-bit register (Note that since there are two results, the two register halves are used). There are four cases of half-word multiplication:

• 16U * 16U, 16L * 16L
• 16U * 16L, 16L * 16U
• 16U * 16L, 16L * 16L
• 16L * 16U, 16U * 16U

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

MAX
Maximum Value

MAX.U
Maximum Value Unsigned

Description
If the contents of data register D[a] are greater than the contents of either data register D[b] (instruction format RR) or const9 (instruction format RC), then put the contents of D[a] in data register D[c]; otherwise put the contents of either D[b] (format RR) or const9 (format RC) in D[c]. The operands are treated as either signed (MAX) or unsigned (MAX.U) 32-bit integers.

**MAXD[c], D[a], const9 (RC)**

\[
\begin{array}{c|cccccc|c}
& 31 & 28 & 27 & 21 & 20 & 12 & 11 & 8 & 7 & 0 \\
\hline
\text{c} & 1AH & \text{const9} & \text{a} & & & 8B_H \\
\end{array}
\]

\[D[c] = (D[a] > \text{sign\_ext(const9)}) \ ? \ D[a] : \text{sign\_ext(const9)};\]

MFCR
Move From Core Register

Description
Move the contents of the Core Special Function Register (CSFR), selected by the value const16, to data register D[c]. The CSFR address is a const16 byte offset from the CSFR base address. It must be word-aligned (the least-significant two bits equal zero). Nonaligned addresses have an undefined effect. MFCR can be executed on any privilege level. This instruction may not be used to access GPRs. Attempting to access a GPR with this instruction will return an undefined value.

MOV
Move

Description
Move the contents of either data register D[b] (instruction format RR) or const16 (instruction format RLC), to data register D[c]. The value const16 is sign-extended to 32-bits before it is moved.
The syntax is also valid with a register pair as a destination. If there is a single source operand, it is sign-extended to 64-bits. If the source is a register pair the contents of data register D[a] go into E[c][63:32] and the contents of data register D[b] into E[c][31:0].

Move the contents of either data register D[b] (instruction format SRR), const4 (instruction format SRC) or const8 (instruction format SC) to either data register D[a] (formats SRR, SRC) or D[15] (format SC). The value const4 is sign-extended before it is moved. The value const8 is zero-extended before it is moved.

**MSUBS.H**

Packed Multiply-Subtract Q Format, Saturated

**Description**

Multiply two signed 16-bit (half-word) values. Subtract the product (left justified if \( n == 1 \)) from a signed 32-bit value and put the result into a 32-bit register. There are four cases of half-word multiplication.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( (n == 1) \) then \( 8000_{\text{H}} * 8000_{\text{H}} = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

**MSUB.U**
Multiply-Subtract Unsigned

**MSUBS.U**
Multiply-Subtract Unsigned, Saturated

**Description**
Multiply two unsigned 32-bit integers. Subtract the product from an unsigned 32-bit or 64-bit integer and put the result into a 32-bit or 64-bit register. The value const9 is zero-extended before the multiplication is performed. The MSUBS.U results are saturated on overflow.

**MSUB.UE[c], E[d], D[a], const9 (RCR)**

MSUBAD.H
Packed Multiply-Subtract/Add Q Format

MSUBADS.H
Packed Multiply-Subtract/Add Q Format, Saturated

Description
Multiply two signed 16-bit (half-word) values. Subtract (or add) the product (left justified if \( n = 1 \)) from a signed 32-bit value and put the result into a 32-bit register. There are four cases of half-word multiplication:

- \( 16U \times 16U, 16L \times 16L \)
- \( 16U \times 16L, 16L \times 16U \)
- \( 16U \times 16L, 16L \times 16L \)
- \( 16L \times 16U, 16U \times 16U \)

On overflow each MSUBADS.H result is independently saturated.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( n = 1 \) then \( 8000H \times 8000H = 7FFFFFFFH \) (for signed 16-bit \times 16-bit multiplications only).

**MSUBADM.H**

**Packed Multiply-Subtract/Add Q Format-Multi-precision**

**MSUBADMS.H**

**Packed Multiply-Subtract/Add Q Format-Multi-precision, Saturated**

**Description**

Perform two multiplications of two signed 16-bit (half-word) values. Subtract one product and add the other product (left justified if \( n = 1 \)) left-shifted by 16, from/to a signed 64-bit value and put the result in a 64-bit register. There are four cases of half-word multiplication:

- \( 16U \times 16U, 16L \times 16L \)
- \( 16U \times 16L, 16L \times 16U \)
- \( 16U \times 16L, 16L \times 16L \)
- \( 16L \times 16U, 16U \times 16U \)

On overflow the MSUBADMS.H result is saturated.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( n = 1 \) then \( 8000H \times 8000H = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

MSUBADR.H
Packed Multiply-Subtract/Add Q Format with Rounding

MSUBADRS.H
Packed Multiply-Subtract/Add Q Format with Rounding, Saturated

Description
Multiply two signed 16-bit (half-word) values. Subtract (or add) the product (left justified if n == 1) from (to) a signed 16-bit value and put the rounded result into half of a 32-bit register (Note that since there are two results the two register halves are used). There are four cases of half-word multiplication:

• 16U * 16U, 16L * 16L
• 16U * 16L, 16L * 16U
• 16U * 16L, 16L * 16L
• 16L * 16U, 16U * 16U

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

**MSUBMS.H**

Packed Multiply-Subtract Q Format-Multi-precision, Saturated

**Description**

Perform two multiplications of two signed 16-bit (half-word) values. Subtract the two products (left justified if \( n = 1 \)) left-shifted by 16, from a signed 64-bit value and put the result in a 64-bit register. There are four cases of half-word multiplication:

- 16U * 16U, 16L * 16L
- 16U * 16L, 16L * 16U
- 16U * 16L, 16L * 16L
- 16L * 16U, 16U * 16U

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( n = 1 \) then \( 8000_{\text{H}} \cdot 8000_{\text{H}} = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

Packed Multiply-Subtract Q Format with Rounding

**MSUBRS.H**

Packed Multiply-Subtract Q Format with Rounding, Saturated

**Description**

Multiply two signed 16-bit (half-word) values. Subtract the product (left justified if \( n = 1 \)) from a signed 16-bit or 32-bit value and put the rounded result into half of a 32-bit register. Note that since there are two results the two register halves are used. There are four cases of half-word multiplication:

- \( 16U \times 16U, 16L \times 16L \)
- \( 16U \times 16L, 16L \times 16U \)
- \( 16U \times 16L, 16L \times 16L \)
- \( 16L \times 16U, 16U \times 16U \)

Note that \( n \) should only take the values 0 or 1. Any other value returns an undefined result. If \( (n = 1) \) then \( 8000_{16} \times 8000_{16} = 7FFFFFFFH \) (for signed 16-bit \( \times 16 \)-bit multiplications only).

### MSUBRS.Q
Multiply-Subtract Q Format with Rounding, Saturated

**Description**

Multiply two signed 16-bit (half-word) values. Subtract the product (left justified if \( n = 1 \)) from a 32-bit signed value, and put the rounded result in a 32-bit register. The lower half-word is cleared. Overflow and advanced overflow are calculated on the final results.

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( (n = 1) \) then \( 8000_{16} \times 8000_{16} = 7FFFFFFFH \) (for signed 16-bit * 16-bit multiplications only).

MTCR
Move To Core Register

Description
Note: This instruction can only be executed in Supervisor mode.

Move the value in data register D[a] to the Core Special Function Register (CSFR) selected by the value const16.
The CSFR address is a const16 byte offset from the CSFR base address. It must be word-aligned (the least-significant two bits are zero). Non-aligned address have an undefined effect.
The MTCR instruction can not be used to access GPRs. Attempting to update a GPR with this instruction will have no effect.
An MTCR instruction should be followed by an ISYNC instruction. This ensures that all instructions following the MTCR see the effects of the CSFR update.

Packed Multiply Q Format

Description
Multiply two signed 16-bit (half-word) values and put the product (left justified if n == 1) into a 32-bit register. Note that since there are two results both halves of an extended data register are used. There are four cases of half-word multiplication:

- 16U * 16U, 16L * 16L
- 16U * 16L, 16L * 16U
- 16U * 16L, 16L * 16L
- 16L * 16U, 16U * 16U

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000_{16} * 8000_{16} = 7FFFFFFF_{16} (for signed 16-bit * 16-bit multiplications only).

MUL.Q
Multiply Q Format

Description
Multiply two signed 16-bit or 32-bit values and put the product (left justified if n == 1) into a 32-bit or 64-bit register. There are two cases of 16*16 operations, four cases of 16*32 operations and two cases of 32*32 operations. Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

MUL.QD[c], D[a], D[b], n (RR1)
(32 * 32)Up --> 32

```
31 28 27 18 17 16 15 12 11  8  7  0
  c   02H n  b  a   93H
```

result = ((D[a] * D[b]) << n) >> 32;

MULM.H
Packed Multiply Q Format-Multi-precision

Description
Perform two multiplications of two signed 16-bit (half-word) values. Add the two products (left justified if n == 1) left-shifted by 16, in a 64-bit register. There are four cases of half-word multiplication:

- 16U * 16U, 16L * 16L
- 16U * 16L, 16L * 16U
- 16L * 16U, 16U * 16L
- 16L * 16L, 16L * 16L

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFFH (for signed 16-bit * 16-bit multiplications only).

MULM.HE[c], D[a], D[b] LL, n (RR1)

**MULR.H**

**Packed Multiply Q Format with Rounding**

**Description**

Multiply two signed 16-bit (half-word) values. Add the product (left justified if \( n = 1 \)) to a signed 16-bit value and put the rounded result into half of a 32-bit register. Note that since there are two results the two register halves are used. There are four cases of half-word multiplication:

- \(16U \times 16U, 16L \times 16L\)
- \(16U \times 16L, 16L \times 16U\)
- \(16U \times 16L, 16L \times 16L\)
- \(16L \times 16U, 16U \times 16U\)

Note that \( n \) should only take the values 0 or 1, any other value returns an undefined result. If \( n = 1 \) then \( 8000_{H} \times 8000_{H} = 7FFFFFFFH \) (for signed 16-bit \( \times 16\)-bit multiplications only).

MULR.Q
Multiply Q Format with Rounding

Description
Multiply two signed 16-bit (half-word) values and put the rounded result (left justified if n == 1) into a 32-bit register. The lower half-word is cleared.

Note that n should only take the values 0 or 1, any other value returns an undefined result. If (n == 1) then 8000H * 8000H = 7FFFFFFFH (for signed 16-bit * 16-bit multiplications only).

**OR.LT**  
Less Than Accumulating

**OR.LT.U**  
Less Than Accumulating Unsigned

**Description**

Calculate the logical OR of D[c][0] and the Boolean result of the LT or LT.U operation on the contents of data register D[a] and either data register D[b] (instruction format RR) or const9 (instruction format RC). Put the result in D[c][0]. All other bits in D[c] are unchanged. D[a] and D[b] are treated as 32-bit signed (LT) or unsigned (LT.U) integers. The const9 value is sign-extended (LT) or zero-extended (LT.U).

**OR.LTD[c], D[a], const9 (RC)**

PACK
Pack

Description
Take the data register pair E[d] and bit 31 of data register D[a] and pack them into an IEEE-754 single precision floating point format number, in data register D[c]. The odd register E[d][63:32], holds the unbiased exponent. The even register E[d][31:0], holds the normalised mantissa in a fractional 1.31 format. Bit 31 of data register D[a] holds the sign bit.

To compute the floating point format number, the input number is first checked for special cases: Infinity, NaN, Overflow, Underflow and Zero. If the input number is not one of these special cases, it is either a normal or denormal number. In both cases, rounding of the input number is performed. First an intermediate biased exponent is calculated, by adding 128 to the unpacked exponent for normal numbers and set to zero for denormal numbers, and inserted into bits [30:23] of the intermediate result. Bits [30:8] of E[d] are inserted into bits [22:0] of the intermediate result. A round flag is calculated from bits [8:0] of E[d] using the IEEE-754 Round-to-Nearest rounding definition, with the PSW.C field acting as an additional sticky bit. If the round flag is set, the intermediate result is incremented by one. Bits [30:0] of the intermediate result are then inserted into bits [30:0] of D[c]. In all cases, bit 31 from D[a] is copied into bit 31 of D[c]. The special cases are handled as described below.

PACKD[c], E[d], D[a] (RRR)

```
31 28 27 24 23 20 19 18 17 16 15 12 11 8 7 0
          c       d        00H   -   0H   -   a     68H
```

int_exp = E[d][63:32];
int_mant = E[d][31:0];
if ((int_mant[31] == 0) AND (int_exp == +255)) then {
  // Infinity or NaN
  fp_exp = +255;
  fp_frac = int_mant[30:8];
} else if (((int_mant[31] == 1) AND (int_exp >= +127)) then {
  // Overflow ? Infinity.
  fp_exp = +255;
  fp_frac = 0;
} else if (((int_mant[31] == 1) AND (int_exp <= -128)) then {
  // Underflow ? Zero
  fp_exp = 0;
  fp_frac = 0;
} else if (int_mant == 0) then {
  // Zero
  fp_exp = 0;
  fp_frac = 0;
} else {
  if (int_mant[31] == 0) then {
    // Denormal
    temp_exp = 0;
  }
```

} else {

// Normal
    temp_exp = int_exp + 128;
}

fp_exp_frac[30:0] = {tmp_exp[7:0], int_mant[30:8]} + flag_rnd;
fp_exp = fp_exp_frac[30:23];
fp_frac = fp_exp_frac[22:0];
}

D[c][31] = D[a][31];

Return From Exception

Description
Return from an interrupt service routine or trap handler to the task whose saved upper context is specified by the contents of the Previous Context Information register (PCXI). The contents are normally the context of the task that was interrupted or that took a trap. However in some cases Task Management software may have altered the contents of the PCXI register to cause another task to be dispatched.

The return PC value is taken from register A[11] (register address) in the current context. In parallel with the jump to the return PC address, the upper context registers and PSW in the saved context are restored.

if (PCXI[19:0] == 0) then trap(CSU);

Return From Monitor

Description

Note: The RFM instruction can only be executed in Supervisor mode.

If the Debug mode is disabled (DBGSR.DE==0) execute as a NOP; otherwise return from a breakpoint monitor to
the task whose saved debug context area is located at DCX (Debug Context Pointer).

The Debug Context Area is a four word subset of the context of the task that took a Debug trap, which is saved
on entry to the monitor routine. The return PC value is taken from register A[11]. In parallel with the jump to the
return PC address, the PCXI and PSW, together with the saved A[10] and A[11] values in the Debug Context Area,
are restored to the original task.

The Debug Trap active bit (DBGTCR.DTA) is cleared.

Reverse-Subtract

Description
Subtract the contents of data register D[a] from the value const9 and put the result in data register D[c]. The operands are treated as 32-bit integers. The value const9 is sign-extended before the subtraction is performed.

\[
\text{result} = \text{sign\_ext(const9)} - D[a];
\]
\[
D[c] = \text{result}[31:0];
\]

Status Flags
C  Not set by this instruction.
V  overflow = (result > 7FFFFFFFH) OR (result < -80000000H);
   if (overflow) then PSW.V = 1 else PSW.V = 0;
SV if (overflow) then PSW.SV = 1 else PSW.SV = PSW.SV;
AV advanced_overflow = result[31] \&\& result[30];
   if (advanced_overflow) then PSW.AV = 1 else PSW.AV = 0;
SAV if (advanced_overflow) PSW.SAV = 1 else PSW.SAV = PSW.SAV;

Reverse-Subtract with Saturation

RSUBS.U
Reverse-Subtract Unsigned with Saturation

Description
Subtract the contents of data register D[a] from the value const9 and put the result in data register D[c]. The operands are treated as signed (RSUBS) or unsigned (RSUBS.U) 32-bit integers, with saturation on signed (RSUBS) or unsigned (RSUBS.U) overflow. The value const9 is sign-extended before the operation is performed.

RSUBSD[c], D[a], const9 (RC)

result = sign_ext(const9) - D[a];
D[c] = ssov(result, 32);

RSUBS.UD[c], D[a], const9 (RC)

result = sign_ext(const9) - D[a]; // unsigned
D[c] = suov(result, 32);

Status Flags

C Not set by these instructions.
V signed:
overflow = (result > 7FFFFFFFH) OR (result < -80000000H);
if (overflow) then PSW.V = 1 else PSW.V = 0;
unsigned:
overflow = (result > FFFFFFFFH) OR (result < 00000000H);
if (overflow) then PSW.V = 1 else PSW.V = 0;
SV if (overflow) then PSW.SV = 1 else PSW.SV = PSW.SV;
AV advanced_overflow = result[31] ^ result[30];

**Shift**

**Description**
Shift the value in D[a] by the amount specified by shift count. If the shift count specified through the contents of either D[b] (instruction format RR) or const9 (instruction format RC) is greater than or equal to zero, then left-shift. Otherwise right-shift by the absolute value of the shift count. Put the result in D[c]. In both cases the vacated bits are filled with zeros and the bits shifted out are discarded.

The shift count is a 6-bit signed number, derived from either D[b][5:0] or const9[5:0]. The range for the shift count is therefore -32 to +31, allowing a shift left up to 31 bit positions and to shift right up to 32 bit positions (Note that a shift right by 32 bits leaves zeros in the result).

If the shift count specified through the value const4 is greater than or equal to zero, then left-shift the value in D[a] by the amount specified by the shift count. Otherwise right-shift the value in D[a] by the absolute value of the shift count. Put the result in D[a].

In both cases, the vacated bits are filled with zeros and bits shifted out are discarded.

The shift count is a 4-bit signed number, derived from the sign-extension of const4[3:0]. The resulting range for the shift count therefore is -8 to +7, allowing a shift left up to 7-bit positions and to shift right up to 8-bit positions.

Shift Packed Half-words

Description
If the shift count specified through the contents of either D[b] (instruction format RR) or const9 (instruction format RC) is greater than or equal to zero, then left-shift each half-word in D[a] by the amount specified by shift count. Otherwise, right-shift each half-word in D[a] by the absolute value of the shift count. Put the result in D[c]. In both cases the vacated bits are filled with zeros and bits shifted out are discarded. For these shifts, each half-word is treated individually, and bits shifted out of a half-word are not shifted in to the next half-word.

The shift count is a signed number, derived from the sign-extension of either D[b][4:0] (instruction format RR) or const9[4:0] (instruction format RC). The range for the shift count is therefore -16 to +15. The result for a shift count of -16 for half-words is zero.

SH.HD[c], D[a], const9 (RC)

```
shift_count = sign_ext(const9[4:0]);
result_halfword1 = (shift_count >= 0) ? D[a][31:16] << shift_count : D[a][31:16] >> (0 - shift_count);
result_halfword0 = (shift_count >= 0) ? D[a][15:0] << shift_count : D[a][15:0] >> (0 - shift_count);
D[c] = {result_halfword1[15:0], result_halfword0[15:0]};
```

SH.HD[c], D[a], D[b] (RR)

```
shift_count = sign_ext(D[b][4:0]);
result_halfword1 = (shift_count >= 0) ? D[a][31:16] << shift_count : D[a][31:16] >> (0 - shift_count);
result_halfword0 = (shift_count >= 0) ? D[a][15:0] << shift_count : D[a][15:0] >> (0 - shift_count);
D[c] = {result_halfword1[15:0], result_halfword0[15:0]};

Shift Not Equal

**Description**
Left shift D[c] by one. If the contents of data register D[a] are not equal to the contents of either data register D[b] (instruction format RR) or const9 (instruction format RC), set the least-significant bit of D[c] to one; otherwise set the least-significant bit of D[c] to zero. The value const9 is sign-extended.

SHA
Arithmetic Shift

Description
If shift count specified through contents of either D[b] (instruction format RR) or const9 (instruction format RC) is
greater than or equal to zero, then left-shift the value in D[a] by the amount specified by shift count. The vacated
bits are filled with zeros and bits shifted out are discarded. If the shift count is less than zero, right-shift the value
in D[a] by the absolute value of the shift count. The vacated bits are filled with the sign-bit (the most significant bit)
and bits shifted out are discarded. Put the result in D[c].

The shift count is a 6-bit signed number, derived from either D[b][5:0] or const9[5:0]. The range for shift count is
therefore -32 to +31, allowing a shift left up to 31 bit positions and a shift right up to 32 bit positions (a shift right
by 32 bits leaves all zeros or all ones in the result, depending on the sign bit). On all 1-bit or greater shifts (left or
right), PSW.C is set to the logical-OR of the shifted out bits. On zero-bit shifts C is cleared.

```
if (const9[5:0] >= 0) then {
  carry_out = const9[5:0] ? (D[a][31:32 - const9[5:0]] != 0) : 0;
  result = D[a] << const9[5:0];
} else {

Arithmetic Shift Packed Half-words

Description
If the shift count specified through the contents of either D[b] (instruction format RR) or const9 (instruction format RC) is greater than or equal to zero, then left-shift each half-word in D[a] by the amount specified by shift count. The vacated bits are filled with zeros and bits shifted out are discarded. If the shift count is less than zero, right-shift each half-word in D[a] by the absolute value of the shift count. The vacated bits are filled with the sign-bit (the most significant bit) of the respective half-word, and bits shifted out are discarded. Put the result in D[c]. Note that for the shifts, each half-word is treated individually, and bits shifted out of a half-word are not shifted into the next half-word.

The shift count is a signed number, derived from the sign-extension of either D[b][4:0] (format RR) or const9[4:0] (format RC).

The range for the shift count is -16 to +15. The result for each half-word for a shift count of -16 is either all zeros or all ones, depending on the sign-bit of the respective half-word.

SHA.HD[c], D[a], const9 (RC)

```

Arithmetic Shift with Saturation

Description
If the shift count specified through the contents of either D[b] (instruction format RR) or const9 (instruction format RC) is greater than or equal to zero, then left-shift the value in D[a] by the amount specified by shift count. The vacated bits are filled with zeros and the result is saturated if its sign bit differs from the sign bits that are shifted out. If the shift count is less than zero, right-shift the value in D[a] by the absolute value of the shift count. The vacated bits are filled with the sign-bit (the most significant bit) and bits shifted out are discarded. Put the result in D[c]. The shift count is a 6-bit signed number, derived from D[b][5:0] (format RR) or const9[5:0] (format RC).

The range for the shift count is -32 to +31, allowing shift left up to 31 bit positions and to shift right up to 32 bit positions. Note that a shift right by 32 bits leaves all zeros or all ones in the result, depending on the sign-bit.

UNPACK
Unpack Floating Point

Description
Take an IEEE 754 single precision floating point number in data register D[a] and unpack it as exponent and mantissa into data register pair E[c], such that it can be more easily processed through regular instructions.

The odd register E[c][63:32] receives the unbiased exponent. The even register E[c][31:0] receives the mantissa.

Note that the sign-bit of the floating point number is available in bit 31 of data register D[a].

To compute the mantissa and the exponent, the input number is first checked for special cases: Infinity, NaN, Zero & Denormalised. If the input number is not one of these special cases it is a normalised number. Bits [22:0] of D[a] are then copied to bits [29:7] of E[c], with bits [6:0] of E[c] cleared to 0. Bit 30 is set to one, as the implicit high order bit for a normalized mantissa. Bit 31 becomes zero, since the unpacked mantissa is always positive. The bias is removed from the exponent, by subtracting 127, and the result placed in bits [63:32] of E[c].

Note: For both normalised and denormalised input numbers the output mantissa is in a fractional 2.30 format.

The special cases are handled as shown in the operation, described below.

XOR

Bitwise XOR

Description
Compute the bitwise exclusive OR of the contents of data register D[a] and the contents of either data register D[b] (instruction format RR) or const9 (instruction format RC). Put the result in data register D[c]. The value const9 is zero-extended to 32-bits.

XORD[c], D[a], const9 (RC)

\[
\begin{array}{cccccc}
31 & 28 & 27 & 21 & 12 & 11 & 8 & 7 & 0 \\
\hline
\text{c} & 0\text{CH} & \text{const9} & \text{a} & \text{8FH} & \\
\end{array}
\]

\[D[c] = D[a] \ ^ \ \text{zero Ext(const9)};\]

XORD[c], D[a], D[b] (RR)

\[
\begin{array}{cccccc}
31 & 28 & 27 & 20 & 19 & 18 & 17 & 16 & 15 & 12 & 11 & 8 & 7 & 0 \\
\hline
\text{c} & 0\text{CH} & - & - & \text{b} & \text{a} & \text{0FH} & \\
\end{array}
\]

\[D[c] = D[a] \ ^ \ D[b];\]

XORD[a], D[b] (SRR)

\[
\begin{array}{cccccc}
15 & 12 & 11 & 8 & 7 & 0 \\
\hline
\text{b} & \text{a} & \text{0FH} & \\
\end{array}
\]

\[D[a] = D[a] \ ^ \ D[b];\]

**XOR.EQ**

**Equal Accumulating**

**Description**

Compute the logical XOR of D[c][0] and the Boolean result of the EQ operation on the contents of data register D[a] and either data register D[b] (instruction format RR) or const9 (instruction format RC). Put the result in D[c][0]. All other bits in D[c] are unchanged. The value const9 is sign-extended.

**XOR.EQD[c], D[a], const9 (RC)**

$$D[c] = \{D[c][31:1], D[c][0] \text{ XOR } (D[a] == \text{sign_ext(const9)})\};$$

**XOR.EQD[c], D[a], D[b] (RR)**

$$D[c] = \{D[c][31:1], D[c][0] \text{ XOR } (D[a] == D[b])\};$$

**Status Flags**

SUB.F
CMP.F
Compare Float

Description
This instruction compares the IEEE-754 single-precision floating-point operands and asserts bits in the result if their associated condition is true:

bit [0] D[a] < D[b]
bit [1] D[a] == D[b]
bit [3] Unordered
bit [4] D[a] is denormal
bit [5] D[b] is denormal
bits[31:06] are cleared.

The ‘unordered’ bit is asserted if either operand is a NaN.

Note: CMP.F is the only FPU instruction that does not substitute denormal operands for zero before computation.

CMP.FD[c], D[a], D[b] (RR)

FTOQ31
Float to Fraction

Description
Subtracts D[b] from the exponent of the floating-point input value D[a] and converts the result to the Q31 fraction format. The result is stored in D[c]. The rounding mode used for the conversion is defined by the PSW.RM field. The exponent adjustment is a 9-bit two’s complement number taken from D[b][8:0], with a value of [-256, 255]. D[b][31:9] is ignored.

Q31 fraction format is a 32-bit two’s complement format which represents a value in the range [-1,1).
- Bit 31 represents -1
- Bit 30 represents +1/2
- Bit 29 represents +1/4
- Bit 28 represents +1/8
- etc.

Inverse Square Root Seed

Description
An approximation of the reciprocal of the square root of D[a] is stored in D[c]. The accuracy of the result is no less than 6.75 bits, and therefore always within ±1% of the accurate result. The operand and result are floating-point numbers. If the operand is ±0 then the result will be the appropriately signed ? . If the operand is a NaN (quiet or signalling), then the return result will be the quiet NaN 7FC00000H.

This instruction can be used to implement a floating-point square root function in software using the Newton-Raphson iterative method.

QSEED.FD[c], D[a] (RR)

```
arg_a = denorm_to_zero(f_real(D[a]));
if(is_nan(D[a])) then result = QUIET_NAN;
else if(arg_a == +0.0) then result = POS_INFINITY;
else if(arg_a == -0.0) then result = NEG_INFINITY;
else if(arg_a < 0.0) then result = SQRT_NAN;
else {
  normal_result = approx_inv_sqrt(arg_a);
  result = ieee754_32bit_format(normal_result);
}
D[c] = result[31:0];
```

SUB.F
Subtract Float

Description
Subtracts D[a] from D[d] and stores the result in D[c]. The operands and result are floating-point numbers.
If any operand is a NaN (quiet or signalling), then the return result will be the quiet NaN 7FC00000H.

ADD.F
UPDFL
Update Flags

Description
The UPDFL instruction takes two 8-bit data fields from D[a], and uses them to update the PSW user flag bits (PSW [31:24]) that the FPU uses to store its exception flags and rounding mode in. D[a][15:8] are the update mask field; a ‘1’ in a given bit position indicates that the corresponding PSW user flag bit is to be updated. D[a][7:0] are the update value field. These bits supply the values to be written to the PSW user flags bits, in the positions specified by the mask field.

Example: Changing the current PSW[25:24] (Rounding mode) to round toward +?, without modifying any of the current exception flag settings, can be accomplished by loading the literal value 0301H into register D[0], and issuing the instruction, UPDFL D[0].

### 3.3 LS and IP Instruction Summary Lists

This section contains two lists; one of the LS instructions and one of the IP instructions.

#### 3.3.1 List of LS Instructions

- **ADD.A** - Add Address
- **ADDIHA.A** - Add Immediate High to Address
- **ADDSC.A** - Add Scaled Index to Address
- **ADDSC.AT** - Add Bit-Scaled Index to Address
- **BISR** - Begin Interrupt Service Routine
- **CACHEA.I** - Cache Address, Invalidate
- **CACHEA.W** - Cache Address, Writeback
- **CACHEA.WI** - Cache Address, Writeback and Invalidate
- **CACHEI.W** - Cache Index, Writeback
- **CACHEI.I** - Cache Index, Invalidate
- **CACHEI.WI** - Cache Index, Writeback, Invalidate
- **CALL** - Call
- **CALLA** - Call Absolute
- **CALLI** - Call Indirect
- **DEBUG** - Debug
- **DISABLE** - Disable Interrupts
- **DSYNC** - Synchronize Data
- **ENABLE** - Enable Interrupts
- **EQ.A** - Equal to Address
- **EQZ.A** - Equal Zero Address
- **FCALL** - Fast Call
- **FCALLA** - Fast Call Absolute
- **FCALLI** - Fast Call Indirect
- **FRET** - Return from Fast Call
- **GE.A** - Greater Than or Equal Address
- **ISYNC** - Synchronize Instructions
- **J** - Jump Unconditional
- **JA** - Jump Unconditional Absolute
- **JEQ.A** - Jump if Equal Address
- **JI** - Jump Indirect
- **JL** - Jump and Link
- **JLA** - Jump and Link Absolute
- **JLI** - Jump and Link Indirect
- **JNE.A** - Jump if Not Equal Address
- **JNZ.A** - Jump if Not Equal to Zero Address
- **JZ.A** - Jump if Zero Address
- **LD.A** - Load Word to Address Register
- **LD.B** - Load Byte
- **LD.BU** - Load Byte Unsigned
- **LD.D** - Load Double-word
- **LD.DA** - Load Double-word to Address Register
- **LD.H** - Load Half-word
- **LD.HU** - Load Half-word Unsigned
- **LD.Q** - Load Half-word Signed Fraction
- **LD.W** - Load Word
3.3.2 List of IP Instructions

- **ABS** - Absolute Value
- **ABS.B** - Absolute Value Packed Byte
- **ABS.H** - Absolute Value Packed Half-word
- **ABSDIF** - Absolute Value of Difference
- **ABSDIF.B** - Absolute Value of Difference Packed Byte
- **ABSDIF.H** - Absolute Value of Difference Packed Half-word
- **ABSDIFS** - Absolute Value of Difference with Saturation
- **ABSDIFS.H** - Absolute Value of Difference Packed Half-word with Saturation
- **ABSS** - Absolute Value with Saturation
- **ABSS.H** - Absolute Value Packed Half-word with Saturation
